**Brentford Photographic Society.**—Third Annual Meeting, Oct. 3, the Rev. T. Eland (president) in the chair. The Hon. Secretary read the report of the Committee as follows:—"Another successful year has been completed, and we begin our third year of existence under most auspicious and satisfactory circumstances. Outsiders are beginning to take an interest in us and our doings. The outings have been successful with one exception—the one to Laleham, which had to be abandoned, the date fixed (the middle of July) being far too near the holiday season. The last annual exhibition was a complete success as regards the number both of visitors and exhibits. Financially also it succeeded, and everything points to the necessity of holding the next one in a larger and more suitable hall, such as the large public baths' hall, which, with its gallery, seems specially suited for the purpose. It is hoped that the Society will increase this year, and enable the Committee to provide in an able manner for the wants of all classes of photographers. Your Committee will lay before you a well-thought-out syllabus, prepared after much trouble, as it was thought advisable to get as many outside workers as possible to contribute. They would suggest that members bring their failures or faulty work to be criticised, and have the mistakes pointed out. Then these could be corrected, and a good print obtained and prepared ready for the exhibition. The same thing applies to lantern slides. The Society, being affiliated to the Royal Photographic Society, will be expected to comply with the new rules concerning exhibitions. The Society has been again indebted to the managers of St. Paul's Schools for the use of the class-rooms for meetings. The question whether a change of meeting-place would be advantageous has been raised. The Society is not in debt, having a balance in hand of about £1 to date (Oct. 1, 1900), but the changes advocated will necessitate a larger income; and the Committee therefore suggest that for the efficiency of the Society's work, the advisability of raising the subscriptions should be considered."

The following were elected officers:—President, Rev. T. Eland; vice-presidents, Rev. Percy West, Mr. F. A. Turner, F.R. Hist. Soc., Mr. A. R. Read; hon. secretary and treasurer, Mr. H. Grundy, of whose services the Chairman spoke in very high terms. Committee: Mr. A. R. Read, jun., Mr. W. J. Squires, Mr. Bonfellow, and Mr. Wilfred Liveridge.

**Croydon Camera Club.**—Following the custom of former years, the eleventh winter session of the Club was inaugurated on Wednesday last by an address from the President, Mr. Hector Maclean, F.R.P.S., in the course of which he touched upon a number of topics of interest to members and to photographers at large. He congratulated the Club upon the interesting outings which had been held during the summer, including visits to Cuckfield Place, Gattam Hall and Park, the home and haunts of Dickens, and a trip up Thames, which latter attracted an attendance of nearly sixty members and friends. As regards the future, a brilliant programme of photographic events was outlined, not the least interesting being the visits of parties of members to the R.P.S., under conditions as regards guidance and admission not generally obtainable. The lantern shows will be more frequent this year than last. Besides the technical fixtures and the annual dinner, it is contemplated to hold a Club concert and also a Club Cinderella. The fourth exhibition is promised for February 20, apropos of which Mr. Maclean plunged into the depths of pictorialism, emphasising that you cannot stumble upon pictorial effect, but must aim for them, and to hit the mark must train the eye and judgment. In the course of further remarks, he dwelt on the works of D. O. Hill, who nearly sixty years ago produced, on calotype, a series of pictorial portraits that held the field for a good quarter of a century. Hill was an artist. The next man heard of—viz., Rejlander—was also an artist, and going through all the well-known names one can scarcely discover any but those who have some considerable art familiarity. But of recent years photographers have trained themselves more by means of the camera than with the brush. Mr. Maclean illustrated his remarks by a large assortment of prints by Hill, Rejlander, and by exhibitors at the lately opened exhibitions, and delivered his opinions upon them as they were displayed. Respecting the two chief exhibitions, he stated that his own preference, as regards landscape only, was that the most meritorious one in the R.P.S. was "After Rain—Evening," by Mr. Charles Job, which was pitched in a delicate half-tone, showing slight coming through haze which softened a riverside landscape. In the above, neither diffusion nor obscurity had been pushed to an extreme. In "The Salon" his preference leaned towards Mr. Charles Moss's gum-bichromate studies. Without bestowing the crowning term "perfect," he admired them, in that they showed design and a large measure of attainment. They evidenced that Mr. Moss is not satisfied to repeat the effects and means of former years. Following the President came a well-arranged demonstration by Mr. Lionel G. Kough, on carbon slides. The lecturer, who is one of the Club's most popular and distinguished technicians, briefly sketched out the advantages of carbon tissue for the production of lantern slides. Not only is it absolutely unchangeable, but it is cheaper and more certain; the results are also not less perfect, and the range of colour very considerable, and yet absolutely constant—a great advantage where a series is required of a particular tint. Following the ex-

planatory remarks was a demonstration of the chief points in procedure. This was carefully noted by a gathering of some thirty members, who subsequently plied Mr. Kough with innumerable questions. In proposing a vote of thanks, which was adopted with a heartiness that indicated that not only the lecture but the lecturer was greatly appreciated, the President said they were particularly beholden to Mr. Kough for giving the session such a good send off. The Club had always endeavoured to provide most of their photographic fare from their own members, and while they could get such demonstrations as that night the policy would be followed with great advantage to all concerned.

**Liverpool Amateur Photographic Association.**—Oct. 4, Mr. Fred Anyon gave a practical demonstration on "Photography for Beginners." He first explained the various parts of the camera, and then went on to deal with exposures. By the aid of several slides which were thrown on the screen the valuable use of stops was clearly illustrated, also the use of a wide-angle lens. Mr. Anyon then dealt with development, printing, and toning, and gave several formulæ.

**FORTHCOMING EXHIBITIONS.**

- 1900.
- October 12–Nov. 3 ... Photographic Salon, Dudley Gallery, Piccadilly. Hon. Secretary, R. W. Craigie, Camera Club, Charing Cross-road, W.C.
  - „ 12–Nov. 3 ... Royal Photographic Society, New Gallery, Regent-street. The Hon. Secretary, 66, Russell-square, W.C.
  - „ 17–20 ..... Rotherham Photographic Society. Hon. Secretary, H. C. Hemmingway, Tooker-road, Rotherham.
  - „ 30–Nov. 3 ... Sefton Park Photographic Society. Hon. Secretary, G. Birtwhistle, 7, Gainsborough-road, Sefton Park, Liverpool.
  - November 7–10 ..... Cripplegate Photographic Society and the Essex and Middlesex Cycling Union, Ltd. Hon. Secretaries, A. T. Ward, Cripplegate Institute, E.C., and G. F. Sharp, Sach-road, Upper Clapton, N.E.
  - „ 12–17 ..... Ashton-under-Lyne.
  - „ 19–24 ..... Waterloo and Blundellsands Photographic Society. Hon. Secretary, W. G. Eyre, 2, Mersey-road, Blundellsands.
  - „ 21–23 ..... Hackney Photographic Society. Hon. Secretary, W. Selve, 70, Paragon-road, Hackney, N.E.
  - „ 21–24 ..... Cleveland Camera Club. Hon. Secretary, F. W. Pearson, 98, Victoria-road, Middlesborough.
  - „ 22–24 ..... Hove Camera Club. Hon. Secretary, C. Ber-  
rington-Stoner, 24, Holland-road, Hove.
  - 1901.
  - January 14–19 ..... Blairgowrie and District Photographic Association. The Hon. Secretaries, Blairgowrie, N.B.

**Correspondence.**

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

**LEVELLING THE HAND CAMERA.**

*To the EDITORS.*

GENTLEMEN,—In using a stand camera the camera back is commonly set vertical by a spherical level. Many photographers also have levels on their hand cameras, and they are very useful, though it is rather distracting to glance from the finder of the level while holding the camera in the hand. It adds one to the other causes of nervousness in taking hand camera pictures.

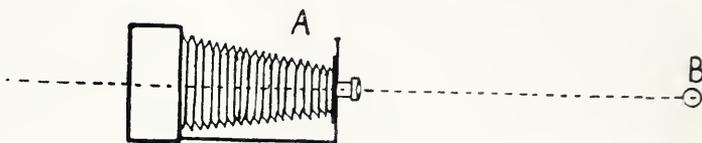

Recently I obtained a hand camera which did not seem to afford any convenient position for attaching a level, and besides had sloping bellows and a swing back, which make it practically very difficult to judge of the horizontality of the camera axis. It occurred to me that a line on the finder would answer the same purpose as a level, and would be in many respects in hand camera work more convenient. Set up the camera A, with its back vertical, square, for instance, to a level table. At a convenient distance set a mark (B) level with the camera axis. The edge of a window sash is a convenient mark, as it can be adjusted in height. Now draw a line on the finder at the image of B. In taking a view choose any point in the view level with the camera, and bring this to the line on the finder. The camera axis is then level. There is only the finder to look at, and it is possible to see also that vertical lines are parallel to the picture sides.

Next as to the swing back. If two lines are drawn on the finder in the way described above, one with no swing used, and one with full swing, the camera can be levelled for these positions by bringing a

point level with the camera to the corresponding line on the finder. Intermediate positions can be judged. At half-swing the level point must be midway between the lines on the finder.

Since I tried this dodge I have had a level fitted to the camera. But, on the whole, I think that for ordinary hand work the lines are more convenient, and they show differences of level more sensitively than the ordinary small levels fitted to cameras. There are cases, no doubt, when the level has the advantage.

Very probably this simple dodge has been used by others, and, of

course, some finders have lines on them. But I have not seen in print any reference to these two points:—(1) That the line on the finder should be on the image of a point level with the camera centre; (2) that in using the line a point level with the camera should be chosen to the image of which the line should be brought.—I am, yours, &c.,

W. C. UNWIN.

Palace Gate Mansions, 29, Palace-gate, Kensington, W.  
Oct. 6, 1900.

**GELATINE LANTERN SLIDES—CINEMATOGRAPHY.**

*To the EDITORS.*

GENTLEMEN,—Some time ago an inquiry, which I think has remained unanswered, appeared in your columns about gelatine magic lantern slides. At the time I could not put my hand upon the information wanted. Now, however, I can give an address.

Reinhard Kluge, 13 Schossergasse, Dresden—A, has such slides of which I enclose you a sample. I should say there are probably manufacturers of such things to be found in Nuremberg.

The first time apparatus of the nature of a cinematograph was exhibited in public was, I believe, at an exhibition of arts or industries at Brussels some ten or fifteen years ago.

It seems to have attracted but little attention (flexible transparent substratum, for photographs was perhaps not then in existence). It was (subsequently, I think), referred to in one or two English photographic periodicals.

I should be most grateful to any one for information or references, which would enable me to trace out this matter, before it sinks into hopeless oblivion.—I am, yours, &c.,

PHOTOPHIL.

[We are much obliged to our correspondent for the specimen of the coloured gelatine transparency—the like of which, however, is fairly common in this country. With regard to early cinematograph displays, we are unable to trace a reference to the Brussels Exhibition, but our correspondent will find much information on the general subject contained in Mr. Henry V. Hopwood's most admirable book, "Living Pictures," published at the office of "The Optician," 125 Fleet-street, E.C.—Eds.]

**NATURAL COLOUR PHOTOGRAPHY AT THE R.P.S. EXHIBITION.**

*To the EDITORS.*

GENTLEMEN,—The fact that the New Gallery is only lighted from the roof created a difficulty in showing in a proper light the first photographs, eighteen in number, ever seen in this country, taken in America by the McDonough-Joly process. This difficulty has only now been surmounted, the photographs being placed on the balcony facing the entrance, where we trust you will inspect them.

The fact that the Government Geologist of the Department of the Interior of the United States, is at the present time using the process in photographing geological formations in the Rocky and Cascade mountains for their geological surveys, is perhaps the best proof that can be given that photography of natural colours has now passed the experimental stage.—We are, yours, &c.,

COLOUR-PHOTO Co.

Birkbeck Bank Chambers, Southampton-buildings, Holborn, W.C.

**PHOTOGRAPHIC HALATION (POSTERIOR); EXPOSURE THROUGH THE GLASS PLATE.**

*To the EDITORS.*

GENTLEMEN,—With some photographers there seems to be some considerable confusion of ideas respecting the principles involved in the phenomenon of photo halation (posterior), which may be rectified very easily by a little reflection concerning the manner in which it is produced, and the nature of the materials employed when the fault is sought to be remedied by exposing the plate or film at the back.

You cannot have a glass plate without two outer surfaces, and, so to speak, two inner surfaces, the uncoated surface having a backing of air, and the film surface a backing of bromide, &c. Now, the light striking the back of the glass, supposing we have the film side the opposite way in the dark slide during the exposure, a portion of the light is reflected, and a portion passes on to the sensitive film forming the image, but a portion is also reflected from it into the glass and passes on to the reflecting surface of air at the back of the plate. This reflects a portion back again on to the back of the film, and exposes it in a diffused form over the adjacent shadows of the picture. As the film is of a pale primrose colour, the active rays of light falling on it in this manner are reflected backwards and forwards during the whole of the exposure, strengthening and extending the effect during the whole time. This has now passed out of the region of theory into actual fact some considerable time. Some writers seem to ignore the fact that the sensitive film in contact with the glass becomes an internal reflecting surface when it is exposed through the glass plate. This, I think, is at the root of the mistaken idea.

The principle here involved was first enunciated by the writer as far back as 1861, and it still holds its ground against all comers, though violently opposed at the time by the magnates of photography, and who at the present time would, if they could, obliterate my name from all connection with the subject altogether, as seen by their own extensive writing on the subject since then, and their present attitude. For why, I know not, unless they are ashamed of the behaviour of their brethren in those far off times. But this, you would think, if they were ordinary human beings, they would be only too glad to rectify. Forty years is a long time to wait for recognition from the parent Society, and when this was suggested to them a year or two ago it was treated with silent contempt by ordering it to be laid on the table, which meant shelve it. Of course, the above refers wholly to posterior halation, which is the result of quite a different set of circumstances to that of anterior when the plate is exposed in the usual way, from motes in the air around windows, &c.—I am, yours, &c.,

G. MARLOW.

80 Lower Sutton-street, Aston-road, Birmingham, Oct. 8, 1900.

## THE ALMANAC.

To the EDITORS.

GENTLEMEN,—For many years back I have had the ALMANAC, and ever since it has grown so fat I have thought that if you could place two stout leaves just at the start and finish of the matter, to divide the advertisements, one could cut through the thick back of the ALMANAC and have a nice-sized book to read. One could save the advertisement part all the same. I do; for four years I have cut through and saved each part. I like to take my ALMANAC to bed for a few weeks and the whole lot is rather heavy to hold up.—I am, yours, &c.,

VACUUM CAPUT.

[We are pleased to learn that our correspondent, an old photographer, finds the ALMANAC such a pleasant bed-fellow! Just now we are in receipt of many suggestions with regard to the make up of the book, few of which, however, are practicable. Nevertheless we thank our friends for their communications. The book, of course, will not be in the hands of the public for at least seven weeks, and yet each day we are favoured with many good wishes for its success.—EDS.]

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

A. TEAR, 5, Westgate-street, Ipswich.—Four photographs of Captain G. Prettyman, M.P.

T. P. BROWN.—The house you name is of the highest respectability, and, of course, still carries on business.

FORMULA WANTED.—T. writes: "Can you give me formula for gum or paste to put on back of stamp-size photos?"—Ordinary dextrine, as sold at the oil shops, made into a mucilage, is as good as anything. A trace of glycerine may be added with advantage.

GEO. MINNS.—We should say, under the circumstances, that the Velox, or other of the gaslight papers, would answer your purpose best. With them you will be able to produce the prints throughout in an ordinary room in the evening. With these papers no dark room is required, and various colours can be obtained.

BOOKS ON PHOTOGRAPHY.—E. CASSON writes: "I have only six months longer before I try for a position as assistant operator and developer. Would you kindly inform me what books I can get which will give me some good advice about posing, lighting, and developing, &c.?"—In reply: Robinson's "Studio, and What to Do In It," Inglis's "Lighting," Henry's "Early Work in Photography," should be of help to you as a start. You may obtain these works of Messrs. Dawbarn and Ward, 6, Farringdon-avenue, E.C.

PAPER FOR TAKING COLOUR.—E. D. asks: "What is the best printing paper for taking water colour? I have tried oxgall for the Ilford matt surface paper, but the result is always more or less smeary. Is there a coarse kind which would take the colour better and have a similar effect to Whatman's water colour paper, and does it require any special process of printing for finishing in water colour?"—We should recommend one or other of the rough bromide papers, or the gaslight papers of the Velox type. Some of them have a surface very like the Whatman papers, and take colours easily.

COPYRIGHT.—A REGULAR SUBSCRIBER asks: "How am I to go about copyrighting a photo? What is the address of the Secretary, the fee for doing so, and how many photos have I to send up, and are they to be on permanent paper? Am I to give the title, or simply only register the negative; and am I bound always to keep to the registered title of the photo?"—In reply: If our correspondent read his JOURNAL a little more carefully, he would have seen that only a fortnight ago we gave full particulars of the course to be adopted in registering photographs. However, let him send our publishers two prints, and 1s. 7d., and they will do the needful for him.

ADDRESSES WANTED.—F. T. TILLEY asks: (1) Where he can obtain small directories of British Colonies, as he wishes to advertise English views abroad. Also (2) the address of a firm who supply views 12 by 10 on plush blocks at wholesale prices.—In reply: (1) With regard to advertising in the Colonies (for that, we take it, is what our correspondent wishes to do), some such firm as George Street and Co., of Cornhill, E.C., or Street Bros., of Serle-street, Lincoln's Inn, would, no doubt, give advice. They might also indicate where the directories required are obtainable. (2) Messrs. Marion, Soho-square; Houghton and Sons, Holborn, and other firms who advertise in the JOURNAL and ALMANAC supply such goods.

COLLODIO-CHLORIDE PAPER.—B. asks: (1) "What are its disadvantages compared with matt bromide paper for prints from small negatives?" (2) White Ink Insoluble in Water.—Is there such an ink for numbering negative cut films so that if later washing be required the numbers will remain? (3) Temperature of Developers.—Is there any good developer which works naturally much below 60°F? In winter it is not easy to get a room not used for other purposes (in a private house) up to 60 to 65, as recommended for hydroquinone, kachin, &c.—(1) None that we are aware of. (2) If oil colour paint, such as is sold in tubes for oil painting, be used, it will resist the water, if allowed to get perfectly dry before the films are re-wetted. (3) The developers will work quite well at a lower temperature than that mentioned, but they will require a longer time for their action.

PORTRAITURE BY INCANDESCENT GASLIGHT.—LIGHT says: "I should feel obliged if you will inform me the candle power I should require to take portraits by incandescent gaslight (Welsbach), using Voigtlander portrait lens, at full aperture, and Barnet E.R. plates, giving about three seconds' exposure. I intend having several plates mounted in an umbrella-shaped reflector. Should mantles be used with or without glass shades?"—We cannot say the candle power required by gaslight to take portraits in the time stated, with the plates and lens mentioned, as we have had no practical experience in that direction. Much will, however, depend upon the distance the light is from the sitter. The arc electric lights generally used for portraiture are from six to ten thousand candle power, and require an exposure of from one to two seconds when placed some distance away from the sitter. This may possibly serve as a rough guide. We should say the lights had better be used with a glass.

MICROPHOTOGRAPHY, &c.—W. E. PARKIN writes: "May I ask if you would kindly advise me as to the following:—(1) What apparatus is required for reducing say  $\frac{1}{2}$ -plates for microscopic slides, similar to the pictures sold with penholders and at seaside places? (2) What book is sold dealing with this subject, and giving hints, &c., for developing, &c.? (3) Could you give me the name of any firm doing this work from amateurs' negatives, with cost of same? (4) Is it possible to purchase view finders which could be used for taking pictures on a  $\frac{1}{2}$ -plate instantograph, where, as in passing views at sea or on board ship, there is no time to focus, &c., and to avoid both a hand and stand camera because of extra baggage?"—In reply: (1) A copying camera, in miniature, similar to those used for making lantern slides from larger negatives, fitted with a microscopic objective of low power, say an inch or inch and a half. With it use the wet collodion process. (2) We know of no work devoted to the subject. (3) Dagron, of Paris, produces this class of picture. We do not know the price charged. (4) Not that we are aware of. Why not employ a hand camera fitted with a scale to which the focus of the lens can be adjusted for different distances? That would overcome your difficulty.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1901.

Edited by THOMAS BEDDING, F.R.P.S.

THE ALMANAC for 1901 will appeal to photographers all the world over as a daily reference guide in practical work. The formulæ will be revised where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

Adhering to an old and much-appreciated custom, we invite short contributions on practical subjects for the pages for the 1901 ALMANAC. Those of our friends intending to co-operate with us in this respect can help us by letting us have their MS., sketches, &c., in the course of this month.

We shall be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, &c.

As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, &c. Those firms who wish to take advantage of this feature should communicate with us at once.

\* \* \* The publishers ask us to remind advertisers that most of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them by Tuesday, October 23rd.

\* \* \* Will secretaries of societies who have not yet sent us lists of officers for inclusion in the ALMANAC kindly oblige us by doing so by return in order that this section of the book may be proceeded with.

## EX CATHEDRÂ.

It frequently happens that a photographer is called upon to execute orders in floral photography in which more or less difficulty is experienced in being able to arrange for a satisfactory method of holding some particular subject *in situ*, and this difficulty crops up quite as often in well-appointed conservatories and greenhouses, where any one would expect to find the utmost convenience for conducting such work, as elsewhere. In photographing what may be termed pot or foliage plants, where no great amount of size has to be contended with, the difficulty generally lies with that class of plants whose form of growth does not permit of their being placed upon a solid iron stool or other rigid support, which can be arranged in position at the most suitable part of the greenhouse, so that the best effects in light and shade may be obtained. A notable example of this kind of subject we find in the pitcher plant, with its overhanging and trailing growths, as seen in its marvellous formation of little water vessels or cups, which are frequently found suspended several feet below the basket containing the root, or body of the plant. It is well known that these wonderfully-formed plants require a very high temperature, and the work of photographing has often to be performed in what are termed stove-houses, with a temperature of 90° F., so that special precautions must be taken to guard against any sweating of the lens, for extreme moisture is always present in these stove-houses. The pitcher plant is just one of those subjects that

can only be properly dealt with by suspension, and in order to obtain the best view of what may be termed the face of the plant (for all plants and shrubs have a best side), so as to depict the charming little cups with their tendrils, they require to be removed from the position they occupy in a stove-house, which is generally at a high elevation over and above the other plants on the stage of the house. The removal of plants of this description to a suitable position for being photographed means the suspending of them by means of long wires or strong cords from a position near the top of the stove-house, and then the difficulty at once begins in being able to get the plants absolutely steady during the time necessary for the exposure of the sensitive plate.

\* \* \*

To many who have never had to deal with subjects of this description, this may appear quite a trivial matter to overcome at any time, especially in a greenhouse, but the fact remains that those subjects often give a lot of trouble to arrange so as to present the best point or face of the plant to the camera, for it must be borne in mind when working in such confined situations as stove-houses there will be found very little latitude for moving the camera to suit the subject, but, on the other hand, it will soon be apparent that the plant must be made to suit the position of the camera. It may be taken for granted, therefore, that one of the first things necessary is the provision of some special means for holding the face of the plant absolutely steady during exposure, for the slightest vibration from any passing vehicle, or even a railway train moving rapidly a hundred yards distant, or a strong gust of wind striking the glass roof of the house, will be found quite enough to cause a movement sufficiently pronounced to be noticeable in the finished picture.

\* \* \*

As a rule, gardeners are very conservative, and careful in all their dealings with rare and valuable specimens, and prefer always to manipulate their plants with their own hands, and in a case of this difficulty presenting itself the first expedient resorted to was the tying of the bottom of the basket, by means of a strong cord, to the iron floor plates of the stove-house; this proved of no use whatever, for not only did the plant present its wrong face to the camera, but the spinning movement was as pronounced as ever for a very long time. The next expedient tried was attaching four black threads to each corner of the basket, and, although this proved somewhat better than the first, it was still of no avail in overcoming movements whenever a cart passed on the roadway in close proximity to the house. After much discussion it was decided to attach a rigid support to one side of the basket, and so fix it that the other end of the bar of wood could be made fast to the wall of the house through the paper background. A firm rod of wood was thus used to place the plant with its proper face to the camera, and this at the same time proved sufficient to overcome any vibration. A rigid support running from the plant to the wall or window of the house was the only means of overcoming the difficulty, and this support was easily so attached to the back of the body of the basket as to be invisible in the finished picture.

\* \* \*

THOSE who have had experience in dealing with another class of subject in floral photography, such as cut flowers, know well how difficult at times it is to arrange the specimens in a

vase so that they yield not only a well-balanced effect but at the same time will permit of the flowers being placed *in situ*, so as to assist the lens in bringing the different planes of the object in fairly good focus all over, for just when it has happened, that after a long and tedious attempt to nicely arrange the cut flowers, and it looks as if success has at last crowned one's effort, a twist in some stalk will give out and a prominent petal will fall out of place and necessitate the whole arrangement being gone over again. A very common method of procedure when photographing subjects of this kind is to place the stems of the flowers in a vase or other receptacle partially filled with water. Now, this is by no means the easiest or most desirable way of undertaking subjects of this kind. In all cases, when possible, the stems of such flowers should be specially prepared for the purpose of being photographed. This may mean wiring them, which is an unfailing preventive of movement, after the stems are once placed in their desired position, but water should never be employed in a vase to hold the stems in position. Let those who have experienced difficulty in this direction just try the effects of substituting sand for water, and they will be surprised at the comfort of the operation, for with such a rigid base as a body of sand, and with the stems of the cut flowers properly wired, they can be made to fall into any position with little trouble.

\* \* \*

THEN as to the other difficulty experienced in bringing the various petals, both at back and front, into a good pleasing focus. Much will depend upon the subject being dealt with, and the size of the object depicted in the negative. It need hardly be said that when working on many subjects of this kind the chief aim is to render the flowers as large as possible. This means the employment of long-focus lenses, well stopped down, and much useful work can be done with single lenses, which are more preferable than many of the double combinations so often used. The best objective, however, of all to use in work of this description is a long-focus portrait combination, for, by unscrewing the back elements of the lens, more or less diffusion of focus, with a delightful softness in effect is introduced, and by stopping the combination down it is surprising what a range of definition can be obtained when an objective of from 21 to 23 in. focus is employed.

\* \* \*

IN floral photography there is no doubt the background that is employed plays a most important part, and novices who for the first time undertake the photographing of such subjects in glass houses or conservatories are not long in finding this out. One of the most common mistakes made in regard to backgrounds is the providing of them too small in size. It is quite surprising the extent of span many subjects will take up. An ordinary paper background of about four feet in breadth by six feet long may permit a large amount of useful work being performed on such small subjects as bouquets or specimens of cut flowers, but for the ordinary run of large pot plants and other subjects in well-appointed conservatories such a small size is quite useless, and any attempt to make it do duty by cramping and other subterfuges will certainly prove most exasperating, and tend to failure. Not only must the size of the background be ample when really serious work of this kind is being done, but some thought must be bestowed upon the colour of the material. As to size, where shrubs and such subjects as palms are con-

cerned, a lantern screen of twelve feet is a most useful adjunct in floral photography. The framework for a sheet of this size is best made of stout bamboo canes not less than one inch in diameter; these canes are very light, and offer no serious trouble in transit. For dark green foliage plants and shrubs an ordinary white linen lantern sheet will work well enough when placed considerably behind the objects, but for flowering plants with a range of white petals a darker tint must be used, and then at times it will be found that a good sample of the homely Scotch blanket, well stretched and out of focus of the lens, will help any one over a stile at a pinch. A good dark grey paper background made by stretching it on cloth and then colour washing the paper surface is also a very useful article to have at command, but where orders have to be executed in outlying situations a blanket and a clean white sheet will do a lot of useful work.

\* \* \*

FROM time to time we hear a great deal about that bugbear halation when dealing with special classes of subjects, but an experienced worker knows how to overcome it; in fact, halation seldom gives those who know how to operate properly any thought whatever. If suitable plates be used, and the exposure be ample, halation will give no trouble in floral photography. Neither will delicate half-tones be clogged up or rendered muddy if proper regard be paid to the lighting of the subject. Properly lighting a subject does not mean flooding it with an overpowering amount of light, neither does it permit of work being done with a poor, weak, dismal light, but rather consists of waiting often many weary hours or days for just that nice amount of diffused daylight that yields brilliant high lights in contrast to half-tone and shadow, all of which may be on one special petal within a close touch of each other. In floral photography it is surprising what a wide and delightful field lies open for those enthusiastic workers who have plenty of time and means at their disposal, and it is gratifying to observe that several of our more important horticultural societies are now beginning to encourage photographic exhibitions in connection with their annual flower shows. This alone will tend to bring this delightful branch of work before the notice of those who have hitherto never given it their attention.

### STUDIO BUILDING.—III.

AFTER considering questions more especially forming part of what may be termed the ground plan of the building, there remain to be dealt with the many-sided problems connected with the actual shape of the studio. As this is a subject on which opinions as varied as absolute—we might almost say obstinate—are held, we do not propose to pick out any one form as being best, we intend rather to show the peculiarities attendant upon each shape. There are three well-known types—the ridge roof, the lean-to, and the sloping roof. The ridge roof has two sides sloping to the walls from a side running the length of the studio. The lean-to has a roof of a single slope, the ridge being on a high wall running also lengthwise, and slopes down to the opposite lower wall. The sloping roof has its ridge at the end of the studio, and it slopes down towards the floor in front of the sitter. Then we have as a sub-division common to all three—the tunnel studio.

We will treat of the latter first. As its name implies, this form of studio has its length increased by means of an unlighted extension usually much narrower than the studio proper, and so requiring less ground space. Primarily, we believe it was devised more especially for keeping the camera itself in comparative darkness, and so increasing the brilliancy of the negative. It answers this purpose effectually, but the same end can be attained by covering the camera with a light screen work. Its disadvantages are that when a distance between the camera and lens involving retiring into the tunnel is required, there can be only one light direction, i.e., from the sitter's right or his left. As one side of a face is so often better than the other, it is obviously disadvantageous having to take a face turned to the light whenever the best side of his face is that upon which the shadow falls. Such so-called Rembrandt lighting does not suit every face. It will be noted that these remarks pre-suppose that the skylight is not open on each side, the great objection to such a form being the fact that unless there are outside screens as well as interior blinds, the sun would have too much power, and render it difficult to keep the room cool.

To a certain extent the sloping front shares the same objection, for unless the background end be of very great height this form resolves itself into a tunnel shape, or its analogue. A great difficulty with studios in winter time is the lodgment of snow, and to prevent or lessen this a fairly steep pitch should be chosen. We do not consider an angle of 45° at all excessive for the attainment of this end. This would work out somewhat as follows: Taking 20 feet as a minimum length for the glazed part, and 8 feet a minimum height for the lowest end, we should need a wall 28 feet high for the background end, or, reducing the pitch to the lowest advisable, a wall of 25 feet. This would involve in a detached studio the increased expense of very great thickness, or an equivalent expense in buttresses with a thinner wall. Further, such studios usually being built north and south, the sun would gain entrance for two or three months on each side of midsummer unless an elaborate series of screens were erected outside, while if a diffusing screen were used inside the place would be very hot. When, however, this form is built against an existing building sufficiently lofty, the chief drawback is the number of windows that would be disestablished. Turning now to the lean-to, we find a tall wall again a necessity. A studio 15 feet wide, with an 8 foot lower wall, would, with the pitch above referred to, require the wall which supported the ridge to be 23 feet high—again excessively lofty, and needing substantial thickness, an objection again removed if the studio be built against another existing building, with also the disadvantage attaching to the previously described form. This shape permits of the sitter being placed at either end, a most valuable point, which should always be aimed at if possible.

Finally, we have to consider the ridge roof form. This is the most compact of any; it needs the least height in the walls, and can be built fairly light, yet be as strong as the other shapes that cost far more to build. Once more working on the 45° pitch, and with a 15 feet wide studio, we get with side walls of 9 feet, only 16½ feet as the highest point of the studio; rafters far less heavy and light-obstructing may be used, and as they are much shorter they could easily be made substantial enough to withstand any strain which might crack the putty and render them leaky. There would also be a perceptibly advantageous gain of light through less obstruction from the rafters or bars' lessened width.

Whatever the shape of bars, it is advisable to have them so shaped as in the event of a leak to carry the leakage away, and not permit it to drop into the studio. Some achieve this end by suspending under each rafter a tin or other thin metal trough running the whole length; others adopt the better plan of grooving the rafters so that leakage might run along the groove. This is by far the better plan, and perhaps the best place for the groove is on the top of the rafter just beyond the recess for receiving the putty.

Finally, we must look into the question of glass. Plate glass is sometimes used, but the thinnest kind is very costly, and is also heavier than ordinary window glass. Furthermore, some plate glasses become quickly coloured when exposed to light, and so exposures would be increased. Rolled or fluted glass absorbs a noteworthy proportion of the light, and "ground" or "obscured" glass should not be used on account of the difficulty in keeping it clean. When window glass is used good English sheets should be chosen. They are far less brittle, and the thickness should not be under that known as 32 oz. glass. Any thinner glass than this would be likely to suffer when a shower of hail fell upon it. One word of conclusion. The best preventive of ulterior leakage is to be found in running a thin line of paint round them where the putty is placed when bedding the glass in the required grooves or furrows of the rafters. We now conclude our disquisition upon this important branch of practical photography, feeling assured we have placed before our readers such a description, brief though it be, as may enable them to plan, when necessary, a studio that shall be useful, convenient, and capable of giving any required style of illumination for almost any kind of work.

**Oil Lamps for the Lantern.**—The lantern season is now about commencing, and many will be unearthing those which have lain by during the summer, and some will find the oil lamps in them in anything but a pleasant working condition, particularly if they were stowed away dirty, or with the wicks and oil still in them. If they are used as they are, with only a perfunctory cleaning, they will most likely smoke and emit anything but pleasant odours. In such cases the lamps should be thoroughly cleaned before they are again taken into use. The oil should be emptied out and the old wicks discarded. The lamp, and all its parts, should be thoroughly cleaned by washing with new paraffin oil and dried, after carefully wiping with clean rag, on a warm stove. New wicks should then be put in, but before they are used they are well dried before the fire, so as to eliminate all traces of moisture, which they sometimes retain with great tenacity. If the wicks are damp when they are put into paraffin lamps, they never burn so well and often emit smoke or inodorous fumes. This is a fact too often overlooked in trimming oil lamps. Complaints are often made that all oil lamps "stink" when used in the lantern. But in nine cases out of ten it is due to the lamps not being clean or the wicks being out of order, things easily remedied. In many cases the smell arises, not from the wicks, but from the evaporation of oil outside the reservoir as it becomes heated. If a well-constructed oil lamp for the lantern is kept perfectly clean, outside and in, and the wicks carefully attended to, there will be no smell from it while burning.

**Photosculpture.**—From a very early period in the history of photography, attempts have been made to apply photography to sculpture, and with more or less success, but, up to the present, with very little commercial success. The first method we call to mind is that of one François Willème, which he patented in the early sixties, and was taken up in this country by the late M. Claudet, but it did not become popular. Since that time numerous other methods have

been devised, but up to now nothing practical has come of them. The examples by Herr Selke's process, now to be seen in the Royal Photographic Society's Exhibition, are attracting some attention, and many are speculating as to how they are produced. Some little time ago we published the specification of Herr Selke's patent (see the last volume), but from that, we must confess, we do not quite grasp how the process is to be worked in practice—the specification seems a little too vague. The examples shown are bas-reliefs and alto-reliefs, and are really very good, but how much of their excellence is due to the process, and how much to hand work on the matrices, it is difficult to say by merely looking at the finished results. Most of the methods of producing bas-reliefs, previously published, have been based upon swelled gelatine methods, emphasising the relief by scraping away certain parts in a cast in plaster, or wax, of a cast taken from the gelatine relief, and doing the same with a cast taken from that. Then from the second cast or mould the final result is obtained, either in plaster or by electrotyping. But Herr Selke's process seems, from the patent specification, to be different from those, and a fuller description of the method will be interesting.

**Carbon Lantern Slides.**—As the lantern season approaches, so will the different methods of making the slides receive attention at the various Society meetings. We see from the report that the carbon process of lantern-slide making was demonstrated before a recent meeting of the Croydon Camera Club. It is somewhat surprising that this process has hitherto been so much neglected by amateurs for lantern transparencies. It is easy to work, a greater variety of colours can be obtained with it than by any other process, and any number of slides can be obtained of identically the same colour, and that is not easy of attainment by any other process that depends upon development and after-toning. The carbon process is also of less trouble than any other that requires the pictures to be toned. The chief and only objection that can be urged against this process is that the tissue is not sensitive enough for it to be used for producing slides from larger negatives in the camera, so that it is necessary to first reproduce the negative to the size of the slide. One of the essentials in the tissue, when it is used for lantern slides, is that it be free from tint, *i.e.*, superficial insolubility, otherwise the highest lights will be veiled and thus mar the brilliancy of the picture on the screen. The kind of tissue generally employed for lantern slides is the special transparency, because it is highly pigmented and the pigment is in an extra fine state of division. It is quite possible that, if there were a demand for it, the manufacturers would put upon the market other coloured tissues having the same characteristics.

**Business Enterprise in Photography.**—The paper read by Mr. J. A. Tennant at the New England Convention, which was published *in extenso* last week, should be read by all photographers about to commence business, and also by many of the older school here, who are now complaining that business is not nearly so good, or so profitable, as it used to be with them in years gone by. What Mr. Tennant said with regard to American businesses applies equally to English ones. At one time, while there was a fair demand for photographs, there were but comparatively few photographers to supply them, and those who did, and could do good work, had only to show specimens and they would quickly build up a good business. The case is very different now. Although the demand for portraits is probably greater now than it ever was, there are very far more photographers to supply them, and, as a consequence, competition is infinitely greater and this competition, unfortunately, has, in too many instances, taken the form of cutting prices, with small profits, accompanied by small returns. Those photographers who, while maintaining their prices, still go on in their old-fashioned reel of twenty years ago, are probably feeling competition most, though their work may be still equal to any. It is those who have greater business enterprise—though not doing better work, perhaps not so good—who are *their* greatest competitors. It is not from the low-priced competition that they suffer most. Although Mr. Tennant's paper was largely devoted to those who are contemplating starting in

business, his remark applies equally well to those who are old-established, if they desire to maintain their businesses against enterprising new comers who do the best class of work.

**What is a Silver Picture?**—This question has more than once occurred to us, as it, no doubt, has to others. In the catalogue of the Royal Photographic Society's Exhibition we find pictures described as "bromide," "gelatino-chloride," and "silver." In advertisements of printers seeking engagements we often notice that they are well qualified in "P.O.P.," "C.C.," and "silver" printing. Now, are not these processes, one and all, silver processes? Would not the term silver apply to every one of them, for they are nothing else? Sometimes collodio-chloride prints are simply called "chlorides." But are not gelatino-chloride and albumenised paper prints as much "chloride" as the collodio-chloride ones? The term "silver" is generally now considered to mean albumenised paper pictures; then, why, when the picture is on paper, should it not be described as albumen—it would not be confounded with the albumen process on glass, and it would be more descriptive. Those unacquainted with photography, visiting the Exhibition, might well assume that the pictures described as bromides and gelatino-chlorides were not silver pictures. With many it is a very general idea that silver prints must necessarily fade and they may be led to assume that pictures, other than those described as "silver," will prove permanent, while they may really prove more evanescent than those by the old albumenised process. In this way the present nomenclature is apt to be misleading, and so it may be to future generations if silver processes should ever become superseded in general practice. We know how frequently the old *sel-d'or* and the old combined toning and fixing baths are often confounded by some modern writers as being one and the same thing, while they are totally different.

#### ON THINGS IN GENERAL.

THE event of the year in things photographic has been the fitting of the Royal Photographic Society's Show to its new quarters in the New Gallery. The opening night was a conspicuous success, socially and pictorially. I am not in the Secretary's confidence, but I do not hesitate to say that the numbers present were far in excess of any that I have ever attended. No little of this may be accounted for by the great popularity of the present President, if I may say so without casting a slur on previous occupants of the Presidential chair. Mr. Dallmeyer, in the natural course of events, is a living and known personality to very many members who never attend meetings; previous Presidents, famous and known by their achievements as they are, have been to the many pure abstractions—beautiful abstractions, it may be, from a literary point of view—not concrete entities to everybody, like the genial host of Saturday a few weeks ago. I heard that we were indebted to him for a very pleasing variation—the addition of music to the other attractions of the *soirée*; a happy thought well carried out.

Of the Exhibition itself, words of praise are deserved. The commercial side of photography was well represented, though in one conspicuous case a little weeding out would have made a better show; quantity is not a useful factor in matters artistic. The side shows (free!), as the apparatus stalls might be not inaptly termed, should prove a financial success, seeing that the charge to the exhibitors was so low. I expect that another year there will, at present prices, be a rush for places among manufacturers generally. The Exhibition proper was distinctly good. (By the bye, why were the staring white number-tickets again used? the Society had distinctly scored on previous occasions by toning them down.) The deadly funereal effect of past exhibitions is not conspicuous in the present gallery, which does not leave such depressing memories as of late years have been forced upon us. Another year, no doubt, there will be a still greater improvement, and pictures with white mounts once more exhibited. For some time past it has been evident that the Hanging Committee literally dare not put up a photograph with light surroundings. I know of pictures rejected which could not possibly have been refused on any other ground. It is useless saying "They're not like dumb-driven

cattle," for the hangers and the hung are alike; they have been driven by the current of popular caprice into countenancing a style of framing which must have driven lumber to a premium. Now that in "another place" a ray of light has illumined the hangers in this direction we may be sure that the R.P.S. will let their own taste have some influence. For the style of the last few years has been as inert as, as ugly, as deficient in taste as originality—an intolerable amount of timber to one halfpenny-worth of photograph, if I may be allowed to play with well-known words.

I freely admit that the Photographic Salon set this fashion, and may claim originality in the matter, whatever it is worth. I had an amusing experience there. An enthusiastic Salonite was expatiating upon the beauties of the contents of the frames. "There's feeling," he said. "That precisely expresses it," said the other, "I myself have a strong feeling of sickness since I came on here." And to the old photographer such a feeling must present itself as he contemplates the inane monstrosities that have been substituted for photographs in such wide profusion. A little opposition is always a benefit to any society or any business; but here the opposition has lost its head and indulged in such grotesque vagaries as to entirely swamp the small residuum of really good work there shown. A well-known reviewer has made an onslaught on the ponderous framing of the Salon, one photograph had, he said, enough timber round it to form a fence to go round the original of the picture. There is some really good work there, not much it is true, and well worth inspection, and not to be pooh-poohed simply because much of it is done by men who exhibit, and exhibit better work, at the New Gallery. I note that the silly preface that has so often afforded merriment has been wisely abandoned, and instead there is an invitation to a cup of tea. Truly, their tea has a better taste than their preface ("Foreword" I believe they used to call it).

When I took up my last *Journal of the Royal Photographic Society* I began after a while to think that by mistake I must have opened a page of *Alice in Wonderland*, for the most delightful topsy-turvydom prevailed that ever characterised a meeting of that august Society, when a paper on "Stops-lenses and Perspective" was read. I don't know what the Kodak Company will say to the writer's dictum that the best lens makers all use another system than the R.P.S. It will, I think be granted that there are more Kodaks sold than any other camera; and their lens stops are all indicated by what is best known as the U.S. system (by the bye, it is known by few that the use of the letters U.S. as describing the R.P.S. system was invented by THE BRITISH JOURNAL OF PHOTOGRAPHY). Next we find twenty inches given as the usual distance for reading and viewing pictures. Well, all I can say is that when a man begins to trombone his paper (which is certainly the case at twenty inches) he ought to use spectacles. But the gems of the suggestions are that hanging committees should examine the photographs to see if they are taken with a rising front and hang them in accordance. After this one is not surprised to find it recommended to take a church tower in horizontal sections and piece them together, like they make wedding cakes in fact. Infected, no doubt, by the *Alice in Wonderland* atmosphere, most of the speakers seemed to lose their usual aplomb and give us "facts" of most doubtful character. Mr. Bolas can give points to most of us yet we find him quoting books as giving about 60° as the angle included by vision. My recollection is that they give a far larger angle. His proof of the amount seen really is ingenious and correct. Further confusion of ideas was introduced by another clever worker, the Rev. F. C. Lambert, who explained Mr. Bolas's next experiment by saying that the lights falling on the periphery of the retina merely showed that there were nerves in that position and not that the lights were distinctly seen. Well, it is a fact that when an astronomer cannot see a faint star when looking straight at it he brings its image towards the periphery of the retina, and then he can see it; surely that is "seeing in the ordinary sense of the word." Lastly, no one could help being struck by the topsy-turvy state of the discussion when Mr. T. Thorne Baker described a photograph of the original, of which the only way in which one could gain any idea was by lying on the ground face up, and holding the photograph above one's head. Possibly at the next R.P.S. Exhibition couches will be provided for readily inspecting photographs of this nature. I would

commend to every anti wide-angle enthusiast the sober, weighty words of the President, "There was therefore, theoretically, no objection whatever to an extremely wide angle provided the perspective was viewed from the true station point." This might form a permanent text whenever the subject is again discussed. It has been said many times before, but the argument leading up to it was cogent and irrefragable.

Mr. Reed, in his article on "Copyright Portraits," touches a sore spot with many photographers; but he may take it the days of 80,000 orders for Royal, or any other photographs, are gone for ever. The illustrated papers have done that for us. Every one now looks for any specially taken photograph to be visible in "any weekly illustrated paper." A lot of money has been made, and will be made, by copyright fees from the illustrators. He is, however, a lucky man who often gets more than a five-pound note for such (and they are trying to establish a maximum of five shillings!), but what have they lost by it for themselves and their brother photographers?—hundreds of thousands of pounds of replicas. And who have gained, except the producers of those wretched, feeble caricatures of photography which are published to the utter degradation of illustrated journalism from the proud and high position it once occupied of artistic eminence and exploiters of the very best examples of the now almost extinct British art—wood-engraving. Finally, Mr. Reed has hold of the wrong end of the stick. It is not the photographers who make the arrangements for publishing their Royal photographs in one journal; it is the proprietors of the journal who make the arrangements, and the photographers merely act as their hired agents; they receive, therefore, a weekly retaining fee! So much for what journalism does to benefit photographers in general.

A great deal of interest has been taken in the alleged photographs taken through a human body by nothing but sunlight; are they fakes or not? One well-known photographer was arguing that there was nothing wonderful in it, as the sun was bound to act through the body if the plate was put there long enough. "Look," he said, "how easily we can see a light through the fingers." This seems a fair argument till it is put into figures. Let us suppose that, in the first case, the sun on an open negative, with a plate behind, could impress an image in a millionth of a second; further, that a section of the body, say an eighth of an inch thick, permitted as much as one-tenth of the received light to pass through. (Both these assumptions are extreme; the power of the sun and the transparency of the body would be much less.) Then the light passing through, say, eight inches of human body would take many million of million years to produce a print! The actual fraction representing the amount would be one with one million for a numerator, and a denominator of one followed by a cipher for each eighth of an inch, say sixty-four ciphers—an amount of light whose minuteness would be beyond the power of the human mind to conceive.

#### DIRECT CARBON PRINTING WITHOUT TRANSFER.

[In sending us the appended note on a non-transfer method of carbon printing with celluloid as a support, Dr. D'Arcy Power remarks: "Accompanying herewith I enclose you a brief description of a method of carbon printing that, so far as I can ascertain, is new, and is certainly not in use. Knowing that carbon printing is more largely practised in Europe than on this continent, I send these notes to THE BRITISH JOURNAL OF PHOTOGRAPHY as the best means of reaching the largest number of workers."]

To obtain an unreversed carbon print without transfer of any kind, and to do this without any greater trouble than is involved in the production of a silver print, is what I purpose to describe.

More than a year ago I experimented on the printing of carbon tissue through a film of transparent celluloid, and found that no perceptible difference of definition resulted from its interposition; on the contrary, that the image was rather benefited than otherwise by its use. In these experiments the carbon tissue was squeegeed direct from the sensitising bath on to the celluloid, the outer surface washed clean, and, when dry, the tissue printed through the celluloid, and, after development in the usual way, the celluloid was backed up by

squeegeeing it in optical contact with paper, or by coating it with a layer of paint. In this way I obtained very beautiful prints, having a highly polished surface, that elicited much praise from those who love that kind of thing, but which on that account did not please me. Some time elapsed before it occurred to me that celluloid with a ground-glass surface could be printed through, but one day I tried the experiment, and I was not a little astonished to find that the image developed nearly as sharp as with unground celluloid. This solved the whole difficulty of direct printing. I coated a sheet of ground-glass celluloid with the usual gelatine and pigment coating mixture. To sensitise it it was only necessary to immerse it in the bichromate solution and hang it up to dry. Printing was done as with silver paper, no safe-edge being required. Development can be proceeded with immediately, the safe-edge being unnecessary, and the moistening and pressure not needed. Direct from the printing frame it passes into the hot water, is washed up, dried, and backed. The backing may consist of paper of any desired tint or grain, squeegeed into optical contact with the print by means of a solution of gelatine, or it may be paint ground in varnish, such as may be bought anywhere. By judicious backing, prints of exceeding beauty may be obtained. The ground celluloid at present on the market gives a surface slightly more matt than is desirable for small subjects with fine details. This however, may be easily reduced to any extent desired by rubbing the matt surface with a mixture of one part of ether in eight parts of alcohol. I expect to soon obtain from the makers a celluloid with a more finely grained surface; and, when this is on the market, and the Elliott or Autotype Company coat the same with pigmented gelatine, carbon printing will be the simplest process in existence. Let me here sum up the advantages of my method of working:—

First. Tissue, after sensitising, dries flat and smooth.

Second. Requires no safe-edge.

Third. No transfer and subsequent waiting prior to development.

Fourth. No second transfer to obtain correct position.

Fifth. A surface that can be readily spotted, retouched, offensive high lights toned down, or painted out, or the whole picture tinted as a crystoleum.

Sixth. After the picture is produced, the power of choosing the tint and apparent texture of the surface it shall seem to possess.

Seventh. A surface that is indestructible and may be washed, thus allowing of framing without glass, whereby the purity of tint of the print is spared the modifying effect of colour in the glass.

Against these many advantages the only added inconvenience is the trouble of coating the celluloid.

Until celluloid coated with pigment can be bought, the worker desirous of using this process may choose one of three courses.

First. He may coat the celluloid himself, which is a little troublesome, as it is more difficult to handle than paper.

Second. He may sensitise ordinary carbon tissue and squeegee it to the smooth side of the frosted celluloid. If he follow this method, he will need to take care that no air bubbles, even the smallest, interpose between the tissue and the celluloid, and he will also need to be careful that as the tissue dries it does not separate from the celluloid surface before printing, or loss of definition over the detached portion will result.

Third. Tissue may be sensitised and printed in the ordinary way, transferred to celluloid, and then backed up. This last method while the same in all respects as single transfer, gives the correct position without a double transfer. It permits of choice of backing, and has the advantage of absolute sharpness of definition. Until coated celluloid is placed upon the market it will hold the first place with the general worker, and is the method I at present employ.

I have not found that any coating of the celluloid with chromatised gelatine is necessary, but some care is required in squeegeeing to the final support, that no air bubbles intervene. They will cause stars on the print. Spotting and retouching is best done with oil colours, and the power of modification is almost unlimited.

Such in brief is the process I would urge all carbon workers to at least try. The facility of working, and the beauty and permanency of the prints will undoubtedly assure it a prominent place among photographic printing methods.

H. D'ARCY POWER, M.D.

1025, Sutter-street, San Francisco.

## THE EVOLUTION OF MODERN LENSES.

[Abstract of the President's Address to the Members of the Royal Photographic Society, October 9, 1900.]

The first doublet specially intended for photography does not appear to have been made by Chevalier until 1840. These doublets were reported upon in detail by the "Societe d'Encouragement," who awarded him a platinum medal, on the ground of less spherical aberration and adjustable focal length. The latter was brought about by an adjustment in the separation of the component lenses. It is interesting to note that a document exists purporting to be signed by Charles Chevalier, was witnessed by Jombard, describing these adjustable doublets, and, although no formulæ or particulars are given, the employment of the iris diaphragm is mentioned for the first time.

This year (1840) was signalled by the advent of the Petzval portrait lens. At this juncture, a most important one in the history of photography, and particularly in lens construction, it is necessary to examine how far the theory of the subject had progressed. So far as I am aware, the only contribution which contained any reference to lenses constructed for the camera obscura occurs in an early classic contribution by the late Astronomer-Royal, Sir George Airy. "On the spherical aberration of eye-pieces of telescopes," contributed to the Cambridge Philosophical Society in May, 1827. The author here treats of three spherical aberrations; distortion, curvature of field, and astigmatism. It is evident from his writing that he considers that lenses hitherto constructed owed their form to "General Rules of Workmen," and at the conclusion of his thesis, he gives a number of practical rules, which conform to his theoretical investigations. There is a short passage referring to the best forms of single lenses, and the situation of the diaphragm "most favourable to the formation of a distinct image" in the camera obscura; they are a plano-convex with the diaphragm placed in front of either two positions, or a meniscus lens, the diaphragm in this case being placed behind the lens in either of two positions. He shows that if a concave spherical surface is used to receive the image, it will be accurately formed upon it. Sir George Airy points out that Dr. Wollaston's periscopic camera conforms to the theoretical conditions.

With the exception of this notable contribution, which threw important light upon optical theory generally, there was no other advance until the epoch-making investigations of the late Professor Petzval. In 1843, Professor Joseph Petzval, in an address to the Arch-duke Ludwig of Austria, described how he had raised the subject of the correction of photographic lenses from the plane of experiment to a definite scientific and mathematical inquiry. He recited how the errors in the formation of images by lenses, due to the employment of spherical surfaces, might theoretically be eliminated. The outcome of this research was to place a portrait lens of high intensity and good covering power in the hands of photographers and photographic investigators; in so doing he earned for himself undying fame in the science, and conferred upon his generation one of the most important means of raising the status of photography. Petzval's theoretical investigations formed the basis of some subsequent elaboration by Seidel, and up to the present date, the Petzval-Seidel theory of the construction of lenses holds its own.

Petzval's first theoretical results were brought out in 1840 by the house of Voigtlander. Petzval had not only calculated the portrait lens, but also a non-distorting landscape lens; the latter, however, did not make its appearance until 1858, and will be referred to later. Soon after the appearance of the first portrait lenses and the publication of Petzval's theory, manufacturing opticians in every country adopted this form of portrait lens, which held its sway until midway in the sixties.

In order to trace the evolution of modern lenses from this period onwards it will tend to least confusion if they are placed under the following headings:—

1. Landscape lenses.
2. Portrait lenses.
3. Triple lenses.
4. Doublets.
5. Telephotographic lenses.

## 1.—LANDSCAPE LENSES.

The first, as we have seen, was Wollaston's periscopic lens, an account of which he contributed to the "Cambridge Philosophical Transactions" in 1812. The next was the early form of single cemented lens composed of two glasses already described as having been constructed by Chevalier for Daguerre. In 1859 Voigtlander issued the landscape lens calculated by Petzval in 1840. It was known as the "Orthoscopic lens," and was hailed with delight as the first non-distorting landscape lens introduced. Unfortunately the claims for its entire freedom from distortion, and spherical aberration, were not borne out, for it was found that it pro-

duced "pin-cushion" distortion, in contra-distinction to the "barrel-shape" inherent in the landscape lenses hitherto employed with the diaphragm situated in front of the lens.

In 1857 the late Thomas Grubb patented a view lens consisting of a meniscus crown lens cemented to a meniscus flint lens, with the diaphragm placed in front of the former. In this lens the correction for spherical aberration was more perfect than in those hitherto constructed, though it was not strictly aplanatic. Grubb claimed that: "It forms more distinct images of objects than either the ordinary view lens, or the front compound lens of a portrait combination, as occasionally used by photographers as a view lens. I do not, however, limit myself in the use of my improved lens to that of taking views, or of being used alone. The lens admits of entering with advantage into combination with one or more other lenses of either similar construction to itself, or of other or ordinary constructions." Thomas Grubb, so far as I can trace, did not employ himself to similar combinations to form a doublet, but his statement in his patent that there was this possibility, subsequently give rise to the suggestion that Steinheil's aplanat and my late father's rapid rectilinear were due to Grubb's single landscape lens, although it seems to be more reasonable to look upon these as an evolution of the symmetrical non-distorting periscopic lens of Steinheil.

In 1859 Goddard constructed a landscape lens which he termed a "Double periscopic." It was composed of a double convex crown cemented to a double concave flint placed in close proximity to a meniscus crown, the concavities facing one another, and the components being mounted in a single cell with the diaphragm placed in front of the cemented combination. This lens is of particular interest as being the first published attempt to eliminate the "barrel-shaped" distortion due to the position of the diaphragm with respect to the lens, when composed of a single cemented combination. The late Mr. Traill Taylor states that he was in possession of the only lens of this form made by Goddard. About the same time Goddard introduced a lens which he termed a "combination landscape lens," which I have included under this heading, although it might possibly also be included under doublets. The lens itself consisted of two combinations, the anterior being a double convex crown cemented to a double concave flint, the posterior combination being composed of a double concave flint mounted in juxtaposition to a meniscus crown. The back combination was practically of infinite focal length, and Goddard suggested the substitution of various anterior achromatic combinations, of different focal length, to be used in conjunction with the posterior combination, so as to obtain various focal lengths. Goddard also claimed freedom from distortion and flatness of field. The late Mr. Traill Taylor stated that he had access to Goddard's work-book after his decease, but I have failed to trace any particulars as to the intensity at which this lens worked. It seems in the main to have been an attempt to perfect Petzval's orthoscopic lens.

The next important advance was due to my late father, J. H. Dallmeyer, who in 1865 patented his wide-angle landscape lens. This lens was the first triple cemented lens, and consisted of a meniscus flint sandwiched between two meniscus crown lenses. It worked at an intensity of  $f-15$  and covered with fine definition a greater angle than any single lens hitherto introduced.

In 1884 I modified this form of lens and by employing an extra light flint glass, in place of the anterior crown employed by my father, attained the highest intensity of  $f-11$ . This lens, however, was not designed to cover so great an angle, but on the other hand to include a narrow angle destined to give more pleasing perspective.

In 1887 I constructed a rectilinear landscape lens which history shows was designed upon similar lines to Goddard's double periscopic. The lens itself differed in that the anterior cemented portion was a double meniscus in contra-distinction to Goddard's double convex crown cemented to a double concave flint.

It is necessary at this point to make a brief reference to a subject, the great importance of which is, in itself, sufficient to have occupied more time than is at my disposal in this address. I refer to the possibilities opened up to opticians for improvements in lenses, particularly in the cure of astigmatism, by the introduction of the new Jena glasses. In the early eighties experimental research was undertaken by Professor Abbe, an Honorary Fellow of our Society, in conjunction with Messrs. Schott and Gen, to produce new types of optical glass. Until their labours were completed and the results obtainable in commerce (in 1888), the only glasses which had hitherto been available for the use of the opticians, were characterised in general by an uniform inter-relation of refractive index with dispersive power: the higher the refraction, the greater being the dispersive power. An examination of the new glasses shows that this old order of things was departed from in several instances, and we were given crown glasses which possess a higher re-

fractive index but a less dispersive power than the flint glasse formerly, and still, employed.

To proceed with the evolution of the single lens: in 1893, Dr. Rudolph, of the firm of Messrs. Zeiss, constructed the first single anastigmat composed of three lenses cemented together. It was aplanatic and worked at an intensity of  $f-14$ ; later in 1895, he worked out a quadruple anastigmat which was also free from spherical aberration, and works at an intensity of  $f-12.5$ . This lens is the most perfectly corrected single lens that has yet been evolved, for in the latter, Dr. Rudolph has succeeded, not only in obtaining freedom from spherical aberration and astigmatism, but also made a very successful attempt at the elimination of coma.

## II.—PORTRAIT LENSES.

The first, as already intimated, was due to Professor Petzval and constructed by Voiglander in 1840.

In 1841, probably before Petzval's work was known to opticians in this country, my late grandfather, Andrew Ross, constructed a portrait lens for Henry Collen, in which both lenses externally were plano-convex, the front being composed of a double convex lens in contact with a plano-concave flint; the posterior combination consisting of a plano-convex crown in contact with a meniscus flint. The lens was not aplanatic and gave a very curved field, so much so, that it was necessary to have the sensitiveness surface upon which the image was received, bent into a spherical form. Andrew Ross shortly after this constructed the earliest of the Petzval lenses which were made in this country in accordance with his theory.

The earlier lenses of this form were not "actinic," that is to say, the chemical and visual foci were not coincident. It is therefore interesting to note that in 1854, Lerebour constructed a lens in which he claims to have accomplished the coincidence of chemical and visual rays.

Until the year 1866 every manufacturer of portrait lenses constructed them upon Petzval's formulæ in varying degrees of intensity. In this year my late father patented a new form of portrait lens in which the front combination was similar in form to that of Petzval, but the instrument as a whole differed from it in some essential features. In Petzval's lens the rays emergent from the front combination were received upon the convex surface of a meniscus flint, which formed the anterior element of the back combination, and emerged parallel upon the "crossed" form of crown lens, which practically determined the focal length of the entire Petzval construction. In my father's lens the anterior element of the back combination was a meniscus crown. The rays emergent from this converged to a focus in close proximity to the lens itself, but are intercepted by the back element, which consists of a meniscus flint, the focus being formed at the focal plane of the entire combination, as free from spherical aberration as occurs in Petzval's lens. The disposition of the posterior combination of this lens not only enabled a flatter field to be attained, but eliminated the tendency to "ghost" and "flare-spot" which existed in Petzval's form. As soon as this patent lapsed, the Dallmeyer model was generally adopted by manufacturing opticians, and for ordinary studio work is as much in use to-day as it was at the time of its introduction.

In the year 1874 Steinheil introduced a rapid form of his aplanat, which will be referred to later, but as it possessed the high intensity of  $f-4$ , I have included it among portrait lenses. Each combination consisted of crown and flint meniscus lenses cemented together so that there were only four reflecting surfaces, a condition which theoretically warrants the claim for increased brilliancy in the image.

The advent of Steinheil's group, "anti-planat," marked an important departure in lens construction, for although the Jena glasses which have been referred to above were not available, Steinheil was first to incorporate in this lens the principle of eliminating astigmatism by combining a "crown shape" lens of high refractive index with a "flint-shaped" of lower refractive index. This he did by constructing the anterior combination of a "crown-shaped" flint cemented to a "flint-shaped" crown, the combination possessing positive focal length, but being very much "under-corrected"; the correction of the whole instrument being brought about by a very much "over-corrected" posterior combination.

In 1895 and 1896 my friend and colleague Mr. H. L. Aldis introduced the "stigmatic" portrait lens which in general terms may be described as my late father's patent portrait lens rendered free from the defect of astigmatism. This lens is constructed of three intensities,  $f-4$ ,  $f-6$ , and  $f-7.5$ .

In 1898 Dr. Rudolph issued a lens known as the "planar," which also works at an intensity of  $f-4$ . It is symmetrical and novel in design, each combination consisting of a single meniscus lens, mounted in close proximity to a meniscus combination composed of a double convex lens

cemented to a double concave. It is thus seen that at the present day we are in possession of two types of lens which maintain the intensity of Petzval's construction, but are free from its defects.

## III.—TRIPLE LENSES.

The first triple lens of which I can find any account is referred to by the late Mr. Traill Taylor as having been constructed by Goddard in 1839. "The front was an ordinary shallow achromatic meniscus, the centre being a bi-concave, and the back a deep meniscus. The centre lens was smaller than the others, but neither it nor the back lens was achromatised. The first achromatic, and the back meniscus, were of similar foci, the power of the intermediate being such as to neutralise the magnifying power of either of them." ("The Optics of Photography," J. Traill Taylor.)

In 1860 Thomas Sutton introduced a lens composed of two achromatised plano-convex lenses of similar foci mounted at either end of a tube with a simple bi-concave lens, similar in power to Goddard's, placed between them; Sutton termed this lens the "symmetrical triplet."

In 1861 my late father introduced his "Triple Achromatic Lens," in which each element was achromatised. This lens was employed for many years on account of its considerable intensity ( $f-10$ ) and its freedom from distortion, an essential feature for architectural photography. Thomas Ross subsequently introduced a triple lens of very similar type; he constructed the anterior and posterior combinations of the plano-convex form, whereas those of the "triple achromatic" were of shallow meniscus form.

In 1890 Professor Abbe and Dr. Rudolph introduced a symmetrical triple lens in which the exterior elements were uncorrected meniscus lenses, the middle being composed of a double convex lens cemented between two plano-convex lenses. According to Mr. Traill Taylor, Dr. Schroeder ante-dated this lens in an objective specially adapted for celestial photography.

In 1893 Mr. Dennis Taylor introduced the most important triple lens which has been constructed up to the present time. Mr. Dennis Taylor attacked the problem in a distinctly original manner by constructing each of the component elements of forms free from diaphragm corrections, and placed the onus of complete correction for the entire instrument upon the middle negative lens, which is equal in power to the combined exterior elements. Mr. Dennis Taylor has succeeded in so far simplifying the construction, that in its present form each of the three component elements is a single glass lens. It is known commercially as the "Cooke Lens."

It is constructed in two intensities— $f-6.5$  and  $f-8$ .

## IV.—DOUBLETS.

The first symmetrical doublet was ascribed by Mr. Traill Taylor to Davidson, an Edinburgh optician, who in 1841 constructed a double combination in which each element was composed of a plano-convex crown cemented to a plano-concave flint, with the diaphragm placed between the combinations. But for the lack of rapidity, Davidson's lens would probably have had a longer life.

In 1863 Harrison introduced his Globe lens, and in 1864 Thomas Ross an unsymmetrical doublet, but neither of these lenses were of high intensity.

In 1865 Steinheil introduced the simplest non-distorting lens which had appeared up to that date. It consisted of two single uncorrected meniscus lenses with a diaphragm placed between them. As this lens, and one introduced by Zentmeyer of a very similar nature, were not actinic, the chemical focus had to be arrived at either by trial-and-error, or calculation. The intensity of these lenses was low, but their simplicity and large covering power caused considerable interest to be manifested in them.

In 1866 Steinheil and my late father were both at work upon achromatising the symmetrical meniscus form of lens, and at increasing its rapidity. The outcome of this work was the appearance of Steinheil's aplanat in 1866 and my father's wide-angle rectilinear in the same year. In the following year he introduced the first "Rapid Rectilinear." In point of publication Steinheil appears to have ante-dated him with the aplanat. In both these lenses, each combination consisted of the Grubb form of landscape lens, but whereas no lens, so far as I can gather, had hitherto been constructed of this form, which was truly aplanatic, these lenses were welcomed as a great advance in non-distorting aplanatic lenses of considerable angular aperture ( $f-8$ ). They practically replaced the triple lenses which had hitherto been in use.

In 1872 Morrison conceived the idea that some advantage would accrue by slightly over-correcting one of the lenses of Harrison's "Globe" and supplying the place of the other with a single crown glass meniscus. It is stated that in the Morrison lens a rather larger angle was included than had been hitherto attained.

In 1887 Dr. Schroder, of the firm of Ross and Co., introduced a very interesting lens known as the "Concentric." In this lens the new high refracting and low dispersing crown glass from Jena was employed, for the first time, in lens construction. Each combination consisted of a plano-convex crown glass of high refraction cemented at the plane surface to a plano-concave lens of lower refractive power than the crown, but of practically the same dispersive power. By this means Schroeder was enabled to strike the internal and external curves of the combination from one centre and still produce a real focus. This lens, although it worked at a low intensity ( $f$ -22), was the first lens which gave a field absolutely free from astigmatism upon a plane surface.

In 1890 Dr. Miethe is credited with having constructed an anastigmat, but I have been unable to ascertain from him its exact construction, as I have only just come across a record of it.

In this year also Zeiss constructed two or three forms of wide-angle double anastigmat, each component being a double combination. These lenses had an angular aperture of  $f$ -17 to  $f$ -18.

In 1891 Rudolph issued his anastigmat-doublet, working at an intensity of  $f$ -7.5. In this lens one combination was composed of glasses of abnormal character and the other of normal glasses; by this method Rudolph claims to have arrived at a perfect correction of astigmatism.

In 1893 Rudolph constructed his anastigmat doublet of a different form, the anterior lens being a double combination, and the posterior a triple cemented combination, the doublet working at an intensity of  $f$ -7.8.

In the same year he constructed the single triple anastigmat already referred to under landscape lenses.

Dr. E. von Hoegh, of the firm of Goerz, about the same time introduced his double anastigmat, which consists of two triple cemented combinations similar to the single triple anastigmat of Zeiss.

It is not my province to criticise controversial matter, but a discussion which has recently taken place in the "Archiv fur Wissenschaftliche Photographie" between Dr. von Rohr, of the firm of Zeiss, and Dr. von Hoegh, is, bereft of certain personal matter, very interesting as showing the claims of Dr. Rudolph and Dr. von Hoegh in respect of the originality of the Goerz double anastigmat. That both these gentlemen have contributed largely towards the perfection of symmetrical anastigmatic lenses is beyond dispute.

In 1894 Dr. Kaempfer, of the firm of Voigtlander, introduced another symmetrical anastigmat known as the "Collinear." Dr. Kaempfer had been working on symmetrical anastigmat constructions as early as March, 1892, but I understand that the exigencies of the Patent Office, which were forced upon him by his competitors, compelled him to restrain his claim to the form known as "Collinear." Steinheil was apparently at work on a very similar lens about the same time which is known as the "ortho-stigmat."

In 1895, after the completion of his quadruple anastigmat Dr. Rudolph issued combinations of these single lenses to form doublets which he terms the "Satz-anastigmat." This lens has an advantage over other lenses which are free from astigmatism, in that the separate elements are individually more perfect when used as single lenses.

In this type of lens again we have been able to trace how the glasses introduced at Jena have enabled modern opticians to increase the angular aperture of their lenses, to produce perfect flatness of field, and freedom from astigmatism.

#### V.—TELEPHOTOGRAPHIC LENSES.

This subject will require but a brief treatment. In 1891 Dr. Miethe and I were working independently to produce an instrument of practical value to photographers, which should enable them to obtain large images in the camera of distant objects. We both worked on the system of throwing the nodal point of the lens forward, and beyond the lens itself, in order to obtain a large size of image without employing a camera of inordinate length. In the preface to a recent contribution of mine upon this subject I have given credit to Duboscq for ante-dating me, but a reference to his patent shows that he employed the system known as secondary magnification. Dr. Miethe concerned himself more particularly to special combinations of positive and negative lenses, while I attacked the problem in a manner which should make any lens then in existence convertible into a telephotographic system. Since I briefly referred to the history of the subject, so far as I had been able to trace it, Dr. von Rohr has come across a work by Canon Zahn, of Wurtzburg, an extract from which appears in THE BRITISH JOURNAL OF PHOTOGRAPHY, May 11, 1900. It is quite clear that Zahn not only applied the Galilean telescope for forming enlarged images, but fully understood the principle involved. Plateau mentions another work by Zahn published in 1685 "Oculus artificialis teledioptricus," &c This volume probably describes the instrument itself more fully, and might

throw more light upon the subject, than is contained in the reference made by Dr. von Rohr. The discovery of Zahn's work was particularly interesting to me, for I take it that no earnest worker can have greater satisfaction than to feel that able men in times gone by have given thought to problems that we may set ourselves at the present day.

In 1895 Dr. Rudolph paid considerable attention to special constructions for telephotographic purposes and introduced single cemented telepositives to be used in conjunction with single cemented triple negatives. The latter are made of such a form that placed in one position they perform best with his telepositives, but when reversed are available for use with ordinary corrected lenses.

During the course of this year I have been engaged upon a new form of telephotographic lens which is specially designed for hand-camera workers; I hope to describe it to you shortly, and that it may be of value.

THOMAS R. DALLMEYER, F.R.A.S.

#### PAINTING AND BLOCKING-OUT NEGATIVES AND TRANSPARENCIES.

[The following very practical article is reprinted from the *Photographic Record*, the quarterly organ of the Manchester Amateur Photographic Society.]

It may often happen that the amateur or professional photographer comes across subjects which he finds would be more suitably and better rendered, for the purpose he has in view, were he to remove them entirely from their immediate surroundings.

The background may be unsuitable, or some object close at hand be too prominent, the removal of either of which may be impossible. Hence comes the necessity of either removing the object to be photographed to more suitable environment, or if that also is impossible, photographing the subject where it is and by after treatment of the negative correcting this defect. In such circumstances, this process of "blocking" or "painting-out" negatives, will be of great usefulness. By its means any portion of a negative not required to be printed from, can be completely obliterated; and thus a great power is placed in the hands of the photographer. This power may be wielded in a variety of ways, and for an astonishing variety of effects, under the hands of a careful and thoughtful worker, and, though personally my experience has been limited to certain branches, still a few hints which have been gained by that subtle and often expensive teacher, "experience," may prove helpful, and may indeed to the earnest mind suggest some fresh scope for this branch of work.

It is in a spirit of inquiry that I give this demonstration, for many of you have I know some time or other utilised the same process, and no doubt gained some knowledge which may be useful to me. I can only hope that in the discussion afterwards they will give the benefit of what they may have learned, for it is chiefly by such mutual help that advancements are made.

I don't know that my methods are any different to other workers, or that my knowledge is either new or stale, for I never remember seeing an article on the same subject in any of the photographic books or periodicals—what little I do know has simply been "picked up" in the course of about six years' work. Under these circumstances it will perhaps be best to explain how I have been accustomed to work, and give you any helpful hints I know of, treating you all alike as "beginners" and making the explanation in as simple form as possible.

To amateurs, the utility of this power of blocking out portions of negatives will be found most valuable in botanical and floral work, and the photographing of statuary, pictures, coins, &c. It will also be found useful for completely blocking out skies in landscape negatives where it is desired to introduce clouds on a print, or for altering an offending horizon line. The same method of work is applied to all these branches of photography with but slight modifications, so that after describing those I have adopted I will leave you to apply them to whichever branch you desire.

Personally, it is in the photography of machinery that I have found the inestimable value of this process. Being engaged in the engineering industry I have had many opportunities of photographing various new machines, when, in all their glory of new paint and polished steel, they are ready for delivery from the works. Any who have been inside a workshop know the surroundings—the grimy walls, benches and the general disorderly state of all that is near. Amidst these surroundings a new machine has been built up, and is standing ready for inspection and delivery. A photograph of it is of great usefulness both to the designer—and for trade purposes. It is impossible to remove it from its surroundings without pulling the machine to pieces and re-erecting (an undertaking not to be thought of), so that one has to do the best he can with the machine as it stands.

I show you here some photographs of machinery taken under these conditions of environment, also prints from the same negatives after they have been treated with this blocking out process, and you will note the wonderful improvement. The machine previously lost amidst its surroundings, now stands out sharp and distinct, every bit of intricate mechanism previously difficult to locate, now outlined against a perfectly white background, whilst the adjacent machinery, which was so confusing before, is no longer seen. Only a portion of the floor of the workshop remains—just sufficient to show that the machine possesses a foundation. That such an improvement is of a practical value cannot be denied, and it, to my mind, fully justifies the amount of time spent upon the negative.

In some instances the negative, possibly taken under adverse circumstances, or through some error of judgment in exposure or development, has turned out bad. It had been developed some time after the machine had been pulled down and despatched, and though anything but right as a negative it has had to be made the best of, being the only record of the machine.

Here are some lantern slides showing that exactly the same treatment may be applied to statuary. We all know how the statuary in our local museums and public places, are often put up in the most unsuitable spots and corners—that is “speaking photographically,” of course. We want to rid them of their surroundings when we photograph them. How many of us have spent hours in making prints from these negatives—utilising all kinds of dodges to secure a more appropriate background than perhaps an iron railing, a papered wall, or a wall hung with pictures. (For myself I must admit having a rather pet fancy for such work.) Yet how many of these are successful, or even satisfying to the one who produced them. To those who desire the best pictures of such subjects, I would advise the making of transparencies (enlarged to  $\frac{1}{2}$ - or full-plate size if their original negative is only a small one). Paint these out in a similar manner to the lantern slides shown, and after suitable mounting hang them for window or lamp decoration. If we wish to produce a print from such a negative with a dark background produced by this blocking-out process, it is necessary to make a transparency from the negative, block out the portions not required on that, and then make another negative from the result, and print in the ordinary manner. But that is rather a tedious proceeding, and there are perhaps other ways more simple—though undoubtedly if we require a large number of prints from one negative this is the simplest and quickest way.

I have selected a photograph of a machine as an example to show you how to work, for on such a negative you need all the combinations and outside aids it is possible to require. Our object with it is to paint out with an opaque varnish those parts which will be found of use, and which will enable a photographer to do any variety of work he chooses, are as follows:—

A couple of sable brushes, preferably a No. 4 and a No. 8 with fine points.

A No. 8 camel hair brush.

A draughtsman's ruling pen.

An ordinary fine writing pen (say a Gillott 404).

A few French curves.

A short flat ruler or set square.

A bottle of turpentine.

A little Indian ink.

A bottle of black varnish or “Photofake” and

An ordinary retouching frame.

The retouching frame or desk is an absolute necessity, and it is of no use to try and dispense with its services. They are to be obtained very cheap, and indeed are such a valuable acquisition to a photographer for a variety of purposes, that few will be found who do not already possess one. I would advise those about to purchase, to secure one which allows the negative to be freely changed from a vertical to a horizontal position. The advantage of this will be explained later.

In working, place the frame in front of a window (preferably looking north to avoid the sun's rays), and by the judicious use of a blind and some brown paper, concentrate the light admitted to the room on to a sheet of paper acting as a reflector, on the base of the retouching frame. Placing the negative in the frame—film uppermost—proceed to carefully examine it. Note all the little corners that have to be filled up, and all the portions of the background which can be seen peeping through the intricacies of the machine. Always have a rough print off the negative at hand for comparison and reference. I generally secure an ordinary ferro-prussiate print for this purpose—they are easily and cheaply procured, and unless there is a lot of most intricate detail work to be blocked out, they are quite good enough.

The first thing I would ask you to remember is this: do not start from the top of the negative and work downwards, always start from the centre and work outwards, turning the negative round on the retouching frame as required. If you have a very steady hand and are expert in the use of a colour brush, pour a little of the black varnish into a small pot or saucer, and, using the No. 4 (fine) sable brush, proceed to paint out all the small portions of the background that are seen through the framework of the machine. Start from a corner (do not work into one) and with a fine line paint round all the small portions of the outline, leaving the long curves and straight lines alone. If you are not thus skilled with a brush, use the writing pen dipped in Indian ink instead. Hold it lightly in your hand at about an angle of 45 deg., with the surface of the plate. Do not press the point of the pen into the film, but pass it smoothly and evenly over the surface. Take care not to try to work too quickly. For the straight lines and long curves it is preferable (whether you are skilled with the brush or not) to use the draughtsman's pen and rule the lines with Indian ink, you are then almost sure to have them smooth and even. The importance of this is made very evident, if enlargements are to be made from the negative afterwards. One must needs be a most expert draughtsman to be able to paint a straight line accurately, by the use of a brush alone. Let those who doubt this statement try and make a line, say a couple of inches long. At first glance it may appear perfectly true, but test it!

It is this difficulty of accurately presenting a long straight line which causes the greatest trouble, and if one judges from the specimen prints of such photographs, exhibited outside many of the leading professional establishments in the city, one cannot help but come to the conclusion that they have not yet mastered the secret of successful work. On a recent negative by one of the principal firms of professionals who make a speciality of this class of work, they had, to their mind, satisfactorily overcome the difficulty by glueing on the film side of the negative a piece of opaque paper that had a clean cut edge. This method is undoubtedly ingenious, but as it could only be brought into use on outside lines, can hardly be called satisfactorily. On the same negative a portion of the background, showing between the different parts of the machine, had been left severely alone. The space was about 1-64th of an inch in width and about 6 inches in length, having about three breaks in that distance. The line was perfectly sharp and true, being between two polished cylindrical surfaces. Had they attempted to put it in by the use of a brush it would have ended in disaster, and this they evidently knew. Yet by means of a ruling pen this would be a comparatively easy undertaking.

In using a ruling pen, hold it perfectly vertical to the surface of the plate and do not try to make the lines too broad. See that it has a smooth and well-rounded point, and in using it hold it lightly and loosely between the first three fingers and the thumb, allowing the little finger to act as guide and to steady the hand as it passes over the plate. Unless you do this you are apt to cut into the film with the point of the pen.

As Indian ink dries very rapidly on exposure to the air it is necessary to constantly wipe out the ruling pen with a piece of rag. Do not take up too much ink in the pen at a time, and before using carefully wipe the outside of the nibs perfectly dry. Use ink that is entirely free from grit and dust, and of such a consistency as will allow it to flow freely and evenly from the pen.

If you require to smooth a jagged edge or to remove a line or any portion of a line which has been put on the negative by Indian ink, this can be very easily done by using a brush dipped in water; but care must be taken to wait until that portion of the negative has completely dried before going over it again with a pen, or disaster will result in the shape of a torn film.

The use of xylonite set squares and curves, such as can be obtained from any drawing material dealers, is to be commended, as, being transparent, they enable you to see exactly the place and length of line you require.

When the negative has been completely outlined by these means, then proceed to fill up the spaces left, with the black varnish, using the large sable brush for the purpose, remembering the note previously given about working outwards from a corner (not into it), and being careful not to have the brush too full of varnish. Should it happen that you accidentally overstep the borderline of Indian ink with the varnish, immediately wipe it back with the tip of a dry finger before it has time to set: the smear, if one should remain, can be easily washed off afterwards by a brush dipped in clean turpentine.

Always have an old piece of cloth or duster handy to wipe off any varnish that may from time to time thus find its way on your hands, otherwise you may cause yourself a lot of extra trouble and annoyance. Whenever you are washing out, whether with turpentine or water,

always wash away from the parts that are to be left showing—that is wash on to the portions blocked out. Should the varnish become too thick to be used evenly, thin it down by the addition of a little turpentine, but only do this sparingly as the turps makes the varnish sticky to the touch when used, and very considerably increases the time of drying.

Always clean your brushes after use, and do not allow the varnish to set hard on them, for nothing so soon destroys the points. Varnish brushes can be cleaned by dipping in a little turpentine and afterwards washing with soap and water. Use brushes with tin ferrules, not with quill holders. An old negative glass will be found useful to be at hand for the purpose of working up a point on the brushes, when a delicate piece of detail work has to be done.

In leaving a portion of the floor showing I generally follow out the lines of perspective, ruling four lines around the base of the machine with Indian ink, and painting up to that with the varnish. Decide how much of the floor you think it suitable to leave in, and, using the ruler, mark this out in black lead on the print. If the object has been placed square with the lines of the floor or wall, these perspective lines can be put in without much difficulty. When this has been done to your satisfaction, rule corresponding lines on the negative with Indian ink, taking care when doing the floor lines on the far side not to cross over any protruding portion of the machine.

If objection is taken to the hard lines caused by the abrupt termination of the floor, this can easily be softened down by means of stippling with a stiff stencil brush dipped in Indian ink. The perspective lines are set out as before, but half an inch wider all the way round to allow for the stippling. Take a piece of paper with a smooth stiff edge, and laying it along the line so marked upon the negative, proceed by means of short quick dabs with the brush to work along the whole length of the line. Start with the brush protruding about half its diameter over the edge of the paper, and after once doing the length of line in this manner go over it again with, say, quarter of the brush projecting, and so until the intensity of the black varnish has been reached along the edge of the paper. Corners are done by placing a piece of paper along each of the two lines, thus forming a V shape.

When first I commenced this painting of negatives I used to coat them with the ordinary transparent protecting medium and worked on the top of that with Indian ink and black varnish, but now I do all blocking out required on the original film and varnish them afterwards for protection if required. This I find answers more satisfactorily, as the bare film is decidedly more easy to work upon, and the protective medium applied when all is done, has the double advantage of preserving both the film and paint out from possible injury.

True, it is easier to make alterations if the negative is first varnished, but these are not growing necessities, rather the reverse, and if the worker decides exactly where and how far a line has to go, before putting it on the film, he will find very little need for the wash brush.

It may be asked why I use this black varnish in preference to other mediums sold for the purpose. Well, its advantages are hardness, quick-drying properties, cheapness and extreme durability. It stands an astonishing amount of rough usage without even the need of a protecting medium. But above all else I use it because of the ease with which it can be used in combination with Indian ink. When we went to block out flower studies, street scenes, and statuary, on lantern slides I undoubtedly recommend the use of the new production called "Photofake." For this class of work there is no ruling to the done—all the work can perhaps be done best by means of a finely pointed brush. It is composed almost entirely of small curves, graceful and sweeping. To do these one undoubtedly needs an artist's hand and tools, not a draughtsman's. They who have a good knowledge of free-hand drawing, or are accustomed to the use of a water colour brush, are the ones who will succeed best in this class of work. Lightness of touch is the main thing to be considered, whether one be using brush, writing pen, or ruling pen. The delicacy of touch can only be attained by constant practice, and to those who would excel in this work I commend this as the first stepping stone to success.

Need I enumerate the many uses this process can be put to? How cloudless negatives can be improved and perfected? How offending trees on a landscape negative can be "stippled" totally away? Trees that offend against the picturesque, and the common laws of composition. How subjects such as those characteristic of Paul Martin can be evolved from a study of humanity in our own crowded streets? No! as I started I will leave off—leaving you to work in whichever direction your tastes or impulses may lead you, hoping that the explanation of one method of working may be of help to another, giving freely of what little knowledge I possess in the hope of further help and assistance being gained from amongst you.

J. W. PRICE.

## NOTES FROM THE NORTH.

GLASGOW Corporation have appointed a Special Committee to prepare an illustrated free course of lectures on the leading enterprises under Corporation control. The lectures will be illustrated with lantern views, the intention being to make the ratepayers better acquainted with the leading schemes on which the rates are at present being spent. For many winters past the Art Galleries Committee have carried on a free course of Saturday Evening Lectures by the aid of the lantern. These lectures have been mainly intended to promote a fuller appreciation of the art treasures in the possession of the city. This winter it is proposed to devote the course to a series of lectures bearing specially upon the various departments of the Art Section of the 1901 Exhibition. Every winter witnesses the opening up of new fields of usefulness for the limelight lantern.

A year ago, when the whole country was agog with excitement over the attempt of "Shamrock" to win back the America Cup, the "Glasgow Evening News," by the help of Mr. Lizars, organised an open-air lantern and cinematographic entertainment on a huge scale, the slides and animated pictures being interspersed in the course of the evening with bulletins showing the progress of the races. Crowds estimated to number from thirty to fifty thousand witnessed the displays nightly. Last week the proprietors of the "News" repeated their demonstration in connection with the General Election, and the crowd each evening was as large as those which took an interest in the yacht races. Impromptu slides were prepared by Mr. Forrest Niven, the "News" artist, as the results came in, the "hits," imperial and local, being greatly relished by the street audiences. These impromptu slides were written or drawn on cover glasses with a soft pen charged with thickish Indian ink. The drying was accomplished in a second by holding them over a gas flame, and in another second they were put into the slide carrier and thrown on to the gigantic screen. Although produced in this rough and ready fashion, they were thoroughly effective.

Mr. John Stuart, owing to indifferent health and bereavement, was unable to send any examples of his work to the Royal Exhibition. He is arranging to pay an early visit to the Metropolis. Like most provincial readers of the "B.J.'s" trenchant criticism of the Salon exhibits, his curiosity has been whetted, Queen of Sheba like, to see if the reality is in accord with the report. He is also planning his exhibit for the International Exhibition in Glasgow next summer.

Several very good 15 by 12 enlargements, taken by Mr. A. Cowie, Alloa, with a  $\frac{1}{2}$ -plate "Challenge" camera are on view at present in the window of Mr. Lizars' retail warehouse in Buchanan-street. Mr. Cowie is an excellent amateur exponent of pictorial photography, but as he belongs to the non-exhibiting school, few, outside the circle of his friends, have many opportunities of seeing his work. His "Melrose Abbey" is a splendid piece of architectural photography.

Another amateur, Bailie Primrose, who has of late years almost forsworn his favourite hobby, is re-entering the field. The "Challenge" type of camera has been his choice since its introduction, and he, too, has several enlargements on view in Mr. Lizars' window.

Mr. W. M. Warneuke recently completed two sumptuous albums to the order of the heads of the numerous departments of the Caledonian Railway for presentation to Sir James Thompson, ex-General Manager, and Mr. William Patrick, his successor. The albums contained the portraits of the donors to the number of over forty, while the front covers were richly decorated with oxidised silver in alto relievo, the arms of the Caledonian Railway Company being in the centre.

Another commission Mr. Warneuke has in hand, and one in which his talent for pictorial photography is finding free scope, is the preparation of an album for Mr. R. B. Cunninghame Graham, ex-M.P., and one of the heroes of the Trafalgar-square riot, for his participation in which he was sent to prison. Mr. Graham has sold the ancestral estate of Gartmore, with its ancient mansion house, and Mr. Warneuke has been occupying every spare day of late photographing the mansion, its most interesting interiors, and the numerous scenes and picturesque spots associated with the family history on the beautiful estate. The memorial volume is to go with Mr. Graham to his flat in London to serve as a visible reminder of the Graham family's ownership of the Gartmore estate for six hundred years, and of his own thirty-five years of happy married life in the mansion he quits for ever at Martinmas.

"Photography as Applied to the Register of Lasines" was the subject Mr. J. C. Lennie chose for his presidential address to the Edinburgh Photographic Society last week. For the benefit of non-Scottish readers, it may be advisable to state that "Lasine" is a Scots Law term meaning the act of giving legal possession of property, or the legal instrument or document by which the fact is proved. It was in the second sense Mr. Lennie used the term, his aim being to show how the process of photo-zincography might be applied, and, under the Land Registration Bill, was likely to be applied to the copying of writs. The old process was slow, and apt to become congested, while the labour of collating was very harassing to those engaged in it. The abolition of the old method and the introduction of photo-zincography would, in his opinion, confer undoubted advantages upon the public, while the cost of the new process was, at any rate, not greater than that of the old. Mr. Lennie exhibited an experimental volume of the writs of Fife for one month, illustrating the exact facsimiles, a necessary condition of the process, produced by photo-zincography.

A Limited Liability Company has been registered—George Bell and

Co. (Ltd.), 152, Sauchiehall-street, Glasgow—to acquire the business and assets of the sequestrated estate of George Bell and Co., Photographers; capital, £1,000 in £1 shares. The first subscribers are William D. Whyte, optician, 144, Broomielaw; James Whyte, photographer, 152, Sauchiehall-street; John Walker, photographer, 152, Sauchiehall-street; James Neil, jun., shipowner, 101, St. Vincent-street; Arthur M. Crossley, inspecting engineer, 52, St. Enoch-square; and Dugald B. Johnston, solicitor, 13, York-street—all of Glasgow. This business, originally located in Argyle-street, was subsequently removed to Sauchiehall-street, to a very high building without an elevator.

Professor Mills, of the "Young" Chair of Technical Chemistry in the Glasgow Technical College, is the only one in the city who conducts a class in the chemistry of photography and the technical side of the subject. His course, which has just begun, covers the preparation and testing of photographic chemicals and materials; testing cameras, slides, shutters, and lenses; determination of equivalent focal length of lenses; the preparation of gelatino-bromide and similar emulsions, and their application to paper, glass, and other surfaces; testing and comparison of plates; making negatives and transparencies (direct or reverse) with the mirror, and by other methods; use of various developers; enlargement, reduction, and copying; photo-micrography; methods of intensification; retouching; varnishing and varnish making; printing-out methods; combination printing; washing; vignetting; printing by development; collodion processes; collotype; preparation of line transfers; half-tone screens, half-tone transfers, and their printing; photogravure; zincotype; lantern slides, &c. Photographers' assistants are received for short terms of instruction in special departments at a fee of £1 1s. for the first week, and 10s. per week thereafter.

In "The Photographer," a monthly journal of jottings, Messrs. George Mason and Co., 120, Buchanan-street, have provided their customers over a lengthy period with a very readable summary of the month's doings, while laying before them their latest trade announcements. The Albion Albumenising Company have decided to follow suit by issuing "Albion Photographic Chat" once a month in the interests of amateur photographers. This new champion for popular favour at a penny a month prints this "Foreword":—"One distinctive feature of this journal, which, we believe, will recommend it to the photographic public, is the exclusion from its columns of the advertisements of dealers in, or so-called manufacturers of, photographic goods, these goods being palmed off at prices considerably over their market value, by the aid of specious puffery, and through the medium of the Parcels Post—for cash paid in advance. If anything more than moral certainty of being overcharged were needed to accentuate the unwisdom of buying a 'pig in a poke,' it would be safe to say that this could be established more easily in connection with the mercantile system endorsed, or at least supported—we regret to say—by some contemporary journals. For apart from the obvious fact that it is always unwise to make purchases 'in the dark' from irresponsible persons, located at some distant or obscure address, the photographer commonly learns to his disappointment, that there are unaccountable delays in the completion of uneconomical bargains, entered into through the post, as we have described. There is this added source of annoyance, besides the intrinsic badness of such bargains in themselves. A feature of our paper will be the description of materials and apparatuses, new and old, so that they will be well tried and approved. That irritating thing, the mere trade 'puff,' will be excluded. We shall be chary with our adjectives, and stick to facts. And we shall endeavour to recognise those circumstances under which 'comparisons are odious' and misleading."

## Studio Gossip.

**COLOUR INFLUENCES.**—Mr. Havelock Ellis, in the "Popular Science Monthly," has an article on "The Psychology of Red," in the course of which he points out that plants growing under blue glass become insensitive and make no progress; those under red glass attain extraordinary development, but the red is not favourable to the ripening of fruit. The foliage under red glass is lighter, under blue darker than under other colours. Red or orange produces the greatest amount of vegetation, but the finest and earliest fruit is from under clear glass, violet glass causing an increase in the amount of fruit, but at the expense of quality. Marshall Ward and others have shown that the blue, violet, and ultra-violet rays, but no others, destroy bacteria. Finsen makes use of this fact in treating bacterial skin diseases. The physical effects on animals seem opposite in character. Beclard found that the larvæ of the flesh-fly raised under violet glass were three-fourths larger than those raised under green glass: the order was violet, blue, red, yellow, white, green. Young found that violet or blue was specially favourable to the growth of frogs, and that fish hatch most rapidly under violet light. The varying effects on plants and animals, Davenport says, are due to the chemical metabolic changes—what is waste for one being growth for the other. Violet rays are, however, often too powerful a stimulant, irritating the skin. The conditions of sun-burn, snow-burn, and snow-blindness are due to them. This can be averted by wearing a yellow veil or painting the skin brown. Freckles can thus be a positive protection to the skin. Finsen's treat-

ment of small-pox in red-lighted rooms, it now appears, was also known in Europe in the Middle Ages, as well as in Japan and China, red bed covers, curtains, and carpets being used to obtain the effect. Red is also beneficial in measles, the rash speedily disappearing and the fever subsiding under its influence. Marti found that feeble irritation of the skin promotes the formation of red corpuscles, while strong irritation diminishes them and also the hæmoglobin. Darkness also diminishes the red corpuscles, while continued exposure to intense light increases them and in some degree the hæmoglobin. Finsen has shown that inflammation of the skin caused by chemical or violet light leads to contraction of red corpuscles. As to the influence of colours on the nervous system, Father Secchi, in 1895, suggested trying it on the insane. Red rays are found more soothing and less irritating than the total rays of uncoloured light. Garbini found that the only light that soothed angry infants was the light through red glass. Red increases the muscular power and the volume of blood in the limbs; so that red is literally a "warm" colour. Nervous patients are more sensitive to colour influences than are normal beings. Blue glass soothes some insane persons. A sombre and taciturn maniac was benefited by remaining three hours in a red-lighted room, and a man with delusions of persecutions became rational under its influence. A violent maniac after a few hours in a room with blue-glass windows became calm and gave no further trouble. After many years' experience, Osburne has found that in the absence of structural disease violet light (for from three to six hours) is most useful in the treatment of excitement, sleeplessness, and acute mania; red is of some benefit in such cases though to a much less degree. (Violet, it should be remembered, contains red). Graber found that animals which prefer the dark are lovers of red, while those that prefer the light are lovers of blue. A worm, even with its head and tail cut off, still preferred red to blue. The cochineal insect with eyes removed and head covered with wax still had delicate sense for colour and brightness. The flea had a finer colour sense than the bee, and nearly all the animals that Graber investigated were more or less sensitive to the ultra-red rays. Among birds, sparrows have an aversion for red and a preference for blue; most other birds seen unaffected by colours. Red, however, is obnoxious to turkey cocks. The fury which red arouses in some quadrupeds occurs among bulls, buffaloes, hippopotami, and sometimes horses.

"A PLACE WITHIN THE MEANING OF THE ACT."—Last week, at the Marlborough-street Police Court, a question of some importance to the ordinary pedestrian was dealt with by Mr. Denman, on a summons taken out by the police against Mr. Frank Curzon, lessee and manager of the Prince of Wales' Theatre, for wilfully obstructing the free passage of the footway. Mr. R. Atkins, barrister, defended. Inspector Brogan stated that on the morning of the 2nd inst. he saw a crowd of thirty of forty people standing on the pavement in front of the Prince of Wales' Theatre looking through lenses at animated pictures of a scene in the piece played at the house. The machine was in the vestibule of the theatre. Witness saw the defendant, and pointed out the obstruction. He replied, "The pictures are on my property, are they not?" Witness replied in the affirmative. "Well, then," answered the defendant, "the crowd outside is for the police to deal with. I shall not remove them till the magistrate makes an order, and then I will." The exhibition was continued, and during the week a constable had to be posted there from ten in the morning till seven at night to keep the people moving. Mr. Atkins: Did you see the pictures? Witness: Yes. Mr. Atkins: Then you helped to increase the crowd. Police-sergeant Sheppard gave corroborative evidence. For the defence, Mr. Curzon said that no part of the machine projected beyond the premises, and it was so adjusted that to see the pictures a person had to stand at least seven feet from it. The pavement was twenty feet wide, so that there was a clear passage in front of and behind the crowd, but the laying of the electric wires had reduced it by a fourth. It was the taking up the flagstones that caused the obstruction. Mr. Henry Jalland, the Acting Manager, added that he was in and out all day, and had no difficulty in passing through when the pavement was in its normal state. The number of people looking at the pictures ranged from six to twenty-three. It would interfere with their own booking business if a crowd collected, and there was a switch in the booking office by which the pictures could be stopped. Mr. Atkins argued that there was no wilful obstruction by his client, any obstruction being due to the pavement being up. Mr. Denman: The more you show the pavement was up, the more you show the necessity for everybody to give free passage to the public. Mr. Atkins: Supposing a man went up in a balloon, would you hold that he should be summoned because a crowd collected to see it come down? Mr. Denman: I will settle that when he is down and comes into court. In giving his judgment, the Magistrate said that he looked on these questions as very important, as bearing on one of the great questions of the future—how the rights of the public to the free use of the highways were to be maintained in the crowded cities in which we had the misfortune to live. The more the rights of the public in general were maintained, the more the excess of the rights of the individual must give way. That was the law of Nature, and it was the law of England. The public was entitled to every inch of every highway without the slightest interference by any private individual. In the present instance they had a modern invention which gave enjoyment and amusement, but which could not, by any strain of language, be termed a necessity. There was a similar case some little time ago, in which patriotic tunes were blown off by a gramophone out of a window, and people were prevented from getting along. It was perfectly clear that Mr. Curzon had caused an obstruction, but if he would give an undertaking to discontinue it no fine would be imposed. Mr. Atkins agreed, subject to an appeal. Mr. Denman: I have no doubt about the law. It cannot be said in these days that the streets can be used for shows, that what little remaining room the public has

left can be used as an auditorium for seeing plays, whether enacted by human beings or pictures. There will be a fine of 40s. and 2s. costs. Mr. Atkins was understood to give notice of appeal.

## News and Notes.

**THE Gospel Oak Photographic Society.**—Mr. W. A. Palmer having resigned the Secretaryship of this Society, Mr. H. Billingsley, of 6, Burghley-road, Kentish Town, N.W., has been appointed his successor.

"**THE Intensification and After-Manipulation of Carbon Prints**" is the subject to be treated and demonstrated by Mr. Ernest Human, at the London and Provincial, on Thursday, the 25th, White Swan, Tudor-street, E.C. Visitors always welcome.

**CRIPPLEGATE Photographic Exhibition.**—Intending exhibitors are reminded that entries for this Exhibition close on Monday next, the 22nd inst. Exhibitors at the R.P.S. deciding to exhibit at Cripplegate will have their pictures collected free. The Hon. Secs. will be pleased to forward entry forms on application to Mr. Alfred T. Ward, Cripplegate Institute, Golden-lane, E.C.

**THE Southsea Amateur Photographic Society** hold their Thirteenth Annual Exhibition on January 29, 30, and 31, 1901, at their headquarters, 5, Pembroke-road, Portsmouth. There are to be six Open Classes, with silver and bronze medals, also certificates in each class. Full particulars may be obtained from the Hon. Secretary, Mr. Gilbert Wood, 10, Pelham-road, Southsea.

**WHEN Mrs. Bishop**, who is a member of the Royal Photographic Society, was travelling in China she took many photographs of the people, of typical scenes, and of little-known places. Some of these are being collected into a picture volume, which Messrs. Cassell will publish. Each photograph will be accompanied by notes from Mrs. Bishop's pen explaining its bearing.

**MESSRS. J. J. GRIFFIN & SONS, LTD.**, of 20-26, Sardinia-street, Lincoln's Inn-fields, write:—"We regret to find that in the brief report which we sent you of a demonstration by our Mr. Nightingale, before the Walton Society, in which he developed an Ilford Chromatic Plate two years old, which resulted in a perfect negative, without fog, no mention was made of the developer. The developer, of course, was kachin."

**A PHOTOGRAPHIC Society for Blaydon.**—A meeting held at Blaydon-on-Tyne on October 11, 1900, Mr. Cowling, of South Shields, in the chair, brought into being "The Blaydon and District Camera Club." The following officers were elected:—President, Mr. Arthur Payne, F.C.S.; Vice-Presidents, Mr. R. Cubey and Mr. A. Cunningham; Secretary and Treasurer, Mr. C. E. Hudson, The Bank, Blaydon-on-Tyne.

**DEVELOPMENT OF Platinum Prints.**—A correspondent writes: "I have come across a French formula for platinotype developer, which, as I find it very good, and as to me it presents some features of novelty, perhaps might interest you:

- "Water ..... 1000 parts.
- Ox. potash ..... 300 parts.
- Alum ..... 25 parts.
- Tartaric acid ..... 3 parts.

"I use it half strength."

**ROYAL Photographic Society.**—Technical Meeting, Tuesday, October 23, at the New Gallery, Regent-street, at 8 p.m. A demonstration of the Ozotype Printing Process, by Thomas Manly. The following are the next lantern fixtures at the New Gallery: Saturday, October 20, "On the Peninsular Coast with a Camera," by R. Child Bayley; Monday, October 22, Illustrated Lecture on Colour Photography, by E. Sanger Shepherd; Thursday, October 25, "The Islands and Highlands of Scotland," by John A. Hodges; Saturday, October 27, "Wonders of the Paris Exhibition," by S. J. Beckett. The Exhibition of American Photographs at 66, Russell-square, is open daily from 10 to 4, Wednesdays, 10 to 8. Admission on presentation of visiting card.

**OPEN CLASSES** will be omitted at the forthcoming Sixth Annual Exhibition of the Borough Polytechnic Photographic Society, to be held during the Christmas week. This step has been taken on the ground that the large amount of work and expense incurred in connection with Open Classes is not warranted by the quality of the work entered. The executive view the matter in the light of open competition being an incentive to better work amongst members of the Society, but when the best workers do not enter, and, further, when the quality of the exhibits received from outside sources is inferior to that shown by the members themselves, then it is thought that the omission of these Classes altogether is justifiable. The next Exhibition will, therefore, consist solely of members' work, in which there will be no sub-division into subject classes, but awards of equal value throughout will be placed at the discretion of the judges.

## Commercial Intelligence.

**MR. ANDREW H. BAIRD**, of 33-39, Lothian-street, Edinburgh, N.B., is issuing a monthly journal of photographic chat for amateur photographers.

**MESSRS. YAMANAKA & Co.**, of Osaka, Japan, have opened a branch establishment at 68, New Bond-street, London, for the sale of Japanese Art Work, both ancient and modern.

**A PHOTOGRAPHER'S ACCOUNT.**—Richard Wicks, trading as the Brighton Photographic Company, 57, Clarence-square, photographer, against Phil Newman, 91, King's-road, Brighton, photographer, was a claim for £9 0s. 6d. for goods sold and work done. Mr. J. Laidman was for the plaintiff, and Mr. A. V. Treacher for the defendant. It was not disputed that the plaintiff had done the work, but whether defendant was personally responsible, or Mayall & Newman, Ltd., liable. Plaintiff stated that when he heard the firm of Mayall & Newman, for whom he was doing the work, was being wound-up, he saw the defendant, who said if witness would continue the work he would make it a personal matter, and see that he was paid. Witness consented, and afterwards received three payments on account of £1 each, leaving the amount now claimed due. Miss Taylor, secretary to Mayall & Newman, was also called, and said the Company's business was now being carried on by the defendant. Mr. Treacher pointed out that all the plaintiff's accounts were rendered to Mayall & Newman, and contended that the liability was the Company's, and not the defendant's personally. Defendant stated that he had recently acquired the business of the Company from the Receiver, but the purchase was not quite completed. Witness never agreed to become personally liable, but promised plaintiff that, as Managing Director, he would give the matter his best attention. The £3 paid on account was the Company's money. His Honour found for the defendant.

**THE Warwick Competitions.**—The following is the list of awards of the Warwick Competition for October:—£10 Prize, H. Price, Dennis Vale, Stourbridge, "A design for a Fan"; £5 Prize, W. Kilbey, 57, Pagoda-avenue, Richmond, Surrey, "Diving"; £1 Prizes, J. W. Anderson, Darncombe-street, Moss Side, Manchester, "Conway Castle"; W. W. Baker, 215, Lewisham High-road, London, S.E., "An Animal Study"; Miss Nelly Blakeley, 5, Wild-road, Birkdale, Southport, "Roses"; Mrs. Delves Broughton, 4, Embankment, Bedford, "The Fallen Monarch"; J. S. Carlines, 13, Warbreck-road, Aintree, "The Quay at Smyrna"; Albert Durn, photographer, Wotton-under-Edge, "Mummy's Pet"; Evan Griffiths, The Square, St. Columb, "Companions"; H. A. Briscoe Harrison, Montague-road, Edgbaston, "Cottage at Knaresborough"; W. Ives, 21, Edinboro'-grove, Armley, Leeds, "Reredos, The Priory"; J. McCleery, Stranmillis-road, Belfast, "Golfing at Newcastle"; F. J. Mortimer, 10, Ordinance-row, Portsea, "Washing Up"; D. Murray, 49, Queen-street, Wolverhampton, "Homeward Bound"; J. D. Murray, Quarry Wood, Ore, Hastings, "Highland Children"; J. C. Oliver, 2, Royal-terrace, Glasgow, "A Good Aim"; W. Page, 36, Ash-street, Walworth, "A Kitchen Interior"; W. R. Prior, Finchley-road, South Hampstead, N.W., "China Tea Service"; A. J. H. Roberts, 5, Castle-arcade, Cardiff, "A Difficult Landing Place"; R. C. Ryan, 43, Compton-avenue, Brighton, "A Somersault Dive"; H. D. Trenchard, 34, Fengates-road, Redhill, "Supplication"; J. Waterall, 387, Chester-road, Manchester, "Doorway in Gloucester Cathedral."

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

October.	Name of Society.	Subject.
23	Birmingham Photo. Society ..	Atmosphere. C. T. Cox.

26	Borough Polytechnic .....	Instruction Evening: Printing and Toning P.O.P.
26	Croydon Microscopical .....	Exposure and Development. Rev. F. C. Lambert.

### WEST LONDON PHOTOGRAPHIC SOCIETY.

The Twelfth Annual Meeting was held on Friday, October 12, Mr. G. F. Blackmore in the chair.

The Secretary's Report showed that the Society had enjoyed a prosperous year, that the membership had increased, and that the attendance and the interest shown in the discussions had been very gratifying to the executive. In addition to a number of practical demonstrations and lantern lectures, a series of lectures to beginners had been successfully carried through. The Annual Exhibition was held in February, and was well attended by the public. Mr. C. O. Murray had kindly furnished a written criticism of the pictures from an artist's point of view, and the thanks of the Society were due to him for his valuable services.

The following officers were elected:—President, W. J. Bull, Esq., M.P.; Vice-President, W. Collett; Hon. Treasurer and Assist.-Secretary,

A. E. Cockerell; Hon. Librarian, W. Taylor; Hon. Lanternist, R. Horton; Council, A. C. Beard, G. F. Blackmore, W. A. Brown, M. W. Cockerell, A. Ebbs, G. Lamley, H. Selby, L. Selby; Hon. Secretary, J. Brown, 28, Weltje-road, Hammersmith, W.

The newly-elected President briefly thanked the members for his election. He said he took a considerable interest in photography, and hoped to be more than an ornamental President, and he would do all he could to further the interests of the Society.

The arrangement of the winter programme was then proceeded with, and all dates filled up. The next meeting will be held at the Society's rooms, Broadway Hall, Hammersmith, on the 26th inst., and intending members are requested to write to the Secretary, who will be pleased to furnish information.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 11.—Mr. R. Beckett in the chair.

Mr. E. A. Robins, of Messrs. Kodak, Ltd., gave a demonstration on the latest cameras of this Company. Among them were the No. 1 Panoram Kodak, which takes pictures 7 in. by 2½ in., including an angle of view of 112°, and an entirely new Kodak ¼-plate size (not yet on the market), which is to be called the No. 3 Cartridge. Mr. Robins also successfully developed a length of film, and showed how the curling up could be avoided by soaking the film for about five minutes in water prior to development, the developer recommended and employed being in a single solution as follows, to which is added a few drops of ten per cent. potassium bromide as required:—

Metal .....	8 grains.
Hydroquinone .....	30 grains.
Sulphite soda .....	1 ounce.
Carbonate soda .....	1 ounce.
Water .....	10 ounces.

Mr. A. L. Henderson then read a paper on "Films in Photography." He showed some waxed paper negatives that were made in 1845, and were still in perfect condition. A number of negatives on various kinds of paper were also shown as results of recent experiments.

In the opinion of the meeting, the film giving the best result was that prepared on coagulated albumenised paper, and which, Mr. Henderson remarked, was extremely difficult to procure.

Mr. Bullen asked Mr. Henderson if he had found any great difficulty in coating waxed paper supports, and also if there was any difficulty in getting the finished negatives to strip. Mr. Henderson replied that he had found no great difficulty in either.

Mr. Everitt remarked that he thought the chief obstacle in the way of the manufacture of paper film was the difficulty of obtaining a suitable support; a film must, to a considerable extent, be permanent, and until a suitable support was found glass only could be used. Mr. Everitt warned those members who intended following up Mr. Henderson's experiments to use pure bees-wax only, as very few combs now were pure wax, owing to adulteration, and Mr. Everitt suggested that the wax be very carefully selected.

#### CROYDON CAMERA CLUB.

THE Platinotype Company's portrait lamp, which was first made known by its inventor, Mr. W. H. Smith, at the Club last year, has since been both simplified and improved. Hence Mr. Smith on Wednesday, the 10th, gave a short address, partly explaining how and why he had modified his original pattern, and partly directing attention to the correct way of using the lamp, and what to guard against. For, as already announced, one of Mr. Smith's lamps will be shortly at the disposal of members of the Club for making figure studies after dark.

Some eight years ago Mr. Smith attempted to take portraits by a less perfect form of oxymagnesium lamp, and, to overcome the excessive shadow, used a swinging lamp; with this arrangement a portrait of Capt. Abney was taken by Mr. Smith at the London Camera Club. A few weeks after Mr. Smith brought out his new lamp last year at the Croydon Camera Club, a German wrote him a curiously funny letter, insinuating that Mr. Smith was merely a plagiarist, in support of which he cited the lecture and demonstration above referred to at the London Camera Club, quite unconscious that Mr. Smith was the man who gave the lecture in question. Prior to making some negatives with the lamp, the lecturer handed round about forty panel portraits taken by himself at the Photographic Convention. They included speaking likenesses of many of those well known in photographic circles. As an example of the power of the oxymagnesium light, Mr. Smith has succeeded in taking a portrait with the light screened by canary yellow medium. Several portraits of members present were taken, including Messrs. Hawkins, Bennett, Stanley, &c. After remarks and questions by Messrs. Salt, Watson, Irving, Isaac, and others, at the instance of the President a hearty vote of thanks was adopted with much applause, in replying to which Mr. Smith stated that the way in which his demonstration had been received by the goodly assemblage of his fellow-members was in itself ample reward for the trouble he had been put to, and if any member required further instruction in the use of the lamp, screens, &c., he would with much pleasure give it during any evening arranged.

Aintree Society.—At last week's meeting, Mr. Nightingale, on behalf of Messrs. John G. Griffin & Sons, gave a demonstration on their new developer kachin, a particularly clean developer, and from which there is no fear of fogging the plate, even during prolonged development, and with good keeping qualities, either in bulk or solution, with the advantage of entire absence of stain, which is one of the disadvantages with our old friend pyro. Kachin is also very suitable for isochromatic plates.

#### FORTHCOMING EXHIBITIONS.

1900.	
October 19, 20 .....	Rotherham Photographic Society. Hon. Secretary, H. C. Hemmingway, Tooker-road, Rotherham.
" 19-Nov. 3 ...	Photographic Salon, Dudley Gallery, Piccadilly. Hon. Secretary, R. W. Craigie, Camera Club, Charing Cross-road, W.C.
" 19-Nov. 3 ...	Royal Photographic Society, New Gallery, Regent-street. The Hon. Secretary, 66, Russell-square, W.C.
" 30-Nov. 3 ...	Sefton Park Photographic Society. Hon. Secretary, G. Birtwhistle, 7, Gainsborough-road, Sefton Park, Liverpool.
November 7-10 .....	Cripplegate Photographic Society and the Essex and Middlesex Cycling Union, Ltd. Hon. Secretaries, A. T. Ward, Cripplegate Institute, E.C., and G. F. Sharp, Sach-road, Upper Clapton, N.E.
" 12-17 .....	Ashton-under-Lyne.
" 19-24 .....	Waterloo and Blundellsands Photographic Society. Hon. Secretary, W. G. Eyre, 2, Mersey-road, Blundellsands.
" 21-23 .....	Hackney Photographic Society. Hon. Secretary, W. Selve, 70, Paragon-road, Hackney, N.E.
" 21-24 .....	Cleveland Camera Club. Hon. Secretary, F. W. Pearson, 98, Victoria-road, Middlesborough.
" 22-24 .....	Hove Camera Club. Hon. Secretary, C. Berlington-Stoner, 24, Holland-road, Hove.
1901.	
January 14-19 .....	Blairgowrie and District Photographic Association. The Hon. Secretaries, Blairgowrie, N.B.

## Patent News.

THE following applications for Patents were made between October 1 and October 6, 1900:—

- CAMERA SUPPORT.—No. 17,429. "Improved Camera Support." Complete specification. G. W. HALL.
- NEGATIVES.—No. 17,581. "Improvements in the Production of Autotype Negatives." Complete specification. A. BRANDWEINER.
- STANDS.—No. 17,632. "Improvements in and in the Construction of Supports for Cameras, Telescopes, Theodolites, and other like Articles." Complete specification. A. KAUFMANN.
- OPTICAL EFFECTS.—No. 17,707. "A New or Improved Apparatus for Producing Optical Effects, especially suitable for Advertising and like Purposes." H. F. STANDING.
- SHUTTERS.—No. 17,716. "Improved Means of Operating the Shutters of Photographic Cameras." J. V. WELDON.
- STEREOSCOPES.—No. 17,727. "Improvements relating to Stereoscopes and other like Apparatus for Exhibiting Pictures." A. E. WOODS.
- STANDS.—No. 17,736. "A New or Improved Means for Attaching Cameras and other Instruments to their Stands or Supports." J. J. HACKETT.

## Correspondence.

- \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### BLUE PRINTING.

To the EDITORS.

GENTLEMEN,—I have read the article in the current issue of THE BRITISH JOURNAL OF PHOTOGRAPHY on blue printers' appliances with considerable surprise. For instance, you state that "in this country the existence of an independent blue printing establishment, to draw us custom from local engineers, architects, &c., &c., does not appear to have occurred to any of the photographic craft." I may say, however, that in Manchester alone there are five or six firms who make a speciality of this kind of work, and there are also a large number in London, Liverpool, Glasgow, Leeds, Derby, and other places, so that you will see there is very keen competition in this business.

You have also evidently been misled as to the time required for printing, as it would indeed be an exceptional light that would give prints every minute, especially in large towns. Then, again, with reference to the cylindrical copying frame, you say that it is stated forty

30 by 40 inches) prints can be turned out per hour. In my place of business this copier is in daily use, and I venture to state that he would be a good printer indeed who could load and unload only the frame 40 times in one hour with 30 by 40 in. prints without allowing any time for printing. The maker of the apparatus, according to his circular, only claims to be able to print two 30 by 40 blue prints in three minutes, and this, allowing, say, four minutes for loading and unloading the frame, gives two 30 by 40 prints every seven minutes, or, say, 17 prints per hour. According to my experience, however, 10 to 12 blue prints per hour from one machine is good work; black and white prints take considerably longer, and can be produced at the rate of about six or eight per hour.

The description of the action of the electric copier is also slightly inaccurate. You say: "It is connected with a simple mechanism whereby it acts as the motive power for slowly rotating the cylinder as it descends." The cylindrical printing frame, however, does not rotate, as being circular and the light being at the centre of the circle, every part of the sensitised paper gets evenly illuminated as the arc light descends from the top to the bottom of the cylinder at a uniform speed.

I may say that I look upon THE BRITISH JOURNAL OF PHOTOGRAPHY as an old friend and adviser, and have written this letter, not in a fault-finding spirit, but merely to correct any false impressions that may be formed of the large amount of work that can be turned out by the blue and kindred printing processes in a short time, and also to point out that the English photographers are as far ahead with the industrial applications of photography as are our confreres on the Continent and in the States.—I am, yours, &c.,  
H. ENTWISTLE.

29, New Cannon-street, and 45A, Market-street, Manchester.

To the EDITORS.

GENTLEMEN,—In the article on "Blue Printing" in last week's BRITISH JOURNAL OF PHOTOGRAPHY, you wonder why professionals do not add this to their ordinary work.

Let me give my version. I approached an engineering firm on the subject some time ago, and their reply was that they never allowed their plans or tracings to be taken off the premises to be printed, as it would be very easy for the printer (outside) to steal copies of their plans, and dispose of them to rival firms, who would thus profit by their patented ideas and improvements.

They evidently possessed a high opinion of the honour of photographers, so I said no more about the subject.—I am, yours, &c.,  
October 15, 1900. OTHELLO.

[We shall refer to this subject in our next. Eds.]

### THE TRAILL TAYLOR MEMORIAL.

To the EDITORS.

GENTLEMEN,—I shall be much obliged if you will inform the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY that the third Traill Taylor Memorial Lecture will be delivered by Mr. F. Ives, on November 16, at the rooms of the Royal Photographic Society. The subject of the lecture will be "The Optics of Trichromatic Photography." Mr. Ives informs me that he will treat the subject from the historical and practical aspects, with illustrations and demonstrations, and that he will have some quite new things to exhibit.—I am, yours, &c.,

P. EVERITT, Hon. Sec.

88, Evering-road, London, N., October 13, 1900.

### THE IMPERIAL DRY PLATE COMPANY, LIMITED.

To the EDITORS.

GENTLEMEN,—Owing to the continued growth of our business, we have again found it necessary to increase premises, plant, and staff. We now have our new factory in full working order, and hope to be able to clear up all outstanding orders during November. Meantime we beg the forbearance of our friends, and assure them that no efforts are being spared to supply all needs.

We take this opportunity of announcing that we have arranged with Mr. John Howson to take a position in the Company as from Dec. 1.

Thanking you, in anticipation, for allowing us to address the trade and public through your columns?—We are, yours, &c.,

THE IMPERIAL DRY PLATE Co., LTD.,

J. J. ACWORTH, Ph.D., &c., Managing Director.

Cricklewood, London, N.W., October 13, 1900.

### AN INVITATION.

To the EDITORS.

GENTLEMEN,—I shall be glad if you will allow me, through your columns, to announce that the members of the Photographic Club will be pleased to see at their meetings any amateur or professional photographer from the provinces who may be in London for the exhibitions. The meetings are held at Anderton's Hotel, Fleet-street, every Wednesday evening, at eight o'clock.—I am, yours, &c.,

EDWARD A. NEWELL, Hon. Sec.

4 Maiden-lane, Queen-street, London, E.C., Oct. 11, 1900

### THE LIPPMANN PHOTOGRAPHS AT THE R.P.S.

To the EDITORS.

GENTLEMEN,—I found in the course of a visit to the R.P.S. Exhibition that the only lighting available is fatal to the unfortunate Lippmann exhibits which—all exceedingly bright with a suitable side-light (diffuse)—show hereabout as flat and uninteresting as Salon prints. As the poor effects (worsened by the placing of the heliochromes at wrong points of view in some cases) may well disgust the interested visitor who hears so much of them, and will see so little, I dare say a timely caution might not be thrown away.—I am, yours, &c.,  
E. D. FAWCETT.

Livermead House, Torquay.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

J. A. Horsburgh, 4, West Maitland-street, Edinburgh.—Photograph of G. M. Brown, M.P.

BORDER.—(1) Not to our knowledge, which goes back to 1885. (2) They are not now to let.

J. H. A.—Qualitatively between the five you name there is perhaps nothing to choose. For lightness and compactness No. 2 possibly stands first; as regards the others, each meets your special requirements.

COPYRIGHT MATTERS.—P. W. M. asks us how to copyright a photograph, and also if it is necessary to mark each print.—In reply: Send our publishers 1s. 7d. and two prints, and they will effect registration for you. It is not necessary to mark the prints.

PHOTO-RELIEF PORTRAITS.—J. H. WILLMORE. For depositing the copper on the relief a Daniel or a Smee battery is suitable. The latter is the form in most general use by those who do not employ a dynamo. It is more cleanly and convenient in use than the Daniel form, but both are good.

SEASON ENGAGEMENT.—PRINTER. We have answered several queries similar to yours lately. An engagement for "the season" is an indefinite term, and may mean any period. Unless you have an agreement for a specified time, you are liable to be discharged at a week's notice, as you are only a weekly servant.

METAL SPOTS ON PRINTS.—N. H. H. The spots on the prints sent are clearly due to the paper, and not to the manipulations. They appear to be caused by metallic particles in the paper itself, as they show even more strongly on the back than they do on the front. There is no way of avoiding them, except by changing the paper.

G. WILSON.—The only way of ascertaining if the photograph is copyright or not is by searching the register at Stationers' Hall. If, however, as we surmise, it was produced in Germany, and it is copyright there, no register of it will be found at Stationers' Hall, but it is copyright nevertheless under the International Copyright Act.

PERMANENCE OF SEPIA-TONED BROMIDES.—M. W. asks "whether sepia-toned bromides are likely to be as permanent, or more or less so, than the ordinary black ones."—In reply: Without knowing the toning process employed we cannot say. But our experience of uranium-toned bromides is that they are prone to change colour in a very few years.

BARYTA PAPER.—THOS. CLAYDEN asks where he can get a quire or so of the baryta paper, such as is used for P.O.P. and collodio-chloride. This paper is generally supplied in rolls, and in wholesale quantities. Messrs. Otto Konig and Co. are the wholesale agents for it, but we rather doubt if they supply it in retail quantities. Marion and Co., who use it for their papers, may supply you with it by the quire. In quire of them.

DESICCATED DRY PLATES.—S. VOLMAR asks: "Can you give me any further information about the desiccated dry plates referred to by Mr. Howard Farmer at the Convention? Is there the advantage in them that was stated at the meeting?"—We can add nothing to what was stated in the paper. Mr. Farmer, in it, promised further information later on. You will have to wait for it. Why not test for yourself by drying a few plates after the method given?

**A BEGINNER'S DIFFICULTY.**—PYRO writes: "On several of my negatives, when placed over a dark cloth, I can see the portrait quite plainly, and it appears very satisfactory, and as a general rule the prints taken from such negatives are thoroughly bad. Could you tell me the reason for this?"—In reply: Not without seeing a negative and a print therefrom. Send us one of each, and we may be able to indicate where you are failing.

**COMPRESSED PYRO.**—T. S. M. W. writes: "Will you kindly tell me in what way ordinary pyro is injured by being compressed? I have used it so compressed for convenience in travelling, but have not noticed any difference."—In reply: We doubt if the reducing powers of pyro are affected by compression. In recent months we have used several samples without noticing any difference in behaviour between them and the flocculent form.

**COMBINED TONING AND FIXING.**—B. MAHON asks for a formula for a combined toning and fixing bath that will keep, so that it can be used from time to time, and not require further additions, and yield permanent prints.—We know of no such bath. We are no advocates of combined baths, unless, indeed, they are used under their best conditions, and that would certainly not be when they are used from time to time without further additions.

**CARBON ENLARGING DIRECT.**—W. S.—Carbon enlargements can be made direct from the negative by means of the Solar camera, but that can only be used when the sun is shining. Therefore it is seldom, if ever, employed commercially in this country. There is no carbon tissue sensitive enough to permit of direct enlargements being made by diffused daylight, as with bromide papers. With the limelight enlarging on carbon tissue direct is quite out of the question.

**ENLARGING LANTERN.**—W. CONWAY says: "I want to get a good enlarging lantern, with paraffin light, for winter use. Whose do you recommend for a professional?"—It is one of our set rules not to recommend any particular maker's goods, and from this we never depart. Better consult the advertisement columns of the JOURNAL or ALMANACS, and write to the different makers for prospectuses. All the leading makers' apparatus are good, and which is the best is very much a matter of opinion.

**UNDER-EXPOSED NEGATIVES.**—W. JONES says: "Will you please tell me the cause of the want of detail in the enclosed negatives? They are on ———'s quickest plates, and exposed the fiftieth of a second, f-22, the same as I have always given on such subjects and got good negatives; so that it cannot be under-exposure."—But it is, and very much under-exposure. You must bear in mind that although the light looks good now, it has not nearly the actinic value it had a few months ago; hence longer exposure is necessary.

**INSTANTANEOUS PHOTOGRAPHS IN WINTER.**—R. GREENE writes: "I wish to take some instantaneous pictures during the winter months in the country, if the lantern size, if the thing be possible. Will you please tell me the quickest lens I can get for the purpose?"—About the quickest lens that can be had for that size is the "Instantaneous Stereo Lens." It is of the Petzval form, and has a working aperture of about f-3½. With that, and extra rapid plates, and the shutter set at a moderately fast speed, there should be no difficulty in a fair light.

**GLASS POSITIVES.**—T. GRIGGS asks: "Is it possible by the old wet-collodion process to get really good pictures; that is, if they are taken in a well-appointed studio, and with a fair amount of skill used in the work? I have been told it is."—The information is quite correct. A good glass positive is a very beautiful photograph, next to the Daguerreotype in detail and gradation. But to produce such results as much skill is required as in the production of a high-class negative. This skill is not expended on the production of this class of picture nowadays.

**REMOVING PAINT FROM STUDIO WINDOWS.**—LIGHT writes: "In the early summer, when the sun was troublesome, I painted the glass in the studio roof over with blue paint. Now I want all the light I can get. Can you tell me how to get the paint off again? I have tried turpentine, and that does not seem to have any effect."—Make a strong solution of American potash. Apply that to the paint, and it will dissolve it, and in a short time it can be washed off with warm water. Of course, if any of the potash solution gets on to the paint on the sash bars, that will also be dissolved; so care must be used.

**ENAMELLING PHOTOGRAPHS.**—H. W. writes: "Can you inform me how to enamel photographs, so that they will be washable? Some time ago we had a man from London, who did them for us, and I have been asked to do some like it, but for the life of me I cannot."—Coat a glass plate with enamel collodion, and then, after it has thoroughly set, place it in a dish of water to wash out the ether and alcohol. Then transfer it and the print to a dish containing a warm dilute solution of gelatine, bring the two together and remove. Then squeeze and allow to dry. Before the print is dry, however, a backing paper should be applied, and when the whole is dry the picture is stripped off. We need scarcely mention that the glass must be treated with French chalk, or waxed, before the collodion is applied, to facilitate the stripping.

**MOTTLED ALBUMEN PRINTS.**—W. H. S. writes: "Will you please give your opinion on the cause of the mottliness of the enclosed prints? They are on ———'s ready-sensitised paper, a piece of which please find herewith. My printer tells me he takes every care, and he cannot account for the appearance. Some are all right, others like these. I think it must be some fault or other of his."—No, it is not; it is the fault of the paper. It has been sensitised on too weak a silver bath, for we found, on exposing the piece sent to the light, it darkened, with the mottled appearance, instead of an even colour.

**RUST ON GLASS.**—A. WILMOTT says: "I have a very excellent portrait lens (no name on it) of three and a quarter inches diameter, and one of the back glasses has a sort of yellow stain on the surface. I have tried to get it off with methylated spirit, but that does not touch it. How can I clean it off?"—The glass is what is called "rusted," and there is no method of getting rid of the stain except by repolishing the surfaces, and that should be done by an optician. The stain, however, does not make any practical difference in the performance of the instrument, except that, theoretically, it is a trifle slower. We should advise you to let the lens be as it is.

**DAMAGE IN TRANSIT.**—PROVINCIAL says: "I sent a negative, from which I expected large orders, to London, to have an enlargement made from it. When it was received back, although it appeared to have been carefully packed, it was broken into several pieces, and the case it was packed in was also broken by the rough usage it had received on the railway. Who is responsible?"—The railway company, of course. But you did wrong in receiving the parcel, seeing the dilapidated state the box was in, without opening it, in the presence of the railway company's servant, and in not signing the delivery form as "received damage." Had you done this, the company could not deny liability. Now they may, as they hold your receipt for the parcel, and that implies that it was received in good condition.

**STUDIO BUILDING.**—IXION writes: "I am about starting in business as a photographer, and would value a few hints from you as to the best way in which to build a studio, and the most convenient size of same. Can you give me the address of a reliable maker of portable studios? What would you advise for material of roof—wood or galvanised iron? Any other information you can give me, such as the best form of blinds, &c., to be used, will be valued."—As our correspondent is evidently a novice in photography, we should recommend him to get Mr. Bolas's work on studio building, published by Marion & Co. From that he will see the form best suited to his requirements and for the site available. A suitable size for professional works is from twenty-five to thirty feet long by from twelve to fifteen feet wide.

**THE COMBINED BATH.**—W. W. D. writes: "Owing to the fact that I have not time to tone and fix my prints in separate baths, I intend to use a combined one, supplemented by an additional fixing bath. Some months ago I saw an account of the following mode of working with a combined bath for crown tones:—First wash prints five minutes. Then transfer to a bath made as follows:—(a) Hypo solution, 2 ozs. to pint; (b) gold chloride, 1 gr. to oz. For use add 3 ozs. B to 30 ozs. A slowly, constantly stirring. When the required tone is reached, wash five minutes. Then place in a fresh hypo (2 ozs. to pint) bath for five minutes. Finally wash two hours. (1) Please say if results will be permanent. (2) Would results be permanent without the additional fixing bath if I don't use combined bath for more than one lot of prints?"—In reply: (1) If the work were carefully done, we see no reason why the prints should not be reasonably permanent. (2) Doubtful, unless the prints were allowed to be a long time in the bath. If the two baths are used, we don't see that much, if any, time will be saved over the usual method of toning and fixing separately, which is preferable.

**RECOLOURING A DAGUERRETYPE.**—W. J. REED writes: "Can you inform me of where I could get an old Daguerreotype recoloured? A friend of mine, a jeweller, had one, and has met with an accident, in not knowing what he was handling, and trying to take off dust has taken the colour off, too. It being a red coat, it is much damaged, and he is in a great way about it, the people he did it for being very put out, and he does not know what to do. Myself I do not know of anyone that can do this kind of work, even if it can be attempted, which I very much doubt; but I should like to know your opinion of the matter. If you could write me direct, or through the JOURNAL, I should feel very much obliged; but, if possible, by letter, as he is most anxious to know, and give some answer to his clients."—We do not know anyone now who could recolour the picture. The Daguerreotype process has not been practised for many years past, and the old Daguerreotype colourists have become an extinct race. We fear, however, that your friend, in removing the dust, has injured the delicate image of the picture; in which case the injury is irreparable. We do not undertake to reply to queries by post.

\* \* \* Owing to exceptional demands upon our time and space this week, we are obliged to hold over several answers to correspondents, reviews, articles, &c., including a notice of the American Photographic Exhibition, "Plastic Psychological Syntheses at Russell-square."

### EX CATHEDRÂ.

WE have been pleased at the receipt from Messrs. A. E. Staley and Co., 35, Aldermanbury, E.C., the British agents of the Bausch and Lomb Optical Company, of Rochester, New York, of a copy of the latter house's microscope catalogue. This well-produced book reminds us that in a very important branch of optical work English firms have to face competition, as stimulating as it is keen, from Germany as well as from the United States. We have quite recently heard that at least two prominent London firms contemplate an attempt to recover some of the supremacy in microscope work that has been lost by this country of late years: Let us hope, on patriotic grounds at least, that they will be successful. The book before us deals very fully with a large variety of microscopes and accessories, and prefatory notes which run to 23 pages, describe respectively the facilities for manufacture possessed by Messrs. Bausch and Lomb, and the points to be kept in view when selecting an instrument. There is, too, a chapter on the construction of the American

type of microscope. The factory and the machinery it contains appear to be perfect for the delicate optical work produced at Rochester: and we are obliged in strict justice to compliment Messrs. Bausch and Lomb on the well-directed enterprise which animates all their undertakings. We know only too well that it is the custom of numerous British manufacturers to treat complaints from customers with high-handed indifference and neglect. Mark the difference in the American style of doing things. Messrs. Bausch and Lomb give a guarantee that the apparatus they produce is inspected and tested before being sent out, and they sensibly add: "It is almost impossible for faulty work to pass unnoticed, but in a business so extensive as ours this may occasionally occur. In such cases we cheerfully remedy any defects at our expense." What could be better calculated to secure a client's confidence than the sweet reasonableness which disclaims workshop infallibility, so often hurled at his clients by the stubborn Britisher? Again, say Messrs. Bausch and Lomb, "suggestions regarding improvements in our apparatus and the making of new and useful instruments are desired at all times." Here manufacturers seldom invite such suggestions, and when they are offered neglect is only too frequently the return.

\* \* \*

THE Annual General Meeting of the Photographic Copyright Union, which was held last week, supplied very little business of importance for the consideration of those who attended. Some useful work has been performed during the past year, and the various Copyright Bills that have been introduced into Parliament have been carefully watched. These attempts to supersede the excellent Act of 1862, which, as we have so often remarked, treats photography very well indeed, number three. Evidently the shameless artists, publishers, and others who have vowed a vow to make photographers "sit up" do not know their own mind in the matter for five minutes. Early in the year they introduced their first Bill, the effect of which, if carried, would have robbed the photographer of all legal protection for the work of his brain and hands; later, the wicked measure was withdrawn, and a second Bill was put forth. This gave general satisfaction to photographers, and, indeed, would have left undis-

turbed the rights conferred on them by the Act of 1862. But it was never seriously meant, for so recently as the end of last July a third Bill was presented. This we saw the other night for the first time: and it appeared to us that those responsible for drafting the Bill must have designedly set themselves the task of making some of the clauses as ambiguous as possible. One clause, in particular, which deals with the ownership of the negative, simply defies interpretation: but its aim is apparent. At present the Courts uphold the right of the photographer to the ownership of the negative, but the opponents of photographic copyright would rob him of it. Of course, the Bills to which we have referred are just now only so much wastepaper: we must wait till Parliament assembles to see what new move the haters of photography will make in their disgraceful attempts to injure it by uncalled-for and brigandish legislation. So few photographers seem to realise the dangers of their position that we submit no excuse for again emphatically warning them of it. As regards copyright, we have no faith whatever in the wisdom of the legislature, which, in matters of minor importance, often very stupidly blunders. Hence, next session the proceedings of the anti-photographic copyright party must be closely followed, as, the matter being of no public interest, there are great possibilities in the way of legalised interference with the existing order of things.

\* \* \*

ONE of the oldest and most respected houses in the photographic trade is that of Messrs. Edwin Osborne and Co., Red Lion-square, London, W.C., whose special work is the supply to photographers of every kind of card mounts and stationery for professional and amateur use. The firm has been established for half a century, and for 20 years of that time we have been personally cognisant of the fact that Osborne's cards and mounts have been highly esteemed by photographers. We have very great pleasure, indeed, in drawing attention to the fact that the firm desires to make two special and enterprising offers of their mounts, &c., to photographers and the trade. Before us are two boxes of samples. One includes a large number and variety of specimen cards, envelopes, and photographic stationery generally. Messrs. Osborne ask us to state that they will forward a similar set, post free, to every professional photographer who applies for it. The second box includes samples of tasteful mounts suitable for amateur use. A similar set will be sent, post free, by Messrs. Osborne, to every photographic dealer who applies for it, and encloses a trade card with the application. These two offers of free samples of photographic stationery and mounts are unique in their way, and Messrs. Osborne will no doubt receive a considerable number of requests for them.

\* \* \*

THE colour photographs by the stained film process of Mr. E. Sanger Shepherd that are being shown at the Royal Photographic Society's Exhibition are generally admired by visitors. We had an opportunity of recently examining a considerable number of these beautiful productions in the binocular, as well as the monocular, forms. There is no gainsaying the fact that in the reproduction of coloured artificial objects the process yields results of striking beauty and fidelity. But it is seldom that an outdoor natural scene quite permits of accuracy of translation by any one of the four colour processes now before the public—the colour record or stain of an open view usually falls short of satisfying, even though it may please, the colour sense of the non-scientific individual. Having regard to the years of experimental work

which Mr. Sanger Shepherd has devoted to the subject of colour reproduction by means of photography, and cognate subjects of study, it may not be out of place if we draw the reader's attention to the fact that a little while back he, in conjunction with Mr. R. L. Cocks, established himself in business at 5, 6, and 7, Gray's Inn-passage, Red Lion-street Holborn, as a scientific instrument maker. But this latter description is singularly unindicative of the wide scope of work embraced by Messrs. Sanger Shepherd and Co. For the above-mentioned system of three-colour work, the necessary apparatus is supplied, whilst light filters for three-colour work, orthochromatic photography, photomicrography, and colour block making in half-tone, form an important department in which great accuracy of adjustment and measurement are demanded. The business, in fact, is unique of its kind, for it is the aim of the firm to supply every requisite for the system of colour-photography specified, as well as for ordinary half-tone and colour block making. We saw on a recent visit to the firm's premises that they were well equipped for these purposes. It is quite needless for us to detail Mr. Sanger Shepherd's qualification as one of our leading experts in colour-photography, but to those photographers especially interested in colour and half-tone work, and to men of science requiring specially-constructed apparatus for experimental purposes connected with light and colour, it may be said that the firm's skill and knowledge should be of especial value. The facilities they enjoy and afford are quite special, and in these times of accuracy of measurement in photographic methods their services should be in constant and increasing request.

\* \* \*

"NATURE" of last week prints Professor W. Stroud's British Association paper on range finders, one of which credited to Messrs. Zeiss, of Jena, may have some interest for photographic readers, as it utilises the idea of Helmholtz's well-known tele-stereoscope, in which, as Professor Stroud points out, two parallel reflectors are placed with reference to each eye in such a position as to produce the optical equivalent of an increase in distance between the two eyes, for the purpose of increasing stereoscopic effect, or, as it might be expressed, exaggerating the relief. Now, still quoting Professor Stroud, by placing a telescope before each eye (and the two telescopes may conveniently be incorporated in the frame-piece supporting the reflectors), we multiply the stereoscopic effect still further, *e.g.*, if the distance between the eyes has been artificially increased tenfold by the reflectors, and if the telescopes magnify tenfold, the stereoscopic effect will be increased altogether one hundredfold. This tele-stereoscopic system is thus adapted to range finding: Suppose, says Professor Stroud, we imagine for the moment the instrument fixed, and that we see in the field of view of each eye the image of a pole 1000 yards away. Let permanent marks be made in the focal plane of each telescope exactly coincident with these images. Then, whenever we look into the instrument we shall apparently see a pole at a distance of 1000 yards. Let a similar pair of marks be fixed corresponding to 1100 yards, and so on. Of the several illustrations to Professor Stroud's interesting paper one is a stereograph showing marks in the field of view of a range finder of this kind, so that if the picture be viewed stereoscopically a mental impression as to the distance of any part of the landscape is obtainable by comparison of the marks. The illustration conveys in a graphic manner the application of the stereoscopic range finder.

## PHOTOGRAPHING SILVER PLATE, &amp;c.

NOTWITHSTANDING all that has, from time to time, been written on the subject of photographing objects with highly-polished and reflecting surfaces, it seems that this class of work still presents difficulties to some. Only a few weeks back we had to reply to a query, in the Answers column, from a correspondent on this subject. The question was thus put: "I have some silver cups, vases, &c., to photograph. Would you please inform me what is best to be done to them previous to photographing? What preparation is put on to prevent glare or halation?" Now, there is nothing very extraordinary in such a question had it come from a novice in photography, but this one came from a professional—a portraitist—who has been some years in business, and has more than one studio in London. We mention this somewhat by way of justification for once more writing on a subject that has several times already been dealt with in these columns. However, what we shall say now may be of service to those who, like the correspondent referred to, have occasionally to do something out of their usual every-day rut, and have not read what has appeared on former occasions on photographing objects with strongly reflecting surfaces.

Let us consider the photographing, say, of a bright silver vase, by way of example. Here, we usually have a part of it of brilliant white frosted, or matt, silver, while the highly-polished portions are black—as black as the shadows of a Daguerreotype picture—when seen in shadow; though where the light strikes, it will be reflected as a glittering white. Here it will be seen at once that we have strong contrasts to deal with, and a highly reflective surface. It is true that may be subdued by various dodges. One is to dull the surface of the metal in some way or other. A plan frequently adopted is to dab, or stipple, the metal evenly all over with a lump of glazier's putty. Another is to place a piece or two of ice in the vessel, so as to rapidly cool the metal, and thus cause moisture to condense upon it in the form of dew. With this method it is, of course, presupposed that the atmosphere of the studio contains moisture, although, if it does not, it is easily added by sprinkling the floor with water, or by ejecting some through a scent sprayer. But there are cases where the owners of the articles will not permit any tampering with them. Therefore, they have, perforce, to be dealt with in their integrity, and that is what we shall assume has to be done in the present instance.

Now, here success depends entirely upon the illumination of the objects, and that, after all, is a very simple matter if the well-known law is kept in mind, that the angle of reflection is always equal to the angle of incidence. Thus at whatever angle the light falls on a bright object, it is reflected back at the same angle. Keeping this fact in mind, it will be obvious that, if the reflecting object be illumined by a front light, the reflections from it will be forwards, and into the lens. Hence, front light must be studiously avoided. In fact, all front and direct front top light should be carefully stopped off. Indeed, it is necessary, in order to secure the best results, to stop off all extraneous light, and to use it from one direction only, and then somewhat concentrated. About the best angle for the illumination of most objects of the kind under consideration is one of  $45^\circ$ , then the reflections from its surface, whatever shape it may be, will be at a corresponding angle and well away from the direction of the camera.

We have just said that the light should be somewhat

concentrated on the object. This, at first sight, may seem somewhat an anomaly, as it will tend to increase the contrasts, which are already strong. Still, it is the best course to pursue in practice. When the subject is illumined in this way there will be no reflections seen on the focussing screen of the camera. The shadow side will, however, be somewhat dark, but this is easily dealt with by softening the shadows by reflected light. A white screen, placed at an angle corresponding with the angle at which the light falls upon the object, and at a suitable distance, will soften them to any desired extent, and, of course, the reflection from that will, again, be away from the lens. Now, we have our subject illumined in such a way that there should be no reflections that can be seen from the camera, or will show in the negative.

Having secured a suitable lighting of the object, the next question is that of the exposure. We now have brilliant white metal in the lights, and, if the metal is tarnished, practically black in the shadows to deal with, and, perhaps, an ebony plinth or stand in addition. The great fault with many photographs of silver plate is that they are much under-exposed—too black and white and hard. In all cases the exposure should be a very full one. The old axiom should be kept in mind, "Expose for the shadows, and let the lights take care of themselves." The development must receive care. It should be commenced with but little pyro in the developer—that is supposing pyro is used—so as to get out all the details in the shadows before the lights begin to acquire printing density. In this way, with suitable lighting, perfectly harmonious negatives may be secured of what some consider difficult subjects to deal with.

If there happens to be an inscription on the vase, and that cannot be tampered with by filling up the lettering with a dark pigment, it may be desirable to illuminate it with a still more direct side light than one at an angle of  $45^\circ$ , so that stronger cast shadows are thrown by the sides of the letters. Sometimes the inscription is on a tablet fixed to the plinth. That will usually be allowed to be taken off. When that is the case it should be taken to a copperplate printer, who will fill in the lettering with printing ink, which will simplify matters very much, as then the inscription will be very distinct in the picture. The ink can be quickly cleaned out with turpentine or benzole after the photograph has been secured. It goes without saying that, in all cases when photographing silver plate, backed plates should be employed.

**The Use of Gas for Heating.**—At the Bradford Meeting of the British Association, Mr. T. Fairly, F.R.S.E., F.I.C., read a paper bearing on this subject containing many points of interest to those employing gas. We recently referred to the work done by Mr. Jones of the Manchester Grammar School showing the effects upon the purity of the atmosphere of the burning of coal gas, a question which, we are sure is not sufficiently considered by the public generally to the extent that is desirable. With regard to burners for heating it may be said that efficiency and perfect consumption go together, or, as Mr. Fairly puts it, "to obtain the best lighting or heating effects, the apparatus must be adapted to the gas." As bearing upon the suitability of gas for heating purposes, the writer of the paper shows the extent to which its illuminating capacity governs its heating efficiency, a matter of considerable importance in view of the belief that is gaining ground that some day Mr. Siemen's idea, of a concurrent supply of two kinds of gas of different prices—one for heating, and one for lighting—will be realised. But, for whatever purpose it be required, Mr. Fairly's

dictum, that "from a health point of view the less gas that can be made to supply the light required the better." The heating valve, he states, is affected by the heavy hydrocarbons, which are of such prime importance for illuminating purposes, though he observes the chief value lies for the former use in the marsh gas and hydrogen. Water gas is coming into much more common use, either enriched with hydrocarbons or as a cheap diluent of coal gas, but we must point out now how very undesirable is it for open burners, used for heating burners, that is, which have no attached flue for carrying away the products of combustion, as there is always danger to health from possible escape into the air of the carbonic oxide which this gas contains so largely.

**Portable Gas producers.**—In connexion with the question of cost of gas, there is in last week's *Nature*\* a remarkable article by Mr. J. A. Purves, upon "Portable Gas-producers," which, if we mistake not, is likely to rouse very general interest. It is, in fact, a description of means for producing with an extraordinary simple apparatus gas of high quality for heating or illuminating purposes. Atmospheric air is charged with the vapour of light petroleum or other similar agent, the action of charging being analogous to the system of dissolving crystals in water (placing them in a loose bag near the surface of the water), the solution as it is formed falling, through its increased specific gravity, to the bottom of the vessel. Mr. Purves points out that air containing hydrocarbons is also heavier than ordinary air, and hence tends to fall towards the ground as it forms. The new apparatus takes advantage of this principle. We have, virtually, a tin canister containing some inert substance soaked with volatile hydrocarbon placed on a perforated shelf two-thirds of the distance from the top of the receptacle. There is a hole in what might be termed the lid of the canister for the admittance of air, there is another hole (to which a top can be fitted) for the exit of the charged air. And that is all. Fuller details will be found in the article referred to; but the broad lines are as simple as we have put them.

**Phosphorescence Experiments.**—A writer in *Nature*—"A.M.M."—describes some experiments he has made bearing upon those of M. Le Bon upon darklight, which we lately gave an account of. It will be remembered that a statue painted with "luminous paint" was rendered luminous by the radiations from a lamp entirely surrounded by an opaque screen. A.M.M. has obtained a similar result by using a slightly heated object, and his inference is that M. Le Bon's results may have been brought about in a similar manner. The writer exposed a surface similarly painted to the heat radiated from a vessel of boiling water, result *nil*. Substituting a smoothing iron at a "temperature ordinarily used," the paint in about a minute's time "glowed brightly;" but the luminosity differed from that produced by light by the quickness with which it disappeared, the visible light being "comparatively transient."

**Lantern Slides ex-Cathedra.**—We have every praise for the action of the Sanitary Institute. Frequent applications having been made to it for the loan of slides and diagrams for lecture purposes, the Council have got together a large number of slides relating to sanitary arrangements and appliances, diseases, &c. These slides, numbering altogether over six hundred, may, by application to the Secretary of the Institute, be borrowed at a small charge for lectures purposes, by members and associates of the Institute. The step is a wise one. Lantern slides form one of the most efficient and popular means of imparting instruction, and, if a few more institutions would follow this excellent plan, an amount of information might be conveyed to students and others who could not readily be reached by ordinary channels.

**Blue Printing.**—Our leader of a fortnight ago seems to have attracted some criticism, some of which is due to misconception. The

\* October 18, p. 601.

first of our correspondents whose letters appeared last week will find on reference to our former article that we had in mind the production of "blue" copies by ordinary photographers when we penned our remarks. At the same time we repeat here that we have been surprised to find no work of this kind done (except in the factories of engineers and manufacturers), in large industrial centres of 100,000 and more population. We know that the difficulty suggested by our second correspondent is a real one; but, as we also know from conversation with those interested, one which would disappear in the course of time. Engineers, too, are not the only *clientèle* of such an establishment. Architects, surveyors, estate agents, and inspectors of all kinds are constantly wanting work of this kind, and would make use themselves of heliographic copies more than they do were they more easily obtainable.

The exposures in the Cleveland Works are not, we consider underestimated. We have ourselves superintended the printing of copies at the rate of seventy seconds each, and, in the clear atmosphere of America, printing may reasonably be supposed to be rather quicker. The efficiency of the electric printer was quoted as stated in the original description, the claim of which, as our correspondent has pointed out, is obviously excessive. We had no wish in drawing up our remarks, to depreciate the state of the blue printing craft in this country, and we are glad to learn that the practitioners in our northern cities are fully abreast of the latest improvements in their trade.

DEVELOPMENT WITH PYROCATECHIN.

I APPEND a developing formula for pyrocatechin with tribasic sodium phosphate as accelerator; this substance, suggested to me by Mr. E. Merck, is a convenient substitute for the mixture of ordinary sodium phosphate and caustic soda, and like the latter gives a more vigorous developer than an equal weight of potash or its equivalent in soda. The most marked property of pyrocatechin in comparison with pyrogallol and most of the other developers is its freedom from stain. In consequence, the concentration of the sulphite of soda may be largely reduced, which increases the speed, and has the further advantage that the development may be prolonged without danger of fogging or of obtaining veiled shadows. The solution of pyrocatechin seems, as far as I have noticed, to keep as well without the addition of sulphite, and since discolouration, are more marked in slow development, and slow development usually follows from under-exposure where more alkali is used, it seems to be more rational to put the sulphite with the tribasic phosphate. The amount of the latter given in the following formula is also small, for, since slow development is not accompanied by stain or fog, it is to be preferred, because a greater proportion of incorrectly exposed plates can be thereby saved.

I have tried the following formulæ on several dozen plates of a degrees of sensitiveness, both in the field and studio, with under normal and over-exposures.

	No. 1.
Pyrocatechin .....	5 grammes or 80 grains.
Water .....	250 c. c. or 10 ounces.
	No. 2.
Tribasic sodium phosphate ..	25 grammes or 1 ounce avoird
Sulphite crystals .....	10 grammes or 3 drachms.
Water .....	250 c. c. or 10 ounces.

- For normal exposures take—
- 1 part No. 1 .. 1 part No. 2 .. 1 part water.
- For slight over-exposures take—
- 2 parts No. 1 .. 1 part No. 2 ..
- For more marked over exposures take—
- 2 parts No. 1 .. 1 part No. 2 ..  $\frac{1}{10}$ -part of ten per cent. bromide solution.
- For under exposures take—
- 1 part No. 1 .. 2 parts No. 2 .. 3 parts water followed, if necessary, by more of No. 1 for density.

The normal developer has about the speed of pyro soda, and yields negatives with well covered lights, and clear shadows with plenty of detail, well suited to ordinary P.O.P.

The developer with bromide of above strength acts very slowly, so that an over-exposed plate, three to five times over-exposed, will not appear for a minute or two, and yet yield a normal negative. One should wait patiently until the image appears, and continue with the same developer unless it has an under-exposed or an over-exposed appearance. In the latter case add more bromide, in the former transfer to a normal developer, or add a small amount of a saturated solution of the tribasic phosphate (about 1:5). This procedure is to be recommended when the exposure is uncertain. Bromide has a very great effect in slowing the action, greater in proportion to the effect upon the character of the negative than with pyrogallol. It has, however, a sufficient effect upon the negative, more than with most of the other organic developers. The saturated tribasic phosphate solution neutralises this slowing, but at the same time also the good effect upon the result.

The developer for under-exposures also works very slowly, and is exceedingly effective in bringing out detail when so diluted that the development requires twenty minutes to half an hour. The resulting negatives are not too dense in the lights, and have clear shadows with good details; this procedure is to be recommended for flashlights which are usually harsh and somewhat under-exposed.

A more vigorous quick-working developer, yielding good, strong negatives from normal exposures, may be obtained by increasing the tribasic phosphate in No. 2 by 50 per cent., or even 100 per cent., the latter being approximately a saturated solution. This developer corresponds to the ordinary formula with phosphate and caustic soda.

The tone is a neutral black to a warm black. If the prolonged development of over-exposures results in a sepia black, the strength of the sulphite may be increased by adding ten grammes of sulphite crystals and a few drops of sulphuric acid to No. 1.

One used to a pyro-soda developer, who substitutes pyrocatechin for pyrogallol, will not find that he has the same old developer with the stain left out, but a new one the acquaintance of which must be made in due form. On this account, and also because the old pyro is still supreme in yielding negatives of beautiful gradation and harmony, it is not probable that "stainless pyro" will replace the old pyro amongst the old friends of the latter.

If pyrocatechin becomes popular, it will be because of its property of being at once very effective for under-exposures and controllable with bromide for over-exposures.

W. S. DAVENPORT.

#### PLASTIC PSYCHOLOGICAL SYNTHESSES AT RUSSELL SQUARE.

A FEW years ago, when Mr. Rowland Briant showed some of his "astigmatographs" at a Society of Arts meeting, Sir William Abney, who presided, dismissed those photographic abortions to the oblivion from which they never emerged, with the feeling remark that they made him sick. He called the things nauseagraphs. But there is some soul of good even in an emetic, for it relieves the stomach of that part of its contents which owe their presence there to a perfunctory application of the laws of scientific dietetics. At least 300 of the 375 prints by the "new school of American photography" now to be seen at 66, Russell-square, have no such redeeming quality, for, by themselves, we fully believe that they would afflict one with permanent colic, if it were not corrected by the presence of a few singularly beautiful and interesting productions, the admiration and appreciation of which neutralises the unpleasant sensations caused by the larger number of the exhibits. All photographic exhibitions are mixtures in varying proportions of the good, the bad, and the indifferent; but to "the new school of American work," as defined by Mr. T. Holland Day, whose qualifications for his self-assumed task of selection and rejection have to be taken for granted, belongs the uncoveted distinction of including the repulsive, and the offensive:

Cluck! cluck!

A month ago, when writing of the so-called plastic psychological syntheses at the Photographic Salon, we gave a quotation from an American "appreciation" of Mr. Holland Day, written by Mr. Hartmann, whose portrait hangs at Russell-square, W.C. As Mr. Day apparently considers himself the master of the new American school, a

further extract from the writings of his obsequious disciple may serve to inform the British photographer what manner of man it is that has come among us to spread abroad the Cult of the Spoilt Print, and bearing aloft a banner with the strange device, "Behold, it is I."

To quote Hartmann:

"He (Mr. Day) has always lived the life of an æsthetic, who appears to all, at the first glance, as an extraordinary extravagant personality, one that excites immediate curiosity. Strange stories, both astonishing and ridiculous, are told about him, and he in no way objects to them. In serious dignity, he applies more of his imagination, for instance, to his mounting of prints than to his artistic productions themselves. To pose is a necessity to him, as it is only when he believes himself something out of the ordinary that he can accomplish good work, which is always an endeavour to realise something out of the ordinary. Many anecdotes are circulated about him. Once a stranger visited him, and, knocking at the door, heard a most cheerful 'come in,' but, entering, found to his great astonishment nobody present. He looked around everywhere, but could find no trace of Mr. Day; then suddenly he heard a clucking sound, he looked up and saw Mr. Day sitting on a shelf right under the ceiling, wrapped in an Oriental costume, smoking a water pipe! There exist also dozens of variations of the curious theme, how he made his 'Christ studies.' He left Boston with a whole troop of male and female models, accompanied by a waggon load of costumes, a wooden cross, and other paraphernalia, for some secluded country spot in the vicinity of the modern Athens. Out there he went at once to work, had the cross erected on the top of that hill, built a sepulchre, and prepared for a long stay. Then began the rehearsing of his company, and the sacred tragedy was played more than a hundred times on the top of that hill, while curious farmers on their waggons with their entire families, came from far and near to gaze at the strange spectacle. There is still some doubt in the profession whether he posed himself for the Saviour or not."

So now we have the essential part of the formula for the very newest kind of American photograph. You must believe yourself something out of the ordinary; sit under a shelf near the ceiling; smoke a water pipe; and make a "clucking" noise—which is what a brooding hen does.

It is such pitiful rubbish as this, seriously published in an American photographic paper some months ago, which makes us suspicious of the sincerity of some of these American photographers. Into their spoilt prints they read—or affect to read—qualities which a conveniently imaginative appreciator is also willing on the smallest provocation to perceive: but which are not apparent to a healthy-minded person with steady nerves and a clear vision. Who does not remember poor George du Maurier's scathing pictorial satire on the æsthetic craze of 20 years ago, of which the explanatory text was something like this: HUSBAND (fondling over teapot): "It is consummate; is it not?" INTENSE WIFE: "It is! Oh, Algernon, let us live up to it." Then that arch-humbug Postlethwaite who into a lily placed in a glass of water read so much that that was utterly utter—to himself alone. Nor have we forgotten the impostor Grigsby, the art critic, who sustained a brief reputation by means of the flabby gush and oleaginous admiration which he flung at works of art. Postlethwaite and Grigsby seem to have revisited the glimpses of the moon and "broken out" in photography!

That curious production, the photo-faker, who, not having succeeded as a professional photographer, takes up the exploitation of "pictorial" photography as a matter of business, objects not unnaturally to the analysis of methods and motives in matters of the kind under review, for if he and what he says and does were understood he would be found out, and people would have no more of him. In the present case there are some i's to be dotted and t's to be crossed. Mr. Holland Day has come to this country to engage in business as a professional photographer. We are sure that in that capacity he will be heartily welcomed, and every one will wish him success. But we very much doubt if he will succeed by some of the methods he has chosen, and we are sure he does not deserve to. When by the acquiescence of the authorities of the Royal Photographic Society he was permitted to advertise himself and his work at Russell-square he, in our opinion, showed a very poor return for the courtesy extended to him by deliberately courting the risk of giving offence to any of the hundreds of visitors to whom, we believe, he and others sent tickets of invitation. A year or two ago some of Mr. Holland Day's sacred photographs with himself as the central figure were exhibited and reproduced in this country, and the almost unanimous condemna-

tion with which they were met—clever though they were—should have warned him that a repetition of the offence was not desirable. It is to be regretted that he has ignored English feeling in this matter by showing at Russell-square a number of crucifixion subjects, the crowning objection to which lies in the fact that he himself poses before the camera as representing one whom so many millions of the earth's people revere as the Divine Founder of Christianity! If this were Mr. Day's first offence it would be open to us to hope that he had acted in ignorance, but as this is not the case we are constrained to say that it has been reserved for a photographer from Boston to be guilty of the most flagrant offence against good taste that has ever come under our notice. If this be the new school of American photography the less we, in this country, have of it and its professors the better.

Among the exhibits at Russell-square there are some by Mr. Yarnall Abbott; Miss Zaida Ben-Yusuf; Mr. A. D. Cook; Miss Sarah I. Eddy; Mr. S. H. Hollinger; Miss Frances B. Johnston; and Miss Weil, chiefly portraits which are good in the two cardinal respects of pictorial and photographic qualities. They comply with Constable's requirement that "a good picture should be seen at a glance." And without feeling ourselves "anything out of the ordinary," "smoking water pipes," or "making clucking noises" we can perceive much beauty and power in some of the work shown by Mrs. Kasebier and Mr. Day himself (whose "first person singular" portraits of some well-known English photographers are grotesque in their falsification of likeness and their frankly bad technique), but most of the productions of Mr. Eugene, Mr. Watts Lee, Mr. Steichen, Mr. Keiley, and their imitators we refuse to accept at any price. In occasional moments of lucidity they stop short at masking their meaning, and then perhaps, we behold in the "I" of those productions some effects which are intelligible if not convincing to others besides their producers. Such things as Keiley's "Study of Hair" (No! we cannot conscientiously repeat the London *gamin's* catch word, for the lady's hirsute adornment is not obvious), Eugene's "Madonna of the Vine"; Steichen's "Vampire" and "Apple-blossoms" certainly tax the imagination, and thus as pictorial puzzles are not without their uses. But if these and other things at Russell-square are put up for our appreciation, admiration, or comprehension, then Constable's glance requires to be lengthened from a second of time into more years than we care to live on this earth—especially with "clucking" photographers for our company.

To do our American friends justice, they show much taste and distinct originality in the mounting and framing—the ensemble, as it were—of their exhibits, and on that account the show is decidedly worth a visit. In the prints the capabilities of the gum and platino-glycerine processes for producing the "sort of things" which the very newest photographers regard as the "last word" in pictorial advance are very fully shown. To the very end of what it is or professes to be this show upsets all the old-fashioned ideals of the English photographer. The teachings of the new American school are frankly heterodox. Fake your negative or your print or both to the limit of your wishes and get a result as unlike the popular idea of what a photograph should be as possible. This is the philosophy of the new American school in a nutshell. But why should we weary the reader with a repetition of that "appreciation" of the Cult of the Spoilt Print which we wrote and printed on September 28th last?

There are still some more-its to be dotted and t's to be crossed. In the United States nearly every responsible photographic writer severely condemns the extreme things to which we have referred. Our brethren across the Atlantic style them "freaks." The wordy Hartmann deludes his neurotic dupes that these faked camera images are plastic psychological syntheses, and the authors of the things, at any rate, appear to believe him. We have a Hartmann this side, smitten just as badly with the curse of words, and whom we need not particularly specify. What holds good here in the matter of schools is duplicated in the States. Two or three "superior" persons make eccentric photographs; gather round them individuals similarly afflicted, and use their best endeavours to persuade the public to believe that outside their small circle of mutual admiration pictorial photography does not exist. To students and onlookers like ourselves who have no mission to boom pictorial photography as a business, the whole thing is funny to a degree. The episode of the three tailors of Tooley-street is a fool to it.

Now, let not the English student of the new American school be persuaded that the Russell-square exhibition is properly representa-

tive. It is not. Suppose a collection of the "British school" to be sent to the United States without including the best samples of their work by William Crooke, H. Walter Barnett, Fellows Wilson, Mendelssohn; Alice Hughes; the Speights; T. C. Turner, of Hull; Warneuke, of Glasgow; Alfred Werner, and a dozen other first-rate portrait photographers whom we could name. This would be a perfect parallel to the case of the Russell-square display. The little coterie which calls itself the new school of American photography is so wrapped up with a sense of its own importance that it has clean forgotten such men as Dudley Hoyt, Pirie Macdonald, Strauss, Falk, Bremner, and scores of other masters of American photographic portraiture. Half a dozen portraits of Crooke's memorable Sheriff Comrie Thomson type, the like of which is also produced in America, would make the Russell-square display look what it largely is—though fortunately not entirely so—a travesty of photography.

But new or old, representative or the reverse, and with all its cleverness, its daring, its suggestiveness, its excellences and its failures, the Russell-square show will not in the least advance the revealed ambition of Mr. Day and his two or three friends to get photography ranked as a fine art. "You are beating the bars of your cage in vain," wrote one well-known art critic a few years ago. And that is a process which may be continued to the crack of doom without persuading universal exhibition executives, or painters, sculptors and composers, to say to poor little photography: "Cofe and be an Art!"

#### FOREIGN NEWS AND NOTES.

**Improvement of Blue Prints.**—In an article upon this subject, which appears in the *Photographisches Wochenblatt*, N. Grün recommends the use of peroxide of hydrogen for giving greater intensity of colour. A blue print, when it leaves the washing water, is much less intense than after it has been dried and exposed to air for twenty-four hours. This change, doubtless due to oxidation, may be accelerated by adding a few drops of peroxide of hydrogen to the washing water. It also has the advantage of not imparting a blue tinge to the whites, which usually follows the use of ferric salts and hydrochloric acid. Those who have to produce blue prints quickly should find the use of peroxide of hydrogen of some value, as the colour is of full intensity as soon as the print is dry. It will also be found useful when the sensitised paper is rather old and gives veiled prints. Sensitised paper that has turned greenish-blue should be considerably over-exposed until a decided image is visible. A little washing soda solution should be added to the washing water, but very sparing use should be made of it. Repeat the washing, if necessary, until the whites are clear. Give the prints a final wash in water, to which a small quantity of peroxide of hydrogen has been added, which will intensify them.

**A Caution to Holders of German Patents.**—H. and W. Putaky, of Berlin, give notice that the date for the payment of fees has been changed, and that it is now one day earlier. If, for instance, the patent is dated October 9, the annual fee falls due on October 8 following. If tendered on October 9, a fine of ten marks must be paid. The six weeks grace, during which fees may be paid subject to a fine, also expires one day sooner. Consequently, if the owner of a patent dated October 9 tenders his fee later than six weeks from October 8, he will find his patent void.

**Indelible Ink.**—We read in the *Photographische Chronik* that the government of the State of Massachusetts has found an ink of the following composition withstands washing and all kinds of atmospheric influence:—

Tannic acid .....	23.4 parts.
Crystallised gallic acid .....	7.7 "
Sulphate of iron .....	30 "
Dilute hydrochloric acid .....	25 "
Carbolic acid .....	1 to 2 "
Water .....	902.9 "

Mix thoroughly.

**Reversal.**—The *Moniteur de la Photographie* reprints an article from the *Photo-Revue*, by Louis Fuilla, concerning direct positives, in reply to the objection that they are the wrong way round when taken in the camera. He points out that a second positive may be obtained by a fresh exposure in the printing frame, by which means the correct position of right and left will be restored. He gives the following table as the result of numerous experiments, from which an idea may be obtained of the exposure that should be given:—

	EXPOSURE.			
	Very hard. m. secs.	Hard. m. sec <sup>s</sup> .	Medium. m. secs.	Thin. m. secs.
In sunlight . . . . .	2 15	1 45	1 15	0 45
In shade out of doors . .	10 —	7 —	5 —	3 30
In a room, two metres from an open window }	25 —	20 —	17 —	15 —

He remarks that it is preferable to expose in the shade if the original is of medium density or thin, and that a green glass should be used if such exposures are made in sunlight for sake of speed. He also finds that, the more rapid the plate, the more satisfactory is the result. Unfortunately, the writer gives no indication of the speed of the plates used for compiling the table quoted above, and it will be seen that the exposures do not harmonise. The exposure indoors varies between 15 and 25 minutes, whilst in sunlight it ranges from 45 seconds to 2½ minutes.

**Preserving Cut Flowers.**—The following hints, given by a reader of the *Photo-Revue*, M. G. Lefebvre, may be of service to those who are interested in the photography of flowers. Cut flowers should not be placed at once in a vase. They should first be lightly sprinkled with perfectly fresh water, and, when quite wet, placed in the vase filled with the following solution:—

Water . . . . .	1000 grammes.
Curd soap . . . . .	30 „
Chloride of sodium . . . . .	3 „

Cut the soap into shreds and see that it is quite dissolved. Add a small pinch of borax to the solution. This is not absolutely necessary, but the writer finds that flowers of brilliant colour retain their brightness better when a small proportion of borax is added to the chloride of sodium. If the flowers are to be kept several days, they should be taken from the vase every morning, turned downwards, and the stalks washed under a stream of running water for about three minutes. Sprinkle them with water again as on the first day, and replace them in the vase. The soap and water should be changed every two or three days. The most delicate flowers may thus be kept for several days, and the writer has seen some that have remained three weeks in splendid condition.

**Reduction of Negatives.**—In the *Photographische Chronik* a communication is published from C. Mischewski, of the Photochemical Laboratory of the Technical High School, Berlin, concerning the action of cerium sulphate as a reducer. Sulphate and nitrate of cerium have been recommended by MM. Lumière and Seyewetz as reducers and they seem free from the disadvantages attending the use of ferricyanide of potassium and hyposulphite of soda. C. Mischewski's formula is as follows:—

Distilled water . . . . .	100 c. c.
Sulphate of cerium . . . . .	10 grammes.
Strongest sulphuric acid . . . . .	4 c. c.

Dilute this stock solution with three times the quantity of water for use. The bath at this strength works with moderate rapidity, and the negative retains its blue-black colour. The solution does not deteriorate if kept in the dark. If the negative is very dense, the concentrated solution may be used, and it acts with such rapidity that the negative is reduced to printing density in a very short time. The concentrated solution appears to act more upon the high lights than does the usual ferricyanide bath.

**The Dangers of Flashlight Photography.**—It is with much regret that we learn that Mr. Ch. Gravier, an advocate of the

advantages of flashlight photography, has met with a serious accident. In the gardens of the Paris Exhibition there is an automatic machine for photographic purposes. As the apparatus is placed in an unfavourable position, a magnesium flashlight is used to supplement the exposure. M. Gravier sat for his photograph, and after the charge of magnesium had been used felt intense pain in the right eye. He complained to the operator, and recommended him to be more careful with other sitters. When the operator handed him the photograph, which was badly over-exposed, he explained that he was not a photographer. For three days M. Gravier could only read with pain. A yellow film then formed upon the eye and afterwards changed to a deep blue. Specialists state that M. Gravier is suffering from injury to the retina and that recovery is rare in such cases. We trust that M. Gravier, who is a sexagenarian, may, with care, regain his sight.

**Reversed Negatives.**—In a paper communicated by Professor Namias to the Congrès de Chimie appliquée et de Photographie, the following process is recommended for obtaining reversed negatives. After full exposure of the plate, which should have a very even film, develop with the following developer:—

Sulphite of soda . . . . .	30 grammes.
Carbonate of potash . . . . .	50 „
Glycerine . . . . .	10 „
Bromide of potassium . . . . .	1 gramme.
Water . . . . .	1000 c. c.

The plate is left in the developer until those parts corresponding to the high lights of the negative are visible from the back. To obtain this effect it is necessary that the plate should remain at least half an hour in the bath. Slight fog is immaterial. Rinse the plate under the tap and immerse it in the following bath:—

Permanganate of potash . . . . .	30 grammes.
Sulphuric acid (commercial) . . . . .	20 c. c.
Water . . . . .	1000 „

This bath dissolves the silver reduced by development and as soon as the operation is complete clear the image by immersion in a one per cent. bath of oxalic acid. This may be done by daylight. The plate should then be redeveloped. The following solution has been found most suitable:—

Metol . . . . .	10 grammes.
Sulphite of soda . . . . .	40 „
Caustic soda . . . . .	5 „
Water . . . . .	1000 c. c.

Wash and dry the negative, and if too dense reduce it with permanganate of potash, acidified with sulphuric acid.

#### A PRESIDENT'S HINTS.

[Notes of an Address by Mr. Thos. W. Robertson, Glasgow and West of Scotland Amateur Association.]

At the annual meeting of the Glasgow and West of Scotland Amateur Association, the new President, on taking the chair, said:—Another summer has passed away since last we met, a summer which, I hope, to all of you has been a prosperous one, and one in which you spent many pleasant hours with the camera. From a photographic point of view, the season has not altogether been everything that one could desire. The weather has been so uncertain that work with the camera suffered a great deal; but perhaps it is consoling to remember that it is often during such uncertain weather that some of our most beautiful effects are secured—effects of sunshine and shadow so dear to the heart of the artist, be he photographer or knight of the brush.

As a change from the cares and worries of our daily life, the practice of photography must ever remain a pleasant and most entertaining relaxation. Our hobby, also, is a means of leading us from many of those undesirable influences that surround our daily life, bringing us to have a fuller and deeper appreciation of all that is good and beautiful in this world. As an educative medium for young and old alike, I know of nothing better than photography.

Nowadays one cannot fail to notice the vast increase in the votaries of our art. Turn where you will by road, or rail, or steamer, the camera is always in evidence, from the pocket instrument to the lordly,

though cumbersome, 15 × 12. One naturally concludes that no matter what hobby may have lost favour with the public, amateur photography has certainly not suffered. As a science, it has advanced by leaps and bounds, improvement has followed improvement, until there seems little or nothing more to be achieved, so far at least as perfection of apparatus is concerned. What a contrast to the olden days, when one had to carry forth into the field, dark room, chemicals, glass plates, and all the necessary paraphernalia for the wet plate process!

At one time, and that at no very distant date, the amateur photographer was looked upon with feelings akin to amusement, and occasionally ridicule, and was generally put down as a cranky individual whose pastime, if not a nuisance, was, at least, harmless. Now all that is changed. The dark days are gone, and the amateur shines forth not only as an artist, but as a benefactor of all his professional fellow-workers. I use the word benefactor advisedly, for to him is due much of the improvement that has taken place in the manufacture of apparatus. In fact, the amateur has been the means of creating the demand for superior appliances the manufacturers have so fully met.

Perhaps the greatest change that has taken place in pictorial photography has been due to the advent of the hand camera. In a sense, it has revolutionised photography, and has almost knocked its big brother—the stand camera—out of the field. To the hand camera I think I may say we are largely indebted for the huge army of workers in photography. To it also are due many of the splendid illustrations that flood our weekly and monthly periodicals. It has been the means of recording numerous passing events of the day, events which crop up secured by any other means. During this year in the war across the seas we have had grand examples of the work done by this handy little instrument. In all our war journals is to be found an array of work of a very high order, which could never have been accomplished without the aid of the hand camera.

Then in our daily life, even in landscape work, results can be produced with the hand camera equal to those obtained with the stand instrument. No doubt a great deal of indifferent work is produced by the hand camera worker, largely owing to the want of experience on the part of the operator and to an improper choice of subject. With some their whole aim is the exposure of plates, firing them off at everything they come across regardless of time, light, or subject. No doubt the chief cause for this waste of material is the cheapness of the dry plate of to-day. There seems to be no cure for this disease, but it generally brings its own reward or punishment, as sooner or later the amateur of that type gets disheartened, and his camera goes upon the market.

Another point worthy of remark is that so many taking up photography for the first time start with instantaneous work, without having made a single time exposure. They begin at the wrong end of the alphabet, and thus make a fatal mistake. Every beginner should master the rudiments first, and, afterwards, if he will, try the classics. If this were done many a shilling would be saved, and much better work be done all round. Regarding the plates used by most hand camera workers, I cannot help saying that quite a large number go astray in selecting the most rapid they can find. If amateurs would only use a plate of medium rapidity they would have better results. There is greater ease in developing them, and less risk of fog, and, in general, fewer failures. In dull weather, or for special purposes, the fastest plates are useful; but I hope to show later in the session some snap-shots taken on slow plates, and when you see them I think you will agree with me that I have reason on my side.

Regarding developers, we are now surrounded with a host of these useful gentry, some strongly advocated, but none, in my opinion, equalling our good old, tried friend, pyro for negative work. For special work, some of the new developers are first-class, such as lantern slide work, bromide enlargements, &c. These have replaced the old ferrous oxalate developer, and done away with all its attendant mess and stains. There is one of the newer claimants I have found very useful for enlargement and bromide work, viz., ortol. It gives very fine black tones, and is very clean to handle, and at the same time economical.

Within the last winter or two there has sprung up with mushroom growth a host of silver bromo-chloride papers, popularly termed gas-light printing papers. These have, no doubt, been tried with varying success, and where warm tones were desired some charming results have been obtained in experienced hands. That they have come to stay I would not venture to predict.

In gelatino-chloride printing out papers we have also quite a host to choose from, but there is one objection to their use, that they require to be toned. I think I am safe in saying that gold toning is a process most amateurs abhor—the tone is so often anything but uniform, or the tone one most desires. Why, then, use a paper that requires toning, when in the beautiful carbon process there is the paper *par excellence* for artistic work? You are sure of having a uniform tone, you have greater speed, you have a wider range of colour, and you can transfer your picture to almost any grade of paper, so that your scope for artistic rendering is endless. The simplicity of the process should alone commend it to all workers, and nothing is more surprising than that it is not more universally used. Possibly many amateurs, when they read the working of the process for the first time, come to the too hasty conclusion that it is much too complicated and entails too much labour, but I am sure the labour entailed is not greater than that

demanding by P.O.P.—and the results—well, they are not to be compared.

In photography, as in all other kindred hobbies, there are branches or bypaths which lead one into some special type or class of work, such as the study of flowers, fruit, animals, birds, &c. Now, perhaps, amongst all the branches of photography that of mountain work is most neglected. Why this should be I cannot say, except that its practice is attended with some degree of physical exertion. Well, I can assure you that in mountain photography there is great scope for artistic rendering of Nature in her smiling or frowning moods; great scope for reproducing those passing charms sacred to the grand solitudes of the everlasting hills. For those who find a delight in the ever-varying beauties of cloudland, the mountains offer the finest field imaginable for photographic work. The subjects are, perhaps, a little difficult, but well worth any amount of labour, and to all sound of wind and limb no more delightful pastime could be recommended.

Besides mountain photography, there are other branches of our art that may appeal to those not inclined for such arduous work. To those scientifically inclined, photomicrography offers pleasant and instructive inducements, so that even in the winter months the camera need not be packed away, as is too often the case with many skilful amateurs.

#### EDINBURGH INDUSTRIAL EXHIBITION.

THERE has been much talk of educating the public to what is "good and true" in photography by means of exhibitions, but an exhibition such as we are now considering must have a greater influence on the mass of the public than any merely photographic show, because thousands go to see this exhibition who would never dream of going to see a photographic one pure and simple; and, once there, it is the photographic section that is the popular one; all the time of our visit it was surrounded by crowds of gazers, and we noticed quite a number of the exhibits sold; but, then, the producers of them did not ask £10 for them. The exhibits in the exhibition comprised 3,500, and the photographic section about 320, divided into no less than 34 classes, some of them, it is true, with only one exhibitor. We have before referred to the want of management; on the third day of the exhibition we could not get a prize list; they had, however, probably in reply to our suggestion of last year, prize tickets on the most of the frames, they had either been lost or withheld, probably the latter, as, although there was much good stuff, the judges' debate at times would be, Which is least bad? and to that one they would award the prize. There are two sets of classes, and duplicates in each class; one is for "amateurs," and has a section where you can enter any kind of print, the other section is reserved for carbon prints, but in these some classes were marked "open," so it was not an easy matter for intending exhibitors to know what was what; the other class was for those who had never won a first prize at this exhibition, and after that came "carbon" classes, without any special note as to who were eligible for them; as a consequence several professionals entered, and the management evidently felt the difficulty they had placed themselves in, for they added two professional classes.

The work all over was of a very mixed order, some very good work and some very poor work. Perhaps the gem of the whole exhibition was a little panel picture of a demure maiden by Miss Buchanan, Edinburgh. The picture was complete with no unnecessary accessories; the arrangement was pleasing, and the range of tone well kept. Altogether it was a picture that any one would be proud of, and only missed the "Evening News" special prize for best work in the class by not having the necessary coupon attached; it well deserved it. Miss McLauchlan, Edinburgh, has evidently a very good cat model, for the photograph of a cat on guard over a mouse trap with which she took first place in Class 34 was a delightful study of cat life. The multiplicity of classes was responsible for several duplicates being in the prize list. E. L. Brown (Edinburgh), Thomas A. Sands (Aston), and C. M. Wane (Edinburgh) were all very successful exhibitors. Mr. Brown has a good landscape in No. 614, although the clouds have an unnatural appearance. He has some good studies of Pomeranian dogs, and in 625 he has a good interior of first-rate technique. Mr. Sands has in 568 a good seashore piece; the distance is well suggested, and there is a fine feeling of atmosphere about the picture; the clouds are perhaps a little "streaky." In 575 he has a gem; seldom have we seen a better representation of "wind" than this girl on a wind-blown sea-wall. His study of pelicans in 601 is satisfactory, the quaintness of these birds being beautifully and variously portrayed. Mr. C. M. Wane, in 627, which gains one of the "Evening News" special prizes, has one of the best things in portraiture he has yet done. It is a beautifully rendered study of a little girl, natural in pose, with a slight similarity to Craig Annan's "Little Princess." His "swan" studies are much in evidence, and look as charming as ever. The manner in which he has again and again secured the traditional curve of the swan's neck can only be appreciated by those who have tried it, although the beauty of it is evident to all. There are a number of snow scenes, but in all there is a lack of gradation in the snow. The ex-

hibitors have yet apparently to learn that snow, as seen in a landscape, is not uniformly white, but rather a picture of fleeting lights and shadows, difficult enough to depict with the camera, but untruthfully rendered if represented in the print by a white mass. T. D. Shiells, Edinburgh, has a magnificent head of an old man in his 631 but it might have been improved if it had a little more breadth. In "Photos not classed," W. J. Byrne, Richmond, has two very fine portrait studies, and the surprise is that he did not get first place. The "first" picture is a mixed up photograph of a girl at a pump, but it is devoid of perspective, the whole picture being in one plane. A lovely flower study in this class is also unaccountably passed over. In both professional classes C. M. Wane takes first place, his swans being again in the ascendency. The band of the Royal Marine Light Infantry was the attraction in the evenings, and as a result the Waverley Market, probably the largest hall in Scotland, was crowded nightly. Mr. Hutchinson has accomplished much in the four years of this exhibition, but he can do yet better in the section in which we are interested if he will but take our hints to heart.

#### THE LATE LEON WARNERKE.

WE are sorry to have to announce the death of Mr. Leon Warnerke at Geneva on October 7 in the 63rd year of his age. Although during the last two or three years Mr. Warnerke's participation in British photographic work was very slight, for nearly a quarter of a century his activity had been incessant. Hungarian by birth, he settled in England about 30 years ago, his profession being that of civil engineer. A taste for photography led him into the paths of experiment, and from a brief biography of him which was published in *THE BRITISH JOURNAL OF PHOTOGRAPHY* nearly 17 years ago, we learn that he first appeared prominently before the photographic public in 1875, when, at a meeting of the old South London Photographic Society, he read a communication on "Paper versus Glass," and exhibited and described his roller slides and sensitive collodion tissue. In 1876 he addressed the Photographic Society of Great Britain on the subject of "Investigations in Collodion Emulsion," in which he gave the results of a series of experiments on the relative values of different salts for emulsion purposes.

From that date forward the record of Mr. Warnerke's writings and papers would be a very lengthy one, for he did not confine himself to the societies and journals of this country, but made frequent appearances at photographic societies in Russia, Belgium, Germany, and France. At St. Petersburg 20 years ago he founded a photographic society and a photographic journal, and we believe that at one time he was commercially interested in dry-plate making in that city. In 1877 he was awarded the prize offered by the Photographic Association of Belgium for the best dry process, and in 1881 the Progress Medal of the Photographic Society of Great Britain was conferred upon him. Until a year ago he was a member of the Society's Council, and one of its most active supporters.

One branch of work brought him very prominently before photographers—actinometry and sensitometry. The Warnerke Actinometer was based upon the employment of a phosphorescent tablet, upon which to record the impress of the light's action, whilst the well-known sensitometer, which bears—or rather bore—his name, also utilised the same principle, and was for a long time the recognised and, indeed the only, standard of speed measurement for dry plates. Until comparatively recently most, if not all, dry plate-makers indicated the speeds of their plates by readings obtained on the Warnerke sensitometer. We believe that to Mr. Warnerke was due the credit of the establishment of the lens standards of the Photographic Society of Great Britain, a committee having been appointed by the Society at his suggestion to take the matter into consideration. He was a constant attendant at the various Photographic Congresses, and it may, in brief, be said of him that British photography is distinctly the richer by the close touch which he served to establish and maintain between photographic progress in this country and abroad.

In more recent years, we remember the very exhaustive account he gave of photographic educational institutions in Berlin, Vienna, and other Continental cities. It was Mr. Warnerke who introduced the well-known optician, Mr. C. P. Goerz, to a meeting of the Photographic Society, when the double anastigmat lens was first exhibited in this country, and to him that English photographers were indebted for sustaining interest in the Lippmann process of interference colour-photography, Messrs. Lumiere's remarkable results being shown by him at a Society of Arts meeting in the year 1895.

To assign a limit to Mr. Warnerke's photographic enthusiasm and unselfishness would be a hard matter. Personally, of a most genial and communicative disposition, his great store of photographic knowledge and experience were always freely offered to all those who sought them. We had the pleasure of the deceased gentleman's acquaintance for about ten years, and we received much encouraging help and information from him. We cannot close this short and imperfect sketch of his useful career without appending the conviction that Fate acted cruelly and unjustly to him in the last days of his life, and that he was the innocent victim of circumstances which hastened his end.

#### ARTISTIC MOUNTING AND FRAMING.

BEFORE the members of the Leeds Camera Club on Wednesday evening, Oct. 10, Mr. A. Keighley (Bradford Photographic Society) delivered a lecture, one of the series of the Yorkshire Photographic Union.

He said it is somewhat strange that in these days when so much is thought, said, and written about the making of pictures, composition, light and shade, that so little attention appeared to be given in the photographic journals or those devoted to other arts, of the mounting or setting in which those pictures appeared. A picture is to its mounting or frame just what a jewel is to its setting, or a flower to the leaves with which it is associated; either of them is incomplete without the other.

It is very strange that this subject of framing never seems to be brought before the students in our Academies on Art, so important a matter seemed to have been altogether neglected, and still stranger that a writer so voluminous and versatile and comprehensive as Ruskin seemed never to have given any attention to this subject in any of his writings.

"The literature on the subject is very scanty indeed, and to give you some idea I took the trouble to go through the whole of the volumes of the "Studio," which covers a very wide field, but I was unable to find a single article with regard to mounts and frames. The reason for this neglect seemed to him to be the limitation and the strict regulations which are imposed on artists at Exhibitions.

The authorities at the Royal Academy and the other principal shows always insist that the pictures, whether oil or water colour, shall be surrounded with a gilt frame for the sake of uniformity, and there is no room left for the exercise of individual taste.

It is a well-known fact amongst artists that the gilt frame is out of harmony with the picture, and artists wishing to exhibit must comply with the rule; and, this rule being firmly established, it followed as a matter of course, that a gilt frame is necessary for any work of art in colour, and the general public have come to accept the gilt frame as the correct thing, and it is only in this way one can understand why artists have given so little attention to the subject.

What is the fundamental principle of a mount? In the first place, to support and project the picture; in the second, to isolate it from its surroundings; and, in the third, to harmonise and enhance its general effect. It seemed to him that generally people hung their walls with pictures not to see the pictures themselves, but simply to decorate the walls.

It is altogether out of my province to speak of the mechanical part of the subject, but to draw attention to the principles which should govern the selection of mounts and frames.

Of what use are mounts? Why are oil paintings framed close up and water colours framed with a considerable mount between the picture and the frame? The reason is that oil paintings were generally large in size, and water colours generally small, and painted in delicate and transparent colours, and improved by a mount placed between the picture and the frame.

Photographs of large size and strong and decided in appearance framed close up in a somewhat heavy frame suited the picture best, and a mount is more suitable if small and delicate in appearance, but no hard and fast rule could be laid down. Mounts in which diagonal lines run from corner to corner emphasising the weak points in the centre of the picture are to be avoided, a little more top or bottom or side to side being much better.

As to tone, by which he did not mean colour, but simply the question of lightness or darkness, the law of contrast applied, a very light print should be surrounded with a white mount. Speaking generally, an absolutely white or black mount should rarely be used, and only in extreme cases; rather than absolutely white, it is better to have a tinted mount, and dark mounts should be used where darker tones prevail, and medium-coloured mounts where a fairly even balance between the lights and shades occurred.

The frames of old English masters struck one by the poverty of design which most of them exhibited; and, turning to the present day pictures, the same feeling applied in regard to many of them. If it was essential that pictures in an Exhibition should be all framed alike, it might be allowed that gilt is as suitable as any other colour, but our opinion, given with diffidence, is that the glare and glitter were sometimes very much out of harmony, and prejudicial to the general effect.

Photographers were not bound in any of their Exhibitions by hard and fast rules, and therefore they got great diversity of style, from heavy cabinet work to very slight frames, but, on the whole, this diversity is better than uniformity. It is so much the custom amongst photographers to follow the prevailing fashion: some amateur sees a masterpiece surrounded with a heavy frame, and so he proceeds to his own frame maker and orders his picture in similar style, the result being that his picture is killed by unsuitable framing."

In conclusion, the lecturer pointed out that frames should be chosen to suit the picture in colour, size, and texture, and might perhaps have details emblematic of the subject of the picture. It should not be unduly eccentric, or divert undue attention from the picture itself: and any part of it carved should be diminished in conspicuousness so as not to detract from the main purpose of the whole.

### THE LATE THOMAS FALL.

WE very much regret to announce the death of Mr. Thomas Fall, photographer, of Baker-street, Finchley, and Bayswater, which took place on Saturday, October 20, at his home, Wensley, Arkwright-road, Hampstead, N.W. The cause of death was heart failure. Mr. Fall had just entered his 67th year. He leaves a widow and several sons and daughters, the former including the Rev. J. W. Fall (of the Church Pastoral Aid Society), Mr. Geo. F. Fall (of the firm of Cooper and Balie, solicitors).

Mr. H. Snowden Ward, who was the last person outside the immediate family and attendants to converse with Mr. Fall, sends us the following notes:—

“The fatal illness was undoubtedly the result of long-continued over-work, and commenced several months ago, while Mr. Fall was taking in Brighton a much-needed and too-long postponed rest. While walking in the street with his daughter he was suddenly seized with heart failure, was taken into the nearest house, and a doctor at once summoned, who for an hour found it impossible to restore animation. In spite of the shock of such a seizure, a few days saw Mr. Fall at work again, rather than disappoint a wedding party which he had undertaken to photograph personally. The exertion proved too great, another heart stoppage ensued, and only by the greatest care was it possible to take the patient to his home, where for months there was a continuous and almost hopeless struggle between life and death. At length, about the end of September, there was a considerable change for the better. Though very much shattered by the long illness, Mr. Fall began to take fresh interest in his old pursuits, about which he had scarcely spoken for some months. His first act was to ask his son to offer a set of lantern slides with notes which he intended to prepare for one of the Royal Photographic Society's lantern evenings. A day or two later he asked for his file of THE BRITISH JOURNAL OF PHOTOGRAPHY, and had his nurse read to him those items of news which had occurred during his illness. Collections of the current works from his studios at Finchley and Baker-street were obtained, and the quality of the work gave him much pleasure; and a day or two thereafter he asked that I should call to tell him “all the news of photography.”

“On October 10, when I was able to spend an hour with him, his mind and memory were wonderfully keen and clear in spite of great weakness. He inquired by name for many of his photographic friends, and asked the present whereabouts of some whom he had not seen for many years. His greatest pleasure seemed to be in remembering the gratitude of so many of the people whom he had been able to help photographically or financially, and in particular he mentioned a young lady who had recently left England for Chicago, and a man, helped many years ago, who was now, or recently, in Yarmouth.

“For another week Mr. Fall seemed steadily gaining strength, but on the 17th there was a relapse, and after two days of pain he passed away peacefully in his sleep in the early morning of October 20.

“Probably no man was more constantly, cheerfully, and secretly busied in helping others connected with photography. His time, his money, and his wide knowledge were ever at the service of those who were in doubt or difficulty, and I do not think that any photographer has an idea of the noble extent of this generosity. Like Traill Taylor, like Richard Keene, he had a history of beneficence and helpfulness quite apart from his life that was known to all of us. Like them, he leaves a great gap in the photographic ranks which we have no one to entirely fill.

“For many years, and particularly during the time that I was Secretary of the Photographers' Benevolent Association, I have been sending to Mr. Fall a steady stream of photographers who wanted help, who wanted situations, who wanted advice or suggestion, and never have I known him lacking in sympathy, interest, and courtesy, even to the most broken-down of unfortunates. It is because I have thus had special opportunity of knowing this beautiful side of his character that I have asked the Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY to allow me to write these lines.”

The late Mr. Fall was born at Leyburn, in North Yorkshire. He was apprenticed to lithographic printing, but in his early manhood took up photography, first as a travelling worker, and afterwards built a studio in Bedale. On coming to London his first engagement was with the (then) new firm of Elliott and Fry. For many years he enjoyed a wide reputation for portraiture, being especially happy with children, and latterly he devoted himself to animal photography with great success.

To Mr. Snowden Ward's admirable tribute to the late Mr. Fall it is only necessary for us to add a few words. We had the pleasure of Mr. Fall's acquaintance for a considerable period, and on several occasions we were the channel by which he conveyed his unostentatious help to his less fortunate brethren. We are sure that his death will be widely deplored, and that general sympathy will be felt for his family in their loss.

### PHOTOGRAPHIC EXHIBITION AT ROTHERHAM.

UNDER the auspices of the Rotherham Photographic Society, a very successful Exhibition was held in the Rotherham Drill Hall on Wednesday, Thursday, Friday, and Saturday, October 17, 18, 19, and 20. Although it was the eleventh annual venture of the organisation, it was the first at which there were competitive classes. Mr. C. B. Keene, F.R.P.S., and Mr. T. A. Scotton, both of Derby, kindly undertook the work of judging, and their awards were as under:—

#### OPEN CLASSES.

A. Photographs, any subject (previously medalled): Silver gilt medal, John Leslie Shawcross (Blackburn); silver medal, Sparham Camp (Sheffield); bronze medal, Greystone Bird (Bath).

B. Photographs, any subject (not previously medalled): Silver medal, Evelyn Boden, F.R.P.S. (Derby); bronze medal, J. H. Lygo (Sheffield); certificate, Greystone Bird (Bath).

C. Lantern Slides (sets of four): Equal bronze medals, Greystone Bird (Bath), Edgar R. Bull (London); G. Cleland (Edinburgh).

#### MEMBERS' CLASSES.

D. Photographs, any subject: Silver medal, J. C. Cox; bronze medal, withheld; certificate, A. S. Lyth.

E. Lantern Slides (sets of six): Silver medal, J. C. Cox; bronze medal, H. C. Hemmingway; certificate, A. S. Lyth.

F. Society's Excursion Work in 1900 (four prints): President's silver medal, H. C. Hemmingway; bronze medal, J. C. Cox; certificate, A. S. Lyth.

The A Class was not a large one. Mr. Shawcross scored with “Head of an Old Man” (sepia platinotype). Mr. Sparham Camp's picture was “Norwich Cathedral” (platinotype), and Mr. Greystone Bird's the well-known “Good-Night” (matt. solio). The B Class was unusually strong and representative, the entries numbering 54. Miss Evelyn Boden's position was obtained with “Head of an Old Man” (platinotype), Mr. J. H. Lygo's with “Gloucester Cathedral Cloister” (carbon), and Mr. Greystone Bird's with “Overhauling the Nets” toned bromide). Lantern slides attracted 10 competitors, and the judge made three equal awards. Mr. Greystone Bird's winning slide was “Launching the Lifeboat,” Mr. Edgar Bull's “Crypt Wells,” and Mr. Cleland's “Waiting.” The Members' Section was disappointing, especially in the D Class. Mr. Cox's “Art Critics” stood easily first. Lantern slides did not show the ability of the members to the best advantage. Mr. Cox again scored with “Glory Hole, Lincoln,” Mr. Hemmingway being placed next with “Window, Wingfield Manor.” Mr. Lyth was close up with “Lady Chapel, Gloucester Cathedral.” There was interesting rivalry for the President's medal in the F Class. Mr. Hemmingway's best work were two Lincoln Minster views, and the “Little Shambles, York.” “St. William's College, York,” was the best of Mr. Cox's series. Mr. Lyth's were an even lot. Turning to the members' non-competitive exhibits, there were several especially noticeable, including the Gargoyles and other architectural curiosities by Mr. J. Leadbeater, as well as the same gentleman's “bits” found in the lake district; and Miss Mary Crossley's landscapes, with figures. Amongst the contributions of invited exhibitors were six enlargements of war snap-shots by Lord Scarborough, several characteristic works by Mr. Alex. Keighley, F.R.P.S., and “An Old Stairway,” by Mr. C. Barrow Keene, F.R.P.S., R. and J. Beck, Ltd., Kodak, Ltd., Messrs. Wellington and Ward (an enlarged copy of “The Curfew Hour”), and others gave their aid. The opening ceremony on the Wednesday afternoon was performed by Mr. J. S. Fullerton, J.P., M.F.H. Dr. Baldwin (President) occupied the chair. The large company included the Mayor and Mayoress, Mr. W. H. Hclland, M.P., and Mrs. Holland, and Mr. G. W. Chambers, D.L. Each evening there were lantern shows, music by the Eastwood Orchestral Band, and other attractions.

### THE DARK ROOM.

Most amateur and many professional photographers in a small way of business find it a great hardship, or at the least very inconvenient, to keep a room especially as a dark room, and where they do keep a special room it is often little more than a cupboard, dark enough, it is true, but stuffy and ill-ventilated, what small quantity of air it may contain at first soon being consumed by the lamp, so that the place is very hot and unhealthy to work in, besides being detrimental to the plates, and, in addition, there is practically no room to move.

If the room could be used to store plates, papers, and chemicals, and also be adapted for developing, printing, toning, and fixing, many of these people would be able to keep a room, and, fortunately, this can be done with very little trouble and expense. A light wooden frame should be made in the style of the following sketch.

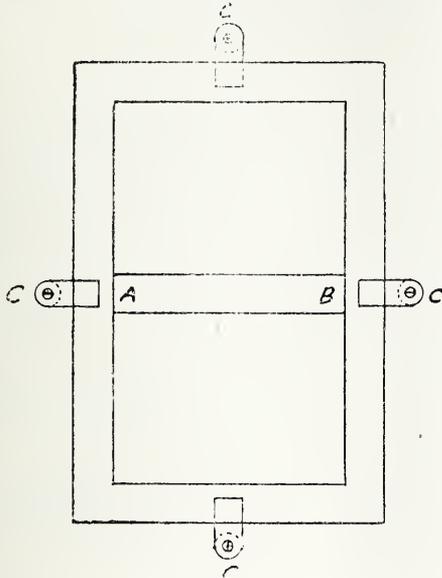

This should just cover the window frame, and be fastened either with buttons on each of the four sides, or perhaps, better still, a little ledge may be fastened on to the wall, either at the top or bottom of the window, for the above frame to fit into, and the other three sides

fastened with buttons. The frame may be covered with red twill, or canvas can be fastened to the frame, and red paper pasted on this, whichever is most convenient.

To ensure that no light enters between the frame and the wall, a layer of thin felt should be fastened to the frame on the side nearest the wall, and, if the buttons are made to press this tightly against the wall, no light will enter.

The frame should be made of deal, and unless the window is a very large one, the sides need not be more than half an inch in thickness and one and a half inches wide. In the case of a very large window, it might be necessary to have a rib across the middle of the frame to strengthen it, as at A B, but this is not usually necessary.

With this frame the room may be used for all purposes, and a great deal of time may be saved, to say nothing of the illuminants, when daylight is available, by taking the frame down from the window, an

operation which may be accomplished in a few seconds, and making all preparations, &c., that can be done by daylight, instead of having to grope about in the dark or use artificial illuminants. It would be necessary to have a small cupboard to keep plates and other materials which would be affected by daylight, or any but a red light, and to get into the habit of putting these articles away before admitting daylight.

This arrangement may be found useful by those photographers who are not necessarily obliged to keep one room for all purposes, as many operations in photography can be conducted much better by daylight than by the aid of artificial light.

The centres of the buttons (C C C) may be the ordinary brass or iron screws such as are generally used for wood, these answering the purpose just as well as anything more elaborate, and a great advantage with them is the fact that they are easily adjustable, besides being economical and readily obtainable.

C. T. SUTTON.

[We have for years used such an arrangement as that described by Mr. Sutton.—Eds.]

A NOTE ON POISONS USED IN PHOTOGRAPHY.

PHOTOGRAPHY, like all sciences allied to chemistry, often requires the use of poisonous materials, and, consequently, all who practise it should know when they are dealing with a poison, and how to use it with the least risk to themselves. A great many persons look upon a poison simply as a chemical which, when swallowed, is likely to cause death; but really the word covers a far larger class of reagents than this. A poison, using the word in its proper sense, is a compound which, when introduced into the system, either through the digestive organs, the skin, or the lungs, will cause ill or even fatal effects to the individual. Looking at it in the light of the above definition, we find that the poisons used in photography are by no means few.

In view of this fact it is well for every photographer to possess the necessary knowledge, so that, like the chemist, when he feels any ill effects at all resembling the symptoms of poisoning, or finds some one else exhibiting these symptoms, he can at once pick out the chemical which may have caused the harm, and then immediately proceed to neutralise its action on his system. It is of the greatest importance in cases of poisoning to do something immediately, for the action of the substance is going on, and the sooner it can be stopped the less damage there will be to make good, and the less chance of serious effects following. Consequently, it is as well for every photographer to know what to do at once, and not to be in a very vague state of mind as to what is best to be done, or having to consult books or papers which he cannot always find when they are wanted.

A great number of the poisonous chemicals used in the dark room can be divided under two heads, acid poisons and alkaline poisons. Now, every one with the slightest smattering of chemistry knows that acids and alkalis neutralise one another; that is, if an acid is acting upon any substance it can at once be stopped by applying an alkali, the compound then formed being almost always an inert one. Thus, to take a homely example, suppose you spill some nitric acid on your coat-sleeve. The acid at once begins eating away the fibres of the wool; but, if you immediately apply a drop of ammonia solution, which is a powerful alkali, the action of the acid is stopped, and no harm results to your coat. The nitric acid is forced to confine its attention to the ammonia, and forms with it a harmless chemical in the fibres of the woollen cloth. You can, therefore, easily understand that if any accidents happen with an acid, an alkali will generally stop any harm being done, and, in the same way, if you get an alkali causing damage, it should at once be stopped by the application of a weak acid. I would point out that the acid should be weak; in fact, whatever the antidote, it should not be applied too strong, or the remedy may be worse than the disease. In the case of an alkali, it is not so important as with an acid. The latter should either be a weak one, or should be diluted before application.

Following up this rule, let us see the best way to deal with some of the cases of internal poisoning likely to arise in the dark room of the photographer. Taking the acids first, we find that he often uses hydrochloric, nitric, sulphuric, oxalic, and pyrogallic acids. Now, suppose we have someone who has inadvertently swallowed a dose of one of these acids, at once give him a glass of magnesia or chalk and water, or, failing this, you can even scrape a little plaster off the walls or ceiling, and stir this up in water and let him drink it. This will at once change the acid into a harmless salt of magnesium or calcium. In the case of our old friend, pyro, it can be removed from the stomach by the aid of an emetic. The weaker acids, citric and tartaric, are not so dangerous. If, on the other hand, an alkali has been swallowed, its action must be stopped by drinking doses of a weak acid, such as vinegar or lemon juice.

There are several chemicals used by the photographer which cannot, however, be classed under these heads, and which include some of the most deadly poisons. Cyanide of potassium, which has, happily, been nearly supplanted by hyposulphite of soda, is a most deadly poison, and, unfortunately, one of its symptoms often is the loss of power to swallow. It behoves you, therefore, to be extremely careful when dealing with this salt. Another deadly poison is corrosive sublimate or mercuric chloride, used in intensification, and it should be used with great care. If by chance you should happen to swallow a few drops of the intensifier, you should at once follow it up with the white of an egg, or drink plenty of milk, barley water, or arrowroot.

Nitrate of silver, being one of the few soluble salts of the metal silver, will, if unfortunately you should swallow any of it, be absorbed into the system with injurious effects; but, if you take a strong dose of common salt dissolved in water, you will turn it into the insoluble silver chloride, which can then be expelled by the action of an emetic.

For an emetic you may try:

- (1) Tickling the back of the throat.
- (2) Frequent doses of warm water.
- (3) A tablespoonful of salt dissolved in a tumbler of warm water

A very rough-and-ready but a very sure emetic is to take one or two blank cartridges, and mix their contents with warm water. This is very prompt in its action. The chemist will also supply two or three emetics which are best administered under his direction. For instance, there is sulphate of zinc, ipecacuanha, and others.

So much for the internal poisons. Now let us turn our attention to the substances which cause harm to the skin. The strong acids if allowed to act on the hands or any other part of the body will have very harmful effects, but their action can soon be stopped by the application of an alkali, as stated above. Ordinary washing soda is always handy and is a very good one. Those of my readers who have learnt chemistry will also know that soap is made of a fat and an alkali. If, therefore, you should get any acid on your hands, it is a very good thing to wash them well with soap and water, the alkali in the soap at once neutralising any acid present. This treatment will be found especially useful in the case of a cut, into which a drop of acid may have trickled.

Weak hydrochloric or a solution of citric acid is very useful for taking out pyro stains on the skin, but the hydrochloric should be well diluted, and even then should not be used where there are any cuts or sores.

It is surprising to see how some workers will persist in dipping their fingers into the various solutions. Apart from the great risk of contaminating the various baths, there is also the danger of getting corrosive chemicals into any cuts or abrasions you may have. All this dabbling is quite unnecessary. The plate can easily be lifted with a match or a slip of wood or a plate-lifter, and partially drained before you need handle it. The intensifying bath is one, for instance, into which the fingers ought never to be dipped. You are never quite certain whether your fingers are absolutely free from cuts, scratches, or wounds of some sort or other, through which this highly poisonous chemical can get, and therefore it is safest not to dip your fingers in at all.

Poisons are best kept in easily distinguished bottles of some peculiar shape or form, so that, even if we do not see which bottle we are handling, we know by the touch that it contains a poison. They should also be kept locked up if possible, so as not to be accessible to the uninitiated, and, in conclusion, I would particularly point out that on

no account should poisons and such things as medicines be kept on the same shelf or in the same cupboard. Many a death has been caused by taking up the wrong bottle.

ALEX. SNAID.

### THE NEW BOROUGH COUNCILS.

ON November 1 the Councils of the newly created metropolitan Boroughs will be elected, and on November 9, having selected their Mayors and Aldermen, they will come into office. Whether the changes which will thus take place in the local government of London will conduce to the ultimate benefit of the long-suffering ratepayers remains to be seen; but there are certain directions in which the process of alteration may be of advantage to photographers from a business point of view.

A large number of existing local authorities will be abolished—district boards, vestries, trustees, and commissioners for the administration of various Acts of Parliament will, within the next fortnight, hold their final meetings. They comprise a great many gentlemen who have for a considerable period identified themselves with parochial affairs, and photographers may find it worth while to suggest to them that photographic records should be made of their last gatherings, or that the outgoing ediles should be photographed, say, on the steps of the town hall, or at some similar place. The officers of the vestries, &c., who have worked together for many years, would also probably like to be included in a group, before the places which have known them so long know them no more. There are other opportunities of this kind which will occur to the man who is on the look-out for work.

In making arrangements for this class of business, it would, perhaps, be best, in the first place, at all events, to seek a personal interview with the Chairman, or some prominent official, rather than to make the proposal in writing.

HENRY EVERETT, F.I.S.

### FARRELL AND BENTZ'S PROCESS OF PHOTOGRAPHY ON SILK.

[Patent No. 17,375 of 1899.]

THE invention refers to improvements relating to the production of photographs upon silk fabrics. Silk is immersed in a dilute solution of nitrous acid with the addition of hydrochloric acid, sulphuric, or other suitable acid, for about twelve hours at the ordinary temperature, or for a shorter period at a sufficiently high temperature, the operation being conducted in the dark.

The silk thus treated becomes bright yellow in colour, being converted, it would appear, into a diazo compound (chloride, sulphate, or other compound corresponding with the acid employed). The silk is then rinsed in water and dried in the dark. We find that the silk thus prepared is very sensitive to light, a few seconds in direct sunlight, or a few minutes in diffused sunlight, sufficing to change the bright yellow colour to a very pale buff. Before exposure to light the silk coloured yellow in the manner above described possesses the property of combining with phenols, such as phenol, resorcinol, alpha-naphthol, beta-naphthol, and their sulpho and carboxy derivatives in alkaline solutions, and with aromatic amido compounds, aniline, meta-phenylene diamine, alpha-naphthylamine, beta-naphthylamine, &c., in acid solutions, forming coloured compounds; after exposure to light the silk which has been treated in the manner described with nitrous acid loses this property, the yellow silk compound becoming chemically changed by the action of the light. We find that silk treated with nitrous acid according to the process above stated, after being placed under a photographic positive, and thus exposed to light, when it is treated with a phenol in alkaline solution or an aromatic amido compound in acid solution, gives a photograph similar to that on the plates under which the silk has been exposed, that is to say, a positive print of the picture on the positive is obtained. In the same way exposure under a photographic negative we find produces a negative print of the picture upon the silk. The colours produced by development as above described may be modified by after-treatment with metallic salts. For example, development with beta-naphthol in alkaline solution gives a bright red shade, which when treated with solutions of cobalt salts changes to a maroon shade. Again, development with resorcinol in alkaline solutions gives a bright golden yellow shade, which when treated with iron compounds changes to a deep brown or olive.

Modified shades are also produced by treating with nickel, chromium, copper, and many other salts. The modified colours thus obtained are in general extremely fast.

The colours obtained by development with aromatic amido compounds, when treated with nitrous acid for a short time and subsequently developed with phenols, naphthol, &c., in alkaline solution, or aromatic amido compounds in acid solution, give new colour compounds which again can be further modified by treatment with certain metallic salts. For example, the colour obtained by the development of the treated silk with alpha-naphthylamine in hydrochloric acid solution is a golden yellow. This when it is acted upon by nitrous acid and then treated with sodium amido naphthol disulphonate (1:8:3:6) gives a greenish slate or what may be termed a greenish-blue colour, or when it is acted

upon by nitrous acid, and then treated with beta-naphthol in alkaline solution, it gives a purple colour. This latter on treatment with an iron salt, for instance ferrous sulphate, changes to an almost black colour.

When the silk which has been acted upon as described with nitrous acid is exposed to light, it does not pass directly from what we assume to be the state of a diazo compound to the state of a compound which no longer possesses affinity for phenols or amido compounds, but it goes through an intermediate stage, a nitroso compound we assume being formed.

This intermediate compound is obtained by exposing to light the yellow-coloured silk compound described for a much shorter time than is necessary to render it chemically inactive with phenols and amido compounds.

When silk thus exposed for a very short time to sunlight is placed in alkaline solution (caustic soda, potash, ammonia, &c.) a brown colour is produced. As what we assume to be the diazo compound of silk does not change colour very much under the action of the alkalis, this property can be utilised for producing positive prints from photographic negatives. Thus we expose the yellow-coloured silk compound obtained by treating silk with nitrous acid in the manner described, under a negative for a sufficient length of time to bring the yellow silk compound in the parts where the light has access to the intermediate (or nitroso) stage, then we treat with an alkali the resulting compound of silk, and we obtain a dark brown positive print on a yellow ground.

We utilise the same property in printing from photographic positives in the following way: We expose the silk treated with nitrous acid in the manner described under a photographic positive, the compound in the exposed places on the treated silk (that is where the sunlight has penetrated) becoming changed into an inactive compound, while the unexposed portions of the silk (that is where the sunlight has not had access) are still in a chemically active state. We then remove the photographic positive and we expose the whole surface of the silk to light for a short time; the inactive parts remain unchanged, but the active portions are changed into the above-mentioned intermediate compound which we then convert into the brown-coloured compound by the action of an alkali as before stated.

The essential feature of the invention consists in the treatment of silk or fabric with the diluted solution of nitrous acid with the addition of hydrochloric acid, sulphuric acid, or other suitable acid, the operation being conducted in the absence of light for the purpose of rendering the silk sensitive to light.

### GIESECKE'S IMPROVEMENTS IN HALF-TONE BLOCK MAKING.

[Patent No. 16,137 of 1899.]

THE object of the invention is to provide means by which half-tone plates of any size and of any grain size can be produced by using only one and the same standard screen.

"I attain these objects," says Herr Giesecke, "by projecting (instead of copying) the standard screen on the sensitive surface, and thereby enlarging or reducing, as the case may be, the width of its net in the proportion desired, and at the same time substituting for the given original to be reproduced a negative (or a diapositive) taken therefrom on a suitably enlarged or reduced scale.

"I place my standard screen out of the camera at a point between the lens and the source of light, and I adjust the screen with respect to the sensitive camera plate so as to obtain on the latter a projection of the screen net in full sharpness and of the width desired.

"Having thus fixed the place of my screen, I take a negative from the original to be reproduced, the scale of this negative being so calculated that its projection on the sensitive camera plate will appear in the size intended for the half-tone, if the said negative is placed in suitable proximity of the screen adjusted as heretofore described. In order to easily have the scale needed for the negative, a tabulated statement may be made use of, containing once for all the several cases which may arise. The said negative (or, if needed, a diapositive taken therefrom by copying the same) is to be used in my invention instead of the original given.

"Having again adjusted my screen to its place as described, I now place the above negative (or diapositive) in proximity of the screen at the point for which its size has been calculated (this point being preferably chosen between the screen and the source of light, or, in other words, beyond the screen with respect to the camera). The photograph is then taken as usual, and a negative thus will be obtained on the sensitive camera plate corresponding to the size required, and provided with a net of the width desired.

"In the case of half-tone plates being to be produced to correspond at the same proportion, as to their size and the size of density of their grain, to the size of the screen and the width of its net, the use of a separate screen can be dispensed with, and the line-ruled negative (or diapositive) can be made use of. To this purpose, I adjust my standard screen as heretofore described, calculating, however, the scale of the negative (or diapositive), so that it will appear on the sensitive plate in the size required, if substituted for the screen in its adjusted position. The negative (or diapositive) then being taken on the said scale, the

standard screen is copied on the same, and a photograph taken from the line-ruled negative (or diapositive).

"By using suitable blinds the character of the screen net projected on the sensitive plate can be differently varied.

"In order to finally obtain the well-known half-tone plate for typographic printing, the negative on the sensitive plate is copied on a metal plate, and the latter etched as usual.

"Another kind of half-tone plate, say for lithographic printing, can be obtained by transferring the picture from the sensitive camera plate to a stone or a zinc plate, the said stone or zinc plate then being prepared as usual in lithography. By printing therefrom, half-tone lithographs are obtained showing fully the character of typographic prints."

## Studio Gossip.

**PERFUMED Calcium Carbide.**—A contemporary states that a Dordrecht firm is bringing out perfumed calcium carbide, which is a step in advance even of odourless carbide, just as that is an improvement on the ordinary or evil-smelling variety. This perfumed carbide smells of thyme, and would seem to have been soaked in the essential oil of that plant. The acetylene made from the carbide has the same agreeable odour, and its illuminating power is increased, if anything. The perfumed carbide has the further advantage that it is less hygroscopic than the baser sort, and will, therefore, keep much better.

**FIGURES in Lantern Slides.**—A correspondent of the "English Mechanic" writes: "Returning from the Exhibition, I was desirous of saying something about it to my friends, and naturally turned to the lantern for help. I got a very fine set of slides, but they contained nothing but buildings. My idea was, when exhibiting the buildings of any particular country, to show some types representing the life of the country; but such slides I could not find, though I looked through all the shops and catalogues within reach. It is strange that the slide-makers, in producing a series of slides for any country, scarcely ever give more than the buildings of the country—sometimes a bit of scenery, but scarcely ever the little points that distinguish one people from another. Why is this?"

## News and Notes.

The Rontgen Society's next Ordinary General Meeting will be held on Thursday, November 1, at 20, Hanover-square. The presidential address will be delivered by Dr. J. B. Macintyre.

**CRIPPLEGATE Photographic Society and Essex and Middlesex Cycling Union Exhibition.**—Late entries for this Exhibition will be received up to Monday next, the 29th inst., when all pictures must be delivered.

The Burnley Camera Club will hold its Second Exhibition of Photographic Work in the Assembly Hall, Mechanics' Institution, Burnley, on Friday and Saturday, January 18 and 19, 1901. The Hon Sec. is Mr. Percy Brotherton, "Express" Office, Burnley, of whom entry forms and all further particulars may be had.

**ROYAL Photographic Society.**—The following are the next lantern fixtures:—Saturday, October 27, "Wonders of the Paris Exhibition," by S. J. Beckett; Monday, October 29, "Through County Donegal with a Camera," by Harry Selby; Thursday, November 1, "Some Swiss Pictures," by John Gunston; Saturday, November 3, "Illustrated Lecture on Colour Photography," by E. Sanger Shepherd. The Exhibition of American Photographs arranged by Mr. Holland Day, at 66, Russell-square, will remain open until November 8. Admission on presentation of visiting card.

In connection with the Musselburgh and Fisherrow Trades Prize Brass Band, a grand Bazaar and Photographic Exhibition and Competition will be held in the Town Hall, Musselburgh, on Friday and Saturday, November 30 and December 1, 1900. The particulars of the Open Classes are as follows:—Class I.: (a) Landscape or Seascape, two prizes; (b) Figure Studies and Portraiture, two prizes. Class II.: Figure or Genre Composition, any size, one prize. Class III.: Best Picture, being the work of a lady, any subject, one prize. All entries to be sent by November 28, to Mr. J. Edington Aitken, 2, Inveresk-terrace, Musselburgh.

## Commercial Intelligence

**THE Austin-Edwards Monthly Film Negative Competition.**—The Prize Camera for the current month has been awarded to Mr. Fred Marsh, 7, Caxton-terrace, Henley-on-Thames, for his negative, "That's Me."

**THE Photo-Button Trade.**—Messrs. Crayon, Ltd., write: "You will be interested to hear that the profits made during the election out of

buttons sold to photographers (not to fancy or toy shop people) directly through our advertisements in your excellent JOURNAL would pay for those advertisements for over three years."

**THE Thornton-Pickard Photographic Competition for 1900.**—We are informed that the fifteen prizes offered in connection with the Thornton-Pickard Prize Competition have been awarded. The Company state that about 1000 prints were sent in, and that the standard of excellence showed a marked improvement on those entered in the competition of 1898. Several of the highest prizes were taken by lady amateurs, who contributed a full share of the best entries, and whose pictures were conspicuous by their refinement and taste. Many photographs taken with the focal plane shutter which were excellently conceived failed to take prizes because of their lack of proper form, or because of incorrectness of exposure. Notwithstanding this a large number of excellent photographs of moving objects were sent in, and show that an ever-increasing number of photographers are turning their attention to this phase of photography, and are meeting with marked success. A new Competition on similar lines, but including time exposures, is being organized for 1901, full particulars of which will be published. The following is the list of the prize-winners:—Class I. (for photographs taken with the Thornton-Pickard Camera and Shutter): First prize, £15, Pierre Dubreuil, 27, Rue d'Angleterre, Lille, France; second prize, £10, Miss Edith Thompson, Stobars Hall, Kirkby Stephen; third prize, £5, Miss Agnes Tomlinson, Fishbourne, Chichester; fourth prize, £3, T. K. Evans, 7, Clarendon-villas, Oxford; fifth prize, £2, J. Cooke Smith, Champery, Valois, Switzerland. Class II. (for photographs taken with the Thornton-Pickard Focal Plane Shutter): First prize, £15, Messrs. Jungmann & Schorn, Werder Str, 8, Baden Baden, Germany; second prize, £10, J. N. Taylor, Christchurch, New Zealand; third prize, £5, Graystone Bird, 38, Milsom Street, Bath; fourth prize, £3, "V. K. R.," Bobouli Vizagapatam-Dist., Madras Presidency, India; fifth prize, £2, W. Kilbey, 57, Pagoda-avenue, Richmond. Class III. (for photographs taken with the Thornton-Pickard Time and Instantaneous and Snap-Shot Shutters): First prize, £15, Miss E. A. Whieldon, Eccleshall Lillington, Leamington Spa; second prize, £10, George Millom, 14, Rue de l'Oratoire, Boulogne-sur-Mer, France; third prize, £5, J. Patrick, 75, Comiston-road, Edinburgh; fourth prize, £3, Miss May E. M. Donaldson, 30, Wellesley-road, Croydon; fifth prize, £2, Gordon Clarke, Greenheys, Little Hulton.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

October.	Name of Society.	Subject.
30 .....	Aintree .....	Social and Dance.
30.....	Birmingham Photo. Society ...	Exhibition of Lantern Views of Swiss Scenery, with Conversational Description and Hints for the Practice of Photographers in Mountain Scenery. Prof. F. J. Allen, M.A., M.D.
30-Nov. 3	Sefton Park ..	Second Annual Exhibition.
30 .....	Thornton Heath .....	Shadows A. C. Baldwin.
31.....	Borough Polytechnic .....	Tele-photography. Ernest Marriage, F.R.P.S.
31.....	Croydon Camera Club .....	Lantern Slides.
31.....	Photographic Club .....	Lantern Night.
31.....	Redhill and District .....	Animals at the Zoo. J. O. Grant.
November.		
1.....	Hull .....	Lantern Photography. W. H. Atkinson.
1.....	Liverpool Amateur .....	Smoking Social.
1.....	London and Provincial .....	Lantern Night.
2.....	Borough Polytechnic .....	Instruction Evening: Printing—Bro- mide Papers, by Contact.

### ROYAL PHOTOGRAPHIC SOCIETY.

OCTOBER 23,—Technical Meeting,—Mr. T. Bolas, F.I.C., F.C.S., in the chair.

#### THE OZOTYPE PROCESS.

Mr. Thomas Manly gave a demonstration of the Ozotype process, of which he is the inventor and patentee, and which is now generally well known. Briefly, it is a method of pigment or carbon printing, in which the permanent support of the picture is itself sensitive to light, a visible image being printed thereon. The printing is conducted by daylight, and as the image is distinctly visible during exposure, the use of an actinometer is dispensed with. The specially prepared "pigment plaster," used in place of the tissue in the carbon process, is not sensitised, but is immersed in a weak solution of acetic acid and a reducing agent (hydroquinone), and squeezed in contact with the washed print. When dry, the picture is developed in warm water in practically the same way as an ordinary carbon print. There is no reversal of the image, no safe edge is required, the fingers of the operator do not come in contact with a warm solution of a bichromate salt, and no blisters are formed. In the course of his demonstration, Mr. Manly showed the method of sensitising the paper—any good paper may be used—pigmenting the print, and developing. In his original paper, read before the Society some eighteen months ago, he explained that the sensitising solution was composed of bichromate of potassium and sulphate of manganese, and he expressed the

opinion that the image produced by the action of light consisted of binoxide of manganese. The discussion following the demonstration dealt mainly with this point.

Mr. A. Haddon said he had recently made some experiments in order to endeavour to discover the composition of the primary image, and, in his opinion, it was not possible for bichromate of potassium and sulphate of manganese, under the action of light, to yield binoxide of manganese. He thought that neither binoxide of manganese, nor, as Mr. Manly had subsequently suggested, manganic acid, was present; but that the image consisted of manganous chromate. The sensitising solution used by Mr. Manly was perfectly clear, but if the neutral chromate was used instead of the chromate, a precipitate would be formed. In the acid condition no precipitate is formed, and by the action of light a certain amount of the chromic acid is reduced. By diminishing, therefore, the amount of chromic acid present, the acidity of the salts was also diminished, and after a time a neutral, or even an alkaline, state would be reached; in that condition the same salt would be formed as if the neutral chromate and manganous sulphate had been mixed. If the washing of the primary print was continued, a certain amount of the image would be dissolved, because manganous chromate was feebly soluble in water, and Mr. Manly had said that ten minutes' washing was sufficient in working the process. Mr. Haddon had made a sensitising solution by substituting bichloride of mercury for sulphate of manganese, and he had also employed the plain bichromate of potassium, and had in each case obtained pigmented images in the same way as by the Ozotype process, showing that binoxide of manganese was not necessary, and, as he had said, was most probably not present. What was formed in the case of the mercury, in the Ozotype process, and in the plain bichromate image? In his opinion, the Ozotype image consisted of chromate of manganese, the mercury image was chromate of mercury, and the bichromate picture was chromate of chromium. He proceeded to detail the experiments upon which this opinion was based.

The discussion was continued by Mr. Chapman Jones and others, but Mr. Haddon's conclusions were not seriously contested.

#### COMING EVENTS.

November 6, Lantern Lecture by Mrs. Aubrey Le Blond, "Cities and Sights of Spain"; November 13, Ordinary Meeting, "Photography in the Eclipse of May 28, 1900," by Mr. E. Walter Maunder; November 16, the Traill Taylor Memorial Lecture, "On the Optics of Trichromatic Photography," by Mr. F. E. Ives.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 18,—Mr. J. E. Hodd in the chair.

Mr. Thompson passed round some enlargements on bromide paper; these, when developed, showed a number of apparently insensitive spots, with a tiny black spot in the centre of each. The paper had been kept some time, and the Chairman put the cause down to impurity in the paper or lack of gelatine in the emulsion.

Mr. Manly then gave a demonstration of "Ozotype." In the course of a few preliminary remarks, Mr. Manly said that any paper can be used for this process except that which is called Art Paper. He then proceeded to sensitise two sheets of different surfaces, for which a special sensitising solution is sold. Two drachms of this sensitising solution is taken and poured in the centre of a sheet of the paper to be used. This is then well worked over the surface by means of a bushy hog-hair brush, 3 in. wide by 2½ in. long. This quantity of solution is exactly sufficient to sensitise a sheet of paper 24 in. by 22½ in. The paper is then dried and cut up as required, and will keep good for about two months. It is printed off in the usual way, and then washed in three or four changes of water and dried. A bath is then made up of:

Glac-acetic acid .....	60 grains
Hydroquinone .....	20 grains
Water .....	40 ounces

and raised to a temperature of 708 to 808 F. A piece of pigment plaster of whatever colour one fancies is then put into this acetic bath for three minutes, taking care to avoid air bubbles. The picture is then also put in, and brought in contact with the plaster. The two are then removed and squeegeed, the excess of moisture taken off by blotting-paper, and then hung up to dry. Care must be taken in taking the print off the squeegeed board not to cause any separation of the picture from the plaster, or white specks will result. When the prints are dry, they are soaked in cold water for half an hour, or longer if over-exposed, and transferred to the final bath of hot water, 110° F. The support which held the plaster is then stripped off, and the soluble plaster dissolved away, until the picture is complete.

Mr. Manly, on being asked if the paper did not require sizing, said that sizing might only be found necessary with the rough Whatman paper, the ordinary kinds of paper not requiring it. The size recommended, where necessary, is composed of:

Nelson's No. 1 gelatine .....	20 grains
Glycerine .....	1 drachm
Water .....	6 ounces

and is applied by a stiff brush, and finished off with a piece of butter muslin.

A hearty vote of thanks to Mr. Manly was proposed by Mr. Haddon and seconded by Mr. Henderson.

#### PHOTOGRAPHIC CLUB.

OCTOBER 10,—Mr. Hans Muller in the chair.

Mr. T. Charters White, M.R.C.S., gave an exhaustive exposition of the details attending the application of photography to the microscope in

the study of minute organisms and structures. After thoroughly discussing the question of apparatus and mentioning several forms commercially obtainable, the lecturer described the apparatus for moderate amplification made by himself. The microscope was next described, and then the focussing of the object to be photographed. The crux of the whole question was the determining exposure necessary to produce the best result. The colour of the object is the first difficulty, in itself sufficient to preclude one from giving a table of approximate exposures, but Mr. Charters White gave a few examples from his register of successes and failures, specifying the magnification, the nature of object, objective used, and character of negative resulting from a given exposure which offered some assistance to the beginner.

The lecture was followed by an exhibition on the screen of a number of anatomical photomicrographs, of the human body and its organs, insect and animal life, which were received with demonstrations of approval by the members and visitors present.

**Croydon Camera Club.**—The demonstration on Wednesday, the 17th inst., was given by Mr. Benjamin E. Edwards, who is not only an adept in many things concerning the gelatine plate, but is also great upon new ideas. Truthful to this last characteristic, he showed members how lantern slides made upon the ordinary rapid gelatine plate (such as Thomas's lantern plates) could be developed in an open dish in a room brightly lit by electric light, much as the slower chloride plate (such as gaslight and crystal) is handled. In order to obtain complete control over results, Mr. Edwards advocated that the development should be sufficiently slow to allow of deliberation in stopping it. For which reason he used a pyro-soda solution, which he found less prone to produce over-development than when ammonia is employed. Mr. Edwards stated that slide-making is so easy that, given a correct exposure, anyone can get twelve good slides out of a dozen plates. But most people did not get six out of twelve correctly exposed, hence the waste of plates. The lecturer developed several plates with the electric lights full on, and subsequently toned several slides with salts of copper and of iron, various depths of "purple"—brown, red, and greenish blue—being obtained. The best result was on a slide which was dipped for five seconds in a solution of ferricyanide of potassium, sulphate of copper, and neutral citrate of potassium. A number of slides illustrating the lecturer's remarks were subsequently shown on the screen. In proposing a vote of thanks, which was adopted with much heartiness by a crowded assemblage, the President stated that the means advocated for changing the colours of the slides were in some respects allied to what he (the President) had shown to the Club in 1898, when similar colours were produced. Some of these were very admirable in effect, but his experience—which others had endorsed—was that there was so much uncertainty in the results which were forthcoming that it was preferable to fall back upon older expedients for obtaining different colours.

**North Middlesex Photographic Society.**—October 15, Mr. J. C. S. Mummy gave a lecture on "Mounting and Framing." The effect of the print, the lecturer said, was greatly affected by the colour of the mount. If the warm tone of the print was desired to be enhanced, the mount should be of a cold colour, and vice versa. This was illustrated in an exaggerated manner by viewing two pieces of grey card in a sort of stereoscope (a cardboard holder with a dividing piece down the centre, like a T upside down), one piece mounted on bright orange-red paper and the other on dark blue. The piece seen on the blue background appeared a brownish yellow, while the other had a distinct blueish tint. With regard to mouldings for frames, he dealt at some length. He advocated a moulding some portion of which was flat, or deeply hollowed out, set off by lines, to give lights and darks. Most of those stocked by framemakers had too much decoration. A dull polish was best, not the rough wood nor French polish, but like that given by raw oil well rubbed in. With regard to glazing, care should be taken in the selection of glass. It should be thin, as colourless as possible, and of high polish. A carbon print of a warm tone with part unglazed, part with one thickness of glass, and part with two thicknesses was shown; the lowering of the tones under the glass was very marked.

**Liverpool Amateur Photographic Association.**—October 18, Mr. F. A. Cooper gave a demonstration on retouching and dodging negatives. He dwelt upon the salient points of his subject in a very chatty manner, showing by means of some excellent lantern slides what may be gained by artistic work, both upon the negative and resulting print. Referring to the filling up of pinholes and scratches upon the negatives, the lecturer gave the members a number of practical hints as to the colours, as well as the manner in which they should be used.

**Burnley Camera Club.**—On Thursday, October 18, Mr. Donald A. Nightingale, the representative of Messrs. J. J. Griffin & Son, gave a demonstration of various velox papers to a good attendance in connection with the above Club. Mr. W. Sutcliffe presided. The following hints given are so valuable as to interest large numbers of workers:—**Exposure:** As a guide to correctness of exposure, make a print on a strip of paper before printing from the whole negative. This method enables one to determine the exposure to a nicety, and economy in paper results. Have your printing frames at a distance of about six inches from an ordinary gas flame or incandescent electric lamp. To ensure even illumination, gently revolve the printing frame. An alternative method, which is more rapidly applicable, in the case of electric light, is to place the printing frame on a table, and, holding the lamp directly above, move it about from time to time, always at a uniform distance from the negative. **Development:** Having made the exposure, or series of exposures, moisten the paper by passing it through clean water in a dish—in the case of carbon velox, it is preferable to apply the developer to the dry print—and immediately proceed to develop, either by means of a tuft of absorbent cotton wool or a soft brush soaked in the develop-

ing solution, or, as for bromides, by immersing each sheet in the developer contained in a dish. In either case development proceeds rapidly, is complete in about twenty seconds with carbon and the ordinary varieties, whilst the special papers develop somewhat less rapidly, in half or three-quarters of a minute. Should the prints on development have greyish whites, add more bromide, say one or two drops of ten per cent. solution to the ounce. In addition to producing slightly increased contrast, the further bromide gives brilliancy to the resulting print. Greenish or brownish blacks will result if too much bromide be present. Over-exposure also occasionally produces similar results. But this, of course, may be determined by the rapidity of development of the print. Greatly over-exposed prints become fully developed in quite a few seconds, and in many cases development is not uniform over the whole print. Rinsing and Fixing: The fully-developed print should be rinsed very rapidly—merely passed through a little clean water contained in a dish—and then transferred to the fixing bath, which for preference should contain the acid solution prepared according to formula. During the first few seconds of fixing each print should be kept moving in the fixing bath, in order to avoid the possibility of stains resulting, and immersion for five to eight minutes in the fixing bath is amply sufficient. When fixed the prints are transferred to the washing water, in which they should remain for about one hour. Drying: Velox prints may be dried by any of the usual methods. Perhaps the simplest is to lay the print face upward on a piece of blotting-paper. Points to be Observed: To avoid stains use fresh developer, and take care that the rinsing, both before and after development, is speedy and thorough. Use preferably an acid fixing bath, as per formula. Avoid excess of pot. bromide in the developer, but whenever the print yields greyish whites increase bromide up to three drops per ounce, in addition to proportion for normal developer. Wherever markings occur on the surface of velox prints erase from the dried print by means of cotton wool well moistened with methylated spirit. Avoid prolonged development, on account of its tendency to produce stains.

Glasgow and West of Scotland Photographic Association.—The Annual Meeting of this Association was held on Monday evening, the 15th inst., in the Rooms, 180, West Regent-street, Glasgow. Mr. J. C. Oliver presided. Mr. William Goodwin, Hon. Secretary, read the report for the year, which showed that, after deleting thirty-two names from the roll, there had been a net gain of ten members on the year. The meeting then proceeded to the election of office-bearers, when the following appointments were made: President, Mr. Thos. W. Robertson; Vice-President, Mr. George Watson; Hon. Secretary, Mr. William Goodwin; Hon. Treasurer, Mr. W. J. B. Halley; Hon. Curator, Mr. G. S. Bryson; Members of Council, Messrs. Oliver, Todd, Arch. Watson, Garry, William Miller, Geo. Chalmers, J. W. Reoch, J. Imbrie Fraser, and A. J. Kay. On the representation of the Council, it was agreed to remit to the Council, with powers to set aside, the resolution of the General Meeting held last April "to abolish classes and to award no medals" at the forthcoming winter Exhibition of the Association. The Council expressed a strong opinion that this experiment should be delayed for a year, in view of the invitation the Association had received to send in selected pictures for the approval of the Photographic Sub-Committee of the Fine Art Section of the Glasgow International Exhibition of 1901. In demitting office as President, Mr. Oliver regretted that the Association were still without rooms of their own, but although not yet owners of their rooms, the subject was not being neglected, as they could not rest satisfied until they had a property of their own which could be fitted up in a manner worthy of the importance of the Association. Cordial votes of thanks were passed to the retiring office-bearers and Members of the Council. The success of the Technical Meetings last winter has decided the Council to arrange for another series this winter.

FORTHCOMING EXHIBITIONS.

1900.  
 October 26–Nov. 3 ... Photographic Salon, Dudley Gallery, Piccadilly. Hon. Secretary, R. W. Craigie, Camera Club, Charing Cross-road, W.C.  
 „ 26–Nov. 3 ... Royal Photographic Society, New Gallery, Regent-street. The Hon. Secretary, 66, Russell-square, W.C.  
 „ 30–Nov. 3 ... Sefton Park Photographic Society. Hon. Secretary, G. Birtwhistle, 7, Gainsborough-road, Sefton Park, Liverpool.  
 November 7–10 ..... Cripplegate Photographic Society and the Essex and Middlesex Cycling Union, Ltd. Hon. Secretaries, A. T. Ward, Cripplegate Institute, E.C., and G. F. Sharp, Sach-road, Uppér Clapton, N.E.  
 „ 12–17 ..... Ashton-under-Lyne.  
 „ 19–24 ..... Waterloo and Blundellsands Photographic Society. Hon. Secretary, W. G. Eyre, 2, Mersey-road, Blundellsands.  
 „ 21–23 ..... Hackney Photographic Society. Hon. Secretary, W. Selve, 70, Paragon-road, Hackney, N.E.

- November 21–24 ..... Cleveland Camera Club. Hon. Secretary, F. W. Pearson, 98, Victoria-road, Middlesborough.  
 „ 22–24 ..... Hove Camera Club. Hon. Secretary, C. Ber- rington-Stoner, 24, Holland-road, Hove.  
 1901.  
 January 14–19 ..... Blairgowrie and District Photographic Association. The Hon. Secretaries, Blairgowrie, N.B.

Patent News.

THE following applications for Patents were made between October 8 and October 13, 1900:—

- CAMERAS.—No. 17,802. "Improvements in the Manufacture of the Photo- graphic Camera." R. F. BROWN.  
 EXPOSURE METER.—No. 17,876. "Nature's Photographic Exposure Meter." H. L. STEVENS.  
 APPARATUS.—No. 17,986. "Improvements in and connected with Photo- graphic Apparatus." A. A. BROOKS and G. A. WATSON.  
 CAMERAS.—No. 18,007. "Improvements in or relating to Photographic Cameras." Communicated by F. A. Brownell. KODAK, LIMITED.  
 CINEMATOGRAPHIC APPARATUS.—No. 18,029. "Improvements in Cinemato- graphic Apparatus." W. GIBBONS.  
 COLOURING PHOTOGRAPHS.—No. 18,121. "An Improved Machine for Mechanically Colouring or Tinting Fashion-plates, Engravings, Photo- graphs, Maps, and the like." J. M. LORIMEY.  
 APPARATUS.—No. 18,131. "Improvements in and connected with Photo- graphy and in the Photographic Apparatus requisite thereto." J. F. LE PAGE.  
 FILM - HOLDER.—No. 18,186. "A Frame or Holder for Facilitating the Handling of Photographic Films and the like." J. NICOLAIDI.  
 PRINTING.—No. 18,252. "Photographic Printing-out Apparatus." A. PICKARD.

Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

SUN PRINTING.

To the EDITORS.

GENTLEMEN,—A print a minute; it takes one's breath away, and makes one say, "Good gracious." Why, sir, my printer is paid £2 a week, and during the summer if he gets off 12 or 15 ferro-prussiate prints in a day, size 40 x 30, he thinks he has done wonders. The exposure here is, I know, at least 12 minutes, and often 15, in the sun, and 20 to 30 minutes if dull or cloudy for each print. Our work is chiefly 40 x 30, from tracings, not glass negatives. To-day (Saturday, October 20) the exposure is 1½ hours.—I am, yours, &c., T. H. A.

THE SAN FRANCISCO SALON.

To the EDITORS.

GENTLEMEN,—Under separate cover please find announcement of the first Salon to be held on the Pacific Coast.

It is hoped by the management that the success of the Exhibition will be so evident, and the interest excited so great, that an annual repetition will be necessary.

We wish you to assist us in giving as wide publicity as possible to the announcement, and in keeping the matter before the public.

The Pacific Coast has always taken a lively interest in the salons of the East, and now that we have one of our own we feel that the bonds are growing closer, thus making it possible to realise that unity of action so frequently advocated in the columns of THE BRITISH JOURNAL OF PHOTOGRAPHY.—We are, yours, &c.,

THE COMMITTEE.

THE LATE THOMAS FALL.

To the EDITORS.

GENTLEMEN,—No doubt you will have many letters expressing regret at the decease of Mr. Thomas Fall. I have known him for

nearly 20 years, and am sure his many acts of kindness speak for the goodness of heart he had. Personally, I am much indebted for his ever ready advice and assistance, and feel sure there are several who will endorse my sentiments that he was a "friend in need" and a "friend indeed" to many. I think it only a fair tribute to his memory that his good qualities should be made known, and I hope to see you make a public announcement of the loss of a good man.—I am, yours, &c.,  
G. W. SECRETAN.  
210a Tufnell Park-road, London, N.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

- A. J. Lovell, 27, Wellington-row, Whitehaven.—*Photograph of Mr. E. G. Hughes.*  
E. H. Roberts, 30, High-street, Marlborough.—*Photograph of Marlborough Town Hall.*  
C. De Lavedré 328, Renfrew-street, Charing Cross, Glasgow.—*Four photographs of R. C. Archbishop C. Eyre, of Glasgow.*  
J. Berry, 28, Mincing-lane, Blackburn.—*Photograph of guns firing, 3rd Lincs. Vol. Art. Photograph of No. 3 Battery, 3rd L. V. A. Two photographs of officers, 3rd L. V. A.*

GLOSS ON PRINTS.—B. M. asks whether the same high gloss can be produced on albumenised paper with a roller burnisher as a bar burnisher.—Yes, if the roller burnisher is a good one, and it is used with heavy pressure and well heated.

MEHAUL.—There is nothing to be said against your selection of the 12-inch lens, if you intend confining yourself to one class of work. But if (as we suspect) you intend varying your subjects, the 9-inch (or mid-angle) would probably prove the more useful in the long run. So far as we can guess your requirements, the latter is our recommendation.

CELTIC.—We are sorry that we cannot break our rule in your case. In reply: (1) We believe the gentleman named to be thoroughly respectable and genuine. (2) As to the Polytechnic, it is an excellent institution. Some of our personal friends are among the teaching staff, and we know many photographers who have profited by the instruction.

"A H. TYLER."—We do not see why you should fail in getting good negatives of the character you desire. If you employ photo-mechanical plates, there should be no difficulty whatever. Try another developer—say kachin or metol and hydroquinone. The wet collodion process will give the character of plate desired better, perhaps, than a gelatine one; but the latter, if rightly manipulated, will yield nearly equal results. Intensification of the negatives would probably help you.

PHOTOGRAPHY IN AUSTRALIA.—B. C. P. writes: "Would it be advisable for me, as a photographer's assistant, to go to Queensland? If so, could you kindly give the name of any paper like yours, and address of office, through which I could advertise for a situation?"—In reply: We think it would be most inadvisable at present. From what we can gather, Australian professional photography is not in a flourishing state. If our correspondent is an able man, he is far more likely to succeed in this country.

A CASE OF UNDER-EXPOSURE.—PYRO writes: "Enclosed please find negative and print. On holding the negative, film side upwards, over anything dark, the image can be seen quite plainly. Could you tell me what is wrong, as this class of negative rarely gives satisfactory prints?"—In reply: The negative is under-exposed, and forced in development. So far as we can form an estimate from the negative and print, at least four times the exposure would have been required. Better devote a little time to experiment.

SENSITISING OPALS.—A. C. PRICE writes: "I should be much obliged if you would tell me how to sensitise opal for bromide enlargement; also if there is any emulsion sold ready prepared for that purpose."—No emulsion is sold for the purpose, and you will, therefore, have to make it yourself. In the ALMANAC for 1896, pp. 282-3, are a number of formulæ for gelatino-bromide emulsions. From those you will be able to select one that will, with a little modification, suit for opals. As you appear to be a novice in the preparation of emulsions, we should advise you to get Abney's work on gelatine emulsion processes.

PHOSPHATE OF SILVER PROCESS.—BEDS asks where he can get some phosphate of silver paper, such as was referred to in the JOURNAL some time ago; also some collodio-chloride rapid paper with the phosphate. So far as we know, the papers have not yet been introduced commercially in this country. The former kind we think is in the American market, but we are not quite sure.

ENAMELLED IRON DISHES.—THOS. RAY. Enamelled iron baking dishes will do very well for the hypo solution for fixing prints, provided the enamel is perfect. If it is imperfect, and there is bare iron exposed, they should be avoided, as the iron would produce stains if the prints laid in contact with it. If the enamel is perfect, enamelled iron ware can be used for all photographic purposes.

RAPIDITY OF LENS.—G. WALLER. We should recommend you to decide on the lens with the larger aperture for winter work. The one with the aperture of  $f$ -5.6 will have double the rapidity of the one of  $f$ -8, when both are worked with their full openings. Though the latter, it should be remembered, will have the greater depth of focus unless the former is stopped down to  $f$ -8; then they will be equal, and of the same rapidity.

TERMS OF LEASE.—W. W. asks: "Who is responsible for the repairs of a studio and rooms when they are taken on a seven years' agreement—the landlord or the tenant?"—It all depends upon the terms of the lease. If you read it through, you will see. In a seven years' lease it is usually specified that the tenant has to keep the premises in repair. But, as we have said before, it all depends upon the terms of the lease. Read it through.

BROMIDE ENLARGING.—J. COX writes: "Herewith please find two bromide enlargements I made with \_\_\_\_\_'s enlarging apparatus. One, you will see, is weak and flat; the other is hard, and the colour is a nasty inky black, with nothing in the lights. Use amidol for developing, and, do what I can, I cannot get results like those done by professional enlargers. Do you think first results can be got with the apparatus?"—Yes, certainly. The fault with the examples sent is in the exposure. The flat one is very much over-exposed, while the other is as much underdone. It is merely a question of exposure. An exposure about mid-way between the two given would have yielded satisfactory pictures.

A COPYRIGHT QUESTION.—"VACUUM CAPUT" says: "To make a trade and scratch a living, I ask parents to bring their babies, or any of their children, to be photographed. I take a flashlight photograph in the evening, and, should the parents wish to buy one, I sell one for sixpence. There are one or two men here who copy my work, and undersell me in larger work. These men cannot work in the evening, and I think they are doing me a wrong. Will you please tell me if the copyright of the sixpenny picture is mine?"—In reply: No; the mere fact that the parents pay you for the photographs settles the matter. And, besides, as we have often pointed out, although the copyright were yours, you would have no remedy unless you registered it at Stationers' Hall.

NEGATIVES FOR VIEW PUBLICATION PURPOSES.—VIEWS writes: "I have been asked by a stationer to take a number of local views (half-plate size), the whole to form a book of views for selling. Not having done any of the kind before, I am asking if you could kindly tell me what is the usual price to charge for each negative, the negatives to become the property of the stationer? Awaiting the favour through your correspondence column."—There is no usual price. It is always a matter of mutual arrangement between the parties. Much, of course, depends upon the excellence of the work, and also the distance it is done away from home, &c. As the negatives are to be the property of the customer, we should say that from 15s. to a guinea each would be a fair price. That is, supposing the pictures are of a good class.

SILVER STAINS.—PRINTING PROCESS.—PYRO writes: "(1) I have got some of my best negatives silver stained. What can I do to get this out of the negatives? (2) I have just commenced business for myself, and have seen in good-class houses a style of printing I should like to adopt, and should be thankful if you could assist me. It is instead of the glossy warm-toned P.O.P.—a sort of black and white on matt paper, but very soft. Is it the platinum toning-bath process on matt paper?"—(1) The stains may sometimes be removed by treating them with a dilute solution of iodine in alcohol until they become pale; then put into the hypo bath. Some stains, however, are very difficult of removal. We should advise you to get a bottle of King's solution for the purpose. It is sold by Marion & Co. (2) The prints you refer to are in all probability platinumotypes.

STUDIO ALTERATIONS.—G. P. W. writes: "Would you kindly advise me as to whether the alteration which I contemplate making in my studio is the best I can make under the circumstances. As you will see by the enclosed plan, the side-light is very insufficient for photographic purposes, and on account of the present low pitch of roof I have suffered much inconvenience both from sunlight and rain. The studio is 37 feet long and 12 feet wide, and the proposed alterations will cost £35. Would you advise rough-rolled plate or frosted glass? I wish to get soft lighting. The sides of the studio are low, but I do not wish to alter them, if possible."—The proposed alteration will be a decided improvement, but it would be a still further improvement if the side could be raised somewhat. It would be a help if the wall at the side were white-washed. Frosted glass is a little difficult to keep quite clean, and when it is dirty it stops out a great deal of light.

## EX CATHEDRÁ.

THERE was a meeting of the Council of the Photographic Convention of the United Kingdom in London last week. The balance-sheet of the Newcastle meeting was presented and adopted, whilst the general balance-sheet—that which deals with Convention finances as a whole—was also passed. Those finances are in such a healthy state that £50 was ordered to be added to the amount already funded, bringing the latter sum up to the handsome total of £200. There are few photographic societies in the United Kingdom which, after payment of all expenses, have a good balance in hand, and two hundred pounds to fall back on in case of need. For this gratifying state of affairs that good man of business, Mr. F. A. Bridge, is entirely responsible, and we are sure that it will delight Conventioners all over the country to learn that the Council unanimously re-elected him Honorary Secretary and Treasurer for the ensuing year. To fill a vacancy in the Council, Mr. W. J. Croall, the well-known and esteemed amateur photographer of Edinburgh,

was chosen. A letter was read from Sir William Herschel cordially accepting his nomination to the Presidency of the Oxford meeting of the Convention, and promising to do all in his power to promote its success.

\* \* \*

LAST week we briefly contrasted the methods of American and British manufacturers, not specially with reference to the production of microscopes, although the contrary was inadvertently suggested; and we have been pleased at the receipt of a vigorous rejoinder from Mr. Conrad Beck, who takes up the case for the defence. Says Mr. Beck :—“ It does seem to me extremely unfair that British journalists should consistently and deliberately belittle their own country, and praise up the foreigners, without any cause whatever. Let me draw your attention to the preface of the enclosed description, where we ask for the support of scientific men to assist us in helping our manufactures. Every year we send a representative round to see every prominent professor in this country and gather his views as to the requirements of his students, and my experience of American methods of doing business is that in questions of courtesy and remedying defects which may occur in the manufacture, Englishmen will always give them points; but it is the fashion of the Press to regularly belittle everything that is done by Englishmen, whereas it is the fashion of both German and American papers to assist their own manufacturers in every way they can.”

\* \* \*

IN the preface to their microscope catalogue Messrs. Beck state : “ We have been able to produce an instrument exactly suited to modern requirements, at a price considerably less than that of any similar microscope, whether made in England or abroad. We ask for the cordial support of scientific men in this enterprise, as, although this instrument has been made from data supplied by our most prominent microscopists, suggestions from earnest workers are our best means of improving our products, and will be gratefully received. We have during the last two years been laying down an extensive plant of American and German machinery.” If all British houses—and we, of course, are

not confining our remarks solely to photography—combined alertness with energy in such a commendable fashion as the honoured firm of Beck manifestly does, there would be fewer of the “belittling” strictures referred to by Mr. Beck published in the newspapers, whose objects, however, we can scarcely agree, are to depreciate home products at the expense of foreign productions. We lean to the view that at a time like the present, when the nation is being attacked by that disturbing complaint known as war fever, it is the duty of responsible journalists to force what are perhaps larger and more important issues before the public eye. For example, an intelligent study of the Paris Exhibition cannot but persuade the thoughtful Briton that the commercial and manufacturing supremacy of this country is being gravely threatened from every side.

\* \* \*

INDEED, at the moment Mr. Beck's letter reached us we were actually perusing a series of articles dealing with this very subject. One passage in them referred to American advances in machines in these words: “It is quite evident that the Americans have certain mental habits and qualities which give them a great advantage. Their curious versatility and inventiveness are mental gifts that probably cannot be acquired, but their remarkable grip of these essential points of a mechanical problem is mainly the result of close attention and thought, and can be acquired perfectly well by English mechanics by systematic training. Their thorough grasp of the fact that cheap manufacturing means perfect interchangeability of parts, and that this is only obtained by extreme perfection in each piece, has induced a practice of accuracy and finish that reacts upon the whole of their work, and is producing an immense effect upon their foreign trade. There can be no doubt, too, that more general interest is taken in practical mechanics in the United States than in England.” We are the last to wish to belittle English manufactures or to unduly exalt the work of our foreign competitors, whose immense progress in most branches of industry, on the other hand, it is foolish to ignore or under-estimate. For the full discussion of such a large subject as this a photographic journal is not the most suitable arena; but we are nevertheless obliged to Mr. Beck for the opportunity he has given us of making these references, while at the same time we congratulate his firm on being in the van of progress.

\* \* \*

THE Report of the Examinations Department of the City and Guilds of London Institute for the session 1899-1900 was issued last week. Intending candidates in the photographic sections of the examination of next May will be wise if they lay to heart some remarks of the examiners on the work done at this year's examination. These gentlemen subject that work to the following strictures:—“The lack of sound knowledge of even the fundamental parts of photographic optics referred to in last year's report is still very marked, and not a single complete answer was given to any one of the questions on optics in either grade. In the Honours Grade, some candidates showed a very fair knowledge of processes, but were lamentably weak in their knowledge of the rationale of the processes as a whole, and of the why and wherefore of the modifications made to meet special cases. More attention seems to be required to the elements of photographic chemistry. In both grades

there are indications that some candidates fail to do themselves justice from want of previous experience in answering set questions; they either fail to grasp the meaning of the question, or fail to answer in sufficient detail. Teachers will always find it useful to themselves and profitable to their pupils to hold written class examinations at intervals during the session. There was also too much of what may be called the ‘general reader’ type of answer—verbose, but vague, and giving no evidence of that precise and definite knowledge which alone (however limited its range) is of real value from a practical point of view.” With regard to the work in the photo-mechanical section, the examiner remarks: “The answers to the questions this year show a marked advance in technical knowledge of the special subjects studied; there is, however, a tendency in many cases to confine attention to only one or two branches. It is desirable, and indeed necessary, that students should master the principles, at least, of each of the sub-sections into which photo-mechanical work is divided, and it is furthermore desirable that the candidates should possess an intelligent knowledge of photographic chemistry. Even the names of some of the chemical substances commonly employed are often incorrectly given, and this has tended to reduce the value of otherwise very creditable papers.” It is only fair to mention, however, that in our opinion the questions set at these examinations are by no means of a simple kind. They might fairly be called stiff. But the Institute and its examiners deserve support in their efforts to raise the standard of photographic knowledge.

#### LOCAL GUIDES.

It has been said that, speaking generally, guide-book publishing does not pay any one. Probably this was not intended to include the printer, who, naturally enough, does not, as a rule, print guide-books for nothing.

Guide-book publishing, like numerous other ventures, probably pays passably well if it is worked on a sufficiently extensive scale, and most districts which are freely visited by tourists have been fairly well dealt with by the well-known guide publishers. They, however, have not quite the monopoly in this matter, for some very useful and attractive publications of this class have been produced locally. But, unless the district has some particular features, it is by no means easy to produce a guide which will prove commercially successful.

Those who should know say that there is evidence of a revival of interest respecting topographical matter; and, among other publishing ventures in the course of preparation, there is an ambitious one, no less than a sort of second Domesday Book, which will deal comprehensively with every county. Whether this record will be illustrated, we are not able to say positively. If it is to be illustrated, it should provide good scope for the energies of the members of the National Photographic Record Association; and it is to be hoped that this useful organisation will be given an opportunity to render any assistance calculated to enhance the value of such a work.

Local photographers might probably, with profit, do more in the way of local guide publishing than they have done. They may not make much profit out of the sales; but, indirectly, they may benefit very considerably.

A photographer, well known in London, has recently

established a branch in the provinces. He has gained a reputation for portraiture, and his clientele includes members of the Royal Family and other distinguished personages; but at his provincial branch he is not content to confine his attention to portraiture, and he has recently issued an attractive book consisting of reproductions of photographs from half-tone blocks, with brief explanatory letterpress, dealing with a well-known personality. The subject, admittedly, is somewhat hackneyed; but, so far as we were aware, it had not been dealt with quite in the same way, and certainly not so comprehensively. As a result, we have a very interesting document, which, apart from the sales, should prove a valuable advertisement to its producer.

A publication such as that just referred to necessitates the expenditure of a considerable sum of money which every photographer cannot afford. But, possibly, those photographers in humbler circumstances could, with advantage, do something similar in a minor way. If he be a dealer in photographic apparatus and materials, he might illustrate his catalogue, which, if it did nothing else, might keep it out of the wastepaper basket a little longer than would otherwise be the case. Besides the illustrations, a certain amount of local topographical matter might be introduced.

If the photographer has his establishment in a district which has not been covered by the guide publishers, he might with advantage consider whether he could not publish something that would prove serviceable to visitors, &c.

In these days, when it is possible to purchase a novel, consisting of some 400 pages, by a well-known author, for a few pence, people expect a good deal of matter for their money. They do not always consider the circumstances. The novel is published in its many thousands; a local guide-book frequently has a limited sale, and, consequently, it is impossible to put the same amount of matter into the latter, and sell it at the same price as the former. Then again local support is a feature usually to be considered in such cases, tradesmen and others being, as a rule, by no means unwilling to advertise in widely circulated guide books of the town in which they conduct their businesses. This should be obvious enough to anybody, but it is not. Good printing, maps, and half-tone blocks cost money. If, however, it is decided to take up the matter, it is certainly desirable to issue something which will directly, or indirectly, prove a source of profit to the publisher. If the profit cannot be ensured from the sales, it is quite possible to see that the publication is effective as an advertisement.

As a model, we would recommend J. Salmon's pictorial guide to Sevenoaks, admirably illustrated by Mr. C. Essenhugh Corke, F.R.P.S. Of course, in many instances, through various reasons, such as a less attractive, and, consequently, a less visited district, the guide would not equal the publication referred to as regards size and attractiveness. This particular guide is one of the best of its class, and it is in every sense of the word a local publication, being prepared and illustrated by local men and printed by its publisher.

In most districts, there are persons well versed in local history and possessing an intimate knowledge of the county. There are writers, too, who make a business of preparing the letterpress for guides. But it is preferable to put the work in the hands of the former rather than the latter, who are sometimes little more than literary hacks, who

expect far more for their matter than it is worth. Some of the members of the latter class require careful handling. In any case, you are more likely to obtain trustworthy matter from a person who has lived in the district for years, and who has made a special study of the country, than from a compiler who is a stranger to the locality. To the former the preparation of the letterpress will be a labour of love, although, of course, he should be paid a reasonable sum for his services.

As to the illustrations, this would be a matter for consideration, and would depend upon circumstances. By all means, if possible, let them be numerous, and be printed on good paper.

---

**The Nernst Lamp.**—It is rather singular that so little is heard of the Nernst electric lamp, especially in connexion with photography. The first use of electric light for studio work on an important scale was on the arc principle; but, latterly, many incandescent light installations have been adopted; each style has its advocates. The latter system is so very simple that it is bound to find favour: a switch equivalent to the tap of a gas burner is turned on and the light is at once ready for use, while with the arc either a special adjustment has to be made each time the light is restarted, or, in the case of an automatic lamp, some little time has to elapse for the light to settle down to a steady value. But much greater intensity and consequent reduction of exposure is better obtainable with the arc than with the ordinary incandescent lamp. The Nernst lamp, however, much more nearly approaches the arc light in intensity of light and in its actinic value. It is true that the Nernst is, on account of its more complex construction, more costly at the outset, and that its life is shorter than the ordinary carbon filament lamp. But against this we have first to reckon that the Company who run the new lamp will allow two-thirds its value if returned when a new one is purchased: and, secondly, the consumption of electricity is less. The power employed in the present type of lamp is from  $1\frac{1}{2}$  to  $1\frac{3}{4}$  watts per candle, and an ordinary lamp needs about double this. It will be remembered that light is produced by the incandescence of a filament of refractory oxides. When cold, this filament will not permit the current to pass; but, when heated first, it becomes much less resistant, and the current causes it to glow at a much higher temperature, and consequent increased brilliancy, than the carbon can sustain. In the first lamp made the preliminary heating of the filament was brought about by a match or a spirit lamp; but as this involved the very practice that the older incandescent lamps were supposed to have banished—the striking a match, &c.—another more intricate form of lamp was designed in which the first heating was brought about automatically by a spiral of platinum wire coiled round the refractory oxide filament, the current then being switched off automatically when the filament was heated, the lamp giving a brilliantly white light. The average duration of a filament is three hundred hours, but this is governed by the mode of use. Thus, if the light be rushed as it were, and the full intensity quickly produced, it does not last so long as when a little time is allowed for the full brilliancy to be obtained.

---

**Personal Risks from Studio Arc Lamps.**—When the arc light first became an important factor in portrait work, the carbons were only adjustable by hand, and there was always the risk of the operator accidentally receiving a "shock" of a dangerous strength, through incautious handling of the metallic adjustment. This lamp was due to the inventive genius of Mr. Vander Weyde, who for the benefit of other users, described the plan adopted by his operator. It was simply to invariably employ one hand only, and, to ensure this being carried out, he made a point whenever he adjusted the carbons of always keeping one hand in his pocket so as to avoid its involuntary use. The intensity of the shock given by interposing the human body in the circuit depends, of course, upon the voltage of the current, and some little time ago Professor Weber of the Zürich Polytechnic, undertook a series of experiments upon his own

person to ascertain the effects of currents of various strengths. The details will be interesting to all who employ electricity in their work. Using his wetted hands to receive the current, he found ten volts to produce feeble trembling of the fingers, and, increasing it by successive increments of ten volts, these effects were gradually intensified till, upon fifty being reached, instantaneous paralysis of all the muscles of hands and arms set in and the hands could not be released. Two seconds was the utmost limit of his endurance of the pain. With his hands dry, he found at forty volts the fingers only slightly tingled; at eighty the hand was cramped and ached in every part, and great effort was required to release the wires. When a further ten volts was added the effect was highly intensified, the hands entirely paralysed and unable to release the wire, and the pain so great he involuntarily called out. Upon returning to the eighty volts the difference was so great that the effect seemed quite feeble in comparison with the ninety volts. Professor Weber's conclusions are that the simultaneous touching of both the poles of an alternating current circuit is dangerous as soon as the pressure reaches 100 volts; and, as it is impossible to set the fingers free, the case must be considered fatal whenever immediate help is not at hand. He describes three cases where death ensued by touching with both hands non-insulated leads at voltages, respectively, of 240, 300, and 500. We may conclude with Professor Weber's dictum, that "in spite of the great number of disasters which have already happened the danger does not seem to have been generally appreciated. . . . That disasters have not more frequently happened is due to the fact that help has been at hand instantly."

**Enamelled Ware in Photography.**—On several occasions lately, we have had to reply in the Answers columns as to the suitability of enamelled ware, which has now become so popular for many domestic purposes, for use in photography. It is, no doubt, its cheapness that has commended itself to the querists. Now there is enamelled ware and enamelled ware, for it is not all of the same quality. The dishes and trays, specially made for photography, are of a much better quality than those usually sold at the hardware shops for domestic uses; but are, necessarily, considerably higher in price. However, the ordinary thing is excellent for most photographic purposes, and it has many advantages over the ordinary "porcelain" dishes. It is, as most are aware, iron or low steel, sandwiched between two layers of the enamel, a quite inert material. But if this surface is imperfect, either from the manufacture or from its receiving injury afterwards so that the metal is exposed, it is manifest that such vessels should not be used for some purposes in photography, such as for containing silver solutions, for example, as then the exposed iron would reduce the silver to the metallic state. They, in this condition, are not suitable for the hypo fixing bath, as the prints if they rest in contact with the metal might be marked or stained. There are many uses to which these vessels may, however, be put, even though the surface be damaged, in photography. Almost from the first, enamelled ware has been employed for the developer in the platinotype process, and here a slight damage to the glaze is not of importance. For washing prints the common ware of the shops answers as well as the best. In the carbon process it is invaluable, common though it be, for, if there be considerable imperfections in the enamel, it will not in any way interfere with the work. One of the great advantages of this ware is that it will stand heat. Boiling water may be poured direct into it with impunity, or a spirit lamp or gas flame may be put under it without risk, though few would care to risk putting hot water direct into a porcelain dish or putting a spirit lamp beneath it to keep the contents warm. It is for this reason that enamelled ware commends itself so well to carbon and platinotype workers, added to its practical unbreakability. Though its surface may, by careless treatment, become cracked, which will render it unsuitable for some photographic requirements, it is still usable for others.

**Retarded Development.**—We have experienced "chill October," and some inexperienced photographers have not realised

its influence on development. A few days ago we were consulted by an amateur who has just commenced the development of a large number of plates exposed a month or two back. His trouble, he told us, was that they were all under-exposed. He said he was sure on that point because the image did not appear until a very long time after the developer was applied, and then, after prolonging the time usually required to get density, the negatives were thin and feeble. Now, as a matter of fact (for we developed some of the plates and they were fully exposed), the tardy appearance of the image was entirely due to the depressed temperature during the short spell of cold weather we had two or three weeks back, and allowance was not made for that. Indeed, the necessity for that was not fully realised by our friend. Not only had the temperature of his dark room become depressed some ten or fifteen degrees, but the water supply from which he diluted his stock solutions of developer had become correspondingly colder, hence the trouble. Had longer time been given with the plates he had developed, good negatives would have resulted, even with the conditions in which he worked. When the temperature of the atmosphere in the dark room, and that of the water for making the developer, is down to the low fifties, 51° or 52° F, development of even fully-exposed plates becomes slow, and a much longer time must be allowed before under-exposure should be assumed. 60° to 65° F. should be considered the standard temperature of the dark room and the solutions, and, as it falls below or exceeds that, due allowance should be made for the deviation in judging the exposure. Our reason for referring to the subject now is, as the weather will soon be getting colder, to call attention to the fact that temperature is a factor, and an important one too, in every phase of photography, and must be met accordingly.

**Coagulating Albumen.**—At a recent meeting of one of the London Photographic Societies reference was made to coagulated albumenised paper, and it was stated that it was very difficult to procure. Although it may be difficult to procure now, it is easily made by treating albumenised paper with alcohol. Strong alcohol however, will not coagulate dry albumen, the presence of water is necessary. If the paper be passed through ordinary commercial alcohol diluted with an equal bulk of water the albumen will be perfectly coagulated, and rendered insoluble in water. The albumen may also be coagulated by heat in the presence of moisture. Dry steam will not coagulate it, but moist steam will. At one time coagulated albumenised paper for silver printing was an article of commerce; but we believe its manufacture has since been discontinued, or at least we have not heard of it of late. It was said to have certain advantages over the ordinary, one was that it did not blister; another was that it kept better after it was sensitised. But, of course, it was somewhat more costly than the ordinary paper.

**Another Application of the Röntgen Rays.**—The uses to which the Röntgen rays are now put, or said to be applicable, are indeed multitudinous. The Berlin correspondent of the *Standard* one day last week, telegraphs that Signor Brigrigi, of the State Archives, in Rome, has found that the rays can be utilised, in certain cases, for the examination of and copying manuscripts concealed under the covers of books, &c., as the rays penetrate wood, leather, and cardboard. This, it is added by the correspondent, can only be done when the ink contains some mixture of lead, cinnabar, or ultramarine, and in that case the rays will also serve for the detection of forgeries in manuscripts. One frequently reads of such things as bank notes being found concealed in old Bibles, and the like, but it is clear that as they are printed in an ink of the same composition as the book they could not be detected by the Röntgen rays. Few inks that are used for manuscripts, again, contain either of the materials referred to, or analogous substances, so that the alleged utility of Röntgen's discovery in this direction is considerably discounted. Still the idea is novel.

NOTES ON THE DEVELOPMENT OF INTERFERENCE  
PHOTOCHROMY.

## II.—EDMOND BECQUEREL.

WE shall occupy ourselves, for the present, with Becquerel's *La Lumière, ses causes et ses effets* (1867-8, 2 vols.) The work is purely experimental in its manner of dealing with the subject, and there are only few theoretical considerations. Both on account of the general interest this book must have for photographers, and for the purpose of gaining some idea of the place which Becquerel gave to his photochromatic investigations in a work containing the greater part of his researches on light for the thirty years preceding the above date—a union which showed, in his own words, that his researches were all directed towards the same end, that of studying the questions of molecular physics which are connected with the transmission of light to the particles of bodies; questions which relate to one of the most important and delicate parts of physics—we will first give a short indication of the contents of the volumes. Then we will go more particularly into his photochromatic experiments and the considerations which he adduced as possible explanations, and which influenced the development of *interference* photochromy.

It should be remarked, *en passant*, that, throughout the whole work, Becquerel gave such full references that his book would be of the greatest value for a history of, for instance, the discoveries on the physical and chemical actions of radiation.

The first volume (1867), on the sources of light, is divided into many books. After preliminaries (general considerations on “*les sources célestes ou météoriques*.”):

Book i. contains the history of works on phosphorescence, chiefly from the beginning of the fifteenth century until 1840.

ii. Luminous effects produced by molecular actions (phosphorescence by rubbing, cleavage, and crystallisation).

iii. Luminous effects produced by heat. Study of sources luminous by the elevation of temperature, comprising not only phosphorescent effects by the action of heat, but also phenomena of incandescence; that is to say, it relates to the majority of luminous sources actually used in industry. Ratios of the lighting powers of these different sources, and pyrometric processes capable of indicating their temperature.

iv. General principles of the analysis of light by refraction and results of researches on the bright and dark (ultra-violet and infra-red) rays of luminous spectra. Spectrum analysis and its meteoric and celestial applications.

v. Luminous effects produced by electricity.

vi. Luminous effects (phosphorescence) produced by the action of light (contains a *résumé* of Becquerel's different memoirs on the subjects). Indication of the methods of preparation of the matters which have been called “*phosphores artificiels*,” and results of observations with the phosphoroscope (which prove that a great number of bodies emit light in virtue of an action proper to them, and that by a persistence of effect due to the influence of the luminous radiation). A specially important and long book.

vii. Phosphorescent effects produced by organic bodies (vegetables and animals).

In the second part, on the effects of light (1868), the preliminaries were devoted to various effects produced by light. Extinction of light, transparency, diffusion, and colours of bodies. Here (pp. 11, 12) we first meet a passage of interest in connexion with our subject: “The various principles enunciated above account for the facts relative to the colour of bodies and to their transparency, independently of every theory. Newton\* proposed an explanation of colours by the phenomenon of thin layers, which supposes that the particles of translucent or opaque bodies are transparent enough for the incident light to experience reflexions, both on its entry and on its departure. After this hypothesis, and following the undulatory theory, the colours of translucent media, supposing that all the particles have the same dimensions,† would be explained, by an effect of interference, as follows: If, in a homogeneous medium, there is a body of an infinitely small thickness into which light penetrates, and,

if the rays are reflected on entering and on going out, the difference of path is zero, but, by the fact of the difference of reflexion of the two rays, one is half an undulation behind the other; the two rays then destroy one another, and one can say that there is no reflexion, and that the totality of the light is transmitted. When the body has a sensible thickness, then the difference of path is greater, the destruction of the bundle less complete, and the thickness increasing. A moment arrives when the differences of the distances described is half a wave-length, and, when the ‘lag’ (*retard*) of the two rays, by the fact of reflexion in two planes at right angles, is a complete wave-length, then the maximum of clearness by reflexion is obtained. It is seen that the rays whose wave-length is the shortest, namely, the violet and blue, will be the first reflected in greater abundance, and, consequently, will be the first to lack for transmission; the tint of the translucent medium must then appear that of the rays of greater wave-length, that is, yellow or red, by transmission.

“This hypothesis alone cannot explain the observed effects of colouration, for the absorption of light by bodies depends on the nature of the latter, and, as we have seen before, each of them absorbs different parts of the solar spectrum, the colouration then of translucent or turbid (*troubles*) media does not depend only on an interference-phenomenon. . . .”

The first book (pp. 15-44) deals with calorific effects; the second (pp. 45-166) with chemical effects;\* the third (pp. 167-234) with photography;† the fourth (pp. 235-300) with physiological effects (on vegetables and animals); and the fifth (pp. 301-372) treats of vision. At present, the fourth chapter of Book iii., on the reproduction of colours by the action of light, chiefly interests us (pp. 209-234). The chapter is divided into sections.‡ We will now study his work as presented in its final (book) form by comparing it with a description of his methods and results written eleven years previously. We shall thus be able to appreciate better any advances he made in that time, and more particularly any new suggestions he may have made in explanation|| of the observed phenomena. Then we shall be able to conclude if, *in this part of his work*, Becquerel had any influence on the very discontinuous train of thought which led to the discovery of interference-photochromy.

We will, then, compare this fourth chapter—“*Reproduction des couleurs par l'action de la Lumière*—with his *Exposé* of 1857.¶

After mentioning Seebeck, Herschel, and Hunt, Becquerel reproduced, almost word for word, the first part of the *Exposé* (from p. 293, line 11 up, first column, to p. 294, line 3, in the below-cited translation). The essential alterations are as follows (which brings us to the end of the first section):—

P. 293, column 2, line 8 up, after “*colourings*,” add: “Another chloride, such as the chloride of potassium, of strontium, &c., substituted for the sodium chloride, gives the same results, and the base of the alkaline salt has no action on the compound of silver formed. The silver-layers must be of great purity, and even previously heated to 300° or 400° C. if they have been already used for experiments with mercurial vapours, then carefully *décappés*, for this process brings out . . . .”

P. 294, after line 3, add from line 13 up, p. 212 to line 20, p. 213

\* General effects of differently refrangible rays. Electric effects produced under the influence of the chemical action of light. Comparison between the intensities of rays of various luminous sources. Extinction of active rays.

† Daguerreotype.—Photography on paper, collodion, albumen, gelatine, &c. Photo-engraving, photo-lithography. Reproduction of colours by the action of light.

‡ § i. Preparation of the sensitive layer. Sub-chloride of silver. § ii. Modification produced by heat and infra-red rays on the sensitive layer. § iii. Effects produced by differently refrangible rays; solar spectrum, uncoloured and coloured screens. § iv. Reproduction of coloured camera-images and of coloured engravings. § v. Alteration of the coloured photographic images produced by sub-chloride of silver in the light.

|| This word must not be misunderstood. The only real meaning it can have is the furnishing of a deductive process by which it *might have been* discovered, without experiments, from a fact or theory already known.

¶ Full translation in THE BRITISH JOURNAL OF PHOTOGRAPHY, 1899, 292-294 and 309-311. On p. 293, column 2, line 11, read “*appreciable: in the violet;*” line 18, for “*should be*” read “*is;*” line 19, for “*where*” read “*either;*” line 20, for “*as where*” read “*or;*” line 22, for “*sensitive*” read “*visible;*” line 27, for “*silver-black*” read “*layer of silver.*” The other misprints are trifling, and cannot present any difficulty to the reader.

\* *Traité d'Optique*, livre 2, 3<sup>e</sup> partie.

† Brücke, *Pogg. Ann.*, lxxxviii., 1852, 63.

of Becquerel's volume; and after line 13, see Becquerel, p. 214, line 24, and so on. On p. 217, Becquerel referred to Poitevin.\*

In section 2, the modification sketched in the translation (from line 20 up, column 1, p. 310 to line 23, column 2) was described in greater detail. In section 3, the effects produced by the various parts of the luminous spectrum were examined; the sensitive surfaces being (1) not heated, and (2) heated, and (3) submitted to the action of the extreme red rays; also by uncoloured and coloured screens (q. v., and also section 4).

The fifth section is closed by a possible explanation† of the effects:—

"How are we to explain in the actual state of science the effects of colouration of the photographic images with the natural colours of the active rays? We have seen in the preceding book that the subchloride of silver when it changes gives rise to an electric current which can easily be detected; now, this current has always the same direction whatever may be the active luminous ray and the colouration of the matter; this circumstance, joined to the production of the uniform grey tint which the substance takes in all rays when the action is sufficiently prolonged, shows that the hypothesis of as many different reactions as there are spectral colours cannot be admitted. There is chemical transformation of the impressionable matter, and at the same time, temporarily, different physical state of this matter according to the refrangibility of the active rays.

"As light is the result of vibrations transmitted from the luminous bodies to the retina, and as each ray of the spectrum corresponds to a different frequency of vibration, it may be that the sensitive substance, which has been acted upon by a ray, that is to say, by vibrations of a certain frequency, acquires the faculty of vibrating more easily afterwards under the action of vibrations of the same frequency as that of this ray. Thus there would be produced in this circumstance the same phenomenon as that which occurs when a reunion of sounds strikes a stretched cord; only the sounds of the same tone (*hauteur*) as that rendered by the cord put the latter in vibration. . . .

"But how is it that other substances chemically sensitive do not give rise to analogous effects, and that only the substance whose preparation I have indicated has (for the present) this faculty of preserving the imprints of the active luminous rays? Further researches will perhaps show this."

We must conclude, then, that no hint was given *here* from which an *interference* theory could be built up. *But* the passage quoted from the "Préliminaires," might afford some grounds for the beginning of a train of speculation, which might end, as with Zenker, in a natural *explanation*, or, as with Lippmann, in a *method*. However, whilst we can affirm that Edmond Becquerel, in his final presentation of his researches, did not in any degree call to his aid an interference method as explanation of *them* (and, indeed, stated most positively, as we have seen before, that it is *not* by an action of the kind which gives place to the phenomena of thin layers that the substance reproduces the coloured impression of light), there still remains a possibility that he was led to such an explanation at an earlier period of his investigations. In any case it will be interesting to trace the course of his thoughts and researches from the beginning. This we propose to do later, but next we will turn our attention to Lord Rayleigh.

PHILIP E. B. JOURDAIN.

Cambridge, October 11, 1900.

#### THE PHOTOGRAPHER'S YEAR: NOVEMBER.

OUTDOOR photography in November! Why, the thing is absurd! What is there to take? As Hood put it—

"No sun, no moon;  
No morn, no noon;  
No dawn, no dusk; no proper time of day;  
No sky, no earthly view;  
No distance looking blue.  
No road, no street, no t'other side the way;  
No end to any row;

\* *Compt. Rend.*, LXI. (1865), 1111.

† Pp. 232, 233.

‡ In the original the word is *villesse*.

No indication where the crescents go;  
No top to any steeple;  
No recognition of familiar people.

\* \* \* \* \*

No shade, no shine, no butterflies, no bees;  
No fruits, no flowers, no birds, no leaves—  
November!"

Miry ways; bare, dripping hedges; a dank, unwholesome earth, perspiring generally in thick fog, under the dullest of low-lying, leaden-coloured skies! It certainly needs something of a Mark Tapley temperament not to lay the camera by for a while. But granted his philosophical dash of optimism, things do not look quite so hopeless. The consciousness of possessing the optimism is in itself a good deal. The feeling of being ahead of other men is as pleasant on a country road in November as it is at being one of the few persons not sea-sick on a water trip in summer. Both may be merely due to a full—but not over-full—supply of gastric juice and bile. If so, it makes no difference. It is men of high vitality, with a correctly balanced arrangement of physical organs working at their best, that are wanted everywhere, but particularly, we claim, in photography. Anything disagreeable that a dyspeptic or bilious subject may say or do in the ordinary conduct of life, as the result of his improperly acting functions is confined to a narrow circle; but when he comes to recording his peculiarities in a picture, ill effects are spread over a far wider area. There is a fatal ease about the photographic process that emphasizes the mischief. An artist suffering from a bilious attack is more handicapped. The expression of his perverted or pessimist ideas takes so much effort to carry out that the associated lack of energy acts as a judicious check; or if he manages to get up a spasmodic spurt by the time he is half through the work a correcting dose of calomel may have stirred up his liver to proper working point, and at the same time cleared his brain to such purpose that he throws the unfinished canvas on the fire. The photographer, with less labour, and in a fractional part of the time, will have finished his picture, and the mischief is done. We are familiar enough with it, and its muddy tones, foggy lights, and out-of-focus effects. "Strivings after artistic expression" is one euphemistic way of describing it; effects of biliousness is another, and more common-sense one. It is a great pity that excess of bile does not totally arrest the action of the brain for the time being, instead of perverting it. How much happier would we not be all round!

This depressing type of photographer is the one who can see nothing in November; who, in spite of all statistics to the contrary, believes it to be the month of suicides. Small praise to him who can only be happy and cheerful when the sun shines. It is he who rises superior to unfavourable external conditions, who even makes them minister to the inward content upon which happiness really depends, that we like to come across. Upon him November's photographic appeal is not lost. He is a proportionate man mentally as well as physically, and knows there must be rainy days in life, or there would be no life and sunshine at all. Possessed with this philosophical belief, he does not grumble at a wet day, but, knowing it to be inevitable and essential, soon gets to notice points of attraction in a wet, foggy, dull landscape that would otherwise have escaped attention. If practicable, it is not pleasant, to take a camera out in a rainstorm; but it is very practicable to photograph the effects of rain. Bare, wet trees standing in flooded meadows, the waving current lines on the face of the river itself; its heaped up rush over a mill dam, a droop-eared horse or group of sheep with sodden fleeces—these are all photographable. They will possess the adventitious charm of being as yet rather unusual, and always act as excellent foils to fair-weather pictures of summer.

Let the worker apply it more closely by asking himself whether he is not rather tired of the disproportion of orthodox summer pictures, soft sunny skies and seas, mellow landscapes, cattle knee-deep in shaded brooks, and so on; and is not ready to turn with pleasure to the contrast afforded by less smiling scenes. We need tonics now and again, and these generally have an agreeable sharp or bitter twang about them.

Probably the reason for there being so few November pictures is in a great measure due to the assumption that because there are fewer photographic possibilities in the month there are none. If the wise man who continues his walks abroad in November will but keep his eyes open for them, he will see plenty, and, in addition, have the walk much brightened by having a pleasant and definite object to exercise his mind upon. The light is bad from a photographic point of view, it must be admitted, but we may be certain that it is right from Nature's.

She elects to fit grey skies to dull landscapes, and it would be as much out of place as useless to long for other conditions, July sunshine to light up a November scene. In practice, with the rapid plates and wide-apertured lenses that we have at command, there can be no great difficulty with the technical side on the very dullest days.

Opportunities are not limited to the country, although there is stronger attraction in the greater ease and freedom in working there. Pitching a tripod to command a view of a winter torrent is a more agreeable matter to a shy and thin-skinned worker than doing so in a town street, with its floating scum of idlers always ready to congregate and indulge in caustic comment. Very good effects are possible, however, with a good hand camera, and a long-focussed lens. There is an artistic charm, that Hood was not open to, in there being—

"No end to any row;

No indication where the crescents go."

The suggestion of crowded size is more deeply, because vaguely, suggested in such a picture than in a clear-cut one at another season in which the houses can be counted. The city is even more strongly opposed to the country in November than in June. Then there are telling little scraps peculiar to the town, and particularly to the town in November. The crossing-sweeper is there in his full glory, and a dull day sets off well the labourers congregated around the brazier of live coals, whilst the plumbers are setting to rights the pipe just laid bare. In November, too, come the municipal elections and mayoral processions, with their wealth of telling and characteristic figure and incident. This also, we are constrained to admit, is work for the full-blooded, healthy man. And one with a ready smile, as much for the selection of happy and cheerful material as the reception of his presence and object by the great unwashed.

The value of the great majority of photographs is not due, by any means, to their worth judged by a hard and fast artistic standard, but by the associations connected with them; otherwise to the degree they touch and express the personality of the one who took them. A man who goes photographing in November shows in the very fact a stronger individuality than he who does not. Further, as subjects are fewer and harder to gain, he is less likely to waste effort in taking anything that does not strongly appeal to him. It is not a summer matter of "having a shot, anyway," in a hesitating and half-hearted way. Between these psychological considerations that hook themselves unconsciously on to the question, it is very likely that pictures taken in the least favourable month, under the most adverse conditions, will be more highly prized than those taken under opposite favourable ones. They are more likely to possess a human, as opposed to an artistic, excellence; and when it comes to a question of which of these is the stronger, there can be little doubt as to the answer.

If the photographer run not to necessary brawn, but more high-strung and nervous, have, like Mr. Pell, "brains all over his body," there is nothing for it but to stay indoors, find fault with the weather through the parlour window, and look over his summer negatives. With all fitting respect for him, we elect for the open air, in common, we trust, with many heartier and happier fellow-workers.

#### RETOUCHING WITH A KNIFE.

In answer to several inquiries from correspondents in regard to the use of the knife in retouching, a few remarks from a practical worker may be of some assistance. In the first place, a good knife is necessary, and I know of nothing better than what is called a microscopic dissecting knife. It is best to have two for use—one rather broad towards the point, the other tapering to a point almost as fine as a pen. The broad one can be used to remove large masses, such as objectionable parts in a lady's dress, &c.; while the smaller one is very useful in removing false lights in the eyes, stray hairs protruding from the hair or beard, blemishes in the face, protruding bones in the neck, reducing the size of the hands and wrists, &c. In the next place a proper edge is desirable, because without this it is impossible to use the knife satisfactorily. For this purpose I find that a piece of Arkansas stone answers well. It should be used with a little oil. Care is necessary, however, when sharpening the knife, not to get a saw edge, as it is impossible to effectively use it when this is the case. To obviate this, hold the knife rather flat on the stone while rubbing, bearing rather lightly, and be sure to sharpen both sides as equally as possible. Always rub the parts of the negative on which you wish to use the knife with the retouching medium, because if this is neglected

you are liable to scrape deeper than is necessary. It is also advisable to test the edge of the knife on some part of the negative, which is not to be printed from. Sometimes, owing to negatives being of a slight yellowish colour, those parts which have been scraped will appear too transparent when varnished. This can be remedied by using a very finely-pointed lead, and going over those parts just lightly enough to fill in where the knife has cut too deep.

C. SCHERHOLZ.

#### PHOTOGRAPHY AS APPLIED TO THE REGISTER OF SASINES.

[A paper read before the Edinburgh Photographic Society by the President.]

I PASS on to bring before you a matter of no small public importance, and one which to us, as a Photographic Society, has a very special interest. I refer to the Land Registration Bill for Scotland, described in the Act of Parliament as a Bill to Improve the System of Registration of Writs relating to Heritable Property in Scotland. The Bill was introduced by the Lord Advocate and Mr. Anstruther. It was read a first time in the late Parliament. There is much in the Bill that is of great importance only to those immediately concerned, but which is in no degree interesting to us as photographers. I will therefore only call your attention to that portion in which photography is specially referred to. By it a radical change is proposed in copying all writs sent into the Sasine Office. Provisions are taken in the Bill to set up under Government a Photographic Department in Edinburgh, entailing an annual expenditure of £14,000, involving as it does the taking of about 200,000 negatives 16 by 10, and reproducing them by zincography. The present system, so far as it is intended to be superseded by photography, employs many whose pecuniary interests are adversely affected, and some authorities even in the Register House are not sufficiently convinced of the superiority of the process to give it their approval. There are differences of opinion, both as regards its practicability and its usefulness. Under these circumstances, I thought the Bill was of such importance that I have ventured to bring it before you to-night. I will first devote a few minutes to the present system and the work it is proposed to supersede. When heritable property changes hands in Scotland, or is bonded in security for debt, the transaction is written down on large folio paper, and duly signed and stamped. This document, or writ, as it is then called, is sent to the Sasine Office in the Register House for registration or preservation. These writs are bulky documents, and contain on an average three pages of closely-written matter. Their number has been increasing rapidly of late years. Many large estates are being broken up and sold in small portions, and a considerable amount of feuing is taking place in the neighbourhood of all our cities. The average number in 1887 was 27,537, and in 1896, 43,053 were presented. It will be quite safe for the purposes of this Bill to estimate the number now at about 45,000. These writs are all carefully copied, letter for letter, into a bound volume, and the utmost care is taken that the work done is an exact copy of the original deed. It is this copying process we have to do with. At present, to ensure such extreme correctness, when the work is done the writer reads it over to an official clerk who is looking on the writ. Then it is again read over by another official to another looking on. Every copy is therefore compared, or collated, as it is called, twice with the original document before it is accepted by the Keeper and passed into the archives of the Register House. The harassing nature of this work will be understood from the following extract from the Report by Lord Low's Committee in 1897, when it was proposed to print the records:—"The engrossed copy of every writ is collated twice with the original writ. The amount of labour involved is shown by the fact that in a year the amount to be collated twice is about 250,000 pages of 200 words each, or, including both collations, 100,000,000 words. The immense amount of collating done, and which experience has shown to be as little as is compatible with complete accuracy, is a serious matter. Everyone connected with the Register of Sasines spoke strongly of the wearing nature of the work and of the mental and physical strain which is felt by those engaged in it." Mr. J. Hope Finlay, the Keeper of Sasines, also in his Report in 1890 refers to the "wear and tear on the eyes and brains of educated men entailed by the double collating." The work of engrossing the writs or copying them by hand is at best a slow process, and may easily fall behind on any sudden increase in the number of writs, and so cause great inconvenience to the public. Printing has been suggested, but there are several serious objections to that method of copying the writs. The labour of collating is rather increased,

for whatever extra proof-reading the printer might adopt, the Keeper would not accept the printed records as official documents until they were twice collated by his own staff. The writers, I may explain, are not on the salaried staff: they are paid so much for every page, including collating. As they at present help in the collating, if they are done away with by printing, then the salaried staff would have to be largely increased, more than doubled, an objection which the Keeper sums up in his report by stating: "But the important point is that not only would printing largely increase the work of the salaried staff, but the increase would be in that branch which is least intellectual and most wearing out and tedious." Another objection is that, as these writs are large documents closely written on both sides, they could not be unstitched and handed over to the tender mercies of the printer. A copy would, therefore, need to be made for him, and so our objections begin all over again. Finally, and I think most crushingly of all, the cost would be enormously increased. Estimates were obtained from a number of leading printers, and it was found that the total cost of printing would be considerably more than double that of engrossing. Under these circumstances, Mr. Hope Finlay, wishing, if possible, to lessen the labour of collating, resolved to try what could be done with the photo-zincographic process, which had been proposed in 1866. So many improvements have been made since then that it might prove quite suitable now for his purpose. On this point I will quote from the notes by the Keeper for the consideration of the Committee of Inquiry:—"Enormous improvements in all the branches of photography have taken place since 1866, not only in application and adaptation, but in rapidity and economy of production." "In his opinion the result of the information he has obtained shows that it is now quite feasible to photo-lithograph the register; that in producing a perfectly accurate record and in overcoming the present delays in the return of writs to agents, the process would be a distinct improvement; that in cost it would not exceed the present system of manuscript, and that it would supersede the necessity for any collating, except such a general examination of the sufficiency of photo facsimiles as experience showed to be necessary or desirable. In describing the process, and in other particulars, the Keeper is quoting the information he has obtained from Mr. George Clulow, manager of Sir Joseph Causton & Sons, printing, lithography, and stationery contractors, London. Mr. Clulow has not only been in correspondence with the Keeper, but he has been two or three times in Edinburgh in the Register House. He has seen piles of writs to be dealt with. He knows their description, their number, and the extra pressure at certain seasons. His business is to consider and enter into contracts requiring organisation and efficient arrangement on a large scale, and his deliberate opinion is that the scheme is not only feasible but would be a success." As an experiment, the county of Fife was selected, and the whole writs presented for a month were photo-lithographed and bound as they would be if the process was adopted. Mr. Hope Finlay was kind enough to lend me a copy of that book, and I will be glad to let you examine it after I have finished reading my paper. Should the Bill become law, the process will probably be carried out as follows:—Premises will be obtained in St. James'-square, in the new building for the Sasine Office. There would be two floors, each about 100 feet long by 40 feet wide—the upper, lighted by a glass roof, to contain the cameras, developing room, sinks, &c.; and the lower floor, of the same size, for the printing presses, &c. In the workroom twelve cameras would be provided for times of pressure, though ten would suffice for ordinary occasions. Such an establishment would be capable of taking 600 negatives and 9,000 prints per day. The method of procedure would be thus: When a writ was received at the Register House, it would be taken to the photographing department, where it would be unstitched by girls, taken separate, and each page pressed smooth against a sheet of glass, then exposed under the electric light to the camera, again put together and stitched up. At no time is the writ out of the custody or withdrawn from the observation of an official of the Sasine Office. The room where the girls work would be entirely divided off from the rest of the workroom by a partition, through windows in which they would expose the writs to the photographers. On the other side of the partition the contractor would begin his work by taking a negative the exact size of the deed. This, to save making another negative, he would do through a reversing prism. The negative is then printed off by electric light upon a sheet of chemically-prepared zinc. The zinc plate is then treated with acidulated water, which leaves in relief all those portions which it is intended should be printed. The whole process is an extremely simple one, and is capable of producing as many copies as may be wanted, which could be supplied

at a nominal cost to the public if ordered when the writ is sent in. These copies would contain exact facsimiles of all the signatures, and would also contain exact copies of any plans attached to the writs. Copies would also be sent to the county towns of all the writs sent in from that county, where they would be much more convenient for reference than the printed extracts which are at present sent. The whole process would be completed in one day—that is, the photo-zincograph would be ready for binding the day after the writ was ready for the photographer. The permanency of the copies is vouched for by Mr. Clulow, who states that the oldest printed books we have are 450 years old, and that the photo-zincographs would last at least five times longer than that; also they would be more permanent than the original writs, and would stand tests which the original would not. The Government Survey Department at Southampton report with reference to the Survey Maps reproduced by a process essentially the same as the one under consideration, that "as to stability, the Domesday Book and National Manuscripts reproduced by photo-zincography have now been in existence some thirty years, and show no signs of deterioration; there is, so far as known, no test of longer duration, but no failure in that respect is anticipated." The paper used would be of the best quality obtainable, water-marked with the Thistle and Crown, and the words, "Public Records of Scotland." The ink would be composed of carbon and oil. The greatest objection against the process seems to be on account of the touching up by which the operator might wish to make good any defect in the negatives or zinc plates. Mr. Matthew Livingstone, Deputy-Keeper of the Records, in his Report states: "It is believed that no process of photography or photo-lithography has yet been so perfected that the necessity of 'touching up' at one or more stages can be dispensed with. No degree of skill or intelligence on the part of the operator will ensure that the words or letters 'touched up' may not—quite unconsciously and unintentionally—be made to read differently, and to convey quite another meaning from that presented to the professional reader of the deed." Lord Low's Committee report: "We were specially careful to inquire into the possibility of tampering with or touching up the plates. Nothing of the kind is necessary. A workman might, no doubt, feel tempted to touch up a blurred or indistinct word, but we think any risk of this kind could quite easily be met by the supervision of the Sasine staff, under rules to be approved by the Court of Session." Mr. Hope Finlay states: "The negatives could not be tampered with without detection, but the photo-lithographic transfer on stone might be tampered with." But Mr. Clulow points out that under the regulations which would be framed "such a tampering would become a crime, and be dealt with as forgery." In the volume which I have here there are 502 photo-lithographed pages, in the production of which no touching up was allowed. Examining these simply from the standpoint of whether they would be accepted as a copy for the purpose of the record, the Keeper of the General Register of Sasines considers that there are 459 satisfactory pages, 31 indifferent pages, and 12 inferior pages which he would have rejected. He does not consider there is any danger to be apprehended from touching up; any accidental inferior pages would just be rejected and destroyed, to be replaced by proper copies.

With regard to the cost, Mr. Clulow's estimate of the rough cost of the suitable equipment of the department to do what is required with regularity and without hitch by any breakdown is £2600. Allowing for fifteen copies per writ, he states that the cost, beyond any question, would come within the figures £10,000 or £11,000—the present cost of engrossing and collating the record. Adding the cost of all the clerks required, as well as the equivalent for the time occupied by the district staff in examining the proofs, the cost of framing the register by each of the three systems is thus:—

Total cost of engrossing and collating .....	£10,670
Cost of photo-zincography and examination .....	14,000
Total cost of printing and collating .....	24,325

It is pleasant to be able to add that provision is made in the Bill for compensation to the engrossing clerks, many of whom have spent long years in their present employment.

J. C. LENNIE.

#### PETZVAL'S ORTHOSCOPE.

[Translated from the "Jahrbuch für Photographie und Reproduktionstechnik."]

THE construction of the orthoscope by Professor Petzval, of Vienna, represents an important period in the history of the development of

photographic optics (see Eder's "Ansfuhrh Handbuch der Photographie," 2nd edition, vol. i., part 2, p. 43), and is more particularly described by Dr. von Rohr in his excellent work, "The Theory and History of the Photographic Objective," published in 1899. But concerning the form in which it was constructed by Petzval in 1857 by the optician Dietzler, of Vienna, we have little exact information, as the data given by Voigtlander, in his controversy with Petzval, differ from those in Petzval's patent specification, as well as the orthoscopes actually made.

It is therefore a matter of considerable interest that Petzval's original patent specification, concerning his orthoscope introduced in 1857, should be published, and I append an exact copy of this hitherto unknown document, which is preserved in the archives of the Austrian Patent Office, Vienna.

No. 10,570 (open).—Vol. VI., fol. 315.

Patent Specification by Karl Dietzler. 1 specification, 1 drawing—367. (Z. 9896/1273.)

"N. 2738 (open).—

"Description A.—An invention by Professor Josef Petzval of a new objective for the camera obscura, by means of which a desirable curvature of image, better and more equal definition and illumination in all parts of the field are attained. With a small diameter of lens the size of the image is considerably increased, and the same efficiency is thus secured at much less cost. 10570/0. Vienna, the 6th October, 1857. (Granted, 28/12/857.)

"Ex. 8 October, 1857. The duty of 20 gulden in current coin has been deposited at the Imperial Royal Treasury for the district.—Knab, M.P.

"(Signed) CARL DIETZLER, M.P., Mechanician and Optician, Vienna. Wieden No. 102. A 26793. XI."

The following patent specification by Petzval is appended to this document:—

"10570/0.

"Patent Specification.—The new objective is composed of two achromatic lenses, of which the first, as well as the second, is formed of two components, namely, a crown glass lens and a flint glass lens combined. The crown glass component of the first lens is biconvex, with the flatter curve outwards, whilst the more convex surface exactly fits the flint glass lens, and is cemented to it. This flint glass lens is biconcave, with the second surface of very slight curvature, so that the entire lens, achromatised by the combination, is almost plano-convex in form. Strictly speaking, however, the outer surface is decidedly convex, whilst the inner is slightly concave. The exact form is given in the drawing.

"The second achromatic lens, formed of a front crown glass, and a back flint glass component, may be at a distance of 1-12 to 1-16 of the focus of the first lens, according to the purpose for which the objective is used, and is of somewhat smaller aperture than the first achromatic lens. The crown glass component is biconcave. Its deeper curve is turned towards the front achromatic lens, whilst its lesser curve is turned towards the interior of the apparatus. The second flint glass component is concavo-convex. Its convex surface is turned towards the interior of the camera, and its position and dimensions are given in the drawings. It is not essential that a scale should be given for the drawing, as the combination may be made of any size, provided it be strictly similar in construction, and it is thus capable of giving images of various dimensions, which are always of excellent quality.

"(Signed) JOSEPH PETZVAL, Professor at the Imperial Royal University."

An exact drawing of the construction of Petzval's orthoscope is appended to the document.

In conclusion, I would remark that Petzval's patent was not a secret one (as understood under the old Austrian Patent Law), but "open." It, therefore, follows that Petzval did not wish to make any secret of his invention, but nevertheless he did not offer facilities for its publication.

DR. J. M. EDER.

This article by Dr. Eder is very interesting historically and scientifically, as may be seen from Dr. Moritz von Rohr's recent work. It is there stated that a patent agent had searched for the patent, but that no such document could be found. Dr. von Rohr adds that he had since discovered, by accident, that the patent was granted to C. Dietzler on the 28th December, 1857. Perhaps this remark led Dr. Eder to make further inquiries, for the above is evidently the document in question. The importance of the discovery lies in the drawing, which accompanies the document. This is reproduced in Eder's "Jahrbuch," but it is remarkable that the drawing, as reproduced, does not correspond with the specification, for the bi-concave lens of the back combination has its flatter side turned towards the front lens. On the

other hand, Dr. von Rohr's drawing of the lens, from data supplied by Fr. Voigtlander, corresponds with the Dietzler patent. Owing to a dispute, Petzval separated his connection with Voigtlander, and made an arrangement with Dietzler for the introduction of this lens. But Voigtlander had been given particulars in 1840, and he manufactured the lens in competition with Dietzler. It is curious to notice that the Voigtlander type has the flatter side of the bi-concave lens turned towards the front combination, as in the drawing attached to the Dietzler patent, but the back combination of the Dietzler type is smaller than Voigtlander's.—Translator.

#### SOME DIFFICULTIES OF CARBON PRINTING.

At the Photographic Club on October 17, Mr. E. W. Foxlee addressed the meeting on the subject of "Some Difficulties of Carbon Printing." He thought he had been badly chosen to speak on the difficulties of the carbon process, as for many years he had not experienced any, unless it was in this room, a couple of years ago, when he could not get water sufficiently hot to serve his purpose.

The sensitising of the tissue is by some considered a difficult matter, and especially the subsequent drying of the tissue. Text books tell us that it should be dried in a perfectly pure atmosphere, and we know that the fumes of gas have a tendency to render the tissue insoluble, and that in the very place where it should not be insoluble—viz., on the surface of the tissue. He remembered the case of a whole roomful of tissue turning out insoluble through being dried in a room where gas was burning at the time. The want of a suitable drying-place was felt by many who sensitised their own tissue. Should the tissue be too slowly dried it will turn out insoluble; wherefore one must contrive that it shall take only a moderate time. In a small way, however, there was no difficulty about sensitising and drying tissue in an ordinary room. A dark room was not by any means essential. For sizes up to about 24 by 18 the way to proceed was to sensitise the tissue in daylight, because sensitiveness to light did not arise until the tissue is dried. The tissue may then be squeegeed on ferrotype plate, ebonite, or zinc, and stood against a wall to dry. The support will protect the surface altogether from the action of light, and the paper itself, stained with the bichromate, is quite sufficient to do the same from the exposed side, even in a fairly strong light. A dark room was, therefore, unnecessary either for sensitising or drying. The tissue when stripped is perfectly flat, and another advantage is that no dust has been able to reach the printing surface. The dry tissue is, of course, sensitive to light, but with care it may be handled in an ordinary room. After printing, if the tissue be removed from the frame and immersed directly in cold water, it becomes at once insensitive, and so we advance another stage, without recourse to a dark room. The carbon process may therefore be quite legitimately styled a daylight process. The next difficulty may be that the tissue will not adhere to the support, or, if it does, will not strip in hot water. This shows that the tissue is insoluble, and it is always advisable beforehand to test the tissue, and see if it be in working condition. A piece of tissue should be soaked in cold water for a few minutes, and then placed in water at about 105°. If the coating dissolve off in ten minutes, it is all right. If not, it may be thrown away. The simplest method for any carbon worker to adopt is to buy his tissue ready sensitised. Such tissue will keep good for three weeks or a month. It sometimes occurs that blisters manifest themselves during development. These often are due to improper squeegeeing. The correct way is to bring the tissue and the support, final or temporary, together under the water, and then, with a firm stroke, pass the squeegee downwards, commencing about one-third from the top. The tissue and support are then turned round, the operation repeated. No air bubbles can then remain; but if one starts from the middle of the print, it generally happens that blisters result.

Development will show whether exposure is correct or not. If under-exposed, the paper will too readily come away, and the details of the picture will appear very quickly. The print may be saved by transfer to colder water. If over-exposed, there may be a difficulty in stripping. In bad cases, it is quite impossible to get the paper off, but sometimes the picture may be saved by the use of hotter water, and the allowance of a longer time for development. There are cases when the ordinary safe edge necessary in carbon printing fails to prevent frilling, notably where a very deep shadow adjoins the safe edge. In such cases it will be better to put the black varnish safe edge on the reverse side, so that the light in printing penetrates under it. Very much in the way of faking may be done during development of a carbon print. To brighten up a part, apply a stream of hot water locally. On the other hand, parts may be kept back by the use of cold water. By working in both ways considerable "improvement" can be effected. Mr. Foxlee laid considerable emphasis upon the utility of a hot and cold water supply to carbon workers. At the present time most houses, he thought, were now furnished in this way. Reference was made to troubles in the double transfer process arising from imperfect waxing of the temporary support. The remedy, of course, is obvious. Tissue is in the best condition for use about a

week after it has been sensitised, or two or three days for home sensitised tissue, which does not keep so well as that sensitised in the making. When a very hard negative is being printed, it is best to expose the print for a few seconds after removal from the frame, and before putting into water. This will produce a slightly insoluble layer on the surface that will cause the lights to hold, but will not degrade them. In reply to a question, Mr. Foxlee said that if the tissue is to be squeegeed after sensitising the solution should be somewhat stronger than if the tissue were allowed to dry spontaneously. Strong black and white negatives are best printed on tissue sensitised in strong solution, and weak negatives in a weak bath. After a short, chatty discussion, a vote of thanks to Mr. Foxlee closed the meeting.

### THE REGISTRATION OF PHOTOGRAPHS.

[In deference to the wishes of many correspondents, we reprint from the *JOURNAL* of September 28 our regulations for the registration of photographs.]

At the head of our weekly Answers to Correspondents it may very often be noticed that a list is given of photographs registered. There are one or two misconceptions prevalent with regard to this matter, which we take this opportunity of removing. In the first place, the announcements relate only to photographs which we ourselves have registered for the convenience of our readers. Secondly, they have no reference whatever to or connection with the official register at Stationers' Hall. Thirdly, they are merely records of registration that we have effected, and they have no legal significance at all, being of the nature of informal receipts only.

It has occurred to us that our readers at large may be usefully reminded that, for their convenience in the matter, and especially that of photographers living at a distance from London, our publishers undertake the registration at Stationers' Hall of copyright photographs. For the guidance of those unfamiliar with the necessary procedure, we here state what is required in order to effect registration through *THE BRITISH JOURNAL OF PHOTOGRAPHY*.

1. Send us two unmounted copies of the photograph to be registered, with a postal order for one shilling and sevenpence.

2. On receipt of these our publishers will forward the photographer a registration form, which he must fill up and return to them.

3. Address all communications on the subject to Messrs. Henry Greenwood & Co., 24, Wellington-street, Strand, London. The fee of one shilling and sevenpence covers the cost of registration (1s.), form (1d.), postage and expenses.

### PHOTOGRAPHY WITH FILMS.

At the last meeting of the Croydon Camera Club, Mr. S. H. Wratten in the chair, the President, Mr. Hector Maclean, F.R.P.S., &c., drew what seemed to be the largest attendance of the present season, when he gave an address, which extended over an hour, on "Film Photography." All were surprised to hear that film photography is older than the glass plate negative, Hill and others, in 1843, having used sensitised paper for producing calotypes. Later Warnerke, in 1876, introduced stripping films. But the greatest step of all was the perfecting of celluloid somewhere about 1838, when Carbutt drew attention to its availability for photographic purposes. Mr. Maclean gave particulars of various methods pursued in making transparent celluloid, and explained why certain kinds of celluloid were calculated to impair the rapidity and the efficiency of the silver emulsion. Although film photography had been growing very slowly in popularity, it had at length fairly caught on, due in great part to the exertions of such firms as Kodak & Co. and the makers of the Frena, and also to the teachings of the cinematograph, which, being entirely dependent on film photography, has thoroughly impressed amateurs and others with the suitability of celluloid films as a support of the sensitive emulsion. The great inventive boom noticeable within the past year, as regards various makes of photographic film, was dwelt on, and the structure and manipulation of the Wellington, the Thornton, and the Cristoid films described.

The question of keeping properties of film was carefully gone into. A sharp distinction was drawn between rollable celluloid film and other rollable film, or flat celluloid film. Several instances were cited of flat celluloid film being reasonably perfect after eight years' keeping.

As regards latitude, some films, such as Cristoid, had far more latitude than an ordinary glass plate. Some celluloid films, if flat, had a large latitude, as was evidenced by a set of five prints and negatives (by Mr. Bynoe) passed round, the latter of which had respectively received exposures on the same subject, and within five minutes of each other, of five, ten, forty, and eighty seconds. There was little to choose between the five.

In the course of the lecture several pieces of apparatus were shown and explained. They included the Panoram Kodak, lent by Mr.

Bishop, of George-street, the new No. 3 Pocket Kodak, and the Folding Frena, which last was immensely admired, combining, as it does, all the advantages of "forty flat films," and the option of using it as an ordinary pocket plate camera.

An ingenious film double back, made by the Sandell Plate Co., was also examined with much interest. It is entirely novel, and seems unusually efficient; it is exceedingly compact, and weighs when charged 2½ ounces.

Other examples of film apparatus were shown, including the Volvo Developing Wheel, a device for those who would like to develop their rollable film without having to dabble in solutions. Any length of film up to six or eight exposures can be attached to the periphery of a wheel, the lower portion of which is made to dip into the developing solution; the whole is slowly revolved until development is complete. After a rinse, the film is fixed by a similar procedure, and finally washed. It is from beginning to end unnecessary to touch the film or remove it from the wheel until it is dry. The above costs but a few shillings. In explaining various ways of developing films, Mr. Maclean dwelt on the need for large dishes and plenty of developing solution, given which a quantity of film exposures could be developed quicker than the like number of glass plates. He described the *modus operandi* from cutting off the picture from the spool (which some amateurs muffed) to drying the glycerined film on a board. Mr. Maclean, in response to a circular sent to all members of the Club, stated that it appeared that of those who replied over 80 per cent. used films, of whom 75 per cent. prefer films to plates, either entirely or for hand camera work.

### THE NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.

ON October 23 the Annual Meeting of the Newcastle and Northern Counties Photographic Association was held at the Y.M.C.A. Buildings, Blackett-street. Mr. J. S. B. Bell occupied the chair.

Mr. W. T. Thompson read the report of the Council as follows:—The Association has probably had the busiest and most successful year since its formation in the season now concluded. Last winter's indoor meetings, almost without exception, drew large audiences, and the annual exhibition was very successful. The Association held an extra exhibition in March, consisting of the work of Mr. J. Craig Annan, of Glasgow, and on this occasion held a members' dinner, which was largely attended. It is to be desired that this dinner may become an annual event. Further, the Photographic Convention of the United Kingdom held its meeting in Newcastle under our Society's auspices, and the meeting proved one of the most successful gatherings in the history of the Convention. It may therefore be fairly concluded that two exhibitions, a dinner, and a Convention are favourable indications of our activity and prosperity as an association. The papers and lectures given last winter were nearly all by our own members, and proved that this is by far the most satisfactory method of filling our programme. As we have now once more secured the great advantages of permanent rooms, and a properly appointed dark room, it is hoped that members will induce others to join, and thus share in the advantages. The membership at date of report is 140.

The election of officers resulted as follows:—President, Mr. G. B. Bainbridge (re-elected); Vice-Presidents, Messrs. J. S. B. Bell, T. M. Clague, W. S. Corder, and J. P. Gibson; Council, Messrs. C. E. Barkas, Parker Brewis, W. E. Cowan, G. Elphick, A. B. Gardner, F. Park, W. Parry, G. L. Snowball, W. Thompson, and Dr. Blacklock; Treasurer, Mr. James Baty; Secretary, Mr. Godfrey Hastings, Station-road, Whitley Bay; Assistant Secretary, Mr. T. Bulman; Lanternists, Mr. J. J. Kirkwood and Mr. Edgar G. Lee.

Mr. Clague referred to the resignation of Mr. W. Thompson, of the office of Secretary, and said that gentleman had raised the Society to a level it had never before attained. He moved:—"That the Society desire to place on record its high appreciation of the services rendered by Mr. W. Thompson during the time he has been Secretary of the Society."

This was carried by acclamation, and the resolution will be placed on the minutes.

On the motion of Mr. W. S. Corder, a cordial vote of thanks was accorded Mr. Bainbridge for the manner in which he has fulfilled the duties of the presidency. Mr. Bainbridge had been a model President, and he well deserved the warmest thanks of the members of the society.

The motion was carried by acclamation.

Mr. James Baty (Treasurer) was also thanked for his services during the past year.

## Our Editorial Table.

CATALOGUE RECEIVED.

S. H. Fry, 12, South-villas, Camden-square, N.W.  
Mr. Fry's new catalogue has a thumb index which facilitates reference

to the various parts of the book. This is one of those little ideas which are appreciated by people who constantly require to look up prices and other details. It saves time, and anything which does that deserves our commendation. For the convenience of his clientele Mr. Fry has extended his list of special lines, and notifies that certain classes of work are delivered free. We have pleasure in reminding our readers that one of Mr. Fry's principal planks, if we may use the phrase, is that he confines his business operations to the supply of enlargements, printing, &c., to professional photographers and the trade only. In this sense, coupled with the always excellent qualities of his work, Mr. Fry makes a very strong bid for the support of our readers. In a special note Mr. Fry adds: "My Card Almanac for 1901, illustrated with carbon print entitled 'When Adam Delved,' will be ready early in January, and will be forwarded free on application to bona-fide professional photographers." Now, Mr. Fry has set our curiosity astir with the title of his carbon print, and we shall be glad when January comes, so that we may learn the subject of this uncommonly named photograph. The couplet runs: "When Adam delved and Eve span, who was then the gentleman?" We wonder how a member of the new American school would fit a photograph to such a title?

THE AMERICAN ANNUAL OF PHOTOGRAPHY and Photographic Times Almanac for 1901 (published by The Scovill and Adams Co., New York) comes to us in a guise which differs from that of its predecessors, and perhaps is an improvement upon it. The new Editor, Mr. Juan C. Abel, has our congratulations upon the excellent work which he has done. Among the numerous illustrations the "New American School" is, of course, represented, the formulæ and tables are full and useful, and the articles varied and interesting, if lacking in novelty of subject. Mr. J. T. Keiley contributes a lengthy paper entitled "Photography and Progress." He recounts some of the most recent scientific and other achievements of photography. He would have been well advised if he had not allowed his pen to lead him beyond the 54th page of his article, for the remainder of what he writes is a womanish wail that some modern writers, ourselves amongst them, do not take some three or four swollen-headed pictorial photographers at their own valuation. Mr. Keiley seems to seek solace in the reflection that history will repeat itself, and that he and his kind have only to wait, as Dr. Emerson did, to come into their own. But Dr. Emerson is not flattered at the comparison. It is true that that distinguished man met with much ridicule and opposition some ten or eleven years ago, but it was obvious to many people that time would clear all that away. For if Dr. Emerson started by destroying many fallacies, he also formulated a full and clear theory of pictorial or naturalistic photography, and backed it up by producing photographs which translated that theory into practice. And all through the piece it was pure anti-fake photography! Now, Mr. Keiley and his friends have gone a different way to work. Photography with them is not the end, but the excuse to produce results which have the least possible resemblance to a photograph as Emerson defined and produced it. They fake, they splodge with gum and glycerine, they "pose"; indulge in the small practices of mutual admiration; write wordy, windy screeds which defy analysis or comprehension, and generally comport themselves in a manner which makes it difficult for people to take them seriously. Even those who opposed Dr. Emerson respected and admired him for his sincerity, but Mr. Keiley and his fellow "martyrs" have so far only succeeded in causing us to laugh at them. The London agents for the book are Messrs. Dawbarn and Ward, Farringdon-avenue, E.C.

## Studio Gossip.

PRICES in New Zealand.—"So we are coming down to popular prices; and penny pictures, or sixteen for a shilling is the latest fancy. They are wonderfully good value for the money," says a writer in "Sharland's New Zealand Photographer," "and when they give six different positions all for the same price, we are not surprised that those who cater for the millions on those terms are fairly rushed. Of course we cannot expect retouched proofs to be submitted, or any re-sitting if not approved. But for a 'Take it or leave it' sort of a game it's well worth the 'Bob.' I well remember some years ago when 'Tom Thumbs' or midgents were introduced at half-a-crown a dozen. A certain gallant gentleman—in fact, a 'modern Major-General'—condescended to patronise a certain establishment for half-a-crown's worth, if you please. He wanted the choice of half a dozen different positions, proofs to be sent to him by post, and he would settle for them 'in account.' What a pity he was a little 'too previous.' If he had only waited till to-day he would have had his dearest wishes fully gratified."

LADIES' Dress in Photographic Portraiture.—An American contemporary quotes an American photographer as recommending ladies not to make their dress too modern and characteristic of the styles of the moment. Nothing makes a picture look so very much out of the mode as some costume of fifteen or twenty years ago, which may have been the smartest thing possible at that time. But fashions change so positively that few of them are tolerable to look at after a decade. On the other hand, a woman who has been photographed with only the head and bust revealed, will never give any sign of the passage of time in the appearance of the picture. She will not have the antiquated, out-of-date look that makes some photographs ridiculous. Puffed sleeves were worn only five years ago, but the picture of a woman taken in one of these dresses is really absurd. Even greater than the changes in the style of gowns is the difference that comes in hats.

Women who had their photographs taken in the style of bonnet worn fifteen years ago must feel like laughing at themselves now. Even jewellery has its effect, as the picture of a woman that I saw the other day very plainly showed. She had on an old-fashioned set of coral earrings, bracelets, pin, and everything that used to belong to the "set." She was disfigured by these ornaments. Nobody would have thought of paying any attention to her face, as the coral jewellery absorbed all the attention of the spectator. It is for such reasons as this that I always tell women who want to continue satisfied with their pictures that they should have only the head and shoulders taken, and drape them with a lace scarf or something else that might have belonged to any time or period, and is not going to look absurdly out of fashion after a year or two. Extremely simple dress sometimes may accomplish the same purpose. But the light draping is always more certain. I can remember when women had a passion for being photographed in snow-storms. The heavier the storm the more they liked it, and the more closely they clutched the fur muffs they always carried in these pictures. It is only necessary to look at one of them now to realise how mistaken all such attempts at eccentric pictures are."

## News and Notes.

THE Holland Fine Art Gallery has been removed from 235a, Regent-street, to more commodious premises at 14, Grafton-street, Bond-street, W.

ROYAL Photographic Society.—Lantern meeting, Tuesday, November 6th, at 66, Russell-square, at 8 p.m., "Cities and Sights of Spain," by Mrs. Aubrey Le Blond. The exhibition of American photographs at 66, Russell-square, closes November 8.

COMBINATION printing can be easily effected by using Thornton films for negatives. Two or three negatives can be made, say, one with clouds, one landscape, and one with figure; the negatives can then be laid one on top of the other in the required position, the films being so thin as not to interfere with the resultant print in any way. This was one of the many hints given by Mr. Walter D. Welford during his interesting demonstration of the Thornton films at the Woolwich Society on the 25th ult.

THE Local Technical Education Committee of Brigg, Lincolnshire, under the Lindsey County Council, decided last week to commence a course of lectures and demonstrations on "Chemistry as applied to Photography," and appointed Miss Breeze, Science Mistress at the Brigg Grammar School, to give the chemical and physical lectures, and Mr. J. Wilmore, of Brigg, to demonstrate the practical portions of the syllabus. Over 20 students have been enrolled in the class, and a successful session is anticipated.

UNDERWATER Photography.—The results of some experiments that have been made in under-water photography are given in an article published in the November number of "Pearson's Magazine." The experiments were carried out by two well-known zoologists, who have made a special study of the habits of fishes, and who have brought the camera to the aid of their investigations. M. Louis Boutan, of the Paris School of Zoology, has succeeded in taking some photographs under water by carrying a camera with him to the sea bottom, where he explored in diver's costume; whilst Dr. R. W. Shufeldt, of Washington, U.S.A., an American naturalist, has been experimenting for years past in photographing the fishes in the aquarium tanks of the United States Fish Commission Buildings in Washington. The experiments of these investigators are described at length in the November "Pearson's," and many of their photographs are reproduced, including one snapshot which shows nearly 500 rainbow trout swimming in an aquarium tank.

SOCIETY of Arts.—The following are the arrangements for meetings during November and December:—Wednesday, November 21, 8 p.m. (ordinary meeting.) Opening address of the 147th session, by Sir John Evans, K.C.B., F.R.S., Chairman of the Council. Monday, November 26, 8 p.m. (Cantor Lecture.) Professor J. A. Fleming, F.R.S., "Electric Oscillations and Electric Waves." (Lecture I.) Wednesday, November 28, 8 p.m. (Ordinary Meeting.) Major Ronald Ross, "Malaria and Mosquitoes." Professor Ray Lankester, F.R.S., in the chair. Monday, December 3, 8 p.m. (Cantor Lecture.) Professor J. A. Fleming, F.R.S., "Electric Oscillations and Electric Waves." (Lecture II.) Wednesday, December 5, 8 p.m. (Ordinary Meeting.) Professor H. S. Hele Shaw, F.R.S., "Road Traction." Sir Frederick Bramwell, Bart., F.R.S., in the chair. Monday, December 10, 8 p.m. (Cantor Lecture.) Professor J. A. Fleming, F.R.S., "Electric Oscillations and Electric Waves." (Lecture III.) Wednesday, December 12, 8 p.m. (Ordinary Meeting.) Professor Frank Clowes, D.Sc., "The Treatment of London Sewage." Monday, December 17, 8 p.m. (Cantor Lecture.) Professor J. A. Fleming, F.R.S., "Electric Oscillations and Electric Waves." (Lecture IV.) Wednesday, December 19, 8 p.m. (Ordinary Meeting.) W. T. Maud (special artist to the "Graphic"), "The Siege of Ladysmith."

## Commercial Intelligence.

THE Southwark Photo Engraving Co., Ltd., of 241, Blackfriars Road, London, S.E., inform us that the title of the company, "W. R. Sleigh, Ltd.," has been altered to the "Southwark Photo-Engraving Company, Limited."

ACCORDING to the "Patent Journal," a Convention has been concluded between the United Kingdom and the Republic of Costa Rica for the reciprocal protection of Trade Marks and Designs, and will come into operation on October 29, 1900.

ON Saturday evening last some premises at Snow-hill, Birmingham, owned by Mr. W. Tylar, of High-street, Aston, and let to a number of small mechanical workers, were partly destroyed by fire. Several hundreds of pounds worth of damage were done, and many men are thrown out of employment.

RE Albert Edward Billows, Photographer, Oakham.—The public examination of the above-named debtor took place at the Leicester Bankruptcy Court on Friday last, before Mr. Registrar Toller. The statement of affairs filed by the debtor disclosed a deficiency of £98 10s. 2d. Replying to questions put by the Official Receiver, debtor stated that he had done a small business in selling photo materials to amateurs, but, being a professional photographer, he was unable to obtain these goods on such favourable terms as the ordinary photographic dealers.—The debtor was allowed to pass his examination.

RE William John Hawker, Photographer, "Nyassa," Talbot-road, Winton, and The Square, Bournemouth.—This debtor appeared for his public examination at the Poole Bankruptcy Court, before Mr. Registrar Dickinson, on October 25. The summary of accounts filed by the debtor disclosed liabilities amounting to £776 4s. 7d., and nett assets estimated to produce £60 12s., thus leaving a deficiency of £715 12s. 7d. In answer to questions put by the Official Receiver, debtor stated that he had been in business in Bournemouth for 33 years. He had no capital of his own when he commenced, but he borrowed some, and for the first 12 years of his trading he had a studio in one of the wings of the Belle Vue Hotel. Afterwards he took premises in the Old Christchurch-road, and about two years and nine months ago he took premises in The Square, Bournemouth. He was solvent when he went to The Square, but he soon discovered that he had made a mistake in going there. He attributed his present deficiency to his trading there. He became aware of his insolvency about six months ago, but he kept on, hoping matters would improve.—Eventually the examination was formally adjourned until the next Court.

## Meetings of Societies.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 25,—Mr. E. Human in the chair.

Mr. Rapson showed two negatives that had been equally exposed and developed; one of these had been left with just sufficient hypo to cover it for 24 hours without motion, and in comparison with the other that had only been left in the usual time, showed a very decided change in colour and density, especially in the half-tones. Mr. Haddon, remarking on this, said that one day he had left a developed bromide print in hypo until the next morning, when on examination those portions nearest the surface showed reddish patches, and the remainder being unchanged, thus showing that without oxygen no change takes place in the developed image. Mr. Henderson remarked that it had often been his practice to take the negative out of the hypo, and stand it in the air to thin it. Mr. Henderson then raised a contention that it was possible to entirely dissolve the developed image in a bromide plate, and challenged Mr. Haddon to prove otherwise, quoting tests that he had made with bichloride of mercury and ammonia and other substances. Mr. Haddon said he would try and find time to settle this question, and prove to Mr. Henderson that it was absolutely impossible to entirely reduce the developed image without removing the gelatine also.

### PHOTOGRAPHIC CLUB.

OCTOBER 24,—Mr. E. J. Wall in the chair.

Mr. George E. Brown read a paper on "Meyer's Silver Phosphate Process." A print-out paper in which phosphate of silver is the sensitive material has been invented by Dr. Johannes Meyer, of New York, and is just now being placed upon the American market. The novelty of the process, as compared with the early use of silver phosphate by Fyfe and by Lyte, is that it is applied to the paper as an emulsion in tartaric acid solution. No gelatine or other vehicle is employed, so that the paper possesses the ease of manipulation characteristic of plain salted paper, while, at the same time, it is about as rapid as gelatino-citro-chloride. The special features from the point of view of the user are the rich brownish sepia tone obtained by simple fixing; no over-printing is necessary, and a much weaker solution of hypo than that generally used can be employed. The paper is amenable to the usual toning baths in which it tones very quickly. The most satisfactory black tones are obtained by slightly over-printing and the use of a platinum bath. Gold, it was shown, does not give a strong tone so easily; delicate greys are obtained in rather weak gold baths. The paper has been received with favour by prominent photographers in America, including Mrs. Kasebier and others of the new American school. A number of prints, lent by Dr. Robert C. Schupphaus, of New York, were shown, and included some from Mrs. Kasebier's negatives. The phosphate emulsion has also been found by Dr. Valenta to be of value as an addition to the ordinary collodio-chloride emulsion. Paper coated with emulsion thus modified is stated by Valenta to be four times as rapid as ordinary collodion paper, and to give a longer range of gradation. It is also stated that paper coated with gelatino-bromide emulsion containing phosphate emulsion prints out by gas light. Mr. Brown proceeded to demonstrate the process, treating several prints, which were subsequently passed round for inspection.

Mr. Archer Clark, inquiring as to the permanency of the prints, referred to some experiments he had made some years before, and said that the only print of the batch made that had faded was a phosphate print. The connection with the present process was not a close one perhaps, but the fact was interesting in a general way.

The Chairman drew attention to the fact that the half of a print that had been fixed when placed against the other half showed a marked shortening of scale at both ends. He saw no advantage in dispensing with gelatine or some colloid in the paper. The prints while wet looked nice, but when dry the appearance was sunken and dead. A small amount of colloid would improve the effect considerably. Of course, the fact that no free silver was necessary in the paper was an advantage, and the paper should keep very well in consequence. The Chairman said he had tried the phosphate emulsion with gelatine and with collodion. It answered very well, but did not increase the speed of the collodion paper so much as it did the gelatine. He had also used it with bromide emulsions, fast and slow, but the printed-out image obtainable was lacking in intensity, and was not worth anything.

After some further discussion, a vote of thanks was passed to Mr. Brown for his interesting communication.

Mr. H. Snowden Ward communicated to the meeting some facts concerning the recent death of Mr. Thomas Fall, who for many years was a member of the Club.

The Secretary was directed to convey to the family of the deceased an expression of deep regret felt by the members of the Club in its bereavement.

A welcome was given to the Rev. J. C. Harris, Vice-President of the Johannesburg Photographic Society. Mr. Harris gave a short account of his Society, which, before the war, was in a most flourishing condition.

**Richmond Camera Club.**—At the meeting on October 8th, Mr. Cembrano gave an elementary discourse on "Development." He commenced by dwelling on the importance of exposure in ensuring good results, and strongly recommended that the beginner should err on the side of over-exposure, as nothing satisfactory could be done with an under-exposed plate. He named the points necessary to obtain correct exposure as follows:—(1) Study the subject; (2) observe the kind of light at the time of exposure; (3) keep to one kind of plate, so as to know its capabilities well; (4) know the capabilities of your lens; (5) and of your shutter; and, finally (6), keep to one developer. Mr. Cembrano strongly advised keeping a note of each exposure, and what is often omitted by those who do this—write against each exposure the character of the resulting negative. He also thought that the use of an actinometer was a great assistance to the beginner. He preferred what is called a quick plate to a slow one, it being more generally useful, and, as a rule, yielding softer negatives than a slow one. As regards the developer itself, he preferred pyro with carbonate of soda, and he mentioned that in the case of an over-exposed plate it was a good plan to add a large quantity of pyro—say, 6 grains to the ounce—to the developer. This stopped development at once, and the alkali could then be added gradually, with the result that a much better printing negative would be secured. Great stress was laid on the advisability of having a good light in the room. Personally, he found that an argand burner shielded by two thicknesses of canary medium was quite safe. Naturally the light was kept low at the beginning of development, and the dish covered. After the image was out, the light could be safely turned up. Of course, this light could not be used for isochromatic plates, and for this reason he seldom used them.—At the meeting on October 22, Mr. Walter Welford demonstrated the merits of the new Thornton film. He commenced by pointing out the advantages as regards lightness, space occupied, and non-liability to breakage that films enjoyed over plates, and, as regards the Thornton film especially, the ability to print from either side without loss of sharpness owing to the thinness of the film. This was of great advantage to process:

workers and printers in carbon, as the troublesome processes of making a reversed negative in the one case and of the double transfer in the other were done away with. He then passed round specimens of the films, unstripped and stripped, and of the backing paper, together with some prints of his own from negatives taken on the films. He also showed the perfect ease with which the film left the backing paper when it was dry, and he showed that with the aid of a piece of cardboard, the film lay flat in the dark slide. After developing and fixing two films, which showed incidentally that they did not curl up in the developer, but lay as flat as plates, he stripped one from the support, and placed it in a dish of plain water to show the extent to which it expanded. It was necessary in this case to float the film on a glass plate to dry, and, if the plate were prepared in the usual way with French chalk, the film could be stripped from it when dry as easily as if it had been left attached to the original support.

**South Norwood Amateur Photographic Society.**—Oct. 25th, Mr. Ramsay, of Kodak, Ltd., gave a demonstration of the various productions of the Kodak firm. He described in detail the mechanism of the new Panoram Kodak, the lens of which turns round through almost a half-circle during the exposure, producing a long narrow picture, in which the objects represented have a much more natural appearance than they have when photographed with a fixed lens camera. The various folding pocket Kodaks were also fully described, and a spool of Kodak film was developed. Mr. Ramsay drew special attention to the care required in wetting the film uniformly before development, and in the avoidance of air bubbles on the film whilst development was in progress.

**North Middlesex Photographic Society.**—October 22nd, Instruction Evening, Mr. A. H. Lisett gave a lecture on "Home Portraiture." He said portraiture was more difficult for beginners than landscape, but the material was always ready at home, and, by keeping on trying, very good results could be obtained. He cautioned would-be portraitists not to copy slavishly the professional. Children made very good models, as they were not so self-conscious as adults. He showed how an ordinary room lit by one window could be made to give very satisfactory results. A reflector of white paper or similar material hung over chairs, or a screen to lighten the shadows, which would be otherwise too heavy, should be placed so the light from the window should be thrown back on the sitter. An incandescent light with opal globe acted as a very good reflector. The lens used should be of fairly long focus, say, 7 in. for a  $\frac{1}{4}$ -plate, and as rapid as possible. As a general rule the eyes should be focussed, and care should be used as to the direction in which they were looking, generally straight out of the face was best. Orthochromatic plates were best, and they should be developed thin.

**Liverpool Amateur Photographic Association.**—October 27th. Business including the election of three new members having been disposed of, the President apologised for the absence, through illness, of Mr. E. R. Dibdin, who was down on the programme as the lecturer of the evening. Mr. Dibdin's place was, however, filled by Mr. Harvey, whose subject, "A Tour in Southern Germany," proved most interesting. Mr. Harvey's journey was by way of Harwich, the Hook of Holland, Cologne, Coburg, Nuremberg, Dresden, and Hildesheim, and the pictures taken en route and shown on the screen were of the highest order. The lecturer pointed his remarks with many pithy anecdotes and quotations.

**Hull Photographic Society.**—October 25th, before more than 80 members of the Society, Mr. Donald A. Nightingale gave a demonstration of Messrs. Griffin's specialities. Notably, in connection with velox, the double-weight paper, produced a most favourable impression. A tube, composed of celluloid, which will shortly replace the glass tubes used for packing Cartol developers, was also exhibited. An excellent lantern slide was also exhibited. An excellent lantern slide was produced on the Gaslyt plates. This same slide was, a few minutes afterwards, projected on to the screen.

#### FORTHCOMING EXHIBITIONS.

1900.

- November 2, 3..... Photographic Salon, Dudley Gallery, Piccadilly. Hon. Secretary, R. W. Craigie, Camera Club, Charing Cross-road, W.C.
- " 2, 3..... Royal Photographic Society, New Gallery, Regent-street. The Hon. Secretary, 66, Russell-square, W.C.
- " 2, 3..... Sefton Park Photographic Society. Hon. Secretary, G. Birtwhistle, 7, Gainsborough-road, Sefton Park, Liverpool.
- " 7-10 ..... Cripplegate Photographic Society and the Essex and Middlesex Cycling Union, Ltd. Hon. Secretaries, A. T. Ward, Cripplegate Institute, E.C., and G. F. Sharp, Sach-road, Upper Clapton, N.E.
- " 12-17 ..... Ashton-under-Lyne.
- " 19-24 ..... Waterloo and Blundellsands Photographic Society. Hon. Secretary, W. G. Eyre, 2, Mersey-road, Blundellsands.
- " 21-23 ..... Hackney Photographic Society. Hon. Secretary, W. Selfe, 70, Paragon-road, Hackney, N.E.

- November 21-24 ..... Cleveland Camera Club. Hon. Secretary, F. W. Pearson, 98, Victoria-road, Middlesborough.
- " 22-24 ..... Hove Camera Club. Hon. Secretary, C. Bertrington-Stoner, 24, Holland-road, Hove.
- 1901.
- January 14-19..... Blairgowrie and District Photographic Association. The Hon. Secretaries, Blairgowrie, N.B.

## Patent News.

THE following applications for Patents were made between October 15 and October 20, 1900:—

- PRINTING FRAMES.—No. 18,297. "Improvements in Photographic Printing Frames." J. WILKINSON and A. WILKINSON.
- CINEMATOGRAPH AND HAND CAMERA.—No. 18,363. "Combined Cinematograph and ordinary Hand Camera." A. ROSENBERG.
- CINEMATOGRAPH APPARATUS.—No. 18,364. "Improvements in Cinematographic Apparatus." A. ROSENBERG.
- FILM-CHANGER.—No. 18,535. "A New or Improved Device for Changing Photographic Plates or Films in Daylight." Complete specification. C. P. GOERZ.
- PRINTING FRAMES.—No. 18,585. "Improvements in Photographic Printing Frames." J. WILKINSON and A. WILKINSON.
- PRINT WASHERS.—No. 18,662. "Improvements in Photographic Print Washers." A. VAN HOORN.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notices taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### PORTRAITS BY MRS. CAMERON AT BROCKENHURST.

To the EDITORS.

GENTLEMEN,—It may not be generally known that a small collection of portraits by the late Mrs. Cameron is in existence in the heart of the New Forest. Some time ago, when waiting for a train at Brockenhurst Station, I strolled into one of the waiting-rooms, and, to my surprise, found it adorned with a collection of photographic portraits. On examination these proved to be by the photographer above mentioned, and I should say are very fine examples. The finest of the series is a portrait of G. F. Watts, though probably that of Sir T. Herschel most nearly illustrates the original treatment for which Mrs. Cameron was noted. Each portrait bears full data, presumably by Mrs. Cameron herself, of the date of the picture's production, the subject's name, &c. The pictures were presented by Mrs. Cameron in 1871 to the waiting-room of the station, as it was in this room she met her son on his return from India. The prints are in excellent preservation, considering their age, the exposure they have experienced, and the utter lack of any care for them. They certainly are a fine tribute to the stability of albumen prints when carefully produced. I interviewed the station-master with regard to their presentation, but he had been appointed to the station subsequently, and referred me to a porter who remembered the occasion. This official informed me that he was the only person who took any interest in them, and that he "dusted them every year." In the interests of historical photography, I tendered him a small honorarium, and begged that he would still continue to exert his beneficent ministrations.—I am, yours, &c., GEORGE T. HARRIS.

Brockenhurst, October 28, 1900.

[We are very much obliged to our friend Mr. Harris for drawing our attention to the existence of some of Mrs. Cameron's pictures at Brockenhurst Station. Dr. Emerson, who resides in the neighbourhood, had previously spoken to us on the subject. In the course of a few weeks we hope to pass a short holiday near the New Forest, and will take the opportunity of inspecting the photographs, and, maybe, of interesting ourselves in their preservation. Eds.]

### THE LATE THOMAS FALL.

To the EDITORS.

GENTLEMEN,—Doubtless all photographers will read with deep regret the decease of Mr. Thomas Fall. I feel I cannot let the time pass without adding testimony. He frequently came to my studio when in Brighton, and did many acts of help, advice, and kindness which I could never hope to repay. I am sure the list of kindly acts done by him to brother professionals must be a very long one, and the spirit that prompted those acts an example that may most safely be followed both by photographers and all men.—I am, yours, &c.

HENRY SACK.

109, Western-road, Brighton.

*To the EDITORS.*

GENTLEMEN,—With very deep regret I have seen your obituary notice of the late Mr. Thomas Fall, and quite endorse your remark as to the loss sustained by those interested in photography in this country. The last time I had the pleasure of seeing Mr. Fall was when he came over to Dublin fourteen months ago, and, though only here for a couple of days, he came in to me to have a long chat. I deeply deplore his loss, along with many of your readers.

May I take this opportunity of thanking your critic of the Holland Day Exhibition for so kindly mentioning my name in connection with his remarks thereon.—I am, yours, &c.,

ALFRED WERNER.

39, Grafton-street, Dublin, October 30, 1900.

## PHOTOGRAPHY OF NATURAL COLOURS.

*To the EDITORS.*

GENTLEMEN,—Your readers may be interested to know that specimens of work by the McDonough-Joly process will be shown, by request, at the following Exhibitions:—

Cripplegate Photographic Society, Cripplegate Institute, November 7th to 10th inclusive.

Ashton-under-Lyne Photographic Society, Town Hall, Ashton-under-Lyne, November 12th to 17th inclusive.

Cleveland Camera Club, Cleveland Hall, Middlesbrough, November 21st to 24th inclusive.

The pictures, which will be on view, are transparencies on glass, and represent the most brilliant tints and hues, as well as the more sombre tones of natural and other colours. We may add that by our process magic lantern slides can be made almost as cheaply as the uncoloured slides of the present day.—We are, yours, &c.,

COLOR-PHOTO Co.

Birkbeck Bank-chambers, Southampton-buildings, Holborn, W.C.  
October 26, 1900.

## THE EXHIBITION OF AMERICAN PHOTOGRAPHY AT RUSSELL SQUARE.

*To the EDITORS.*

GENTLEMEN,—I do not suppose you wish to arouse any discussion as to the propriety of such photography as Mr. Holland Day's sacred subjects in the above exhibition, but your very vigorous references to these studies and their maker in your article of the 26th, impels me to ask space for a few lines of defence of one who has been an intimate friend for some years. Let me say at the outset that a copy of his picture, "The Seven Last Words," has been in my possession for over a twelve-month, and has been shown to very many friends and visitors, without at any time eliciting anything but complete approval, and with a complete absence of any feeling of disrespect or irreverence. I remember that I ventured to warn Mr. Day that such work might prove but waste labour over here, and perhaps in his own country prove dangerous, as it might lead to a discipleship that would produce things which, by their incompleteness, mistakes, or shortcomings, would prove irreverent, as suggesting things the reverse of what a successful effort would suggest in connection with so sacred a theme.

Mr. Day has been successful because he has proved so wonderful a model, as any dispassionate study of "The Seven Last Words" will at once show; and this brings me to your chief point against him, his own posing as the Christ model. I would like to ask this question: If Mr. Day had taken the Ober-Ammergau actor, Joseph Mayer (or his successor) as his model, and used him as he has used himself, would your denunciations be as fierce, or would they even exist? I do not remember your ever having fulminated against the photographs of the Ober-Ammergau actors, in every stage of the sacred drama, though they have been published in this country. I have now before me a small collection of C.D.V. portraits in character of these actors published by Marion and Co., and I would ask where is the difference? In both cases a living person is used as the model because of a supposed suitable personality. You utterly condemn one. It will be interesting to have your opinion of the other. Or suppose Joseph Mayer to have been gifted with Mr. Day's photographic skill and taste, and that he had photographed himself in his actor's robes as the Christ, as Mr. Holland Day has done, would you have approved him, or have meted out to him the sentence "Guilty of the most flagrant offence against good taste that has ever come under our notice?" Is it possible that what is proper and commendable in a Bavarian is vicious, a "flagrant offence" in an American?

It is to be hoped that some of the visitors to Russell-square will also have been visitors to Ober-Ammergau. What will their feelings and opinions be? Yours, or those which permit thousands of religious people, lay and clerical alike, from Dean Farrar downwards, to witness each Ober-Ammergau festival with approval and satisfaction?

If you had not known Mr. Day to have been his own model, would your opinion have been of the same sort and as extreme? If so, it is because the pictures themselves arouse by their treatment a feeling of intentional disrespect to the Saviour of Mankind, a feeling which, to me, seems a sheer impossibility for the pictures to arouse in any one.

I think a sense of fairness in journalism would have suggested leaving the feeble extravagances of poor Mr. Hartmann alone, and not using them as a lever by which to force or bias public opinion against Mr. Day and his works, by the gratuitous assumption that he himself was in sympathy with, or responsible, for their ineptitudes. I can vouch personally for Mr. Day's entire singleness and simplicity of

purpose in these works; indeed, a reverence of motive, an entire absence of vulgar straining after false effect, a quiet dignity and pathos, inform each study; but how otherwise could it be from an artist and a gentleman? Is it conceivable that he should undertake such labour merely to shock and outrage public taste, and proclaim himself the irreverent trickster your articles infer he is?

Your journal has a history that is associated with an amount of fairness and impartiality that makes your recent departures particularly unfortunate. Any new departure in photographic work should be met with criticism, real critical criticism, destructive and constructive, not with mere expressions of likes or dislikes, or such unfair personalities as your quotations from the unlucky Hartmann. If you had quoted them as condemning them, but not necessarily their subject also, what a different flavour would have been imparted to your article.

Hoping you will favour me and your readers with your opinions on the Ober-Ammergau actors and their photographs in relation to your condemnation of Mr. Holland Day's photographs of similar subjects,—I am, yours, &c.,

FREDERICK H. EVANS.

27, Fairfax-road, Bedford Park, W., October 19, 1900.

[It has probably escaped the notice of Mr. Evans that in THE BRITISH JOURNAL OF PHOTOGRAPHY of February 24, 1899, we referred in the following terms to some of Mr. Holland Day's "sacred" photographs, which had shortly before then been shown and reproduced in this country:—"We believe there is something very widely repugnant in the idea of persons posing before a lens in sacred character, and that, no matter how skilfully and reverently the photographs have been produced and treated, the incongruity and doubtful taste of nineteenth-century persons presuming to make up as actors or participators in dramatised portions of what so many millions of persons regard as the Divine redemption of the human race, can never be obliterated from the minds of those called upon to contemplate the photographic results." We then proceeded to consider some reproductions of "three photographs purporting to represent the Crucifixion and the Entombment, by one of the most intellectual photographers yet produced by the United States—we mean Mr. F. Holland Day—whose pictorial work for the last two or three years has been favourably known on this side of the Atlantic." The remainder of our remarks was as follows:—"The titles of Mr. Day's photographs are 'Into Thy Hands,' 'The Entombment,' and 'I Thirst'; and we mean no offence when we say that to us, as photographers, they are exceedingly repulsive, in virtue of their obvious reliance upon the 'art' of the person who made or built them up. The ruthless lens reveals every little trick or artifice employed in 'faking up' the originals; and we confess it is with something of a shock that we contemplate these photographically vamped-up representations of what are so generally regarded as three of the most moving incidents of the World's Tragedy figuring in the pages of an illustrated magazine. To the best of our belief and knowledge, sacred art, so called, has not yet inspired British photography. At the moment we can only recall three pseudo-sacred photographs publicly exhibited—a 'Christian Martyr' and two 'Magdalenes,' and this in an experience of about twenty years of the exhibitions. Those attempts were coldly received by the photographic public, and we cannot discover that any inducement has been forthcoming to other photographers to select even graver themes than those mentioned. We hope matters will remain so. The lens and the dry plate do not idealise as the painter or the draughtsman can or may. The very finest skill of the foremost British photographers, we are convinced, would break down at any attempt to divest a sacred subject, taken by means of the camera, of those insistent and cartographical details which impart an element of repulsiveness, in our eyes, to Mr. Holland Day's photographs—repulsive because we are conscious that the individuality of the originals has not been, cannot be, so completely masked or subdued as to destroy the mental persuasion that we are looking at the image of a man made up to be photographed as the Christian Redeemer, and not at an artist's reverent and mental conception of a suffering Christ. We hope that neither Mr. Holland Day nor anybody else will misunderstand our motive in drawing attention to this matter, as to which we believe we give expression to sentiments almost universally entertained by British photographers. Not only for the reasons given are sacred subjects best denied treatment by the camera, but also in the interests of photography and photographers themselves, who would surely provoke the hostile opinion of the educated public by any appreciable attempt to deflect camera work from its legitimate paths. A moment's reflection will show that the scope opened up by allowing that sacred subjects are admissible for photographic treatment is practically illimitable, and that the possibilities of offending the deepest susceptibilities and convictions of millions of minds are just as great. We trust Mr. Holland Day's example will not find imitators in this country, and that in his own it will speedily be recognised that the reasons for denying to 'sacred art' photographic treatment are so numerous and weighty, that a very serious responsibility is incurred in ignoring or overlooking them." This extract should convince our correspondent that our objections to Mr. Holland Day's sacred art photographs were just as emphatic nearly two years ago as when penning our article last week. We concede at once that Mr. Evans makes for a strong point by asking our opinion of the Ober-Ammergau Passion Play, and the photographic representations of it. We object to both, and for reasons which the foregoing extract should

make plain to the extent desirable. The other points in Mr. Evans' letter can only be dealt with very briefly. "The feeble extravagancies and ineptitudes of poor Mr. Hartmann" appeared in an American paper, "The Photographic Times," and they were illustrated by some of Mr. Day's photographs, presumably supplied for the purpose. Mr. Hartmann appears to be appreciator-in-chief to the new school of American photographers, and if those ladies and gentlemen are not in sympathy with his point of view, it is curious that they give him such excellent facilities "for writing them up." We are not unfamiliar with the way in which the gentle art of interviewing is practised. The penultimate paragraph of Mr. Evans' letter, in which, after charging us with partiality and unfairness on very unsubstantial grounds indeed, he considerably tells us how to write our articles, adds a touch of humour to a literary production which, perhaps, will not be taken quite so seriously as the author expects.—Eds.]

### BLUE PRINTING.

To the EDITORS.

GENTLEMEN,—The letter of your correspondent, "T. H. A.," is interesting from two points of view. The exposure of ferro-prussiate paper as at present turned out by competent makers is, under a tracing, one to two minutes in sunshine—that is clear and unobstructed sunshine. It may reach five minutes under unfavourable circumstances, such as we have to contend with in large towns and manufacturing districts. With photographers' negatives it may be from two to ten, or even fifteen minutes, in sunshine, according to the density of the negative, which, we know, is a very uncertain factor. But the difficulty arises when the two conditions of lighting are compared.

If in the one case of sunshine it takes 10 to 15 minutes to expose a print fully, it must at least take a day, or the better part of one, to make an exposure to the same grade of intensity without sunshine. If, on the other hand, dull or cloudy light will produce a print in 20 to 30 minutes, the same paper will print in sunshine in less than a minute. We are producing papers to order that are three times as quick as stock papers usually sensitised. It is intended for winter exposures, and has rendered services in many instances where it could be used under circumstances which were prohibitive for ordinary paper.—I am, yours, &c.,

J. R. Goetz.

215, Shaftesbury-avenue, London, October 25, 1900.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

- A. W. Sargent, 12, Albany-road, Cardiff.—*Photograph of the Rev. M G Pearce.*
- J. White, 7, Beach-road, Littlehampton.—*Photograph of C.I.V. memorial tablet.*
- L. Varney, Buckingham.—*Photograph of 56th and 57th Imperial Yeomanry Companies.*
- B. Redford, 11, Summerhill-street, Newcastle-on-Tyne.—*Photograph of Cathedral, Newcastle-on-Tyne.*
- A. Young, 2, Pall Mall, Manchester.—*Photograph of Tysoe v. Bennett on the mark for three-quarter Championship of the World.*
- F. Coghlan, 31, Carlisle-road, Londonderry.—*Photograph of Colonel Chamberlain and Officers of Counties Derry, Donegal, and Tyrone, R.I.C.*

DRY FERROTYPED PLATES.—R. O. C. These plates may be had from Fallowfield's, Charing Cross-road.

F. A.—"Wilson's Photographic Magazine," published at 289, Fourth-avenue, New York, perhaps meets your requirements. A copy may be obtained of Messrs. Dawbarn and Ward, Farringdon-Avenue, E.C.

IN TROUBLE.—We do not know the name of the maker of the lenses referred to; but as you ask for a city address, perhaps if you inquire of Messrs. A. E. Staley and Co., 35, Aldermanbury, E.C., they may be able to help you in the matter.

PRINTING PROCESSES.—F. G. asks: "Would you please inform me the cheapest paper to use for printing views on, and where I should get it; also the name of a firm that would print cheap albums of views?"—In reply: Our correspondent's question is not so explicit as it should be. Does he refer to photographic or letterpress printing? Let him say, and we will advise him accordingly.

VULCAN.—The formulæ were quoted for the intensification of negatives by the Lippmann process. A thousand grammes is probably meant, a figure having been dropped. For a metal solution dissolve 1 part to 10 of sulphite in 10 ounces of water.

M. A. C.—(1) We can only reply to you in the terms of the answer given to "All" elsewhere in this column. (2) Develop your negative as you would for gelatino-chloride prints, and it will answer well for reproduction purposes—the requirements are moderate density, clearness in the lights and middle-tones, and unclogged shadows.

BOOK ON RETOUCHING.—STAMP PRINTING FRAME.—E. WATKINS asks: (1) Can you tell me where I could get a good book on retouching? (2) Also, where I can get a stamp printing frame?—In reply: (1) Robt Johnson's book, published by Messrs. Marion and Co., Soho-square, W.C. (2) We believe Mr. George Jobson, of Horn-castle, can supply you with such a machine.

"ALL."—It is against our rules to recommend apparatus or offer such opinions as you ask for. We can, therefore, only reply to you in general terms. Better get the catalogues of a few dealers or makers, and, so guided by your requirements and your financial resources, make your choice. There are dozens of cameras on the market with which you can do the kinds of work you mention.

BOOKS ON WORKING-UP BROMIDES.—"Book" writes: Will you kindly tell me if there is a book published on colouring bromides in water-colour and oils, and, if so, where can I get same?—In reply: A little book by Mr. Bool, published by Messrs. Percy Lund and Co., Bradford, may help you. Consult the chapters on the subject in Johnson's book on retouching, published by Messrs. Marion, Soho-square, W.C.

PHOTOGRAPHY IN SOUTH AFRICA.—PYRO asks: (1) Whether there will be any scope for photography in South Africa after the war? (2) If the prices of paper, plates, chemicals, &c., are much more expensive? In reply: (1) According to the newspapers, the Military Authorities are constantly warning intending emigrants to defer going to South Africa until the country is in a settled state. Possibly in a year's time there may be some chance for you. (2) No doubt there would be a considerable advance in the prices.

RESTORING SPOILT BLUE PAPER.—G. R. writes: "I have a large roll of blue paper for iron printing, but it appears to have lost its sensibility, although still a good blue colour. I presume the climate has ruined it. I shall be obliged if you can tell me of any means of resensitising it."—In reply: If the paper has been ruined by the climate we fear there is no method of restoring it to its pristine condition. If there were, the trouble involved would be more than the paper is worth, and even then it would not be very satisfactory; certainly not so good as at first.

COLOUR PRINTING.—W. T. writes: "I should be obliged if you would kindly let me know the addresses of some printing firms who would produce small quantities of imitation colour photographs, the same as seen in railway carriages? I have written several houses who go in for colotype printing, but cannot find any one who does such work as I want."—In reply: The "railway carriage-process" is worked by the Photochrom Co., of 121, Cheapside, who might quote our correspondent for his requirements. But a "small quantity of imitation colour photographs" is an order which in all probability he will find it difficult to place.

GRANULARITY IN ENLARGING.—J. C. S. writes: "I am enlarging a silver print photo of a deceased friend, and find the negative I have taken for the purpose gives a 'granulated' print. I have taken several negatives, and they are all alike. Can you tell me the cause, and suggest a remedy? The plates used were Ilford chromatic, and but for the defect mentioned, would have been satisfactory."—In reply: The cause of the granularity is that the print is not rightly illuminated. Light in such a way that the granularity does not show when the image is examined on the ground glass. Let the light reach the picture at such an angle that it is reflected away from the lens, and not into it.

BELITZSKI'S REDUCER.—"R. S." writes: (1) In the ALMANAC potassium ferric oxalate is given as one of the ingredients, but this is not kept in stock by photographic dealers or chemists. Where can it be procured? (2) The Barnet Book, p. 239, gives a different description of this reducer, the formulæ having more chemicals than that in the ALMANAC. Is it an improved form?—In reply: (1) You might get the substance from Messrs. Harrington Bros., Oliver's-yard, City-road, London, E.C., or some other firm of manufacturing chemists. (2) Perhaps for bromide paper the formula in question would tend to prevent dissolution of the image and whites; but we have not tried it.

LENS APERTURE AND DEVELOPMENT FOR PORTRAITURE.—S. Watteau asks: "What is the best stop to use for portraiture? Is it desirable to slightly over-expose to get more detail, and which is the better plan of the two?—to put all the accelerator they mention in formula and retard by use of potassium bromide, or to add the accelerator by degrees, and not to use any bromide? I should feel deeply grateful for any hints in the development of portraiture, and how to tell when you have sufficient density?"—In reply: In portraiture use the largest stop that will give the desired definition over the plate used. Give the right exposure. There is no use in over-exposing. Employ the developer as recommended by the makers of the plates. The requisite density is judged by looking through the negative as it is developing. Judgment is the only guide, and that is easily acquired.

**DECIDING A WAGER.**—C. W. As the prints are sent to us, as you say, merely to decide a bet, we decline to give any opinion on them whatever. The object of this column is not to decide bets, but to give useful information to such as require it.

**WILLESDEN PAPER.**—P. CONWAY asks our opinion of Willesden paper for roofing a studio, and where it is to be obtained? We have had no experience of the material for the purpose referred to, so cannot express an opinion on it. The address asked for is the Willesden Paper Co., Willesden Junction, N.W.

**FAULTY LIGHTING.**—GEO. LEAMER. The only fault in the portraits for warded is in the lighting. In all of them there is far too much direct front top light, hence their general flatness. Subdue the top light, and use a stronger front light. Probably the same amount of side light would suffice if more of the top light were blinded off.

**OLD NEGATIVES.**—BEGINNER IN BUSINESS writes: "I have just opened a business here, and a photographer who once had a studio in the place, some time ago, has a large number of negatives, portraits, which he took by the wet-collodion process, and they are all on patent plate glass. He has offered me the lot for the price the glass cost him, but, as there are some thousands of them, they will come to a lot of money. I should like to have your opinion as to whether it would be a good speculation before deciding."—We should say not. As they were taken in the wet-collodion days, they must be something like twenty years old, and fashions in dress have changed greatly in the time, and the sitters, if living, have also changed greatly, and would not be likely to order duplicates from the negatives.

**FIXING COLLODIO-CHLORIDE PRINTS.**—ZETA writes: "Please state your candid opinion as to bodily lifting the whole job lot, 400 prints or more, cabinets and cartes, by the one hand direct out of wash for toning, and holding the same firmly with the other hand, and depositing them as clogged together direct into the hypo bath? They could not be separated singly in a minute, and afterwards returned as usual to complete fixation?"—In reply: If the 400 prints were put in a "lump," sticking together, in the fixing bath, as stated, stains would be the inevitable result from imperfect fixation in parts. The prints should have been put into the hypo solution singly, or in batches of half a dozen or so, and immediately separated and kept in motion while the remainder were similarly dealt with. It is no wonder that the lot were spoilt. It is only what might have been expected under the circumstances.

**STUDIO BUILDING, &c.**—PYRO asks: "My studio, which faces N.N.W., gives too strong a light, although I have white blinds and dark green ones at the side, the green over the white, and white ones at the top, with buff ones underneath. The glass (12 feet) at the top is clear white glass, and at the side it is ground glass. When I have the double set of blinds down, and also a head screen, I have too much light. Would it answer to paint the clear glass with white paint inside? (2) Can you inform me, also, what to use with the spotting colour to give a gloss to the spots, so as to correspond with the remainder of surface when burnished? Would liquid gum mixed with the colour answer the purpose?"—In reply: (1) We see no reason, with such an arrangement of blinds, to make any alteration as regards the glass. The blinds only require to be rightly used to get any kind of lighting required. (2) A solution of gum will answer the purpose well.

**REFLECTIONS IN PLATE-GLASS WINDOWS, &c.**—AMIDOL writes: (1) I am in rather a difficulty to photograph a shop owing to the shops on the opposite side reflecting their wares in the one I have to take. The said shop is very open and dark, being a workshop, and the articles are plainly seen at the back of the shop reflected. What is the best remedy? (2) Is a photographer bound to give a resitting if the sitter disapproves of it, although the photograph is perfect in our estimation?"—In reply: (1) The only course open is to photograph the shop at a time when the sun is at such an angle as not to reflect the shop on the opposite side on the windows. A suitable time for that can, no doubt, be selected. (2) If the photographer, as many do, guarantees satisfactory portraits, certainly he is. Anyhow, a photographer is very unwise, in his own interests, to refuse a resitting for a portrait that is considered unsatisfactory, good though he may consider the photograph to be.

**LENS QUERIES.**—FOCUS writes: "Kindly reply to the following in next week's paper: (1) For a  $\frac{1}{2}$ -plate, if you had a R.R. lens of about six inches focus for interior and confined situations, would you for general instantaneous work (with it I include working under unfavourable conditions of light), and general outdoor work, prefer a R.R. for a  $\frac{1}{2}$ -plate of 9 or 10 inches focus? Should you consider the 10 inch too long a focus, and that its advantage of better covering power is counteracted by the additional inch of focus? My question purely applies to the R.R. combined, and has no reference to the single combinations being used for landscape lenses at present. I do not feel disposed to buy a stigmatic lens working at  $f-6$ , but want the best possible substitute of the R.R. type working at  $f-8$ , and have been strongly advised to buy a lens of 10 inch for a  $\frac{1}{2}$ -plate. Do you think when I have the 6 inch focus R.R. for interiors, &c., that I could do better than get the 10 inch?—In reply: The 10 inch focus lens should certainly cover the  $\frac{1}{2}$ -plate well with its full opening, and therefore is an excellent lens for that size. But it should be borne in mind that a lens of that focal length includes but a very moderate angle on a  $\frac{1}{2}$ -plate.

**LANTERN SLIDES.**—W. C. TURNER writes: "Which process do you think yields the best lantern slides—wet collodion, collodio-bromide, or gelatine lantern plates?"—In reply: That very much depends upon the excellence of the work by the different processes. All are good in skilful hands. Collodio-bromide yields results that are difficult to surpass, but they must be produced by a skilful collodio-bromide worker. One unskilled in either of the processes would doubtless get the best results with the ready-made gelatine lantern plate.

**STUDIO LIGHTING.**—SOMERSET writes: "Enclosed please find a cabinet photograph. Will you kindly suggest how I may improve the lighting of studio? This is 28 feet long, but only 12 feet of the roof at one end and 12 feet at one side are glazed; the roof (or half of it) with clear glass, and the side light with ground glass. I have a set of white blinds at the side, and over these a set of dark green ones. The roof, also, has double blinds; but white and buff instead of white and green. I also use a head screen, and yet I get too much or too strong a light on the face. I may mention that half the roof and the wall opposite the side light are painted a dark green."—In reply: With such a studio and arrangement of blinds, you should be able to get perfect lighting on the sitters. The portrait sent shows that there is far too much direct side light, which makes the picture hard and lacking in half-tone on the lighted side. The lighting is bad generally, but that is not the fault of the studio or the blinds, but the way they are used. As you appear to be somewhat a novice in portraiture, cannot you get some one in your district to give you a few practical lessons in lighting? They would help you much.

**A SHATTERED DREAM.**—"T. M." writes: I have been dabbling in photography for a few years as an amateur, and lately I have started as a professional, thinking my work would please the public; but, alas! my dreams have been shattered. The enclosed is my first effort in group-taking since I started professionally, half a dozen of which were finished and sent, but the old lady of the group will have none of them. She writes to say they are awful things to look at, and will not have them at any price. (She paid 8s. for half a dozen.) I am afraid I have been rather premature in starting as a photographer. This is a bad beginning for me. Still, I fancy I have seen as bad work coming from professionals of long standing. Would it trouble you to say what you really think of the photo? Your verdict will mean a great deal to me one way or the other. I may say the photos were nicely mounted, and looked all right.—In reply: Although we think that the work is perhaps too well paid for at sixteen shillings the dozen, it is fairly good. Hundreds of professional men do far worse and yet seem to thrive. Do not be discouraged because at your first attempt you have not pleased a lady sitter. You must flatter the fair sex if you wish to succeed as a professional photographer.

**COPYRIGHT.**—B. G. writes us concerning a photograph which he took of the storm on the night of Friday last. "On Saturday morning I took these photos, and had them in the shop for sale in the afternoon. The local correspondent of a newspaper bought one, and they have published copies of my photograph, with slight alteration, in the editions of their paper to-day without asking my permission. They have not had the decency to put my name to it, or to say in any way that it was done by me. There has been such a rush for their paper to-day on account of this photo that a copy could not be obtained at 11 o'clock. Have I any remedy against them, as I think it a glaring infringement of my copyright? It is very hard after one works hard to get such things as these out to be served in such a contemptible way."—In reply: (1) The case stands thus: If the photographs were registered before the piracy you would have a clear case for infringement, and you could recover a very handsome sum. As they were not registered before the reproduction, your success in an action would be doubtful. Were we in your place, however, we should feel inclined to proceed, as we believe that in the circumstances of the case the Courts would impose heavy penalties. Better consult a solicitor conversant with copyright law and practice.

**BLISTERS ON BROMIDE PRINTS.**—"BLISTERS" writes: "I shall esteem it a great favour if you can enlighten me on the following: (1) Cause of blisters on the enclosed print. It is developed with hydroquinone (Ilford formulae). It sometimes appears in first washing, and sometimes in fixing, but it does not always appear, just in a batch now and again, but developer used for same stock solutions. (2) Can you let me know the best way to imitate snow on a negative? (3) In using the phosphate toning bath—i.e., 30 grains phosphate, 20 ounces of water, 1 grain gold—and it is made up about one hour before use—sometimes this bleaches a great deal, and sometimes hardly at all; can you account for this?"—In reply: (1) As the blisters do not always appear it is clear that they are not due to the paper, or the developer, but to the manipulation. The only suggestion we can make is to use all the solutions at an uniform temperature. If that is always done, no doubt, there will be no further trouble. (2) We imagine you mean falling snow before the sitter. If so, splash the negative with a pigment, say, by touching the ends of a hard brush, like a tooth brush, on the paint, and then spraying it on the negative by passing the finger over the bristles. Or the paint may, if made thin, be projected on to it by a scent sprayer. (3) If the bath be made under uniform conditions, and used under such, its action will always be uniform, and it will not reduce more at one time than at others.

### EX CATHEDRĀ.

WE are asked to announce that the Traill Taylor Memorial Lecture will be delivered on Friday evening next, November 16, at the rooms of the Royal Photographic Society, 66, Russell-square, W.C. The lecturer will be Mr. Frederic E. Ives, who has chosen for his subject "The Optics of Trichromatic Photography." Admission will be free to the meeting, which is timed for eight o'clock, and the President of the Society, Mr. T. R. Dallmeyer, has kindly consented to take the chair. The choice of a lecturer is an exceedingly happy one. For over 20 years Mr. Ives has devoted himself to the study of three-colour heliochromy, and as far back as the year 1888 he publicly exhibited transparencies by the system which bears his name. His recent introduction of that ingenious instrument, the Kromskop, wherein one sees the coloured images in stereoscopic relief, will be readily recalled by our readers. To Ives is due the credit of having successfully applied the colour-vision theory of Young and Helmholtz and the colour-sensation theory of Professor J. Clerk Maxwell to the production of natural colour transparencies. Upon the main subject

his writings and experiments have been exhaustive. The Franklin Institute has awarded him its gold medal for his work, which has, so far, not met with the recognition in this country which it manifestly deserves. We trust Mr. Ives will have a large and appreciative audience next Friday evening.

REFERRING to a recently published book entitled, "The Work of War Artists in South Africa," which consists of a selection of pictures produced by the several artists attached to the illustrated papers, the writer of the Art Notes in the "Pall Mall Gazette"—who, by the way, is responsible for the illustrations in the handsomely produced "Pall Mall Magazine," and has just been appointed its editor—makes some allusions to the work of the photographers on the battlefield. This subject has already been fairly dealt with in this JOURNAL, and readers may remember that some remarks by the same writer in the same paper (the "Pall Mall Gazette") were quoted in the early part of the year. However, as the subject is of considerable interest, it may not be necessary to apologise for again referring to it. The writer referred to says: "The South African war has opened a new chapter in the history of the war artist. For the first time he has come directly into competition with the camera. In Greece and Cuba the photographer was not unknown, but the conditions of the battlefield did not give him the opportunities afforded by the veldt and the widely scattered incidents of the Transvaal campaign. Unquestionably, the camera has to be reckoned with in future, not as a rival, but as a corrective and assistant of the artist. . . . One point stands out distinctly from this interesting collection. A photograph even of a hotly-contested field is the tamest affair imaginable. The lens, gaping to the horizon, has no power of selection, and loses the heated moment of the battle in the vast spaces of unoccupied ground. On the other hand, it has had a wholesome influence in taking out of the picture much of the melodrama. . . . The influence of the photograph has been all for the good of art, although it has enormously increased the labours of the artist, and once more the foolish ones who

imagined that in future the photographer would hold the field alone are out of court." We have never been among those who have assumed that in the immediate future there would be no need of the war artist. For one reason, there must be many critical engagements when neither the photographer nor the artist could be eye-witnesses. The photographer could do nothing, whereas the artist would produce a vivid picture from verbal descriptions and rough sketches furnished by the actual participants.

\* \* \*

No one is more aware of the limitations of photography than the photographer himself; but it is a moot point whether the artist or the photographer has scored most during the South African war. Indeed, on this point, it might be interesting to give the opinion of the writer of the "Pall Mall Gazette's" art notes, published in that paper on January 31 of the present year. He then wrote: "I would like to say that the artists score off the photographer, but they do not. The public want the facts as near as may be, and are too deeply stirred to be put off with melodrama." He also wrote: "Now, in the uncompromising craze of the day for reality, the photographer has gone to the front—into the fire zone even—and the result, *if not so imaginative*, is vastly more interesting." The italics are ours. Formerly, not infrequently, actuality was sacrificed for art's sake. It would be impossible to say how many excellent pictures have been drawn from small snapshot photographs; and it would be churlish and unjust for any artist to deny that the camera man has done much—probably more than the artist—to bring home to us the grimness and the tragedy of war during the South African operations. Some of the artists, Rene Bull, for instance, have done excellent work with their cameras. Probably the latest photographs of Prince Christian Victor were taken by this skilful draughtsman.

\* \* \*

CONSIDERING the great beauty of the results possible of achievement by utilising silk as a printing medium in photography, it seems strange that this and other kindred materials are not more largely employed. With the uninitiated, no doubt, there is an opinion that to produce photographs on silk means the employment of some peculiar process which differs entirely from that of ordinary printing on paper, and even among a large number of amateur workers a belief exists that, although printing upon such mediums is quite a practical thing in photography, it is much too difficult for any one who has not some special knowledge in this particular branch of work. It need hardly be said that both of these opinions are erroneous, the fact being that to print any suitable negative on a silken support is one of the easiest of all photographic printing operations. No doubt the stumbling-block, with those who consider the work beyond their capabilities, lies in the fact that sensitised silk is not generally kept in stock by photographic dealers. Therefore the moment they come to face the alternative of sensitising their own material, they sweep away all thoughts of utilising this beautiful fabric for printing their negatives. From time to time a few enterprising firms have struck out a fresh departure in this line of business, and not long ago a most excellent quality of silken fabric was placed upon the market in a ready-sensitised condition. A few dealers here and there at the time brought this material under the

notice of their customers, but, like many another good thing, the venture did not apparently meet the support it deserved.

\* \* \*

A YOUNG lady who has learned to appreciate the pleasure of printing on silken fabrics came to us the other day and said, "I've got my eye on auntie's silk blouse; wouldn't it be just the thing for printing a few photographs on? The summer is nearly over, and she will be having a new one next year." So in time auntie was wheedled out of her blouse, and we were wheedled into providing a few suitable half-plate negatives. The scissors were soon at work, ripping open the seams of the silken article, and in less time than it takes us to pen these lines quite a number of lovely silken panels were produced that are intended to adorn a stall in a bazaar during the winter. How was this accomplished? The blouse in question was made out of what is termed washing silk; this material is particularly well suited to photography; it can easily be detected from other qualities of silk by placing a small portion in a little cold water, when it at once assumes a hard, horny appearance. It has a brilliant lustre when dry, and will, with careful rubbing, stand washing with soap and water. After washing, an old sample is wrung out and dried and ironed in a damp condition, when it will look as good as new. In this state it is ready for being salted. Nothing can be simpler than this operation. Take a pinch of salt in, say, half a teaspoonful of water, and when dissolved pour it into a flat dish, immerse the silk in this for a few seconds, and dry before a fire. To prepare the sensitising solution is also so ridiculously easy an operation as to cause any one to laugh when they see it done. Dissolve 60 grains of nitrate of silver in about 1½ ounces of water. Place the same at an open window in a small white glass bottle, or in the sun, for a day or so. In a short time it will begin to discolour and throw down a dirty deposit (the organic matter present in the water). When it again becomes clear and bright it is ready for use. To sensitise, place in a flat dish. Say, for a quarter-plate size, of material about half a teaspoonful or less of the silver solution, and immerse the salted silk, or rather let the silk saturate itself with the silver solution. When equally saturated all over, dry again before an ordinary fire, and repeat this operation once, holding it from the opposite side during the second drying. If this is done fairly quickly in a room which is not too brightly lighted there will be no injury from the light, but it is well, if possible, to close the shutters, or use a room with gaslight. When dry the silk is ready for the printing frames.

\* \* \*

As to toning, some workers seldom tone at all. Let the printing be carried deeply, and then when the pictures come from the frames they receive a good washing in several changes of water, and are placed straightway into the hypo fixing bath. The whole operation is so easy, and so rapidly performed, as to cause surprise to those who have never seen it done. In some books of instructions the addition of gelatine or other similar matter for the salting solution is recommended, but on textile fabric working some photographers of our acquaintance got along best by using nothing but plain salt and water; and, seeing that the sensitising of a piece of silk can be accomplished in a couple of minute of time, it is not advisable or necessary to so prepare the nitrate of silver solution as will allow of the sensi-

tised silk being kept for any length of time before being used in the printing frames. Another great charm about pictures on silken fabrics will be found in the suitability of the colour to the nature of the subject. Moonlight effects are produced by using suitable negatives, and warm, rosy tints can be selected to suit other class of subjects. Any lady or gentleman who once takes to this class of work will not be long before he or she gets quite enthusiastic over it. Beginners should rest content with small sizes to start with; lantern plate negatives or quarter-plates are quite large enough, and with these sizes ordinary silken close texture materials are very suitable to employ. After a time larger sizes may occupy attention.

\* \* \*

THE printing of large photographs on silk (sizes, say, 12×10 or 15×12) is quite a different matter from manipulating tiny quarter-plate; and then provision has to be made for stretching the fabric, so that it lies flat in the frames. This is best done by stretching it to a sheet of cardboard, so that it will be sure to occupy the exact same place after being inspected during printing. For such large sizes a ribbed quality of material is perhaps the most suitable to employ. The material known as Bengaline is among the most useful samples. In selecting negatives for printing on silk, it will be found that bold, vigorous printers will throw the best pictures. Poor, thin negatives, in fact, are quite useless for this purpose, and the work should not be attempted with their aid. In printing of this description it will be found that much beauty is added at times by the employment of masks. This permits of a clear margin when desired all around the picture, and in some instances this is of value, for it must be borne in mind that, as a general rule, these pictures have eventually to be attached by means of needle and thread to their intended supports. For very small sizes, lantern masks do nicely; for other larger sizes, any photographic dealer will supply truly cut-out masks up to whole-plate size, and ovals, domes, or cushions can be selected according to the nature of the work the picture is intended for.

#### ACCURACY IN FOCUSING.

THAT accuracy in focussing is of the utmost importance in most branches of photography is well known to the merest tyro. Intimately associated with the operation is the nature of the apparatus employed. In landscape work the provision generally made in the shape of a sheet of fine ground glass, as supplied with ordinary cameras, suits the purpose well enough. Some experienced landscapists perform the operation in a rough and ready manner by marking on the baseboard of their cameras a series of lines, corresponding to the lenses they employ, and seldom resort to a close scrutiny of the image by means of a magnifier. Such a method of working, however, is out of the question in many branches of photography, where the utmost care is required to get the image in good focus. In portraiture we have a striking instance of the necessity of rendering aid to a lens by the adoption of a particular form of camera, which enables an operator to bring into a focus the varying planes of the sitter's image on the ground glass. As is well known, this is accomplished in first-class studios by introducing a certain amount of diffusion of focus in the lens by separating the back elements more or less, and in using the lens so

prepared, in conjunction with a special movable back in the camera that permits of the finest adjustments at top and bottom and both sides, by means of screw movements.

It is not only, however, in portraiture that we see special provision made in respect of focussing. We see the same thing necessary also in microscopy, and in some of what may be termed the higher branches of work, among which may be mentioned combination printing through the camera, and again, in a still more equally popular branch, the production of the sharpest possible images of negatives intended for projection by means of an optical lantern. In much work of this class, the ordinary ground glass of a landscape camera, and an ordinary double dark slide for exposing a sensitive plate, it may be said do not provide a sufficiently accurate means for focussing an image. No doubt camera-makers, as a rule, turn out their focussing screens as nearly as possible in a true plane with the rebates of their double dark slides; and, to enable a fair amount of nicety being arrived at, even in microscopic work with low powers, perhaps no better plan was ever suggested and given to the public than that of the late J. Traill Taylor, who, whenever an ordinary camera was employed in conjunction with a low power in microscopic work, advised having recourse to a very simple little dodge, in so doctoring the ground glass of a camera as to enable the finest degree of focussing to be performed by its aid, and this idea of Mr. Taylor's has been carried into effect by one or two of our very best camera-makers. It consists of having in the centre of the screen a small disc or circle of plane glass, and it may be remarked that this is easily added to any ground glass screen by drawing two lines from each corner of the focussing screen, so that they cross exactly in the centre. At the point where these lines cross, an ordinary microscopic cover-glass is cemented by means of a drop of Canada balsam, and when dry this will permit of the utmost degree of sharpness in focussing being performed, provided the dark cells are working true to the plane of the screen.

It is in this latter respect, however, that many outfits fall short, and where the utmost exactitude is required a double form of dark slide is not to be compared with a wet plate slide; the mere construction of the double form, very often with their protection plates a fixture, being quite unsuitable where delicate work has to be performed. A single wet plate form of slide (so seldom seen by amateurs nowadays) has many extremely good points in its construction. First, we have the folding door at the back, by means of which, when the shutter is drawn, any one can look right through from back to front of the camera. By this means much indoor work can be performed without ever removing the slide from the camera, and a focussing screen in the camera is actually not required for studio work of some kinds; whilst in the field, such a form of slide, when used in conjunction with a changing bag, will permit of plates being changed in a second or two with the greatest of ease, and it has often been a matter of surprise to us that some of our enterprising manufacturers have never made a speciality of pushing a slide of this description in conjunction with a changing bag. In indoor work, however, the great advantage of a wet plate slide lies in the fact that it provides a ready means for any one making certain that the image is in true focus; and, indeed, in combination work where such extreme nicety is required in registering one part of a picture to that of another, a slide of this descrip-

tion is absolutely indispensable. Take, for instance, the case of printing a combination lantern slide from two or more negatives. To perform an operation of this kind with a double form of dark slide would mean the withdrawal of the slide at least two or three times, and where such extreme accuracy is necessary so as to avoid even the semblance of overlapping (for it must be remembered such pictures have to be eventually magnified to an enormous extent on the screen), it is next to an impossibility to secure such accuracy when once a slide has been withdrawn to refocus and adjust another negative. How different, however, with a wet plate form of slide, which enables an operator to do the work and make as many exposures as he likes without ever withdrawing the slide at all. To accomplish this, by closing the shutters of his dark room, he can open the back door of his slide, and, by the aid of any simple little means he chooses to adopt for correctly registering the focussing screen and the sensitive plate, by merely pressing with the finger the ground glass tightly into the lower left-hand bottom corner, and doing the same with the plate he is exposing, make absolutely certain that the plate occupies the exact place desired. Of course, where such extremely delicate work has to be performed, some means has to be provided for marking the ground glass in the rebate of the dark slide at those parts where a junction of images has to be made. Sometimes ordinary ground glass will be found too coarse for this purpose, and then a piece of plane glass can be used instead, and the utmost nicety of focussing be performed with its aid also.

In microscopic work, again, a wet plate form of slide will prove invaluable in focussing with the aid of an ordinary eyepiece and low power objectives. One of the best methods adopted in microscopic work, when performed with what may be termed a practical home-made form of apparatus, consisting of a Zeiss microscope and whole-plate camera, padded well up on innumerable thicknesses of sheets of paper to prevent vibration, lies in employing a thin board of wood which corresponds to the ordinary thickness of the focussing screen. This sheet of wood has an aperture cut out exactly in its centre with a brace and bit seven-eighths of an inch in diameter. After the image has been roughly focussed on the ordinary ground glass, and the size required finally decided upon, the glass focussing screen is removed, the sheet of wood with its cut out aperture made to take its place in the wet plate slide. An eyepiece belonging to the microscope is now inserted in the cut out aperture. The camera by this means, after the microscope is inserted in its proper position in the front, becomes practically a draw tube added to the microscope, and then the enlarged image is focussed just as if the same were being done in the ordinary manner by means of the instruments without the camera. By this means those who have never performed their focussing without difficulty will be surprised at the ease with which they can secure accuracy. Of course, when this method of working is employed, all adjustments must be made with the microscope screw; the tail of the camera must not be altered.

Among the more practical branches of photography, where accurate focussing also plays a very important part, is that of enlarging. Here, again, we see the need of some special provision being made for making the most of a negative that is capable of being enlarged. In daylight enlarging there is no doubt much comfort in working with a lens of

large angular aperture, such as the Petzval Portrait Combination, for often in dull days, where the density of the negative and extent of enlargement are such as make it a difficult matter to see the enlarged image clearly, the utmost amount of light possible must be projected through the lens, which can be stopped down eventually during exposure of the sensitive material; and here, again, by adopting a system somewhat analogous to that already referred to by means of a wet slide, the utmost exactitude can be secured, for when a portrait combination is employed, and the easel has a small cut out aperture into which a sheet of the finest oiled ground glass, or even a sheet of plain glass, the focussing is finally performed with a certainty that the most has been made out of the negative. When working at very close quarters on such subjects as flowers and plants, it is often a matter of the greatest difficulty to bring those arranged at the rear in a fairly equal focus to those in the front. One dodge is to do this kind of work by means of a mirror, and, if the disposition of the mirror to the object is such as it ought to be, the double surface image objection to the use of mirrors, which we hear so much about at times, will be unnoticeable to nine out of ten observers.

---

**Carriage of Gas Cylinders.**—The lantern season is now on, and many are now interested in knowing how they are to get their supply of oxygen in cylinders, for the railway companies do not appear as yet to have relaxed any of their restrictions with regard to their conveyance. We note that the District Railway have reposted their notices to the effect that cylinders of compressed gases will not be conveyed as passengers' luggage or otherwise, nor will the cylinders be allowed on the Company's premises under any conditions whatever. When reading the notice we could not help speculating as to whether the Company did not very frequently convey cylinder of compressed gas as personal luggage? We can answer for it that they have done so, and possibly will do so many times again. One or a couple of two-foot cylinders will go very well in a leather Gladstone-bag which is easily carried in the hand, and the railway company be none the wiser. It would probably be wiser, perhaps, if they permitted the cylinders to be conveyed openly in the luggage van, for, if there were any danger in the carriage of them, there would be more safety there than amongst passengers. Of course there is no danger at all with them, owing to the precautions now taken by the compressors. The difficulty of the conveyance of gases it may be mentioned, is overcome to a great extent by the manufacturers, for they are fully aware of the restrictions, and the conditions of the different railway and carrying companies, and conform to them. Therefore any one ordering need have no anxiety as to the receipt of what he requires. But, as a bit of advice, we should recommend that the gas be ordered some days before it is actually required for use, in order to ensure its being received in time, because, owing to stupid restrictions, it may be delayed in transit. What is more vexing than that, at the time fixed for a lecture or entertainment, the gas has not arrived?

---

**The Approaching Star Shower.**—At the meeting of the British Astronomical Association, last week, Dr. Downing said that, in conjunction with Dr. Stoney, he had been engaged upon computing the perturbation to which the swarm of Leonids had been subject during the last revolution in their orbit, viz., in the last thirty-three years. These investigations, he said, were with special reference to the approaching shower, if we have one. It will be remembered that last November a very brilliant display of the Leonids was expected, and many prepared to photograph them, but they did not arrive. It was then said by astronomers that they would probably be seen this year. Dr. Downing does not seem to be

ery sanguine, however, that they will, but advises that a watch should be kept for them on the nights of the 13th, 14th, and 15th. The most probable time to see the display will be about three a.m. on the 15th. If the missing shower of last year should turn up this, there is a better chance of seeing and photographing it than there was then. Last year, at the time it should have arrived, the moon was at about its full. This year it will have passed its last quarter, so that photographers will have a better chance, if they put in an appearance, than they would have done if they had arrived at the computed time last year. Anyhow, as the really brilliant display of the Leonids only occurs every thirty years, those interested in photographing them should be prepared on the nights mentioned to catch them as they pass.

**The Great Explosion in New York.**—The City of New York has been the scene of a terrific explosion which, in its force and disastrous effects, seems to have been somewhat like that which occurred at St. Helen's not long back. At present the cause of the explosion appears shrouded in mystery. One account says it was due to a barrel of turpentine and fifty pounds of collodion exploding. Now, neither turpentine nor collodion would explode, they would take fire and burn, the latter with great violence. The vapour from either, however, would explode if mixed with a certain proportion of air, the collodion with more violence than the turpentine, but we doubt if with sufficient force to cause all the damage that resulted. A later account says that large quantities of chlorate of potash and sulphur were stored on the premises. It will be remembered that the explosion at St. Helen's was due to chlorate of potash, though, up to that time, it was thought that that material, by itself, was perfectly harmless, even when subjected to great heat. But it was proved by experts that under certain conditions it was a dangerous explosive. A mixture of chlorate of potash and sulphur, we all know, is highly explosive, but it is scarcely likely that these materials would be kept mixed in any warehouse. So, up to the present, the actual cause of the disaster has not been determined.

**Abolishing the Studio.**—A regular contributor to one of the leading illustrated weeklies recently suggested that it was high time that the professional photographer's orthodox studio was abolished. In his opinion, the portrait obtained as the result of a formal sitting in a studio did not come up to, in point of naturalness, that obtained from an enlarged snap-shot, taken unbeknown to the person, and he suggests that methods should be adopted to secure more naturalness in expression and pose. Similar suggestions have, of course, been made before; and professionals will probably themselves admit that many of their most successful portraits have been the result of an exposure made when the sitter has had his attention momentarily diverted from the matter in hand. The knowledge that they are being photographed is to many people disconcerting; but one would not care to argue from this that the studios should give place to an open-air garden or a brilliantly lighted room in which several assistants, armed with hand cameras, are secreted ready to snap the unsuspecting person as he enters, this being the method proposed to secure a more lifelike and natural expression. From the several snap-shots taken, enlargements are to be made, and one or two of the most pleasing finally selected. This scheme may have its advantages, but it could hardly be recommended on the score of economy. Not infrequently an amateur succeeds in securing a portrait, taken in homely surroundings, which, though possibly technically inferior, has some attractions which the professional photograph taken in the orthodox studio does not always possess. But this particular picture which pleases may be one of many the majority of which may be anything but satisfactory. The average professional has to obtain, or is expected to obtain, a satisfactory portrait at a minimum cost, and he cannot afford to experiment with his sitter. Theoretically, perhaps, he should not require or desire to.

## MARIOTYPE: A CARBON PROCESS WITHOUT TRANSFER.

THE Mariotype process is probably unknown, even in name, to the greater number of modern photographers. It is a modified carbon process in which the image is a visible one and is not reversed, so that no second transfer is required to make it correct as regards right and left. In this process a very interesting principle is involved. It is now pretty generally understood by every one that the action of light once started in a bichromated gelatine film, such as carbon tissue, continues to progress after it is removed from the light and kept in perfect darkness. The action set up by the light on the surface seems to penetrate deeper and deeper into the gelatine, thus rendering a thicker layer of it insoluble than would exist if pictures were developed directly it was removed from the negative. It is for this reason that carbon prints, unless they are developed soon after they are printed, will turn out darker than they were intended to be. Therefore allowance has to be made for that by printing them lighter in the first instance if they have to be kept for any length of time.

As an illustration of this fact, a print may receive but a third of the exposure that would have been required if it were developed at once, yet, by keeping it long enough, it may be developed as a fully printed picture; or, by still longer keeping, an over-exposed one. The time this will take will vary according to circumstances. It may take six, twelve, twenty-four, thirty-six or more hours, or it may take much less than even six hours. Under other conditions the prints may be kept for many months without any change whatever. The presence or absence of moisture in the tissue is the governing factor.

For example, if prints after exposure be thoroughly desiccated, and kept so by being sealed up in an air-tight metal or glass tube, they will remain unchanged for months, both as regards their depth and the solubility of the tissue. I have kept exposed prints under these conditions for six months, and, although only half printed when put away, they had gained nothing in depth by the long keeping, and the tissue was as soluble as it was at first. On the other hand, if the partly exposed pictures—say one fourth the normal—are kept in a moist atmosphere, at a warm temperature, 75° F. for example, they can be developed in an hour and a half or so as fully printed pictures, or, if kept an hour or so longer, they will prove very much over-printed, possibly quite ruined. The reason why I refer to this here is that what is to be described later on may the better be understood.

This continuing, or "continuing action of light," as it is usually termed, was well known to the very earliest workers of the carbon process, indeed it would have been impossible for any observant worker not to have been cognisant of it. But at that period it was not known that the action of light set up in one bichromated film could be communicated to, and continued in another one that had not been exposed at all, by its being merely kept in close contact with it for a certain time.

It was the late M. A. Marion, the founder of the well-known house of Marion & Co., Soho-square, who first demonstrated this fact, and worked out a practical process based upon it. The process he named "Mariotype," and he described and demonstrated it before the London—now the Royal Photographic Society—in 1873. M. Marion's process was this. He took paper thinly gelatinised, but in the paper which he read before the Society he said that it would be better to have it albumenised, warped, and gelatinised. I am now quoting from that paper, which was published on page 242 of the JOURNAL for 1873. The prepared paper is floated on a six per cent. solution of bichromate of potash, to which a "little" sulphuric acid has been added, for about a minute, and dried. It is then ready for printing. It is exposed under the negative until the details of the picture are fully out. Then a piece of unsensitised carbon tissue is taken and immersed in a two per cent. solution of bichromate of potash till softened. It is then squeegeed on the printed picture, in the same way as ordinary exposed carbon tissue is mounted upon the support prior to development. Then it is placed between blotting-paper, under pressure, to prevent its drying, for from eight to ten hours. It is better, M. Marion told us, to deal with a number of prints at a time, so that they could be stacked one on the other, and thus more effectually prevent their drying. Under these conditions the

continuation of the solarisation goes on by transmission to the tissue, for, when it comes to be developed, it is found to be fully printed.

After the prints have rested for the necessary time—and more recent knowledge tells us that that is largely dependent upon the temperature at which they are kept—the prints are put into warm water at a temperature of from 40° to 50° C., say 105° to 120° F., when after a short time, the back of the tissue can be stripped off and the print developed exactly as in case of an ordinary carbon picture. Now, it will be seen that with this process we have a visible image to begin with, which is a guide to the right exposure, and, as the print is a direct one, a reversed negative or a second transfer, is not required to have the picture correct as regards right and left. Such is the process of the late M. Marión.

At the time it was published I made some experiments with the process, and satisfied myself that it was a perfectly practicable one but, as it did not seem to me to offer any real advantages over the ordinary carbon process for every-day work, I did not proceed further with them. Having recently, as a matter of business, had to make some researches in connexion with bichromated gelatine processes, in which the continuing action of light is indirectly concerned, I was led to give some attention to the Mariotype process, and I found that, by a very slight modification of it, the time of keeping the prints after the tissue is applied could be considerably curtailed. From eight to ten hours it can be reduced to from an hour and a half to three hours, or less, according to temperature. Instead of sensitising the paper on a six per cent. solution of bichromate of potash containing sulphuric acid, I have employed one of greater strength (seven and a half per cent.), and in a neutral or alkaline condition. The solution used for mounting the tissue on the exposed paper is also a little stronger, and is acidified. For the benefit of those who may be sufficiently interested in the process to experiment with it I here subjoin the formulæ and method that has worked well in my hands, as it may save them some time at the beginning.

Any good paper that will stand soaking in warm water can be used. That I have employed is a Steinbach paper, such as is used for bromide and similar papers. It is coated with a warm two per cent. solution of gelatine. The gelatine I employed was Creutz's "soft." The simplest way of coating the paper is by floating in on the solution for a few seconds, then it is hung up to dry. When dry it is ready for sensitising. The bath I found to answer well is as follows:—

Water ..... 1 litre.  
 Bichromate of potash ..... 75 grammes.  
 Liquor ammoniæ about ..... 5 c. c.

Or

Water ..... 40 ounces.  
 Bichromate of potash ..... 3 "  
 Liquor ammoniæ about..... 3 drachms.

An excess of the ammonia does no harm, as it flies off as the paper dries. The paper is sensitised by floating it on the solution for a couple of minutes or so. It is then hung up to dry, in the dark of course, when it is ready for printing. The negatives I have found most suitable are those of medium density and contrasts, although there is some scope for ameliorating or increasing the contrasts, as I shall point out presently. The printing should be carried sufficiently deep for all the details in the lighter portions of the picture to be distinctly seen, the image being brown over pale lemon-coloured ground. The printing will take a somewhat longer time than is the case in the usual carbon process. When printed, a piece of carbon tissue (unsensitised) is taken and immersed in the acid solution of bichromate of potash. The following I have found suitable:—

Water ..... 1 litre.  
 Bichromate of potash ..... 25 grammes.  
 Acetic acid (glacial) ..... 35 c. c.

Or

Water ..... 40 ounces.  
 Bichromate of potash ..... 1 ounce.  
 Acetic acid (glacial) ..... 10 drachms.

As soon as the tissue has softened (but not so much as is usual in mounting exposed carbon tissue on its support) a print is slipped under it, in the solution, and the two removed and well squeezed together. It is then put under pressure between two glass plates to prevent its drying. Where a number of prints are dealt with at a time, they are, of course, placed one on the other between the glasses, and are thus prevented from drying, for they must be kept with a certain amount of moisture in them. They are then kept in this condition for the required time, which may be from one and a half to three hours, or more, according to the temperature. The warmer it is the more rapid is the continuing action, and the longer the prints are left the darker they will become. If they are left much too long, they will be difficult to develop and will require very hot water.

When it is judged that the continuing action has been sufficiently long, the prints are soaked in cold water, with two or three changes, for about half an hour, to get rid of most of the free bichromates. That, however, is not necessary, but I have done it for the reason that my skin is, unfortunately, somewhat sensitive to the bichromate. The prints are put into warm water at a temperature of from 110° to 115° F. when, after a short time, the paper backing of the tissue can be stripped off and the development proceeded with just as in the usual method of carbon working, by washing away the unaltered pigmented gelatine. When sufficiently developed, the prints are washed in cold water and then put into the ordinary five per cent. alum solution till all traces of the bichromate are removed; the pictures are then finished.

If the backing of the tissue does not strip off easily after the prints have been soaking in the warm water for five or six minutes, the temperature of it should be increased, and if it does not then strip it is an indication that the time of keeping has been overdone. The prints may, possibly, yet be saved by removing them from the warm water to cold, to which has been added a little liquor ammonia, and allowing them to remain in that for about a quarter of an hour or longer. They may then be replaced in warm water, when they will probably develop quite freely.

Just now I said that there was scope for enhancing, or ameliorating, contrasts in the prints. If there are too strong contrasts in the negatives, the prints should be somewhat strongly printed in the first instance, and the time of keeping after mounting curtailed. If, on the other hand, the negative is weak and flat, the print should be more lightly printed, and a longer time allowed for the continuing action, as that has a tendency, by going more deeply into the pigmented gelatine, to increase contrasts.

In the foregoing I have given the formulæ and method that has worked satisfactorily in my hands, but I do not pretend to say they are the best. The best can only be arrived at by a long series of tentative and exhaustive experiments, which my time will not permit of at present, particularly as this modification offers no special advantages to me, at least, over the ordinary carbon process with which I am quite *au fait*. The process may, however, be useful to some, inasmuch as there is a visible image as a guide to exposure, and, as the print is a direct one, there is no reversal of the image, and consequently no retransfer to get it the right way about. From a scientific point of view, however, Mariotype is a very interesting process, as illustrating how the action of light, set up in one bichromated gelatine film, can be transmitted to a second one that has not been exposed to it in any way, and the same results obtained as if it were.

I should mention that the tissue I have employed has been the ordinary commercial tissue as supplied by the Autotype Company and others; but, from my knowledge of the carbon process, I should say that such is not the most suitable for Mariotype. One containing more pigment and a larger proportion of sugar in its composition would, I think, be preferable. That, however, is but conjecture, as I have not had time to make a tissue specially for the purpose, so as to speak positively on the subject.

E. W. FOXLEE.

NOTES ON THE DEVELOPMENT OF INTERFERENCE PHOTOCROMY.

III.—LORD RAYLEIGH (1887) AND OTTO WIENER (1889).

IN a paper "On maintained vibrations," \* Lord Rayleigh had briefly treated a subject to which his attention was recalled by Glaisher's Address to the Astronomical Society, † in which was an account of the treatment of mathematically similar questions in the Lunar Theory, by Hill ‡ and by Professor Adams. § Though Hill's analysis was in many respects "incomparably more complete" than Rayleigh's, yet Hill's "devotion to the Lunar Theory" led him to pass by many points of great interest which arise when his results are applied to other physical questions. In a paper, dated June 19, 1887, "On the Maintenance of Vibration by Forces of Double Frequency, and on the Propagation of Waves through a Medium endowed with a Periodic Structure," || Lord Rayleigh took up the question again.

The equation of motion of the vibrating body may be put into the form:—

$$(1.) \quad \frac{d^2w}{dt^2} + 2k \frac{dw}{dt} + (\theta_0 + 2\theta_1 \cos 2t)w = 0$$

Hill's method was applied to this equation, and, besides, it was shown that the same method is applicable when the co-efficients of

$\frac{d^2w}{dt^2}$  and  $\frac{dw}{dt}$ , as well as of  $w$ , are subject to given periodic variations.¶

We may write—

$$\Phi \frac{d^2w}{dt^2} + \Psi \frac{dw}{dt} + \Theta w = 0,$$

where

$$\Phi = \sum \Phi_n e^{2int}, \quad \Psi = \sum \Psi_n e^{2int}, \quad \Theta = \sum \Theta_n e^{2int}.$$

Assuming  $w = \sum_n b_n e^{ict + 2int}$ , we obtain, on substitution, as the co-efficient of  $e^{ict + 2int}$ :

$$(2.) \quad -\sum_n b_n (c + 2n)^2 \Phi_{m-n} - i \sum_n b_n (c + 2n) \Psi_{m-n} + \sum b_n \Theta_{m-n}$$

which is to be equated to zero. The equation for  $c$  may still be written  $\Delta(c) = 0$  (a determinant analogous to that introduced by Hill in the same notation). Some special cases were then considered, and an application made to a stretched string which is periodically loaded and which propagates transverse vibrations.\*\*

"One of the most interesting applications of the foregoing analysis is to the case of a laminated medium in which the mechanical properties are periodic functions of one of the co-ordinates. I was led to the consideration of this problem in connexion with the theory of the colours of thin plates. It is known that old superficially decomposed glass presents reflected tints much brighter, and transmitted tints much purer, than any of which a single transparent film is capable. The laminated structure was proved by Brewster; and it is easy to see how the effect may be produced by the occurrence of nearly similar laminae at nearly equal intervals. Perhaps the simplest case of the kind that can be suggested is that of a stretched string, periodically loaded, and propagating transverse vibrations. We may imagine similar small loads to be disposed at equal intervals. If, then, the wave-length of a train of progressive waves be approximately equal to the double interval between the loads, the partial reflexions from the various loads will all concur in phase, and the result must be a powerful aggregate reflexion, even though the effect of an individual load may be insignificant."

¶ *Loc. cit.*, p. 151.

\*\* *Loc. cit.*, p. 156.

Rayleigh found that a wave travelling in either direction is ultimately totally reflected, and this does not require a special adjustment between the frequency of the waves and the linear period of the lamination; and he finally remarked, in a note:\*

"A detailed experimental examination of various cases in which a laminated structure leads to a powerful but highly selected reflexion would be of value. The most frequent examples are met with in the organic world. It has occurred to me that Becquerel's reproduction of the spectrum in natural colours upon silver plates may perhaps be explicable in this manner. The various parts of the film of subchloride of silver with which the metal is coated may be conceived to be subjected, during exposure, to stationary luminous waves of nearly definite wave-length, the effect of which might be to impress upon the substance a periodic structure, recurring at intervals equal to half the wave-length of the light; just as a sensitive flame, exposed to stationary sonorous waves, is influenced at the loops, but not at the nodes.† In this way the operation of any kind of light would be to produce just such a modification of the film as would cause it to reflect copiously that particular kind of light. I abstain at present from developing this suggestion, in the hope of soon finding an opportunity of making myself experimentally acquainted with the subject."

In this note, after Mascart,‡ the idea of "stationary waves," appears to have been first emitted. Mascart had previously§ attributed this to Wiener, who developed the notion rather more explicitly, and, apparently, independently of Lord Rayleigh. We propose to give an account of Wiener's (1891) memoir.||

The experiments of Hertz¶ on the nodes and loops of electric oscillations before a plane conductor, analogous to the effects of the reflexion of sound on a wall, gave Otto Wiener the idea of seeking if it were possible to show the interferences which should exist between the luminous waves which fall on a mirror and the reflected rays.

Suppose, in a more general manner,\*\* that the mirror is covered with a transparent layer of index  $n$ . For an exterior incidence  $i$ , the incidence  $i'$  on the mirror is  $\sin i = n \sin i'$ ; the 'lag,' (la différence de marche) of the incident and reflected waves at the distance  $e$  from the surface is  $2ne \cos i'$  and the corresponding difference of phase  $\delta = 2\pi \frac{2ne \cos i'}{\lambda} = 4\pi \frac{e \cos i'}{\lambda'}$ , where  $\lambda'$  denotes the wave-length in the layer.

If the primitive vibration is perpendicular to the plane of incidence and of amplitude  $a$ , the amplitude of the reflected vibration is  $ah$ ; calling  $\alpha$  the loss of phase due to reflexion, the vibrations to be compounded are of the form  $a \sin \omega t$  and  $ah \sin (\omega t - \alpha - \delta)$  ( $h$  supposed positive).

The maxima of intensity correspond to the values  $\alpha + \delta = 2m\pi$  and the minima to the intermediate values  $\alpha + \delta = (2m+1)\pi$ . The ratio of the difference of the extreme intensities to that of the maxima is

$$p = \frac{(1+h)^2 - (1-h)^2}{(1+h)^2} = \frac{4h}{(1+h)^2}$$

The common distance  $d$  of two successive maxima or minima is  $\frac{\lambda'}{2 \cos i'}$ ; half this value represents the distance from a minimum to the following maximum. Finally the distance  $d_1$  from the first minimum to the surface is  $\frac{\lambda'}{4 \cos i'} \left(1 - \frac{\alpha}{\pi}\right)$ .

|| "Stehende Lichtwellen und die Schwingungsrichtung polarisirten Lichtes," *Wied., Ann.*, xl. (1890), 203-243; Mascart, ii., § 625 (Interférences des rayons incidents et des rayons réfléchis), 572-577. Wiener's paper was communicated in an extract to the 62. Versammlung deutscher Naturforscher und Aerzte, 1889 (*Tageblatt der Versammlung*, p. 209).

¶ Together with a paper by P. Drude ("Bemerkungen zu der Arbeit des Herrn O. Wiener. . .," *Wied., Ann.*, xli., 154-160), this memoir was noticed in the *Jahrbuch über die Fortsch. der Math.*, 1890, 1033-1036 (*Wangerin*).

\*\* *Wied., Ann.*, xxxiv., 1888, 609. Hertz thus determined the phase-variation due to reflexion of electric vibrations.

\*\* The following investigation is due to Mascart (*loc. cit.*).

When the primitive vibration  $b \sin \omega t$  is in the plane of incidence, the reflected vibration is of the form  $bk \sin (\omega t - \beta - \delta)$ ; it makes with the incident vibration an angle  $2i'$  (if it is counted so that its projection on the surface is in the same sense as that of the incident vibration). Their resultant is elliptic in general and the sum of the squares of the axis is (Mascart, § 163) :—

$$A^2 + B^2 = b^2 [1 + k^2 + 2k \cos 2i' \cos(\beta + \delta)].$$

The maxima and minima correspond to the conditions  $\beta + \delta = 2m\pi$  and  $\beta + \delta = (2m + 1)\pi$ ; the first gives the maxima or the minima as  $\cos 2i'$  is greater or less than 0.

The distance of two successive maxima or minima and their respective distance have the same expressions as before. Finally, the ratio of the difference of the extreme intensities to that of the maxima is :—

$$q = \frac{4k \cos 2i'}{1 + k^2 + 2k \cos 2i'} = \frac{4k \cos 2i'}{(1 + k)^2 - 4 \sin^2 i'}$$

Apart from the rôle of phase losses on the surfaces and the relative intensity of the interfering rays, these conditions are exactly the same as for coloured rings.

For normal incidence, in particular, one must make  $a = \pi$  in Fresnel's theory (at least in what concerns vitreous reflexion), and  $a = 0$  in MacCullagh and Neumann's. The one or the other of these two theories will then be verified according as the surface is a maximum or a minimum.

When the vibrations are normal in the plane of incidence, the interferences can only disappear if the factor  $h$  becomes zero. If they are comprised in the plane of incidence, the interferences vanish, whatever the factor of reflection, for  $\cos 2i' = 0$  or  $i' = 45^\circ$ , i.e., when the incident and reflected rays are perpendicular to one another. For the vibrations to be compounded are then rectangular and the intensity is independent of their phase-difference.

These localised interferences were called "stationary waves" (stehende Wellen), by Wiener. For the experimental details of Wiener's work (which do not any more concern us) we refer to Wiener's paper and Mascart (*op. cit.*, pp. 574-576); for the consequences on Drade (above), and Cornu, Poincaré and Potier (*Compt. Rend.*, cxii., 1891, 186, 365, 383, and 456).

It is interesting to note that Wiener refers \* to Zenker.

"The only one, so far as I have followed the literature of the subject, who has explicitly used standing light-waves for the explanation of certain phenomena, is Zenker. In his book on Photochromy he seeks to explain the reproduction of natural colours with silver chloride by means of standing waves. The objections of Schultz-Sellack † are to my knowledge not yet set on one side. The solution of this question would certainly be of great charm; not less that, in how far standing waves could be made useful for the problem of photography in colours."

PHILIP E. B. JOURDAIN.

Cambridge, October 24.

#### P.O.P. IN INDIA.

I HAVE always thought it a pity that such a beautiful paper as the P.O.P. should be found unworkable by most people during the hot season in India. Amateurs who use only P.O.P. for printing on have, since its introduction, invented a new season, which we never heard of when albumen paper was the only one used, I refer to the photographic season. This season, of course, corresponds with the cold season. For my part I have found the paper perfectly workable all the year round, the paper is fairly durable, the tones which it allows of are exceedingly beautiful, the picture is as permanent as with albumen paper, and any amount of gloss can be obtained in a very simple manner. The reason why we hear so much of P.O.P. troubles is that it is comparatively a new paper, and enough has not yet been written as to how to work it. I hope this article will help to remove most of the difficulties we hear of so often.

1. In India, with the temperature over  $100^\circ\text{F}$ ., the paper often gets bone dry and hard. In this case the roll must be removed from the pasteboard tube, and without manipulating the papers in any way,

\* *Op. cit.*, 205.

† *Pogg. Ann.*, cxliii., 1871, 449.

the roll should be left in a damp room for some days until the roll open out of itself, and the papers become limp enough for working with. have often used by bathroom for the purpose. When the papers have become limp enough, they should be rolled up and kept in a tin tub to prevent them drying again. Of course, the damp room should be darkened before exposing the paper in it.

2. In the rainy season, on the other hand, the paper sometimes get too damp and tacky. In this case the papers should, each one, be once opened out and left to dry in a warm, darkened room. When the tackiness has quite disappeared the papers must be rolled up and kept in a tin tube. In either of the above two cases the paper must not be refused, because the fault is with the climate, and not with either the paper or the dealers. If, however, the paper arrives at all discoloured it must either be refused or thrown away, because it is never satisfactory to work with old discoloured P.O.P. In hot climates P.O.P. discolours faster than in cold.

3. For India and other tropical climates, tin tubes are more suitable than the usual pasteboard ones, but the lid need not be soldered on, an elastic band or waterproof paper round the joint being sufficient. The fumes caused by soldering may perhaps prove injurious to the paper.

4. While cutting up the paper for use the fingers must not touch the gelatine surface, or stains may form. Any wooden, bone, or ivory paper-knife will do for cutting up the paper into the sizes required. A steel knife, which might contain rust, should not be used.

5. The printing must not be carried on in direct sunshine, but under the diffused light from a broad expanse of sky. The printing should be continued until the shadows are buried in obscurity, and the high lights, such as a shirt front, or cuffs, look slightly, yet distinctly gray. Most beginners never print deep enough, and I would recommend such to print a few papers to an extent which they would consider altogether too much, and the chances are that those will turn out the finest and best toned ones of the batch.

6. The quality and tone of the prints always depend chiefly on the character of the negative. A thin over-exposed negative can only yield feeble and badly-toned prints. A negative which cannot show a lamp-post through the densest parts if held up and looked through is made too dense to print well. If the negative be placed on a sheet of pure white foolscap paper the paper should not show pure white in patches, but even in the deepest shadows should look more or less grey. This means that there should not be clear glass anywhere. If the negative answers to the above tests, and looks sparkling and full of life when held up against the sky or other very bright light, it will certainly yield good and nicely toned prints. But there should be no sparkle about the negative if seen through against the white walls of a room or other mildly-lighted object.

7. As this article has no concern with the development of a negative, I will not enter much into that subject, but will just give one hint here which will help the beginner very much. My advice is that you should never once during development remove the negative from the ebonite developing dish in order to hold it up against the lamp to examine it for density. While actually developing a negative no thought whatever should be given to density. We must simply watch the progress of the shadows, viz., the white patches as they appear in the dish, and keep on developing until the whitest patch begins to look greyish and distinctly darker than the white margins of the plate. When this has happened the plate should forthwith be washed. If by this mode of development we find the high lights have turned out too dense, that simply shows that the pyro-soda, or any other developer used, was made too strong, and we should dilute it with half its bulk, or even more, of water, and try again. The density will be probably correct this time, and a fine, good printing negative result. In this way the mode of altering the developer to suit the negative will soon be learnt, so that nothing could be left to chance. The only proper time to think of the density of your negative is when you are making the exposure, and preparing your developer. But when actually engaged in the development of a negative your sole and undivided attention should be given to the sufficient and accurate development of the shadows.

8. The best time for trimming the prints is immediately after taking them out of the printing frames. This will give them clean edges, which will prevent prints tearing and scratching each other in the after processes, and the removal of the black edges will save a lot of gold in the toning bath; if the black edges be left they will eat up all the gold, and leave none for the prints. The trimming should be done in very subdued white light, or preferably yellow light or lamp light, and the trimming shapes could be easily made at home of the exact sizes required out of a sheet of pale yellow glass, with the help of a glazier's diamond.

9. In cold climates the first washing of the prints can be carried out as directed by the makers. The only things to be remembered are that no accidental splashes of water should fall on the prints before actual immersion, and that no prints should be allowed to remain for any length of time in water which the prints have rendered milky. The first few changes of water must therefore be more rapidly made than the last few, as the latter do not get so quickly milky. This first wash must be very thorough, about six changes being sufficient.

10. If, however, as during the hot season in India, the temperature ranges from 90 to 110°F., the above mode of washing would never do, as the gelatine would dissolve in the very first change. Ice must then be employed, and I use it as follows: I arrange five good-sized dishes in a row, the first four containing water, and the fifth a solution of chrome alum of the strength of one grain to each ounce of water. I also have a jug at hand full of water. In all the dishes and in the jug I put lumps of ice, sufficient to bring the temperature down to below 60°F. I then pass the prints through all the dishes until the fifth is reached. The water in the first dish is thrown away, as it gets milky, and is replaced by the cold water in the jug from time to time. Whilst I attend to the first dish, an assistant attends to the prints in the other dishes, and keeps them constantly moving about. The prints are gathered together in the water, the whole lot of them lifted out together and dropped into the next dish, and there separated and kept on the move. With very high temperatures it does not do to lift up each print singly to transfer it to the next dish, as the gelatine softens by contact with the heated air. The prints lie in the chrome alum bath for 20 minutes, by which time they will be so thoroughly hardened that all the subsequent manipulations could be leisurely carried on with uncooled water or solutions without the least fear of the gelatine softening. The film can, in fact, now be vigorously rubbed between the fingers without in any way injuring it. After the chrome alum bath two or three changes should be given to wash out the alum thoroughly, and then the prints are dropped into a salt water bath made to taste distinctly briny (about 1 to 30 ounces), and kept there till they become lobster red. They are then again washed in two good changes, and then are ready for toning.

11. I have mentioned above that one grain to the ounce chrome alum solution should be used. In very hot weather I dissolve the chrome alum powder in iced water, as then I get it exactly one grain to the ounce, whereas adding lumps of ice to the prepared solution dilutes it, and renders it less effective. Adding a larger proportion is useless, and merely makes the solution more green, which then might slightly stain the prints a faint green colour. Besides, adding more chrome alum tends to soften the prints instead of hardening them. I once arranged a number of glasses in a row containing uncooled solutions of chrome alum varying from  $\frac{1}{2}$  a grain to 10 grains to each ounce. I then kept strips of unwashed P.O.P. in each glass for 15 minutes, and noted down the results. Half a grain was fairly efficient; 1 grain thoroughly efficient;  $1\frac{1}{2}$  grains very slightly more so, but the solution was greener; at 3 grains the film was soft; at 4 still more so, and at 5 grains to the ounce the gelatine was so rotten that the least touch with the finger rubbed it off the paper. This result astonished me at the time, but the explanation probably was that the stronger solutions hardened the surface of the gelatine to such an extent as prevented the alum acting on the deeper layers of the film, which thus softened under the influence of heat and moisture, and made it leave the paper support. As mentioned above, the solutions used in the experiment were not cooled, and possibly the results would have been different had cooled solutions been employed. But in no case can it be necessary to use stronger solutions than one grain to the ounce. Formalin could, of course, also be used, but for hardening prints would be much more expensive, I believe, than a chrome alum solution of the strength I have recommended.

12. In paragraph 10 I have mentioned that the prints should be gathered up together, and the lot transferred at once to another dish. The prints will have by this method all stuck together, and the beginner will be at a loss to know how they are to be separated without lifting each print out of the dish. Even if the weather be cool, and lifting each print out of the water be therefore unobjectionable, it would soon ruin the prints if finger-nails, toothpicks, or pen-knives were constantly to be used to start the separation of each print by one of its corners. The prints must always be induced to separate themselves without our having even to touch them. This is done by using dishes much larger than the prints, so that when the prints are all pushed to one side of the dish, there is a space of two or three inches on the opposite side of the dish. A certain splashing movement made in the water with the fingers in that space is all that is needed. The four fingers are put into the water edgewise at the end of the space nearest to us, and with a rapid movement from the wrist, carried

through the water with a splashing movement up to the top end of the space. This movement is to be rapidly repeated, always in the same upward direction, until the prints float up and separate from each other. The prints will at the same time come floating towards the fingers making the movement, and when they come quite near a space will be left on the opposite side of the dish, where the movement must then be repeated with the fingers of the opposite hand. Thus the prints will not only be kept separate, but constantly on the move from one side of the dish to the other. Any two refractory prints which refuse to separate by this method must at once be brought to the surface, and carefully separated with the fingers. In this connection I may add that when we wish to remove a print from water or any solution singly, it is always best to make it float up first before laying hold of it. To make a print float up to the surface all that is needed is to rub the surface of the water, &c., from side to side with a quick splashing movement with the flat palm of the hand.

13. The toning may be done with the formulæ recommended by the makers if the results satisfy you. If the tones are not satisfactory, and red tones or double tones result, then other formulæ could be tried. The formula to be used will depend entirely on the kind of tones you personally prefer. A friend of mine thought his own formula first-rate, because in his views the near trees looked red and the distant ones blue! I advised him to stick to his formula as the results pleased him. For my own part I like a formula which will never give double tones, and one which will tone up to a fine purple black. To produce such a tone the negative must be a vigorous one, the printing carried to the degree I have recommended in paragraph 5, and the chloride of gold the purest and most expensive obtainable. After spending so many pounds sterling in lenses and cameras, it can never be wise to try to save a few pence in chloride of gold. I always prepare my own chloride from Chinese leaf gold. If prepared with an English sovereign the solution is green, instead of a fine golden yellow, and it gives extra trouble to remove the chloride of copper which it contains. My toning formula is as follows:—

Pure rain or distilled water .....	8 ounces.
Sulpho cyanide of ammonium .....	30 grains.
Chloride of gold .....	2 grains.
Bicarbonate of soda .....	2 grains.

The ingredients are mixed in the order above given. The sulpho-cyanide I keep as a 30 grains to the ounce solution, and the gold as a grain to the drachm solution. I therefore begin by taking 6 ounces of water instead of 8, and when all is mixed I bring the whole up to 8 ounces. If the solution be placed in a tumbler it looks yellowish when first prepared, but if kept exposed to light it soon loses that colour, and looks like water. When that happens, toning should be begun at once. The above quantity will tone a little more than half a sheet of P.O.P., how much more depending entirely on the character of the prints. Vigorous prints take up much gold, while delicate vignettes take up but little. In any case the above formula will tone to a fine black, or some shade of black, and double tones will never occur with it. It tones so fast that only one large, or about four small prints, are toned in it at a time. The prints are lifted out of the toning bath from time to time, and looked through against mild daylight or bright lamp light. The moment all the redness has disappeared from the soft shadows, and a little redness still remains in the deepest shadows, the print is at once popped into the salt bath referred to in paragraph 10. If a sharp look out be not kept, and the toning continued until all the redness, on looking through the print, has disappeared from even the deeper shadows, the print has been over-toned, and will not look bright when finished. I have used the word "redness" and not "warmth" as in the maker's directions, because warmth is a technical expression not understood by everybody, especially in India. If several sheets of P.O.P. have to be toned, I prepare a solution in which all the ingredients are double that shown in the formula, making 16 ounces in all. When the bath works slow, and seems pretty well exhausted, which generally happens after about a whole sheet or a sheet and a half has been toned, I never strengthen the used-up bath, but prepare fresh baths for the subsequent sheets, 16 ounces each time. This plan is more economical than preparing a large quantity of the solution at once to begin with. I myself like very much the tones which the formula produces, but I do not know if such black tones would be suitable for ladies' portraits. It would be advisable, perhaps, in such cases to print less deeply, and thus secure with the formula delicate shades of grey. I have sent to the Editor a portrait deeply printed, and one less deeply printed, to see and keep, and he will be able to state whether the tone is a pleasing one or not. These prints were toned by me with the formula above given, more than six years back, and the por-

trait taken in an ordinary verandah. This portrait, by the way, reminds me that for P.O.P. retouching must be more carefully done than for albumen paper, which never shows the marks of the pencil so much. A very hard pencil should be used, say a five H, on the unvarnished film, then again on the varnished surface. If that is not sufficient, a transparency must be made by contact, faulty high lights and cross lights in the eyes, &c., removed on it, and a negative made back from the transparency. This negative, if retouched both on the unvarnished and varnished surfaces, will enable one to complete all the retouching that can possibly be required. In the portrait in question a strongly turned-up nose was thus made fairly straight without any difficulty. Most beginners find toning a difficult process, simply because they forget that a wet print looks quite different when dry. They tone until the print assumes the appearance it ought to have when dry, the result being that the prints get much over-toned. A wet print that looks weak and red in the shadows when looked through will look quite bright and black, without a trace of redness when dry and finished. I would recommend every beginner to go to a photographer's and buy a nice black toned, unmounted print. He should then examine it thoroughly by looking first at it, and then through it, and then soak it in water, and see what difference that makes! The lesson will be one which he will never forget.

14. When all the prints have been toned and got into the salt bath, they must be washed in two or three changes and fixed with hypo. My own impression is that P.O.P. prints are seldom fixed as thoroughly as they should be. There is the constant dread lest the gelatine may soften, and thus all the processes of washing, fixing, &c., are hurriedly and imperfectly gone through. If, however, the printing has been done to the depth recommended above, and the prints hardened with chrome alum, there need be no hurry at all, and the fixing could be thoroughly done in two hypo baths, each containing four ounces of hypo in 24 ounces of the solution. I keep the prints moving about in one bath for 15 minutes, then wash them in two changes, and fix them again in the second bath for 15 minutes more. All this fixing is not a bit too much for hardened prints. By this time the prints will look clear and bright when looked through, and a good deal of the image will show through the back of the prints as they lie in the solution.

15. The washing of the prints after fixation can be done in any of the washing troughs sold, but the prints must be washed in a few changes before being placed in running water. Every half hour, though running water has been used, the trough should be completely emptied out, and the water allowed to run again. About three hours of such washing is sufficient, and a final wash may be given by lifting each print out of a dish into another containing clean water three or four times. It is difficult to find troughs large enough to wash large prints satisfactorily, and for such prints it is quite sufficient to keep on lifting the prints from one dish to another of clean water. About 30 such changes would certainly wash the prints thoroughly. Labour is cheap in India, and any little boy can be taught to do this washing. The fact that a properly fixed print is easy to wash need never induce any one to do this final washing in a perfunctory manner. Prints which have been hardened with chrome alum require a much longer wash than those less hardened. If the tap be connected directly with the main, it would be advisable to tie a bag over the tap, to break the force of water, and to prevent iron rust, sand, and foam getting into the washing water.

16. To dry the prints, a sheet or clean towel may be placed on the sloping back of an easy chair, and the prints laid on in rows. Some space should be kept between each row, so that the drippings from the row above could not wet the row below. The spaces absorb the moisture from the prints above. For my own part, I use my reflector, which contains two flaps, both of which can be turned to any position from the vertical to the horizontal. I place a clean unstarched sheet over each flap, and arrange the prints on it in rows. At first, while the backs of the prints are very wet, the flaps are kept in an almost vertical position, so that the water on the surface of the prints could flow down quickly. But as the backs get drier the flaps are fixed more horizontally, and finally quite horizontally, when all fear of the prints, provided the latter have not been trimmed, but clips are in any case bad for large prints on P.O.P., because while wet they are very heavy, and the corners by which they were hung break off, and the prints get ruined by falling to the ground and catching dirt on the film side.

17. And now I must explain in detail the process by which the surface is rendered glossy. It cannot but be most annoying and discouraging if

after all the trouble already taken on the prints, the latter should after all stick to the glass! There are many little points which require being attended to very carefully, and I will tell them all as concisely as I can. (a) The more the print is hardened the less will be the chance of the print sticking. In cold climates it will be found quite sufficient to use common alum as directed by the makers. In very hot weather chrome alum must be used as recommended in this article. The more the print is hardened the less will be the resulting gloss, so that if a very high degree of gloss is wanted the prints should never be hardened too much unnecessarily. In cold weather the finest gloss would be attainable, because in such weather it would be quite unnecessary to harden the prints at all with any kind of alum. At the same time I must say that the higher the gloss the sooner does the gloss deteriorate by keeping. The moderate gloss of hardened prints is much more durable, and so in the course of time these hardened prints actually come to look better than the others. So, for my part, I prefer to harden the prints in all cases with common alum in cold weather and chrome alum in very hot weather. (b) The glass plate must be, on one side at least, quite free from scratches and bubbles. A mark must be made with a diamond to show which is the best side of the glass, and henceforth only that side should be used, and never the other side. The plate on the marked side especially must be thoroughly cleaned. It is better not to use the glasses of spoilt negatives for the purpose, because the least trace of gelatine left on the glass would certainly cause sticking. After washing the glass and polishing it with a rough bathing towel, the marked side must be vigorously rubbed with a ball of cotton wool dipped from time to time into French chalk. When the surface acquires a fine ground glass appearance it is ready for use, after the excess of French chalk has been removed with a perfectly dry camel-hair brush, gently applied. Any excess of chalk left on the glass will stick to the print and spoil its appearance. (c) No accidental splashes of water should be allowed to fall on the prepared plate prior to placing a print upon it. Such splashes remove the talc at those parts, and there the prints may stick. If such splashes have taken place the plate must be wiped dry and chalked again and brushed. (d) If the prints have been hardened, many of them may be placed in a dish of clean water at once, but if not hardened only one print should be put into the water at a time, so that it could not remain in it for any length of time sufficient to soften the film too much. (e) The print should be removed from the dish, dropped face down on to the surface of the water, and before it has time to sink, the print must be seized by two of its corners diagonally, raised up, allowed to drain just for one moment, and not too much, and placed almost dripping wet on the prepared plate. The plate is now held slantingly to allow of the excess of water dripping off. A double fold of clean unstarched Horrock's long cloth (I use my clean pillow cases for the purpose) is next placed carefully on the print, so that not a single crease exists in the cloth, and the cloth rubbed very gently with the hands till it rests quite flat. I then use a rubber squeegee in all directions, at first with a very light hand, and lastly with a free, vigorous movement on the surface of the cloth. The cloth is now removed, and another dry one put on, and the squeegee again applied from the centre outwards in every direction. By this time every bubble has probably been driven off, and it only remains now to dry the print on the glass. (f) This is done by placing the glass with the print attached to it in bright sunshine. The hotter the sunshine the better. The back of the print must, however, always face the sunshine or the source of heat, and never the other side of the glass. It is generally inattention to this rule that causes most of the failures. If the glass side is made to face the heat, the glass gets warm, the gelatine softens, and the prints stick. If, on the other hand, the back of the print faces even the hottest sunshine, the evaporation from its surface cools both the paper support, the gelatine film, and the glass plate, and the print can then never stick. So long as the back of the print or the glass plate feels cold to the hand, the print has still some moisture in it. When the glass gets warm that shows that the print is quite dry and ready to drop off. If hot sunshine be not available, then the heat of a fireplace or a stove could be used at such a distance as to make it equal to the hottest Indian sunshine, but not hotter than that. Of course, the back of the print must in this case also face the source of heat. Merely to keep the plate in a room on a shelf or table and let it slowly dry of itself is never satisfactory when dealing with unhardened prints. For such, the sooner the drying is done the better, and I have often noticed that such prints have stuck owing to clouds having unexpectedly gathered, thus unduly prolonging the drying process. For such prints I always try to select a hot sunshine day as being the most suitable. In dull weather I arrange the glasses around a charcoal stove at such a distance that it feels uncomfortably warm to the face, the backs of the

prints facing the stove. This practice would be the most suitable in England during all except the hottest summer months. (g) As for the time which the prints take to loosen or drop off, I would say that in the burning hot sunshine of India prints which have not been hardened in any way take from 15 to 20 minutes, and they never drop off till quite dry. Prints hardened with common alum take less time, and those hardened with chrome alum adhere to the glass so feebly that they drop off even before they are quite dry. I doubt if these latter could be made to stick to the glass even if we wished them to do so! But if we wish to produce a particularly fine gloss, and have therefore purposely not hardened the prints in any way, then, to avoid their sticking to the glass, all the instructions given above will have to be very carefully followed.

18. If the finished prints be kept between the leaves of a book, each two of them should be placed face to face, so that the gelatine side does not keep in contact with the printed matter.

Broach.

K. B. COOPER, Civil Surgeon.

### PHENOMENA OF VISION.

At the last meeting of the Physical Society, Dr. Shelford Bidwell exhibited some "Experiments illustrating Phenomena of Vision." The first phenomenon illustrated was that known as "Recurrent Vision." A vacuum tube, illuminated by an induction coil, was made to rotate about a horizontal axis, and was seen to be followed, at an angle of about forty degrees, by a feebly luminous reproduction of itself. A spot of white light, projected upon a screen and caused to move slowly in a circular path, was also followed by a less luminous spot. The same effect was shown by spots of green and yellow light, but in the case of red light no ghost was visible. The phenomena of recurrent vision are due principally, if not entirely, to the action of violent nerve fibres. The next experiments related to the non-achromatism of the eye. The lenses of the eye do not constitute an achromatic combination, although under ordinary conditions a bright object is not surrounded by fringes of colour. The effects of chromatic aberration are disguised by the luminous haze which surrounds the object, produced by a defect in the eye regarded as an optical instrument. A six-rayed star, formed by cutting a hole in an opaque screen, was illuminated by a gauze-covered condenser containing an incandescent lamp. The star was fairly clearly defined, and there were no fringes. More attentive observation showed a luminous haze. This haze is formed in consequence of the cellular structure of the eye, and the brightest rays—orange, yellow, and green—are chiefly instrumental in forming it. If therefore these rays are obstructed, the conditions are most favourable for the observation of chromatic aberration. The rays were consequently cut off by means of coloured glasses, and the general hue of the star was purple; to some it appeared bordered with dark blue, while to others (long-sighted) it appeared bordered with red.

Two oblong patches, one red and the other blue violet, and of approximately the same intensity, were then produced, side by side, upon a screen. An observer with very good eyesight was able, at a distance of 10 feet, to focus the patches alternately with perfect distinctness. In general, the blue patch was said to be more or less blurred. With an achromatic eye it should be possible to focus both together.

Dr. Bidwell then showed some lantern slides, illustrating the complex form seen when viewing a small luminous spot through a gauze-covered lens placed so as not to be in exact focus.

Some experiments were performed illustrating the principle of the colour top. When a bright image is formed on the retina, after a period of darkness, it has, in general, a red border, which lasts for a fraction of a second. A dark patch, suddenly formed on a bright ground, has a blue border which lasts for a similar time. These effects were attributed by Dr. Bidwell to a sympathetic action of the red nerve fibres. When the various nerve fibres occupying a limited portion of the retina are stimulated by ordinary white or yellow light, the immediately surrounding red nerve fibres are for a short period excited sympathetically, while the violet or blue and green fibres are not so excited, or in a much less degree. Again, when light is suddenly cut off from a patch in a bright field, there occurs a sympathetic insensitive reaction in the red fibres just outside the darkened patch, in virtue of which they cease for a moment to respond to the luminous stimulus; the green and violet fibres, by continuing to respond uninterruptedly, give rise to the sensation of a blue border. By a simple experiment it was shown that the explanation of the colour top, depending upon changes in the convexity of the eye and non-achromatism, was untenable. By the use of a strong light it is possible to get negative after-images, after looking at a brightly-coloured object. These images are complementary in colour to the object, and are formed even if the object is only viewed for a fraction of a second. By means of proper illumination and a disc rotating at the proper speed, a red wafer was so arranged that, upon looking at it,

it was impossible to recognise the wafer itself, but only the continuous green after-image.

The Chairman expressed his interest in the last experiment, in which it was possible to see the negative after-image of an object and not the object itself.

Prof. S. P. Thompson said these experiments threw a doubt on some of the accepted notions about the properties of the eye. Dr. Bidwell asks us to believe that the yellow haze is due to a cellular structure in the eye. Is there such a structure? Can it be observed with a microscope? And do its meshes correspond in magnitude with those necessary to produce the effects? By diminishing the size of the pupil the haze is diminished, and the sharpness of the image is increased. The effects seem to be due to ordinary aberration. Prof. Thompson said that the achromatism of the eye was simply shown by covering half the object-glass of a telescope and viewing a bright object with it. The object then seems bordered with coloured fringes.

Mr. Blakesley, referring to the colour patches used by Dr. Bidwell, pointed out that, although the patches were the same distance from the lens, yet they did not possess the same magnification. The last experiment shown did away with the theory of persistence of vision, because the space between the object and the negative after-image was evidently not illuminated.

Mr. Trotter asked if red and green were the only colours which gave complementary negative after-images.

Dr. Bidwell, in reply, said the effect was obtainable throughout the length of the spectrum.

### Studio Gossip.

THE Theatres Committee of the London County Council have sanctioned a plan, submitted by Mr. J. G. Buckle on behalf of the Directors, showing a cinematograph house which it is proposed to erect on the concrete flat outside the back wall of the stage of the Alhambra. The house in question will be built in brickwork, with a corrugated iron roofing.

ZOLA'S New Hobby.—"Pray excuse me," said M. Zola to an interviewer as he crossed the threshold of his comfortable sanctum, "for keeping you waiting. This is the time of day which I usually devote to a new hobby of mine: photography. When you arrived I was developing some snapshots I had taken this afternoon at the Exhibition. Every man should have a hobby, and I confess to a wondrous love of mine. In my opinion, you cannot say you have thoroughly seen anything until you have got a photograph of it, revealing a lot of points which otherwise would be unnoticed, and which in most cases could not be distinguished. Now, pray, take a seat, and let me know what I can do for you."—"The King."

THE Spirit of Modern Science.—"I am afraid," remarked the Countess of Warwick, in a recent address to the Essex Field Club, "that we as a nation have hardly yet risen to that high-water mark of scientific culture which should characterise a great civilisation. I do not mean to imply that we are lacking in scientific ability, that we are devoid of originality, or that we have failed to contribute our share of knowledge to the sum total of human progress. But I fear that the spirit of modern science has not sunk into the public mind—it has not permeated the rank and file to that extent which is required by the age in which we live, the century of science par excellence. Our purses are ever open, and have always been opened, in the names of charity and philanthropy, religious endowment and missionary enterprise, political organisation, and popular sport. But science, upon which the national welfare and our position in the scale of nations ultimately depends, has to go begging for her tens, while thousands are forthcoming for these other objects."

THE Tella Camera and its Uses.—Last week, Mr. W. E. Dunmore, of the Tella Camera Company, Ltd., London, delivered a lecture on the above subject in the Masonic Hall, Whitehaven, under the auspices of the Whitehaven Photographic Society. Mr. Dunmore's discourse to a very large extent covered the wide field of the mysteries of hand camera work, and at the same time illustrated by practical demonstration the possibilities of the Tella camera. Among the many advantages which he claims for it were that it was lighter and smaller than any other camera taking flat films, any number of films up to fifty could be inserted at one time, from one to fifty taken out without disturbing the others, that no special films were necessary, that it could be loaded with the latter number of films in from three to five seconds, that both the lenses gave an unusual crispness and depth of focus, and that it was unusually light when fully loaded and singularly compact. The gathering was apparently very much struck both with the complex construction of the Tella and the ease with which it is worked; and in the second part of the lecture, which was devoted to lantern slides, the applause which greeted most of the reproductions was strongly expressive of the company's approbation. The lecturer possessed not only a very intimate knowledge of the art of photography, but expressed himself in clear and terse terms, mingled with a good deal of humour and dropped many hints gained from practical experience, all of which tended to make the lecture both interesting and profitable.

## News and Notes.

THE Exhibition of the Longton and District Photographic Society will open on February 11, 1901, and continue for the following five days.

ROYAL Photographic Society's Ordinary Meeting, Tuesday, November 13, at 66, Russell-square, at 8 p.m.—"Photography in the eclipse of May 28, 1900," by E. Walter Maunder.

ROYAL Institution.—A General Monthly Meeting of the members of the Royal Institution was held on the 5th inst., Sir James Crichton-Browne (Treasurer and Vice-President) in the chair. Mr. W. H. Maw, Mrs. R. Middleton, and Dr. W. H. Perkin, F.R.S., were elected members. The special thanks of the members were returned to Dr. Frank McClean, F.R.S., for his donation of £50 to the Fund for the Promotion of Experimental Research at Low Temperatures, and to Dr. Rudolph Messel for his present of a Bronze Bust of Sir Humphry Davy.

A RIVAL to Acetylene.—According to a newspaper report potato spirit, mixed with pyridene, is fast coming into favour in Germany as an illuminant, and it is said to be most economical in lamps of 70 candle-power and upwards. The report adds that the gardens of the Imperial Palace of Sans-Souci, Potsdam, are lighted with 220 incandescent lamps burning this spirit. If this illuminant be what it is said to be, it should be admirably suited for the lantern in place of acetylene or paraffin, both of which have several disadvantages, as the users of them are aware. Possibly, however, this new light may have corresponding drawbacks. If it has not, there is very little doubt it will soon be introduced here, for there is still room for a good illuminant for lanterns where gas is not available.

MATCHING Colours.—Under the auspices of the Society of Dyers and Colourists, a lecture was given at the Bradford Technical College on "Colour-Matching," by Mr. Arthur Dufton. The authors exhibited a number of patterns dyed to approximately match in daylight, but which showed very great variations when seen by gaslight or the electric arc. By means of a series of absorption spectra they explained how these variations in colour arose, and traced the difficulties of colour matching to the fact that all colouring matters were more or less transparent for red light. Artificial illuminants, gas, incandescent gas, acetylene, the electric arc, all differ in character from daylight, and great inconvenience is experienced by dyers owing to the lack of a reliable light for matching in dark weather. Messrs. Dutton and Gardner have invented a lamp which promises to be of great value to all workers in colour. It consists of an electric arc lamp enclosed in a glass globe of pale blue tint of such character as to bring the light into exact accord with daylight.

THE Rontgen Rays in War.—Dr. J. B. Macintyre, in the course of his presidential address to the members of the Rontgen Society, at 20, Hanover-square, last week, said that the question of the employment of the X rays in war had everywhere naturally created a considerable amount of interest. It was only after the Soudan expedition that anything like a definite idea could be obtained of their utility in the field. It was too recent to say anything about the work in South Africa generally. They were looking forward to a paper from one who had been engaged in the field. He was pleased to report, by the courtesy of Surgeon-General Jameson, the Director-General of the Army Medical Department, that the X rays were found most useful in the hospitals at the base and on the line of communication, although not actually on the field. There was now a regulation list of apparatus for Army work, seventeen sets were sent to South Africa, and they were being adopted in all the larger military hospitals.

THE Royal Society.—The following is a list of those who have been recommended by the President and Council of the Royal Society for election into the Council for the year 1900 at the anniversary meeting on November 30:—President: Sir William Huggins, K.C.B., D.C.L., LL.D. Treasurer: Mr. Alfred Bray Kempe, M.A. Secretaries: Sir Michael Foster, K.C.B., D.C.L., LL.D., Professor Arthur Wm. Rucker, M.A., D.Sc. Foreign Secretary: Dr. Thomas Edward Thorpe, C.B., Sc.D. Other Members of the Council: Professor Henry Edward Armstrong, V.P.C.S., Mr. Charles Vernon Boys, Mr. Horace T. Brown, F.C.S., Mr. William Henry Mahoney Christie, C.B., Professor Edwin Bailey Elliott, M.A., Dr. Hans Friedrich Gadow, Ph.D., Professor Wm. Mitchinson Hicks, M.A., Lord Lister, F.R.C.S., Professor William Carmichael McIntosh, F.L.S., Dr. Ludwig Mond, Ph.D., Professor Arnold William Reinold, M.A., Dr. Robert Henry Scott, Sc.D., Professor Charles Scott, Sherrington, M.D., Mr. J. J. H. Teall, M.A., Professor J. Emerson Reynolds, Sc.D., and Sir John Wolfe Barry, K.C.B.

MESSRS. Blades, East, and Blades have been good enough to send us a copy of the invitation card to the banquet given by the Corporation of London, at the Armoury House, Finsbury, E.C., to the Officers, N.C.O.'s and Men of the City of London Imperial Volunteers, on their return from South Africa, October 27, 1900. The following is a description of this cleverly designed and well executed production:—A series of pictorial representations of the chief events in the history of the Regiment form the principal feature of the card. At the head of it is a trophy of flags and guns, and the monogram C.I.V. encircled with a crowned laurel wreath. Flanking the trophy on either side are portraits of Field-Marshal Lord Roberts, V.C., and the Right Hon. the Lord Mayor (Sir Alfred James Newton, Bart.), and underneath is the portrait of Colonel W. H. Mackinnon, commander of the regiment. On the right a female figure, emblematical of the City of London, with Guildhall in the background, grasps the hand of a C.I.V., in welcome of the gallant regiment on its return; at her feet are the Arms of the City of London. On the left are views depicting the hoisting of the flag at Pretoria and Bloemfontein, and the march past St. Paul's Cathedral and the Mansion House.

These views are separated from the body of the card by a riband bearing the names of the various engagements in which the regiment has taken part.

## Commercial Intelligence.

MESSRS. E. Krauss and Co. (of Paris), whose agents are Messrs. A. E. Staley and Co., of 35, Aldermanbury, E.C., are now supplying Kodak cameras fitted with Krauss-Zeiss Anastigmats.

MESSRS. Newton and Co., of 3, Fleet-street, E.C., have issued a supplementary list of lantern slides for the season 1900-1901. Amongst many others there are series dealing with the Transvaal and the War; the War in China; Hoffmann's Life of Christ; the Paris Exhibition; and many others.

Mr. Charles H. Atkinson, of 66, Victoria-street, Liverpool, writes that the partnership heretofore subsisting between him and Mr. Frederick Atkinson, carrying on business as Photographic Dealers as Atkinson Brothers at the above address, has been dissolved. The business will in future be carried out by Mr. Charles Harold Atkinson alone.

A New Firm.—Messrs. H. Armytage Sanders and H. A. Crowhurst inform us that they have opened premises at 71, Shaftesbury-avenue, London, for the sale of optical instruments and apparatus of every description. Mr. H. A. Sanders was with Messrs. W. Watson and Sons, of High Holborn, for nearly twenty years. The production of projection apparatus will be his special care, also the publishing and colouring of lantern slides. Messrs. Sanders and Crowhurst have been appointed sole West-End agents for the sale of Messrs. Watson's instruments. We wish the new firm success.

CINEMATOGRAPH Films of the C.I.V. Procession.—Messrs. W. Butcher and Son, of Blackheath, inform us that the following films were taken from the roof of the Gloucester Gate Lodge, Hyde Park; they show the procession coming from the Marble Arch:—No. 1, showing Mounted Police, Band of the Honourable Artillery Company, Hussars, Colonel McKinnon, Major-General Trotter, and other Officers and C.I.V.'s, 63 ft.; No. 2, showing Battery of the C.I.V., Band of London Rifle Brigade, C.I.V.'s, and Band of the London Scottish Rifles, 71 ft.; No. 3, C.I.V.'s, with flag captured from the Orange Free State, 31 ft.; No. 4, Infantry Battalion of the C.I.V. (remainder), Machine Gun Section of the C.I.V., Ambulance Waggons with invalids and detachment of Guards, 68 ft.

MESSRS. Walker and Company, Cinematographers, of 19, Bridge-street, Aberdeen, write:—"In the matter of high-class cinematograph entertainments, we may mention that our programme is always carefully built up, the one item leading to the other, making every programme a valuable education. We judiciously enter into fun where it can be introduced. We also introduce all the natural effects. Then, where explanatory matter is required, full information is given from the platform. We raise our audiences like the waves of the sea, at times at loud applause, the next second you can almost hear the watches ticking. If everyone connected with this form of entertainment would take a personal interest in the subject, it would at once place it on a higher platform, instead of relegating it to the last turn in the music-hall programme."

THE Lac Industry of Assam.—A recent report of the Assistant-Director of Agriculture in Assam, says "The Times," deals in detail with the lac industry there. Lac occurs in its natural state in various parts of the forests of Assam, as well as of Burma, but chiefly in parts of the Khasi and Garo Hills, and the export in recent years has averaged 16,000 maunds, or something over 500 tons, but in some of the forests, owing to the ravages of the Kolaazar epidemic and depopulation, the production is declining. The production of Manipur is not sufficient for the local needs, and quantities of the lac are sent away from Assam in the crude form, or stick lac; shell and button lac are made, to some extent, but lac dye is not now prepared anywhere in Assam, and lacquer wares are only produced in two places, so that this once considerable industry would seem to be dying out. The black lacquer of Manipur is really not a lac preparation at all, but only the juice of a tree sent from the Kubo Valley. In Assam the lac is usually collected twice a year, first in May and June, and then in October and November. The first is mainly used for seed purposes, while the second forms the export. A few days after the collection, pieces of stick lac containing living insects are tied on to the branches of the trees on which the next crop is to be grown. The usual plan is to place the lac in small bamboo baskets and tie these on the twigs of the trees. The insects soon crawl out, and spread over the young branches, on which they promptly begin to feed, and secrete the resin. This is allowed to go on for about six months, when the lac is collected; but, if the secretion has been defective or insufficient, the insects remain undisturbed for another six months.

MANUAL Training in Germany.—On October 1 last, twenty-four years had elapsed since the movement having for its object the manual training of boys was inaugurated in Germany. In this space of time the idea has certainly been disseminated largely in the country, and over two thousand teachers have given their co-operation to the movement; nevertheless, says the United States Consul at Glauchau, both the internal and external conditions connected with this new branch of tuition leave much to be desired. The original training in home industries and home occupation has almost entirely disappeared; it is carried on at present only in a few places in Holstein and in 17 institutes for the blind. Most of the other educational establishments in Germany, including 18 orphanages and 46 deaf and dumb institutes, have already introduced manual training into their curriculum. The endeavour, however, to pre-

pare the pupils in the schools directly for the eventual handicraft has obtained importance in only two of Germany's institutions of learning. The majority of the German home-industry schools only deal pedagogically with the subject. There exist at present in Germany, distributed in 605 places, 861 schools and institutes wherein manual training is carried on in 1,514 workshops. Of this number 836 schools and institutes conduct the training on a pedagogical basis. Prussia has 570 manual-training schools spread over 435 places and distributed among 596 workshops. Industrial centres take the lead as follows:—Prussia, Upper Silesia, the Rhenish province, and the kingdom of Saxony. The 1514 pupils' workshops comprise 286 independent manual training schools, and 238 public schools, of which 16 are auxiliary schools, where the work is obligatory; 17 middle-class schools, 41 high schools—made up of 8 gymnasiums, 12 technical and technical high schools, and 15 boarding schools—7 preparatory institutes, 26 teachers' seminaries, and 93 boys' asylums, while the remainder is made up of various kinds of private educational establishments. The organisation of the handicraft tuition in the individual schools and institutes is varied in character. Sixty-nine institutes have adopted the whole curriculum as recommended by the German Association for the dissemination of Manual Skill, while 16 dispense with the preparatory work; of the rest, 177 schools and institutes confine themselves to three branches, 261 limit themselves to two, and the remainder to one branch only. Five hundred and thirty-five workshops are devoted to wood-carving, 527 to working in cardboard, and 336 to the carpenter's bench; of these, 68 are closely connected with wood-carving, 77 with preparatory roughing out work, 35 with metal work, 11 with turnery, and 11 with modelling in clay. Pedagogical manual tuition has branched out in three directions; the practical formal method, which regards handicrafts as a means to general culture; the direction advocated by those who aim at the so-called school manual dexterity; and the system which would make the manual training serve as the basis of individual branches of teaching, and utilise these in order to influence the method of instruction in schools. The first two are becoming more and more amalgamated. In the third direction, Professor Kumpa, at Darmstadt, School-Inspector Scherer, at Worms, and Herr Bruckmann, at Königsberg, are at present engaged in making thorough experiments in public schools. The participation of German teachers in the efforts of the German Association is steadily increasing. Over 2,200 German teachers have up to now been taught to become instructors in manual training. Of these, 950 were taught in Leipzig, and 1,250 acquired training in 33 places in other parts of Germany.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

November.	Name of Society.	Subject.
13-17 .....	Aintree .....	Seventh Annual Exhibition.
13.....	Birmingham Photo. Society ...	Light and Shade. C. T. Cox.
13.....	Royal Photographic Society ...	Photography in the Solar Eclipse of May 28, 1900. E. Walter Maunder.
13.....	Thornton Heath .....	Lantern-slide Making. Benjamin E. Edwards.
14.....	Borough Polytechnic .....	Bromide Enlarging. John H. Gear, F.R.P.S.
14.....	Oroydon Camera Club .....	Fifty-first Public Lantern Show.—Snapshots on the Spanish Seaboard. R. Child Bayley.
14.....	Photographic Club .....	Demonstration: Ozotype, the New Carbon Printing Process without Actinometer Transfer or Safe Edge. Thomas Manly.
14.....	Redhill and District .....	Lantern-slide Making. J. A. Hodges, F.R.P.S.
14.....	Scarborough .....	The Dales and Coast of Yorkshire. Godfrey Bingley.
14.....	Sefton Park .....	Stereoscopic Photography and Projection. W. H. Tomkinson.
15.....	Hull .....	Narrow and Wide-angle Lenses and Subjects. W. E. Debenham.
15.....	Liverpool Amateur .....	Three Continents in Six Weeks. George E. Thompson.
15.....	London and Provincial .....	Open Night.
16.....	Bognor .....	Monthly Competition.
16.....	Borough Polytechnic.....	Instruction Evening: Defects in Negatives: Prevention and Remedy.
16.....	Oroydon Microscopical .....	Lantern Slides: Royal Meath and County Wicklow.—A Day and Night in Newspaper Land.
16.....	Royal Photographic Society ...	On the Optics of Trichromatic Photography. F. E. Ives.

### ROYAL PHOTOGRAPHIC SOCIETY.

NOVEMBER 6,—Lantern Evening,—Mr. J. J. Vezey in the chair.

#### CITIES AND SIGHTS OF SPAIN.

Mrs. Aubrey Le Blond inaugurated the Lantern Meetings of the Session 1900-1 with an exhibition of slides illustrating her lecture on "Cities and Sights of Spain." Mrs. Le Blond, who is better known to photographers as Mrs. Main, has made several tours in Spain, on the first occasion being alone, and has collected a very comprehensive and most interesting series of photographs of many parts of the country which, although easily accessible and well provided with hotel accommodation, are seldom visited by British tourists. She emphasised the fact that she had been allowed to take photographs practically everywhere, the only necessary preli-

minary being a polite application to the custodians of cathedrals, churches, palaces, and other buildings, for permission to do so. Permission had always been readily granted, the officials having been most anxious to render assistance, and this with no view to a subsequent pecuniary consideration. Travelling was easy and cheap, the first class fare for an extended railway tour of some 3500 miles, with facilities for breaking the journey at any point, being about £13. The beautiful photographs shown related principally to the architecture of Spain, beginning with the prehistoric buildings and proceeding through the Roman and Romanesque to the Late Gothic and Moorish, the final series consisting of typical scenery, street scenes, and curiosities of the country and the people. The localities illustrated included Barcelona, Tarragona, Segovia, Martorell, Merida, Cordova, Gerona, Leon, Tudela, Burgos, Toledo, Manresa, Avila, Seville, Montserrat, Salamanca, and many others, the slides being very charmingly and eloquently described. The lecture and exhibition were much appreciated by an overflowing audience, and a most successful start was given to the new series of lantern meetings.

#### COMING EVENTS.

November 13, Ordinary Meeting, "Photography in the Solar Eclipse of 1900," by Mr. E. W. Maunder; November 16, the Traill Taylor Memorial Lecture, "The Optics of Trichromatic Photography," by Mr. F. E. Ives; November 27, Technical Meeting, "Analytical Portraiture," by Mr. Francis Galton.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 1,—Mr. J. E. Hodd in the chair.

The Chairman passed round a bromide enlargement that had been toned in copper, as per Fergusson's method, some eight months ago, and which now showed a metallic iridescence over the entire surface of the picture.

Mr. Haddon put this down to insufficient washing. Mr. Beckett suggested that this iridescence might be got rid of by rubbing over with waxing solution.

The Chairman also showed a new exposure meter and a granitine plate for use in the development of rollable films in the length. The meter is by Mr. Watkins, and intended for interior photography with Kodak cameras, the tint being such as to show a correct exposure on Kodak film at f-16. The granitine plate is an arrangement with supports on either side, so as to leave a small space underneath, the ends being rounded off. This is stood in the developing tray, and the film (film side down) passed underneath backwards and forwards, the granitine plate thus keeping a certain length of film always in the developer.

Mr. E. Human then gave a demonstration on the intensification of carbon prints and transparencies by means of a number of aniline dyes. In the course of the development of the carbon pictures, he made reference to a brush he usually employed, which was composed of a wedge of indiarubber covered with felt.

Mr. Haddon thought that this brush, as described by Mr. Human, would be very detrimental to a carbon image, which, as a rule, required such gentle handling, and suggested the use of velvet or plush instead.

Mr. Drage said he was of the opinion that velvet or plush would answer, as it would get so hard.

Mr. Beckett remarked on the difficulty of keeping the high lights completely clear, as in all cases a slight film of gelatine remains, and it is impossible to remove it.

### PHOTOGRAPHIC CLUB.

OCTOBER 31,—Mr. John Nesbit in the chair.

Mr. W. L. H. Skeen showed an excellent series of slides illustrative of the manner and customs of the Cingalese and of Ceylon landscapes. Those of the natives were of particular interest, as showing the differences between the two or three races that inhabit the island. Some of them were taken at considerable trouble, far in the interior of the island, to preserve a record of a scanty and disappearing tribe still living in the forests, and others gave an excellent idea of the dresses affected in various parts of the island.

Mr. H. Snowden Ward described, as they appeared on the screen, some slides of places connected with Dickens and his famous characters. All parts of the country possessing associations with the author were visited, such as Exeter, Portsmouth, and Rochester, and London, of course, contributed very largely to the series.

Mr. Hans Muller showed some pictures taken on the Rhine and Moselle, while others of a miscellaneous character were also projected on the screen.

### FORTHCOMING EXHIBITIONS.

1900.	November 9, 10 .....	Cripplegate Photographic Society and the Essex and Middlesex Cycling Union, Ltd. Hon. Secretaries, A. T. Ward, Cripplegate Institute, E.C., and G. F. Sharp, Sach-road, Upper Clapton, N.E.
"	12-17 .....	Ashton-under-Lyne.
"	19-24 .....	Waterloo and Blundellsands Photographic Society. Hon. Secretary, W. G. Eyre, 2, Mersey-road Blundellsands.
	21-23 .....	Hackney Photographic Society. Hon. Secretary, W. Selve, 70, Paragon-road, Hackney, N.E.

- November 21-24 ..... Cleveland Camera Club. Hon. Secretary, F. W. Pearson, 98, Victoria-road, Middlesborough.
- „ 22-24 ..... Hove Camera Club. Hon. Secretary, C. Ber-  
rington-Stoner, 24, Holland-road, Hove.
- 1901.
- January 14-19 ..... Blairgowrie and District Photographic Association.  
The Hon. Secretaries, Blairgowrie, N.B.

## Patent News.

THE following applications for Patents were made between October 22 and October 27, 1900:—

- ROCKER.—No. 18,824. “A New or Improved Apparatus for giving a Rocking Motion to Dishes and the like used for Photographic Purposes and the like.” H. J. CLEVERLY.
- FOUSSING.—No. 19,033. “An Improved Arrangement for Focussing in connexion with Photographic Cameras.” M. BRETT.
- PRINTING.—No. 19,059. “Improvements in or in connexion with Photographic Printing Processes.” S. G. FRY.
- FILM CARTRIDGES.—No. 19,108. “Improvements in or relating to Photographic Film Cartridges and the like.” Communicated by M. J. Ehlman. KODAK, LIMITED.
- SHUTTERS.—No. 19,172. “Improvements in or relating to Photographic Shutters.” J. H. P. WALKER.
- IMPROVED PROCESS.—No. 19,284. “An Improved Process of Photography.” S. J. F. MARCHAND and B. C. LE MOUSSU.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

### THE EXHIBITION OF AMERICAN PHOTOGRAPHY AT RUSSELL SQUARE.

To the EDITORS.

GENTLEMEN,—As an onlooker, it appears to me that Mr. Holland Day would have been far better advised had he undertaken the task of replying to his critics, instead of relegating the job to an admirer such as Mr. Evans, or that other gifted American, who, in the last issue of a contemporary, under the thin disguise of a criticism of British photography, devotes two-thirds of his article to railing at all and sundry who fail to appreciate all the work at Russell-square.

The author of this article, however, we can forgive, for most men, I take it, who have seen his work at Russell-square will not fail to recognise in him the making of a first-class humourist. Dealing collectively with this brilliant and intellectual coterie, the American school, and their friends in this country, it seems to me that the position they take up is somewhat as follows:—Admire these pictures, and recognise Mr. Holland Day as “The Master.” Fail to do this, and we brand you as rude and ignorant. Why should this be so? The only reason I can suggest is, though possibly I may be wrong, that the leaders of this school are afflicted with the most colossal brand of vanity. This opinion is borne in upon me, in view of the fact that Mr. Holland Day is stated to have said in the course of an address made by him before the members of the Royal Photographic Society at Russell-square, “That there was as much art in applying chemicals to a print to bring out a particular tone, as there was in the work of the artist who applies colours to his canvas through the medium of a brush”!!! Mr. Evans, in his letter of this week, takes the trouble to assure us that Mr. Day is an artist and a gentleman, a totally superfluous statement. Mr. Day's personality does not interest me one little bit. I am only concerned about his pictures, and I take it that this is the attitude of most men interested in the subject. In conclusion, may I add that I should have far greater respect for Mr. Day if he replied to his critics, instead of leaving the matter in the hands of his admirers, who, in their enthusiasm for the man, lay themselves open to the charge of writing a great deal of “piffle.”—I am, yours, &c.,

TACOMA.

To the EDITORS.

GENTLEMEN,—In reply to Mr. Evans' letter in your last issue, may I be allowed to point out that, although I, in common with thousands of other people, do not hold your views on the Passion Play, yet I quite agree that there is something distinctly objectionable in the photographic representations of it, and also in Mr. Holland Day's pictures.

Now, why is it? Is it true that “the lens and dry plate do not idealise as the painter or draughtsman can or may”? The subject has inspired some of the greatest painters; their masterpieces have been painted from living models made-up to be portrayed as the Christian Redeemer! Is Photography so far removed from Art? Is the camera so far beneath the painter's brush that an artist must needs lay aside all hope of using it as a means of evoking “a reverent and mental conception of a suffering Christ”??

I think not! The fault, I feel sure, lies with the artist's method, rather than with his tools. If Sir Joshua Reynolds had attempted to paint a “Descent from the Cross,” he would have utterly failed, and, on looking at his work, however technically perfect, we should have felt that we were looking at the dressed-up image of a human man. But yet Rembrandt's masterpiece strikes the most sceptic heart with awe.

The two methods are admirably illustrated in the Wallace collection. Look at Sir Joshua Reynolds' finest portraits, and then on the wall opposite turn to Rembrandt's “Unmerciful Servant.” The former has faithfully laid to canvas the minutest details of his fair sitter's features and dress. Nothing that long, patient, and attentive study of his model could detect has been omitted; yet the picture, however true to Nature, lacks life. In Rembrandt's work, on the contrary, detail is made subservient to light and shade; the whole interest centres on the expressions of the principal subjects; there is no superfluous detail to distract the attention, but just sufficient has been brought out to give life and vigour to the whole composition.

This is no plea for the new school of photography. No one more thoroughly despises the faked, fogged, and smudged platitudes exhibited by the vast majority of would-be creators of a new American school than I do; but also no one more cordially detests the sharp, shallow-focused, over-retouched, and badly-lighted productions shown by some of our leading London photographers.

Will our self-styled artists never realise that if any measure of success, however small, is to attend their efforts, they have much to unlearn? Will they never realise that a technical knowledge of photography, however perfect, will not enable them to produce one single piece of artistic work if they have no artistic talent, and have not developed it by careful study of the old masters? That an artist, however bountifully endowed with Nature's rarest gift, can never do himself justice with the camera if he does not possess a thorough theoretical and practical knowledge of photography and dark-room chemistry? But to the artist who is also an expert photographer the camera is, I believe, the potentiality of producing works of Art beyond the possibility of the draughtsman's pencil, equal perhaps to the painter's brush!

I am, yours, &c.,

TUCK.

To the EDITORS.

GENTLEMEN,—I am one of those who cannot understand the *raison d'être* of the photographs from living models of subjects which many people hold sacred. The prosaic realism of photography surely cannot be compared to the idealising genius of a great painter, no matter how much “personal control” the photographer may exercise. When people purchase photographs of those who take part in the Passion Play at Ober-Ammergau, they surely purchase nothing more than the photographs of actors. And Mr. Holland Day is an actor, for the time being, posing as model to represent Christ. Just because Mr. Day is alleged to bear some resemblance to the general conceptions of Christ, is this any reason why he should photograph himself as such? What is the object in view? What purpose is served? Mr. Day's photographs are only photographs of himself; what else can they be?—I am, yours, &c.,

J. A. REID.

Cutcliffe-grove, Bedford, November 2, 1900.

To the EDITORS.

GENTLEMEN,—As the subject of photography in relation to sacred subjects has been again raised by the Exhibition now being held at the house of the R.P.S. in Russell-square, I shall be glad if you will allow me to make a few remarks supplementing what I said on the opening evening of that Exhibition.

I regret to find that I differ very materially from the views of my friend, Mr. F. H. Evans, who wrote so eloquently in your last issue in defence of Mr. Holland Day.

I think it will help us to a right conclusion if we keep in mind the

act that the essential feature of all photography is realism. A photograph cannot be good unless it accurately represents the original from which it was taken. Now, as there are no originals left of sacred subjects, it seems to me there is no field for photography in this direction. You may dress up and pose as a model to represent a particular person, but when you have photographed it you have only a portrait of that model in costume.

The question has been asked: "Why are painters allowed to treat sacred subjects if photographs may not do so also?" To this I reply, that a good painter always tries to idealise his subject, if it be a sacred one, and even if he employs a model it is only to suggest ideas, and in no case does he attempt to paint a simple portrait of his model. In looking at a photograph you cannot forget that it is a representation of something which existed when it was taken.

As to the question of good taste in reference to such a photograph as Mr. Day's "Seven Last Words," can any one have the presumption to suppose that he can, in his own countenance, express faithfully the overwhelming suffering and sorrow the Saviour of the world endured in His last moments? Where, then, can be the pleasure or profit in looking at a feeble attempt to portray this? Is such a moment one which, under any conditions, you would wish to perpetuate by photography? If you were standing by the bedside of a dear friend dying in excruciating agony, would you consider this a fitting moment to take his photograph? There can be but one answer, emphatically "No." Consider, then, the pain you must inflict on many pious people in placing before them such an attempt at reproducing so sacred a subject.

As to the Ober-Ammergau pictures, those I have seen simply represent the actors in their various costumes. I have seen none in attitudes of intense suffering; but, if there are such, I should certainly object to them, as I do to Mr. Day's pictures.

I have said on a previous occasion that I do not charge Mr. Day with being wilfully irreverent, but I certainly do think he has not given the subject sufficient consideration, or he would not meddle with such sacred matters.

No one who heard his address at the opening of the American Exhibition can doubt his sincerity or his enthusiasm, but I do hope he will confine his attention to mundane subjects, which will furnish him with ample scope for his talents.—I am, yours, &c.,

J. J. VEZEY.

188, Lewisham High-road, Brockley, S.E., November 5, 1900.

To the EDITORS.

GENTLEMEN,—Have you noticed what a writer in a contemporary says in commenting upon your criticism of the "American School of Photography?" It is this: "Ah! . . . if the tenth part of your professional readers could only do half as well, how vast would be the uplifting of English studio portraiture!" Ye gods and little fishes! what an insult to your readers, and, indeed, all professionals. I can only put such an exclamation down to the writer's ignorance of the profession, and must leave it for more abler pens than mine to deal with him, as he so richly deserves. I am a poor struggling professional living in the provinces, and had not a family affair taken me to London I should never have seen the "Exposition Hollandaise," which is now contaminating the beautiful rooms of the Royal Photographic Society. I, of course, had read certain eulogistic accounts of it. It is all very well for scribblers about art, soul, feeling, &c., to sit in their easy chairs, with a bath bun and a glass of milk beside them, and go into ecstasy over such work; but let them come out into the world and try a little "bread and butter" work, and I am thinking they would slink back to their lairs with a new mind loaded up with good intentions to elevate the poor professional, instead of endeavouring to drag him down to his ruin. What other remark do I see in the same issue? It is this: ". . . that horrible style, the P.O.P. print on a gold bevelled edged olive enamel mount in a mora gilt bevelled glass stand!" I wonder if the writer of that knows of any one who has made lots of money out of "the horrible gold bevelled edged olive enamel mount?" I have an idea that I do. Ah, me! what a good weathercock some folks would make.—I am, yours &c.,

A PROVINCIAL PROFESSIONAL.

### THE CITY AND GUILDS EXAMINATION.

To the EDITORS.

GENTLEMEN,—You give in last week's BRITISH JOURNAL OF PHOTOGRAPHY the report of the examiners in photography for the City and Guilds of London Institute.

This report, similar to several previously given, is mainly to the effect that the elements of photographic chemistry and optics do not receive sufficient attention.

As practically the whole of the professional students who sit at this examination come from here, I shall be grateful if you will allow me to say a few words on behalf of these students, and ourselves as teachers.

The City Guilds give two certificates, one for photography pure and simple, and the other a full technological certificate, to those students, only, who have studied chemistry and optics, or drawing, and yet, notwithstanding this special certificate for accessory subjects, we get an undue proportion of scientific questions, and a continual complaint of insufficient knowledge of science in an examination, which is represented to be for pure photography.

Any one with a little knowledge of chemistry and optics, by spending a few hours in reading an elementary text book on photography, and with the merest smattering of practical knowledge, can go up to the examination and get a pass, or very likely gain medals—that is to say, come out at the top, whilst earnest and sensitive students, who are brimful of more useful knowledge, and of immeasurable superiority as photographers, do not even get a second-class pass. On what grounds can such results be justified.

No one can know better than we teachers that the great majority of professional photographers lack knowledge in chemistry and optics, but the point is this, consciously and unconsciously, the City Guilds give great prominence to, and unduly encourage, these subjects, and a feeling is produced among educational authorities, the public, and students (the latter too young to judge for themselves) that these, and these only, or mainly, are the subjects which determine a young photographer's proficiency and progress. At the present moment this school is full to its maximum accommodation with professional students, and we have reluctantly been compelled to refuse many entries. May I ask, under these circumstances, what is the duty of a teacher, who feels more painfully every day, the misdirection of youthful energies which this excessive forcing of elementary science involves, shall he also by continually lecturing upon these subjects, encourage the less fit and discourage the more fit.

There is an old saying that one example is worth many sermons: look down the names of a few of those who are eminent in photographic chemistry or optics, and tell me where is the evidence of their superiority, as photographers; on the other hand, also make a list of those you consider eminent as photographers. The chances are that very few, in this latter list, could pass the elementary grade of the City Guilds examination. Do not let it be supposed from these remarks that I wish to discourage the study of chemistry or optics—for plate makers, camera makers, lens makers, some teachers, and many others, they are fundamental; to photographers, they are useful auxiliaries, but not essential, and should, if possible, be studied as subjects separate from photography, for in the majority of cases, as surely as undue attention is given to what may be termed the science of the subject, so surely will the students go backwards, instead of forwards, in their progress as photographers. And if public diplomas or certificates are given, and labelled, as for photographic knowledge, surely the injustice of branding those students as failures who have the fullest essential knowledge, but not the scientific faculty, can be avoided?

In conclusion, I wish to say that during the years this school has been open, we have received everything that could be wished for in the points of courtesy and kindness from the City Guilds, and if they could only be persuaded to take an active interest in the examination, by bringing their official representatives in actual contact, and association, with photographers and students, they would be the first to admit that very radical modifications in the examination are required.—I am, yours, &c.

HOWARD FARMER.

The Polytechnic, 309, Regent-street, W.

### A SOCIETY FOR SOUTHEND.

To the EDITORS.

GENTLEMEN,—Yesterday evening, a new Photographic Society was inaugurated, to be called "Southend-on-Sea Photographic Society." Mr. Bullivant, Principal of the Ascham College, Westcliff, kindly placed a room at the disposal of the members until more suitable accommodation can be found. The rules are practically the same as those of the Photo Club, and the meetings every alternate Wednesday, at 8.15. As there was no organisation of the kind in this district, it should be a success. I thought you would like to know any photographic movement of this kind.—I am, yours, &c.,

EDWARD DUNMORE.

Westcliff-on-Sea, November 2, 1900.

### PHOTOGRAPHS REGISTERED:—

A. J. Ashbolt, 29, High-street, Southampton.—*Photograph of A. Lee.*

S. Powell, The Studio, High-street, Rushden, R.S.O.—*Photograph of Miss Willoughby.*

A. W. Sargent, 12, Albany-road, Cardiff.—*Photograph of family group, including five generations.*

B. Graham, Esplanade, Whitley Bay, Northumberland.—*Photograph of Cullercoats Railway Station, flooded.*

Barker & Price, 117A, High-street, Croydon.—*Photograph of school group, North Park College, Croydon, and photograph of gymnastic class.*

## Answers to Correspondents.

\* \* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.*

\* \* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\* \* *Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.*

**F. DRADER.**—We have no experience of the plates. A letter addressed to Mr. G. F. Wynne will, no doubt, elicit the information.

**CHRISTMAS MOUNTS.**—C. H. E. These may be had in great variety from any of the large houses, such as Marion's, Houghton's, Fallowfield's, and others. Consult the advertisement columns, and write for samples, enclosing your business card.

**H. GRAHAM GLEN.**—The names of the actual makers we do not know, but plush goods are obtainable from such firms as Marion and Co., Houghton and Son, and others.

**H. RAYMOND.**—It is against our rules to give such recommendations. Can you not have the camera sent to you on approval, and satisfy yourself? You are the best judge of your own requirements.

**CELLULOID TABLETS.**—CELLULOID writes: "Can you give me the address of a firm that supply celluloid tablets suitable for putting carbon pictures on?"—In reply: Probably Messrs. S. Guitermann and Co., of 35, Aldermanbury, E.C., could supply you.

**FELLOWSHIP OF THE R.P.S.**—INQUIRER writes: "I should be greatly obliged if you would inform me how one may become a F.R.P.S.?"—In reply: Address the Secretary of the Society, 66, Russell-square, London. We have many times given the particulars asked for, but cannot now spare the necessary space.

**FOCUS.**—(1) A R.R. lens of good quality, of 9½ in. focus, will cover a half-plate very well. (2) Not at all, you would have better covering power with the 10 in. (3) Either before or behind the lens, whichever is most conveniently fitted to the camera. One position is as good as the other.

**S. WATTEAU.**—Better do as we told you last week. Use the developer according to the formula given by the makers of the plates. If the plate proves under-exposed, use more accelerator. If over, employ more restrainer. As you appear to be quite a novice in photography, we should advise you, as you are going in for portraiture, to get a few practical lessons from a professional. It will save you trouble.

**CLUB PORTRAITS.**—J. H. MOODY writes: "I would feel obliged if you could give me the names of a firm of painters for club work?"—In reply: It is one of our inflexible rules never to recommend any particular firm's work, and that we never depart from. Better consult the advertisement columns, and there you will find several names who lay themselves out for that class of work. Write to them for specimens and prices.

**DRY MOUNTING.**—"Stickey" writes: "Can you inform me how I can make the backs of photographs adhesive, so that by simply wetting them they will stick to cards? I want them to dry quick—not longer than 5 or 10 minutes."—In reply: The best way is to coat the back of the prints with starch paste, and allow it to dry. Then in mounting them simply slightly damp the mounts with a moist sponge, and after placing the prints in position pass through the rolling press.

**EDGBASTON.**—It is against our rules to recommend particular makes of apparatus. We have successfully used Nos. 1 and 3 in your list, and have many excellent pictures by No. 2. You must make your own choice, for the personal equation in photography counts for much. As to plates versus films for "yielding the best negatives," our personal choice is for plates, of which we have used some thousands; on the other hand, we have negatives on cut and rollable film than which we could wish for nothing better. The advantage of keeping quality lies with the plates; that of lightness with the film.

**BLISTERED OPAL.**—"Othello" writes: "A customer has brought me a picture to be restored. It is an oil painting on an opal base, presumably bromide opal, as it is a club picture. Around the edges of the vignettted bust the gelatine film of the opal seems to have blistered up very similar to paint that is exposed to the sun. As I never saw a similar case, I should be glad if you could tell me how to reduce the blisters, as I don't want to tamper with the thing if I cannot do the work properly? I notice no blisters occur where paint has been spread, only on the bare portions."—In reply: In all probability the picture is a bromide, and the film has blistered. We know of no means of reducing the blisters. It is possible, however, that the film may be removed from the whole of bare portions by washing it off, or by rubbing it off with fine pumice powder. Then the picture on those portions can be re-coloured.

**CHRISTMAS CARDS.**—H. W. Surely you do not read the advertisement columns of the JOURNAL, or you would not have to inquire of us where you can get mounts suitable for Christmas cards. Refer to the advertisement pages.

**ACTION OF METHYLATED SPIRITS ON ALBUMEN PRINTS.**—A. F. P. writes: "I am using albumenised paper again to some extent, after having discarded it for some years. I have been much troubled with 'blisters,' but find a bath of methylated spirit before first washing a perfect cure. Will you kindly say if any possible injury can result from its use, either to the permanency or appearance of the finished print? Will it affect the toning bath, which in the ordinary way improves by use?"—In reply: The spirit will have no injurious effect whatever either on the prints or the toning bath. So you may employ it without fear.

**PYRO STAINS.**—S. F. writes: "I use pyro soda, made up as follows: pyro 1 oz., a few drops of nitric acid, water 8 ozs., equal quantities of sulphite and carbonate soda. After development my hands get fearfully stained, and even with hydrochloric acid I cannot get it off. Can you give me a formula which will remedy it? I have tried adding half the sulphite to the pyro, but I cannot get density then."—In reply: Pyro stains, when they are strong, are difficult of removal. You might try a strong solution of chloride of lime. It is easier to avoid the stains, by using care, than sometimes to remove them. There are several developers that do not stain the fingers, such as kachin, and several others. Why not employ one or other of them if you cannot avoid stains with pyro?

**A CRITICISM.**—REMBRANDT writes: "I am taking the liberty of sending you a print from a negative of my own taking, and wish to ask you to criticise it, also, if you think it is of any value to enlarge and prepare for an exhibition picture, or if you could suggest any way in which it might be utilised with a view to exhibition? I may say it is not a studio picture, but was taken outdoors without any arrangement to produce the lighting. Of course, it has been retouched, and the high lights just slightly strengthened with colour, no other work, however, has been put upon it."—In reply: A pleasing and pretty child study. If enlarged it might find acceptance at one of the minor Exhibitions. One of the illustrated magazines might purchase it from you for reproduction purposes. Better register the copyright before you submit it for sale.

**PORTRAITURE.**—"Aspirant" writes: "I have been practising photography—portraits—at home in all my spare time for the last four months, and can produce excellent pictures, as you will see by the enclosed. Do you think I could get an appointment in a good class studio as operator? I do not require to go as an improver, as I consider my work good. I should not mind accepting 35s. to £2 a week to begin with."—In reply: We should say not. The work sent, though promising, would certainly not suit a good class house—or we may say a second class one. We should advise you to seek an engagement as improver, for we may tell you, without wishing to discourage you, that the work requires much improvement. There are plenty of experienced operators who can do far, very far, better work than that sent, who would be glad of employment for a much less sum than you mention.

**CAMERA OBSCURA.**—C. F. HEWITT writes: "I am thinking of erecting a camera obscura here for next season. Can you kindly give me the name and address of the makers of the revolving arrangement for top? I want to have a picture on table of about 5 feet diameter. Will you also kindly tell me about the best lens to use, as I have several surplus lenses, and perhaps one of them might do? I have an old 3½ in. diameter, by Lerebour et Secretan, Paris. Would that do? It would be for public exhibition on the beach, so, of course, should want the best."—In reply: The lens mentioned will answer very well, if it is of sufficiently long focus to give an image of the size desired, though we are inclined to doubt if it will. That you can prove by trying it. Some of the lenses of the makers referred to were, however, of very long focus for their diameter. We do not know of any one who makes a speciality of the revolving top; but, of course, any optician will construct it to order.

**MARKS IN PLATINUM PRINTS.**—F. M. writes: "I should be much obliged if you could inform me as to the cause of the markings (dark spots without sharp edges) on the enclosed print? It is a platinum print on A.A. paper, developed cold, and made from a varnished negative. The spots appear persistently, though I have made several fresh batches of developer, and the dishes are not used for anything else. On some hot bath paper, which I tried, and which was treated in identically the same manner, and with the same developer heated, the spots did not appear. I have been told that it is due to a defect in the sizing of the paper, which seems probable, as you will see that the spots do not appear in the whites of the print, as they would if they were due to defects in the solutions or manipulation. The developer has been analysed, and no impurities found. Needless to say, the company will not accept any liability, but content themselves with bluff. I feel that I ought to apologise for troubling you at such length, but it is a somewhat important matter to me, as my employer blames me for what I feel sure is not my fault."—In reply: We cannot account for the spots. But as the spots do not appear when the solution is heated it would seem that they are not due to the paper, but rather something in the manipulation. We are sorry we cannot help you more definitely.

### EX CATHEDRÁ.

WE again remind our readers that this (Friday) evening the Third Traill Taylor Memorial Lecture will be delivered at the rooms of the Royal Photographic Society, 66, Russell-square, W.C., by Mr. F. E. Ives, who has chosen for his subject "The Optics of Trichromatic Photography." The meeting takes place at eight o'clock, and admission is free. We have learnt that Mr. Ives has travelled specially from America in order to read his lecture in person. He proposes treating his subject very exhaustively, and we hope that he will have a large and interested audience. In whatever aspect it is presented, colour photography maintains a firm hold on public attention. Early in the year no meetings were so well attended as those at which Professor R. W. Wood discoursed upon his diffraction grating process. To

this day the young American professor's wonderful grasp of his subject, and his readiness to impart or receive information on any point connected with it, are pleasantly remembered by very many on this side the Atlantic. Of the same splendid type is Frederic Eugene Ives, in whose voluminous writings on the subject of heliochromy one aspiration above all others is apparent, that for scientific truth. The distinction of which Mr. Ives will this evening be made the recipient is richly deserved, for he has largely added to our knowledge of colour photography, and has inflexibly refused to accept any illegitimate advantage in return for his work. When the full history of colour photography comes to be written, we are confident it will be made plain that Ives has borne a great and honourable part in it—all the more honourable because he has steadily held himself and his great knowledge well out of the reach of the unscrupulous company promoter.

\* \* \*

SOME interesting experiments in image transference by means of photography formed the subject of a short communication by Mr. F. E. Ives to the Franklin Institute a few months ago. He showed a photograph which had been made by exposing in the camera a card coated with luminous paint, then removing it to the dark room and placing it in contact with a photographic sensitive plate, which was afterwards developed in the usual way. In reply to a question, Mr. Ives said that he believed the luminous paint card, if it had been kept in total darkness for several days, need not be exposed in the camera very much longer than would be necessary for a photographic sensitive plate, provided that it was exposed with a larger aperture lens and the object illuminated by sunlight, and the card immediately removed to the dark room and pressed in contact with the sensitive plate for several hours. If the card was exposed in the camera for a few seconds under the conditions he had named, it need not remain in contact with the photographic plate for more than two or three seconds. He also showed a photograph which had been obtained in total darkness by the action of reflected heat rays, which were made to form

an image of the object by means of a rock-salt lens. The object was a polished metal key check, exposed to the rays of a limelight, from which the visible rays had been absorbed by a screen. The test screen for this purpose was a sheet of vulcanite. The luminous paint card was first exposed to daylight, to make it evenly luminous, and then to the invisible image, which produced a dark image upon the luminous surface by exhausting the luminosity. The card was then placed in contact with a photographic plate for a few seconds, and the plate was afterwards developed, as in the first experiment. So far as he knew, this was the only photograph of an object ever made by reflected heat rays, made to form an image in the camera. In this week's JOURNAL we also reprint a short paper on the allied subject of "Picture-making in the Dark," contributed by Mr. M. I. Wilbert to the Franklin Institute. The subject is an exceedingly fascinating and complex one.

\* \* \*

As the subject of photographic representations of the Ober-Ammergau Passion Play has lately been referred to in our pages, the remarks published in one of the London daily newspapers of Monday last, with reference to a public exhibition in which photography was the sole agency at work, may be worth while quoting. The report reads as follows:—"It cannot be said that the representation of the Ober-Ammergau Passion Play by means of photographs and animated pictures which was given on Saturday in the Concert Room at the Crystal Palace came up to the usual high level which marks the Sydenham performances. Knowing the great possibilities of animated photography, the audience, who came probably hoping to see the whole of the wonderful Passion Play reproduced before their eyes, met with a disappointment. The programme consisted of a mixture of coloured views of Ober-Ammergau, of photographs of famous pictures representing incidents in the life of Christ, together with a sprinkling of animated photographs of scenes in the Passion Play, such as the Triumphal Entry into Jerusalem, the Garden of Gethsemane, and the Crucifixion, and lengthy explanations. In the brief interval between the two parts of the programme a member of the audience loudly asked whether the photographs had been actually taken at Ober-Ammergau, a question to which no public reply was vouchsafed by the lecturer. At the close of the performance there was an absence of applause, and two or three of those present, who had themselves been at Ober-Ammergau, complained that even the animated photographs bore but little resemblance to the scenes in the play as they were actually performed." Objection seems to have been chiefly taken to the inferior quality of the photographs shown; but, given the utmost excellence obtainable, it is doubtful if the Passion Play is quite suitable as a subject for a concert-room entertainment. But if society generally takes the view that it is, by all means let the photographs be as good as it is possible to get them.

\* \* \*

MR. HOWARD FARMER, in his letter commenting on the report of the examiners in photography for the City and Guilds of London Institute, touches once more on the much-debated question of theory *versus* practice. This is a question which has given rise to endless discussion in the

engineering trade particularly, where there are many highly-skilled, highly-practical men holding responsible positions in eminent firms whose theoretical knowledge is very limited. It is quite conceivable that a man may have a profound knowledge of photographic chemistry and optics, and yet be a poor photographer; and, on the other hand, a man may have a very limited theoretical knowledge and yet be highly skilled and eminent as a photographer. But the practice of photography—*i.e.*, the taking of photographs—is only one aspect, although, of course, a very important one. There is also the manufacturing and the scientific aspect; and it is here where a knowledge of photographic chemistry and optics, and we may add practical mechanics, is essential. It is not quite clear how the examiners arrive at the fact that the elements of photographic chemistry and optics do not receive sufficient attention, because, though the answers to the examination papers may tend to show this, it does not necessarily prove that such is the case. But it is evident from Mr. Howard Farmer's extremely interesting communication that for the generality of professional photographers he rates practical knowledge before theoretical knowledge. "Do not let it be supposed," he says, "that I wish to discourage the study of chemistry or optics—for plate-makers, camera-makers, lens-makers, some teachers, and many others, they are fundamental; to photographers they are useful auxiliaries, but not essential, and should, if possible, be studied as subjects separate from photography, for in the majority of cases, as surely as undue attention is given to what may be termed the science of the subject, so surely will the students go backwards, instead of forwards, in their progress as photographers." This rather curious observation will doubtless receive the attention it deserves, coming from a teacher of Mr. Farmer's extensive experience.

\* \* \*

ANOTHER paragraph in Mr. Farmer's communication is very relevant. It is as follows:—"The City and Guilds give two certificates—one for photography pure and simple, and the other a full technological certificate—to those students only who have studied chemistry and optics, or drawing, and yet, notwithstanding this special certificate for accessory subjects, we get an undue proportion of scientific questions, and a continual complaint of insufficient knowledge of science in an examination which is represented to be for pure photography." It certainly does seem to us that here Mr. Howard Farmer has a distinct grievance. The question as to what constitutes well-directed technical education is a most important one; but it is not at all certain whether the City and Guilds authorities have themselves settled this point. How many of the students at the City and Guilds Technical Colleges at Finsbury and South Kensington, it may be asked, are capable of taking full advantage of the training offered? We doubt not that the percentage is comparatively small; and it is well known that some of the students who pass out of these colleges equipped with a profound theoretical—we might say, to coin a word, professorial—knowledge find it difficult to obtain suitable employment in works. Mr. Howard Farmer further says: "At the present moment this school (at the Polytechnic) is full to its maximum accommodation with professional students, and we have reluctantly been compelled to refuse many entries. May I ask, under these circumstances, what

is the duty of a teacher who feels more painfully every day the misdirection of youthful energies which this excessive forcing of elementary science involves? Shall he also by continually lecturing upon these subjects encourage the less fit and discourage the more fit?" No one can deny that a knowledge of the scientific principles underlying practice is very desirable. At the same time, we must admit that Mr. Farmer has asked a question which it is not easy to answer. We have referred to the technical training given at the City and Guilds Technical Colleges. It might fairly be said that if all the students attending those colleges could take full advantage of the training given, they would all be eligible for professorships when they left. What is desired is the ability to acquire scientific knowledge and the ability to apply such knowledge to practical purposes.

\* \* \*

THE important question of scientific training was dealt with by Professor John Perry in his recent presidential address to the members of the Institution of Electrical Engineers. As the "Times" points out, Professor Perry's address "merits the serious attention of a far wider audience than that to which it is primarily addressed. For it deals not with any special problem of electrical engineering, but with the general question of scientific method and training which underlies every department of industrial activity." Indeed, Professor Perry struck at the very root of our present system of education. He says: "All men should be more alive to the importance of scientific work. It was again the fault of our methods of education that all our great men, our poets and novelists, legislators and lawyers, soldiers and sailors, manufacturers and merchants, clergymen and schoolmasters, remained ignorant of physical science, the application of which by a few men not ignorant was transforming all the conditions of civilisation." When we are agreed as to the importance of scientific knowledge, there is still the problem as to how such knowledge should be imparted. We rather think that, instead of attempting to force a vast amount of scientific knowledge on the young mind in a short space of time, we should commence sooner, and impart the knowledge gradually. The cumulative effort of investigators, inventors, and manufacturers has made the pursuit of photography to modern practitioners a comparatively easy affair; but if it is desired to produce really good work something more than mere manipulative skill is required—a theoretical and practical knowledge of photography, an artistic talent, and an art training are all necessary. And then is the pursuit of photography to be regarded as a profession or a trade? As the "Times" points out, "there are people in many departments of life who like to call their trade a profession, because the word has a loftier sound. But that does not lift them out of the category of tradesmen. If a man is continually dealing with new problems and bringing to their solution alike the systematised results of past experience and the new ideas springing from continual acquisition of new knowledge, then what he pursues is a profession. If, on the other hand, he merely deals over and over again with problems already solved by others, in accordance with formulas to which he has nothing to add, then he is only a tradesman, no matter how he may borrow professional prestige from association with men of a different character."

## STUDIO BLINDS SCREENS.

IN accordance with a suggestion that the practical value of our recent articles upon studios would be considerably enhanced if some instructions upon fitting with blinds were added, we propose to carry out the suggestion by giving what might be called a few working details. The subject will naturally divide itself under several headings—shape, distribution or arrangement, mode of hanging and working, and material. Before discussing these severally, it will clear the way if we consider the object of using blinds. This may be briefly described as to enable the photographer to modify the direction, the volume, and intensity of the illumination, without requiring any movement on the part of the sitter. We thus qualify the object in view in recollecting the mode of working of a once-famous photographer and contributor to our pages, who, perhaps a quarter of a century ago, did excellent work without having a single blind or screen in his studio. He had a very large working area: the skylight was almost in the middle of the roof, and he obtained every variety of lighting by the simple process of moving his sitter under this light so as to bring it more or less overhead and more or less in front. He produced, as we say, excellent work, the chief objection to his plan being the need of a large studio, especially when, as in the present day, full-length pictures are required, and, further, the undesirability of disturbing the sitter's equanimity by repeated changes of position. Otherwise the plan has many advantages.

Next approaching this plan in simplicity is that once adopted in another studio of using one single blind only. It was a sloping front studio, and one huge curtain, with a sufficiency of slack, was supported under its whole surface on two iron rods. It could be moved towards and away from the sitter, and also, by reason of the slack, to a certain extent sideways. There was thus a considerable, though by no means complete, power of control over what on first thoughts might be considered an unwieldy, bulky arrangement.

There is amongst a large body of workers in studios one singular prevailing idea with regard to blinds or light screens, which should nevertheless be rejected—at any rate, as far as regards its need for light controlling. We refer to the almost universal plan of fixing the blinds close against lights or windows. This means, if we take a room 18 feet wide with 9 feet side walls, and only a 45° pitch of roof, 18 feet from the floor. Such a plan is as useless as it is wasteful of material of construction and time in working. If all the blinds are placed at a height of, say, 12 feet, they are in easy working distance, and easily adjusted if (as, however, ought never to happen with a properly devised scheme) they get wrong and jam. A system so arranged gives as efficient a control as is possible, and is entirely independent of the shape of the roof, which, when single figures were being taken, might be of a pitch of 30° or as high as a steeple without altering the illumination one iota.

Before entering into constructive details there is one more point to be considered, and that is, convenience in working the blinds when once erected. Let us at the outset express our unhesitating opinion—an opinion arrived at after examining the methods of a very large number of studios—that a system without cords or pulleys is infinitely to be preferred. No matter how well devised the system, there is always the liability of the cords going wrong somehow—

they break or stick, or perhaps jerk the whole arrangement on to the floor, and we know these contretemps always happen at the most inopportune moments. A plan where sliding blinds are moved by a loose rod or pole, though less mysterious than pulling a cord, is infinitely to be preferred. These observations, it will be understood, refer more especially to the heavier opaque blinds, rather than to the translucent screens for diffusing the light.

In purchasing the fabric to be made up into screens, a decision will be required as to the material and the colour. The colour will have to be chosen from several considerations—its power to stand light without fading, the greater or less capacity it imparts to the fabric, and, finally, the extent to which it will harmonise with its surroundings. This latter may seem a matter of no importance to some of our readers, but the harmony of the whole surroundings of the studio should be part of the scheme of decoration, and discordant colour contrasts should be avoided wherever possible.

As regards the fastness of colour, we have seen blue-dyed cotton material used, the under side of which, after ten years' continuous exposure, has been almost as good as on the day it was first put up. Many kinds of fabric lend themselves for blinding purposes, the simplest plan being to inspect all the materials and colours at the drapery stores and choose one with as little stiffening as possible. So long as material of the right substance is selected, we do not think it necessary, or even desirable, that its opacity should be complete, as all the shadowed side of the subject would have a tendency to heaviness, though, of course, this might be counteracted by suitable reflectors. Again, this would be governed by the colour of the walls of the room; if they were light or of an actinic colour, as blue or light grey, the illumination of the subject would be decidedly influenced. At one time it was considered the proper thing to use blue, but it is so crude as a decorative tone that it is now far less in demand than was once the case.

For the blinds or screens of semi-translucent material many substances may be used—nainsooks, muslin, jaconet, or the like; but for general efficiency, combined with the minimum loss of light, nothing approaches architects' tracing cloth, and this is best chosen with a glossy surface on each side. It is more commonly stored with one side dead, but this would not keep clean for so long a time as the other. The drawback of this material is that it will not double or run in folds; it has to be fenced on rigid skeleton frames or used on rollers. It will not be possible to include in a single article all that it is desirable to say, and as we have stretched our space to the utmost limit, as we have already said, we will shortly return to a further consideration of the remaining points which we have classified.

---

**Becquerel Radiations.**—We have from time to time made our readers acquainted with Becquerel's investigations into remarkable actinic radiations emanating from uranium and its compounds, and we are pleased to note that the Royal Society have adjudicated to Professor Antoine Henri Becquerel the Rumford medal for his discoveries in radiation proceeding from uranium, and Her Majesty the Queen has been graciously pleased to approve of the award.

---

**Brazing Cast Iron.**—There are, doubtless, many of our readers who are amateur mechanics, and occasionally wish to

satisfactorily braze cast iron, which is not such an easy matter. We were present last week at a demonstration in which a piece of cast iron irregularly broken, and with surfaces measuring one and a half inches square, was perfectly brazed in fifteen minutes. The operation consisted of first cleaning the surface with spirits of salts, smearing a special preparation, called Ferrofix, on to the same and then brazing with spelter and a special flux termed Borfix. The joint was so perfect that, even after considerable force had been used with a sledge hammer and anvil, the piece of iron broke in a new place. The operation is so simple that, although we have had no experience in brazing, we successfully brazed a small piece in ten minutes. Mr. A. E. Hubsch, of 3 Broadway, Ludgate Hill, E. C. will be pleased to forward full particulars on application.

---

**Phenomena of Vision.**—In reference to the article on this subject in our last, an esteemed contributor has described to us a very instructive experiment on the want of achromatism of the eye which can be made at almost any railway station after dark. Dr. Shelford Bidwell threw on the screen a patch of blue, violet, and of red, for the audience to test the difficulty of focussing both in the eye at the same time. The experiment we refer to is made with one of the purple signal lights now usually seen outside railway stations, and consists simply in observing such a light first with one, and then with the other eye. It is found more frequently than not that the colour appears different with each eye, one eye will focus correctly for distance the blue constituent of the light, which will then appear quite blue; the other eye may find a focus of the red constituent and the lamp will appear red. Experiments like these greatly assist in understanding the achromatism of photographic lenses, though it is to be remembered that the term has by no means the absolute meaning usually attached to it. The achromatism of the ordinary lens is really confined to two colours only, though since the advent of the Jena glasses three colours are combined in the more modern lenses.

---

**Steadiness of Camera Supports.**—For photo-micrographic work and other delicate photographic investigations a firm support for the instrument is an absolute necessity, and those who have devoted time to the use of high powers know how next to impossible it is, especially in large towns, to obtain the desired stability. A room in the basement is absolutely essential to avoid the jar and tremor caused by passing vehicles, and is not always an efficient preventive of vibration. Some idea of the extent to which the traffic in great cities induces tremor will be found in the Report of the Paris Observatory for 1899 just issued. M. Bigourdan has made a series of experiments on the subject, and he finds that even at a depth of 87 feet 7 inches the earth is not absolutely free from the effects of vibration caused by the passage of trains, though that attributable to the passage of cabs and omnibuses in the streets contiguous to the Observatory is practically insensible at such a depth. At our own Kew and Greenwich Observatories the great trouble comes from the working of electric railways and trams, which so greatly interfere with magnetic observations that it has been felt necessary to hold a private conference at the Board of Trade to see what can be done to ameliorate matters.

---

**An Early Investigator on the Chemical Action of Light.**—A very interesting article upon the investigation of the chemical action of light upon plants, by Domenicho Cirillo, appears in a recent number of *Nature* over the signature of Italo Giglioli, and is well worth reading by students of the history of photography. It is more in the nature of what it is the fashion to term "an appreciation" of that unfortunate man, who died a hundred-and-one years ago. It is, of course, outside the province of a practical journal like ours to enter into the life history of plants, but the article shows how near these early investigators were to the discovery of a photographic process; but their work lay rather in the direction of the discovery of first causes than in that of invention. Yet their results are a complete and conclusive answer to the parrot cry of *Cui bono*, so often uttered when descriptions of purely scientific investigation are published. The-

references in Signor Giglioli's paper show how many philosophers were working upon the various branches of the one subject, and the marvel is that a process of what we call photography was not thought out before. Nothing is said in Signor Cirillo's treatise or his eulogist's comments upon it to lessen the force of the claims made upon Schultze's first publication in 1727 and of Scheele's vitally important experiments in 1770, but less known names of men who have all worked in the same mental quarry are given. There is mention of Senebier's work in 1782; of Alessandro Barca in Padua in 1782; of Antoin Maria Vasalli, who in 1794 investigated the results of light action on chloride of silver; but, as we all know now, their results had been anticipated by the work of Schultz and Scheele.

A SIMPLE WATER-HEATER FOR CARBON WORK.

It is very remarkable that so few photographers, amateur or professional, take up that most interesting and beautiful of all photographic printing methods, carbon printing. It is simple, easy to manipulate, inexpensive, capable of the widest variety and range of gradation and colour, and is beyond comparison for transparency-making for enlarged negatives; yet how many photographers are there who make any use of it; and what is the cause of its comparative neglect? I take it that the causes are threefold. Firstly, the fatal facility of bromide work for enlarging. Secondly, the fact that so few dealers stock the materials, and nowadays people will not be at the trouble of writing for their photographic requisites, they expect to find them on sale next door. (One reason, perhaps, for this non-stocking of carbon materials is that they afford so little profit as not to be worth storing.) Thirdly, the necessity for the use of hot water.

We are all familiar with the amateur and his dark room—bath room, the sole resource that domestic exigencies permit the enthusiastic worker; but to use it for carbon printing also would involve too many possibilities of obtrusive chemicals in the wrong spot at the wrong moment. As to the professional, he usually has a copious supply of cold water; but when a question of hot water is involved it seems to involve so much "time and bother"—that is the way I have often heard it put—that he does not care to make a start. My present purpose, beyond saying a word in favour of a beautiful and neglected process, is to describe a method I have lately adopted for overcoming the hot-water trouble. My studios have hot water laid on. I have almost every variety of gas-burner for heating purposes, but in summer time we do not always have the fire going that heats the hot-water system, and, excellent as are the gas-burners for heating that are now attainable, their use involves a certain amount of preparation and attention that means loss of time. What is wanted is a self-acting heater where you light the gas, turn on the cold water tap, and have hot water running out. This sounds rather a chimerical expectation; nevertheless, it is an accomplished fact. A hot-water apparatus is constructed that exactly fulfils these requirements, and can be set up without the need of that useful but expensive workman the plumber.

Below will be found an illustration of the apparatus, and a few particulars only are needed to explain how I adapt it to a photographer's requirements.

The apparatus is made by Messrs. Fletcher & Russell, and their own working instructions are as follows:—

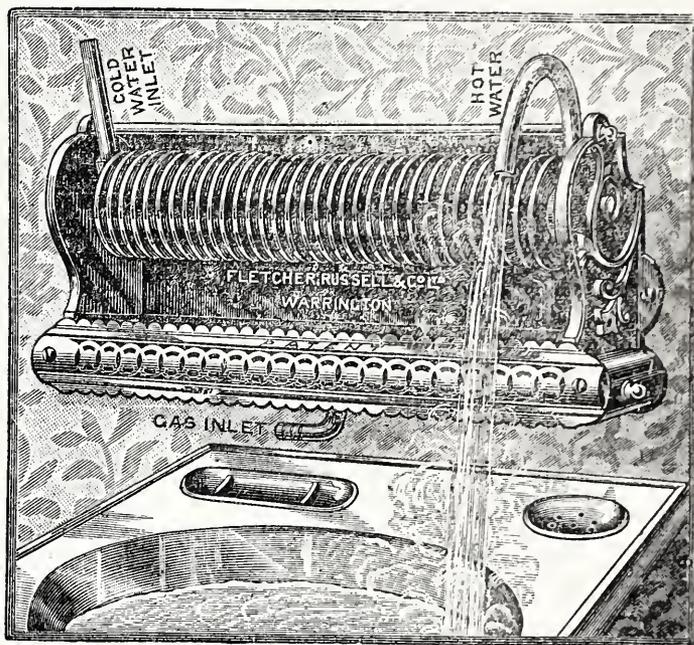

*Horizontal Pattern.*—The use of F. R. & Co.'s Patent Solid Webs for conducting the heat of the burner to the water renders it possible to construct very powerful and efficient water-heaters of an exceedingly small size. This pattern is only 14 in. wide, and 6 in. high over all, small enough to be fixed behind any lavatory without inconvenience. It will deliver one quart of water per minute, heated from 60° to 125° F. (scalding hot). It is free from drip or mess, and is also free from smell, unless worked with an excessive pressure of gas, and beyond its intended power; in this case the tap should be turned down a little until the smell disappears.

The inlet and outlet are now made at the same end. This is, as it appears, simplicity itself; but the plumber and his myrmidons looms in the distance, yet I repeat he is not needed

A glance at the illustration shows that three requirements have to be fulfilled.

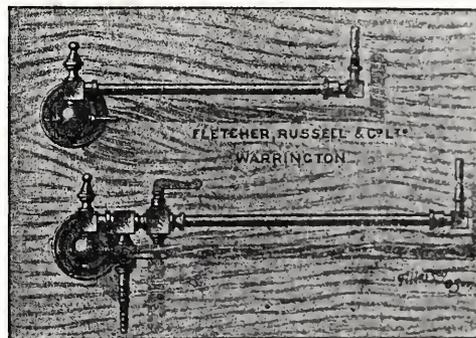

1. The apparatus must be fixed.
2. Gas must be connected to it.
3. Water must be brought to it.

As to the first, all that is needed is to get two pieces of tin or sheet iron about three inches by one, and to nail them about nine inches apart

to the wall, sending the nail through one end and leaving the other end projecting upwards (two nails would add to the stability). There is at the back of the above apparatus a metal plate inside which the two pieces of tin are thrust, and the apparatus is at once suspended.

Connecting the gas to it: Here again Messrs. Fletcher & Co. come to our help. One can purchase for a very small sum a little arrangement illustrated below.

To obtain a supply from an ordinary bracket. The engraving shows a bracket with and without the attachment.

The bracket arm is unscrewed from its position, and the arrangement screwed on instead; and then the arm is rescrewed to the attachment into a place reserved for it. The bracket subserves its usual purpose and has in addition, as will be noticed, a projecting piece to which can be attached an ordinary piece of gas-tubing; the other end of which is attached to the water apparatus.

Third. We are now supplied with gas, and only want the water supplied. This is readily done by attaching to the top another piece of rubber tubing, to one end of which is secured an ordinary self-fitting union, such as one is familiar with in a garden hose, and which costs about a shilling. Further, Messrs. Fletcher & Co. soldered at my instructions a wider piece of metal tubing at the cold water inlet (see illustration), and on this the other end of the rubber tubing is simply slipped. The apparatus is then complete.

and ready for use. If required, it can be taken down in a second and brought from one room to another where there is gas and water. If kept in one place, the rubber water pipe can be attached and disconnected in a moment without interfering with the use of the tap for ordinary work.

There is no need for more to be said, the manner of use of the apparatus is as self-evident as its usefulness is indubitable.

G. WATMOUGH WEBSTER, F.C.S., F.R.P.S.

### PHOTOGRAPHS IN RELIEF.

PROFESSOR NAMIAS read an interesting note on this subject before the International Congress of Applied Chemistry and Photography recently held in Paris. The well-known property of chromated gelatine and colloids ceasing their water-absorptive power after exposure to light is taken advantage of, and the author stated that he preferred to take the sitter in profile, and to powder the face, and light it in such a manner as to get a strong picture.

The chief point in the process which is novel is the coating of the colloids on a sheet of glass and subsequent sensitising, a mixture of the sensitiser and the colloids not being successful. Another novel point is the increase of the relief by the use of an admixture of gum arabic: the actual mixture consists of—

Gelatine .....	20 parts.
'Gum arabic.....	10 "
'Water .....	100 "
'Glacial acetic acid.....	1 "

The acetic acid keeps the mixture, so that it can be kept in bulk in a stock, and a little taken out and melted, when required for use, in a water bath.

When melted it should be poured on to a levelled sheet of glass to the thickness of two or three millimetres, and when set should be dried in a horizontal position. For sensitising, a three per cent. solution of ammonium bichromate with an excess of ammonia should be used. The plates thus prepared require a longer exposure than those that are sensitised with the bichromate alone, but they will keep longer, about ten days, and give a considerably higher relief; the bichromate acts even during the drying on the gum, whilst the monochromate only does this, as is well known, very slowly. It might be thought that the gum would dissolve in the sensitising, but this is not the case.

The exposure under the negative, which should be somewhat vigorous, is rather long, from a quarter to half an hour in the sun, and the printing frame should be so placed that the sun's rays fall on it as perpendicularly as possible.

If the plate is placed in plain water, considerable relief will be obtained; but this is, on account of the presence of the gum, irregular, and shows a coarse grain. This trouble is overcome, however, by placing the plate in a two per cent. solution of alum, to which two per cent. of glacial acetic acid has been added. This solution allows the film to swell without dissolving the gum, for the solubility of the latter is probably the cause of the irregular swelling and the formation of the grain.

After some hours' soaking considerable and perfect relief is obtained, and great resistance, which is not only suitable for casting in plaster of Paris, but also after dusting with graphite enables one to obtain an electro from it. When using the relief for the latter purpose, it is as well to paint the edges of the relief with varnish before or after printing, which prevents the film stripping when for a long time in the acid sulphate of copper bath.

The author points out that the relief thus obtained is very suitable for the reproduction of line drawings for books, and this is much cheaper than the ordinary methods.

### PICTURE-MAKING IN THE DARK.

[A paper read before the Photographic and Microscopic Section of the Franklin Institute.]

PHOTOGRAPHY is usually understood to be the production of images by means of chemical changes in certain substances, such as silver chloride, bromide or iodide, by radiant energy. If this be the limitation of the

word, much of what I wish to call attention to in this paper has nothing to do with photography, for, as I will try to prove, radiant energy, as we know or understand it, is not necessary to the production of a true image on a sensitive photographic plate.

It is well known that we are influenced by forms of energy not readily recognised by our unaided senses. For instance, many sounds are not audible to us that are readily recognised by many of the lower animals. The spectrum contains many rays outside of the portion visible to us. Scientists, from time to time, have devised many ingenious pieces of apparatus to aid in discovering, defining and differentiating these obscure forms of energy. The work done in this direction is sufficient to show that there is still a great field for research and experiment. The photographic plates provide us with means of detecting many of these elusive rays, and it is my purpose to call your attention to the ease with which many of these experiments may be carried on.

The pictures are produced inside of a box such as that used for holding dry plates. The sources of energy that may be used to produce images are as follows:—

1. Transmitted light.
2. Phosphorescence and fluorescence.
3. Heat.
4. Chemical energy.
5. Electrical energy.
6. X rays and kindred phenomena.

Ordinary opaque bodies are only comparatively opaque; the common cardboard, though impervious to diffused daylight, is not opaque to direct sunlight.

About four years ago, when the X rays were first announced, many experimenters thought they discovered X rays in sunlight.

The pictures obtained by exposing a photographic plate, properly protected, to sunlight were produced by transmitted light. These experiments may be duplicated in an interesting and instructive way by placing a sensitive photographic plate in a box, so as to have the gelatine side in contact with the bottom of the box, then placing a coin, a piece of glass and a piece of black paper on the box, bottom side up, and setting the combination in sunlight for an hour or two. On developing the plate it will be found that the sun has acted where the plate was not protected by an additional opaque substance. For instance, the piece of glass offers little or no resistance to the rays of light, differing in this respect from the X rays, which are largely absorbed by glass.

Phosphorescence and fluorescence are phenomena that for many years have attracted little attention, but the discovery of the X rays has revived interest in them. About fifty years ago two eminent Frenchmen, Niepce de St. Victor and Antoine Becquerel, whose fame in connection with the development of photographic processes is well recognised, made extended experiments and observations on these phenomena. St. Victor, especially, made exhaustive studies, and among his numerous contributions to the subject, the most interesting, probably, are those on "invisible phosphorescence." He discovered that many substances, while not visibly phosphorescent, would still appreciably affect sensitive silver salts. He also recorded the fact that these substances, or rather many of them, could be protected so that they would retain active properties for some time, such as a week or ten days. The protection to which he refers consists in placing the substance, after it has been exposed to sunlight for an hour or more, in a tin box with a close-fitting lid.

There are many substances that seem to have this faculty of absorbing light and emitting it again in the dark, among them, blocks made of plaster of Paris, white sugar, white, and especially glazed white, paper. Broadly speaking, we may say that any white substance will give us practically the same results. We may take advantage of this property in various ways. If we take, for instance, a print made on a piece of glazed white paper and place it in the sun for some time, then place it in the dark room, face downward, on a photographic plate, leave it there for two or three hours, on developing the plate we may obtain a fair negative. The same result may be obtained with a piece of white marble with black streaks, or a piece of china or a tile with coloured figures.

Heat is a great factor in bringing about chemical changes, and it would be surprising, indeed, if it did not affect the easily decomposed active agents of photographic plates. As a matter of fact, heat contributes as much as any other source to producing fog, or spoiling photographic plates.

Heat may give, under certain conditions, a passable image of metallic objects.

If we heat a coin or a piece of metal having on its surface any design in relief and lay this on a photographic plate for a second or two, then develop the plate, we will find that we have a very fair image of the design.

Chemical action is a form of energy the possibilities of which for picture-making do not seem to have been recognised in this country. In England considerable attention has been given to the effect of chemical emanations on sensitive photographic plates. Among others, Professor W. J. Russell, Vice-President of the Royal Society of London, has made several communications on this subject, especially an exhaustive paper published in the "Chemical News" of a recent date.\*

In this paper Mr. Russell offers many suggestions for experiments. He is the first, I think, to observe that the change produced on the surface of many metals by oxidation in air is such that it may be made to record itself on a photographic plate. Among the common metals that may be employed are zinc, magnesium, and copper, and their alloys. Iron seems to have a slight action under some conditions.

The requisite for success is to begin with a perfectly bright surface of metal. The easiest means of obtaining this is by scratching the surface with coarse sandpaper. If we lay the brightened piece on a sensitive plate for several hours, on developing it will be found that the metal has affected the plate to a marked extent. Substances such as glass, celluloid, or thin layers of any metal, do not allow of any action on the photographic plate through them, while such materials as woven fabrics or paper only intercept the action to a limited extent.

Many inorganic compounds will give results of a similar nature. I have experimented with a number, but more with a view of finding penetrating qualities similar to those developed by compounds giving us the so-called Becquerel rays, which I will mention later. Many organic compounds may be used. Among the most active are the "terpenes," chief among them being the ordinary oil (spirit) of turpentine. If we put a few drops of this oil on a piece of porous paper (blotting-paper answers very well), allow all excess of moisture to evaporate and place this paper and a photographic plate together in a closed box for from five to fifteen hours, on developing the plate in the usual way it will be found that there has been a marked change. If we interpose sundry articles between the sensitive plate and the turpentine paper, we will obtain an outline image of the harder and impervious articles, while the pervious or porous articles will allow the fumes to penetrate more or less, depending, of course, entirely on their thickness or porosity. Among the other terpenes that are particularly active I may mention orange, lemon and bergamot oils, any of which will act readily in the same manner.

Speaking in a general way, I may say that any substance emitting oxidising vapours, such as nascent oxygen from hydrogen dioxide, or any strong odorous substance like turpentine, will effect a change in the sensitive materials of a photographic plate. It is generally admitted, I think, that the odour of a substance depends on its emitting a more or less minute quantity of a volatile principle. That this emission does not necessarily affect materially the weight of a substance is readily demonstrated in the case of musk, which will continue to give off the characteristic odour for years, without material decrease in weight.

In this connection it may be interesting to mention that odorous woods, or such as contain a resin or volatile oil, readily impress their images on a photographic plate in the dark, the active agent, of course, being the fumes or odorous vapours that are emitted by the oils or resins contained in the wood.

If we place a piece of Southern pine on a photographic plate, we will obtain, in the course of a few hours, a very good image of the grain of the wood. We may leave a piece of inodorous hardwood, such as hickory, in contact with the photographic plate for weeks without the latter being affected. Another very active agent is linseed oil. This, singularly enough, seems to increase in efficiency for some time, due, no doubt, to the fact that the process of drying is really a process of oxidation, and a comparatively slow one. This brings us to an interesting application of the phenomena. Printers' ink is, or rather is supposed to be, made up chiefly of linseed oil as a base. By taking advantage of this fact we may obtain positive images of printed matter, by simply laying a printed sheet on a photographic plate for some time and then developing the latent image.

Electricity of high potential is another source of energy acting on

photographic plates through almost any protecting envelope. The effect may be accomplished with or without the actual spark.

The pictures produced without actual spark are the most interesting. If we lay a piece of metal or a coin on a plate, enclose them in a box, and then place the box in the influence of the silent discharge of an induction coil, we will, on developing the plate, obtain what looks like a very much over-exposed negative image of the coin or piece of metal. Actual spark pictures, while interesting and sometimes quite pretty, can hardly be said to be good images.

The penetrating qualities of the X rays are so well understood that a mere mention of them will suffice. A closely related, if not identical, series of phenomena, known as the Becquerel rays, has been attracting the attention of scientists of late. These rays seem destined to play a very important part in the development of our knowledge as to the physical properties of matter, and it is even possible that they may lead to a revolution in our theory of matter and its ultimate composition. At the present time much remains to be learned about them. We know that they are emitted by compounds of uranium, thorium, and the supposed new element, polonium.

The compounds of uranium are comparatively cheap and quite active. The rays emitted have the property of traversing opaque substances, very much like the X rays. They will affect photographic plates through an appreciable thickness of wood, cardboard, aluminum, glass, or many other substances, as X rays do. They are largely absorbed by the dense, hard substances, while the softer or thinner layers offer little or no resistance to their passage.

I should add that in making a series of experiments I have obtained decided action on photographic plates by salts of molybdenum, vanadium, cerium, bismuth, zinc, and aluminum. It remains, however, to prove definitely whether this action is due to chemical emanations or to the Becquerel rays.

In conclusion, I would like to say a word as to the "spontaneous emission" of these rays. Personally, I think it would be wise to hold this assertion in abeyance, as from our present knowledge of the subject it is not at all unreasonable to suppose that some one will find a way of generating, or at least of increasing the intensity of these rays, so as to make them available, in an economic way, to take the place of the cumbersome and somewhat costly induction coil and vacuum tube.

MARTIN I. WILBERT, Ph.G.

### THE UNAR: A NEW UNIVERSAL LENS OF HIGH INTENSITY.

[Translated from the *Photographische Mitteilungen*.]

THE Unar, which was brought out commercially by the Carl Zeiss Optical Works, at Jena, in April of this year, has in a very short space of time found extensive application and recognition. It may therefore be of interest to many persons to learn some particulars of the construction of the lens and the uses to which it may be applied.

In calculating the lens, I set myself the task of finding a type which would permit of the attainment of an anastigmatic, flat field, with large relative aperture, by the most simple means. The image should be anastigmatically flat over a field of sufficient extent for instantaneous exposures, and the aperture should be larger than that of the best objectives hitherto made, viz.,  $f-6.3$ , with anastigmatic flat field. This aim had been realised in the Planar, which was placed upon the market in August, 1897, but the means were not of sufficient simplicity, and certain limitations to its use for the purposes of the amateur photographer were thus imposed. The price was of necessity high, and the use of the lens was restricted to instantaneous photography, photo-mechanical work, and projection.

The Planar in its smaller sizes has a relative aperture of  $f-3.6$ , and an angle of view of  $70^\circ$ . At the same time it is practically free from spherical and chromatic aberrations, so that the focus remains unchanged in using the several stops of the lens. These properties rendered the Planar of particular value as a special lens for the finest line work, enlargements, and projection. For the hand camera with plates  $6 \times 9$  c. and above, the Planar is too large and too heavy, the lenses of shorter focus, which have an aperture of  $f-3.6$ , being of considerable diameter. Moreover, the lens is less suitable for architectural photography, interiors, and landscapes, and, although it is valuable for the most rapid instantaneous work, such as cinematographic and sporting purposes, it still leaves something to be desired for the general wants of the amateur. The Cooke lens—or Triple

\*See also *Science*, II. (1900), 487.

Anastigmat, as it is called by Messrs. Voigtlander and Son, Ltd.—is notable for its simplicity of construction and general usefulness, but it is not equal to the Zeiss Anastigmats, Voigtlander's Collinear, and the Goerz and Steinheil lenses. It will be seen from the price lists of the Brunswick firm, wherein the sizes of the plates are given, that the Cooke lens (Portrait Anastigmat), with a relative aperture of  $f$ -4.5, has an available angle of barely  $45^\circ$  extent, and with an aperture of  $f$ -7.7 (the Triple Anastigmat) an angle of about  $70^\circ$ . The Portrait Anastigmat is therefore an instrument which can be recommended for portraits, but not for the use of the amateur for instantaneous photography, as the angle of field is too small. The Triple Anastigmat has sufficient angle of field, but its effective aperture is not large enough for very short instantaneous exposures when the light is not good.

Soon after completing the calculation of the Planar, my studies concerning the principle by which anastigmatic flatness of field is attained in that lens suggested a type to me, which, in the course of subsequent closer consideration, led to the Unar as a means of satisfying the requisite conditions.

The Unar, brought out by Carl Zeiss under the Series Ib, is composed of four thin single lenses, and the glasses employed are of the most desirable transparent descriptions in use, and very easily made. The lens has a relative aperture of  $f$ -4.5, and gives a sharp image over a field of  $65^\circ$  extent.

We would here remind the reader of what has been achieved in modern lenses, prior to the Unar, in comparison to the means employed. The Zeiss Anastigmat, or "Protar," as it has recently been called, has a field of  $96^\circ$ , which is obtained with four lenses and a relative aperture of  $f$ -9, or with five lenses and a relative aperture of  $f$ -6.3, a field of  $85^\circ$ . The Cooke lens, with three lenses and a relative aperture of  $f$ -7.7 or  $f$ -4.5, a field of  $70^\circ$  and  $45^\circ$  respectively. The symmetric doublets, or Double Anastigmat, Collinear and Orthostigmat, with a relative aperture of  $f$ -7.7 and six lenses, a field of about  $80^\circ$ . The Stigmatic lens, with six lenses and a relative aperture of  $f$ -4.2, a field of about  $55^\circ$ . The Planar, with six lenses and a relative aperture of  $f$ -3.6, a field of about  $70^\circ$ . The Double Protar of Zeiss, with eight lenses and an aperture of  $f$ -6.3, a field of  $80^\circ$ . The ten lens, symmetrically constructed Anastigmats, have not been used much, and they stand upon the same level as the eight lens instruments in regard to their performance.

In accordance with these figures, the Unar takes a unique position amongst modern anastigmats with regard to its efficiency. Combined with its other characteristics, it ranks as the best adapted lens for all-round work with the hand camera.

The Unar will therefore be of considerable importance for small plates between about  $6 \times 9$  c. and  $13 \times 18$  c., provided the manufacturers of cameras understand how to utilise its advantages. The amateur will then be able to avail himself, in practice, of the advantages of a lens of short focus, as compared with one of longer focus, which fact has long been known theoretically. It is acknowledged that the depth of definition of the image is greater, the shorter the focus of the lens used. It consequently follows that a view taken with a lens of short focus upon a small plate will yield more uniform definition when enlarged, and will be more harmonious than the same scene taken directly with a lens of longer focus upon a plate of the larger size. The enlargement issued with this number of the "Photographische Mittheilungen," representing the Palace of Justice at Munich, is from a film negative  $6 \times 9$  cm., and was taken with a Unar lens at  $f$ -4.5, focus 112 mm, and demonstrates the fact. The waggons were at a distance of about 10 m., and the building behind them about 60 m. from the camera, and the exposure was made without support. The depth of definition with an aperture representing 1.4.5 of the focus is sufficient to permit of enlargement to four diameters. Such exposures could not be made with a large camera, quite apart from the fact that the amateur would not care to drag about so large an apparatus in frequented places, and thus attracting the attention of the public.

As it is proved that lenses of short focus give greater depth of definition than those of long focus with the same relative aperture, the opposite must also be true, that for the same required depth of definition a lens of short focus can be used with a larger aperture than a lens of long focus. In using small plates and short focus lenses it is thus possible to give shorter exposures than when using larger sizes. As more transitive incidents may be thus secured, sharper pictures of moving objects and certainly greater facility in obtaining well-exposed plates must also follow. In one word, the possibility is presented of making all kinds of photographs by hand exposure, without a stand, be they architecture, landscapes, street scenes, portraits, groups, or

figure studies. In using the Unar for hand cameras of small size a new field of amusement is opened to the amateur, which, besides being an interesting pastime, must also be one of the highest satisfaction. It will overcome further difficulties which stand in the way either of amusement or of art.

The Unar implies the possibility of an instrument for exposure such as the camera-makers have never yet turned out. It is only quite recently that such apparatus has been made, viz., the "Film Palms,"  $6 \times 9$ , of the Jena Camera Factory. It permits of shortest instantaneous exposures, as well as time exposures of any length. Near or distant objects may be accurately focussed, according to circumstances, and it is adapted for the use of rollable films, with daylight changing. During my recent holiday I have used the apparatus, and I think the results I have secured are very satisfactory. The photograph published in the present number of this paper will enable the reader to form his own opinion.

DR. P. RUDOLPH, JENA.

#### SOME AFTER-REFLECTIONS ON THE EXHIBITIONS.

I suppose the recent exhibition of American work was intended by its organisers to be of an epoch-making character. This is a matter of opinion, which time will decide. If every visitor to the show had jotted down his impressions before leaving in a book provided for the purpose, what an entertaining volume we would have had. I really think the organisers ought to have provided a book for this purpose. Perhaps they will do so on another occasion. They ought to have no difficulty in finding a publisher for it, and the profits would help to pay the incidental expenses connected with the exhibition. One visitor's verdict was that there was some very fine work among a good deal that was only fit for the dustbin. What a delightful series of expressions have been called into being by the critics: "Plastic psychological syntheses," "nauseographs," "the cult of the spoilt print," "bubbles," "freaks," &c., &c. Some of these charming phrases will doubtless become classic.

"Individuality at all hazards" appears to be the motto of this "new" school of heaven-sent geniuses, the producers of photographic masterpieces. Some of the stuff shown was probably the queerest that has ever claimed to be art. Some of the things were absolute "doubles"; others were very much under-exposed (perhaps designedly), the result being that we were presented with full-face portraits of persons appearing to possess but one eye; others were allowed two eyes, but no body. Some of the "masterpieces" exhibited to an unbiased and unprejudiced person were not even clever; they were only queerly titled. Two were most appropriately entitled "Uncertain" and "Still Uncertain." Some of these American workers do not appear to be very fortunate with their lady models or sitters. Certainly in this country we could do with a little less adherence to convention. By all means let us have naturalness in pose and expression, but if some of the things shown at the recent exhibition of American work were not spoilt prints, it is absolutely certain that similar things produced in this country have, up to now, been considered so. But there are plenty of people ready to prove that black is white.

Works of art need not, of course, be pretty, but they ought, at least, to be intelligible; and some people prefer them to be agreeable. No mortal man could understand some of the "pictures" exhibited by these American geniuses, and even their most ardent followers have admitted this. Some of the work the writer thought very good indeed, and such can be appreciated just as well by those who have relentlessly criticised and ridiculed some of the absurd pretensions of those who ask us to read a story where no story, and apparently no motif, exists, as by those fulsome flatterers who lump the lot together and call them all photographic masterpieces. Had the rubbish been weeded out, we would have had a fine show, if somewhat small. At least that is the humble opinion of the writer.

As the Salon is a private Society, nobody has much right to question its right of existence; but it would be rather interesting to know how it would fare if it were not held contemporaneously with the larger exhibition. This, coupled with the fact that the New Gallery and the Egyptian Hall are in close proximity, is certainly not detrimental to its success.

The strongest supporters of the Salon would hardly claim that photographers journey from the provinces specially to inspect the not very numerous works exhibited there, and merely visit the exhibition of the Royal Photographic Society as an after-thought, or to fill in a spare hour or two. Comparisons are odious; but, for my part, if it was a question of one and sixpence—a shilling for entrance and sixpence for the catalogue—I have not two opinions as to which exhibition I should visit. Many of those exhibiting at the Salon also exhibit at the larger show. There was some choice work at the Salon, of course, as would be expected when the producers are men (and women)

of taste, culture, and refinement; but precisely why there should be two exhibitions held contemporaneously it is not easy for the uninitiated to understand. The photograph most popular, from a selling point of view, was of small size, and a straightforward piece of work—certainly neither a “fuzzygraph” nor a “faked” photograph. Perhaps next year the Royal Photographic Society will woo the Salonites, and get them to reconsider whether it is not possible to patch up any petty differences that may exist. I know that this is dangerous ground, but it seems to me that the Council of the Royal Photographic Society is desirous of encouraging and fostering photographic effort in every way. There were many works at the larger show not dissimilar in aim and object to those exhibited at the barn-like Salon. The professional, however, does not seem to have responded very freely to the Council's invitation. But, taking it on the whole, most visitors will doubtless agree that it was a most interesting show, and a credit to all concerned. This includes those who were responsible for the catalogue. But what a hubbub the exhibitions make.

J. A. REID.

### THE INTENSIFICATION OF CARBON PRINTS.

[Paper read before the London and Provincial Photographic Association.]

It is my intention to-night to bring before your notice a few experiments I have made during the last few months in the intensification and after-manipulation of carbon prints, and I may say that for the purpose of this paper I have gone somewhat further into the matter than I otherwise should have done, and I shall endeavour to show you at a later stage that almost any colour may be obtained on one class or colour of tissue by the means of what are generally called intensifiers, a word, by the way, that I rather object to, as, so far as I can see, carbon work is not intensified at all, so far as we understand the word.

What takes place is, I think, a dyeing of the gelatine in the tissue. I stand, however, open to correction on this point, which needs a more able chemist than I am to work out. But I am, perhaps, getting on a little too far, and maybe a little wide of my subject; and to enable me to show you a few results, and how I obtain them, I ask you to bear with me a short time whilst I develop one or two prints.

I take this course because I find that the intensification or dyeing takes place much quicker and the results are, I think, better when done direct from the last washing than if allowed to dry.

In all books on the carbon process I have access to, particular stress is put upon the fact that the prints must not be touched with the fingers or anything during development. Well, as I have at times 400 to 500 prints to get through in a day, you can quite understand that I cannot give the time needed for automatic development that I should were I dealing with some six or seven prints or working for mere pleasure.

The result is that I more often than not hurry up development in the way I now show you, giving the print first a short soaking in the hot water. I take, as you see, a common letter-book damper brush and gently sweep the larger part of the spare pigment off quickly. Another short soaking, a gentle splash or two, and our print is done.

I do not, of course, recommend this plan to every Tom, Dick, and Harry, or for every make of tissue. Elliott's is what I am using to-night, and is the make I have used throughout my experiments, and I would here say that their transparency is not to be treated in this rough and ready way, owing to its lack of gelatine.

What is wanted is a tissue containing a fair amount of gelatine, a brush that is soft and free from grit, and a very, very light touch.

This is a five per cent. solution of pot. permanganate, and we shall find our print after a few seconds in this solution has changed to a very nice deep purple, which will, you will find, change to a rather pleasing brown during the final washing, which need not be more than three or four minutes under running water. I may say that you can by longer immersion in the permanganate bath get the denser parts absolutely opaque.

The exact change that takes place I am not chemist enough to say, but possibly the pot. permanganate is decomposed, and an oxide of manganese formed. Should you by any chance get your print too deep, you may reduce or discharge the colour by an application of a weak solution of ammonio-sulphide, as you see. At this point, I had obtained exactly what I wanted at the time, and here I left the process until two or three weeks ago, and I have during that time gone somewhat further and tried various aniline dyes, using both glass and celluloid. Speaking of celluloid brings to mind an article that appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY of October 23, from, I think, an American source, to the effect that by using this material as a base for the pigment the safe edge and any transfer could be entirely done away with by printing from the back of the celluloid, being so thin as not to interfere with the sharpness of the image. I myself worked somewhat on these lines some two years ago, squeegeeing the freshly sensitised tissue direct on to the celluloid, and allow-

ing it to dry in contact. I pass round one or two results so obtained, along with a piece of opal for backing them. Of course various coloured papers or metals might be used for backing purposes, and thus some very pretty effects could be obtained. Those who object to the glazed surface have, of course, only to use matt celluloid, which is just as handy to obtain as the plain.

I had intended to demonstrate the use of the various dyes here, but the quantity of bottles and dishes required, about eighteen each, put a stopper on this, so I content myself with the next best course and made results, using engraving black tissue. I tinted the prints with green, blue, brown, scarlet, magenta, violet, black, and mauve dyes.

You will see from these prints that an almost endless amount of colours can be obtained. I also pass round a few prints made on various coloured tissues, and treated with various dyes, as marked on the back. For the dyes I have not yet sought for any reducing or discharging agent. As to their permanency I cannot say; at the same time I see no reason why they should not stand, providing, of course, that your dye is not a known fugitive, or, at any rate, made to do so by treating with a mordant, chrome alum or tannic acid, for instance. Here I must leave what has been to me, and I hope to you, an interesting subject, and in doing so I think I cannot do better than ask you a question that has occurred to me again and again, and that is: If the gelatine contained in carbon pigment lends itself so readily to these dyeing processes, why cannot a gelatine treated with pot. bichromate only be used in the same way?

E. HUMAN.

### POLITE PHOTOGRAPHY.

Mr. Harold Baker favoured a crowded assemblage of the members of the Croydon Camera Club on Wednesday, 7th inst., with his views and hints upon taking people at their best, and treated his hearers to a delightful and profitable discourse on certain technicalities of posing, exposing, lighting, &c., his remarks being illustrated by a number of lantern slides and of large prints. A remarkable illustration of the peculiar effect on time of exposure by changing the backgrounds was shown. Contrary to what might be generally expected a figure posed before a white background was said to need thrice the exposure of what would be required were a black background used. To avoid the need for much retouching isochromatic plates and a full exposure were prescribed. Speaking about the amateur, Mr. Baker said that the professional was very much the worse off, as instead of being able to pick his time and subject, he had at almost a moment's notice to turn out a flattering picture of the most impossible of sitters. Some ladies, too, had a remarkable faith in the power of the camera to conjure. Thus one called on the lecturer with a portrait by him representing a girl's fascinating face framed in a mass of luxuriant golden fluffy hair. "I want you to do my little pet just like this," said she. Her little pet turned out to be a plain child with dark short-cropped hair. A number of instructive studies were shown indicating badly posed hands, and compared with others of the same model, in which a better arrangement was arrived at. A good many other points of similar import were touched upon, and some much-appreciated anecdotes related, from one of which one may guess that the portrait painter sometimes owes more to the photographer than is suspected.

In the subsequent discussion, Mr. Ralph W. Robinson spoke of the importance of unobtrusive backgrounds, of the value of facial expression in the making of an acceptable portrait, and stated that too much importance was apt to be placed on the studio and apparatus at command. His "at home" portraits, which the President had so flatteringly alluded to, were taken wherever his sitters happened to be with an ordinary R.R. lens. The great point was to know what to aim at, and then a little common sense and experience would enable the photographer to get what is wanted.

In reply to a question respecting the value of Mr. Smith's oxy-magnesium portrait lamp, Mr. Baker said he had not yet been able to try it for portraiture, but intended doing so. Only the previous day he had been asked to photograph an interior which six other firms had refused to attempt. To accomplish this he had used Mr. Smith's lamp, and by its aid obtained pictures of the above which were unusually charming examples of interior work.

### NOTES FROM THE NORTH.

THE weather, photographically and otherwise, has been very wretched for the last three or four weeks, and studio work has been slack. No complaints are heard from the dealers. The lantern season is in full swing, with an increased demand for the cinematograph. Some evenings every available operator is out, and orders have to be refused. Already, too, there is a brisk demand for Christmas and New Year card mounts, a line in which the amateurs have undoubtedly shown the way to their professional brethren. Even yet a bromide midget is the best many a professional has to offer in the way of an artistic

Christmas card, although, as Mr. John Stuart says in his seasonable announcement, the interior of a favourite room, a picture of one's home, &c., may make a very pretty card, possessing an intrinsic value which the ordinary commercial card does not. It isn't a question of price, as a section of the public are ever prepared to pay for ideas what their creators ask.

On every hand one hears impressions of the London shows from those who were fortunate enough to see them. It is emphatically a case of "tot homines quot sententiæ," as the Romans used to say, or as our own poet put it, "No two watches are alike, yet each believes his own." There is general agreement regarding the position the Royal Society now holds as the headquarters of the art, and satisfaction that it is at last housed in worthy premises.

Early as the lantern and cinematograph season is, complaints are heard of the thoughtless and cruel treatment of operators sent into country districts. Many responsible for such entertainments seem to think the canons of hospitality have been observed in the spirit and in the letter if they offer the young man a glass of whisky. In these cases it is whisky or nothing, although a refreshing cup of tea or coffee with a slice of toast would send the grateful operator home by the midnight train with a heart overflowing with gratitude. When, as occasionally happens, the hapless operator has to spend a Sunday in a district unblest with an hotel, he often finds himself put on prison fare and miserably housed for the night. One operator who lately had an experience of that nature was off duty for a week, and he was supposed to be the guest of a clergyman.

Tanquerey is endeavouring to secure dupes in this quarter. His well-known circulars are being delivered wholesale by the Post Office. He must be using an out-of-date as well as a copy of the current issue of the Glasgow Directory, as I have received one of his "offers" at my present address, and another which was sent first of all to the address at which I was to be found up till May, 1898. There is no saying how their names come to be in his list of "customers who had portraits made in our studio, and are delighted with our work," but it may mislead some to find his methods recommended by a well-known Glasgow Bailie and by an equally well-known Glasgow physician. Among the press testimonials is one, professedly, from the "Scotsman."

There is happily, generally speaking, little or no cause for jealousy on the part of the professional worker of the efforts of the amateur, but a black sheep does stray into the amateur fold on occasion. The office-bearers of one of the Glasgow Amateur Societies lately received a hint that an advertisement offering cheap enlargements was appearing in a country paper, and that there was every reason to believe it had been inserted by a member of the Society, and that the cheap enlargements were being made in the Society's rooms with the Society's apparatus. Inquiry practically substantiated the charge, and steps were immediately taken to put an end to such wilful misuse of the Society's privileges. No one is more ashamed of such double-dealing than the amateur who is disinterestedly interested in the welfare of photography.

Formal invitations have now been issued by the Committee of the Photographic Section of Glasgow International Exhibition 1901, of which Mr. James Craig Annan is Convener. The various societies have been invited to make up a collection of work done by their members to be submitted to the Committee for the approval. Judging from the promises of support, the section will comprise the finest collection of photographic art ever brought together under one roof.

The Glasgow Photographic Association has fallen upon evil days. For three or four years past its membership, while suffering from the inroads made by death and resignation, has not been recruited by as many as half a score all told. The monthly meetings for several winters have been attended by a handful, and altogether it seemed as if the Association would shortly cease to be, through sheer decay. Rather than court this fate, the office-bearers and the faithful few who answered their summons to a recent general meeting resolved to suspend the Association meetings for a twelvemonth. If it is found by the beginning of next winter that the meetings have been missed, and that there is a prospect of another term of usefulness before the Association, they will be resumed. In Mr. Charles Macdonald the Association has of late had a most enthusiastic and energetic Honorary Secretary, but he found it impossible to galvanise into life what was plainly moribund. He hopes, however, to organise a "Smoker" during the present winter so that the "faithful" may not entirely lose sight of one another during the period of hibernation. As this was the professional Association par excellence, the "bread and butter" men are now without a visible nexus.

Full advantage was taken of the photographic possibilities presented by that great ecclesiastical event, the Union of the Free and United Presbyterian Churches. Since May last, when the Union passed the border line of probability and became an all but accomplished fact, Mr. Thomas Pursey, 2, South Charlotte-street, Edinburgh, has been engaged on a commemorative picture of the U.P. Synod. The members were photographed individually to the number of about 900, and then skilfully grouped so as to make up a faithful representation of the Synod in session, with the Moderator at his desk, the clerks at

the table, the members crowding the area, the ladies and others in the side seats, and the public galleries occupied. The picture is now nearing completion. During the Union Assembly week Mr. Pursey's studio was visited by over 2,000 members, who were more than astonished on finding themselves face to face with a picture measuring twelve feet by six. The picture is to be reproduced in various sizes and processes ranging in price from two guineas to ten. Mr. Pursey has also on hand a commemorative picture of similar interest and proportions of the last Assembly of the Free Church of Scotland. Both are very certain to be paying ventures.

The limelight lantern as an educative agency has long enjoyed the approval and stimulus of the Glasgow Corporation, but its scope is to be greatly extended this winter, the intention being to enlighten the citizens regarding the great enterprises on which the rates are being spent. It will be seen from the syllabus given below that the course of lectures, admission being free, covers a very wide range, and as each lecture is to be given by the responsible official of the department concerned, the matter of the lectures will be thoroughly trustworthy. The officials have gone very heartily into the scheme, the task of lecturing in public being by no means new to most of them. With the Corporation purse at their service, nothing will be lacking to make the course a success. The scheme is one sister Corporations may be expected to copy, and by and by there may be an interchange of slides and lectures that the leading Corporations may become better acquainted with each other's work. The following is the syllabus:—

- November 10, 1900—"The Water Supply," by Mr. Robert Wilson, Treasurer, Water Department.
- November 24—"The Municipal Electric Service," by Mr. W. A. Chamen, Electrical Engineer.
- December 8—"The Houses of the Poor," by Mr. Peter Fyfe, Chief Sanitary Inspector.
- December 22—"The Cleansing of the City," by Mr. D. M'Coll, Superintendent of Cleansing.
- January 12, 1901—"Subterranean Glasgow: How the Sewage Reaches the Sea," by Mr. A. B. M'Donald, City Engineer.
- January 26—"The Fire Brigade," by Mr. Wm. Paterson, Chief Officer of the Fire Brigade.
- February 9—"The Gas Supply," by Mr. A. Wilson, Manager, Daws-holm Gas-works.
- February 23—"The Haunts of Disease," by Dr. A. K. Chalmers, Medical Officer of Health.

#### ON SUBMITTING PHOTOGRAPHS TO THE ILLUSTRATED PRESS.

SOME interesting letters recently appeared in this JOURNAL respecting the question of the disposal of blocks after they have been used by the journals to which the photographs, from which the blocks had been made, had been contributed. It was stated by a correspondent that, requiring blocks which had appeared in the illustrated press for the purpose of illustrating a book, he wrote to the respective journals, and obtained the blocks desired. He was informed that it was not necessary to consult the various photographers concerned. The question naturally arises, Have editors any right to dispose of photo blocks in this way, reference being made, of course, to blocks made from photographs submitted in the ordinary way, and not photographs which have been specially taken for the journal in which they first appeared, and reproduction fees paid accordingly?

When photographs are submitted to journals for reproduction, it is inferred that all that is being disposed of is the right to reproduce the photograph in that particular journal to which they are contributed, and the writer cannot see that any statement in writing to this effect should be considered necessary. There can be no doubt, however, that it is necessary in many cases. There is reason to believe that quite a business is being carried on in the disposal of blocks that have been reproduced in certain of the illustrated papers. If the editors or the managers of the journals in question claim the right, after paying a few shillings to the photographer, to dispose of the block to anybody willing to purchase, they will, doubtless, also consider that they have the right to dispose of facsimiles of the block to more than one person, and blocks of the original photograph might be thus used by an indefinite number of persons and an indefinite number of times, the photographer not being consulted at all.

Only the other day a letter appeared in one of the leading literary papers from a well-known traveller, who complained that some valuable photograph taken by him had been made use of in an important book of travel without permission or acknowledgment, and that he was taking steps to put the matter right.

Proprietors of papers have had to pay heavy damages for disposing of photo blocks for further reproduction purposes without the sanction of the photographer. This is in the case of copyrighted photographs; and, as a protective measure, all photographs used for reproduction purposes should be copyrighted.

No editor of an illustrated journal would care to take the risk of disposing of the blocks of photographs taken by firms represented on the Committee of the Copyright Union. The photographs of such firms are

to a great extent the stock in trade of many of the illustrated journals, and friction with them would not be politic, apart from the question of expense.

There can be no doubt that the Copyright Union is an excellent trade union. By its rules no member shall allow a copyright portrait photograph or a copyright photograph of landscape or public ceremonials which belongs to him to be reproduced for a less fee than 10s. 6d. Such fee gives the right to use the photograph for one issue only.

There must be many other photographs which could not be described as a portrait, landscape, or public ceremonials, which might be regarded of considerable value, not necessarily of great commercial value, by their authors, such as of scientific phenomena, &c.

Therefore it might be considered that the wording of the rule is not sufficiently comprehensive. The leading members of the profession know how to protect themselves, however.

We might briefly consider the case of the humble amateur who may desire to minimise his photographic materials bill by contributing stray photographs to the illustrated press. Providing that the photograph is sufficiently striking, and that it is reproducible, it may be regarded as possessing value for this purpose, but in many cases considerable difficulty would be experienced in obtaining the Copyright Union's minimum reproduction fee. Moreover, some editors accept photographs and hold them over indefinitely; and, through some cause or other, they may never be published at all. And in some cases great difficulty will be experienced in obtaining payment for published photographs.

It cannot be too strongly urged that photographs to be used for reproduction purposes should be copyrighted, and care should be exercised so that the copyright of such photographs is not signed away on receipt of the few shillings received for the use of the photograph. No respectable journal would demand this.

J. R. ELSTOW.

#### THE GLASGOW CAMERA CLUB EXHIBITION.

THE Annual Exhibition of the Glasgow Camera Club, late the "Evening Times" Camera Club, was held in the club room, 46 Gordon-street, Glasgow, on Monday evening. The show is mostly confined to members' work, there being only one open class, and even the catalogue shows that the majority of the members do not send in to the annual exhibition. This is a pity, as members should remember that they are part of a corporate body, and the strength of that body depends on the active support to its welfare given by the individual parts thereof. Too often do we find that, while many members are willing to accept all the benefits a Society has to offer, they make no effort to in any way help forward the prosperity of the Society by their assistance, but leave all the work to a few who really have the welfare of their Society at heart—but this is a digression.

About 100 pictures and 20 sets of lantern slides are exhibited. The Society, we notice, still adheres to the antiquated system of dividing the classes according to size, and, for what reason we know not, has sprung a new class upon us, viz., "Prints in Glossy P.O.P."—there's a novelty, just after all the critics had seemed to agree that P.O.P. for exhibition work was dead, we find a class specially devoted to it.

The most successful exhibitor is James Douglas. In Class A, under half-plate, he is second with "Swamp," a hard rendering of a commonplace subject with an awkward wave of light in the sky. In club outing work, he is first with "Silver Birches." The lighting is well managed, and the quality of the birch is well rendered. In lantern slides he occupies second place with a set of good figure studies, clear in technique, figures well and naturally arranged, and good sunshine effects. In the Open Class Mr. Douglas comes in first with his painter-like, "A Portrait Study." It is easily first in its class, and is a strong portrait drawn with no nervousness, but with a firm and confident hand.

We should next notice Thomas Walker, who takes first place in the Novice Class with a good group of fisher laddies, the standing figure is not like the rest of the "loons," but the main group is singularly happy in its composition. In the Lantern Slide Class our friend the novice comes in first, beating some much-bemedalled workers. His set of landscape displays good clear technique, while he shows the effect of strong sunshine without the aid of mudflats, &c.

A. H. Duncan, an old friend of the Club and a strong worker on its behalf, takes first place in Class A with "Beach Study," which shows a well-composed foreground, and second in Class B with "Harbour" (Millport). The subject is one that would specially appeal to the "stock-view" worker, but Mr. Duncan has lifted it out of the ordinary rut, and given us a pleasing picture.

W. L. Primrose, who has many successes to his name, has to be content with a first in Class B, where an architectural study, "Ripon Minster," gives him first place, but it is not in Mr. Primrose's best vein. We have seen him turn out very much superior work to what he exhibits on the present occasion.

J. Peat Miller (Beith) takes the bronze medal in the Open Class with a beautiful study of a child's head, which clearly betokens that, although he has now made photography a "bread and butter" question, yet he has not forgotten how to turn out a good thing.

Messrs. J. Craig Annan, F. H. Newbery, and W. Goodwin acted as judges.

The following is the full prize-list:—

Class A—Any subject; size, half-plate and under:—Silver medal, A. H. Duncan, "Beach Study"; bronze, James Douglas, "Swamp."

Class B—Any subject; size, about half-plate:—Silver medal, W. L. Primrose, "Ripon Minster"; bronze medal, A. H. Duncan, "Harbour" (Millport).

Class C—Club Outing Work:—Silver medal, James Douglas, "Silver Birches"; bronze medal, James Gray "After the Day's Work" (Water-foot).

Class D—Confined to those who have never won a prize:—Bronze medal, Thomas Walker, "Young Fishers."

Class E—Lantern Slides:—Silver medal, Thomas Walker; bronze medal, James Douglas.

Class F—Prints on Glossy P.O.P., any subject, any size:—Bronze medal, John Gibb, "In the Woods."

Class G—Open Competition, any subject, any size:—Silver medal, James Douglas (Glasgow), "A Portrait Study"; bronze medal, J. Peat Miller (Beith), "Study of a Head."

## Our Editorial Table.

### PHOTOGRAMS OF THE YEAR, 1900.

Published by Dawbarn & Ward, Farringdon-avenue, E.C., 192 pp., illustrated, price 3s.

THE sixth issue of this welcome annual adheres closely to the lines that were traced by its predecessors, although it appears to us that for the purposes of illustration less reliance than hitherto has been placed upon publicly exhibited photographs. Many of the pictures in the book will, therefore, be new to the great majority of its readers, who, besides that, have been given little opportunity of studying reproductions of work by the new American school. Here and there the illustrations to "Photograms of the Year" are commonplace, and we cannot avoid the impression that this department of the book shows signs of some lack of discrimination in selection. But we are aware that the Editors' task must be full of difficulties, and that they cannot always reproduce all the photographs they would like to. The literary contents of the volume are decidedly more interesting than anything of the kind we have before read in "Photograms of the Year." The very notable paper called "Bubbles," which Dr. Emerson contributed to the Newcastle Convention (a paper, by the way, which Conventioners may be interested to know has been reproduced in photographic periodicals all over the world), is here reprinted, and references are given to the photographs, reproduced in "Photograms of 1899," which the Doctor very trenchantly criticised. "Bubbles," therefore, is quite a valuable little study in constructive and destructive criticism. A feature of the book is Mr. A. R. C. Carter's detailed review of the two "great" (why "great"?) Exhibitions. Mr. Carter is a professional art critic, and his well considered opinions printed in the book before us should appease those persons who declaim against the shortcomings of weekly photographic criticism. The international character of the book is well maintained, Mr. Demachy writing of French pictorial photography, and Mr. J. T. Keiley representing America. In all seriousness we advise the latter gentleman to be less querulous and petulant towards those who differ from him in matters pertaining to pictorial photography. This advice, too, may be tendered to Mr. Keiley's fellow clubman and worker, Mr. Steichen, who has apparently crossed the Atlantic to demonstrate the fact that endurance of adverse criticism is not the forte of the new American school. "Photograms" of 1900 should be in the hands of all those who are interested in the trend of modern pictorial photography. It is well produced and printed.

### INTRODUCTION TO MODERN SCIENTIFIC CHEMISTRY.

By Dr. Lassar-Cohn, 348 pp., 38 illustrations, price 6s. London: H. Grevel & Co., 31, King-street, Covent Garden.

THE translation of this useful book has been done by Mr. M. M. Pattison Muir, M.A. It is such a work as one who has mastered the elements of his subject may take up as a guide in his more advanced studies. Dr. Lassar-Cohn appears to have used care in keeping abreast of recent discoveries, for in his list of the elements we find argon, helium, xenon, neon, krypton. Some lately-published tables that we have seen do not contain mention of these new elements. Again, acetylene duly finds a place amongst the illuminating gases described. As a means of mapping out a systematic study of the principal elements, the book should be found of the very greatest service by chemists. Dr. Lassar-Cohn is happy in his translator, for his lectures, as they are here printed, are reproduced in simple language which goes straight to the understanding of the student—a valuable feature, not always to be found in chemical text-books. The illustrations are not so good as they might be; but this is only a minor drawback to an otherwise valuable little manual.

## THE DOUBLE-WEIGHT CARBON VELOX.

Manufactured and sold by J. J. Griffin & Sons, 20-26, Eardonia-street, Lincoln's Inn-Fields.

MESSRS. GRIFFIN are introducing a new grade of velox, called double-weight velox, in reference to which they kindly send us the following explanatory notes:—"The carbon velox is the most popular of the seven grades, and its introduction in double-weight thickness is in answer to repeated requests from regular users of velox. It differs only from ordinary velox in thickness, the manipulation being precisely the same. On account of the heavy backing to the emulsion, double-weight velox gives more detailed and delicate prints than with papers of ordinary thickness. The choicest results are obtained by printing with a white margin, paper somewhat larger than the actual photograph being used. A more roomy printing frame than usual is fitted with plain glass upon which the negatives must be placed. Strips of black paper are pasted over the edges of the negatives and made to extend sufficiently to form the desired margin. No mounting is required. It is very convenient for prints to be carried in the pocket-book. The paper will take ink or colour, and is therefore most useful for making Christmas, postal, or New-year cards, giving charmingly soft and effective results."

Double-weight velox is put on the market at an opportune moment. The specimen print sent (one of admirable beauty and delicacy) shows that the process is very well adapted for postal or for Christmas card purposes, for which we strongly recommend it to our readers. We congratulate Messrs. Griffin on their ingenuity in providing photographers with many refined and dainty ideas in printing.

## CONTRIBUTIONS TO PHOTOGRAPHIC OPTICS,

By Otto Lummer, D. Ph., translated and augmented by Sylvanus P. Thompson, D.Sc., price 6s. London: Macmillan & Co., Ltd., St. Martin-street.

WE look upon this volume as one of the most valuable contributions to the literature of photographic optics which has appeared in the English language of recent years, and we feel that the student of this branch of optics owes Dr. Sylvanus Thompson an expression of gratitude for the recognition of the merits of Professor Lummer's papers, and the careful and lucid translation he has made of them. The papers were first published in the "Zeitschrift für Instrumentenkunde," in the latter half of 1897, and have great merit as a clear exposition of a complicated subject. Dr. Lummer's object was to set out the theoretical considerations which must be taken into account in forming a judgment of the possible performance of a lens. This he does by discussing the various aberrations, and showing how they may be removed by judicious combination of the various factors of construction in different lens types. To formulate the conditions which must be fulfilled, Professor Lummer gives an account of Seidel's theory, and in an appendix Dr. Sylvanus Thompson gives a detailed account of this theory, which will be much appreciated by the reader who is unable to read the original. A second appendix is on the sine-condition, which is taken from Professor Lummer's edition of the "Optics of Muller-Pouilles." The third appendix gives Seidel's formulæ for calculating the path of a ray through an optical system. The investigations which led up to these formulæ were undertaken by Seidel at the request of his friend, C. A. Steinheil, and the formulæ were used by Dr. Adolph Steinheil in calculating the Aplanat.

Dr. Thompson has made certain additions to Professor Lummer's text, and has devoted an additional chapter to some recent British objectives. He is infelicitous in describing the Satz-anastigmat as a wide-angled portrait lens, when used in the double form, and the statement that the concentric lens with aperture ratios of  $f-16$  to  $f-45$  gives excellent definition, misses the purpose for which the larger aperture was given to the lens—namely, the attainment of soft and artistic effects. For good definition the makers recommended the use of stop  $f-22$ , or smaller. Details of the construction of the stigmatic lens are also given; likewise an account of the Cooke lenses. Dr. Thompson is in error concerning the collinear lens of Voigtlander. This is not manufactured in England by Messrs. R. and J. Beck. They are the licensees for the manufacture of Steinheil's orthostigmats. Although the collinear was made in Germany prior to the orthostigmat, the manufacture of the collinear is by license from Messrs. Steinheil. Some particulars are also given of the new Zeiss lens, the Unar, and as this is the latest lens from the Jena factory, these particulars are of much interest. Turning to the telephoto lenses, we find the illustration, a view of Munich, attributed to Dr. Miethé. A reference to Eder's "Ausführliches Handbuch der Photographie," in the volume on photographic cameras, will show that these photographs were taken with Steinheil lenses, and that they are supplementary to an article by Dr. Adolph Steinheil on telephotography.

We have drawn attention to these errors, which are of minor importance, in case it is found desirable to issue a second edition of the volume. The work, as we have already said, is of great merit, and Dr. Sylvanus Thompson has rendered a service to photography by publishing it.

## PENROSE'S PICTORIAL ANNUAL: THE YEAR BOOK FOR 1900.

Edited by W. Gamble. London: Penrose & Co., 8, Upper Baker-street, Lloyd-square, W.C.

WE heartily congratulate the accomplished editor, Mr. Gamble, and all concerned in the production of this superb book—a very mirror of the present stage of photography as it is applied to the purpose of illustration. It is the golden age of process work, according to our authority, and the completeness with which photographic blocks monopolise the non-textual portions of modern books as illustrations lends support to this pretty fancy. The introductory article on "Catalogue Illustration," by the Editor, contains a wealth of sound advice, which we strongly urge those photographers who make a speciality of working for reproduction to take the opportunity of perusing. It is the outcome of sound practical knowledge. The remaining articles on monochrome and colour work are by such authorities as General Waterhouse, Max Jaffe, H. Schnauss, Chapman Jones, M. Wolfe, E. Senior, Namias, Zander, &c. There are hundreds of specimen illustrations, flawless as reproductions, if occasionally uninteresting as photographs. But this is no more than saying that the book is a splendid example of printing and get-up. "Penrose's Pictorial Annual" is a sure guide to the present position of process work, and it should find its way to the desk of everybody directly interested in the subject of modern illustrations.

## Studio Gossip.

LIME Water for Reducing Carbon Prints.—The "Photo-American" states that Dr. S. Hendrickson, of Brooklyn, has been perfectly successful in reducing over-printed carbons by the use of a more or less weak solution of chloride of lime. Our contemporary adds:—"We have often had the ill-luck to over-print when making carbons, and unless extra hot water (which is pretty sure to blister the prints) would bring them around, there was nothing to do but throw them away, or else use as a transparency. As the lime would not act on the unalterable pigment, this property of reducing must be due to the fact that lime does eat gelatine wonderfully fast, and hence attacks the gelatine that holds the pigment in suspense. Dr. Hendrickson states that if a strong solution be used, or if the prints are left long in the bath, the print would sooner or later become entirely eliminated, which shows conclusively that it is an effective reducer. The best time to use it is while the print is still wet, though an over-printed carbon many years old will succumb to the treatment if allowed a little more time. We should advise the use of about one ounce of a saturated solution of lime in a pint of water to start with. Place the prints to be reduced in this bath and watch them carefully, noting how much they become reduced every now and then; and rinsing them frequently. When properly reduced, they should be washed well, and a very weak solution of citric or tartaric acid might be advantageously used to stop the action of the alkali and rid the paper of it. This hint will be of very great value to those who make carbons; especially beginners, whose tendency seems ever to be towards over-printing. Moreover, we may sometimes be mistaken in the depth we obtain on wet carbons, the water lends much transparency and they seem lighter than they really are. Since the lime water acts about as well on a dry print, we may, if we find we have mistaken the depth, treat the print to a slight reducing again if we fail to entirely clear the whites. This solution promises to be of great aid in saving what would otherwise have to go into the waste-basket, and so beautiful and valuable does any carbon appear to the maker that he hates to see so precious a thing consigned to a vulgar waste-basket with old "glossy types." The value of lime water for locally treating prints and lantern slides cannot be appreciated until tried. So much of the photography of to-day depends for much of its beauty on local touching up, adding a high light here and there, making a shadow more transparent, and other handwork, that to have such control over our carbons is a very great aid to the production of artistically perfect work, as well as a most economical idea for the saving of prints that would be of little value otherwise."

## News and Notes.

THE Woodford Photographic Society's Annual Exhibition of members' work will take place at the Wilfrid Lawson Hall on Thursday, Friday, and Saturday, December 6, 7, and 8. Mr. E. N. Buxton has undertaken to perform the opening ceremony.

THE Redhill and District Camera Club's Second Annual Exhibition and Conversazione will be held on Friday, November 30, 1900, in the Large Assembly Room, Market Hall, Redhill. The judge will be Mr. Harold Baker. The classes are open to members only.

THE Thirteenth Annual Exhibition of the Southsea Amateur Photographic Society.—The gentlemen selected to judge the works in this exhibition, which is to be held on January 29, 30, and 31, 1901, are Messrs. Snowden Ward, H. Simonds, and W. West. All particulars of exhibition and entry forms may be obtained from the Hon. Secretary, Mr. Gilbert Wood, 19, Pelham-road, Southsea.

FROM Mr. W. F. Slater, of 5, Firs-parade, Lee, S.E., we have received a framed platinumotype photograph representing the party forming the South London Photographic Society's excursion to Germany last August. There are fifty-four portraits in the group, which was printed by the Platinumotype Company. A copy was sent to each member of the party. The picture forms a very pleasing memento of the excursion so admirably organised by Mr. Slater.

ROYAL INSTITUTION.—The Annual Course of Christmas Lectures, specially adapted to young people, at the Royal Institution, will be delivered by Sir Robert S. Ball, F.R.S., Lowndean Professor of Astronomy in the University of Cambridge, whose subject is "Great Chapters in the Book of Nature." The first lecture will take place on Thursday, December 27, at three o'clock, and the remaining lectures will be delivered on December 29, 1900, and on January 1, 3, 5, and 8, 1901.

SYSTEMATIC PHOTOGRAPHY.—The Company which has the contract for the great New York subway is making systematic use of the camera to put on record the various stages of their operations. Often when excavations are made property owners claim damages for the settling of buildings, &c. The contractors now make a complete set of views of every square, from various directions, before beginning work. If a building is "out of plumb" or cracked, the picture will show it, and damages cannot be secured later. The dated photographs also make a complete history of the job, and at small expense.

THE Biograph in Battle.—Our literature on the war would in no wise be complete without such a book. Naturally it has been written by Mr. Kennedy Laurie Dickson (says the "Daily Chronicle"), who took the biograph through ten months of campaigning. Mr. Dickson is of Scottish family, one of Edison's "young men," and now again settled on his own side of the Atlantic. He took eighty-two thousand war pictures while with Roberts, Buller, and the other generals in the field. He kept a diary of all he saw and heard, and so the book, which Mr. Fisher Unwin will publish, will have sketches by Mr. Dickson besides "biographs."

SOCIETY OF ARTS.—The Society of Arts will hold the opening meeting of its session, the 147th since the foundation of the Society in 1754, on Wednesday evening, November 21, when an address will be delivered by Sir John Evans, K.C.B., F.R.S., Vice-President and Chairman of the Council. For the meetings previous to Christmas the following arrangements have been made:—November 28, Major Ronald Ross, "Malaria and Mosquitoes"; December 5, Professor H. S. Hele-Shaw, LL.D., F.R.S., "Road Traction"; December 12, Professor Frank Clowes, D.Sc., "The Treatment of London Sewage"; December 19, W. T. Maud (Special Artist to the "Graphic"), "The Siege of Ladysmith."

At South Norwood, on November 8, Mr. Sandell gave a demonstration of the use of the Cristoid roll films. The ease and certainty with which the films were developed in the Pyrocatechin developer much interested the members of the Society. Mr. Sandell showed that it was not necessary to take any particular care to avoid air bubbles or developing marks, since parts of the film which were not covered by the developer at first would catch up the other parts towards the end of the development. Neither was it necessary to keep the film flat during development. The film could be rolled up into a ball without any bad effect whatever. Large variations of exposure without interfering with the final result were also shown to be possible, and, generally speaking, it may be said to have been clearly shown that with the Cristoid films, in addition to giving very perfect negatives, were practically free from the many dangers attending development of some other types of roll films.

"OVER-EXPOSURE to Rontgen Rays."—Extraordinary statements were made at the opening of the inquest on the body of a widow, named Catherine Fanny Wilson, at Hastings, last week. Mrs. Wilson fractured the neck of the thigh in a bicycle accident in March. She was taken home, and on April 7 Rontgen rays were applied with a view to locating the injury. A second application was carried out on April 27, after which an eruption formed on deceased's stomach, near where the rays had been applied. Her niece called in another doctor on July 7, and a third physician later on. Death, however, took place on Monday last. The rays were applied the first time for two hours, and on the second occasion for two hours and ten minutes. A letter in deceased's handwriting, and marked, "Not to be opened until after my death," was found under the bed, in which she said: "The pain and anguish I suffer almost continuously from this painful sore is at times almost more than I can bear, caused by cruel over-exposure of Rontgen rays. If death does not speedily come I tremble to think of the consequences. I pray I may retain my reason." The niece, in her evidence, stated that deceased did not retain her reason. The letter was written about a month ago. The Coroner intimated that several experts would be called, and the inquiry was adjourned.

## Commercial Intelligence.

MESSRS. LEVI, JONES & Co., of 29, Hoxton-square, Old-street, N., have sent us a fully illustrated price list of optical lanterns, slides, jets, regulators, screens, lenses, limes, &c.

MR. ALFRED WATKINS, who in future will trade as the Watkins Meter Company, specialists in photographic instruments, Imperial Mills, Hereford, writes under date October 30:—"I have this day purchased from Messrs. R. Field and Co., 142, Suffolk-street, Birmingham, their interest as licensees, their goodwill, and all book debts relating to the Watkins Exposure Meters and Eikonometers, and shall carry on the business at Hereford under the title of the Watkins Meter Company. The general policy adopted will be as hitherto—to work in sympathy with the trade. This transfer does not affect Messrs. Field's general business as opticians, which they continue."

RE Frank Edwards Brown, manufacturer of photographic apparatus, 36, Charlotte-road, Edgbaston, and 3, Exeter-street, Birmingham.—The

public examination of the above-named debtor took place at the Birmingham Bankruptcy Court, before Mr. Registrar Glaisyer, on Thursday last. The statement of affairs filed by the debtor disclosed liabilities amounting to £1503, and assets estimated to produce £193. The debtor, in reply to questions put by the Official Receiver, stated that until 1898 he was engaged with his grandfather, who was a manufacturer of photographic apparatus at 3, Exeter-street, Birmingham. His grandfather agreed to transfer the business to him, on condition that he paid his grandfather an annuity of £156, which after his death was to go to debtor's mother. No balance-sheet was prepared, but the premises were mortgaged to their full value, and the fixtures and available assets were not sufficient to pay the debts. He made an arrangement with his bankers to increase the overdraft from £1200 to £1500. He thought that with perseverance and attention to the business he could make it pay. He had sustained one loss of £500 in respect of some cameras which were constructed for a special film. He first found that his trade was falling off in March of the present year. The debtor was allowed to pass.

SEQUEL to an Unsuccessful Photographic Company.—Paul Boyer, Ltd., v. Edwardes.—The plaintiffs in this action, Messrs. Paul Boyer, Ltd., photographers, sued Mr. George Edwardes, the well-known theatrical proprietor, in the Queen's Bench Division of the High Court, before Mr. Justice Darling, sitting without a jury, to recover the sum of £200 and interest, which it was alleged was due from him as the holder of two hundred £1 shares in the Company. Mr. Herbert Reed, Q.C., in opening the case on behalf of the plaintiffs, stated that Paul Boyer was a Parisian photographer, and invented a new process for instantaneous photographs, which in 1898 excited considerable attention. In that year plaintiff came into contact with several gentlemen interested in art, and they agreed to underwrite a certain number of shares in a company which it was proposed to form to acquire the invention, and among those gentlemen was the defendant, who agreed to underwrite two hundred shares. On July 18, 1898, the defendant signed an underwriting letter to take that number of shares in a company, on condition that eight thousand shares (Preference) were irrevocably applied for by persons residing in France. Mr. Totsi, a gentleman residing in France, underwrote £800 worth of Preference shares, and duly paid the application money, which amounted to £1000. At a subsequent meeting of the directors, in consequence of the public subscription being so small, it was determined not to allot any shares to the public. That being so, the underwriters became liable to take the whole of the shares they had underwritten. These shares were duly allotted to the persons put upon the register, including the defendant. Unfortunately, the plaintiffs' invention, for which so much was hoped, had not as yet produced very great results, and on May 3, 1899, the Company went into liquidation. On behalf of the defendant, it was contended that he never applied for the shares, and that he refused to subscribe, or accept them, on the ground that the condition relating to the £8000 worth of shares being applied for by the public in France had not been complied with. That condition had not been complied with; therefore it was submitted that the defendant was released from liability. The consideration Mr. Boyer was to receive was £4000 in cash, and counsel on behalf of the defendant suggested that one could readily conceive that Mr. Totsi put forward his application for eight thousand shares for the express purpose of getting over the difficulty set out in the agreement, and thereby attempted to make the underwriters liable. Eventually His Lordship held that the plaintiff had not complied with the condition in the underwriting letter, and gave judgment for the defendant with costs.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

November.	Name of Society.	Subject.
19.....	Camera Club .....	{ Some Simple Optical Curiosities. Rev. F. C. Lambert, M.A.
19.....	Doncaster .....	{ Exhibition of Members' Lantern Slides.

23.....	Croydon Microscopical .....	{ Lecture: Rejlander and his Work.

## ROYAL PHOTOGRAPHIC SOCIETY.

NOVEMBER 13,—Ordinary Meeting,—Mr. T. R. Dallmeyer, F.R.A.S. (President) in the chair.

## NEW MEMBERS, &amp;c.

Twenty-four new members were elected, and twenty candidates for membership were nominated.

It was announced that the following Societies had been admitted to affiliation:—Arbroath Amateur Photographic Association, Carlisle and County Amateur Photographic Society, and the Preston Scientific Society (Photographic Section).

## ECLIPSE PHOTOGRAPHY.

Mr. E. Walter Maunder read a paper entitled "Photography in the Eclipse of May 28, 1900." He referred, at the outset, to the paper which he read before the Society some eighteen months ago on the subject of "Exposures in Coronal Photography," in which he expressed the opinion that, given a total eclipse of the sun, the sky clear, the sun high, and all conditions favourable, any exposure from one-sixtieth of a second up to one-half second might be expected to give a valuable result with a lens aperture of  $f-15$ . In that communication he also stated that exposures of from one-sixtieth to one-fifth of a second were greatly needed, in order to bring out to the best effect the prominences and important details of the lower corona. He also alluded to the success of Mrs. Maunder's exposures in the 1898 eclipse, which being equivalent to 125 seconds, with  $f-15$ , had recorded the faint outer streamers of the corona to a much greater distance than it had previously been thought they could possibly be photographed. The conclusion to which he then came was that the exposures required were either much shorter or much longer than those which were commonly given. Mr. Maunder's views, embodied in the paper referred to, were received with general approval all over the world; the official instructions issued by the United States Naval Observatory for the eclipse of May last were avowedly based upon them, as were those of the Yerkes Observatory, and English astronomers in general had acted upon them, with the result that there had been a great increase in the proportion of beautiful and serviceable photographs of the inner corona. The lantern slides which Mr. Maunder proceeded to show, in illustration of the work done at the last eclipse, included reproductions of photographs taken by his own party in Algiers, by the British Astronomical Association in North Carolina, by the Astronomer Royal in Portugal, and by the Rev. J. Bacon, Professor Barnard, Professor Burckhalter, Mr. Nevil Maskelyne, Mr. Evershed, Professor Todd, and others. An interesting series of slides were those taken with Professor Burckhalter's apparatus for taking a perfect view of the whole of the corona in a single photograph, this device consisting of a fan revolving on a pivot running through the centre of the plate, and so graduated as to pass practically the whole of the rays from the outside of the corona whilst almost entirely cutting off those close to the sun. In no case, in the last eclipse, were the long streamers traced to anything like the same distance as in the eclipse of 1898, and Mr. Maunder thought this was due partly to the fact that the illumination of the sky was very much greater in Algiers than in India, and probably also to the fact that these extensions did not really reach the same distance in 1900 as they did in 1898. But although the long exposures did not succeed in rendering the extensions so far as on previous occasions, they were not thrown away; they were interesting from the fact that they brought out what Mr. Maunder at first thought was a new feature—namely, the dark rays in the corona which were shown in Mr. Ranyard's photographs of the eclipse of 1871. Reference was made to Mr. Shackleton's suggestion for photographing the corona, when the sun is unobscured, by using a sensitive plate of limited range as to colour, so as to confine its sensitiveness to the immediate neighbourhood of the coronium line, a suggestion which, in Mr. Maunder's opinion, would in course of time meet with much success, although it would not really be a solution of the problem of photographing the corona in full sunshine. Further slides explained Professor Todd's apparatus for securing a very large number of photographs. This instrument was controlled by a brass barrel with projecting studs, something like the barrel of a musical box, each stud working electric contacts which operated a large number of automatic cameras.

A brief discussion ensued, and, in reply to some of the questions raised, Mr. Maunder said that one or two observers of the late eclipse photographed the corona by polarised light, not for the purpose of securing an image of the corona, but in order to ascertain the amount of polarisation in it. He thought, however, that it might be worth while to adopt a suggestion made by the President, that an attempt should be made in the direction indicated. He and many other observers used some multiple-coated plates. They would no doubt be very advantageous for securing detail in the lower corona with a considerable amount of extension. A pinhole camera would not be suitable for work in an ordinary eclipse, as the corona was not sufficiently bright; but he had taken very successful pinhole photographs of the sun. With regard to a question whether ordinary cameras were of any service in an eclipse. Mr. Maunder said that although a large number of amateurs obtained photographs, the lenses employed were usually of too short focal length. With a lens of 9 inches focus the image of the sun was only one-twelfth of an inch diameter, and that was not much good. A professional photographer, who was not an astronomer, secured a fine series of photographs of the eclipse in India with an ordinary camera, but he removed the back combination of his lens, so that its focal length was about 32 inches. With a focal length of not less than 30 inches, an ordinary camera, rigidly fixed, would do very good work.

## COMING EVENTS.

November 16 (to-night), the Traill Taylor Memorial Lecture, by Mr. F. E. Ives, on "The Optics of Trichromatic Photography"; November 27, Technical Meeting, "Analytic Portraiture," by Mr. Francis Galton.

## PHOTOGRAPHIC CLUB.

NOVEMBER 7, 1900,—Annual General Meeting,—Mr. Frank Haes (Trustee) in the chair.

The notice convening the meeting having been read, the Hon. Sec. presented the 21st annual report and balance-sheet. A motion for the adoption of the report and balance-sheet having been proposed and seconded, the Chairman made a few references to the affairs of the Club, alluding to the fact that this was its 21st birthday. The report and balance-sheet were then adopted.

Messrs. H. E. Hull and Ward were appointed scrutineers of the ballot for officers and committee. The following is the result of the ballot:—Trustees: Mr. F. A. Bridge, Mr. Frank Haes. Committee: Mr. George E. Brown, Mr. E. W. Foxlee, Mr. J. W. Mason, Mr. W. R. Stretton, Mr. H. P. Smith, Mr. G. W. Tottem, Mr. H. Snowden Ward, Mr. Charles Wallis. Recorder: Mr. A. W. W. Bartlett. Curator and Librarian: Mr. Hans Muller. Hon. Sec. and Treasurer: Mr. E. A. Newell.

Votes of thanks were passed to the Scrutineers, the Hon. Sec., the Trustees, the late Librarian, and the Lantern Committee for their services during the past year.

**Liverpool Amateur Photographic Association.**—November 10. Mr. Walter D. Welford demonstrated on the subject of films *versus* plates, with special reference to the new Thornton film. Mr. Welford laid special stress upon the fact that, as compared with plates, films had the advantage of being light, portable, unbreakable, and easy of storage, and with regard to the Thornton film, which is coated on a gelatine base, instead of the usual celluloid, there is no chance of the sensitive film deteriorating.

**Hackney Photographic Society.**—November 6, Mr. W. Rawlings presiding. Mr. Robins, of the Kodak Company, showed a number of the firm's cameras, one of the most interesting of which being the Panoram Kodak. Examples of work done by this showed it to be a very useful instrument for certain purposes, giving a very realistic representation of subjects broad in extent. A number of other forms of Kodak were also shown, all being noteworthy for the ingenuity of their construction, and for their compactness. Mr. Robins showed also a handy device for facilitating the cutting of exposed lengths of roll film. He then demonstrated the development of the latter. Several were developed together in a dish, using metol-hydroquinone as a developer. Particular points to remember in developing the roll film are that the film must be soaked in water before placing into developer, and after the final washing a bath of 2 per cent. glycerine must be used to prevent curling after drying. A discussion followed Mr. Robins' demonstration, in the course of which several members spoke highly of the quality of the Kodak film.

**West London Photographic Society.**—On the 9th inst. Mr. L. Selby read a paper on Silver Printing Processes, dealing more particularly with bromide printing. Whilst the ordinary smooth papers had their uses, he called special attention to the pictorial advantages of those which were coated upon a tinted paper, such as Eastman's Royal and Wellington's Cream Crayon. He spoke highly of the permanence of such papers, provided they were properly fixed, and recommended the bromide as the best printing process for amateurs who had not time and facilities for carbon or platinum. Next meeting, "Ozotype," by G. F. Blackmore, on November 23.

**Eastbourne Photographic Society.**—At the last meeting of the Eastbourne Photographic Society Mr. E. J. Bedford was voted to the chair. Mr. W. E. Dunmore lectured on the "Tella" hand camera. He claimed that it was the smallest, lightest, and handiest camera in the world, when it was considered it had the capacity for carrying as many as forty or fifty films. The lecture concluded with a series of lantern slides; they included some very picturesque views in South Germany, and also a quantity of studies from Nature, taken at the London and Brussels Zoological Gardens.

## FORTHCOMING EXHIBITIONS.

1900.	
November 16, 17 .....	Ashton-under-Lyne.
" 19-24 .....	Waterloo and Blundellsands Photographic Society Hon. Secretary, W. G. Eyre, 2, Mersey-road Blundellsands.
" 21-23 .....	Hackney Photographic Society. Hon. Secretary, W. Selfe, 70, Paragon-road, Hackney, N.E.
" 21-24 .....	Cleveland Camera Club. Hon. Secretary, F. W. Pearson, 98, Victoria-road, Middlesborough.
" 22-24 .....	Hove Camera Club. Hon. Secretary, C. Ber- rington-Stoner, 24, Holland-road, Hove.
1901.	
January 14-19 .....	Blairgowrie and District Photographic Association. The Hon. Secretaries, Blairgowrie, N.B.

## Patent News.

THE following applications for Patents were made between October 29 and November 3, 1900:—

ACTINOMETERS.—No. 19,331. "Improvements in Photographic Actinometers." A. WATKINS.

NON-ACTINIC LAMPS.—No. 19,369. "An Improvement in Non-actinic or Monochromatic Lamps." J. W. NEWELL.

- VELOPMENT OF FILMS.—No. 19,396. "Improvements in Apparatus for Developing Photographic Films." J. W. MEEK.  
 DARK CHAMBERS.—No. 19,465. "Improvements in Photograph Dark Chambers." E. HOCHSTRASSER.  
 ANTERN-SLIDE CARRIERS.—No. 19,487. "An Improved Apparatus for Exposing and Covering Lantern Slides in the Magic Lantern." G. W. BROWN and G. R. BEAUMONT.  
 FILM CARTRIDGES.—No. 19,694. "An Improvement in Photographic Cartridges." J. T. SANDELL.

## Correspondence.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
 \* We do not undertake responsibility for the opinions expressed by our correspondents.

### ENAMELLED WARE.

To the EDITORS.

GENTLEMEN,—Can you use your influence to induce the manufacturers to give us, experimentally, still one more variety of the above, which, as now existing, sooner or later deteriorates from the iron oxidising through cracks of the enamel. My suggestion is to enamel dishes, &c., made of thin copper, which, while more costly, would, I think, for those who want the best, be worth the cost. I should like to know from somebody of experience if the idea is practicable.—I am yours, &c.,  
 J. WHITFIELD.

### THE SITTERS' RECOMMENDATION.

To the EDITORS.

GENTLEMEN,—The article by A. Lockett in THE BRITISH JOURNAL OF PHOTOGRAPHY of October 5 is no more than a statement of facts known to most professionals. Still, it may serve to remind some of us of our shortcomings, as not a few inexplicably refuse to profit from their consciousness of forces militating against their prosperity. In my opinion, the whole of one issue of the JOURNAL might be filled with an account of the pitfalls that beset us. Here is a very peculiar one of my own experience, which probably has, with variations, been that of others of our craft. An amateur asked for loan of my dark room. I readily acquiesced. After a time he asked for the loan of my studio to photograph his wife! This I felt unable to do, not having arrived at the philanthropic stage of my career. A week or so ago I very nearly lost an order worth a fair amount, and, when I inquired what had I done to merit punishment, it was explained to me that the officer who had the disposal of the work (and who was, be it noted, a friend or acquaintance of the lady) had mentioned, in the hearing of my informant, that I was a dog-in-the-manger fellow who wouldn't let an amateur change his plates in my dark room. Now, if it is remembered that I never have yet refused to lend my dark room; that (damning fact) my informant mentioned the name of the lady's husband as the injured party, it must be sadly admitted that this lady (?) had deliberately lied with the express intention of doing me an injury, for she knew the work was of regular recurrence. I blame the woman, because I know the man, and he is a man. What are we to do to be saved?—I am, yours, &c.,  
 H. HANDS.

C. P., East India, October 24.

[We have no doubt that many of our professional readers could relate some interesting experiences of the cool impertinencies to which they are occasionally subjected by their amateur patrons. An instance occurs to us. One of the best-known photographers in Britain was, some time ago, taking a family group in his studio. The group needed a very considerable amount of arrangement—sufficient, indeed, to call for the exercise of very high skill by the photographer. When the exposure was made, one of the party (a gentleman who had with him a small hand camera) stepped out of the group, and asked to be allowed to photograph it before the arrangement was disturbed. Our friend's reply to this modest request was an offer of the loan of his studio on a future occasion.—EDS.]

### A FIXING AND HARDENING BATH.

To the EDITORS.

GENTLEMEN,—The following formula has come under my notice as a fixing and hardening bath:—

(a) Alum .....	1 ounce.
Water .....	10 ounces.
(b) Sulphite of soda .....	2 ounces.
Hyposulphite of soda .....	6 ounces.
Water .....	10 ounces.

Add solution (a) to solution (b), when it is ready for use.

I do not like combined baths of any kind, but not having been entirely satisfied with the separate solutions in this case, I mixed two pints in the proportions given. Result: a fine sample of rich cream.

I did not consider it ready for use in that condition, so I filtered out the precipitate, 2½ ounces, when quite dry. I thought my alum at 7lbs. for a shilling might not be pure, so I bought some extra pure at the chemists, and with it mixed half the former amount—viz., two half-pints. Result: richer cream, 1½ ounces of dry precipitate.

Having mixed the two clear solutions together, I proceeded to fix and harden two ¼-plate negatives. Result: they both floated off the support beautifully as soon as they were put in the washing water. When washed I collected them on a piece of glass. Result: two fair negatives about 5×4, which, when dry, stripped from the glass as nicely as a squeegeed print.

Taking small quantities of solutions (a) and (b), I poured (a) into (b) and (b) into (a), with and without agitation. The result was equally rich cream either way.

By this time I became rather interested, and curious to know what the chemical action was that had taken place, where a mixture was evidently intended. My chemistry is very rusty; I passed my examination thirty-five years ago, and have had no occasion to keep posted since.

I dug out my old chemistry books, looked up the symbols (modern notation) in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, used up several half-sheets of paper struggling with the reaction, but without definite result.

The fact that the bath had no hardening action, but retained its fixing power, indicated to me that the alum was destroyed, and the hyposulphite of soda was not.

The conclusion I came to was that the sulphite of soda, Na<sub>2</sub>SO<sub>3</sub>, took from the alum, AlK(SO<sub>4</sub>)<sub>2</sub>, a portion of sulphur, and became hyposulphite of soda, Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, and that the precipitate was a double salt, an insoluble sulphate of alumina and sulphate of potass, much the same as that found in alum stone. I therefore heated some of the precipitate, with the result that an acid gas (probably sulphurous) was given off plentifully, turning damp litmus paper brilliantly red.

The original precipitate, when washed in water, made the water sufficiently acid to turn blue litmus paper pink. The roasted precipitate made the water sufficiently alkaline to turn the litmus paper blue again, but was very slightly soluble.

Possibly, if all the acid was driven off only protoxide of potassium (KO) and sesquioxide of aluminium, Al<sub>2</sub>O<sub>3</sub>, would remain, and the KO, being soluble, would cause the alkaline action.

These blunderings of an inexperienced chemist may be of little or no interest to you or the photographic public, but I think your expert corrections of the blunders would be of interest and value all round, especially to those who put forward such formulæ for the misguidance of the unlucky amateur who tries them.

You will find my name and address below, but should you publish my letter, I will sign myself  
 P.O.P.

[The addition of the alum solution to that of the hyposulphite of soda always throws down a considerable precipitate. The mixture should be allowed to stand for a day or so for the decomposition to be complete, and for the precipitate to subside. Then it is ready for use as "the acid fixing bath." Had it been prepared in this way, the film would not have left the glass.—EDS.]

### CARBONA PAPER.

To the EDITORS.

GENTLEMEN,—Some time ago you were good enough to draw attention in your JOURNAL to a sentence in our booklet, "Artistic Photos with Carbona P.O.P.," which was of a somewhat sweeping nature. We omitted at the time to draw your attention to the fact that we immediately corrected the paragraph. Consequently we are sending you a copy of the booklet showing you that we have made the necessary alteration. The paragraph, as it stood previously, was unnecessarily severe, and did not express our ideas so truly as the altered sentence does.—We are, yours, &c.,

JOHN J. GRIFFIN & SONS, LTD.

[The passage to which Messrs. Griffin refer now reads as follows:—The "Compleat" Photographer will learn all the subtleties of the various printing processes—the Carbon, the Platinum, the Velox, the P.O.P., and will know how to adopt that which best suits the subject in hand. Of the P.O.P. class, "Carbona" should receive attention for these reasons: 1st. It prints-out quickly, and tones easily with rich effects. 2nd. It has two surfaces and qualities—matt, for effects of breadth and atmosphere; glossy, for detail and concentration. 3rd. The colour of the image is pigment-like, giving rich browns and deeper blacks, very much more pleasing from an artistic standpoint than the purple-blue and chocolate of the orthodox printing-out papers.—EDS.]

### THE THORNTON-PICKARD MANUFACTURING COMPANY LIMITED.

To the EDITORS.

GENTLEMEN,—The similarity between our name and that of a local film-manufacturing company is answerable for so much misunderstanding that we shall be glad if you will inform your readers that we are not, nor have we ever been, connected with the Thornton Film Company. Much confusion is caused by the fact that we are constantly receiving communications from customers who are under the erroneous impression that we make the films which have recently been placed on the market by this Company.

We are, yours, &c.,

THE THORNTON-PICKARD MANUFACTURING COMPANY, LTD.  
Altrincham, November 12, 1900.

### PYRO STAINS.—GRAIN IN COPYING.

To the EDITORS.

GENTLEMEN,—Replying to "S. F." in last week's number, oxalic acid, or superoxalate of potash, will remove pyro stains from the hands. My plan is to damp my hands, put in the palm of one half a teaspoonful of the powdered acid, or salt, and rub well on the stains, afterwards rinsing off in plenty of water. It is desirable to use soft water, if obtainable, as, if there is any lime in the water, a disagreeable, slimy oxalate of lime will be formed on the hands.

Referring to a recent query as to avoiding the "grain" appearance in copies, I would remark that, where prints are made for copying, it is best to use matt P.O.P. to produce them on. Copies from prints on this paper show scarcely any more "grain" than if made by a transparency, as witness enclosed print [which is grainless.—Eds.].

I am, yours, &c.,

THOS. STOKOE.

Clare, Suffolk, November 12, 1900.

### AMERICAN PHOTOGRAPHY AT RUSSELL-SQUARE.

To the EDITORS.

GENTLEMEN,—My letter has had the accustomed result when any discussion on deeper matters than usual is started: it has provided an opportunity for the disreputable person to expose himself.

"Tacoma" states that I wrote at Mr. Day's instigation. It should be superfluous for me to have to deny this, and to say that Mr. Day knew absolutely nothing of my letter till it was in your hands.

The only hope for "Tacoma" is that he seems enough ashamed of his accusation to have to hide it under the veil of anonymity; and should he be pleased to doubt my assertion, it will be as his nature demands, and on a par with his accusation.

I should not have written at all had your article been the mere criticism I think it should have been; but my sense of justice made me resent your unfair habit of quoting only the silliest things you could find written about Mr. Day, and ignoring whatever of good might have been said of his work, and even Hartmann has said some true and critical things. It was less my desire to approve or disapprove these sacred subjects as work for the camera (that is a matter every one must judge and decide for himself upon) than that I wished to place on record that one at least had the courage to disapprove of your journalistic methods, and I am greatly obliged to you for the printing thereof.

I am, yours, &c.,

FREDERICK H. EVANS.

November 12, 1900.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

W. B. Bruuskill, Sunbeams, Lake-road, Windermere.—*Photograph of R. Rigg, Esq., M.P.*

A. Miller, Barrhill-road, Old Cumnock, Ayrshire, N.B.—*Photograph of Rev. Dr. Chrystal Auchinleck.*

P. W. Morehen, 12, Shakespeare-road, New Brompton, Kent.—*Two photographs entitled "The Handy Ladies."*

J. Jackson, 79, Oxtou-street, Walton, Liverpool.—*Photograph of Miss M. Morrison and Mr. J. Bergin. Photograph of Mr. J. Bergin.*

EDDISON, LTD. (Liverpool).—The address of Messrs. Clement and Gilmer is 8 and 10, Rue de Malte, Paris.

IN JUDICE.—Messrs. Otto Konig and Co., of 27, Cross-street, Finsbury pavement, will supply you with baryta paper.

F. H. S.—A lamp for the purpose was put on the market some year ago by the Platinotype Company. We do not know if it is now obtainable. Better write the Company.

DETERIORATED SULPHITE OF SODA.—G. BROGDEN. If the sulphite of soda is "crumbly and starchy-looking," and the pyro solution discolours directly it is poured on the plate, it is unfit for use; better throw it away, and procure fresh, as you will do no good with it.

ADDRESS WANTED.—W. H. R. writes: "Will you please give me the address of the firm that supplies the double salt of thiosulphate of soda?"—Every one who supplies photographic chemicals. It is generally known, by them, under the name of hyposulphite of soda.

F. G. (Boscombe).—1. The majority of the prints are produced either on albumenised paper or gelatino-chloride. The former process would be the more suitable for the purpose. 2. Surely letterpress printers are plentiful enough in your neighbourhood? You get such work done cheaper in the country than in London. Try Messrs. Mate, of Bournemouth.

FINISHING PHOTOGRAPHS.—A. C. writes: "Will you kindly give me a little information about finishing photographs—i.e., (1) what advantage (or otherwise) has a burnisher over a roller plate? (2) What firm makes a speciality of them?"—In reply: (1) Only that the burnisher gives a more highly polished surface, which some prefer. (2) Both rolling presses and burnishers are supplied by all photographic dealers. There are a great variety of each.

PRECIPITATED GOLD.—J. O'CONNOR. The phosphate bath refusing to tone is fully accounted for if the stock solution of chloride of gold has turned brown, and there is a sediment at the bottom of the bottle. The chloride of gold was either dissolved in impure water, or the solution was made in a dirty bottle, and so the gold has been precipitated to the metallic state, and in that form it is useless for toning.

THE BENEVOLENT ASSOCIATION.—A. F. THOMAS writes: "Can you inform me whether there are any funds available for grants in connection with the late "Photographers' Benevolent Association," and, if so, to whom application should be made? I know of no case of extreme need, where immediate assistance would be of the greatest service."—In reply: The fund in question is, we believe, exhausted. We cannot undertake to answer questions by post.

BOOKS ON PHOTOGRAPHY.—F. GOUGH writes: "Would it be troubling you too much if I were to ask you to tell me the best publications I can procure on photography generally? I want a book which embraces all parts of the work, and gives good illustrations."—In reply: No one book on photography will meet our correspondent's requirements; "photography generally" is a vague phrase. If he will let us know the branch or branches he is interested in, we will recommend him some books.

COLOURS ON VELOX PAPER.—W. M. writes: "I have been making some prints on velox paper, and I want to get a very warm colour, almost a red. Sometimes I get just what I want, and at others I do not, although I use precisely the same developer. Can you give a hint as to why?"—In reply: Yes; you do not give identically the same exposure in each case. The colour of the prints is entirely dependent upon the exposure, and identical tones are only to be obtained by identical exposures.

GAS BAGS.—"Oxon." writes: "It is very difficult for me here to get my oxygen in cylinders, and I think of making my own. I have the offer of a pair of gas bags for 30s., which, when new, cost four guineas. They have lain by for several years, and are very hard, but the owner says they are none the worse for that. Do you think it would be well to try them?"—In reply: We should say very doubtful, as very likely the rubber has perished. It is always very risky to buy old bags, particularly when they have been out of use for years.

THE ARC LIGHT FOR THE STUDIO.—ARTIFICIAL LIGHT writes: "Will you please tell me how many electric arc lamps it requires to light a studio for photographic purposes, and about the cost of same? What candle-power does it require for studio work?"—I reply:—Only one arc light is required. The candle-power usually employed for portraiture is from 6000 to 10,000. The price of the apparatus varies according to the power of the light. Write to Messrs. Gwynne and Co., Brook-street, Holborn, E.C. They will quote you prices for the requisite apparatus.

THE CITY AND GUILDS EXAMINATION.—PEGASUS asks: "(1) Is a knowledge of algebra and mathematics necessary in order to pass the Honours examination of the City and Guilds of London (photography)? (2) Where could I obtain some lists of questions set in former examinations? (3) What books would you advise me to study when working for this examination? (4) Is a knowledge of retouching necessary or helpful in the practical part of the examination?"—In reply: (1) Not necessary. (2, 3 and 4) For several years past we have printed the questions set at the examination. However, your simplest and cheapest way of getting full information on the subjects you specify is to procure a copy of the Handbook to the City and Guilds Examination. It is published by Messrs. Whittaker and Co., Paternoster-square, E.C., and it sets forth questions, lists of books, and all that an intending student requires to know.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1901.

Edited by THOMAS BEDDING, F.R.P.S.

THE Fortieth Annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published early in December. The total number of pages in the 1901 ALMANAC is 1,552, and the volume is the largest yet produced. The text portion of the book occupies about 500 pages. It will, as hitherto, be issued in paper covers, price 1s., or cloth bound, 1s. 6d.

The frontispiece is a bromide print by Messrs. Morgan and Kidd, of Richmond, Surrey, from a negative by Mr. W. Crooke, of Princes-street, Edinburgh. A number of other illustrations will also be found in the text matter. Over eighty articles on practical subjects, contributed by well-known photographers, form a feature of the volume. The principal advances of the year are synopsised in the "Epitome of Progress During 1900," and in the other sections, "Patented Inventions of the Year," "Miscellaneous

Information," and "Practical Notes and Suggestions of the Year," there will be found much useful matter, which, with the large collection of formulæ, tables, and other data for photographers, places at their disposal for daily reference a mass of information not to be found in any other photographic annual.

\*\* The 1898, 1899, and 1900 editions of the ALMANAC (20,500 copies) were each sold out within a few months of publication.

## EX CATHEDRÂ.

SOME time ago we published an article (reprinted from "Nature") by Mr. Francis Galton, describing his process of what he called "Analytical Photography." Readers interested in the subject will find a very similar process, published in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1900, described by F. H. Glew, under the title of "Differential Photography." It might be of interest to quote Mr. Glew's article here. It is as follows:—

Minute comparison can be effected by the following little-known photographic method with speed and accuracy obtainable by no other means.

"Take a negative A, say of a landscape, from some particular corner of a window or other fixed spot, and at some later time, weeks or months, take with the same lens another negative B, from exactly the same point of view. Now, if a transparency is made from B, and this transparency is placed in contact with negative A, the most minute differences between the two views will be instantly apparent without any measurements, thus showing changes too small to be detected in any other way. In this way it is most interesting and instructive to study the growth, decay, and general effect of vegetation, structural alterations and defects; such comparisons often yield unexpected results of great interest. This method is specially useful in astronomical work."

Mr. Galton, it will be remembered, applied his similar process to the study of people's portraits.

ACTING upon a suggestion that was made in these pages a few months ago, the Committee of the London Photographic Club has decided to celebrate the interesting fact that this year the Club attains its majority. The Photographic Club was founded in 1879—a long time ago in photographic history, which commonly, if perhaps not quite accurately, dates its beginning from 1839, when Daguerre communicated his invention of the Daguerreotype to the Paris Academy of Sciences. The “majority celebration” of the Photographic Club will take the form of a dinner, to be held on Saturday, December 8, at Simpson’s Restaurant, 76, Cheapside, under the presidency of Mr. F. A. Bridge. The Honorary Secretary of the Club, Mr. E. A. Newell, of 4, Maiden-lane, Queen-street, E.C., informs us that a large number of old members and friends have already signified their intention of being present, and he states that he will be pleased to hear from any others who may desire to be of the party on this interesting occasion. It goes without saying that a pleasant gathering will result. Ever since 1879 the pages of this JOURNAL have borne witness to the useful practical work which the Photographic Club has accomplished, and a list of those who have taken part in its proceedings would include the names of many who have had very prominent shares in the development of modern photography. Time, and the decentralisation of photographic interests and knowledge have not left untouched the unique position formerly held by the Photographic Club as one of the very few English societies that were in the forefront of “the movement”; but we are convinced that the possibilities of usefulness that lie before it are as great as ever they were. We hope that the celebration of the Club’s majority will mark the starting-point of a new and vigorous stage in a career to which the word *finis* will never be written so long as photography itself exists.

\* \* \*

THE remarks we have recently made with reference to German and American competition in optical production indirectly receive the most unqualified endorsement in an article published last week in “Nature,” under the title of “Instruments of Precision at the Paris Exhibition.” The writer, after eulogising the German optical and mechanical exhibits, quotes from a specially-prepared catalogue of the Exhibition the noteworthy information that in the last ten years the annual value of the instruments imported from Germany, including the optical glass used for lenses, rose from something over £200,000 to over £700,000. Comparing the French and German optical exhibits, he wrote, obviously before the close of the Exhibition: “Not that the sight is one which brings great pleasure to an Englishman, and if he moves on to examine the English exhibit his thoughts cannot fail to be very grave. There is nothing which can be compared with the German show; some well-known firms have won well-deserved prizes; there are some few interesting pieces of apparatus from South Kensington, and here and there in the electrical department one comes across a case of instruments. For the rest, the visitor will find, not collections of scientific apparatus, but small portions—attractive portions, it is true, in many cases—of the windows of well-known opticians’ shops. As much apparatus as is possible is packed together in a small space, there is much repetition, there is no organisation, there is no

attempt to instruct the learner or to attract the man who comes with inquiries with a view to purchase; English mechanics and opticians have no unity of aim, and their art, with some few exceptions, is but loosely linked to pure science.” Again, he contrasts American and German methods of supplying information to inquirers with those of the English exhibitor: “The German exhibit is under the skilled care of Dr. Robert Drost, with some three or four scientific assistants. One or more of these gentlemen is always ready to give information about special instruments. When I visited the exhibition I asked for a catalogue, and inquired if I could examine more closely certain special instruments. By all means, was the reply, and Herr Drost gave me several hours of his time opening cases, taking apparatus out, looking up special catalogues, and loading me with information. At the end of this time we were both tired, and he suggested that if I found, on looking over the catalogue and my notes, that I had omitted anything, I should come again. I returned next morning, and spent nearly as long a second time. So also with some American measuring and testing apparatus; the cases were opened, and I was allowed to handle the apparatus; one gentleman gave me a very full demonstration of the use of a new testing machine, which combines a multitude of ingenious devices. Contrast this with the English exhibit. A courteous commissionaire was, when I saw it, in charge of the whole; there were some notices as to where to apply for price lists of some of the firms exhibiting; the nearest approach to a catalogue was a set of cards hung on the wall relating to the excellent exhibit of the Scientific Instrument Company. These I found of real value, but they could not be carried away for reference.” Much of what appears in the “Nature” article (the whole of which deserves to be studied) reads like an echo of what we wrote apropos of the English exhibits at Paris in the JOURNAL last July, and still more recently on October 26 and November 2. In face of the poor show made by Great Britain at Paris, who can be surprised that so eminently practicable a man of business as the Prince of Wales has expressed his disappointment with it?

\* \* \*

THE Committee of the West Surrey Photographic Society—an active and well-managed body—is making a novel attempt to attract public attention to the Society’s existence with the view of increasing its membership. “It is so difficult,” writes Mr. J. T. Price, the President, “to get at the amateur in his native haunts that we thought the simple lure as herewith might perhaps secure him.” We might add that, from the point of view of photographic society management, the professional is not less shy and disinclined to take his share in teaching others, or being taught. This by the way. The West Surrey’s particular “lure,” as Mr. Price happily calls it, is nothing less than a well-printed show-card containing information about the Society’s meeting place, objects, subscriptions, Secretary’s address, and so forth. In the centre it bears a very excellent photograph indeed, printed either in platinum or bromide, with an inscriptive line which sets forth that the photograph was taken by a member of the West Surrey Society. The idea is entirely good and well carried out. Judiciously hung in suitable positions in the neighbourhoods of Clapham, Wandsworth, and Battersea, which, to our personal

knowledge, simply teem with unattached photographers, this show-card and the attractive specimen of photography mounted upon it should largely increase the membership of the enterprising West Surrey Society, which also issues some very tastefully-prepared prospectuses, photographically illustrated, setting forth the advantages obtained by photographers who join that Society.

\* \* \*

WE are within what the late Mr. Gladstone might have termed "measurable distance" of the close of the century, and this fact has moved a friend of ours to send us a few telescopic peeps at futurity. Zadkiel, he points out, has overlooked the photographic world in his surveys of the passing years, so our friend supplies the omission of the great prophet with regard to the next century. Here are a few extracts from Photo-Zadkiel's prophecies. The complete document would form piquant reading, but we prefer to date it, place it among our private archives, and leave it to posterity to apportion to our friend exactly the reputation for far-sightedness which time may show he has earned. "1. Pictorial photography will have passed away by the middle of the new century, and no one will even trouble to write its history. 2. Direct photographs in natural colours will be produced, and the monochrome print will become a curiosity. 3. Photographs will be taken without lenses. 4. Japanese cameras will be introduced and used for all kinds of work. 5. There will be three great classes of photographers, and only three—the scientific class, the trade class, and the toy class, chiefly schoolboys. 6. THE BRITISH JOURNAL OF PHOTOGRAPHY will be——." But our natural modesty bids us halt here, although we share our friend's confidence with regard to our future. We have not printed the most interesting of Photo-Zadkiel's prophecies; but Nos. 2, 3, 4, and 5 of those given above will probably turn out to be not very wide of the mark. As to Japan, at the present time she is quietly preparing to compete in the markets of photographic manufactures, and the world will not be very much older before Japanese dry plates and printing papers find their way to London.

#### REVERSED NEGATIVES IN PRACTICE.

THERE cannot be a divided opinion as to the increasing taste for photographs in other than the orthodox photographic colour. In all exhibitions we find reds, sepias, browns, blacks, and other colours in strong evidence. Also in professional portraitists' show-cases and reception rooms we see pictures in different colours, and on papers with different surfaces, made a speciality of, and this may be taken as a conclusive proof that this class of picture is appreciated by their clientele. Seeing this is the case, it becomes a question as to which is the best and simplest method of producing them? It goes without saying that both points are of importance, alike to professionals and amateurs, for it must be admitted that both, while desirous of obtaining the best results, like to obtain them with the least possible trouble.

For blacks and sepia the platinotype process fulfils all requirements, but with it we are confined to these two colours. With bromide papers and those of the Velox type, we have the means of obtaining a great variety of

colours, but they both require a modified method of development, with very accurate exposure to obtain them uniformly. With these papers a variety of colours may also be obtained by after toning with uranium or other agents, though perhaps with questionable stability of the pictures. Still, the methods are practicable enough. Now, although it is easy enough with these papers to produce a great variety of colours, it is not quite so easy to produce a number of prints all of the same colour—a given tint. Every professional knows quite well how difficult it is to supply a dozen cabinet portraits all of the same tint, say, in red chalk, for example, as selected by the sitter, unless he has a very careful and skilful printer; and, even then, there is often a number of "wasters." With amateurs the exact tint is not of so much importance, as with them often "variety is charming."

How, then, is the greatest variety of colour to be obtained with the greatest degree of certainty, and by the simplest means? There is but one answer to the question—the carbon process. With that any colour whatever may be obtained with the certainty that all the prints will be of a uniform colour, and, what is more, they may be obtained on any surface paper if the single transfer method be followed, for the double transfer is not well suited for rough papers, and it is more trouble in practice, as it involves an additional operation. The single transfer method, however, involves the production of a reversed negative, otherwise the picture will be reversed as regards right and left. It has been stated that this does not matter with portraits, but that is a mistake, as every portraitist is aware. Hence with the single transfer method, which is simplicity itself, a reversed negative becomes imperative, and that brings us to the point, How is that best or most easily produced?

There are many ways of producing reversed negatives. It may be done by reproducing the negative, say, by the powder process, by taking advantage of the reversing action of light, or by reproducing the negative through the agency of a transparency, &c. But all these methods are more or less troublesome, and require some considerable skill to obtain the best results; for this reason they have been but little practised by portraitists or by amateurs. Another method, which is most generally followed by those who make reversed negatives for the mechanical processes is to take the negative directly reversed by the aid of a prism, or reversing mirror. This method, however, does not commend itself to the portraitist or to the amateur. The latter, if he uses any of the rollable films—stripping or otherwise—has at once a negative which is both reversed or non-reversed, according to the side from which it is printed. But these films are, for the present, at least, not likely to find much favour with professional portraitists.

Reversed negatives are, however, easily obtained by stripping the film of an ordinary negative from the glass. This is looked upon by some as a difficult and risky operation, while it is nothing of the kind. It is simplicity itself. Premising that the negative has been alumed, or treated with formalin, to prevent the film from curling or expanding when stripped, what has to be done is this: Place it on a levelling stand and pour on some enamel collodion so that it is about the thirty-secondth of an inch thick. This by reason of its thickness will take an hour or

more, according to the temperature, to thoroughly set. When set it is placed in water to wash out all traces of the ether and alcohol. It will be found more economical, and save time, if some more pyroxyline be added to the collodion, as then a thinner coating will suffice, and it will take less time to set. After all the solvents of the collodion are washed away a penknife is run round the margin of the plate to cut through the films. It is then put into water, to which a few drops per ounce, of hydrofluoric acid have been added. In a short time the film will begin to detach itself from the glass, when it may be lifted off and placed on blotting-paper, or on a sheet of glass, to dry. We then have a negative just analogous to one taken on a rollable film, which can be printed from either side as desired.

A method which will probably commend itself better to the professional portraitist is that of exposing the plate in the camera with the glass side next the lens, of course making allowance for the thickness of the glass after the image has been focussed. This is not a difficult matter, seeing that the dry plates now supplied are, of a given batch, all of practically uniform thickness, a very different condition of things from what prevailed in the earlier days of gelatine photography. The glass is also practically free from air bubbles which would show in the picture. It need not be mentioned that the back of the glass must be cleaned from any emulsion that may be on its surface before the plate is put into the dark slide. But, with the perfection of modern coating machines, this is a very trivial matter.

There is no more difficulty in developing a negative taken through the glass than one taken in the usual way, if the first appearance of the image—which will be rather longer in showing itself—be watched for from the back instead of the front. Its density is, of course, judged of in the usual way. There are really advantages in portraiture in taking the negative through the glass. One is that halation from the back of the plate is avoided, which often shows strongly in portraits, as when there is, say, white lace on a velvet or black dress, for few portraitists back their plates to avoid it. Portraitists who make a speciality of pictures in different colours would often do well to take two negatives—one through the glass and the other in the usual way. Then either could be employed as occasion required—dry plates are cheap enough nowadays.

Although the latter remarks are intended more particularly for professionals, they apply also to amateurs. They, when they desire to produce prints in various colours, may also expose the plates through the glass, and thus secure reversed negatives without after trouble. They will then have negatives from which they can obtain prints of any desired colour or tint, with the certainty of getting them all alike, without the trouble of after toning, and of assured permanency of the results.

**Cambrian Art in London.**—An interesting Exhibition of Paintings was opened last week at the South London Art Gallery, Peckham-road, by the Mayoress of Camberwell. The Exhibition is interesting inasmuch as the pictures are all by the members of the Royal Cambrian Academy, and it forms an excellent representation of the work that has recently been produced in the Principality. There are some eighty oil paintings and nearly sixty water colours, also some in black and white. Hitherto Wales has not been very prominent in Art matters, though every valley has its bards and

musicians, and we all know of their qualities. Now that the Principality has its Royal Academy, like England and Scotland, we have little doubt that Wales will not long be behind in Art matters. The Exhibition will be open to the public from 2 p.m. to 10 p.m., and on Sundays from 3 till 9, until the end of February. Our readers will do well to pay this Exhibition a visit.

**Constable's Pictures.**—There has been on view for some days at Leighton House, in what used to be the studio of the late Lord Leighton, a very fine collection of mezzotints of Constable's paintings. Constable's works appeal specially to landscape photographers, for most of them are just the subjects that they delight in depicting. Furthermore, many of them are of places that are now the happy hunting grounds of photographers, and most of them are near home. For example, there are the Hampstead sandpits, Dedham Vale, bits of the Stour valley, Flatford Mill, several of the locks and weirs of the sleepy stream that marks the border between Suffolk and Essex, &c. It will be interesting to photographers to see how their well-known subjects were dealt with by this great master in landscape painting. Those who wish to see the collection must lose no time, as the brief exhibition, unfortunately, closes to-morrow.

**The Missing Leonids.**—A fortnight back we made reference to the fact that the great star shower, that is said by astronomers to occur only every thirty-three years, did not put in an appearance last year, and that it was expected they would this November; also that Dr. Downing, in a paper read before the British Astronomical Association, was not over-sanguine that they would, though it would be well to keep a good look out for them on the 13th, 14th, and 15th, and many, we know, did and had cameras ready. But the display did not show up, though the atmospheric conditions were not in most places unfavourable for photographing them if they did, and the light of the moon would not have interfered. We learn, by a Reuter telegram from New York, that at Minnesota over seventy meteors were noted during the night at the Goodale Observatory, and during the early morning a number of Leonids were observed, also a considerable shower was seen from the constellation of Gemini, which was quite unexpected. There were, it is mentioned, five distinct groups of showers. At Greenwich, however, though a sharp look-out was kept all the week, nothing more was seen beyond what is usual in November, when "shooting stars" are always expected. It would almost seem that the Leonids have deserted us, and, in the opinion of some astronomers, become a thing of the past.

**Acetylene.**—During the past few years acetylene as an illuminant has made considerable progress in this country, and it is more particularly in connexion with the lantern that it is, perhaps, best known amongst photographers. Although it has been advancing here, it has clearly not made the same progress in England as it has done in Germany. We see that Dr. F. Rose, the British Consul at Stuttgart, in his report on the trade, agriculture, and finances of Württemberg for the year 1899 and part of 1900, which forms one of the diplomatic and consular reports issued from the Foreign Office last week, makes special reference to the acetylene gas industry during the past five years. He says that in Europe alone 120,000 horse power is devoted to the manufacture of the calcium carbide, and the manufacture is increasing; also he claims that Germany was foremost in the field with its manufacture, and has secured an advantage which she has since easily maintained and considerably increased. Dr. Rose mentions that, up to July 1898, 62,000 jets of acetylene were installed; by the end of 1899 the number of jets had increased to 170,000, and at the present time it amounts to at least 200,000 jets, adding that it is at present impossible to predict the ultimate struggle between this new illuminant and its rivals; but he speculates that petroleum will suffer most, and coal gas next, particularly for the lighting of small towns. Dr. Rose further adds: "Not content with producing carbide in Germany, German capital has gone to foreign countries, notably to Norway and Switzerland, and carbide works have been erected which are managed by German engineers."

From this report it would seem that this country is a long way behind Germany in the calcium carbide and acetylene industry. But shall it remain so? If we had more water power at our command, we doubt if that would be the case.

**The Alleged Death from Röntgen Rays.**—In a paragraph last week the alleged death from the effects of the Röntgen rays was briefly reported. The allegation was made by the deceased, in a letter she wrote some month or more before she died, and it has been made, by some of the lay press, quite a sensational case of; so much so that, if the verdict of the jury on Saturday last did not dispel the ideas that the rays had anything to do with the cause of death, many persons would be induced to decline the application of Röntgen's discovery in cases even of urgency; just in the same way that some, in the case of an operation, dread the effect of chloroform as much as they do the operation itself. However, the evidence of several independent medical men and experts at the inquest showed that, although the long-continued action of the rays has a tendency to cause skin trouble, they have no further ill effect. It would have been interesting to know what coil and what tube were used to necessitate so long an exposure as thirty-five minutes for one plate and forty-five for the second—an hour and ten minutes for the two exposures; in subsequent radiographs it ran to forty-five minutes. The photographer who took the radiographs is reported to have said that with up-to-date apparatus he would have only given five minutes. As an expert the medical officer of the Electrical department at St. Bartholomew's Hospital was called, who stated, having regard to the instruments used and the part of the body photographed, he considered that there had been a proper exposure; but he added that the risk of an X-ray "burn" was always present in long exposure, and, in reply to a question, said that with up-to-date apparatus the usual exposure was seven or eight minutes. Now it is manifest that, seeing there is always a risk from X-ray "burns" with long exposures, the most improved apparatus should always be employed, so as to minimise the risk as much as possible. It is a well-established fact that it is only a prolonged exposure to the rays that results in trouble; therefore such apparatus should be used as will curtail the exposure to a minimum. It is not such a very costly matter nowadays.

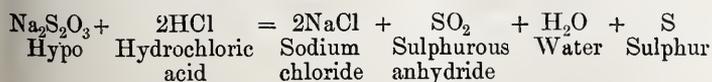

#### THE ACID AND OTHER FIXING BATHS.

THE addition of an acid to the ordinary fixing bath was first suggested by Eder,\* we think for use with plates, the addition being made to obviate the intense yellow stain due to pyro and the fixed alkali developers; but the addition of any acid to hyposulphite produces a decomposition with an immediate slow deposition of sulphur which makes the bath cloudy. In 1889 Reeb suggested the use of acetic acid, and advised warming the bath and allowing it to settle, and then decanting or filtering from the deposited sulphur.

In 1889 Lainer† stated that, if an acid were added to a solution of sodium sulphite first and then added to the hypo solution, no deposition of sulphur took place. He also suggested the use of acid sulphite lye, which is a cheap commercial article in Germany, and is an extremely concentrated solution of acid sulphite of soda with free sulphurous acid, which is used in the dyeing and brewing trades.

The use of alum in the fixing bath was first suggested by De la Ferronay‡, its object being, of course, to prevent stripping and frilling of the gelatine film. In this case as in the former, the hyposulphite of soda is decomposed and the solution becomes milky.

The reactions which occur in both cases are somewhat complex, and were supposed to be capable of representation by the following equation in the case of acid:—

\* "Handbuch der Photographie," 1885, p. 237, vol. iii., 3rd edition.

† "Photo Corresp." 1889, p. 171.

‡ "Photo News," 1883, p. 142.

and in the case of alum by the following:—

The most important contribution to our knowledge on the point of the action of acids and alums on thiosulphate of soda is that by Seyewitz & Chicandard. "Sur les réactions engendrées par la décomposition de l'hyposulfite de soude dans le fixage des images photographiques," † in which they point out that it is necessary to differentiate between the two cases, the one in which an acid is in excess, and the other in which the hypo is in excess. In the former case the above equations are practically correct, though it would be more correct to assume that the acid sets free hypo-sulphurous acid  $\text{H}_2\text{S}_2\text{O}_3$ , which decomposes into the other sulphurous products and water. When, on the other hand, the hypo is in excess it would be more correct to assume the formation of an acid hyposulphite of soda:—

and that this acid hyposulphite then split up as follows:—

From this we get a secondary action between an equal quantity of the sulphuretted hydrogen and sulphurous anhydride through which pentathionic acid is formed:—

this acid reacts on the hyposulphite, giving hypo-sulphurous acid and pentathionate of soda:—

A further reaction occurs between the sulphuretted hydrogen and further hyposulphite of soda:—

so that briefly we may say that the result of adding an acid to excess of hypo is the formation of (a) sulphurous acid, (b) sulphuretted hydrogen, (c) a sodium salt of the acid employed (d) sulphate of soda, (e) sulphur, and that the secondary actions are a) sodium bisulphite, (b) pentathionate of soda, (c) acid sulphide of soda.

When alum is added to hypo the reactions are also somewhat complex, but one arrives at practically the same standpoint finally, and the steps as traced by the same experimenters are as follows:—

(a). Aluminium sulphate acts on the hypo giving sodium sulphate passes and aluminium hyposulphite:—

(b) the last salt is extremely unstable, and in the presence of water into aluminium sulphate and sulphuretted hydrogen:—

(c) the sulphuretted hydrogen decomposes slowly an excess of hypo and gives sodium bisulphite, acid sulphide, and sulphur:—

From these remarks it will be obvious that an acid or alum fixing bath is totally unfitted for use with printing-out papers, and may be a source of danger both for negatives and developed prints if formed by the simple addition of acid or alum to a solution of hypo, because not only of the danger of the sulphuration of the image, but of the deposition of sulphur itself in the gelatine.

As we have already pointed out, Lainer stated that sodium sulphite prevented the deposition of sulphur, and Reeb ‡ also stated that sodium bisulphite would act in the same way. Sulphites and bisulphite do not decompose hyposulphites, and Chicandard and Seyewitz, in their paper already quoted, point this out, and state that alum combines with the bisulphite or sulphite to form the corresponding

\* It will be noted here that the simple formula of aluminium sulphate has been adopted, the true formula of all alums being  $(\text{M}''')_2(\text{SO}_4)_3 \cdot \text{M}'_2 \cdot \text{SO}_4 \cdot 24\text{H}_2\text{O}$ . —Eds.

† "Bulletin de la Société Française de Photographie," 1895, p. 55.

‡ "Bulletin de la Société Française de Photographie," September, 1894.

aluminium salt and sodium sulphate, and that these have no action on hypo—

In the case of an acid it is obvious that bisulphite or acid sulphite of soda and the soda salt of the acid used are formed, and thus, though the bath is acid, there is no decomposition of the hypo. They also point out that it is by no means necessary that the whole of the aluminium sulphate should be converted into the bisulphite or sulphite, and that, when the proportion of alum to the hyposulphite is as 1 to 20, the weight of the bisulphite need only be one-fifth of the alum.

Lainer in his paper suggested the following formulæ:—

Solution of hypo (1 : 4) ..... 1000 parts.

Acid sulphite lye ..... 50-100 "

or failing lye, a mixture of organic acid, such as citric or tartaric, and sulphite of soda solution may be used:—

Solution sodium sulphite (1 : 4) ..... 60 parts.

" tartaric acid (1 : 2) ..... 20 "

a stronger bath may be obtained by using—

Solution of sodium sulphite (1 : 4) ..... 70 parts.

" " citric acid (1 : 2) ..... 40 "

For the alum bath he proposed:—

Saturated solution of alum ..... 1000 parts.

" " sulphite ..... 300 "

Solution of hypo (1 : 4) ..... 1250 "

Mercier \* pointed out that the addition of an acetate prevented the deposition of sulphur when an organic acid was added to the fixing bath, and that the citrates and tartrates acted in precisely the same way, and that these additions further, prevented, the decomposition of the alum in an alum fixing bath when a plate was immersed in the same without washing after development, this procedure, as is well known, giving rise to a deposition of alumina, and when a caustic alkali is used some curious markings which look as though the film had, at those points where the alumina is precipitated, become partially liquefied. He further stated that an excess of citrate considerably softened the gelatine, and it was also advisable to add some chloride of sodium to prevent the decomposition of the silver hyposulphites and thus enable the bath to be kept longer, and finally suggested the following formula:—

Anhydrous sodium hyposulphite ..... 100 parts.

Potassium metabisulphite ..... 20 "

Sodium citrate ..... 5 "

" chloride ..... 20 "

Potash alum ..... 20 "

Water ..... 1000 "

Carbutt, the well-known dry-plate maker of the States, suggests in his instructions for use the following bath:—

Sulphuric acid ..... 4 parts.

Sulphite of soda ..... 60 "

Chrome alum ..... 30 "

Hyposulphite of soda ..... 480 "

Warm water ..... 1920 "

For Velox paper the makers suggest—

Hyposulphite ..... 1000 parts.

Water ..... 4000 "

Sodium sulphite ..... 30 "

Acetic acid ..... 180 "

Powdered alum ..... 30 "

Water ..... 330 "

From what has been said it will be obvious that the only correct method of making either an acid or alum fixing bath is to dissolve the

\* "Action des acétates et des citrates alcalins dans les fixateurs. Nouvelles formules de bains de fixation,"—"Bulletin de la Soc. Franç. de Phot., 1894, p. 356.

sulphite and add the acid or alum, and then add this to the hypo in solution. Organic acids such as citric, tartaric, and acetic, are preferable to the inorganic, such as sulphuric, &c., and personally we think it better to omit the alum altogether, and replace it with about five per cent. of formalin. Those who have never used an acid fixing bath will be surprised at the freedom from stains, &c., and the long time the bath keeps free from discolouration and deposit, and when properly made it is superior to the plain bath for both plates of all kinds and developed prints.

## THE OPTICS OF TRICHROMATIC PHOTOGRAPHY.

[The Third Traill Taylor Memorial Lecture.]

### I.

THE search for a direct method of pigmentary colour photography, such as was dreamed of by the fathers of photography and the world at large, appears to have been practically abandoned, every seeming clue to such an achievement having proved a delusion. Nevertheless, so much has been accomplished in the direction of practical colour photography by indirect methods, that the subject has become a very large and important one, and so specialised that it would be impossible to do justice to it in a single lecture, or even in a treatise of considerable size. I even doubt if any one man possesses such a full knowledge of both the science and history of this subject as would make him competent to treat it fully, and with absolute impartiality.

This is the more surprising in that every method which has achieved or promises to achieve a notable degree of practical success is based upon the same underlying idea of a composite trichromatic image.

The most that I can hope to do in this lecture is to give such a concise critical review of the history, and science, and mechanism, of these methods as may serve to disclose the conditions of success, and help to clear away some of the lumber of ignorance and misconception, which has stood and still stands in the way of general progress.

I have chosen to treat the subject historically, as well as practically, not only because the history of the subject is very interesting in itself, but because by no other means can correct methods be established so well as by critical comparison with incorrect methods, which to the mind of the layman may appear to have been reasoned out with equal logic, and to superficial observation with even greater definiteness.

It is my sincere wish to give full credit to the pioneers of these methods, but at the same time to clear from the path the stumbling-blocks of their errors and misconceptions; for I have observed that the very men who commence and carry forward a great work often leave it encumbered with rubbish which impedes further progress, and which must be cleared away by somebody before the defects can be corrected and the work carried on to perfection.

I have myself devoted many years to trying to clear away the rubbish, correct the mistakes, and supply missing material to bring this work to perfection, and I presume that I may accept the honour of being asked to prepare this lecture as a recognition of my efforts, and a justification for such a treatment of the subject as must have been expected from me, in the light of my past record as a writer upon this subject.

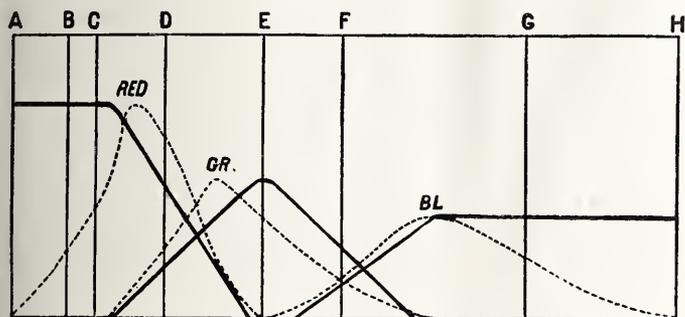

I purpose to begin with a concise statement of the principles of successful trichromatic photography, and to follow with an analysis of the various methods which have been proposed, showing the progress towards the recognition and attainment of the conditions of success, and at the same time the specific defects of each method and device; but, for greater clearness, I shall divide my subject into sections, treating first of the principles of the more important processes, then of the optical and mechanical inventions designed to facilitate their practice, and last of all of special developments of the idea, and the optical devices pertaining thereto.

The trichromatic process of colour photography consists essentially in (1) the production of three photographic images which represent

the physiological analysis of all colours into three simple spectrum colours, and constitute a colour record, and (2) synthesis by optical superposition of the three elements of the colour record in the three simple colours, whereby the sensations of all the original colours are reproduced to the eye.

Such analysis and synthesis is possible because there are three spectrum colours, which by admixture in suitable proportions will reproduce to the eye the sensation of every other spectrum colour. These three simple colours are the red of the spectrum, about the Fraunhofer line c, the green near B, and the blue near G.

What particular colours must be employed, and the proportions in which they must be mixed to reproduce to the eye the sensation of the intermediate spectrum hues, was first determined by Professor James Clerk-Maxwell, and is shown by his famous "colour curves," which I reproduce.

These factors have been redetermined by Sir William Abney, with an improvement upon Maxwell's colour box, but Maxwell's results are shown to be *substantially* correct, and I therefore prefer to use Maxwell's diagram in illustration, because of its historical bearing upon the subject.

Maxwell's curves are *colour-mixture* curves, and not to be confounded with *colour-sensation* curves, which assume a fundamental green sensation which no part of the spectrum excites exclusively. In trichromatic photography we have to deal with mixtures of actual spectrum colours.

The relative height of the respective curves at any point indicates the proportions of the simple colours required to reproduce to the eye the colour of the spectrum at that point.

It follows that in order to obtain a trichromatic colour record of the spectrum itself, three photographs of the spectrum must be made, in each of which the distribution of photographic action is such as would be represented graphically by the respective curve in Maxwell's diagram.

The picture to represent the red element in the analysis must be made not only by the action of the red rays, but by the action of orange-yellow and yellow-green rays, in proportion to the relative amount of red light required to represent the latter colours in the synthesis, by admixture of green; and, as shown by the "red" curve in Maxwell's diagram, the strongest action of all, instead of being in the red, will be in the orange, which is reproduced to the eye in its correct relative luminosity by mixing the greatest amount of red with a little green.

Similarly, the negative to represent the green element must be made by the joint action of orange, yellow, yellow-green, green and green-blue light, with the strongest action in the yellow-green, as shown by the second curve; and the third negative by the joint action of green-blue, blue and spectrum violet light, as shown by the third curve.

If the distribution of photographic action does not correspond to the form of these curves, the analysis will be imperfect, and correct synthesis becomes impossible. If the yellow of the spectrum does not act in both the red and green negatives, it must be reproduced either as red or as green; and if it acts in both negatives, but not in the correct relative proportions, it will be reproduced either as orange or as yellow-green. To ensure accurate results, the photographic analysis must be a *quantitative* analysis, and a correct quantitative analysis and no other will admit of the synthetical reproduction of the spectrum itself, with all its gradations of colour and luminosity.

All the colours in nature are mixtures of spectrum colours; therefore it may be taken as an axiom, that *the ability or inability to reproduce the spectrum itself credits or discredits any trichromatic process.*

If you can obtain by photography such a colour record of the spectrum as I have described, you can by the same means obtain true colour records in photographs from nature and works of art; but, if the spectrum test in any way fails, no real accuracy can be guaranteed or should be expected.

To secure negatives of the required character, we must employ colour-sensitive photographic plates, and filter the spectrum rays through suitable coloured mediums, testing by exposures in the photo-spectrograph and modifying the colour filters until the density curves conform to Maxwell's colour curves. Such adjusted colour filters I term "colour-curve screens." This system of photographic analysis I call "colour-curve analysis," and the photographic records "colour-curve records."

Although there are various methods of synthesis, positive (photo-chromoscopic) and negative (colour prints), the photographic record that is correct for one is correct for the other.

*An incorrect colour record cannot be made to yield a correct synthesis by any means whatever.*

Positive synthesis may be obtained by making a positive colour record (a transparency) from the negative colour record, and projecting the three images separately in three magic lanterns, each with light of the simple colour which it represents, and all superposed in register to form a single sharp composite image upon the screen.

Lest a most important point be missed, I repeat that the synthesis must be obtained with the simple colours, red, green, and blue, although the records have been made by the action of mixtures of various spectrum colours. Thus, although the record for red is made by the joint action of red, orange, yellow, and yellow-green light, this image must be pure red in the synthesis. Correct synthesis, therefore, demands the use of "pure colour" screens, in contradistinction to the "colour curve" screens pertaining to the process of analysis.

If we were to use the same screens for both analysis and synthesis, the results, in dealing with the spectrum, could not possibly be correct. The reason for this should be evident to any one who has followed my argument, but in a few words I will give one or two illustrations.

Suppose we make our colour records of the spectrum through "pure colour" screens; then only the two ends of the spectrum and a band in the middle will be reproduced, the remaining portions appearing as broad, dark spaces in the synthesis, because such screens transmit none of the intermediate spectrum rays. Suppose, on the other hand, that we attempt the synthesis with the "colour-curve" screens; the simple colours red, green, and blue, cannot be reproduced, because the respective screens transmit other spectrum colours along with these.

In short, it is absolutely necessary, in order to obtain a true colour record, to photograph through "colour-curve" screens, and correct synthesis is possible only with "pure colour" screens.

It is true it may happen that, in dealing with compound colours, the effects of departure from theoretically correct conditions will not always result so disastrously as in dealing with the spectrum itself; but no reliance can be placed upon any but fundamentally correct methods.

It is also true that the habit of the eye and mind, due to familiarity with monochromatic photographic reproductions, makes some dilution of colour acceptable to most people, but a recognition of the principle I have stated is necessary in order to introduce this dilution without change of *hue*. The dilution must be equivalent to admixture of white light only, and this is most perfectly effected by broadening the spectrum bands which are taken as synthesis colours without materially displacing them.

In positive synthesis we build up our composite colour photographic image by adding light to light, red, green, and blue, as already described; but we may also employ a method of negative synthesis, producing fixed colour prints upon paper or glass, in which case we commence with our white surface, and build up the picture by superposing coloured shadows (transparent colour prints) upon it.

This method is essentially complementary to the other, and the colours of the transparent prints are like the shadows of the corresponding positions in the white field of the triple lantern.

Red, green, and blue, being the colours in positive synthesis, *minus* red, *minus* green, and *minus* blue, or cyan blue, bright crimson, and yellow, are the printing colours.

If our white surface, against which these colour prints are superposed, were a white made by mixing red, green, and blue spectrum rays, no further definition of the printing colours would be necessary. Inasmuch, however, as our white is ordinarily made up of all the spectrum rays, it becomes necessary to consider the absorption of the colours in the intermediate spectrum regions.

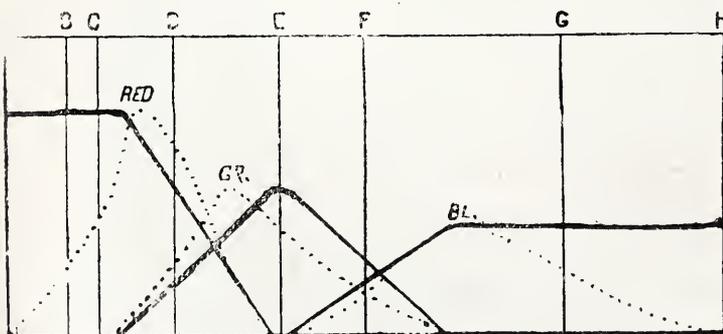

The function of the printing colours is to most efficiently subtract from *ordinary* white light the visual impression belonging to the respective simple colour elements. In other words, the printing colours as seen in *ordinary* white light should appear to match as nearly as possible the *minus* (shadow) colours which may be produced in the physiologically white field of a device for positive synthesis.

This would not be accomplished by absorptions complementary to the correct photographic action, for the reason, for instance, that a *minus* red (c line) is considerably more antichromatic to the red element than a *minus* yellow (D line), although the yellow is more active than the red in the production of the respective negative, in accordance with Maxwell's curves.

I will give one practical illustration. The absorption of the dye cyanine is in approximate concordance with the Maxwell red curve, and, when it is used as a colour sensitiser on a suitable photographic plate, it yields a density curve also pretty close to the Maxwell red curve; but this colour, in ordinary daylight, is no more like our *minus* red than cobalt-blue glass is like signal green.

*The relative efficiency of the absorption falls as we go towards the next "primary" in the spectrum, because it involves simultaneous damping of the visual impression of that other "primary."*

It follows from this that the absorption of the printing colours should not conform to the Maxwell curves, but should be greatest for the "pure" colours, and fall gradually to the position of the next "primary" in the spectrum. Such absorptions are shown in the diagram given herewith, the Maxwell curves being shown by dotted lines, and the printing colour absorptions by the full lines.

These three absorptions, added together, make a neutral black or grey in ordinary white light, but absorptions according to the Maxwell curves would make a dark purple, because the pure red and violet spectrum rays would not be all absorbed. This drawing, although imperfect, sufficiently illustrates a principle which I have long recognised and tried to make clear to others.

I hope the illustrations which I have now given will make it sufficiently clear that in negative synthesis the printing colour absorptions should differ from the photographic analysis curves for the same reason that in positive synthesis it is necessary to employ "pure colour" screens instead of "colour curve" screens; but it is also evident that the distinction cannot be as complete, nor the result as perfect, because of the different character of the white light in the two cases.

As I have frequently pointed out, and as analysis of all the absorption diagrams will prove conclusively, synthesis by colour prints introduces a perceptible though not necessarily offensive dilution or

degradation of colours, which, however, should disappear altogether if the prints are viewed in a mixture of pure red, green, and blue light.

In short, it is not possible, in ordinary white light, to reproduce all of the spectrum colours undiluted by means of any three printing colours, for the same reason that it cannot be done in positive synthesis by means of "colour curve" screens; but the best approximation may be obtained by using the printing colours most specifically antichromatic to the respective colour elements in ordinary white light.

Let me here emphasise the fact that the slight degradation of colour which the spectrum test will disclose even with such printing colours as I have indicated is in no material degree the fault of the photographic analysis, but is inherent in the printing colours. Analysis of the absorption curves of *any* three printing colours will demonstrate that by no means whatever can they be combined to reproduce the spectrum without some dilution or degradation, which may be either general and reduced to the lowest minimum, as with the colours I have indicated, or localised, so as to introduce changes of *hue*, which would be far more objectionable.

It is also necessary to point out that the comparatively short scale of correct gradation of the photographic process is always working against a tendency to weaken colour contrasts which might otherwise be expected, but also that, just in proportion as the colour contrasts are thus intensified, other, and I think more important, qualities are sacrificed. It is generally far better to sacrifice something of the purity of colours than to alter their hues.

Synthesis by the positive method offers the advantage not only of far greater simplicity, but of yielding every other quality along with practically undiminished purity of colour.

When I originally stated these propositions, they were dismissed by many as "mere assertions," "speculations, unsupported by argument or experimental proof," "pretentious and unfounded judgments," "theories, which have nothing to do with practice," &c.

It has always seemed to me that they were such logical deductions from the experimentally verified facts of spectrum colour analysis, that it would be an insult to intelligence to devote time and space to argument and illustration. I am of the same opinion still, but have nevertheless, tried to fortify myself this time with some arguments and illustrations, which I think go as far as should be necessary for anybody who can comprehend a simple theory.

It was by adhering to the conditions which I have laid down that I succeeded, at a time when the capabilities of trichromatic photography were almost universally discredited, in reproducing test subjects to the entire satisfaction of a committee of scientists appointed to investigate the subject.

I shall now proceed to consider the genesis of the various methods which have been proposed, showing as well as I can what elements of success were contributed by each worker, and wherein each failed, until all the conditions of success were realised.

The first suggestion was made by Prof. James Clerk-Maxwell, in a lecture at the Royal Institution, May 17, 1861. This lecture was never published in full, but a report of it was printed in the *Journal of the Royal Institution*.\* According to this report, he

\* "Experiments on the prismatic spectrum show that all the colours of the spectrum, and all the colours in nature, are equivalent to mixtures of three colours of the spectrum itself, namely, red, green (near the line E), and blue (near the line G).

"The speaker, assuming red, green, and blue as primary colours, then exhibited them on a screen by means of three magic lanterns, before which were three glass troughs containing respectively, sulphocyanide of iron, chloride of copper, and ammoniated copper.

"A triangle was thus illuminated, so that the pure colours appeared at its angles, while the rest of the triangle contained the various mixtures of the colours, as in Young's triangle of colour.

"The graduated intensity of the primary colours in different parts of the spectrum was exhibited by the coloured images, which, when superposed on the screen, gave an artificial representation of the spectrum.

"Three photographs of a coloured ribbon, taken through the three coloured solutions respectively, were introduced into the lantern, giving images representing the red, the green, and the blue parts separately, as they would be seen by Young's three sets of nerves separately. When these were superposed, a coloured image was seen which, if the red and green images had been as fully photographed as the blue, would have been a truly coloured image of the ribbon. By finding photographic materials more sensitive to the less refrangible rays, the representation of the colours of objects might be greatly improved."

proposed the production of three photographs to represent the three fundamental colour sensations, by exposing photographic sensitive plates through colour filters, and synthesis by triple lantern projection through the same colour filters. I am inclined to believe that the principle of colour-curve analysis and pure colour synthesis was fully recognised by Clerk-Maxwell, and that it was only by an oversight that this distinction was not set forth in the brief report of his lecture. In short, I believe that his invention may have been theoretically complete for the recording of colours by photography, and their reproduction by triple lantern projection, but that it was lost to the world by insufficient publication.

The next published suggestion was made by Henry Collen, in a letter to *THE BRITISH JOURNAL OF PHOTOGRAPHY* (p. 547, Oct. 27, 1865). Collen, who accepted Brewster's theory of three primary colours of light, red, yellow, and blue, proposed the production of a separate negative by the action of each primary colour, and negative synthesis by the production and superposition of transparent colour prints. He suggested that the negatives should be made on thin pellicles, and that they should be superposed two and two to print transparent images of the third colour; thus, the negative made by blue light and the negative made by yellow light should be superposed and used as one in making the red print, the red and blue negatives for making a yellow print, and the red and yellow negatives for making a blue print.

There were three defects in this proposition, any one of which would have been fatal. First, the wrong idea as to primary colours. Second, the fact that prints in true red, yellow, and true blue cannot be made to even approximately reproduce all colours. Third, that the combination of two negatives doubles the opacity of all whites and greys, without altering the opacity in the records of the pure colours.

The result of this would be that when the printing was carried far enough to show details in the whites (opaque in two negatives), the pure colours (each opaque in only one negative), instead of printing like the whites, as they should, would print half way down to the deepest shadows in density, and reduce the relative luminosity of colours by nearly 50 per cent. in the finished prints.

*In a trichromatic colour record, only one of the three colour elements can be represented in each negative image in its proper relation to the whites and greys.*

Collen's idea was to make one complete negative image by superposing two single element records.

Baron Ransonnet, in Austria, is also credited with a crude suggestion of trichromatic photography, in 1865.

Louis Ducos Du Hauron, in France, applied for a patent on the trichromatic principle in November, 1868. Du Hauron elaborated the idea very much, suggesting not only triple negative colour records, positive synthesis by triple lantern projection, and negative synthesis by superposed colour prints, but also positive synthesis by a photochromoscopic apparatus, and a process in which a single screen made up of juxtaposed coloured lines was substituted for three separate colour screens, and the operation reduced to the production of a single photographic image.

Du Hauron displayed extraordinary ingenuity, but, like Collen, he was misled by Brewster's theory of colour, and there were fatal defects in every method which he proposed.

One of his mistakes was in the assumption that pure colour screens should be used in the photographic analysis intended for positive synthesis, and that the same screens should be used again in the synthesis. Another was that negatives of a totally different character would be required for the purpose of negative synthesis by superposed transparent colour prints.\* He recognised that the opacities of each of the three negatives intended for positive synthesis should represent a single colour element only, but not that they should be made through "colour curve" screens, for synthesis with

"pure colour" screens. With respect to the character of negatives required for colour print synthesis, he made exactly the same theoretic mistake as Collen. He assumed that the opacities in each negative employed to make colour prints should represent two of the colour elements instead of one only; but, instead of superposing two single element negatives, he proposed to allow two colour elements to act together in producing each negative.\* For instance, he would allow both the blue and the yellow to act in the production of the negative for making red prints. The principle is exactly the same as that enunciated by Collen, and has the same fatal defect. Du Hauron himself saw that two colour elements could not be fully represented in a single negative in their relation to the whites and greys, but declared that in practice the defect was not as great as would naturally be expected, and made an ingenious but wholly inadequate argument to explain away the difficulty.

No amount of argument can nullify a fact.

It has been asserted that Du Hauron's "binary" spectrum colours in reality correspond to the true "primaries," the descriptive term and not the colours themselves being erroneous. Writers who have made this assertion imply that I have misunderstood and misrepresented Du Hauron's work, but they are mistaken. Du Hauron not only plainly specified the "sifting of the rays of the two other colours," in contradistinction to exclusive sifting of the simple colours, but he distinctly said that *yellow and blue objects* must act alike (and as white) through the "green" screen, and while admitting that a cobalt blue glass is better than a "violet"† one for the blue-red negative, he adds that "there is here presented a physical fact not in accord with the theory."

This error of Collen and Du Hauron dies very hard, and is perpetuated with supreme assurance by new writers every little while.

One fact which must not be ignored is that, although Du Hauron's theory was that the printing colours should correspond to his idea of the primary spectrum colours, red, yellow, and blue, the colours which he actually recommended are not very far removed from the *minus* colours of the true "primaries." His blue (prussian blue) is a greenish blue; his red (carmine) is a crimson red; and his yellow is a *minus* blue. The fact is, that sheer experience led him to depart very considerably in the right direction from the requirements fixed by his theories; but his conclusion, most positively stated, that the photographs for positive synthesis should be made by "exclusive passage of the single colour corresponding," while the photographs for negative synthesis should be made by "rays of the two other colours," is proof positive that he utterly failed to grasp the true relation between the two kinds of synthesis—the *plus* and *minus* character of the synthesis colours themselves—which certainly demands *identical* colour records for both purposes, and also that they shall be "single element," "colour curve" records.

Du Hauron's most important new contribution to the development of trichromatic photography at this period was his suggestion of a photochromoscopic device, of which I shall speak in another part of my lecture.

This may seem scant treatment of Du Hauron's early exploitation of the principles of trichromatic photography, in view of the fact that many people have regarded his early writings as the fountain head of this science; but I must take the facts as I find them, and his more or less natural errors do not in any way detract from my admiration of his prophetic spirit, and ingenuity, and fertility of imagination, which should be an inspiration to everybody who can read his original treatise on trichromatic photography.

Du Hauron's first patent application was dated November 23, 1868, but his first printed publication appeared in *le Gers*, March 11, 13, 16, 18, 20, 23, and April 1 and 6, 1869, and shortly afterwards in pamphlet form. According to his brother, Alcide Ducos Du Hauron, he had communicated his ideas very fully, except in the matter of negative synthesis, in a *mémoire* transmitted to a French scientist

\* "Each of the images, instead of being obtained by a sifting of the rays of the corresponding simple colour through a space of that colour, is obtained by a sifting of the rays of the two other colours through a space of the double colour complementary to its own."—*Du Hauron in 1869.*

† He describes "violet" as a colour containing a large proportion of red, showing that he means purple, which is called for by his theory.

\* "When the reader has read this book entirely through, he will recognise that, in the method described in Chapter IV., and which constitutes the direct method [for positive synthesis] . . . each of these images is obtained by the exclusive passage, or sifting of the rays of the simple colour corresponding, through a space of the same colour. Proceedings are not the same for the method of inversion" [for colour print synthesis].—*From Louis Ducos Du Hauron's treatise of 1869.*

and Member of the Institute, M. Lélut, July 14, 1862. It is a curious fact that this *mémoire*, said to have been intended for formal presentation to the Institute, but which was not published until 1897,\* discloses several important ideas which are not to be found in any of Louis Ducos Du Hauron's writings which were published prior to 1897, and which had meanwhile been published or patented by others. I shall have occasion to refer to this *mémoire* again.

F. E. IVES.

### OZOTYPE.

Mr. Thomas Manly gave a demonstration of his "Ozotype" process, at the usual weekly meeting of the Photographic Club on Nov. 14—a process of carbon printing in which the image is printed on any paper, and to which the pigment is applied afterwards in the shape of a modification of the ordinary tissue called a pigment plaster. Any paper of a good, pure character can be used. The image is a visible one contrary to the case with the carbon process. The carbon process requires that the pigmented tissue shall be sensitised in bichromate prior to printing. In the Ozotype process the pigment plaster is never sensitive to light; it may therefore be kept for any length of time, and there is no waste resulting from the gelatine becoming insoluble. Having selected a suitable paper, the operator proceeds to coat it with the sensitising solution supplied. This is done by means of a good flat hoghair brush, of about three inches width. Mr. Manly pinned down a piece of paper, 24 x 20 inches, a size in his opinion most convenient to coat. Two drachms of the sensitising solution are required for this area, and it is very important to be exact. The first few strokes of the brush may be heavy, getting lighter and lighter as the solution is distributed over the paper. The next stage is the drying of the paper. This should require about a quarter of an hour in a warm room. In a damp room the solution would be inclined to soak through the paper, and it is very essential that this should not be allowed. The dried paper may then be cut up and printed in the way usual with P.O.P., &c. When one can just see the detail of the high lights the paper may be removed and kept till the batch of prints is made, or placed direct into a dish of cold water. Washing is complete in a quarter of an hour under running water, or half an hour in frequent changes. Prints at this stage were passed round, having a very faint and weak appearance. One may now decide what colour the result is to be, and take of our stock of pigment plasters accordingly. We now require a bath containing a very weak solution of acetic acid and hydroquinone and a few grains of a metallic salt, the sulphate of copper or iron. There is a great difference in the actions of these salts in some cases, but in the Ozotype process they answer one purpose. The copper is more convenient to use. This bath, which consists of

Water .....	40 ounces.
Glacial acetic acid .....	60 minims.
Hydroquinone .....	20 grains.
Sulphate of copper (10 per cent. solution) .....	1 drachm.

should be heated to about 75° to 80°. In the summer time it is not absolutely necessary, but at this time of year one must have the aid of a stove. In this bath the pigment plaster is soaked for a few minutes when it is ready to have the print placed face to face with it in the bath, withdrawn, and squeegeed on a zinc, vulcanite, or other support. Two hours after this is done the plaster is ready to be developed. In that time an action has gone on between the print and the plaster whereby the latter has been rendered variably insoluble, according to the lights and shades of the picture. Development is effected in hot water; the print takes to itself nearly all the pigmented gelatine from the plaster, when the two papers are stripped, and the soluble gelatine is then removed in the ordinary way by agitating the print in the tank or by dashing the water over it with a mug. From the fact that the original print takes up the pigment, it will be seen that no transfer is required to preserve the rights and lefts of the picture.

The best negative is one entirely free from fog or veil, as with the carbon process, but considerable variation may be made in the acetic acid bath to meet particular cases. The larger the proportion of acetic acid and the smaller that of the reducing agent, the harder will be the picture. On the other hand, more reducing agent and less acetic acid renders the picture softer. Of the phenol-derived reducing agents hydroquinone is the best for the Ozotype process.

Rough or smooth papers may be used. Rough papers, however, require sizing either before or after sensitising in order to make the pigment plaster adhere properly. Glycerine is a very useful agent. It softens the paper and assists the gelatine to secure a grip of the paper. A solution of equal parts of glycerine and water is helpful in ridding one of the chances of air bells, if the prints be dipped therein before

\* "La Triplique Photographique des Couleurs et l'imprimerie." Alcide Ducos Du Hauron, Paris, 1897, p. 450.

squeegeeing, and better contact is obtained. It is well to wipe the surface of the pigment plaster before use to rid it of specks and dust. A size for application after sensitising, drying, and printing the paper is made up of the following:

Fish glue .....	2 drachms.
Glycerine .....	1 ounce.
Water .....	6 ounces.

An insoluble sizing must be employed if the paper is to be sized before sensitising. The prepared paper must, of course, be dried in the dark.

Before mounting, the prints have to be treated with alum solution. Mr. Manly mounted his prints wet, after dipping in the alum bath and washing in two or three changes of water.

If the backing of the pigment plaster refuses at times to come away from the gelatine, it may be due to under-washing of the print—the free bichromate rendering the gelatine insoluble. The remedy is obvious. White specks are caused by imprisoned air-bells. These air-bells only cause spots, not blisters. The speed of the paper is about that of platinum paper.

The demonstration was attentively followed, and a hearty vote of thanks was given to Mr. Manly.

### PHOTOGRAPHERS, THE PUBLIC, AND THE ILLUSTRATED PRESS.

THE contributor who writes under the nom-de-plume of "Free Lance" commented on some notes I wrote dealing with the subject of "Copyright Portraits," and, with the Editors' permission, I would like to traverse his statements—although not in any captious spirit—because the matter is, I think, of some interest to photographers generally.

"Free Lance" wrote: "It is not the photographers who make the arrangements for publishing their royal photographs in one journal; it is the proprietors of the journal who make the arrangements, and photographers merely act as their hired agents; they receive, therefore, a weekly retaining fee! So much for what journalism does to benefit photographers in general." I do not think it is very material whether it be the photographer or the proprietors of the paper who make the arrangements. As a matter of fact, in many cases, it is the editor—the proprietors may not be consulted—and in some cases it is quite conceivable that it may be the photographers who make the suggestion; but the point was that there are people who do not think photographs of Royalty, more especially of Her Majesty, should be exploited for the benefit of one particular paper. In the particular instance I had in my mind, I doubt whether the photographer receives a weekly retaining fee; but of that I cannot say for certain.

"Free Lance" also said: "A lot of money has been made, and will be made, by copyright fees from the illustrators. He is, however, a lucky man who often gets more than a five-pound note for such (and they are trying to establish a maximum of five shillings!). But what have they lost by it for themselves and their brother professionals? Hundreds of thousands of pounds of replicas. And who have gained, except the producers of those wretched, feeble caricatures of photography which are published to the utter degradation of illustrated journalism from the proud and high position it once occupied of artistic eminence and exploiters of the very best examples of the now almost extinct British art—wood engraving." I am aware that this is not the first time that "Free Lance" has given expression to similar opinions. His remarks are certainly not very complimentary to those who supply the photographs including those well-known firms who photograph Royalty and distinguished personages, to which I referred in my article. Many of us can fully appreciate the wood-cuts of such artists as William Nicholson, who, by the way, clever artist as he is, can appreciate good portrait photographs, and who has never, I feel sure, said anything so sweeping about the Press reproductions of photographs, as "Free Lance" has done. If we cannot prevent the force of circumstances, why shed vain tears?

As to the loss in replicas these producers of "wretched, feeble caricatures of photography" have suffered, I am not aware that there is any compulsion about the matter. If it is not to the advantage of these photographers to allow their work to be reproduced in the illustrated press, why, then, have they not an obvious remedy? The photographers of the class of subject to which I referred are not very numerous, and as they are business men I presume they do not allow their photographs to be published in the illustrated press unless it pays them to do so; they do not pose as philanthropists.

"Free Lance" says the days of 80,000 orders for "Royal, or any other photographs, are gone for ever." "The illustrated papers have done that for us." But, as I have remarked, I am not aware that there is any compulsion in the matter.

The exploiting of photographs of members of the Royal family for purely commercial purposes is to some minds an anomaly, and to a great extent a monopoly, against which a good deal might be said.

Speaking generally, I agree that it is a moot point whether professional photographers benefit by allowing their work to be reproduced

in the illustrated Press. Certainly it seems more likely that the public would purchase an original photograph if it were not reproduced, *i.e.*, assuming they knew the photograph had been taken. At the same time, I think it will be generally agreed that editors should pay reasonable and remunerative reproduction fees. Some day, perhaps, the Copyright Union will induce all the editors of illustrated papers to agree to their conditions and not to publish any photographs without paying the Union's minimum fees. This would be the simplest plan, if it could be effected. At present, the papers to which it is worth any one's while to send photographs are not very numerous. For one thing, there are so many photographers who are willing to accept any fee for a photograph that is published. When editors can obtain the use of amateurs' photographs for nothing, or next to nothing, it is not likely that they will pay professional photographers bigger fees for the same class of subject. In the case of photographs of Royalty and of distinguished personages, however, the supply is much less limited, and in this field "amateurs" and photographers generally have not much scope. Consequently the fees are not cut. It is curious that well-known amateur pictorial photographers allow their best pictures to be published in very rapidly printed and not over well produced papers, necessitating a complete disfigurement frequently of the original and a loss of all tone values to get an impression.

Money can be made by contributing photographs to the illustrated press; but I am not one of those who think it likely to prove a little El Dorado to the average professional; and, to some extent, such work is really in the province of the journalist. J. A. REID.

AINTREE PHOTOGRAPHIC EXHIBITION AWARDS.

THIS exhibition had a most successful run all last week, and the judges, Messrs. R. Talbot Kelly, R.B.A., Paul Lange, and G. Watmough Webster, F.C.S., with Mr. Frederick Anyon in the Lecturette class, were so highly pleased with the splendid work sent in that they awarded no less than fourteen extra medals and diplomas, over and above the thirty-six which the Executive had provided for. The best picture was "Golden Harvest," an enlargement in carbon, and was awarded a gold medal, the competitor being Mr. T. E. Corney Wilson, of Liverpool.

Lecturette Class.

- Silver, Algernon Brooker, Hastings.
- Bronze, G. S. Bryson, Pollokshields.
- Diploma, Wm. A. Taylor, Liverpool.

Landscape or Seascape.

- Silver, C. E. Walmsley, Ambleside; C. M. Wane, Edinburgh.
- Bronze, Wm. A. Taylor, Liverpool; T. B. Sutton, Babington; Dr. Llew. Morgan, Liverpool; H. Burkinshaw, Belper.
- Diplomas, William E. Inston, Liverpool; J. R. Clarke, Whitehaven; W. P. Baker, St. Helens.

Architecture.

- Silver, A. B. Gregory, Liverpool.
- Bronze, A. J. Loughton, Southwell.
- Diplomas, E. L. Brown, Edinburgh; Sparham Camp, Sheffield.

Enlargements.

- Gold, T. E. Corney Wilson, Liverpool.
- Bronze, Dr. C. F. Grindrod, Malvern; Dr. Llew. Morgan, Liverpool.
- Diploma, T. A. Sands, Birmingham; Charles F. Inston, Liverpool; L. Henry, Liverpool.

Figure Studies.—Amateur.

- Silver, Miss Evelyn Boden, Derby.
- Bronze, J. A. McMichael, Chester; James Walker, Birkenhead.
- Diplomas, Mrs. McIntyre, Aintree; Dr. Llew. Morgan, Liverpool; D. G. Monair, Blairgowrie.

Figure Studies.—Professional.

- Silver, Graystone Bird, Bath.
- Bronze, C. M. Wane, Edinburgh.
- Diploma, R. Yerburgh, Edinburgh.

Hand Camera Work.

- Silver, William E. Inston, Liverpool.
- Bronze, Thomas Hartley, Waterloo; E. R. Collins, Dulwich; S. R. Midgley, Stonycroft.

Lantern Studies.

- Silver, Edgar R. Bull, London.
- Bronze, Algernon Brooker, Hastings.
- Diploma, Graystone Bird, Bath.
- South African Class.—Withheld. Insufficient competitors.

GOtz'S NEW FILM HOLDER FOR DARK SLIDES.

[Patent No. 24,689 of 1899.]

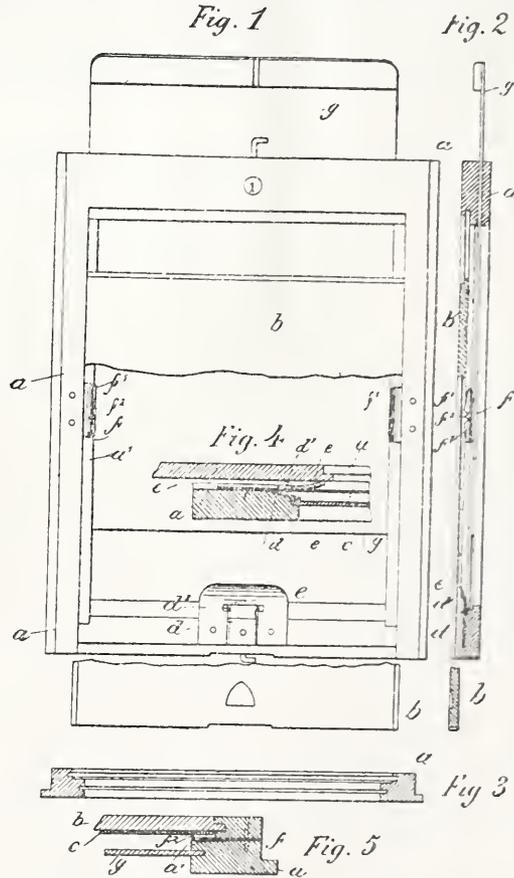

THE invention relates to a method of holding the sensitive material, the latter being pressed back on to a solid support on which it rests for exposure, and the plane of the focus being laid not against a rebate,

but just in front of the said solid support, allowing for the thickness of the material carrying the sensitive surface.

By this means the use of a carrier is avoided, and the sensitive film is held in the slide, without any such device as a stretcher or frame, or whatever the special carrier may be called.

Fig. 1 is a back view, Fig. 2 a longitudinal section, and Fig. 3 a cross section of a single dark slide embodying the invention. Fig. 4 shows a clip or gripping device, and Fig. 5 a holding-down spring on a larger scale. *a* represents the body or frame of the dark slide, *b* the sliding support or drawer, which Figs. 1 and 2 show partly drawn out and broken off, in order to show the parts situated behind it.

If a film or sheet *c* of paper, celluloid, or similar material, were inserted into the slide without any other support, the drawer or sliding

door *b* would, in the act of closing, carry the film with it, and thus displace it from its required position.

Mr. Gotz adds: I therefore insert into the frame *a* of the slide a gripper *d* having two or more small teeth *d*<sup>1</sup>, and over that a plate *e* acting as a spring, so that, when the sliding door *b* is closed, the plate *e* presses the film *c* on to the teeth *d*<sup>1</sup> of the gripper plate *d* and holds it in the proper position, as indicated by Fig. 4.

The sensitive film *c* is inserted with its front edge into the gripper, which, as soon as the drawer or sliding door *b* is being closed, holds the film firmly in its right place.

In order to keep the sides of the film in contact with the rigid sliding door, springs are used, which may be of various descriptions, their object being in all cases to hold the film down on to the rigid drawer; that is to say, in a direction opposite to that of the springs usually applied in dark slides.

These springs are inserted into the rebates *a*<sup>1</sup> and body *a* of the slide, one or more being placed on each side of the same.

I prefer to use a pair of metallic springs, *f*, *f* inserted into the body *a* of the slide and coming out flush with the rebate *a*<sup>1</sup>, which is cut away to make room for the spring, as shown in detail by Fig. 5. Each of the springs *f* has a turned-over edge *f*<sup>1</sup> with one or more teeth *f*<sup>2</sup> to hold the sensitive film on to the rigid surface of the sliding door *b*.

THE GRENIER ART COMPANY'S PROCESS OF COLOURING PHOTOGRAPHS.

[Patent No. 13,317 of 1900.]

THE portrait or other picture or design is photographed on the silk or other material, preferably by methods employing any well-known suitable sensitising emulsions or solutions that are free from gelatine or albumen. After printing it on silk the picture is fixed by means of a hyposulphite bath and thoroughly washed so as to free the fibres of the silk from all traces of the hyposulphate. Then take a solution of

alum, using preferably one part of alum to sixteen parts of water by weight, and while the silk is still wet lay it with the back or unprinted surface downwards on the surface of the alum solution, without letting the alum solution flow on to or over the printed face of the silk. In ten or fifteen seconds the picture is taken out of the solution, allowed to drip, and then dried. As a result of this the fabric is impregnated with the alum. The evaporation of the water leaves the impregnating alum in the fabric. The fabric so prepared is ready to receive colours, which are applied by brush, as desired, using water colours. Permanent colours are the best colours to use, but aniline colours give very beautiful effects, especially for pictures of flowers. Alum solution may also be added to the colours before they are applied. The alum prevents the colours from running or blurring while drying, it renders them more intense and more durable, and it makes them practically waterproof, though this does not mean that the photographs will withstand violent rubbing or abuse while wet. The picture after being so coloured may be additionally protected by coating it with celluloid or other protecting and transparent material.

In applying the process to heavy fabrics, such as tapestry, the alum bath may be allowed to completely cover both the printed and unprinted surface of the fabric.

## Our Editorial Table.

### CATALOGUE RECEIVED.

Messrs. Perken, Son, & Co., Limited, 99, Hatton-garden, E. 7.

THE neatly-produced catalogue of the well-known "Optimus" house, which has just been issued, numbers about a hundred pages, and the illustrated descriptions of the firm's specialities in apparatus, lanterns, and accessories are lacking neither in fulness nor variety. Lenses of the narrow angle, wide angle, portrait and rapid landscape type are given first place; then follow hand camera and cinematograph objectives. Next come hand and stand cameras, complete sets, shutters, stands, levels, focussing glasses, dark room lamps, washers and the hundred and one requirements of the practical amateur or professional photographer. About forty pages of the catalogue are devoted to the lantern department, and the book concludes with a lengthy alphabetical list of lantern slides.

The productions of Messrs. Perken, Son, and Co. need no recommendation at our hands, but, as many of them have recently come under our observation, we may take the present opportunity of congratulating the firm upon the unvarying excellence of the apparatus which leaves the Hatton Garden establishment. Especially is this so in respect of the Optimus lenses and cameras. The former have long been noted for very high optical qualities; while as for the cameras, be they are of the cheaper or more expensive kinds, they are always well and carefully constructed. Quite recently we inspected a magnificent direct enlarging and reducing camera, 36 x 20, specially built, which is one of the finest bits of photographic cabinet work that we have seen. The esteemed firm of Perken, Son, and Co., modernised in name, of course, will soon have been in existence for half a century. It retains its vitality undiminished, and amongst British photographic apparatus manufacturing houses is assured of a position of the greatest prominence and esteem.

### FLAME, ELECTRICITY, AND THE CAMERA.

By George Iles, 398 pp., 94 illustrations and 22 plates, price 7s. 6d. London: Published by Grant Richards, Henrietta-street, Covent Garden.

MR. ILES has made his book very good reading matter, for he has clothed his ideas in the florid language of the newspaper "leader" writer. He gives in a popular form an account of the principal modern achievements of physical, chemical, and mechanical science in the service of man, and writes throughout so enthusiastically about his subject that he conveys the impression that he lives in a veritable heaven of optimism. His main object "is to show how profoundly recent accessions to knowledge are transforming the foundations of social, political, and economic life, while at the same time they are correcting and broadening the deepest convictions of the human soul!" But, alas; and alas! Mr. Iles, with all that the century's science has done, the work-houses, prisons, and the lunatic asylums have no lack of occupants. "grim visaged war" stalks abroad in the three continents of Asia, Africa, and America; and want, misery, and crime do not seem to diminish! But we may allow Mr. Iles the indulgence in his beautiful optimism as a reward for the excellent work he has put into his book. His illustrations are instructive and well chosen. The hundred pages devoted to photography are not by any means free from errors of names, dates, and facts; but, like the remainder of the book, the section forms very good reading, and may induce many into whose hands the book will fall to take up a closer and more detailed study of photography. We can recommend "Flame, Electricity, and the Camera" as a gift-book suitable for general reading, or to place into the hands of a youth with scientific tastes. If hardly to be regarded as a textual authority, it should stimulate inquiry and promote a taste for popular science. The volume is beautifully printed and bound.

THE BOOK OF FAIR DEVON. 209 pp. Many illustrations. Price 2s.

Published by Iliffe, Sons & Sturmer, 3, St. Eride-street, E.C.

ISSUED under the direction of the United Devon Association, 17, Bedford-circus, Exeter, of which an old photographic friend, Mr. Chas. R. Rowe,

M.J.I., is Secretary, this tastefully-produced book should be assured of succeeding in the object that has led to its publication. It is, in fine, a capital advertisement of one of the several English counties that dispute for supremacy in respect of natural beauty and historical interest. There are about 30 half-tone reproductions from photographs printed in the text, which is further broken up by scores of clever sketches. In setting forth the attractions of Fair Devon to the invalid, the tourist, and the holiday-maker, the co-operation of many specialistic writers on sport and other subjects has been secured, and we note as a point of some interest that Mr. Rowe himself is responsible for the article on "Golf." A world of care has been expended in the compilation of the work, which supplies a great deal of pleasant and useful reading, even to unfortunates like ourselves, who have not yet set foot in the Fair County. But, apart from its value and interest as a specimen of bookmaking, the volume before us appears to be so complete and conscientious that its wide distribution, especially in America, should surely be followed by the invasion next year of a large number of tourists and others. "The Book of Fair Devon" is neatly bound in green cloth, is clearly printed, and, as well for its main purpose, deserves even as a volume of reference to find a place on the book shelves of all lovers of that "dear homeland," in the crown of which Fair Devon is admittedly one of the brightest gems.

## Studio Gossip.

THE Colonial Secretary has added amateur photography to his other accomplishments, and has been taking snapshots of Italian scenery. He is the only photographer in the Cabinet.

AN "Objectionable" Poster.—Considerable excitement was caused in Manchester last week by a rumour to the effect that a theatrical poster, placarded on an advertisement hoarding in the city in connection with a production of "Hearts are Trumps," at the Theatre Royal, had been obliterated by order of Mr. Peacock, the Chief Constable. The poster, which was issued by a London company, represented a kissing scene, with a photographer in the background. It appears, however, that the rumour was incorrect in one particular. Some time last week the Chief Constable received several complaints by letter about the poster, the writers regarding it as highly objectionable. The correspondents remarked that the general effect was such that many respectable fathers and mothers would be thankful if the picture were not allowed to remain on the walls and hoardings. Mr. Peacock thereupon wrote to Mr. Courtneidge, the manager of the Theatre Royal, and communicated to him the general effect of the letters, without, however, giving any orders as to the removal of the poster, which, as a matter of fact, it was beyond his power to do. Mr. Courtneidge, in reply, affirmed that he had no desire to publish any advertisement which might be deemed offensive, and that as complaints had been made the pictorial poster should be obliterated. He explained that, although he saw the posters beforehand, it was not for him to choose which should be given, and which withheld, as the Drury-lane Theatre Company brought out the piece, and sent ahead all the illustrated advertisements, and they might have objected to his interference.

JOURNALISTIC Changes in America.—From "Wilson's Photographic Magazine" we take the following announcement: "The 'Photographic Times' has our congratulations on the return of Mr. W. E. Woodbury to the editorial chair, which he vacated more than a year ago, to join the Nepera Chemical Co. During Mr. Woodbury's absence our contemporary was of somewhat fluctuating value, though for the last few months it has regained much lost ground under the able control of Mr. Juan C. Abel. Owing to ill-health, due partly to overwork, Mr. Abel has felt compelled to resign his position, and will, we understand, after a brief holiday for rest and recuperation, be interested in another phase of work. Mr. Woodbury contemplates some innovations in the magazine, which will be altogether on the lines of improvement." "The Photo-Era" also announces its absorption of the "American Journal of Photography" of Philadelphia, of the past career of which it supplies the following details: The Journal was first published in its present form by Thos. H. McCollin, of Philadelphia, in 1886, under the editorship of John Bartlett. Previous to this, photographic journals were almost unknown in this country [America]. It was devoted exclusively to professional interests, or in the interests of some progressive concerns, and its timely articles on current topics excited praise and admiration both here and abroad. Such leading men as Dr. Emerson and H. P. Robinson of our neighbours beyond the sea were attracted by its new departure, and their laudatory letters did much to establish its reputation. Illness forced Mr. Bartlett to retire from the editorial chair in 1890, and the work continued under the direction of Mr. Sachse. Again in 1897 Mr. Bartlett resumed his work, changing the scope of the magazine and subordinating the scientific to the purely artistic element. In 1899 Mr. McCollin disposed of the magazine, and Mr. Austin C. Leeds became the owner, until the present arrangements were concluded."

A LADY Astronomer.—For the first time in the history of science, the President of the Royal Society has a wife almost equally gifted and famous in the special science for which the distinction is bestowed upon the President. If it were possible to appoint a lady President, Lady Huggins has every qualification for the post. And it is not a case in which the wife has simply shared the labours of a distinguished husband; lady, commenced the study of astro-physics and gained some renown by and adapted herself to her environment. Lady Huggins, who is a Dubliner, her writings quite independently. When but a girl she would sally forth

at night with a lantern and star atlas, and with the aid of her father's telescope study the position of the astral bodies. Astro-physics she studied by means of a sixpenny prism, picked with critical care from a basket of odds and ends in a second-hand shop. With this simple apparatus, she had the satisfaction of repeating in a humble way the first experiments of Newton and Fraunhofer, and especially the epoch-making one of Kirchoff. After her marriage with Sir William Huggins, then Doctor Huggins, she continued her studies in conjunction with her husband, and with the splendid equipment provided for them at their Tulse Hill residence by the Royal Society. The result of their labours has been to entirely open up and popularise the science of astro-physics, and will rank as one of the great scientific achievements of the reign. Their house at Tulse Hill is one of the most interesting houses in London, full of gems of art and scientific curiosities—in fact, a very Pandora box of surprises. The garden, too, of which Lady Huggins is justly proud, is quite unlike any other garden one ever sees. Her aim has been to make a "natural" garden. There is nothing artificial in its arrangement; everything seems to have grown up spontaneously, and to be the result of Nature's own handiwork.

## News and Notes.

ROYAL Photographic Society, Technical Meeting, Tuesday, November 27, at 66, Russell-square, at 8 p.m., "Analytical Portraiture," by Francis Galton, F.R.S.

BURNLEY Camera Club.—The Judges for the Burnley Camera Club's Exhibition, on January 18 and 19, are Messrs. C. Barrow Keene, F.R.P.S., Derby; Alex. Keighley, F.R.P.S., Keighley; and Dr. Lewellyn Morgan, M.R.P.S., Liverpool.

THE Royal Meteorological Society have established a memorial to the late Mr. G. J. Symons, F.R.S., the distinguished meteorologist and founder of the British Rainfall Organisation, in the form of a gold medal, to be awarded from time to time by the Council of the Royal Meteorological Society, for distinguished work in connection with meteorological science. The committee have decided to keep the list of donors open until the end of January, 1901.

MR. J. T. Ashby, of the Woodford Society, gave a lecture on "Pictorial Competition" before the North Middlesex Photographic Society on November 12. He entered a little into the roles of perspective, and then gave hints as to the selection of subject and the proper use of figures as an adjunct to the landscape. He gave no hard and fast rules, saying they were better avoided. He also showed a selection of slides by the best workers in his Society, the slides being of very good quality.

THERAPEUTICAL Treatment with Light.—The "Elektroteknisk Tidsskrift" of Copenhagen states that a Danish electrical engineer has invented an electrical lamp which will cause a considerable advance in the therapeutical treatment with light followed by the Danish Professor Finsen. The lamp has been tested at "Finsen's Hospital for Treatment with Light," in Copenhagen, and has been proved to produce in an especial degree those chemical rays which are necessary for the purpose.

ACETYLENE to the Rescue.—Owing to the recent disastrous floods having submerged the coal gas works of Calcutta, the "Pioneer Acetylene Gas Company of India" were suddenly called upon to light Howrah Railway Station, the largest in India. Five of the Thorn and Hoddle Acetylene Gas Company's generators were at once fixed, and the whole installation was at work within three days. The Coal Gas Company wrote heartily thanking the Acetylene Gas Company for coming so promptly to the rescue.

THE Edinburgh Photographic Society's Annual Exhibition of Photographs will be held in the rooms of the Society, 38, Castle-street, Edinburgh, from Saturday, February 16, to Saturday, March 9, 1901. Entries close on Wednesday, February 6, 1901, at 4 p.m. Reception of pictures closes on Saturday, February 9, 1901, at 10 p.m. The following classes are open to all—(Gold, silver, and bronze medals in each class): Class 1, Portraiture and Figure Studies; Class 2, Landscape and Seascape. All communications should be addressed to the Secretary, Mr. J. S. McCulloch, W.S., at 10a, George-street, Edinburgh.

PHOTOGRAPHIC Exhibition at Grantham.—In connection with the Grantham Industrial and Fine Art Exhibition, to be held on January 16, 17, and 18, 1901, and which will be opened by Her Grace the Duchess of Marlborough, there will be a photographic section open to amateurs in the United Kingdom. The following are the classes: Landscapes, Seascapes, and interiors, in sets not exceeding six pictures; portrait and animal studies, in sets not exceeding six pictures. Each picture judged separately. We learn that last year the photographs were a great feature of the Exhibition. The general manager is Mr. George Jackson, Launder-terrace, Grantham.

X RAYS in Operations.—Before the Hastings Coroner, last week, the inquiry was concluded into the circumstances attending the death of Catherine Fanny Wilson, a widow, aged 68. Evidence had been given that X rays were used to locate a supposed fracture of the thigh, the result of a bicycle accident, and that shortly after an eruption broke out on the stomach. A letter had been written by deceased in which she alleged "cruel over-exposure of the X rays." For five weeks before death she was not of sound mind. Dr. H. Roberts, who was called in when the eruption occurred, said that death was due to exhaustion from effects of shock, evidently resulting from the fracture of the thigh and

application of the Rontgen rays. The photographer, Mr. Blomfield, stated he gave exposures of 35 and 45 minutes each. Dr. Lewis Jones, medical officer in charge of the electrical department of St. Bartholomew's Hospital, London, said he considered proper exposures had been made. Some persons were sensitive to X rays, and some were not. It was not known why this was so, but it was believed to be due to the state of the skin at various times. Some risk from X ray burn was always present in long exposures. Witness had never heard of a case in which an X ray burn had caused death.—The jury returned the following verdict: "That deceased met her death from shock and exhaustion following an accident and the effects of the X rays on a weakened system. No blame attaches to either the medical man or the photographer."

## Commercial & Legal Intelligence.

MESSRS. Thom and Wiggins have commenced business as photographic material dealers at 15 and 16, Giltspur-street, London, E.C.

PATENTS in the Late Orange Free State.—The Comptroller-General of H.M. Patent Office is informed by the legal adviser of the Military Governor that the patent laws of the late Orange Free State have been in no way altered or disturbed, and that persons interested in obtaining letters patent or renewing patent rights already granted should proceed as they would have done had no war taken place. All applications, specifications, &c., may be drawn up in the English language. The Patent Office, which has been of necessity temporarily closed, will be reopened as soon as circumstances permit.

THE following is the list of the awards in the Austin-Edwards Lantern Slide and Film Negative Competitions for the current month:—£3 cash prize: Rev. E. T. Clark, Gloucester, "A Devonshire Lane"; £2 cash prize: H. Holt, West Kirby, "Vicarage Passage, Evesham"; £1 cash prize: J. Smith, Liverpool, "Atmosphere, River Derwent"; £1 cash prize: J. Walker, Birkenhead, "After a Storm"; £1 cash prize: Miss E. M. Barrows, Edgbaston, Birmingham, "An Old Yorkshire Cobbler"; £1 cash prize: E. R. Bull, Forest Hill, "In the Baronial Hall, Haddon Hall"; £1 cash prize: H. C. Leat, Bristol, "Entrance, Little Cloisters, Gloucester." Film Negative Competition.—The Frena Camera given each month for the best negative on an Austin-Edwards film has been secured by J. H. Bridgford, of Christchurch, Hants, for his negatives, "Street Scenes."

ALLEGED Breach of Contract.—At the Clerkenwell County Court, on Thursday last, before his Honour Judge Edge, Walter D. Welford, of 166, Romford-road, Stratford, photographic dealer, sued Walter Charles Grubb, trading as The Camera Construction Company at 38, Eagle-street, Holborn, to recover the sum of £15, damages for breach of contract.—Mr. Warren, who appeared for the plaintiff, called evidence to prove that his client had to go to Leeds to get an order executed in consequence of the failure of the defendant to complete the order for photographic goods within the time specified.—Mr. Grosser, on behalf of the defendant, said he would have been willing to execute the order from the plaintiff if he had received the cheque at the end of the month, but the plaintiff did not send it.—After considerable legal argument, his Honour said he would reserve his decision, as the point raised was an important one to the commercial community.

AT Bow-street Police Court, on the 19th inst., John Thompson, alias A. T. Homes, was charged, on remand, with being in the Royal Photographic Society's house, 66, Russell-square, W.C., on the evening of the 13th inst., with the intention of committing a felony. It appeared from the evidence of Mr. A. W. W. Bartlett, Assistant Secretary, that the prisoner had been present at a meeting of the Society in the winter of 1898, and, having been recognised as having been present at a previous meeting when an overcoat was found to have been stolen from the cloak-room, was asked by Mr. Bartlett, in the presence of some of the members, for the name of the member introducing him. He gave the name of Mr. Chancellor, of Dublin. Mr. Chancellor, on being applied to, denied all knowledge of the man. The prisoner on this occasion signed the attendance book J. Thompson, with an address in Gower-street, which was afterwards found to be an empty house. On the evening of the 13th inst., on the occasion of Mr. Maunder's lecture, Mr. Bartlett again noticed the presence of the prisoner, and, knowing that since 1898 he had served a sentence of imprisonment for stealing coats, ordered that he should be detained. It was found that he had signed the attendance book as a member under the name of A. T. Holmes, and he was given into custody. It was proved that the prisoner had been convicted of stealing overcoats, and had undergone sentences of four months and eighteen months' hard labour. He had also been charged recently with the unlawful possession of a lady's fur cloak, but there was not sufficient evidence to convict.—The magistrate sentenced the prisoner to twelve months' hard labour.

THE Britannia Works Company, Ltd.—The Directors' Report for the year ended October 31, 1900, to be presented at the Fourth Ordinary General Meeting to be held at Winchester House, Old Broad-street, E.C., on Wednesday, November 28, 1900, states that after payment of working expenses, directors' fees, income tax, &c., and making provision for doubtful debts, the net profit for the year's trading is £53,278 19s. 5d. This amount, with £3,552 19s. 5d., brought forward from last year, gives £56,831 18s. 10d. for appropriation. The directors have paid an interim dividend on the ordinary share capital for the half-year ended April 30, 1900, at the rate of 8 per cent. per annum, free of income tax,

absorbing £7,600; and for the same period they have paid the dividend on the Six per cent. Preference shares, amounting to £5,700. Since then the second dividend on the Six per Cent. Preference shares has been paid. From the balance the directors recommend that a dividend be paid on the Ordinary Share capital for the half-year ended October 31, 1900, at the rate of 12 per cent. per annum, free of income tax, making with the above interim dividend, 10 per cent. for the year. This will absorb £11,400. On this dividend, by the terms of the profit-sharing scheme, £766 11s. 3d. will be paid as bonus to the employees. Of the balance, £25,665 7s. 7d., the directors recommend that £15,000 be written off goodwill, processes, &c., and that £8,000 be placed to reserve, and the balance, £2,665 7s. 7d., carried forward. The business continues to show satisfactory progress, and, notwithstanding the wars in South Africa and China, which have seriously affected the Company's trade in those countries, the sales have been considerably larger than last year. The title of the Company being altogether unidentified with the Company's productions, which are known throughout the world as "Ilford" goods, the directors propose to change the name to "Ilford, Limited."

**The Strong Man's Photo.**—De Saurin v. Rosenstein. The plaintiff in this action, Alfred De Saurin, sued Maurice Rosenstein at the Liverpool County Court, before his Honour Judge Collier, to recover possession of a photo, or its value, £3. The plaintiff was described in a local music-hall as "The Herculean Marvel—The Monarch of all Iron-Jawed Men." The posters also set forth that, having met and defeated all the so-called champions of America, he has just returned to the scenes of his former triumphs, and had no equals, but was the undisputed champion, the consequence being that his engagement was "a most important and expensive one." The plaintiff's case was that in March last he lent his photo to one Barnett, a barber in Brownlow-hill. It was hung up to advertise "The Marvel," and the customers saw it and admired it. Barnett gave up his shop, and was succeeded by the defendant, Rosenstein, who allowed the photo to remain an ornament of his tonsorial saloon. From time to time "The Marvel" looked in to get his hair cut or a shave, and last, but not least, to admire his photo. After a time he grew dissatisfied with the manner in which the defendant exhibited it, cobwebs began to gather on the photo, which was almost life-size, the gilt frame became tarnished, and there were not so many customers as there were formerly, and "The Marvel" came to the conclusion that as an advertisement his photo was of little value in the defendant's saloon, therefore he asked to be allowed to remove it. Certainly, replied the barber. "The Marvel" thereupon unhooked it, and was walking out of the shop with it, like Samson with the gates of Gaza, when the barber stopped him, and said he must have a receipt. "The Marvel" then wrote the following marvellous receipt, "Received my photo, which was placed here for advertising myself.—De Saurin." The barber, however, was not satisfied, and insisted that the photo should be returned. The defendant pleaded that the photo was part of the "goodwill" purchased from his predecessor, Barnett, and in the alternative, he said, "How do I know the photo is 'The Marvel's'?" It may be him, but it may not be his. Somebody else might claim it, and then when it's "gorn" he will be coming round for it, and I shall be held liable ag'in. I want a definite decision as to what I am to do.—A definite decision was soon forthcoming, and defendant was ordered to return the photo, or in default to pay the £3 claimed for it.

an enlargement and one a direct print—suggesting that the enlargement was apparently of a different perspective to that of the smaller print.—Several speakers suggested that this would be explained by the fact that the enlargement was much more vigorous than the smaller print and that the difference in the scale of gradations would lead one to the conclusion already detailed.—Mr. Philip Everitt asserted that it was an optical illusion. He and Mr. Fry agreed that it was only a question of angle of view. Looked at from a fixed point, the appearance was as suggested, but if viewed at the same angle, and therefore different distances, the prints had a perspective common to both.—Mr. S. H. Fry referred to a formula for getting sepia-platinum prints by development of the bath including bichloride of mercury, chloride of copper, and acetate of lead.—A Member remarked that such a bath used hot with cold bath paper gave nice warm tones—much redder than usually obtainable—which, unfortunately, were very fleeting.—Mr. J. W. Marchant had experimented in this direction, dividing the print into two, and exposing one in a window. In a few weeks the warm tone had gone, and, compared, the other portion of the print had become decidedly fainter.—Mr. Fry said that this answered a further question he was about to put regarding the permanence of prints so prepared, or, indeed, of any sepia-platinum prints.—Mr. Everitt said that Mr. Willis himself, speaking of the use of bichloride of mercury in the platinotype process, expressed a doubt about the permanence of results so obtained.—Mr. Fry remarked that a mercury intensified negative would not give black tones on platinum paper unless the negative is varnished.—Mr. E. T. Wright gave a short lantern lecture on "A Trip Round the East Coast with a Camera." The views embraced lay between the Thames and the Tyne, and included glimpses of Lowestoft, Boston, Gateshead, &c., shipping and harbour scenes.—A vote of thanks was given to Mr. Wright.

**Liverpool Amateur Photographic Society.**—Mr. Geo. E. Thompson lectured before the Liverpool Photographic Association on Thursday November 15, his subject being "Three Continents in Six Weeks" (part 1). Mr. Thompson, who was introduced by Mr. Paul Lange, took his audience for a delightful tour down the Mediterranean, calling at Syracuse and Athens, then by way of the Dardanelles to Constantinople, and back again to Palestine. Landing at Jaffa, Mr. Thompson journeyed to Jerusalem, visiting the Mount of Olives, the Mosque of Omar, the Garden of Gethsemane, &c., then on to Bethlehem, Jericho, and the Dead Sea, where this part of the lecture finished.

FORTHCOMING EXHIBITIONS.

1900.  
 November 23 ..... Hackney Photographic Society. Hon. Secretary W. Selve, 70, Paragon-road, Hackney, N.E.  
 ,, 23, 24 ..... Cleveland Camera Club. Hon. Secretary, F. W. Pearson, 98, Victoria-road, Middlesborough.  
 ,, 23, 24 ..... Hove Camera Club. Hon. Secretary, C. Berington-Stoner, 24, Holland-road, Hove.  
 ,, 23, 24 ..... Waterloo and Blundellsands Photographic Society. Hon. Secretary, W. G. Eyre, 2, Mersey-road Blundellsands.  
 1901.

Patent News.

- THE following applications for Patents were made between November 5 and November 10, 1900:—  
 CAMERA.—No. 19,800. "Improved Photographic Camera." A. KERSHAW.  
 ROLLABLE FILM.—No. 19,884. "Improvements in the Method of and Means for Exposing and Changing Rolled Film in Photographic Cameras, also Applicable to Colour Photography." C. A. BURGHARDT, C. G. WARNECKE, and W. H. HEATH.  
 SHUTTERS.—No. 19,925. "Improvements in Photographic Shutters." F. A. ROEBUCK.  
 STEREOSCOPIES.—No. 20,011. "Improvements connected with Stereoscopes or Similar Instruments for Holding and Discharging Stereoscopic Views and for Adjusting Purposes." H. HEYWOOD.  
 ROLL-HOLDERS.—No. 20,015. "Improvements in Cameras, Roll-holders, and Film-spools." J. E. THORNTON.  
 DEVELOPERS.—No. 20,052. "Improvements in Photographic Developers." F. T. PARSONS.  
 STANDS.—No. 20,180. "Improvements in Apparatus for Supporting Photographic Cameras when in Use for taking Photographs." R. W. SHIPWAY.  
 DEVELOPING BATHS.—No. 20,195. "Improvements in Developing Baths for Photographic Purposes." H. S. MORGAN.  
 PLATE-WASHER AND DRAINER.—No. 20,230. "Portable Photographic Plate-washing and Draining Rack." E. M. ROSHER.  
 FOCUSING MOVEMENT.—No. 20,226. "A Sliding Movement for Focussing the Lenses in Cameras." H. B. TATTERSALL.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### A FIXING AND HARDENING BATH.

To the EDITORS.

GENTLEMEN,—As you have done me the honour to publish my letter re "Fixing and Hardening Bath," and to add your valuable comment thereon, I venture to offer a few more words on the subject.

Undoubtedly what you say is correct, though hardly satisfying. I think the film, in this case, would probably have left the support in the washing water, after any fixing bath, if no alum bath was used, it being intended that it ultimately should do so.

I fear that, owing to the interest I took in the theoretical side of the question, I lost sight of the practical.

What I should like to draw attention to, as misleading, is that the bath in question will not harden, although it will fix, and that probably no bath composed of hyposulphite of soda, sulphate of soda, and alum can be made to perform both functions.

What you say as to the precipitation, when forming the "acid fixing bath" you mention, is quite correct, but the precipitate formed when alum is added to the sulphite of soda is quite different—of a thick, gelatinous appearance, and much more plentiful, resembling rich cream.

What it consists of it is of no practical value to know, but there are people like myself who "want to know, don't you know."

A friend, better up in chemistry than myself, says it is sulphite of aluminium, but I "hold the same opinion still."

What is of practical value to know is that alum and sulphite of soda will not remain in solution together, but that the alum will be entirely destroyed.

The clear solution left, after the bath prepared according to the formula given in my former letter, reveals no trace of alum, when tested with ammonia or caustic potash.—I am, yours, &c.,

P. O. P.

### COLOUR SCREENS ON SHUTTERS.

To the EDITORS.

GENTLEMEN,—My attention has been called to an article in your issue of October 5 treating of an arrangement for using colour screens on shutters.

It may be of interest to yourself and readers to know that the mount of our Vademecum set of lenses is fitted with an arrangement for using the screens, which are formed in the shape of Waterhouse stops and placed between two lens combinations. When not in use a brass ring is turned to cover the slot into which the screens are inserted.—I am, yours, &c.,

HENRY F. PURSER.

33, Hatton-garden, E.C., November 19.

[We are obliged to Mr. Purser for his letter; but, for the information of our readers who may not recall our paragraph of October 5, it should be mentioned that the arrangement then described, due to the suggestion of Lieutenant-General Tennant, consists of attaching the screen to the fronts of shutters of the Thornton-Pickard type. The use of screens between the lenses is another thing altogether, and, as no doubt Mr. Purser is aware, a comparatively old device. Eds.]

### AMERICAN PHOTOGRAPHY AT RUSSELL-SQUARE.

To the EDITORS.

GENTLEMEN,—I regret to see that Mr. Fredk. H. Evans, in his letter to you of the 12th inst., has considered it necessary to indulge in somewhat vulgar denunciation of one who, whatever statements he may have made concerning that gentleman, made them under the misapprehension that his letter of November 2 was inspired by Mr. Day.

I accept, however, Mr. Evans' denial, and, in doing so, beg to tender him my apologies for having, at any rate inferentially, made a statement which appears to be contrary to fact.

Mr. Evans' assumption that I screen myself under a nom-de-plume for the purpose of attacking a man holding views antagonistic to my own is puerile. Personally, I do not derive any pleasure or satisfaction from seeing my name in print; and I may also add that I do not "advertise," at least, not in this way. With regard to the last paragraph of Mr. Evans' letter, in which he undertakes to give a few hints to the Editors of the oldest photographic journal in this country as to the manner in which they should conduct their paper when criti-

cising the work of an undoubtedly clever photographer (who, by the way, happens to be a personal friend of Mr. Evans), I have nothing to say further than that Mr. Evans seems to have caught the contagious egotism prevalent among leaders of the new American school.—I enclose my card, and again subscribe myself, yours, &c.,

TACOMA.

[The foregoing letter, written by a gentleman who occupies a position of independence in relation to the controversy between Mr. Evans and ourselves, may close a discussion whose length has given an aspect of importance to a subject which it does not really possess. It is not the first time that we have been so unfortunate as to differ from Mr. Evans in our opinion of his own and other people's photographs, as well as in regard to our method of conducting this JOURNAL; but we hope one day to please him on all counts, difficult though our task undoubtedly is. Meanwhile, let us say, in all sincerity, that, though Mr. Evans's defence of Mr. Day fully attests his chivalry and kindness of heart, it is at the expense of his discretion. Mr. Day, as his writings show, is quite able to answer for himself; but, apparently, he does not consider it worth his while to do so. Four years ago, viz., in the JOURNAL of November 20, 1896, Mr. Evans also voluntarily defended Mr. Day against the exhibition methods of Mr. Alfred Maskell and the Photographic Salon, which latter institution was sharply criticised by Mr. Evans, on behalf of Mr. Day. But things have changed since then, and by 1904 it may be our privilege to receive the blessings of both Mr. Evans and Mr. Day. Our present reward for having given up so much space, which should have been utilised in a more profitable manner than the ventilation of Mr. Evans' opinions regarding ourselves, is that the matter has its comic side, and irresistibly recalls to our mind the relationship of the two principal characters in Michael Cervantes' immortal satire, "Don Quixote. Eds.]

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

A. E. Goodfellow, 47, High-street, Wincanton, Somerset.—Photograph of Colonel Ridley.

H. Phillips, Peabody-road, Farnborough, Hants.—Photograph of illuminated address to Sir R. H. Buller.

W. Randall, 25, Hopwood-street, Barnsley, Yorkshire.—Photograph Esq., M.P., addressing electors of Barnsley.

RIVES PAPER.—H. VOLMER. Unprepared Rives paper may be had from Marion and Co., Soho-square. We cannot say its present price, as photographic papers, generally, have advanced lately.

LENS FOR PROJECTION.—"LENS" writes: "I wish to work with a lantern at 40 feet distance from the screen, and with a lens of 10 inch focus. Would a better result be obtained with a lens of 2½ inch diameter in preference to one of 2 inch diameter?"—In reply: All things being equal, the larger size would be preferable.

BLINDS.—"G. B." says: "Our studio blinds have just been washed and rehung, but now they will not hang flat, or run true on the rollers—spring rollers. What can I do with them?"—In reply: Holland blinds, after they have been washed, rarely work satisfactorily, as they stretch unequally in the washing, even when they are afterwards calendered. We are sorry we cannot give a remedy.

OIL LAMP TROUBLES.—THOMAS HIGSON complains that the three-wick lamp with which —'s lantern is fitted smokes and covers the room with soot, and also "stinks abominably" after it has been burning for a quarter of an hour or so, and asks how that is to be avoided?—In reply: It is, we can safely say, no fault of the lamp. The "stink" is, no doubt, due to the outside of the lamp not being perfectly clean—free from oil that has crept down from the wicks when out of use. The smoke is due to the wicks not being properly trimmed and adjusted before the lamp is lighted. It should be borne in mind that after the lamp has been lighted for a little while the size of the flame increases, and the wicks should be turned down a little, otherwise the lamp is sure to smoke.

**SOLUTION OF GELATINE.**—G. WILLOW asks: "What is meant by a two per cent. solution of gelatine?"—In reply: It means simply a solution made with two parts of gelatine in a hundred of solution, say, two ounces of gelatine dissolved in ninety-eight ounces of water.

**FORMULA WANTED.**—"CONSTANT READER" writes: "Will you kindly give me a formula for a concentrated pyro-soda (10 per cent.) developer (one that will keep well)?"—In reply: "Pyrogallic acid, 1 ounce; sulphite of soda, 3 ounces; water, to 10 ounces; carbonate of soda, 1 ounce; sulphite of soda, 1 ounce; water, to 10 ounces. This will give both solutions at 10 per cent., and they will keep indefinitely. It is usual, however, to make the soda solution much more concentrated than 10 per cent."

**REMOVING TARNISH FROM A SILVER-PLATED ARTICLE.**—"F. R. R." writes: "Will you kindly tell me what solution will take off the tarnish on a silver-plated pot? It is very dark in tint, having been kept under a board floor for several years. If it must be rubbed on, to fetch the tarnish out of the stamped or engraved portion, it would endanger fetching the silver off the prominent parts?"—In reply: A solution of cyanide of potassium will remove the tarnish. It will be well to mix it with whiting, and apply with a stiff plate brush.

**TONING COLLODION LANTERN SLIDES.**—"COLLODION" writes: "Will you please give me the best formulæ for toning lantern slides, taken by the wet-collodion process?"—In reply: Collodion lantern slides may be toned with a solution of chloride of gold, say, two grains to the ounce of water, very slightly acidified with nitric acid; bichloride of platinum may also be used in the same way. So also may be the bichloride of palladium. The latter, especially, yields excellent tones. The tones yielded by all the above are permanent.

**ADDRESSES WANTED.**—"W. J. A." writes: "Would you kindly oblige me by telling me where there is a good place for enlargement in all classes, as I have tried several places which are no good at all? Also where I can get my photos done by the embossed enamel? If you could let me know the same I should be very much obliged."—In reply: Such questions as these we are unable to answer, as it is quite against our rule to recommend any particular house's work. We must refer our correspondent to the advertisement columns. There he will find many sources from which he can obtain what he requires.

**SUBJECTS FOR CHRISTMAS CARDS.**—W. COSWAY says: "I have a lot of  $\frac{1}{4}$ -plate negatives that would make excellent subjects for Christmas cards. Will you please tell me the best publishing house to submit them to? As the time is short now to Christmas, I shall feel obliged by an answer in your next issue."—In reply: We may tell our correspondent that his subjects will be of no use for this year's issue, as all the publishers have long since been at work on the cards they will issue next year. We should advise him to submit prints from the negatives to different publishers of these cards, that is if he fancies they are good enough; they must be artistic, or they will not be of any use.

**IDENTITY OF PROCESS.**—"GREEK" writes: "Would you be so kind as to let me know how the enclosed photograph is made; they are sold here at 1s 9d per dozen? How is the negative fixed up so as to print name and address on card? Where could I obtain material to do them; also about camera, are they taken, say, six at once on  $\frac{1}{4}$ -plate?"—In reply: It is merely a bromide paper print copied from a mounted photograph with the photographer's name on the mount. With a repeating back camera six may be taken on the half-plate. Any of the large photographic dealers will supply cameras for the purpose.

**SUBMITTING PHOTOGRAPHS FOR PUBLICATION.**—"HONOUR" asks: "Is it the usual thing in the case of photographs of current events to send them to a number of papers for illustration, or is it deemed more honourable to confine yourself to one paper? You see, in the latter case, they may not choose to insert, and then the chance is perhaps gone, because you may not have reply for some days, and then it is old."—In reply: To the extent of our knowledge there is no "usual thing" in the matter. But here in London photographers doing work for publication often submit prints to the illustrated papers in turn. In your case, living as you do in the country, we should recommend you to attach yourself to one paper.

**PRINTS FOR CRITICISM.**—"GENRE" writes: "I am enclosing some rough proofs of photographs which I took some time ago, and wish to know (1) what you think of them from the artistic point of view. (2) Whether you think they would do for publication in some of the journals—that is, if they are good enough. (3) I should be obliged if you also would state what salary that kind of work would be able to command in a first-class house. (4) If it is not too much trouble, will you kindly mark ones which you consider the best, and return them? (5) These photos were vignetted in the camera, according to method which you gave in your JOURNAL; are the vignettes good ones?"—In reply: The prints sent incline us to think that our correspondent is skilled in the production of pleasing studio portraiture. The effects are refined, and the lighting, posing, and vignetting good. Some of the illustrated monthly magazines might utilise such subjects for illustrations. We can give no idea of the salary our correspondent could command. Let him finish his prints and submit them to one or two good photographers. That is the only test.

**WARMING A DARK ROOM.**—R. POPE writes: "I have a dark room in the basement of my house, about 15x12 in size, fitted with gas water, and all necessary appliances. Unfortunately, there is no fireplace and no flue, and no means that I can see for taking flue to the outside. The level of the dark room is also below the level of the heating apparatus used for warming the other parts of the premises. Under these circumstances, I shall be glad to know how the place can best be heated? Is there any gas or oil-stove that could be used in a dark room for the purpose which would not at the same time be prejudicial to the health of those who have to work therein?"—In reply: Under the circumstances we can suggest nothing better than one or other of the forms of oil stoves burning paraffin oil. These, if kept clean and the wicks carefully attended to, will emit no unpleasant fume, and, if they did, they are not prejudicial to health. Rippings and Co. have several convenient forms. They may be obtained through any ironmonger.

**VARIOUS QUERIES.**—"CLAPHAM, S.W." writes: "(1) I notice in last week's BRITISH JOURNAL OF PHOTOGRAPHY an article on printing photos on silk. Could you tell me if there is any firm now who sells this silk ready sensitised? If so, I should be much obliged if you would give me their address. (2) Could you also tell me where I can obtain stripping films for placing on white porcelain &c. (3) If you could also inform me if there is any encyclopaedia of photography published in which one could turn up any branch of photography, and so learn the different methods, I should be much obliged? What I require is a handy reference book for photographic receipts, &c."—In reply: (1) So far as we know the silk ready sensitised is not a commercial article. (2) The Novita stripping film would answer the purpose very well; but we have an idea it has been withdrawn from the market. We know of no other. (3) Walls' Dictionary of Photography. It may be had through any of the photographic dealers, or booksellers.

**LENSES FOR STEREO WORK.**—"STEREO" writes: "I want a pair of first class stereo lenses, 5 in. or 6 in. focus, working at f-6 or f-7, and have been looking through makers' lists till I am confused. Can you kindly help me in this, either by indicating your preference or by directing me to some reliable little work on the choice of a lens? It seems to me that a non-symmetrical has this advantage over a symmetrical, that the former allows of the front lens alone, or the back lens alone, being used, so giving different focal distances, while the complete lens gives a third. I suppose a symmetrical gives only two. Has it other advantages to compensate? I have the lists of Beck, Busch, Cooke, Dallmeyer, Goerz, Ross, Wray in the BRITISH JOURNAL ALMANAC?"—In reply: The stigmatic gives three different focal lengths. The Cooke also can be used in a similar manner, so can some of the unsymmetrical anastigmats, such as the Satz anastigmatic. All these forms are good, either when used in their entirety or as single lenses.

**LENS QUERIES.**—"COPY" writes: "I am thinking of going in for copying large designs, some of which are 20 inches square, more or less making negatives same sizes as the designs. Can I do so with my R.R. lenses of 11 inches equiv. focus? If not, then, what lens should be large enough for that purpose, covering sharp to the corners with the largest stop? My R.R. lens, 11 inch focus, covers well a whole plate; what size will the same lens cover sharp same size as the original? I have also a R.S. lens of about 8 inch focus, which appears to cover whole-plates almost sharp up to the corners. What size will the same cover, same size as the original?"—In reply: No. You will not be able to copy designs twenty inches square with a R.R. lens of eleven inches focus. The best lens for that class of work is one of the anastigmatic type, a lens that has a flat field, which the R.R.'s have not. A lens of this type will, no doubt, cover the size with a medium stop if its focus is not less than about seventeen inches. The lens named will probably not cover a much larger field, with sufficient flatness and even illumination, than those mentioned unless they are worked with very small stops.

**A CURIOUS EXPERIENCE.**—"VARNISH FORMULA. AN ARMENIAN READER" writes: "(1) Several months ago I developed a plate exposed to a drawing, but, having forgotten to open the shutter of the dark plate holder, nothing came out, even after 40 minutes' development. I washed and dried the plate in order to make another experiment upon it. A few days ago I put the above-mentioned plate upon a negative of a landscape, expecting to have a positive, giving an unusual exposure, or to have nothing on. I put the printing frame to a most strong light in shade in the studio. I gave an exposure of 250 seconds, developed the plate in the usual way in pyro-soda solution. I had a perfect negative. (2) You published a formula for making a negative varnish in which Manila copal should be digested in epichlorhydrine. Epichlorhydrine is something not easily found here. Can I substitute another easily-found substance instead of it? If not, can I use the mixture containing equal parts of glycerine and hydrochloric acid? The medium is to be used for retouching."—In reply: (1) The negative result was, no doubt, due to the reversed action of light from the prolonged exposure. (2) Copal is a resin of not easy solution, and samples of copal vary considerably in their solubility. Try digesting the resin in alcohol, and then add a little benzole. That will bring some samples into solution. The varnish, when dry, will be found too hard to retouch upon without a medium to cause the pencil to "take."

Information," and "Practical Notes and Suggestions of the Year," there will be found much useful matter, which, with the large collection of formulæ, tables, and other data for photographers, places at their disposal for daily reference a mass of information not to be found in any other photographic annual.

\* \* The 1898, 1899, and 1900 editions of the ALMANAC (20,500 copies) were each sold out within a few months of publication.

## EX CATHEDRÁ.

At the end of the year photographic journalism in London will see an important change, for we learn that our old friend, Mr. E. J. Wall, retires from the editorship of "The Photographic News." Mr. Wall returns to an early love, laboratory work, and, as Secretary and Works Manager of the European Blair Company, will enter the wide field of celluloid film and printing-out paper manufacturing. He will there have full scope for the exercise of the very great amount of technical photographic knowledge which he possesses, and it is unnecessary to add that he will be followed in his new enterprise by the sincere good wishes of a worldwide circle of friends and readers to whom he is known either personally or by name. As we have long been in the secret of Mr. Wall's desire to take command of a photographic works, perhaps we may be allowed to say, on his own authority, that the change he is making does not in the least disturb the amicable relations that have hitherto existed between himself and those with whom he has been associated, nor will it lead to a discontinuance of his photographic writings. Still, happily, in the prime of life, Mr. Wall can look back on a splendid record as editor, author, lecturer, and experimentalist, and we should confidently anticipate that the new career upon which he is shortly entering will be the means of still more closely and successfully linking his name with the progress of modern photography. A staunch friend, a loyal comrade, as Mr. Wall has always been to us, we cannot refrain from heartily wishing him the utmost success in his new sphere of work. We

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1901.

Edited by THOMAS BEDDING, F.R.P.S.

THE Fortieth Annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published early in December. The total number of pages in the 1901 ALMANAC is 1,552, and the volume is the largest yet produced. The text portion of the book occupies about 500 pages. It will, as hitherto, be issued in paper covers, price 1s., or cloth bound, 1s. 6d.

The frontispiece is a bromide print by Messrs. Morgan and Kidd, of Richmond, Surrey, from a negative by Mr. W. Croke, of Princes-street, Edinburgh. A number of other illustrations will also be found in the text matter. Over eighty articles on practical subjects, contributed by well-known photographers, form a feature of the volume. The principal advances of the year are synthesised in the "Epitome of Progress During 1900," and in the other sections, "Patented Inventions of the Year," "Miscellaneous

understand that he is to be entertained by some of his friends to a complimentary dinner on Thursday, December 13, at the Frascati Restaurant, Oxford-street. Mr. W. E. Dunmore, the Managing Director of the Tella Camera Company, 110, Shaftesbury-avenue, W., has the arrangements in hand, and those desirous of being present should communicate with him.

\* \* \*

DURING the last month or two we have received many requests for information concerning the Photographers' Benevolent Association, from which it would seem that there is a widespread ignorance of the fact that that institution is no longer in existence. It may be as well, therefore, to state once and for all that the Benevolent Association was wound up some time ago; that the whole of its funds have been spent, and that nothing whatever in connection with it is left except the melancholy reflection that it was killed by the apathy and neglect of those in whose interests it was administered for over a quarter of a century—professional photographers and their employés. The cases that have been brought to our notice are sad in the extreme, and, as far as we can judge, deserving; but the tide of help for such as these no longer flows, and the only comfort that can be offered to them is the cold one that the little source to which the destitute photographer formerly looked for help in his misery or assistance in an honest effort to right himself in the battle for bread is dried up for ever. From time to time suggestions reach us that a new photographic Benevolent Institution might be established; but the idea receives no encouragement from us. In the case of the extinct Benevolent all was done that could be done to induce photographers and their assistants to lend it their practical support, but these efforts resulted in almost total failure, and we therefore cannot bring ourselves to believe that a renewal of them would be likely to end successfully. We believe we do not err in saying that during the last few years of its existence what financial support was given to the Benevolent came almost entirely from non-professional photographers. No; the Benevolent is dead beyond hope of resuscitation, and the more widely that fact is made known the better, for it may be the means of undeceiving some heedless photographers who, though at present in prosperity, are hiding "at the back of their heads" the fond idea that if one day adversity overtakes them, financial help will be forthcoming from some photographic friendly society to which they have carefully refrained from subscribing in "flush times."

\* \* \*

MR. Sadakichi Hartmann, whose writings on the new American school of photography have been frequently quoted and commented on in our pages during the last eight months, contributes an interesting letter to our Correspondence columns this week. With that communication he was good enough to enclose us a leaflet of criticism relating to a number of books of which he is the author. "Christ," "A Tragedy in a New York Flat," "Conversations with Walt Whitman," "Buddha," are the titles of these books, which seem, by the tenor of the criticisms, to be of a decadent character. Of the work last mentioned in the preceding sentence, one of Mr. Hartmann's critics says that it is "strange, gaudy, fantastic—a thing all colour and incense; something gilded and monstrous as the temple of Benares." The writer adds that "by way of frontispiece,

there is a picture of the author—a long-limbed, gaunt figure of a man, with a shock of black hair and a curious Oriental face. He is half German and half Japanese, I understand. There is a racial mixture which might, one fancies, produce almost anything. In this case it has produced a poet. I use the word advisedly. Sadakichi Hartmann is a poet; he is fantastic, and, it may be, frenetic, but he has the poet's insight into life, and has, withal, the art which the poet creates for himself and can in no manner learn from others. It will be difficult for me to give you any adequate idea of this man's dramatic poem. It is vast and visionary. It is not all admirable. At times it is clouded with a green and unholy mysticism. It is built on black basalt—that black rock of pessimism which is set in the foundations of the world. It is a very strong poem. Indeed, were it not for certain frippery of verbal decoration, 'Buddha' would be in the way of being a masterpiece. As it is, I would say that there is no work of recent years (in this country) which so well deserves the attention of the critic, who sees in books something more than printer's ink and paper." It is to Mr. Hartmann that we are indebted for the application of the term "plastic psychological synthesis" to a photograph. His is a personality, apparently, of considerable interest, for to that of author Mr. Hartmann joins the profession of art critic. In the book "Buddha" we are told that there are such phrases as "rorulent love maidens," "lutescent hills," "a croak disaster," "perlaceous pallidity," &c. Readers who are not tired of reading about the new American school, may this week find a little amusement in perusing Mr. Hartmann's letter by the light of the self-revelation with which that gentleman has supplied us in the circular from which we quote.

\* \* \*

THIS week we reprint from the "Journal of the Royal Photographic Society" the address delivered by Mr. Holland Day at the opening of the Exhibition of American Photographs, at 66, Russell-square. Mr. Day's remarks have not hitherto been published in full, and probably of the many who have inspected and discussed the collection of photographs which he brought over from America, few have had the opportunity of reading what Mr. Day himself has had to say about them and their producers. We must do Mr. Day the justice of noting that, unlike many of his fellow-countrymen and some persons on this side of the Atlantic, who have interested themselves in the progress of pictorial photography, he expresses his ideas on the subject, unconventional though they plainly are, with clearness and moderation. The discussion which followed Mr. Day's address brought out one point only, viz., that some of those who had previously looked at the American photographs on the walls "did not know," as the handy colloquialism conveniently expresses it, "what to make of them." In reference to the sacred subjects, Mr. Day said it was his custom at home to hold an annual exhibition of the year's work, and that so much discussion was created by the pictures referred to that he issued special invitations to a private view of them. The persons invited numbered between 200 and 300, and included clergymen, very many members of the Church of England, and representatives of a variety of religions from Quakers to Jews, two-thirds of whom came to see the pictures with a very strong prejudice against them, but he had yet to learn that but one single

individual left the exhibition with those same prejudices. Finally, he added the following item of information, which will, we think, surprise most English photographers: "In America a photograph is regarded more as a portfolio-piece, or as a piece to hang as a foil near a painting or a larger drawing. That, of course, is almost the opposite view to that which is most generally held in England; but we have felt that a photograph is too choice to be placed upon a wall where it can always be seen, 365 days in the year, without having a rest from it. We have adopted, perhaps, the Japanese line of thought, and I believe that if a photograph is taken out occasionally and looked at in the hand, in the same way that one would treat etchings or lithographs, it will be more highly appreciated." We have referred to Mr. Day's address and his subsequent remarks with the object of placing our readers in full possession of the motives by which he was actuated in the organisation of a most remarkable exhibition. At the same time our extracts will perhaps help to a better understanding of Mr. Day's aims and ideas, which, if they do not commend themselves to our notions of what is desirable in photography, are at least entitled to attention.

\* \* \*

SIR John Evans, K.C.B., F.R.S., the new Chairman of the Council of the Society of Arts, devoted his address at the opening meeting of this session to the subject of the origin, development, and aims of our scientific societies. Incidentally, he pointed out that a society is an association of persons united together by common tastes and anxious to improve or extend some particular branch of knowledge, or even the whole range of scientific inquiry. With this object in view it becomes necessary to hold periodical meetings for the discussion of subjects in which the society is interested, and for taking such action in respect of them as may seem desirable. The holding of such meetings involves an organisation and the appointment of presidents to take the chair at meetings, of secretaries to summon them, and of a treasurer to receive those subscriptions without which an association of the kind cannot exist. Moreover, Sir John added, for the determination of questions of policy and finance, especially when the society issues publications, a council of some kind becomes a necessity. It is on this organisation that the success or failure of a society mainly depends, and the questions as to the length of period that presidents and others should remain in office, what proportion of new blood should be infused into the council each year, and how far those in power are carrying out the views of the bulk of the members of the society, have frequently been discussed with more or less warmth. In some instances the too conservative apathy of the council has led to disruption and the foundation of new societies, or to the society under their charge being reduced to a state of inanimate slumber, while, on the other hand, too revolutionary measures have led to diminutions in numbers, if not to absolute rebellion. Much, of course, of the welfare of a society depends upon the character of its publications being kept at a high level, and on their being brought out with scrupulous regularity.

\* \* \*

THESE wise words should be borne in mind by those responsible for the management of the two or three hundred photographic societies in this country, for in indicating the

main lines on which these bodies may be successfully conducted, they also mark out for notice the pitfalls to be avoided. We have in mind at this moment only too many societies whose condition of inanimate slumber is clearly traceable to the faults of executive apathy. The parent learned societies, according to Sir John Evans, are the Society of Antiquaries and the Royal Society, all other learned societies being offshoots of those two. The Society of Arts, he also pointed out, is the source of origin of many societies devoted to engineering, chemistry, sanitation, art, education, &c. One of the first, if not, indeed, the first public exhibition of pictures, he tells us, was that held in the Society of Arts' rooms in 1760, and from this exhibition sprang the Royal Academy, the first exhibition of which, comprising 136 works only, was opened in 1769. "We may, therefore, here claim the Royal Academy as in a certain sense an offshoot from our body. The Royal Institute of British Architects, founded in 1835, may also in some degree be regarded as connected with the Royal Academy, which admits architects among its members. The Photographic Society also grew out of an exhibition of photographs, the first of the kind, held in our rooms. The foundation of the Royal College of Music is likewise due to the exertions of the Society of Arts." The history of the connection of the Photographic Society with the Society of Arts is perhaps not generally known.

#### STUDIO BLINDS AND SCREENS.

CONTINUING our study of this subject, we may now consider the shape that it is desirable that the blinds—opaque transparent—should be made. It is obvious that it would be quite out of the question to give a list of the forms of blinds in the various studios to which we have been privileged of entry. It will suffice if we select a typical studio, real or mentally outlined. But, in the main, it will be found that the opaque blinds run either lengthwise or across the studio, the translucent either following or opposing the direction in which the former work.

Taking the opaque screens first, it will be observed that the greatest control of effect is obtained by blinds moving in a direction from and to lens and sitter or vice versa. When they are placed at a height of ten or twelve feet it will be found that a vast difference is produced by an advance of the light screen to a distance of two or three inches only, the shadows under the eyes and in the cheeks being intensified or reduced as the blind is moved nearer or further from the sitter. Hence our preference would be given to a series of blinds parallel to one another, starting from the light nearest the floor and continuing up the side and along the roof till they cease to screen the light at all. A useful width is forty inches, that being a common width of fabrics suitable for the purpose.

These blinds, then, suitably suspended, work backwards and forwards between sitter and camera. The blinds, on one set of supports, should not, however, be in a single piece, but should be divided into at least three sections, with as much extra length as would suffice to extend half as long again as the space to be screened is long. By doing this it will be observed that an illuminating pencil of light, narrow or broad, can be made use of at any point in each

tier of blind, a plan that will permit of equal light control at either end of the studio, and so permit the sitter to be placed either near the east or the west wall. Further, the blinds being thus arranged and placed in tiers, the illuminating pencil can be directed from either zenith or horizon or any point between, or include the whole range between. How are the blinds to be held or suspended? The usual method is to fit up the studio with pairs of iron or brass rods, and run the blinds along them by brass rings attached at intervals. The disadvantage of this system is the cost and time involved by the need for employing a skilled workman to fit the rods securely and the difficulty of making any alteration in their arrangement when once fitted up should it be thought that any improvement could be made. Otherwise they answer admirably. A far simpler, cheaper, and equally serviceable method is that described in our columns a quarter of a century ago by an esteemed contributor long gone over to the majority, Mr. Sutton, who had seen the plan in operation in one of Mr. Watmough Webster's studios. The blind supports are simply lengths of iron wire rendered quite taut by screws such as are used for iron wire fencing. A five-inch screw of this kind is quite long enough to screw up twenty or thirty feet of strong wire as tight as a violin string. Instead of stitching the rings to the blinds, Mr. Watmough Webster, we believe, now threads the rings permanently on the wire and attaches the blinds to them by a special sort of curtain hook, which can be purchased at the ironmonger's. When the wire is made taut the blinds work so freely that the whole length may be reefed up close and sent from one end of the studio to the other with one push from a wooden rod used for arranging them. Cords and pulleys are needless. In arranging such a system due care must be taken that a certain amount of overlapping is allowed for, or light would come in between the tiers and spoil any special arrangement desired. A distance of six inches between each suspending ring will be useful, which will involve each tier, or, at any rate, horizontal tiers, being about four inches apart (in addition to the allowance for overlapping).

Translucent blinds will be useful for two purposes—to reduce the intensity of the light from any particular region or as interposing media to prevent direct sun rays passing into the studio. It would be as futile as difficult here to lay down special instructions, as the causes for their being made use of are infinite. The first objection that naturally arises would be the readiness with which most white fabrics gather dust and so become yellow and light-obstructive rather than diffusive. For this reason the employment of such blinds is, in many studios, more honoured in the breach than the observance. Where they are employed they are more frequently put upon rollers than hung from supports, like the opaque blinds. The great objection to this plan is, as we have stated, the use of cords and pulleys that are so apt to stick and jam at the most inopportune moment. There is an immense variety of fabric available—jaconet, nainsook, book muslin, butter muslin, tracing cloth, &c., &c. As we have already said, the latter is unsurpassable, but it has one great drawback, it can only be used either on rigid screens or wound and unwound from a roller; it will not wrap or run in folds like a soft fabric. As simple a plan as any is to wind it round an ordinary blind roller

fixed suitably, perhaps across the roof rafters and kept from swaying by one or more strained wires on which it rests when unwound. If the blind is supplied with the usual wooden or other bar at its end, this can have a cord attached, and the whole pulled and kept tight by securing the cord to any of the ordinary contrivances for securing blind cords.

With regard to all these blinds and screens, their varieties, arising from special needs and varying shapes of studios, are so great that it would be possible to write a goodly-sized treatise on them alone; but we trust that we have been able to condense our instructions sufficiently to be of practical use to any intending studio constructor.

---

**Wide-angle Portrait Lenses.**—Since the improvements in the manufacture of optical glasses, by the Jena firm, which have put such a power in the hands of opticians, of new photographic lenses there seems no end. The latest achievement is, of course, the "Unar," an article on which, by Dr. P. Rudolph, appeared in our columns a fortnight ago. This new lens has an aperture equal to  $f-4.5$ , which corresponds pretty nearly with that of most of the commercial portrait lenses of the Petzval form, but it covers a much larger field. It is said to include an angle of  $65^\circ$ . This means, roughly, that a lens of twelve inches focus should cover a ten by eight inch plate, and we may take it from so good an authority as Dr. Rudolph that the Unar will do so. But will portraitists be wise to employ the lens on the full size it is capable of covering? The usual Petzval portrait lens, for whole-plate pictures, is as a rule about sixteen or seventeen inches equivalent focus, and we know that, to take a three-quarter or half-length portrait with such a lens, the camera must be approached pretty close to the sitter, with the result that the perspective becomes violent and unpleasant; therefore what will it be if a ten by eight plate portrait is taken with a lens of twelve inches focus? It is generally conceded that the most pleasing perspective, in portraits, is secured when the focus of the lens is not less than double the length of the longest dimension of the picture. It is for this reason that the ordinary cabinet portrait lens is from eleven to twelve inches in focal length, which permits the camera to be placed a good distance from the sitter, and we all know how pleasing are these pictures. But what would be the result if the camera were placed so close to the sitter that a ten by eight portrait were taken with the same lens, if it had the power of covering that size plate, and the Unar would do so? The form of the lens, or the glass it is constructed of, makes no difference in the perspective, that is governed by its focal length and the size of the picture taken within it. This lens, like the stigmatic, puts an immense power at the command of portraitists, but will they display wisdom in using them to their fullest extent? We think not when pleasing portraits are the chief objects of the photographer's consideration. The most satisfactory results in portraiture are those which are taken when the camera is placed at a considerable distance from the sitter, and this comes to the fact that the lens used must be of much longer focus than is necessary to cover the size of plate used. An artist, when he paints a portrait, always places the sitters at a much greater distance from him than is customary with photographers to have the camera from them. These new lenses are great acquisitions to portraitists, though they should be used with discretion, that is, not used to the full capacity of their covering powers. This is no new theme with us, as we have several times pointed out that portrait lenses of too short foci, although they may cover the size plate they are catalogued to do, are too frequently employed, hence the most pleasing results obtainable are not secured.

---

**Granularity in Negatives.**—Complaint is often made that the coarseness of the particles of silver forming the image makes itself painfully manifest in enlargements. This is generally more noticeable in enlargements from very small negatives than it is in the case of larger ones. For example, given two

negatives, one, say, two inches square, and the other the usual quarter-plate size, and both enlarged to the same size, which we will suppose to be twelve by ten inches: the former will appear much coarser than the latter, for the reason that the particles of silver forming the image of the smaller negative are of the same size as those composing that of the larger one, and obviously they are magnified in proportion to the enlargement, and thus become more manifest than if the amplification were less, as in the case of the larger-size picture. Hence lantern slides made from very small negatives appear much more granular when shown on the screen than do those which are taken, say, on quarter-plate negatives. How, then, can this granularity be ameliorated in making enlargements on paper? It may to a great extent be done by making the enlargement with the lens slightly—very slightly—out of focus. This, if judiciously done, will not materially degrade the general sharpness of the picture, though it will subdue the coarseness or granularity to such an extent that it will not be painfully manifested. Professional enlargers are fully cognisant of this fact, and often take full advantage of it. So they do when they have a portrait which has been elaborately, yet coarsely, retouched to deal with. By making the enlargement with the lens very slightly out of focus, a harmonious result is obtained which otherwise would be crude and offensive.

#### **Sepia Platinum Prints and their Permanency.**—

There is no question that the platinotype process is more generally practised now than it ever was before, and of late years there has been an increased taste for prints, by this process, of a sepia tone. At a recent meeting of the London and Provincial Photographic Association a question was raised as to the stability of platinum prints when the sepia colour was obtained by the aid of mercury and other metallic salts. The general consensus of opinion, as given in the report of the meeting, seemed to be that they were not stable, or at least not so stable, as those of the usual black tones. Now, the platinotype process, where the image is developed with the usual oxalate developers, does yield results that are undoubtedly permanent, and if the prints made of the sepia colour, by the aid of mercurial or other metallic salts, are not, it should be more generally known, that is, if it be a fact. Some authoritative statement, one way or other, would be interesting to those who employ the process for this colour of picture.

**Lectures on Different Artists' Work.**—At the meeting of the Photographic Club, last week, Mr. J. P. Goodwin gave a very interesting and able lecture on Fred Walker, A.R.A., and his Work. The lecture was illustrated with a large number of slides of his pictures. They were made from his paintings, sketches, and from engravings from them, and some from his early drawings for the wood-engraver. Now, the whole of Walker's work shown was just of the character, whether landscape or figure subjects, that could be successfully essayed by a photographer with artistic ability, the subjects being all of the homely, every-day nature, yet perfect pictures, which told their own tale. If societies would cultivate this class of lecture, one man's work throughout, it would tell more than any number of discourses on art, composition, &c., what should be and what should not be. All who are familiar with Fred Walker's work, some of which is in our national collection at the Tate Gallery, know quite well that it is the very antithesis of that affected by most of the so-called new school of "art" photographers.

## THE OPTICS OF TRICHROMATIC PHOTOGRAPHY.

[The Third Traill Taylor Memorial Lecture.]

### II.

AFTER Du Hauron applied for his patent, but before there had been any publication of his method, Chas. Cros, of Paris, proposed a system of trichromatic photography in a communication which appeared in *Les Mondes*, February 25, 1868, and it is stated that he had described the same system two years before in a sealed *mémoire* deposited in the Academy of Sciences.

Cros also proposed both positive and negative synthesis. He at first appeared to accept red, yellow, and blue as the primary colours of light, and described methods of positive synthesis by triple lantern projection, by application of the principle of the zoetrope, by an arrangement of transparent reflectors, and by a prismatic device, employing in each case photographic positives from the original negatives, and red, yellow, and blue lights. For the production of colour prints he said the same negatives could be used, and the prints made in the "antichromatic" colours, "green, violet, and orange." Cros here clearly avoided the mistake of Collen and Du Hauron of trying to record two primaries in each printing negative, and it is remarkable that his printing colours, "green" and "violet" (purple), are just as near to the true printing colours, *minus* red, and *minus* green, as are true blue, and red. Afterwards, in the same article, he expressed the opinion that it might be better to make the negative by "green, orange, and violet" rays, and the prints in their "antichromatic" colours, "red, blue, and yellow."

Cros did not recognise red, green, and blue as the correct triad of primaries, nor that the "blue," and "red," or "green," and "violet," printing colours should be green-blue and crimson-red. There was no suggestion of anything so definite as analysis by colour-curve screens to be followed by positive synthesis with pure colours.

Cros' suggestions were generally of a somewhat speculative character, and he amusingly disclaimed any wish to submit himself to the "painful" labour which he could foresee would be necessary to arrive at a practical realisation of colour photography by such a system. He said he preferred to show the way, and to claim the credit after somebody else had done all the hard work. By this decision he proved himself to be, from a material point of view, one of the wisest men who ever attacked this problem, and, this being his position, he could afford to be somewhat vague—the more so the better; but some of his suggestions now appear wonderfully acute and prophetic, and are worthy of special notice.

For instance, Clerk-Maxwell and Collen both recognised the necessity for colour-sensitive photographic plates in order to practically realise their ideas, and Du Hauron was content to give enormously prolonged exposures so as to utilise the extremely feeble colour sensitiveness of the ordinary photographic plates of that time. Cros, who also recognised this difficulty, pointed out that a photographic plate can only be acted upon by light which it absorbs, and said he thought it might be possible to make the plates colour-sensitive by incorporating suitable dye-stuffs. In this publication he clearly anticipated the "principle" of "optical sensitisers," as it was afterwards stated by Dr. Vogel, and, although he appears to have thought that the mere colouration of the film might serve to make the plates colour-sensitive, it is a remarkable fact that he said a search should be made among a class of dye-stuffs, some of which actually do confer colour sensitiveness to bromide of silver plates!

Cros not only anticipated Du Hauron in the matter of actual publication, but was quite as fertile in original suggestions, and was, I think, more of a scientist, if less of a mechanic, than his rival.

I believe the names of Clerk-Maxwell, Harry Collen, Baron Ransonnet, Louis Ducos Du Hauron, and Charles Cros complete the list of independent inventors of trichromatic photography.

Although Clerk-Maxwell was the first, there is in the original publications of Collen, Du Hauron, and Cros, internal evidence of independent conception of the idea.

Assuming that I have correctly set forth the essential conditions of success in trichromatic photography, and that I have fairly represented the publications of the original inventors, propositions by which I am prepared to stand or fall (I have recently studied the publications of Du Hauron and Cros most carefully), it follows that, brilliant as were the conceptions of these inventors, they failed to recognise requirements essential to success; and I do not hesitate to say that this is the true explanation of the discredit into which this idea had fallen after many attempts to reduce the methods to practice.

Du Hauron and Cros continued to try to perfect and exploit their ideas, but made very little real progress that I have been able to discover, except that Du Hauron made distinct improvements in cameras

for making the colour records, and Cros in 1879 ("The Review of Games, Art and Sport," Feb. 15, p. 221) had definitely settled upon "orange, green and violet," as the "primary" colours of light, and stated that the prints should be made in pigments which suppress the respective primaries. After nearly twenty years (from the dates of Du Hauron and Cros' publications), although all the materials requisite to experimental success had long been at hand, the principle had not been confirmed by a single really successful result, and was apparently universally discredited.

Meanwhile Dr. H. W. Vogel, in 1885, stated as a "new principle," that the negatives should be made by the same spectrum rays that are absorbed by the printing colours, and in the same proportions—in other words, that the "optical sensitisers," or colours spectroscopically identical with them, should be the printing colours. This was only another way of stating Cros' principle of printing in colours "antichromatic" or complementary to those which produced the negatives.

Dr. Vogel's statement of this "principle" disclosed no recognition of the relation which the negatives or printing colours must bear to the physiological analysis of the spectrum colours, thus missing the most vital point; and it is under no circumstances a true principle in trichromatic photography, but at best involves precisely the same error as the theory that positive synthesis should be effected by screens which transmit all the various rays which have acted to produce the respective photographic "colour curve" records. I hope I have made it clear that the true function of the printing colours is to subtract most efficiently (specifically) from ordinary white light the visual impression belonging to the respective colour elements, and that this is not effected by colours complementary to the correct photographic action. Notwithstanding the errors involved in Dr. Vogel's theory as applied to the trichromatic process (he also proposed a more complex analysis), the weight of his authority caused it to be generally accepted in Europe, and it is still a stumbling-block for many experimenters.

It was the acceptance of this theory that made Von Hübl, in 1888, declare that the Young-Helmholtz colour theory is not a suitable basis for a theory of three-colour printing, and that he could not see in what way it had indicated to me the correct printing colours.\* Having no theory to guide him but Vogel's, Von Hübl worked out the details of a method which, assuming that he actually worked to his diagrams (see the *Amateur Photographer*, January, 19, 1884, p. 47), would reproduce the spectrum itself as three broad bands of equal and much diluted colour, with only very narrow spaces of blending between.

Thus does false theory lead to error; and yet this method, which would completely break down upon the spectrum itself, is described in one of the technical journals, nearly six years after the publication of the principle of colour curve analysis, as "enriching our literature on this subject with the clearest exposition of the theory yet propounded!"

Dr. F. Stolze, of Berlin, published a series of articles treating of the theory of trichromatic photography, the date of which I cannot give, having never seen them in the original. Translations appeared in *Anthony's Photographic Bulletin* in September, October, and November, 1888, but it has been stated that the original publications appeared some years before. Dr. Stolze was probably the first to mention the Young-Helmholtz theory of colour vision in connection with this subject, and to point out that the most that could be expected of a trichromatic process was that it should more or less perfectly counterfeit most of the spectrum hues to the eye by colour mixtures physically different from the original colours.

Dr. Stolze's writings were not reproduced in English, and did not come under my observation until long after I had published similar observations, which he then claimed, very justly I have no doubt, to have in some measure anticipated. He treated of the subject only as applying to the production of colour prints, and did not formulate a definite principle, or recognise the practical bearing of the Maxwell measurements of spectrum colour mixtures, and his conclusions were distinctly antagonistic to hopes of practical success. My own experiments commenced early in the year 1878, and before the end

\* *Process Photogram*, April 1888, p. 53.

of that year I had at hand all the material means requisite to success such as perfect colour-sensitive plates, control of the absorption of colour screens, a method of producing half-tone process blocks for carrying out the idea in typographic printing, &c. Nevertheless, my results, even in lantern projections, were crude and discouraging. My theoretical knowledge of the subject was inadequate to discover the sources of error. Like Du Hauron, I gradually improved my results by sheer experience, but I am now perfectly convinced that complete success could never have been achieved by such a process of trial and error.

I became convinced that a quantitative analysis of the various spectrum hues in terms of three spectrum colours must form the basis of a successful method, and stated this principle and the method of its application somewhat clumsily in a paper read before the Franklin Institute in February 1888.\*

My analysis was, however, imperfect, and it was only after some reference to Maxwell's work in spectrum colour analysis which appeared in Rood's "Modern Chromatics" came under my observation that I was able to perfect my method, and to clearly and perfectly enunciate the principle of colour-curve analysis and pure-colour synthesis, which I did in a paper read before the Franklin Institute in November of the same year.†

The application of this principle resulted in the accurate reproduction to the eye of the colours of the objects photographed—something which I then believed, and still believe, had never before been accomplished, and which probably never would have been accomplished by a trichromatic process without recognition of this principle.

I think I am correct in saying that the soundness of my theoretical exposition of the subject was soon recognised by Dr. Stolze, Victor Schumann, and Sir W. Abney, but that it was actively discredited though without argument, by almost everybody who had previously become identified with the subject in the public mind.

Apparently unanimous condemnation by "practical experts" had the effect of persuading most people that my method must be wrong and my results tricked, and the wheels of progress continued to be clogged by voluminous writings which served chiefly as a negative means of discrediting an important truth.

I mention these facts in explanation of the aggressiveness which I have shown in my fight for recognition of this principle, and which has often been mistaken for a mere ebullition of egotism. I submit that, as a conscientious teacher, I could not do otherwise than maintain that by the application of this principle the problem of recording and reproducing colours by photographic analysis and optical synthesis was finally solved.

This course on my part has been all the more necessary because in some pretentious treatises, such as that of Alcide Ducos Du Hauron, published in Paris as recently as in 1897, the principle of colour-curve analysis, to be followed by pure colour synthesis, is not even stated, and the principle of analysis is no more definitely stated than that the negatives should be made by "orange," "green," and "violet" light; and in the "melano-chroscope" credited to Louis Ducos Du Hauron, and only recently manufactured for sale, the photographs are supposed to be made through the same screens that are used for synthesis. Such loose methods may serve as playthings, but they no more represent scientific trichromatic photography than a child's use of a sixpenny prism represents the science of spectrum analysis.

Since this part of my lecture was in manuscript I have had the great pleasure of perusing a treatise on trichromatic photography by an English author, who has not only recognised the principle of colour-curve analysis and pure colour synthesis, but has presented the subject in a most admirable manner. No doubt many who have found my own essays too concise and dogmatic in style to appeal to them successfully will find Mr. Tallent's fuller arguments and illustrations sufficiently convincing. It needed only the publication of such a treatise as this to put a period to my aggressiveness in a fight which has become distasteful to me.

Owing to the great number of factors in this solution of the problem of colour photography, a very great amount of work remained to be

\* *Journal of the Franklin Institute*, Philadelphia, May 1888.

† *Journal of the Franklin Institute*, Philadelphia, January 1888, p. 58.

done in order to realise the conditions of successful every-day practice and general application.

Without special cameras for making the colour records automatically and special devices for accomplishing the synthesis, the method could never have much practical value. Both Du Hauron and Cros recognised this fact, and the former especially sought to provide for these requirements, and made some brilliant suggestions, without, however, meeting all the practical requirements.

The principal optical devices employed in carrying out the process in its ordinary forms are special cameras, triple lanterns, and photo-chromoscopes. Within the legitimate limits of this lecture I cannot describe these in detail, but will mention their characteristic features, and will give such references as will enable anybody to verify my statements and study the more intricate details.

A feature common to most of the cameras and photo-chromoscopes which have been proposed is the use of transparent reflectors, so disposed as to form three images with one objective or one view point when used as a camera, or to superpose the three photographic images upon the retina when used as a photo-chromosome. Both Du Hauron and Cros proposed the use of plane parallel clear glasses for this purpose. Du Hauron went further; recognising that the two separated reflecting surfaces would double the outline of the images and produce confusion unless the positive images were optically at an infinite distance, he proposed the introduction, between the reflectors and the image, of convex lenses at exactly their focal distance from the images.

This arrangement, as originally conceived, was optically efficient as a photo-chromosome, with the three images situate on different planes. In 1876 (British Patent No. 2873, July 22), he designed a camera involving the application of this principle, in which the three convex lenses were used as image-forming objectives, with a separate adjustable diaphragm for each lens, in order to equalise the exposures, and the use of convex lenses in front of the camera to parallelise the rays for near objects. As the rays can only be parallelised for one plane at a time, objects situate in all other planes would still be doubled in outline.

In a combined camera and photo-chromosome the construction of which was first published in 1887, and which has been named the "melano-chromosome," the plane parallel glasses and convex lenses are so disposed as to bring the three images all on one plane;\* but this construction involves the application of new ideas which I patented in 1884,† and a description of it is therefore not altogether in place at this point in my lecture. Waiving this objection to such an order of presentation, I will point out some of the defects of this instrument.

In the first place, it is optically imperfect except when used under certain well-defined conditions, because the convex lenses are at three different distances from the view point. The effect of this is to introduce different degrees of barrel-shaped distortion in the three images, when used as a camera; and while this does not prevent the instrument from superposing the same images in synthesis, provided that they are images of distant objects, it is incapable of perfectly superposing to the eye three equal images, and it cannot be used successfully for photographing near objects, because, the image-forming lenses being at different distances from the object, the three images will not focus alike either as to definition or size.

Any photo-chromoscopic device which is designed for analysis and synthesis with the same colour screens, like this one, I would class as a toy. Made as two separate instruments, one adjusted for photography and the other for synthesis, it could be made to meet scientific requirements for the reproduction of landscapes in miniature, but the difficulty and cost of obtaining clear glass reflectors with perfectly plane-parallel surfaces, the fact that the images are not available for synthesis by other methods because not identical in perspective, the impossibility of focussing near objects on all three sections of the plate at once, the impossibility of diaphragming separately for the three lenses, and the small angle which the images subtend to the eye,

are all serious defects. Another defect in the instrument as now constructed, due to the fact that the clear glass reflectors disposed at 45° angle to the axial ray have polarising properties, I shall describe later, also a defect of illumination of the image due to the relation of incidence and reflection with glass mirrors.

Charles Cros suggested positive synthesis by persistence of vision with a device constructed upon the principle of the zoetrope, and his brother, A. H. Cros in 1889,\* patented a device for carrying out this idea. Cros' instrument was of the three-step form characteristic of photo-chromosome, constructed with two transparent and one silvered reflector, but the images were blended by means of a rapidly revolving wheel having four plane silvered and two clear open sectors, in combination with another plane silvered mirror occupying parallel planes disposed at 45° to the axial ray, and the wheel revolved by pulling a string wound upon its axle. This device was intended to be used also as a camera for making the three negatives through the same colour screens.

F. E. LYBBS.

### THE NEW SCHOOL OF AMERICAN PHOTOGRAPHY.

[An address delivered before the Royal Photographic Society on October 10, 1900.]

In acknowledging, some months ago, an invitation to show in your rooms a series of my own prints as a "one man exhibit," I took the opportunity of saying that I hoped I should be able before the end of the year to lay before your Council a far more interesting proposition, in the shape of an offer of a collection of work by the leaders of the new school of photography in America. That hope is this evening realised, and I believe I am quite within the truth—in spite of the fact to be regretted that some well-known names are absent from the catalogue—when I assure you that never before has it been possible for any outside the United States, to see, in a body, so complete a collection of prints by those who are the acknowledged leaders on the other side of the Atlantic.

Through the kindness and sympathy of many of you here in England, British work is, I think, better known in New York Philadelphia, and Boston than is ours in London. The causes for this state of affairs are manifold, and it would be as unprofitable as uninteresting for me to enter upon them at this time; but I wish most heartily to show my appreciation for the opportunity of hanging the collection under your auspices, and of pointing out a few essential differences in the point of view adopted by our workers to that which seems to be the general ground taken in England.

That we have in the States two distinct schools of photography is far more apparent than in the work I have had the pleasure of knowing as produced here: with us they are designated the old and the new schools, the chief point of theoretical difference being that the new school holds tenaciously that photography may be, if it is not yet, a fine art, and that the day is not far distant when it will be generally so acknowledged—while the old school, well, they smile the smile of time-honoured incredulity. During the past two or three years, however, I am glad to say, this smile has become less aggressive, less certain, and somewhat inclined to suspect its own justice.

That the special theoretical differentiation of schools is a good deal of a personal hobby with me, perhaps I need not affirm; and perhaps, too, I should note that I have had the honour of making addresses on the subject at Harvard University, and before the State Normal Art School for teachers of Massachusetts; but these statements will tend to show you something of the awakening which is beginning to be so strongly and widely felt in America to the new possibilities of the camera.

With us the painter is more ready with serious encouragement, more open to conviction, that the photographer, as well as the etcher, may possess the right to go hand in hand with him. This feeling in the painter is one of so much seriousness that a few have already taken up the camera; in the first place, possibly, as an aid to their colour work, but ultimately as a distinct end in itself. Of this class there are at least three represented in the collection now upon your walls: Mrs. Sarah C. Sears, of Boston, who has two colour portraits in the Paris Exposition which have secured "honourable mention," and which are hung "on the line" between those of Mr. Whistler; Mr. Frank Eugene, of New York, who received his art training in Paris and Munich and has been a portrait painter of eminence for some

\* British Patent No. 9012, May 30, 1899.

\* "La Triplique Photographique des Couleurs et l'imprimerie," Paris, 1887, p. 357.

† That he did not originally contemplate a one-plate arrangement is proved by the wording of his specification of 1876, p. 15, lines 48-54.

years; and Miss Sarah J. Eddy, of Providence, for a decade a successful painter of "genre."

Of another group but once removed from these, are a handful of artists—yes, I dare call them artists—who have served their time at Juliens or other institutions for art training, to return home and aptly what they had learned to the work not of the brush but the camera. Of these Mrs. Gertrude Kasebier, of New York, is unquestionably at the head, and although her work has not been known through exhibition more than two or three years, her right to a very high place among the genuine portraitists of the world, whose medium of expression is the camera, is not contested—at least by painters. Others who have taken up the camera after an art training are Miss Eva L. Watson, Mr. C. Yarnell Abbott, Miss Mathilde Weil, all of Philadelphia; and Miss Ben-Yusuf, of New York; while Mr. Eduard Steichen, of Milwaukee, is at present devoting himself to the study of both painting and photography in Paris.

Of the appreciation of painters, the most cordial praise of Mr. Whistler for Mr. Clarence White's "Girl with the Pitcher" naturally stands first, quite as much perhaps from the well-known antipathy of the butterfly to photography in general, as on account of his pre-eminence. Boutel de Monvel has been very enthusiastic of prints now before you, while Daniel French, J. W. Alexander, Wm. M. Chase, Robert Vonnough, Frederick Vinton, L. C. Perry, and Denman Ross, all artists medalled or otherwise honoured in Europe, have freely expressed their entire sympathy and approval in the new movement. While this appreciation, perhaps, may be individual and personal, there is one, if less authoritative, yet more widely felt and recognised as such by the many—I mean that of our art institutions themselves. So long ago as 1896, while M. de Sezuerenne was writing for the "Revue de Deux Mondes," his then exhaustive article, "Is Photography a Fine Art?" there was held in Washington the first exhibition of photographs in America to be known as a Salon. From this collection the Smithsonian Institute—practically the department of Fine and Liberal Arts of our Central Government—purchased a large number of prints for perpetual exhibition in their galleries. Two years later the Pennsylvania Academy of Fine Arts in Philadelphia opened its doors to the photographer. The paintings were removed from the walls of two of its largest halls, and during six weeks the public were able to attend what is termed the First Philadelphia Salon. This exhibition was so eminently successful that last autumn found it repeated with even a grown enthusiasm, when it was estimated that between ten and twelve thousand people visited the second Salon. From these exhibitions numerous purchases were made by the Fairmount Institution of Philadelphia, one of similar aims as your South Kensington Museum, where a special section is devoted to the uninterrupted exhibition of the new school of photography. This spring found this recognition spreading, when the Art Institute of Chicago held a small but very choice exhibition of photographs; and at the present moment, as you are doubtless aware, the third annual Salon is about to be opened in Philadelphia, while in Boston the full consent and approbation of the authorities of the Museum of Fine Arts has been granted for such an exhibition in the near future. Mere local organisations like the Carnegie Art Institute of Pittsburg, the Case Library of Cleveland, and the American Institute of New York—which, by the way, is the oldest photographic society in America, almost equalling yours in point of age—have for some years shown annually collections of photographs, while the first-named has proved a worthy patron as well as a hearty appreciator.

These facts will show very strongly, I believe, that although less than almost any other, we in America have, in the mass as well as the individual, taken a quicker, keener interest, and evinced a surer belief in the possibilities of the camera as a medium of artistic expression than has any other people.

How many, I wonder, in discarding a piece of camera work, stop to consider from what it is they remove it? or whether its maker felt what he produced more keenly than the maker of half the paintings hung in any annual show? or whether the man who created it were master or but a 'prentice? These questions will be found of some assistance if applied with even the most limited knowledge behind them.

If painting be the only department of art with which comparison is made, it is obviously an unfair one, because the element of colour is here—to the many at least—the chief characteristic; and to them the values of colour found in a Durer engraving or a Whistler etching is as nought as in a photograph. But it cannot be said that colour

alone is that which produces art, for even the doughtiest critic would not proclaim as art the theatrical poster so commonly seen.

The other perfectly obvious element is drawing. Let us, for example, turn to the illustrated pages of the catalogue issued by any manufacturer of machinery. Here we find the acme of proficiency in drawing; the hand which constructed these pieces of architectural line was as completely trained as Da Vinci's; but we can hardly name the production art. Again, if we look through any large collection of paintings with care, we are sure to discover canvases whereon appear eminent names, which will display as faultless drawing as the machinery catalogue, and as sure evidence of colour as the poster—but nothing more—nothing of what is termed art. In another room, perhaps, we may find a small print from an etched plate by Rembrandt or Leyden without visual colour, and as lacking in anatomy, but yet we unhesitatingly pronounce that it possesses this subtle quality for which there is no name. It is as elusive as quicksilver, as intangible as perfume, and as vital as the fame it insures. This quality cannot be considered one of pigment or medium. Time was when its possessors knew not canvas and brush, when mallet and chisel and stone were the chief means through which it found expression. Bronze and silver were wrought in the round long before impressions from incised plates were known to be possible as a fine art, and it is only during the present century that lithography has been accorded its proper place as a medium.

Too many, as I have elsewhere said, to most perhaps, a photograph is a photograph and only a photograph, and because a photograph of little or no consequence as art; but just as soon as they will learn to examine it for qualities not dissimilar to those which make etched prints and lithographs so full of charm and real value, they will find, to their own great surprise, that these qualities actually exist there in as abundant richness, providing the skill of the creators has been equal. The values of light and shade as produced with a lens run as wide and as truthful a gamut and are capable of as delicate variations as were ever produced by means of slabs of stone or plates of copper. The feeling in textures is presented with as much nicety in a print from a photographic negative as in that from a piece of engraved metal. Yet we have discovered that all this may be and no art exist, unless our example possess that subtle quality of great verity.

With you here in England, in France and Germany, and with us in my own country, there are a few earnest workers who are bending all their efforts to prove that this quality may be as fully possessed by one who chooses to express it through the means of a camera, as his brother who has made choice of other implements. The critic, too, should bear in mind that the medium is new, that scarce half a century has gone by since its inception, and not more than five and twenty years—nay, not so much—since the discovery of many of the processes which are of inestimable advantage towards the production of what he will, I believe, sooner or later be forced to acknowledge the new art.

Many years ago, before even the most sanguine of us held photography as other than a mere reproductive process, Ruskin wrote under the bias of his time, although admitting that a far-seeing eye had been led to question.

"As a photograph," he says, "is not a work of art, though it requires certain delicate manipulations of paper and acid, and subtle calculations of time, in order to bring out a good result, so neither would a drawing like a photograph, made directly from nature, be a work of art, although it would imply many delicate manipulations of the pencil, and subtle calculations of effects of colour and shade. It is no more art to manipulate a camel's hair pencil than to manipulate a china tray and a glass vial. It is no more art to lay on colour delicately than to lay on acid delicately. It is no more art to use the cornea and retina for the reception of an image than to use a lens and a piece of silvered paper. But the moment that inner part of the man, or rather that entire and only being of the man, of which cornea and retina, fingers and hands, pencils and colours are all the mere servants and instruments; that manhood which has light in itself, though the eyeball be sightless, and can gain in strength when the hand and foot are hewn off and cast into the fire; the moment this part of the man stands forth with its solemn "Behold, it is I," then the work becomes art indeed."

Now I, personally, hold that the time has come when this seriously uttered "Behold, it is I," may be heard in many directions. If this were not so, how should you be able to distinguish, as most of you can, without hesitation, the authorship of many prints? I cannot

imagine the veriest button-pusher in the kingdom who could not say "This is a Horsley Hinton," and "This is a Craig-Annan,"—what is this if it be not the "Behold, it is I?" Why should a Hofmeister differ from a Demachy if each man did not infuse into his work that of his personality which makes it individual? And what is this personality which makes it individual? And what is this personal individuality if it be not the "Behold, it is I?"

I must, then, assume that there can be no adequate reason presented which shall hinder the affirmation that a photograph may be as fine an achievement—not to step outside either monotone or reproduction processes—as a print obtained from any other surface than that of gelatine; the fact always being kept in mind that the line and mass and values shall be as ably rendered in the one as the other. But just here we find the chief reason which withholds the possibility of naming as art so many photographic prints, *i.e.*, ignorance of even the most elementary rules of a picture's anatomy. A painter spends years in acquiring a knowledge of how to handle his lights and shadows to produce the required modelling, and more years in mastering the manipulation of tone; while the man with the camera presses the button, and idly imagines the rest will be done for him. No, let me repeat, that to produce art with the camera just as much serious thought, just as much hard study, just as much rigorous training is necessary as to produce the same end through any other medium—and perhaps a little more. This time of service in the school of sight and handling is indispensable. Save in instances the most rare the eye sees not itself unaided, and the learning to see is as difficult as the learning to walk, or sing, or read. We may walk along the Chelsea Embankment for years, yet do you suppose we will see what Whistler saw, and what he drew upon copper and stone? We may have been born under the very shadow of Ely Cathedral, but do we find in the magnificent pile what Mr. Frederick Evans has brought out in his masterly photographs?

Neither the arts of lithography nor etching were declared in a day. The former languished for years early in the century before one of Napoleon's marshals forced it into recognition in France, and with centuries added to the birth of etching, it still held no acknowledged position, as a fine art, until within the memory of many of you, Sir Seymour Hayden and Hubert Herkomer won for it the place it deserved.

It is not, then, from the performances accomplished beyond the Atlantic wherewith we arm ourselves for any strife—but it is rather that we feel we have taken one or two steps in the forefront—perhaps excited, hectic, youthful steps—yet steps outward toward a serious end in which we have grave confidence.

F. HOLLAND DAY.

#### A PLEA FOR STEREOSCOPIC PHOTOGRAPHY.

(Abstract of Paper read at the November Meeting of the Edinburgh Photographic Society.)

THE most convenient method of securing such photographs is, of course, to take them simultaneously by means of a pair of lenses on the two halves of one plate. This entails the possession of such a pair of lenses and of a camera that will hold them side by side, but lack of such facilities need not debar any one from making stereoscopic pictures.

Many subjects will permit the two necessary negatives to be taken with one lens at two exposures, the lens or the camera being moved latterly over a distance equalling the separation of the eyes between the two exposures. For instance, I show you a tripod head which I constructed for use with a  $\frac{1}{4}$ -plate folding pocket camera of the well-known Shew pattern. It permits the camera to be moved any distance latterly up to  $3\frac{1}{2}$  inches. In using such a camera the only difference from the ordinary practice of monocular photography is that in filling the slides each  $\frac{1}{4}$ -plate should be numbered with pencil in one corner. The plates being exposed consecutively, if the right hand exposure is invariably made first, the odd numbers will always be the right, and the even numbers the left hand negatives. The necessity of this identification will be apparent when we come to consider the printing process.

Another method with one lens is to use a  $\frac{1}{2}$ -plate camera provided with a removable flexible division which practically converts it into two  $\frac{1}{4}$ -plate cameras side by side. The lens being mounted on a sliding cross-front, or eccentrically on a revolving front, consecutive exposures can be made on the two halves of the same plate by moving the lens opposite each half.

Still another method useful for occasional work is simply to fix a piece of black card in the folds of the bellows so as to screen one-half of the plate, the screen being moved across at the same time as the lens.

Many modern cameras are so constructed that the front is too narrow to permit the necessary movement of the lens. In such a case, an instrument known as "The Stereoscopic Transmitter" may be used. It consists of small mirrors so arranged in front of the lens that two pictures are formed side by side on the same plate. I cannot speak from experience as to this method, but, as a lens of sufficient focal length to cover a half-plate must be used, the pictures formed on the half of the half-plate may be of rather narrow angle for some subjects. On the other hand, as the pictures are automatically reversed by the mirrors, the operation of mounting prints or making transparencies will be greatly simplified.

The use of one lens, moved between exposures, necessarily limits the choice of subjects, since nothing in motion can be so dealt with. Yet this need not deter any one from accumulating a most effective collection of stereo slides. "Still life," such as statuary, and especially flowers and foliage, are amongst the most effective subjects for this branch of photography. Architectural and most landscape subjects can also be taken with consecutive exposures. It is necessary that the two exposures should follow one another rapidly, so that any change in the position of shadows may be avoided, also that the exposure of the two plates should be as equal as possible. A trifling difference of density in the two negatives does not matter, but no detail must appear in one that is not also visible in the other, otherwise the effect is most distressing. For the same person any motion of foliage in a landscape will entirely spoil the slide.

The methods I have referred to serve excellently for occasional work, but it must be confessed that any one who practises stereo work regularly will desire to possess the means of securing all classes of subjects. This entails the use of a pair of lenses of equal focus fitted to a camera capable of taking the two pictures simultaneously. The outfit need not be expensive. Single or "landscape" lenses are often recommended, but if they are to be of good enough quality to be used at fairly large aperture they will cost nearly as much as rectilinears of fair quality. My own pair of lenses are nameless rectilinears—of French origin I understand—working up to  $f/6$ . They cost me 30s. each, and I have every reason to be satisfied with the work they do. The enlargement I have brought for your inspection is from a negative taken at  $f/11$ —a "snapshot"—and is enlarged a little over 6 diameters. It speaks well for the virtues of cheap lenses (when carefully selected), and shows that one may go in for stereo negatives entirely, as I have done, and yet have pictures to exhibit. You will shortly see also that lantern slides can be made from those negatives. Expensive lenses are a luxury when one can have them, but they are not a necessity for this class of work.

The camera for a pair of lenses may be of any kind, about half-plate size, that has a front wide enough. It must, of course, have a division in the middle to prevent the two images from overlapping at the inner sides.

My own desire was to possess a stereo hand-camera, but at the time I wanted it there was none on the market that fulfilled my ideal. Therefore I began to make one, but in the course of manufacture new ideas sprang up, and when finished it was a sort of universal camera for stereo purposes, therefore I have brought it for your inspection.

As it comes from its case it is a box hand-camera, but at the time I wanted it there was none on the market that fulfilled my ideal. Therefore I began to make one, but in the course of manufacture new ideas sprang up, and when finished it was a sort of universal camera for stereo purposes, therefore I have brought it for your inspection.

As it comes from its case it is a box hand-camera, set for "infinity," and ready for use on drawing the slide. A camera that requires more preparation than this often loses pictures.

A lever with a graduated scale gives a focussing motion from "infinity" to five feet, more than sufficient for hand-camera purposes. By opening the front and pulling out the finder a further extension is possible, to double the focus of the lenses, thus allowing me to make flower studies of life-size, also to use the camera for making stereo transparencies from negatives by "copying in the camera." It is fitted for use on a stand for work that requires time exposure. The shutter is a roller-blind, "time and instantaneous," regulated from outside the box. A T level on the top is a vital necessity, as a level base line is a great assistance in properly trimming the prints.

The size of plate commonly called stereo size,  $6\frac{1}{2}$  by  $3\frac{1}{4}$ . I do not like, the pictures of necessity being square. Sometimes  $6\frac{1}{2}$  by  $4\frac{1}{4}$  is recommended, but it is not always easy to get these plates, and the saving in cost is small. I have adopted the  $\frac{1}{4}$ -plate because it is easily bought anywhere, and because the height of it allows the use of the rising front with which my camera is fitted in place of a swing back. The camera was first fitted with three double slides, and I have since added a Pullman changing box, thus giving a capacity of fourteen plates if necessary.

The interior of the camera is lined with black velvet, because when photographing flowers, &c., against a dark background reflections from the sides of the camera intruded themselves. The velvet lining is a great improvement, and I think no camera should be without it.

The focal length of the lenses is  $4\frac{1}{4}$  inches. This is somewhat

shorter than some authorities advise, but the lenses of  $5\frac{1}{2}$  or 6 inches often used seem to me to give too small an angle for many subjects. The distance between the two images of any object on a stereo slide must not greatly exceed the distance between the eyes of the observer, and at the most cannot exceed 3 inches. With a base line of 3 inches a lens of  $4\frac{1}{2}$  inches focus gives a pleasant angle of view, while with a longer focus many subjects would, I think, be difficult to deal with.

One advantage of the shorter focus is that the back combination, when well stopped down, serves as a long focus lens when the subject requires it, the focus being about  $7\frac{1}{2}$  inches.

The shutter—which is built into the front of the camera—carries a pair of sliding panels, on which the lenses are mounted. This allows the separation of the lenses to be varied from  $3\frac{1}{4}$  to  $2\frac{1}{2}$  inches.

Whether the twin-lens or a single lens camera is used this matter of the separation of the lenses is of the utmost importance. When we look at a distant object the axes of the eyes are nearly parallel, and so are the axes of the lenses of the camera. Therefore, if the two photographs are viewed in the stereoscope they give an impression of the separation of the eyes, the photographs will represent what the eyes see under a similar aspect. If, however, the object is near at hand, the eyes in the act of viewing it will be turned inwards, and the separation between their axes will be decreased, but if the lenses of the camera remain at the previous separation they will, when used upon the nearer object, see as it were further round it than the eyes with their reduced separation can see, therefore when the resulting photographs are viewed in the stereoscope they give an impression of exaggerated relief, suggesting a cardboard model of theatrical scenery rather than the natural object. By bringing the lenses closer together this defect is obviated, and an adjustment of this kind should always be made when objects less than about ten feet distant are photographed. As a matter of fact, it will be found in practice that to arrange a similar composition on each half of the focussing screen the lenses must be approximated if the object is very near, otherwise the displacement is so great as to throw part of the subject out of one of the pictures.

In using a single lens camera, of course, the same adjustment is secured by limiting the travel of the lens or the lateral movement of the camera.

While speaking of lenses it is well to note that a Waterhouse stops are preferable to iris diaphragms, owing to the difficulty of exactly adjusting the latter so as to secure equal exposure on the two negatives. The aperture employed should be such as to ensure fair definition in all planes of the picture; "fuzziness" is entirely out of place in this class of work.

Exposure should always be full, and development should be such as to give a soft negative full of detail. The somewhat exaggerated contrast which gives a feeling of relief and boldness to a monocular photograph is out of place in a stereogram. The high lights, which merely suggest light in an ordinary print, become superfluous in stereo prints, because relief is obtained in a more natural way, and any white paper in the print suggests snow or white frost. Therefore the negatives should be rather thin, printing should be deep, and if anything appears white in the print which is not white in nature it is advisable to sun it down to a grey tint.

My own practice is to use isochromatic plates for all subjects. In landscape work they are of special value, owing to the superior detail given in green shadows amongst foliage, and it is needless to say that for flowers and foliage they are invaluable. My favourite developer for these plates is amidol. This class of developer, by first giving detail and then density, allows development to be stopped before any hardness appears. Amidol is an ideal developer for isochromatic plates, as the dichroic fog, which more alkaline developers sometimes give, never appears with this reagent.

Prints must be made on a smooth surface. The question of artistic surface does not arise in this branch of photography. The chief aim is rather to eliminate surface altogether, and to give the impression that the picture is standing out in space. Any grain on the surface of the paper will appear to float as a haze in front of the picture, therefore the most suitable surface is evidently a highly enamelled gelatine print. The examples I show to-night are printed on Solio paper, and toned with platinum, which gives a pleasant brown of varying depth somewhat after the shades of brown found in carbon tissue. Tone is, of course, a matter of taste, but both in prints and transparencies warm tones seem more natural than blacks or purples.

Trimming prints for stereograms requires care and some little thought—but although the directions may sound a little puzzling, a single trial enables the worker to see the requirements clearly.

If the prints are from single quarter-plate negatives they must be marked on the back when filling the printing frames so that the right and left hand prints can be distinguished. They are trimmed to a common base line and to a common height—according to subject—as the height is only limited by what the stereoscope will take in. The width, however, is more important. Our eyes do not exceed three inches apart, and do not even reach that except in rare cases. The average is probably  $2\frac{3}{4}$  inches. Now, as the axes of the eyes when

directed towards a distant object—and consequently parallel—are only  $2\frac{3}{4}$  inches apart, it is evident that if the photographs are to be seen under similar conditions the two images of the distant object should also be only  $2\frac{3}{4}$  inches apart on the mount. This limits the width of the print to  $2\frac{3}{4}$  inches. The construction of the stereoscope, however, as I shall shortly show, allows this width to be exceeded a little if necessary to include the desired picture, but the maximum width should never exceed 3 inches, and  $2\frac{3}{4}$  is better.

A stereogram which is just a little too widely mounted may be seen clearly enough, but will in most people cause a sense of strain or fatigue in the eyes, which detracts from the pleasure which the practice might otherwise give.

In trimming stereo prints a pleasing effect will be produced if they are so cut that the inner edges of the prints show a trifle more of the picture than the outer, or, in other words, some object or detail should be seen at the inner edge of each picture which is not seen at the outer edge of the other. This has the effect of throwing the image apparently behind the mount, which thus looks like a frame. The reason of this will appear if one looks out of a window at the outside view with each eye alternately, when it will be noticed that each eye sees a little of the view that the other does not see. By reproducing this condition in the stereogram in relation to its mount, we get the impression that the picture is beyond the mount just as the view is beyond the window. In practice it will be found that this condition will be fulfilled if some object in the extreme foreground is kept at the same distance from the edge in each print. The different positions of foreground and distance in the two prints are such that, if the prints are symmetrical with regard to a foreground object, they cannot be so with regard to a distant object. This method of trimming prints is a refinement merely, and not vital to stereoscopic effect; it is difficult to explain in words, but very easily seen in the marked print which I now show you.

When the two stereo negatives are on one plate the prints must be separated and transposed from right to left. The necessity for this is more easily shown than described in words. The two negatives are each independently reversed when looked at from the film side. If now a print is taken on a piece of paper of sufficient width to hold both pictures, on lifting off the print to look at it one of the halves will be carried right over the other, and the right hand one will now be to the left of the other. If the paper is divided down the middle, however, the prints can be turned over independently, hence the necessity for cutting and transposing.

I have had so much to say about trimming prints that I fear I may have created an impression that there is a lot of trouble about it. In practice, however, it will be found that there is merely the trouble of trimming two prints instead of one, and surely, if a print of any kind is worth trimming at all, it is worth a little care.

For mounting, cabinet mounts do well for subjects which allow a height of about four inches, while for square pictures the ordinary stereo mounts will do. The prints should be accurately in line at their bases, and should be separated by a space of about one-eighth inch.

The finest effects are undoubtedly to be seen in glass transparencies, the great range of gradation and the wealth of detail obtainable in these being particularly useful. Obviously to cut and transpose the glass in the same manner as paper prints would be troublesome and tedious, but by printing either end separately—transposing the negative and plate at each operation—the same end is gained, and I propose to demonstrate this process to you at the close of the paper.

Transparencies can also be made by copying the negative in the camera on a transparency plate. In this case no transposing is necessary, as each negative is reversed by the lens, and appears in its proper position. I regret that I cannot speak from experience as to this method, because it practically involves working by daylight, and I have found the operations of negative making, printing, and enlarging fully sufficient to occupy all the daylight hours I can devote to photography. Therefore I prefer to reserve transparency work for winter evenings, and probably most people will agree with me. Glass transparencies should be backed with a translucent medium to cut off the view of objects lying behind. Ground glass is often used, but for my part I prefer plain glass coated with an emulsion of white lead in collodion, as suggested by the editor of THE BRITISH JOURNAL OF PHOTOGRAPHY. It can be made of any degree of opacity, and shows no grain. When the subject is such that reversal does not matter, the coating may conveniently be on the cover glass, but in landscapes the cover glass should be transparent, and the coated glass can be placed temporarily behind in the stereoscope.

WILLIAM GOODWIN.

#### THE HACKNEY PHOTOGRAPHIC SOCIETY'S EXHIBITION.

The Annual Exhibition of the Hackney Photographic Society was held at the Morley Hall, Hackney, N.E., on November 21, 22, and 23. At the conclusion of the show, the medals, &c., were presented by the Viscount Horncastle, the first Mayor of Hackney.

We always look forward with pleasurable expectation to our annual

visit to the Hackney Society's Exhibition. Our visit is paid some hours before the public are admitted, but we invariably find the arrangements are complete as far as the work of the Society's officials is concerned. When we mention that at the present exhibition there were 375 frames, a larger number than were included in the pictorial section of this year's R.P.S. Exhibition, that many of the pictures have to be unpacked from cases, and all of them have to be fitted with rings or plates and numbered according to the catalogue, that they have to be arranged and hung on the walls, besides other incidental work, it will be conceded that the task the Exhibition Committee undertake is one of some magnitude. We understand that for several years past the whole of this work has been performed in one day, and that before the hall is locked up for the night the last picture has been hung, and, as far as the display of the photographs is concerned, everything has been complete. That such a thing is possible points to an admirable system of organisation, and it is only fair that we should render a tribute of praise to those to whom it is due.

In the quality of the work shown a very fair advance has been made since last year's show, and it was a noticeable feature that the walls, glancing at them from a central position, looked more harmonious. It was not that any difference had been made in the arrangement of the pictures, but was due partly to the increased average size of the frames and the less number of small frames which, however arranged, are apt to make the walls look spotty, and partly to the entire absence, at any rate on the members' side, of those bright-coloured mounts and gaudy mountings which used to be so beloved of the inexperienced exhibitor. While referring to the framing of the junior members' work in this laudatory way, we should also say an appreciative word as to the general improvement that has taken place in the work itself. Of course, the difference between the work of the most skilful and the least skilful of the Society's members is immense, but this difference was not accentuated in the present exhibition by the presence of photographs showing utter want, not only of skill, but of care. Indeed, there were few exhibits without some meritorious points. That the average quality of the work was so high is the more remarkable from the fact that out of 130 members of the Society no less than 41, that is to say nearly one-third, were exhibitors.

But, while we congratulate the Society upon its general progress, we must once more repeat our warning as to the danger it runs of losing its well-earned position by its persistent neglect of portraiture and figure subjects. That a Society which contains the talent that the Hackney Society does should be content to show about a dozen pictures of this class as representing a year's work is unaccountable and lamentable. The signs of the times all point to an increasing interest being taken in portraiture and figures. Our country has easily maintained its position in the pictorial rendering of landscapes, but we are being strongly assailed from abroad in a branch of photography which we have unduly neglected, and in which the pictorial possibilities are infinite. We look to societies like the Hackney to keep us from lagging behind our competitors.

The judges appointed were Messrs. Craig Annan, F. Hollyer, and J. C. S. Mummery. Mr. Hollyer, however, did not act. In the Members' Classes, portraiture and figures were classed with animal studies. Of the former, as we have said, the number of exhibits was small, and the judges did not distinguish any of them with an award. W. A. I. Hensler had a portrait of a lady at a window which was sufficiently good to encourage him to further work in this direction. Mr. Hensler looks upon himself, we believe, quite as a beginner in this class of work, and he naturally fell into some of the mistakes a beginner encounters in the treatment of such a subject. Many of these he will, no doubt, see for himself and rectify in future attempts. Mr. Rawlings had a good rustic figure in "The Wood Gatherer," and he, again, obviously owes his want of success to inexperience. The striking fault in this was the want of relief of the figure against the background. A. Glass made a rather ambitious subject in a nude half-length figure of a girl entitled "Meditation." There was nothing whatever offensive about its nudity, but, pictorially, it would have been very much better had the figure been draped. The animal studies were mostly of animals and birds in the Zoo, and were obviously in many cases enlargements from smaller negatives. It was a remarkably good class as a whole, and many of the exhibits deserved almost extravagant praise. This, the judges evidently recognised, as each of the principal exhibitors received an award. They were Messrs. J. O. Grant, W. Selfe, A. Rose, and F. E. Roofe. We should also say a good word, too, for the dog studies of L. S. Wilks, whose work has very much improved.

The Architectural Class was not a very large one, but it contained a fair proportion of really good work. It would be difficult to imagine anything better than W. Rawlings' "The Triforium, Gloucester," and, though it required closer examination to see its beauties, "The Cloisters, Wells," by the same artist, pleased us almost as well. "Founder's Tomb, St. Bartholomew's," by G. W. Haslam, "Cloister, Fountains Abbey," by W. A. I. Hensler, and "Staircase, London University," by S. C. Stean, were also notable among the interiors. The last-mentioned deserved special recognition on account of the skill dis-

played in producing a harmonious result in a subject that required the use of magnesium to supplement daylight. We noticed several examples of a class of subject which should be more frequently attempted. The titles "A Street in St. Ives, Cornwall," by Dr. Roland Smith, "A Quaint Corner, Hawkhead," by W. A. I. Hensler, and "At the Base of the Monument," by W. Selfe, will explain the kind of thing to which we refer.

The Landscape, Seascape, and River Scenery Class, as usual, attracted the largest number of exhibits, the number of frames being more than equal to the aggregate of those in the other members' classes. We noticed with satisfaction that there was a greater variety than last year in the choice of subjects, and also in methods of treatment. Of course, the Hackney Society made its reputation in the scenery of the forest, marsh, and mudflat. There was quite sufficient of it in the exhibition to satisfy tradition, and there remains still a noticeable tendency to impart to whatever scene is attempted a sense of dreariness and melancholy. This is, perhaps, the more noticeable, as it appears particularly in the most important part of the work. The gold medal for the best picture on the members' side was awarded to W. Rawlings for "A Snow-bound Harbour," a picture which required some study before its merit could be realised. There is no doubt, however, that those who would take the trouble to examine it and get in sympathy with the subject would endorse the judges' decision. Mr. Rawlings supports his reputation in his other work in the class. W. A. I. Hensler had in "The Mill Stream," which received the silver medal of the class, a subject of a different kind from what he usually attempts, a mill stream, not of the rural kind, but such as may frequently be found in the manufacturing districts of Yorkshire, bordered with buildings, picturesque only in their irregularity. He has managed to infuse a glamour of romance into the subject by his skilful treatment of it. Among Mr. Hensler's other exhibits, which were quite up to his usual form, was a little circular blue picture entitled "Silvery Moonlight," which was unusually successful for a thing of the kind. E. J. Hunt's "On the Heath" contained a tenderly rendered atmospheric effect. It was awarded the bronze medal. The pictures which received certificates were "Temple Stairs, Thames Embankment," by H. W. Jane, which visitors to the recent R.P.S. Exhibition will perhaps remember. "The Path through the Woods," by J. J. Westcott, a very pleasing picture of sunlight and forest scenery. "Evening," by G. H. Capper, one of the most striking pictures in the exhibition, and "The Lady of the Forest," by J. Carpenter, quite in Mr. Carpenter's dainty style. Other exhibitors of notable work were E. Puttock, Dr. Roland Smith, W. Selfe, W. L. Barker, S. C. Stean, F. E. Roofe, J. Featherstone, and J. O. Grant.

In the Open Classes the gold medal for the best exhibit was awarded to C. H. Oakden for a very fine cathedral interior. In the class for portraits and figures the awards were: Silver medal to J. Auld for "Reverie;" bronze medal to J. Burns for "The Wind Bloweth from the Sea;" and certificate to W. Illingworth for "A Philosopher in Humble Life." The last-mentioned three pictures were all exhibited at the recent R.P.S. Exhibition. Other notable exhibitors in the class were Miss H. Padgett, J. L. Shawcross, J. W. Hodges, A. E. Lane, Graystone Bird, E. A. Price, and W. J. Shelley. Among the exhibits we noticed one or two heart-rending attempts at imitating the American school.

In the General Open Class the Society scored a distinct success in the silver medal being awarded to W. A. I. Hensler for the picture which obtained the first award in the Members' Class last year. H. W. Bennett received the bronze medal for "The entrance to the Sixteenth Century Chapel, Ely," and T. E. Freshwater, F.R.M.S., a certificate for a frame of "microphotographs" of "sniders." Among the other notable exhibitors were G. H. Gill, Dudley Hoyt, O. G. Pike, J. M. Whitehead, A. T. Ward, Mrs. K. Knapp, J. T. French, E. J. H. Felce, H. Quilter, Graystone Bird, and W. Illingworth.

The lantern slides in both the Members' and the Open Classes were neither very numerous nor of extraordinary merit. The class for stereoscopic transparencies, an open class, contained some very good work, also some very bad. It is interesting to note that the three awards were all made to members.

The trade exhibitors were Messrs. H. W. Cox, Ltd., Burroughs and Wellcome, the Doe Portable Electric Light Syndicate, Spratt Bros., R. and J. Beck, W. D. Welford, and the Rotograph Photographic Company. A silver medal for the best general exhibit was awarded to Messrs. R. and J. Beck, and a bronze medal for the best photographic novelty to the Doe Portable Lamp Syndicate for a portable electric dark room lantern.

On the evenings the exhibition was open there were concerts, lantern, and cinematograph entertainments, and other attractions for visitors.

#### LIST OF AWARDS.

##### Members' Classes.

Best Picture in Classes A to D: Gold medal, W. Rawlings. Class A: Silver medal, J. O. Grant; bronze medal, W. Selfe; certificate, F. E. Roofe; certificate, A. Rose. Class B: Silver medal, W. Rawlings; bronze medal, G. Guest. Class C: Silver medal, W. A. I.

Hensler; bronze medal, E. J. Hunt; certificates, H. W. Lane, J. Carpenter, J. J. Westcott, and G. H. Capper. Class D: Silver medal, S. C. Stean; bronze medal, not awarded. Class E: Silver medal, F. E. Roofe; bronze medal, W. A. I. Hensler; certificate, W. Selve.

#### Open Classes.

Best Picture in Classes F and G: Gold medal, C. H. Oakden. Class F: Silver medal, J. Auld; bronze medal, J. Burns; certificate, W. Illingworth. Class G: Silver medal, W. A. I. Hensler; bronze medal, H. W. Bennett; certificate, T. E. Freshwater. Class H: Silver medal, Graystone Bird; bronze medal, W. Page; certificates, E. R. Bull and Dr. Roland Smith. Class I: Silver medal, A. D. Fort; bronze medal, W. L. Barker; certificate, L. S. Wilks. Best Trade Exhibit: R. and J. Beck. Most Useful Photographic Novelty: Bronze medal, The Doe Electric Lamp.

## Studio Gossip.

"OUR Youngest Constant Reader."—Mr. Crawshaw, photographer, of 2, Wellmeadow-road, Hither-green, S.E., sends us a photograph of his little son, bespectacled and pipe in hand, engaged in perusing a copy of the JOURNAL. We hope our young reader will grow into an old one, and that the JOURNAL may help him to a successful photographic career.

"A RELENTLESS Snap-shooter."—A writer in our excellent contemporary, "The Referee," describing an interview with Mr. George Alexander, the manager of the St. James's Theatre, says he found that gentleman and his company about to be photographed on the stage in their habit as they appear in Mrs. Craigie's much-debated play," and that, "in spite of his impending capture by that relentless snapshooter, Mr. Alfred Ellis, Mr. Alexander displayed an unruffled calmness." Mr. Ellis's confrères in the profession of which he is such a prominent member will surely smile at the description of him as "a relentless snapshooter."

THE Yarmouth Murder.—At Great Yarmouth, last week, in the course of the magistrates' inquiry into the murder case that is attracting so much public attention, Mr. James Richard Conyers, who for twenty-five years has photographed Yarmouth visitors on the beach, identified a beach photograph, which he said he took on the forenoon of September 20. He asked for the lady's patronage, and he remembered that she required a great deal of persuasion. Witness then gave a detailed description of the way the lady was dressed. Mr. Wiltshire, counsel for the prosecution: As an artist, you took all these things in?—Witness: Yes.

ILLUSTRATED postcards, like theatrical placards and automatic peep-shows, says the "Daily Chronicle," are all the better for the criticism of public opinion. In Austria a collection of illustrated postcards has been obtained which would not be suitable for a drawing-room table. Dr. Wach, of the Vienna criminal courts, has carefully preserved all the cards seized in the Austrian capital, two hundred in number, and other Austrian tribunals have joined him in this interesting work, sending each its contingent of scandalous designs. Dr. Wach has made an album of the whole collection, which the Government has photographically reproduced, sending copies to all the provincial courts.

TANQUEREY in Glasgow.—His lavish distribution of circulars has already justified the faith of M. Tanquerey that wherever there is an aggregation of men and women there are certain to be a proportion waiting to be taken in by the wiles of the first deceiver. The Glasgow press is now devoting space to the wailings of the victims of his promise to give "portraits for nothing." It is the old, old story of a photograph sent to Paris, followed by a note stating that "one of the finest crayon portraits it is possible to produce, and at the same time a perfect likeness," has been completed; and that, thinking "a handsome frame might be wanted," a catalogue was enclosed. A frame, including boxing, packing, &c., was ordered at a cost of £1 4s. The receipt of the money was acknowledged, and the portrait promised in thirty days. By and by the portrait arrived, with 4s. to pay for carriage. Delivery was refused, but, repenting, the box was given up on payment of an additional 1s. 6d. Inclusive of postages, &c., the portrait and frame cost 30s., and the recipient's testimonial is thus expressed:—"The frame is execrable rubbish, and the portrait an exceedingly coarse, inartistic production—the two together not worth 10s.; while the easel promised to every purchaser of a frame was not sent." This is typical of the complaints of M. Tanquerey's simple-minded victims, but a solitary letter has appeared setting forth that the writer has received a beautiful crayon portrait on remitting 8s., and was so pleased with it that he got another on the same terms. We have no quarrel with M. Tanquerey so long as he trades in a legitimate fashion, even though his portraits may not be the high-class works of art he sets forth they are; but, in face of the payments of 8s., where does his offer of "portraits for nothing" come in? The eight shillings, the champion of Tanquerey admits, was not spent in carriage, &c., as he says the portraits were sent in pasteboard tubes, and that the postage was trifling.

## News and Notes.

THE proposal to erect a National Physical Laboratory in the Old Deer Park at Richmond has been abandoned.

The Brentford Photographic Society's Annual Social Evening will be held on Wednesday, January 2, 1901, at eight p.m., in the Large Hall, Public Baths.

THE Leyland Photographic and Scientific Society has lately been formed. Mr. James Iddon is President, and the Hon. Secretary is Mr. J. Lomax, Westby Cottage, Leyland.

ROYAL Photographic Society.—Lantern meeting, Tuesday, December 4, at 66, Russell-square, W.C., at 8 p.m. "Lantern Slides, Pastoral and Sundry," by Colonel J. Gale.

Hove Camera Club Exhibition.—The following is the list of the judges' awards in the open classes: Challenge Salver, Douglas English, "Fantaisie Americaine," No. 306. Class A (Landscape and Marine)—Silver medal, E. R. Collins, No. 41; bronze medal, W. H. Rogers, No. 32; certificates, R. C. Foskett, No. 60, C. Berrington Stoner, No. 34. Class B (Figure and Portraiture)—Silver medal, C. W. Walker, No. 93; bronze medal, H. Lawrence, No. 107; certificate, Percy Lankester, No. 111. Class C (Architecture)—Silver medal, E. J. H. Felce, No. 138; bronze medal, A. J. Loughton, No. 135; certificates, Chas. H. Ookden, No. 139, C. W. Walker, No. 131, F. J. Walker, No. 120. Class D (any other subject than classes A, B, and C)—Silver medal, Douglas English; bronze medal, Miss MacLachlan, No. 150; certificate, J. M. Whitehead, No. 158; special certificate, Douglas English, No. 169.

THE Trade Journal.—The trade journal, says the "Age of Steel," is not a newspaper, as the term is generally understood. It is strictly business. It is a purveyor of industrial information, and of all things related thereto. Every class of industry has its representative paper. The shoemaker, the boilermaker, and the candlestick-maker; the cotton-spinner, the glass manufacturer, the architect, and the engineer; the man who handles jewellery; and he who makes pig iron, tin plates, or horseshoes, and all the way along the line from a pocket-knife to a locomotive, can put his finger on what he wants to know in his particular trade journal, as easily as he puts on his gloves or his hat. Nothing can take the place of the trade paper in this matter. The average newspaper has neither room nor inducement to specialise on strictly technical matters. The general public demands something more savoury and sensational, and has no direct interest in what is being done in a machine shop or a shipyard. The taste for spiced viands has to be gratified, and a yacht race or a prize fight, a sensational crime or a malodorous scandal, is a raker in of shekels and a feeder of popular patronage. The trade journal is not a garden of garlic, or a laundry for politicians, and its patrons are restricted to industrial circles. In this lies its special virtue. It has one object and it sticks to it. If a manufacturer wants a machine or mechanic, or latest improved tool, he has but to consult his trade journal to get in its pages what he cannot get elsewhere. He can make his comparisons of costs and efficiency, can place his orders at the price of a postage stamp, and with a pen or a typewriter can in a few minutes make and close important transactions. It is the trade journal that makes this possible. Otherwise the sales agent or the vagrant circular, and a mail-bag of inquiries would be the time-eating and money-eating conditions of locating a manufacturer, and getting a full text of his specialities. It is this feature of the trade journal that makes it the best advertising medium of modern times. It brings buyer and seller in closer contact. The arrow goes straight to the mark. If a pump is needed, or a windlass, a lathe, or a drop hammer, an anvil, or an iron bridge, the advertising of the same in the trade journal is frequently the only up-to-date directory of places and persons where such can be had. It goes without the telling that most of the sales of machinery, tools, and related equipment, are brought about by advertising literature in trade journalism. This fact in many instances ought to be more appreciated than it sometimes is, at the selling end of modern business.

## Commercial & Legal Intelligence.

CHANGE of Address.—Mr. H. F. Purser informs us that in future his business and its connections with the Rathenower Optische Industrie Anstalt (late Emil Busch) and the Busch Camera Company will be carried on at 31, Hatton-garden, London, E.C.

CHRISTMAS Cards on Thick Bromide Paper.—Messrs. Wellington and Ward, of Elstree, Herts, are issuing a special thick bromide paper (2½ times the weight of the smooth or rough grade) for use when prints are not required to be mounted, and therefore suitable for Christmas.

THE Objectionable Poster at Manchester.—Mr. Arthur Collins, of the Theatre Royal, Drury-lane, sent the following letter to the Editor of the "Manchester Courier" for publication in that journal:—"I have refrained from writing to you with regard to the action of the Manchester police in respect to a poster exhibited by the manager of the Theatre Royal, where 'Hearts Are Trumps' was being played, in case your readers should imagine that I was seeking advertisement. As, however, the Drury-lane Company have left Manchester, it will be obvious that I am not seeking publicity in expressing my surprise at the action of the Chief Constable. The poster in question has been exhibited for months in London and various large towns without exciting any remark as to its impropriety from any section of society, whether playgoers or not, and the course pursued by the Watch Committee, as represented by the Chief Constable, is the more surprising, and quite on a par with their attitude towards the manager of the Comedy Theatre. I have always been under the impression that Manchester was one of the artistic centres

of the provinces, but, after this display of puritanical priggishness, I am afraid that it will sink considerably in my estimation. As to the action of Mr. Courtneidge in his haste to fall in with the view of the Chief Constable, I may remark that he was under the impression that the poster referred to was that of the Academy picture, which, being a representation of a semi-nude figure, might possibly have offended this Mr. Stiggins of a constable. Believing that it was the "Wood Nymph" poster objected to, he gave orders for its withdrawal. Had Mr. Courtneidge known, as we do now, that it was the very harmless poster representing a scene in a photographic studio, he would doubtless have told the Chief Constable to mind his own business."

LORD Rosebery on American and German Competition.—In the course of his recent Rectorial address at Glasgow University, Lord Rosebery observed: The United States Consul at Chemnitz has remarked that, "If an industry in Germany languishes, immediately a commission inquires into the causes and recommends remedial measures, among which usually is the advice to establish technical or industrial schools, devoted to the branch of business under consideration." In a word, they go to the root, to the principle, to the source. This is thoroughness, this is the scientific method applied to manufacture, and we see its success. The Americans, I gather, have hitherto applied themselves rather less to the principles than the applications of science. I do not pretend to say which are right. The Germans are alarmed at the development of American commerce, and we are alarmed at both. At any rate, both in Germany and the United States you see an expenditure and a systematic devotion to commercial, and technical, and scientific training. I know that much is done, too, in Great Britain. But I doubt if even that is carried out in the same methodical way; nor is there anything like the same lavish, though well-considered, expenditure. It always seems to me as if in Germany nothing, and in Britain everything, is left to chance. It has been said that the true University of our days is a collection of books. What if a future philosopher shall say that the best University is a workshop? And yet the latter definition bids fair to be the sounder of the two. The training of our schools and colleges must daily become more and more the training for action, for practical purpose. Are there not thousands of lads to-day plodding away, or supposed to be plodding away, at the ancient classics who will never make anything of those classics, and who, at the first possible moment, will cast them into space, never to reopen them? Think of the wasted time that that implies; not all wasted, perhaps, for something may have been gained in power of application, but entirely wasted so far as available knowledge is concerned. And if you consider, as you will have to consider in the stress of competition, that the time and energy of her citizens is part of the capital of the commonwealth, all those wasted years represent a dead loss to the Empire. If, then, these recent events and the present conditions of the world induce thinkers and leaders in this country to test our strength and methods for the great struggle before us, they must reckon the training of man. On that, under Providence, depends the future, and the immediate future, of the race; and what is Empire but the predominance of race?

BROMIDE Prints in lieu of Platinotypes.—At Marylebone County Court, last Friday, before Judge Stonor, Mr. Francis John Tilly, photographer, 45, Donaldson-road, Brondesbury, N.W., brought an action for the recovery of seven guineas from Mr. A. P. J. Boland, 40, Priory-road, West Hampstead, N.W., the claim being in respect of silver, platinotype, and bromide photographs said to have been supplied to order. Mr. J. Heath, solicitor, appeared for the plaintiff, and Mr. Calfax, solicitor, defended.—The plaintiff stated that in August last he received orders from the defendant for certain silver and platinotype photographs. These were supplied, and their price, £1 19s., was duly paid. Shortly afterwards he received further orders for large platinotype groups and cabinets of single figures taken from the large negatives. He explained that these would be rather expensive, particularly as the background of the cabinets would have to be put in by hand. The defendant's reply, however, was that he did not mind the expense so long as a satisfactory job was made. Three proofs were submitted and approved, and the order was then executed. The defendant retained the photographs for seven weeks, but when pressed for payment he sent some of the prints back, and complained that the charges were excessive.—The Judge: I see you charge 10s. for the platinotype groups, 10s. 6d. each for the panels, and the groups of servants, and 4s. each for the 21 cabinets.—Mr. Calfax (cross-examining): The cabinets, as well as the large prints, were to be done by the platinotype process, were they not?—The Plaintiff: Yes.—Do you know how to distinguish between platinotype and bromide prints?—The only test is by examining the surface, at least I know of no other way.—Have you never heard of the bichloride of mercury test?—There may be such a test, but I never heard of it.—Do you mean to say that the small prints were done by the same process as the large one?—They may not be quite exactly the same, but they are identical as regards appearance. I could not have done them by any better process at the price.—Mr. William Hilder, photographic printer by trade, said that he printed the larger photographs for the plaintiff by the platinotype process. The smaller ones were bromide prints. There was not much difference between platinotypes and bromides in appearance, but the bromides, having a gelatine surface, became sticky on being wetted, whereas the platinotypes were not so affected when dampened. That was the simplest test. Considering the artistic skill required for putting in a new background to the cabinets, he did not think that the plaintiff's charges were excessive.—The defendant maintained that he ordered platinotypes and not bromide prints; moreover, he denied receiving all the prints enumerated in the account. His chief com-

plaint, however, was that he had not been supplied with the kind of photographs which he ordered.—Counsel for the defence submitted that by the plaintiff supplying bromides when platinotypes were ordered, he vitiated the whole contract, and so could not recover.—Solicitor for the plaintiff contended that the evidence went to show that at least the larger prints were platinotypes, as ordered by the defendant, and that the cabinets were, to all intents and purposes, just the same.—The Judge: Goods supplied "to all intents and purposes" the same as those ordered does not, in the general way at least, mean a proper performance of the contract. I find for the plaintiff for three guineas only—for the goods which were in accordance with the order.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

December.	Name of Society.	Subject.
3.....	Doncaster .....	Beautiful Britain. R. S. Wright.
4.....	Gospel Oak .....	New Kodaks. W. J. Ramsey.
4.....	Newcastle-on-Tyne .....	Lanternist's Night.
4.....	Rotherham .....	Negatives and Prints—their Improvement and Modification. A. Horsley Hinton.
5.....	Croydon Camera Club .....	A New Print-out Paper. E. F. Ley.
5.....	Edinburgh Photo. Society .....	Photography in Medicine and Surgery. W. E. Carnegie Dickson, B.Sc. (Edin.).
5.....	Woodford .....	Intensification—A Comparison of Different Methods. H. W. Bennett, F.R.P.S.
6.....	Darwen .....	Lecture: Negatives and Prints.
6.....	Hull .....	Bromide Printing. F. Woollons.
6.....	Leigh .....	A Cruise about Europe. Dr. Joseph Jones, M.B.
6.....	Liverpool Amateur .....	Demonstration: Ozotype, the New Carbon Printing Process without Actinometer, Transfer, or Safe Edge. Thos. Manly.
6.....	London and Provincial .....	Lantern Night: India. Thomas E. Freshwater.
6.....	Röntgen Society .....	Stereoscopic Fluoroscope and a New Rotary Mercury Break. J. Mackenzie Davidson, M.B.
7.....	Aberdeen .....	Developers. J. S. Anderson.
7.....	Borough Polytechnic .....	Instruction Evening: Trimming, Mounting, and Framing.
7.....	Croydon Microscopical .....	Demonstration: The Use of the Panoram and other Kodaks, Development of Kodak Films, &c. Mr. Ramsay.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

November 22, Mr. S. Herbert Fry in the chair.—Mr. T. E. Freshwater, Acting Secretary, reported the acquisition of a new bookcase, which would enable the librarian to put the books in better order. He suggested that some of the members might find amongst their collections many duplicates of books they did not wish to keep that would be useful additions to the Association's library.

Mr. J. E. Hodd passed round two negatives developed with adurol and imogen, and typical, he thought, of the results given by the two developers. He then drew attention to a short paragraph in a contemporary, wherein the writer said that by opening the camera back in the full glare of daylight sufficient light is often retained by the bellows to fog a rapid plate. Mr. Hodd wondered whether the possibility of utilising bottled-up light was thus opened up.

Mr. A. Haddon remarked that almost all substances bottled up light, but the time during which such light was given out varied considerably. Some things gave it out in a fraction of a second; others retained it for a long time, giving it up but slowly. Coral took up light during the day to a considerable extent, and gave it out at night. It was, of course, possible that the material used in the bellows of the camera repeated these phenomena. Becquerel carried out many interesting experiments in this direction, and it was to them that he referred.

Mr. R. P. Drage remembered a former discussion upon the subject at another place, when the idea was thoroughly laughed down.

Mr. A. Mackie said he had recently come across a paragraph which dealt with the possibility of exposing in place of the plate a luminous painted screen. This screen was then placed in contact with a sensitive plate, the image being finally developed on the plate.

Mr. P. Everitt passed round a vitrified enamel portrait made by Mr. J. S. Teape. It had the double feature of being from a hard collodion negative and enlarged over two times.

Mr. T. E. Freshwater gave a chat upon the reflecting stereoscope. He regretted that the popularity of this instrument had so much died down, especially when one considered how, by its use, with what ease stereoscopic pictures of any size could be seen. Wheatstone was the man who designed the reflecting stereoscope. It consisted of two mirrors set at an angle of 90°, in which are received the images of the two prints of a stereoscopic pair of photographs, and from whence they are received by the eyes and combined. The advantage is that pictures of any size may be viewed, instead of those of only limited size that are possible with the ordinary stereoscope. Wheatstone's reflecting stereoscope is not usually found anywhere but in lecture theatres, &c.; but with the introduction of stereoscopic radiography, hospital authorities found in them a ready means of viewing the pictures of fractures, &c., which have been of so much help in locating the seat of injury. Mr. Fresh-

water showed several stereoscopic pictures in two stereoscopes of the reflecting principle. He referred those who desired detailed information about stereoscopic photography to the several articles that have appeared in past years in THE BRITISH JOURNAL PHOTOGRAPHIC ALMAMAC. Having replied to a number of incidental queries, he was accorded a hearty vote of thanks.

#### PHOTOGRAPHIC CLUB.

November 21, Mr. Charles Wallis in the chair.—Mr. J. P. W. Goodwin gave a chat on "Fred Walker, A.R.A., and his Work," illustrated by slides from many of his pictures. During the early years of photography progress was visible mainly in the direction of mechanical improvement, and its secrets—now secrets no longer—were only gained after years of patient effort. But, with all the spreading of knowledge, the ability to obtain perfect instruments, and the growth of skill in their manipulation, there still remains a vast field for conquest, known in familiar language as "pictorial photography." He refrained from discussing the possibilities of the chances of photography being numbered amongst the fine arts, but as a step in the right direction he wished to urge those desirous of improving in the knowledge of what was pictorial in photography to study the works, not of successful photographers, but of great artists. The laws of composition, the rules that govern the introduction of light and shade, must, of course, be studied, but not with the idea that they are as fixed and immutable as the multiplication tables. They were arrived at by close study of the works of the greatest artists in all ages. It is for us to examine the examples of the genius of these artists. The opportunities lie thick around us, with the national collections, the frequent exhibitions, and the numberless reproductions that—once impossible—are now to be found in periodicals and magazines. The works of Fred Walker, A.R.A., he instanced as particularly worthy of study by the pictorially-minded photographer. To what his appetite he had come down to speak of the career of this, one of England's greatest painters. Considerable attention was given to the running commentary Mr. Goodwin made as the reproductions of the pictures were shown on the screen, and a cordial vote of thanks was passed to Mr. Goodwin for his lecture.

Mr. Wm. H. Wilkins (R. and J. Beck, Limited) showed and described the No. 8 new folding Frena camera, fitted with Beck-Steinheil two foci Orthostigmat lens. He also showed photographs made by the whole-plate form of this lens, used normally, and also on a 12 × 10 plate, with examples taken with the single components to show the rectilinearity of lines.

**West London Photographic Society.**—On November 23, before a large audience of members, Mr. G. F. Blackmore read a paper on the Ozotype process (this will appear in our next), and practically demonstrated its working. He also showed some very satisfactory prints made by this process. In a discussion which followed the opinion was expressed that the process was perhaps a little premature and that doubtless improvements would be forthcoming.

**Adys-road Evening Continuation School, East Dulwich.**—Wednesday, November 21. Mr. J. T. French gave a demonstration on enlarging to the members of the Photographic Class of this school. The class much appreciated Mr. French's work, and the home-made apparatus with which he did some capital enlarging, was much admired. Mr. G. G. Lewis, the responsible teacher, proposed a vote of thanks, which was carried with acclamation.

**North Middlesex Photographic Society.**—November 19, Mr. A. G. Lawson in the chair.—Mr. E. R. Rawkins gave a lecture on "Lantern Slides." The lecturer showed by means of the lantern what sort of negatives were suitable for the process, and slides from them. He also showed the effects of bleaching with mercury and blackening with various substances to get various tones. The uses of ferridcyanide of potash and hypo as a reducer, to clear away fog, lightening distances, and modifying the gradation in the foreground were also illustrated and explained. He thoroughly explained all the details of the process, both by contact and reducing in the camera, illustrating the apparatus required. To sum up, the lecturer said that to get good results in lantern slides he recommended sticking to one plate and one developer. Evenness of work resulted, and much less waste than if they were constantly changed.

**Croydon Camera Club.**—Mr. Walter D. Welford drew a capital audience on Wednesday, 21st inst., when he lectured on the Glassoline film. He began with a humorous comparison of Films v. Plates, and, although this part of the subject is getting threadbare, his illustrations proved very entertaining. Indeed, entertaining very fitly describes the greater part of the lecture and demonstration. If one can manage to amuse, it, in our days, goes a very long way, particularly with amateurs, who do not care to "overlay with toil their pleasure." One thing about Mr. Welford, in his advocacy of the Thornton film, is that he did not try to prove much too much. Its chief claims appear to be that it is light, lies flat in the developer, any reducer can be used, density is easily judged, it can be enlarged by stripping it from its support before drying, and, greatest of all, it is as cheap as glass plates. Has it any drawbacks? Has anything without a drawback been invented? Those who were present judged for themselves whether the advantages of this ingenious film outweighed its shortcomings. Anyhow, as the President observed, it is a very convenient material for producing those photographic monstrosities known as composite negatives, by sticking bits of one film negative upon parts of another, when something which is neither truth, beauty, nor art may result. Quite an interesting little discussion

ensued, in which leading parts were taken by Messrs. Kough, Salt, Rogers, Stanley, Isaac, Wratten, and Edwards. The latter considered that hypo used in a developer produced relative increase of density, and was particularly useful—when pyro is not employed—for both negatives and positives, bromide paper and slides, where an increase of brilliancy and a shortening of time of development is required. Mr. Isaac supported the contention. The power of a very weak solution of hypo to dissolve silver salt was questioned, Mr. Salt opining that there was no limit to the dilution, but that a weak solution meant a proportionately small amount of silver dissolved out. Others contended that the amount of silver present in a dry plate is so small that a 1,000 per cent. solution of hypo in a few ounces of water is more than enough to combine with all the salt present in the plate, but that a certain strength of hypo is needful in order to set up the action. From the evening's proceedings it would seem that the photographic plate is undergoing much change. Having got rid of the glass, it now appears that we are in a fair way of getting rid of the silver in the film and of the reducer in the developer, so that a time may be at hand when nothing but gelatine is exposed in the camera and nothing but hypo used to bring out the image. Mr. S. H. Wratten, however, brought the meeting back to a prosaic attitude when he deprecated the objectless meddling with reducing solutions by adding hypo, whereby apparently only unforeseen results followed.

#### Glasgow and West of Scotland Amateur Photographic Association.

The monthly meeting was held in the rooms of the Association, West Regent-street, on the evening of the 18th inst., Mr. Thos. W. Robertson in the chair. Four new members were admitted. Mr. W. J. B. Halley, Hon. Treasurer, submitted his financial statement for the year, showing that the Association was only £6 down as compared with the balance in hand a year ago, although there had been extraordinary expenditure to the amount of £25 during the year. The balance in their favour was £483 16s. 10d., and of the arrears of subscriptions £15 might be reckoned as good. The Association's assets stand in the books at £213 4s. 9d., so that the members have every reason to be proud of the financial condition of the Association. A hearty vote of thanks was accorded to Mr. Halley for his devotion to his duties. Mr. J. C. Oliver then gave a demonstration of the Venus and Verel Khaki printing-out papers, pointing out the superior qualities they possessed for pictorial purposes over those of P.O.P. For his part, he preferred the tones they gave without further toning, but he sent round prints toned with gold and platinum, according to the makers' formulæ. He found a great saving of time effected in using these papers, as they printed faster, toned quicker, required briefer washing, and dried quite flat when laid on blotting-paper. His best results were obtained with dense negatives, thin negatives being of no use. Mr. J. Imbrie Fraser followed with a demonstration of platinotype printing and developing by the hot and cold bath processes, after which Mr. William Goodwin, Hon. Secretary, explained how to salt such a paper as Whatman's drawing with a size made of arrowroot and chloride of ammonia, sensitising it with nitrate of silver to produce a printing paper capable of giving a very pleasing tone with platinum at no very great outlay. Votes of thanks were given to the demonstrators.

**Blairgowrie and District Photographic Association.**—The monthly meeting of this society was held in the Club-room, Blairgowrie, on November 20, when the President (Mr. A. Geekie) gave his annual address. It was unanimously agreed, on the motion of Mr. J. B. Mac-lachlan, seconded by Mr. D. G. Monair, to affiliate with the Royal Photographic Society, and the Secretary was instructed accordingly. A report was given anent the forthcoming Exhibition in January, which showed that numerous inquiries had been received for prospectuses during the past week, besides many inquiries from England, Scotland, and Ireland, a large number of inquiries had been received from France, also from Italy and Austria. Entertainments are to be held every night the exhibition is open, and altogether a record show is prophesied.

## Patent News.

THE following applications for Patents were made between November 12 and November 17, 1900:—

- DISHES.—No. 20,310. "Improvements in Dishes employed in Photography and for like Purposes." T. C. TWINING.
- LENSES.—No. 20,349. "Improvements in and relating to Photographic Objectives." H. MEYER.
- CINEMATOGRAPHS.—No. 20,457. "Improvements in or connected with Cinematographs." A. WRENCH.
- PLATE-HOLDERS.—No. 20,511. "Improvements in Photographic Plate-holders." Communicated by A. Gaffney. Complete specification. P. M. JUSTICE.
- LANTERNS.—No. 20,738. "Improvements in Magic Lanterns." A. G. MANIFOLD.
- ROLL-CAMERAS.—No. 20,776. "Improved Roll-camera." Complete specification. J. A. PAUTASSO.
- COLOUR PHOTOGRAPHY.—No. 20,788. "Improvements in Devices for the Simultaneous Production of several Photographic Pictures for Use in Colour Photography and the like." C. H. E. A. MIETHE.
- COLOUR PHOTOGRAPHY.—No. 20,789. "An Improved Process for Projecting Multi-colour Photographs and Apparatus therefor." C. H. E. A. MIETHE.

## FORTHCOMING EXHIBITIONS.

1901.

January 14-19..... Blairgowrie and District Photographic Association.  
The Hon. Secretaries, Blairgowrie, N.B.

February 16-March 9 Edinburgh Photographic Society. Secretary, J. S.  
M'Culloch, W.S., 10A, George-street, Edinburgh.

## Correspondence.

\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*\* We do not undertake responsibility for the opinions expressed by our correspondents.

## COLOUR SCREENS ON SHUTTERS.

To the EDITORS.

GENTLEMEN,—With reference to your note on Mr. Purser's letter in THE BRITISH JOURNAL OF PHOTOGRAPHY of Nov. 23, allow me to explain that the arrangement which I showed you originated in an attempt to attach a yellow glass temporarily, so that no change should be required in lens or any other part which could not be cancelled. Having satisfied myself that the addition was useful, I proceeded to get it made in a permanent form. It is not the place of the screen which seems to me the improvement (for that is not of much importance), but the fact that the plan I have adopted allows the screens to be put on, changed or removed at will without disturbing the camera, or shaking it; it also allows an experimenter to insert any piece of glass (not too thick) for trial if he cuts it to a rectangular form of the proper width, all necessity for mountings, cells, &c., is done away with, and any form of lens can be used: my own is a Cooke, which would not allow of the arrangement mentioned by Mr. Purser.

In order to allow of the use of glass of different thicknesses, it would be desirable not to make the receptacle too shallow (the maker of mine has not attended to this part of my instructions), for there can be no harm from a slight looseness; no one would shake the camera while exposing.—I am, yours, &c.,

J. F. TENNANT.

November 23, 1900.

## ARTISTS, PAINTING, BUSINESS, AND INDIVIDUALITY.

To the EDITORS.

GENTLEMEN,—Having to call on photographers about enlargements and paintings, the writer has often been struck with the disproportion between the show of specimens that is made and the small number of orders resulting, and the general complaint is that "People do not seem inclined to spend their money on such things"—that is, they will not go beyond a very moderate sum when paying for them. Perhaps it would be worth while to seek the cause of such a state of things, and, if possible, to find a remedy. It does not appear, according to experience, that the public have ceased to care for large portraits in monochrome or colours, or miniatures, but rather that for anything beyond an enlargement merely "finished," which can be obtained of sufficient quality to satisfy a certain class of customers at an extremely low price, the photographic "art" production has fallen somewhat into disrepute, whilst fashionable painters of oil portraits, pastellists, and miniaturists have little need to echo the art-photographers' bitter cry, the most celebrated among them being literally besieged, and having commissions booked years in advance. Yet, it may be more than suspected, photography—that Cinderella of the arts—is frequently their useful but ill-thanked and often unacknowledged handmaid. Now, there are two widely different reasons why people with something more than a guinea or two to spend on a portrait for the walls, or a miniature case, hesitate to give their commissions to a photographer. The first is, they are not sure of intrinsic value and satisfaction as to the likeness; the other reason being that, even if satisfactory in the above respects, there is no éclat in possessing a work of art other than a purely photographic one that has been turned out by a photographic establishment. The fact is, people want to be able to mention the name of the artist, and in this respect the humblest and least-known outsider of the "painter" order has a decided advantage over the most distinguished photographer, whose great disadvantage is precisely that he is unknown to the public; and the wise photographer, with more prudence than vanity, therefore will recognise his position

and whereabouts his own bread might be buttered. For the cheap enlargement "finished" by hand, or with the aërograph, nothing need be done; as already admitted, it is good in its way, and suits a client of modest means or ordinary taste. The question is, "How to attract the bigger fish?" and the following suggestions, like the foregoing remarks, being perfectly candid and sincere, it is hoped they will be taken in the spirit in which they are offered.

There should be good faith and good value. Do not take an order from a specimen done by one artist and let it be executed by another, and, furthermore, instead of expecting an egregious profit, be content with a reasonable one, apportioning to the colouring or other artistic work a sum that will admit of a good artist bestowing proper time and pains on the work. When much is done to a photograph the danger of losing the likeness is great. To avoid this the artist must be really competent, and, besides, must have every facility of communicating with the client, and of taking sittings when possible.

Now comes the miniature on ivory, the pastel, and the oil-painting: in each case pure and genuine paintings without photographic base whatever, and signed with the name of the actual artist. Why should not the acute and businesslike photographer take advantage of the fact that he has a clientèle and the clichés to supply the demand which there really is for such things? He has only to sacrifice his own name in the matter, and secure the continual or exclusive services of the artist by a simple agreement, at the expiration of which supposing a renewal to be unfeasible, he will at least have had the satisfaction of pocketing some honestly gained coin, and of having helped to bring out to the light of day, and helped on the road to success, some rising talent, and possibly even some genius.—I am, yours, &c.,

INDICATOR.

## AMERICAN PHOTOGRAPHY AT RUSSELL-SQUARE.

To the EDITORS.

GENTLEMEN,—Allow me to correct a few of the misstatements that have appeared in your JOURNAL (October 26) in an article entitled "Plastic Psychological Syntheses at Russell-square."

I am neither an "obsequious disciple" of Mr. Day, nor the scribe of the "new school of American photography;" on the contrary, the pictorial photographers mentioned are nearly all my bitter enemies, and would not even admit me to the sanctity of their studios, as the eulogies I have written about them did not seem to them half laudatory enough. I have always fought for photography "pure and simple," photographic work that depends largely on the camera, the chemicals, and the work that depends largely on the camera. If the writer of your article were in any way familiar with my writings in the "Photographic Times," "The Camera Notes," and various other magazines, he would know that I am a fanatic on that question, even to that extent that my articles, "What is Legitimate," and "J. T. Keiley, a Japanesque Photographer," in which I brandished him as a freak, were refused by the editors of the "Camera Notes" and "Photographic Times." They all saw something in Keiley which I failed to see.

As for my "oleaginous admiration" (I have no fault to find with the expression), well, I think, a magazine article should, first of all, be interesting, it should be read by a layman, and this cannot be accomplished by restricting oneself to dry technical analysis. I have written about photographers in the same way as I have written about pictures, and, although it seemed to me ridiculous at times to apply terms to a Eugene or a Kasebier, which would be more adequate in an analysis of a Whistler or Sargent, I did it in order to help "artistic photography," and my work has not been in vain. Their names have become better known to the public at large, and their work has found appreciation more readily than hitherto.

I admire Mr. Day. I consider Day and Stieglitz the only two men in America that are worthy to be considered seriously by an art critic. I praised (perhaps too lavishly) what I considered praiseworthy in his work, and there my connection with the new school of American photography came to an end. I am also astonished that the writer of your article did not perceive the slight vein of sarcasm which runs through my whole article on Day. In New York it was also received in that spirit.

I was attracted to "artistic photography" because I learnt to admire the sincerity and unselfishness, the patience and perseverance, which certain men like Stieglitz, Day, and even Keiley applied to their vocation. They merely worked for the sake of working, of advancing the artistic side of photography, and with no other aim in view, a quality rarely met with in modern art. Kasebier, Ben Yusuf, and Eugene, on the other hand, are strictly mercenary, and I have said so whenever I had the opportunity. If Mr. Day is willing to enter their ranks—he has probably good reasons to do so—it is none of my affair; nevertheless, I would like to remark that it has not been my habit to write advertising articles; I have left that to press-agents.

As for the assertion that photography will never be ranked as a fine art, that is merely a matter of opinion. I have claimed for it, and shall continue to do so, a modest place among the graphic arts, and only in case that colour-photography (on one plate) should ever be invented, and kinoscope photography ever artistically handled, would I claim for it the name of an independent art, as only then an element would enter its power of expression, which no other art possesses, namely, movement in pictorial representation.—I am, yours, &c.,

SADAKICHI HARTMANN.

New York, November, 1900.

[Although we last week closed our columns to any further discussion on the subject of the American Exhibition at Russell-square, we nevertheless concede to Mr. Hartmann the right of a reply to the remarks of which we made him the object, and we have much pleasure in publishing his letter. We have been diligent readers of the whole of the American photographic magazines for nearly 20 years, and nothing that Mr. Hartmann has written in them has escaped our perusal, but we must confess that we have not hitherto regarded him as a fanatical upholder of "pure" photography. Evidently we have done him an injustice, and we therefore cordially welcome him to the ranks of the "photographic" critics. The sarcasm of the article on Mr. Day was too subtle for our perception. May we suggest to Mr. Hartmann that future efforts of the kind should be labelled, in the phraseology of Artemus Ward: "This is rote sarcastick?" We must compliment Mr. Hartmann on the moderate tone of his interesting letter, which will, at any rate, amuse some photographers on both sides of the Atlantic. Eds.]

## Answers to Correspondents.

\* \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPH REGISTERED:—

V. N. Green, Trealaw, Rhondda Valley.—*Photograph of Dr. K. Datta and medical staff.*

C. C. C.—By the insertion of your letter we should lay ourselves open to an action for libel, even if the statements contained in it were true, and we have very strong doubts if they are.

SCRATCHED CINEMATOGRAPH FILMS.—G. Balmer. The "firework or lightning" appearance on the screen is due to the films being scratched in places, and there the strong light of the electric arc passes unobstructed in all its brilliancy, and produces the effect that has caused your wonderment.

MICRO-PHOTOGRAPHY.—"ENTHUSIAST" writes: "Now the long winter evenings are upon us, I thought it would be an interesting variation from lantern slide making, &c., to be able to produce those microscopical photographs seen in the ends of pencils, &c., but have no idea how to go on. I have seen no mention of it in the various publications, and see no book on it. Could you, through your most instructive paper, inform me on the process, if it is very difficult, and what kind of apparatus I require, also if I can obtain a book dealing with the subject?"—In reply: These are produced in precisely the same way as lantern slides are made from larger negatives, using, of course, a lens of much shorter focus. A suitable lens for the purpose is a low-power microscopic objective of, say,  $1\frac{1}{2}$  inch focus. Usually these pictures are made by the wet-collodion process, because, with that, the grain is much finer than with gelatine. No work on the subject is published.

FAULTY CAMERA.—F. Stoker says: "I have a hand camera (focussing) that I have just bought, and I cannot get the negatives sharp. I focus them sharp enough on the ground glass, but the negatives come out all out of focus. Now, can I remedy it?"—One of two things is certain. Either the dark slide or whatever holds the plates, is not in register with the focussing screen, or the lens does not work to focus. The latter is, however, scarcely probable with a modern lens. See to the camera, and have the needful done if you are not mechanic enough to do it yourself.

APPRENTICESHIP AGREEMENT.—"C. G. T." writes: "A gentleman, wishing to place his son under my care to learn the photographic business, would come to terms on three years' apprenticeship. Could you give me advice whether a black-and-white agreement is binding as to time served and other articles of agreement, without the services of a solicitor? As I am not receiving any premium. I should like to avoid all further expenses."—In reply: Yes, if properly drawn out and duly stamped. The indentures should, however, be drawn out by a solicitor, so as to make sure that they are properly done. We suppose you are aware that an apprentice is not bound to serve after he becomes twenty-one years of age.

LECTURE ON COLOUR PHOTOGRAPHY.—H. FRANKTON writes: "Might I ask your assistance in the production of a short lecture upon colour photography? I have to give one of about half an hour's length in about a fortnight, and it occurred to me that you might have something of the kind that you would give me the loan of, or, failing a complete lecture, one or two articles upon the processes invented in that direction."—In reply: In THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1898 we gave a simple outline of the principal processes of colour photography. If our correspondent does not possess or cannot procure the volume, we recommend him to obtain a "Handbook of Photography in Colours" from Messrs. Marion and Co., Soho-square—unquestionably the best book of the kind yet published.

SPOTS ON PRINTS.—"MATT-COLLODION" writes: "Could you tell me the cause of spots on enclosed prints? Those two were mounted to-day, and spots appeared a few hours afterwards. They are collodion prints, mounted with gelatine. They were very carefully toned washed, &c., by myself. I mounted a number of same batch on gray cabinet mounts, and see no signs of spots. I am inclined to blame mounts, but will await your verdict. I have prints by the same paper which are as good as newly done after a number of years. This fault has only lately crept in."—In reply: As the spots are noticed so soon after mounting, we suspect they existed in the prints before they were mounted, and that they could have been seen had they been carefully examined. If there were any faults in the mounts, it would not affect the prints in so short a time, and the same may be said of the mountant. If that were acid, as some gelatines are, it would not show its evil influences in a couple of hours.

LENS FOR STUDIO WORK.—"Rapid" writes: "(1) Kindly inform me of the cheapest and most suitable make of lens for instantaneous studio portrait-taking, and about the price of one to take from whole-plate downwards; also kindly inform me how in purchasing I am to ascertain whether, at a distance of twenty feet, I can take a full-length C.-D.-V. photo. My studio is well lit, and I should for instantaneous work (children) use special rapid plates; but I realise that speed rests with the lens a great deal. (2) Also the best and cheapest made burnisher (gas) for P.O.P. prints."—In reply: (1) The best lens for the purpose is the usual portrait lens. The price will vary according to the maker. Better get catalogues from different makers and see whose price suits your pocket best. Price and quality generally go together. On page 1,130 of the ALMANAC you will find a table giving the size of image, at different distances, with any focus lens. (2) It is against our rule to recommend any particular maker's goods. Better consult the advertisement columns.

COLLODION DRY PLATES.—"I. G." writes: "During the past seven or eight years we have occasionally used (for making lantern slides) the Hill-Norris dry plates; these gave great satisfaction. In my hands the results have always been really excellent, and I found the plates to possess the following special features:—(1) That almost any ordinary negative developer could be used with them. (2) They do not require any more care in handling than gelatine plates, while possessing the advantages of speedy washing, easy intensification with silver, &c. (3) That they could be obtained in varying degrees of sensitiveness. (4) The plates kept well. I have a few by me that have been kept six or seven years and do not seem to have suffered in any way. I am informed by Mr. Tylar, of Birmingham, that, owing to the limited demand, Dr. Hill-Norris has given up his plate factory and is devoting the few remaining years of his life to other work. I have heard this with much regret. Although our own use of these plates is very limited, I should have thought there would have been very many persons who would have appreciated the results obtainable on collodion plates, especially when the trouble of wet-plate work could be avoided. Could you kindly inform me (a) whether you know of any other collodion dry plates on the market possessing qualities similar to those I have mentioned. (b) Could you refer me to any special treatise or articles specially dealing with the preparation of collodion dry plates and indicating methods to be adopted to secure (1) variations in sensitiveness as required; (2) good keeping qualities; (3) a plate that will stand any ordinary gelatinobromide plate developer, and (4) a plate that does not require special care in handling?"—In reply: If Dr. Hill-Norris has ceased making we do not think there are any dry collodion plates on the market. So little has been done in the direction of dry collodion of late years that all we can do is to refer you to back volumes of the JOURNAL—say fifteen years or so back. Formulæ for collodion-bromide emulsions are given on pp. 1,089-1,092 of the ALMANAC. All of these are well suited for lantern transparencies.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1901.

Edited by THOMAS BEDDING, F.R.P.S.

THE Fortieth Annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published next week. The total number of pages in the 1901 ALMANAC is 1552, and the volume is the largest yet produced. The text portion of the book occupies about 500 pages. It will, as hitherto, be issued in paper covers, price 1s., or cloth bound, 1s. 6d.

The frontispiece is a bromide print by Messrs. Morgan and Kidd, of Richmond, Surrey, from a negative by Mr. W. Crooke, of Princes-street, Edinburgh. A number of other illustrations will also be found in the text matter. Over eighty articles on practical subjects, contributed by well-known photographers, form a feature of the volume. The principal advances of the year are synthesised in the "Epitome of Progress During 1900," and in the other sections, "Patented Inventions of the Year," "Miscellaneous

Information," and "Practical Notes and Suggestions of the Year," there will be found much useful matter, which, with the large collection of formulæ, tables, and other data for photographers, places at their disposal for daily reference a mass of information not to be found in any other photographic annual.

\* \* The 1898, 1899, and 1900 editions of the ALMANAC (20,500 copies) were each sold out within a few months of publication.

## EX CATHEDRÁ.

WE learn from photographers in various parts of the United Kingdom that high anticipations have already been formed of a successful meeting of the Photographic Convention of the United Kingdom at Oxford in July of next year. It is agreed that no more interesting, central, and beautiful a meeting place could have been chosen. Thus early the local Committee has taken in hand the work of organisation. Mr. G. W. Norton, the Hon. Secretary of the Oxford Camera Club, who will also act as Local Hon. Secretary of the Convention, informs us that a working committee of 30 has already been appointed and that a Reception Committee is also in process of formation. The President-elect of the Convention for 1901-2, Sir William J. Herschel, is also President-elect of the Oxford Camera Club. Next year it may be presumed that the distracting effects of the war and the Paris Exposition will no longer be making their influences felt, and that the Convention will be beneficially affected by a large attendance. It is, of course, full early to discuss preliminary arrangements, but perhaps Conventioners generally will be interested in knowing that at the first meeting of the Oxford Camera Club for the New Year an address will be delivered by the present President of the Convention, and that a part of the evening will be set aside for a short lantern lecture on the subject of past Conventions and some of their principal features.

\* \* \*

At a recent meeting of one of the metropolitan societies a paper was read entitled "The Intensification of Carbon Prints." The paper will be found on page 725 of our issue

for the 16th ult. The title of the paper would naturally lead one to imagine that it was paper prints that were being dealt with, but we opine that it was transparencies or negatives on glass or other transparent media that were referred to, for it is difficult to conceive how any carbon print on paper could well be improved by "intensification," particularly by the methods described, as, after all, it is simply dyeing with coal-tar colours—which we all know are of doubtful stability. Also, of course, the paper would be dyed as well as the gelatine. However, as we have just said, we assume that carbon transparencies or negatives were really meant, and it is to them that what we shall here say applies. There are many methods of intensifying carbon transparencies and negatives that are well known, and have been for decades past to practical carbon workers, without having to resort to coal-tar colours, though, apparently, from the paper referred to, they do not seem to be known to some. That coal-tar colours are very undesirable ones to employ in connection with gelatine goes without saying, when the same end may be obtained with others of undoubted permanency. The carbon process is one of permanence, but if, say, a window transparency that has to be printed from or a negative be "intensified" with a fugitive dye, one can well realise what the result would be after a more or less brief period, and, of course, it would be a retrograde step to employ any such means. There are, however, a variety of methods of rendering the pictures denser, and modifying their colour, by the deposition of more pigment in the gelatine film, and that may be of any desired colour.

\* \* \*

ONE of the oldest, best, and simplest methods of intensifying carbon transparencies or negatives is with a solution of permanganate of potash. That is one of the earliest, and the one employed by Lambert in the contertype process in the early seventies. With it all that has to be done is simply to pour over the surface of the picture a solution of the permanganate until the desired density is obtained. The strength of the solution is very immaterial—the stronger it is the more rapid is its action, and the weaker it is the longer does it take to do its work. This is a real intensifying process, inasmuch as an oxide of manganese is deposited in the film, and this is a permanent pigment. Carbon transparencies can be intensified with silver in exactly the same way as collodion negatives are intensified. The dry transparency is immersed for a few minutes in, say, a one per cent. solution of nitrate of silver. It is then slightly rinsed under the tap, and the usual acid pyro intensifying solution poured on with, if necessary, a few drops of solution of nitrate of silver added, until the desired density is obtained. This method yields a fine brown tone very suitable for lantern slides.

\* \* \*

TONES of velvety black (more or less purple) can be obtained by simply immersing the transparency in a dilute solution of, say, the perchloride of iron, and, after slight rinsing, treating it with a solution of gallic or pyrogallie acid. In this way gallate of iron is formed in the film. By substituting other salts of iron for the perchloride, and in the place of using the gallic acid employing an infusion of nutgalls, tannin, logwood, &c., a great variety of purple black tones may be obtained, which are permanent. If

we desire a bright blue, it can be obtained in this way. The picture is first put into a solution of a proto-salt of iron—say the proto-sulphate—and after rinsing the surface it is then immersed in a solution of ferro cyanide of potassium—the yellow of Prussiate of potash—when Prussian blue is precipitated in the gelatine film, another permanent pigment. Should we desire a yellow, we obtain it by first treating the picture with a solution of acetate of lead, followed by one of bichromate of potash. In this way we get the yellow chromate of lead—a permanent pigment—deposited in the film, which becomes very non-actinic. A bright red is obtainable by first treating the transparency with iodide of potassium, followed by bichloride of mercury. In this way we get the red iodide of mercury—a pigment with somewhat doubtful stability.

\* \* \*

THE methods here described are analogous to those employed by dyers in dyeing fabrics, and an actual solid pigment is formed in the gelatine film in addition to what it already contains. The intensification of carbon pictures, it may be explained, is entirely different from that of the intensification of gelatine negatives. In the latter it is the material forming the image—*i.e.*, the silver—that is acted upon, the vehicle holding it—the gelatine—being inert. With the carbon picture the case is just the reverse; here the pigment remains inert, and it is the gelatine only that is affected. For this reason, when carbon transparencies have to be modified by after treatment, a tissue should be chosen, which is thin, of pigment, so that the light penetrates deeply into the film and thus secures a maximum thickness of gelatine, while there is a minimum of pigment; for it must be borne in mind that whatever colour we obtain in the after treatment must, necessarily, be plus the colour in the tissue.

#### SIC TRANSIT.

WHY is it that photographs which perhaps we admire very much when they first come before us with the charm of novelty, seem to lose their attraction, or even to become absolutely distasteful after a certain lapse of time? That portrait of ourself, for instance, how we extolled its merits at sight, and thought it almost beyond the possibility of improvement; and now we take it out of its frame, and relegate it to obscurity, without a kind word or regret.

Is it that familiarity has bred contempt—a survival of the principle that, like a child with his new toy, old favourites get discarded in favour of the latest comers? Shall we say that in infancy and childhood things please but a short time, and as we grow older they charm us longer, but still never lastingly? If so, why are we not tired of our old paintings, our antique furniture, and those dainty odds and ends of bric-a-brac which delight the eyes of the modern housewife? Is it that these latter have an abiding beauty that time cannot destroy; that in their way they are perfect, while the photograph has an inherent imperfection that becomes more and more visible with further acquaintance?

First of all, however, we must not forget to take into consideration the fact that photographs tend to deteriorate with age. This is, of course, most marked in silver prints, but, in spite of their theoretical permanency, even platinumypes and carbons do not escape. To be sure, in the latter it

is the paper or support which goes wrong, rather than the image, but the evil effect is there all the same. If it were simply that we miss in our older photographs that sparkle and brilliancy of tone and colour which at first so pleased us, the difficulty would soon become cleared up. But no, after all this is a very superficial view of the question. It is beyond doubt that photographs often cease to please long before the unkind hand of Time begins to touch their pristine beauty. Perhaps, then, it is the originally imperfect picture, whose imperfection was hidden from our tolerating sight when its first beauties were seen, but which further acquaintance reveals to our now more critical judgment.

Suppose, for example, a picture in every way excellent, but with just one trivial fault in composition only be noted by the eye of an expert after careful scrutiny. Nine people out of ten, probably, will miss the flaw, and give a whole-hearted praise to the work. But after a while the excellences of the picture are taken for granted, and the eye grows more and more discontented with the lurking fault, all unconsciously perhaps, and without ability to give a name to the cause of its dissatisfaction. Let us call to mind a certain famous exhibition portrait, medalled at the "Royal," and once quoted everywhere as a perfectly satisfying and superb specimen of art and technique. Only recently some of us may remember to have read of the same picture, now again shown amid other surroundings, as hardly producing that feeling of pleasure and admiration which it at first excited. Better knowledge of the picture has not, however, revealed any fault; it still remains as an unchallenged type of photographic skill. What, then, is that mysterious "something" which has stepped in to prevent its continued triumph? It has not been placed alongside better pictures, nor even with those equally good, and yet general opinion agrees that it has lost in attraction—where once it was "facile princeps."

For the purpose of arriving more easily at some conclusion, we will limit our ground to the consideration of portraits. There is no really valid reason why what is said should not apply equally well to all photographs, but it will undoubtedly be easier to understand our likes and dislikes if we confine ourselves to a narrower road. We want to get at those first principles of Art which come into vital contact with photographic practice. Sometimes an anecdote lightly told may throw invaluable illumination on a doubtful point. A tale that has its lesson for us appeared lately in a well-known daily newspaper. The Pope, it seems, was giving a sitting to a famous English portrait painter. "How old you are making me!" said the venerable ecclesiastic, as his lineaments grew more visible on the canvas. "But are you not old, your Holiness?" deprecatively suggested the artist. "Ah, that may be," said the Pope. "But the idea I represent—the Papacy—is always young!"

Here we have an exponent of religion and morals unconsciously giving sound artistic teaching. The best picture is not that which most closely imitates nature. As Sir Joshua Reynolds observes:—"So far, therefore, is servile imitation from being necessary, that whatever is familiar, or in any way reminds us of what we see and hear every day, perhaps does not belong to the higher provinces of art, either in poetry or painting. . . . If our judgments are to be directed by narrow, vulgar, untaught, or rather

ill-taught reason, we must prefer a portrait by Denner, or any other high finisher, to those of Titian or Van Dyck, and a landscape of Van der Heyden to those of Titian or Rubens; for they are certainly more exact representations of nature."

But what has all this to do with photography? Why simply this, we are getting appreciably nearer to an understanding of how and why a photograph loses its charm for us. One more anecdote, this time about Sir John Millais, may serve to rivet the point. The great artist was painting a landscape out in the open fields, a curious rustic meanwhile gazing over his shoulder, with that calm, unabashed curiosity which only a rustic can show. "Did ye never try fertography, sir?" said the latter at last. "No," said Sir John, tolerantly. "It's much quicker," resumed the yokel. "Yes, it is," rejoined the artist. "And it's more like," concluded his critic, with a semi-pitying inflection, after a few minutes' profound silence.

That was the judgment of a rustic, altogether. It is precisely because the photograph is "more like" that it is, in esse, farther from the artistic ideal. It is too like, and it is this over faithful rendering of everything that is one of the greatest obstacles in the way of those photographers who aim to produce "things of beauty" that shall be a "joy for ever."

There are photographs, to be sure, that one never tires of, though they belong to a very small and select minority. An examination of such works will show, almost at a glance, what pains the producer had been at to avoid everything that jarred on an harmonious effect, and how he must have waited patiently till the exact moment came for obtaining a pleasing result. Then, also, it is generally evident how he has taken care to avoid too closely copying his subjects.

The camera is liberal to excess in what it gives us: the mechanical fidelity and exactness with which it reproduces everything before it is its most serious drawback, when that beauty which falls not is desired. The minute rendering of the texture and material of a coat or dress, with its every peculiarity of style and cut; the seizing of one momentary, fleeting expression of the face, rather than its normal characteristic look; in a word, the emphasising of all that we would most fondly suppress, are terrible obstructions to the photographer who wishes to produce broad and sympathetic work. Then, again, photographers are, on the whole, very apt to adopt mannerisms, and to follow too obediently what is considered "the right thing" in their own little coteries. And so we find the pictures that once were raved about and captured full many a medal looked down upon as early and crude examples, very good in their day, perhaps, but now quite improved out of existence.

In order that a photograph may have a lasting title to be considered a work of art, its producer must, necessarily, be well aware of what is artistic and what is not. In addition, he must be thoroughly master of his business, so that his work may obey his control, and show forth his individuality. With these preliminary qualifications, he will need strong self-restraint to prevent him making that full use of the possibilities of modern lenses, which is so fatal to breadth and harmony, also originality and daring to overstep conventional methods, and to defy the dictates of fashion and custom.

As an instance of what a photograph should be, many of

us may remember an excellent portrait of Her Majesty the Queen, produced by a photographer whose name is a household word at the time of her Diamond Jubilee. We look at it still with unabated pleasure and interest, and feel quite sure that future generations will do the same. The technique is perfect, the pose and expression so natural and characteristic that the picture seems to tell the story of a life, the history of an idea, rather than the changing aspect of an hour. Let us compare it with so many other portraits of celebrities, that have been or are being produced, and very little consideration is needed to show how artificial and stilted so many of them are, in obedience to false ideas. The photographer needs to study more, to compare the productions of his camera with those of the other arts; not attempting that which is beyond his province, but striving to turn out the very best that his craft is capable of, in full assurance that that way lies an abiding success—a success, moreover, of which he need never be ashamed, since it will represent to him the triumph of conscientious and able work, attained by patient and honest adherence to that which he knows is true and beautiful, yet not too beautiful to be true.

**Nickel Light.**—For some time past it has been understood that sulphate of nickel, crystallised with seven molecules of water, was included in the list of substances acted upon by light; but quite recently a paper by E. Dobroserdoff, has been published in the *Journal of the Russian Physical and Chemical Society*, in which he proves the belief to be erroneous. He says if the crystals occupy a small portion only of the containing vessel they lose water, falling into another state of hydration, whether light is allowed to fall upon them or not. And, again, they are not changed by the action even of strong sunlight, if the air surrounding the crystals is saturated with water, nor if kept in filter paper saturated with turpentine, nor yet if the containing vessel is filled with the crystals.

**Time and Labour involved in Preparing the Star Atlas.**—To the outside observer who knows that the heavens are mapped out into small regions, each of which is taken charge of by a particular observatory, for the ultimate production of the great Photographic Star Atlas, it would seem a simple affair enough to tabulate and count them. But the recently published report of the Melbourne Observatory contains some interesting data, which are well worth extra charge, to show the immensity of the task involved. They have published catalogue plates of regions above 80° of declination, and many of them have been exposed in triplicate, so as to prevent any error, by giving three images of each star. A special micrometer for measuring the stellar images has been constructed, and is now successfully at work. It is estimated that the total number of stars on these plates is about one million and a half. Two observers, relieving each other every hour, measure from 400 to 500 stars per day. The authorities hope that six observers working six hours daily each, and making use of three efficient measuring machines, will be able to get through the whole of the work in about six or seven years!

**Lantern Exhibition by Colonel Gale.**—At the Royal Photographic Society's Lantern Meeting on Tuesday evening last, Colonel J. Gale exhibited about a hundred lantern slides from his own negatives, which he described generally as "Pastoral and Sundry." This title, if somewhat indefinite, was quite appropriate, for the collection included a very wide range of subjects—haymaking and carting, ploughing, sheep and cattle, sunrises and sunsets, storms, figure studies, and indeed, examples of almost everything, with the exception of the purely architectural. Almost every slide was a

perfect picture, and effectually controverted the assertion which has sometimes been made that an artistic lantern slide is an impossibility. Many of the photographs were taken at the outings of the Amateur Photographic Field Club, an organisation which was founded in 1858, and is probably the oldest photographic society in the world. Its meetings, according to the official statement, are held 'By Mead and Stream,' and Colonel Gale's pictures afforded ample evidence of their pleasurable character. Several of the slides were representations of scenes which now no longer exist; for, as he remarked of one of them, "I took it last year—this year the County Council have taken it."

**A Reproach Removed from X Rays.**—In the early days of X-ray work a strange affection of the skin was produced in the hands of some of those who had been demonstrating their properties to the public. As their use became more fully understood, it was found that acute dermatitis or inflammation of the skin, and a destruction of the hair, were set up by directing the rays for a sufficient length of time upon a particular portion of its area. It is evident, however, that there is something more yet to learn as to the exact action of the rays, for, at a recent meeting of the Vienna Society of Physicians, Dr. Krenböck introduced a man on whom the rays had had an exactly opposite effect, in fact his baldness was cured by them, although he had lost his hair some years ago. A round patch on the scalp was exposed six times for fifteen minutes to the rays, and the treatment extended over two months. The parts of his scalp untreated remain as bald as ever, but on the treated portions the hair has come again, thick and dark-coloured as of old. The subject is one that has so long been the practice to treat from a peculiar standpoint but at the same time it is obvious that we have very much more to learn about the action and properties of Röntgen's wonderful discovery.

#### MR. H. DAY'S CRYPTOGRAMS.

THE great American Republic has produced some of the keenest intellects of the century, and some of the biggest quacks, and of these last "Christian Scientists," "horse dopers," and "freak photographers," are the lowest and crudest types.

We sons of the old country welcome to our shores both kinds; but we respect the one, and use the other for amusement, as our kings in the old days kept paid fools or court jesters.

But what is one to say when our old Society welcomes and prints such puerile nonsense as Mr. Day's opening address? We are constrained to beg the rulers of our Parent Society in future to abolish these opening addresses, which can but bring ridicule upon us, and to leave such babblings for the columns of the *Amateur Journalist*.

But to traverse this tissue of ill-conceived, ill-written, and illogical babble.

We are told there are two schools in the wonderful country of the wooden nutmeg—the old and the new, and that *all* are leaders; and so the worthy tradition of Charter oak is maintained, and Washington (who never told a lie) is not stultified. Think of it. Two schools, the old and the new, and all "leaders." Now, did we not read various American magazines, we might be inclined to swallow this statement; but this so-called new school has been repudiated in the land of its birth, and we in this country have seen many photographs of the so-called, arbitrarily named, "old" school more worthy of regard than the "spoiled prints" of the braggart new school. And it is all the funnier because, in sober truth, *there is no American School of Photography at all*. The motifs, methods of presentment, and even argument for recognition, are just thefts from Great Britain. Nothing new has the American photographer devised, he is a follower, an imitator, but no originator; the best brains of the land of the dollar being engaged in pursuit of the elusive oof-bird. We in Great Britain are glad to see and welcome what the scholars of *our* school are doing; but let Mr. Day learn at once that the educated British public will not stand for a moment his unblushing effrontery, egotism and braggadocio, though it will welcome some of his best photographs.

And here I am bound with true British brutality to tell Mr. Day that he must learn to speak and write the English—our—language. To

write correctly and lucidly is an art far more difficult of acquirement than the production of "artistic" photographs. I cull some choice specimens of this Photo-Americanese.

"That we have in the States two distinct Schools of Photography is far more apparent than in the work I have had the pleasure of knowing as produced here."

"A smile. . . that suspects its own justice" beats wooden nutmegs and "freak photographs"—"a special (sic) theoretical differentiation," is a wonderful thing—and so is a "colour portrait." Explain this, men and angels—or this: "How many, I wonder, in discarding a piece of camera work, stop to consider from what it is they remove it?" and—prodigy of down East Yankeedom—what is "a visual colour?"

Poor, poor Mr. Day, who suffers from the itch of scribbling, you really must not bring such trash to this country, for we have a large educated public here. This is not America, the appreciator of E. P. Roe, the novelist?

To follow Mr. Day with his illogical, paste-and-scissors defence of photography as a fine art were to court madness, for there is no logic in the whole thing: much ignorance—i.e., the condemnation of our theatrical posters, many of which are art-works, the comparison of instrumental machine drawing with Da Vinci's hand drawing, to quote the poor babbler and moralist, J. Ruskin, in one of his most obtuse passages, e.g., "that manhood which has light in itself—though *the eyeball be sightless*," that mad creation which though blind, sans eyes, sans mouth, sans breath, sans anything, can yet shriek hysterically, "Behold, it is I." Poor Ruskin! poor Day!

Mr. Day wants educating badly, very badly. Many, many artists in this country and abroad have approved of the work of our British photographers when Mr. Day was wisely obscure; many trained artists (trained too in France) have practised photography long before the artists whose names he quotes as though they were some newly developed race of men carrying their heads beneath their arms, and their cameras on their necks. Yes, poor, poor Mr. Day! you should truly have informed yourself, it has all been tried and rejected in England, years and years ago, for we have found the drawing of the lens is not as the drawing of the artist; and photographs, it has been proved by artists and by some of our best writers, are false as Judas to the form of things as we see them, and even Mr. Demachy has at last learnt this lesson.

The speciousness of Mr. Day's time-worn propositions about the individuality of the print requires no answer—the wise on this side never dream of advancing such an exploded thesis. Poor Mr. Day!

And lastly, we resent as vulgar and false the braggart statement that these photographers across the seas "are one or two steps in the fore-front."

Mr. Day, we understand, is new to this country, and we cordially welcome him as a photographer—a professional photographer we believe he is; but we must warn him that our educated classes are not so gullible and raw as his American public, and, in fact, that he has got into bad company here—the company of the ex-counter-jumpers and gutter journalists, who are ignored by our cultured people, and we would ask him to heed Carlyle's famous words, "Silence is golden," and to take Mr. J. C. S. Mummy's most sensible advice "to make good his claims by his work." ARGUS.

## THE OPTICS OF TRICHROMATIC PHOTOGRAPHY.

[The Third Traill Taylor Memorial Lecture.]

### III.

ATTENTION is here called to the fact that in this device the reflecting surfaces were inclined to the optical axis in the perpendicular plane; and there is no publication of the idea of inclining them in the horizontal plane previous to 1894. Chas. Cros, in a communication to the Photographic Society of France, in 1879 ("The Review of Games, Arts, and Sports," February 15, p. 221), in describing a transparent mirror device, expressly states that the mirrors are inclined at 45° to the *sides* of the box. Neither this nor any other persistence of vision device for this purpose has ever come into practical use.

The next conception of a photo-chromoscopic device was my own, for which I applied for a patent in February 1892.\* In this device, the two transparent and one silvered reflector are supplemented by additional silvered reflectors disposed in parallel planes, in such manner as to dispose all the images on one plane, and the doubling of outlines was avoided by employing slightly wedged clear glass reflectors. This instrument could not well be made stereoscopic, and although perfect in its performance as a monocular photo-chromoscope, it was too costly and delicate in its adjustment for commercial manufacture.

In March 1894,† C. Nacet, of Paris, patented a device in which two of the images were blended to the right eye by the aid of a thinly silvered or platinised mirror, and the third image, made from a different view point, was seen directly with the other eye. This was an attempt to make a combined photo-chromoscope and stereoscope—but, owing partly to the fact that very few people (if any) can successfully "blend" two primaries through two eyes, it was soon abandoned. This idea, first published by M. Nacet, is fully set forth in the *mémoire* attributed to Louis Ducos Du Hauron as of the date July 14, 1862, but first published in 1897: nevertheless, it is credited to Nacet on page 360 of the same book in which it first appears as belonging to Louis Ducos Du Hauron in 1862.

In September 1894, Carl Zink, of Gotha, published a description of a photo-chromoscope having three rectangular "steps," and two transparent and one ordinary silvered mirror, and a "cosmorama" lens. The new features in this device were the horizontal disposition of the steps, inclination of the mirrors in the horizontal plane, and all disposed to reflect from their upper surfaces, and an adjustment of angle to secure the best direct illumination of the reflected images. A horizontal disposition of the three mirrors had never before been published, although it appears in the Du Hauron 1862 *mémoire* already referred to, with one of them disposed to take the reflection from the under side. Zink's publication was anticipated by my application for a patent upon the same and several other important improvements in the "step" photo-chromoscope with transparent mirrors. My patent application, dating July 3, 1894,‡ discloses on only the arrangement shown by Zink; but (1) an efficient contraction to two steps instead of three, whereby the apparent area of the picture is nearly doubled, (2) the use of coloured glass reflectors by which doubling of outlines is avoided without the use of convex lenses or "thin silvering,"§ and the construction and adjustment proportionately simplified, (3) a stereoscopic construction, whereby the illusion of reality is brought to perfection, (4) a modification by which the images are disposed in line upon a single plate.

None of these ideas had been published before my dates of record.

Some months after the publication of my patent, Nacet claimed the same construction on the strength of a clause in his patent which was to the effect that two transparent mirrors instead of one could be used in his three-image stereo-chromoscope. The natural inference from the wording of this clause was that he meant one in front of each eye, the construction since adopted in the "Kromaz," and not an arrangement involving a totally different idea like my own. Even if it is assumed that he may have meant that two transparent mirrors could be used in front of one or both eyes, the fact that he so disposed his transparent mirror as to reflect from *below* proves conclusively that he had then no thought of direct lighting of the reflected images and the use of a folding chromogram, which I patented and which he reproduced, along with other details shown in my patent drawings, such as a tray base and strut for fixing the inclination, months after the publication of the patent.

Inclination of the mirrors in a horizontal plane, with the reflections

\* U.S. Patent No. 475,084, published May 12, 1892.

† French Patent No. 237,394, March 29, 1894.

‡ U.S. Patent No. 531,040, published December 18, 1894.

§ The possibility of employing coloured glass reflectors was first disclosed in my U.S. Patent No. 475,084, published May 17, 1892; but the particular relation of the colours of the glasses to the respective images was first published in the *Journal of the Society of Arts*, May 19, 1893, p. 666, and patented in the U.S. in 1894. In his treatise published in 1897, Alcide Ducos Du Hauron publishes this for the first time as a proposition of his own: and it is only one of many ideas which have been claimed by Du Hauron only after they had been published or patented by others. Even Clerk-Maxwell and Harry Collen are totally ignored in this book.

taken from the upper surfaces, and the three images disposed in line upon one plate, patented and first published by me, also appears in Du Hauron's Melano-chromoscope.

As before stated, inclination of the mirrors in a horizontal plane, but at opposite angles, is disclosed in the Du Hauron 1862 mémoire. It is remarkable that the three-image stereoscopic construction patented by Nachet in 1894, a stereoscopic construction with three pairs of images, a two-step construction, methods of stereoscopic projection, and other ideas first made public by others, appear in this mémoire, and are first published as Louis Ducos Du Hauron's inventions twenty-eight years after he was challenged by Charles Cros to show a record antedating Cros' sealed mémoire of 1867. Du Hauron's reply to this challenge appeared in *Cosmos*, July 24, 1869, when he said, "I myself could have, at the conception of my idea [which he then dates back 'five or six' years] consigned its generalities to a sealed letter . . . I gave up to the higher ambition to give to society and to France a system of heliography sufficiently elaborated," &c. This is his reply in 1869, seven years after it is now stated that he had prepared expressly for presentation to the Institute of France a mémoire of nearly 3000 words, describing a remarkably elaborate system, and that this mémoire was duly acknowledged and commented upon by M. Lélut, and read by at least one other member of the Institute, preserved all this time, and even now referred to as a "publication" in 1862. Although it may be inferred that his failure to get his mémoire presented to the Institute decided him to try to reduce the method to successful practice before trying again, it would seem most natural that he should have produced such conclusive proof of priority in reply to Cros if he was able to do so.

It is quite probable that the inconsistencies which I have noted may be satisfactorily explained away, but it seems proper, under all the circumstances, to raise the question, and I hasten to say that, for reasons well known to many, this can be done without questioning the integrity of Louis Ducos Du Hauron. I don't think the question would have been raised in my own mind if I had not already regularly found my own published ideas reappearing in France as French inventions, dated back without evidence, and my own publications totally ignored.

My 1894 "two-step" photo-chromoscope (to which I have given the distinctive name Kromskop) has never been rivalled by any other form of viewing device, and has been finally perfected by two "improvement" inventions.

As originally constructed, it was found that the inclination of the transparent reflectors between the eye and the green image introduced such a distortion of that image that the red and blue images, reflected from plane surfaces, could not be perfectly superposed upon it. The reason for this can be readily shown by tracing the path of the rays from the top and bottom of the green picture to the eye, both direct and as changed by refraction through the inclined transparent mirrors, the amount of distortion depending upon the thickness of the glasses; but I need not take up time with such a demonstration here. Suffice it to say, that I soon found two ways of correcting this defect, both of which were rather unsatisfactory from the manufacturer's point of view. One was to employ slightly wedged reflectors, so disposed as to correct the distortion, and the other was to introduce a similiar distortion in the reflected images by attaching springs to the reflectors, so as to make the reflecting surface slightly cylindrical.\* The first method, although efficient, called for weakly prismatic glasses, which cannot be obtained of sufficiently uniform accuracy by commercially practicable methods of grinding and polishing. The second method, although quite practicable in a commercial manufacture, is less perfect, and somewhat clumsy and troublesome. The final solution of the problem, a most obvious one when you come to think about it, was the introduction of a plane glass under the red image, equal in thickness to the sum of the two transparent mirrors, and inclined at the same angle.† This leaves the blue image uncorrected, but the error is only one-half what it would be in the red, and is of far less critical importance in the result, so that the image is now satisfactory to the eye. A kromskop made up without this compensation would now be instantly condemned.

\* U.S. Patent No. 622,480, published April 4, 1899.

† U.S. Patent No. 635,253, published October 17, 1899.

Another defect which troubled me for a long time grew out of the fact that the coloured glass reflectors have polarising properties, while the silvered mirror which illuminated the green image did not have this property. With a grey sky as a source of illumination this did not much matter, but with a polarised blue sky the amount of light reflected by the transparent mirrors of the red and blue images varied with the angle of polarisation, so that an instrument which gave a bluish-white field when pointed to a portion of the sky near to the position of the sun, would give a yellowish-green field when pointed in a different direction, towards a part of the sky which appeared still bluer to the eye. The amount of light reflected from the silvered mirror was the same for all positions, but the amount reflected by the transparent mirrors sometimes varied enormously. There are half-a-dozen ways in which this defect can be lessened, but it is now eliminated by substituting a bundle of glasses for the silvered reflector in front of the green image.

The fields of the kromskop also became green by reason of the light gradually darkening the red screen, and this defect has been remedied by employing a different colouring material.

With these and other detail improvements, the performance of the kromskop is perfect, and, although the public is slow to appreciate its value and importance, it is coming into use in the United States in the fields of entertainment, art, medicine, and commerce, and will probably be regarded as a necessity for many purposes in course of time, as it is the only means of producing perfect visual reproductions of thousands of objects.

Another form of the instrument, which I call the "miniature" kromskop,\* is a modification of one of the plans of construction which I showed in the original patent, permitting of disposing the three images in a line upon a single plate. To simplify the construction, images of the kromogram are looked at obliquely, and the consequent distortion corrected by introducing a prismatic lens and a 7° prism. This construction is practically very much cheaper than anything else that has been proposed, and the images, although small, appear larger than in the far more costly melano-chromoscope, which Du Hauron has produced by grafting some of the same ideas upon his original conception. Probably, I should say, which Alcide Ducos Du Hauron has produced by grafting some of my ideas upon his brother Louis Ducos Du Hauron's original conception.

With the exception of the "miniature" kromskop, all the forms of photo-chromoscope can be adapted for making the photographic colour records; but not one of them is a desirable construction for a camera, and no one who knows all the requirements will waste his time trying to make them interchangeable. Even if the general plan was suitable for both purposes, it would be both better and cheaper to construct two instruments, one specially adapted for each purpose, than to provide all the substitutions and readjustments necessary to make a single one efficiently interchangeable. This conclusion has been forced upon me after making several interchangeable instruments myself, and examining those which have been made by others.

Moreover, the most efficient viewing instrument is the kromskop, with images in three planes, and no camera for making kromskop pictures will ever prove permanently satisfactory unless the three images are produced upon a single plate. I am so sure of this that I would feel justified in ignoring all three-plate cameras, but for the fact that the construction of some of them involves ideas which also enter into the one-plate cameras, and have had a part in their evolution.

The idea of employing as a camera an instrument essentially like the kromskop, with dark slides attached, is a favourite one with many; but, besides the objections to trying to make such an instrument efficiently and conveniently interchangeable, and the objection to trying to use three separate sensitive plates, it has some very serious optical defects as a camera. In the first place, the illumination of the images will be uneven, because the amount of light reflected from a transparent mirror varies with the angle of incidence, which differs for different parts of the cone from the objective, and the illumination of the images formed by rays reflected from the transparent mirrors is greatest just where it is weakest in the image formed by transmitted rays, or by reflection from

\* *Journal of the Photographic Society of Philadelphia*, March 1900 p

succeeding silvered mirror. In the second place, the proportionate illumination of the three images necessary to make the exposure required equal for the three plates cannot be readily controlled except by the use of compensating screens at the objective, which are almost certain to upset the selective absorption, especially if in the form of a party-coloured adjustable diaphragm aperture.

In the third place, the polarising properties of the transparent mirrors will under some circumstances introduce serious errors in the colour record. This is an important matter, of which I shall speak again. Here are five counts against trying to make an efficient camera out of an efficient photo-chroscope.

Louis Ducos Du Hauron divorced cameras and viewing instruments at an early date.\* He originated the method of controlling the relative degree of illumination of the three images by employing three objectives and three separately adjustable diaphragms, a principle which I once thought belonged to me; but he does not appear to have recognised the necessity of correction for unevenness of illumination across the images, which I accomplished by inclination of the diaphragms in the optic axis. This may appear to be a small matter, but the absence of such correction really constitutes a fatal defect.

The next step was to dispose the three images upon one plate, and this I did in 1892,† in trefoil, and in 1895,‡ in a line. In 1899,§ I devised two new and simpler transparent mirror cameras disposing the images on a line. Hundreds of successful negatives have been made with the 1895 cameras; the 1899 cameras, although equally efficient and of much simpler construction, will probably never come into use because already superseded by a still simpler camera of a different type, which I have since devised, and which, at least as a view camera, can have no rival.

Now, with respect to the defect introduced into triple cameras by the polarising properties of transparent mirrors of glass, a defect which nobody else has yet noted. Suppose that we have a camera with two transparent and one silvered mirror inclined in parallel planes one behind another in the optic axis, and that we are photographing a landscape view in which there is a portion of polarised sky. Naturally, the red image will be formed by reflection from the silvered mirror, and the blue and green images by reflection from the transparent mirrors. If the sky polarisation is at such an angle as to oppose free reflection from the transparent mirrors, the sky will be under-exposed in the blue and green images relatively to the other parts of the view, but will be fully exposed in the red image; in the reproduction the colours will be quite incorrect. The same will be true if the red image is made by light directly transmitted to the plate through the transparent reflectors. Other complications arise if one of the transparent mirrors is inclined in a perpendicular plane, and the other in a horizontal plane. In either case, every coloured surface which has polarising properties may be expected to be falsely rendered.

There is a remedy for this defect, so far as it applies to polarised skies. By placing a quarter-wave mica film in front of the camera aperture the light may be circularly polarised before reaching the transparent reflectors, and it is then reflected like unpolarised light. The mica film should be in a revolving mount, in order to set it always with the axis at 45° to the plane of the incident polarised ray.

It is true that the setting of the quarter-wave film, which is correct for the sky, may be quite wrong for other polarising objects which appear in the view. Water and even foliage give polarised reflections, and kromskop landscape reproductions have often been criticised for defects due solely to the polarising properties of the transparent mirrors in the camera.

Transparent mirror cameras possess one special merit, which is that, when properly constructed, they give, with one exposure, absolutely identical view-points for the three images. This would be very important indeed when utilising large apertures or photographing very near objects; but no constructions, so far mentioned, of transparent-mirror single-plate cameras permit of the employment of

a large aperture, and they all require a good deal of knowledge and skill to properly construct and adjust.

Recently I have devised a one-plate transparent-mirror camera which can be made to fulfil all theoretical requirements with apertures as high as  $f/8$ , but its construction involves the employment of two large and very costly blocks of optical glass, and the angle of view is small, so that I still prefer for general studio work successive or alternating exposure cameras, one type of which I patented some years ago in England.\*

We now come to the newest view camera; but, as leading towards it, I must go back to a suggestion made by Mr. Dallmeyer in 1891,† and which had the merit of great simplicity together with the defect of separate view-points. I refer to the use of rectangular prisms for dividing the light into three image-forming portions at the diaphragm aperture of the lens. This was a three-plate camera, and the use of rectangular prisms necessitated three separated diaphragm apertures in order to secure equality of illumination across the plates, the amount of separation of the diaphragm apertures depending upon focus of lens and angle of view. I used a similar arrangement myself in 1888, and a one-plate camera with triple aperture in 1890, but, although I published the fact in 1888 that I had a camera which made the three negatives simultaneously from "very nearly the same point of view." I cannot find that I published the construction.

In 1889‡ I modified this construction by substituting equilateral prisms for rectangular prisms, and thus obtained what may be described as a single, narrow, party-coloured aperture, giving practically a single view-point, and yet transmitting enough light to make kromskop pictures of landscapes with five-second exposures. Finally, by employing rhomboidal prisms, I projected all the images backward upon a single plate, and, taking advantage of the property of the higher refractive index of glass as compared with air to extend the focal point, so calculated the form and size of the prisms as to make the images identical in size and perspective upon one plane.§ This camera, which, notwithstanding its small aperture, is as quick as any of the efficient transparent mirror cameras, except the new one last mentioned, is incomparably simpler and easier to construct and adjust than any other efficient one-plate triple camera ever devised, and is entirely free from the polarisation defect.

This form of camera can be made stereoscopic, and it can also be adapted to work with a comparatively large aperture and single view-point for studio work by mounting the rhomboidal prisms on a rectilinearly vibrating support, so that the light is transmitted to the different images alternately in rapid succession. The movement of the prisms does not disturb the position or definition of the images, so no shutter is required, and the exposure is always going on in such a way as to make one as independent of fluctuations in the light as with the smaller-apertured view camera. All other alternating exposure cameras which have been devised require a shutter to cover the lens aperture during the movements, involving considerable loss of time in making the exposures. There are so many obvious ways of carrying out the idea with this limitation that they are not worth mentioning.

I have now come to the end of the list of triple cameras which seem to me to contain original features of practical value. The sliding back for making successive exposures upon a single plate still has the advantage of being much cheaper than anything else, and is efficient in a steady light with still objects. I make this in stereoscopic form with inverting prisms in front of the objectives, so that the stereoscopic pairs are reversed and transposed ready for mounting for correct vision in the stereoscopic kromskop.

I believe the first special triple lantern for colour projection was used by me in my demonstration at the Franklin Institute in February 1888. On a single lantern body there were three complete optical systems, disposed side by side, with the objectives adjustable for register, and three lime lights. The three positives were mounted on a single wooden slide.¶ This lantern was made to fold very com-

§ U.S. Patent 655,712, August 14, 1900, and another, not yet published.

pactly, according to a principle which I patented in 1885,\* and was adapted for ordinary dissolving views as well as colour projections.

In 1891 Albert Scott devised a quadruple projection apparatus with one source of light, one condenser to parallelise the rays, and four smaller condensers and four objectives to project the four images, which were of very small size. It is obvious that a triple-image apparatus can be made upon the same principle.

At the annual meeting of the American Association for the Advancement of Science, at Springfield, in 1895, I employed a "lantern kromskop," which was substituted for the ordinary lantern front in order to make trichromatic projections. In this device a small condenser parallelised the rays from an electric arc, and the light was divided into three portions by an arrangement of bundles of clear glass and silvered mirrors, after which it passed in parallel beams to three separate condensers, colour screens, and positives, coning into three objectives, adjustable for register. In front of these objectives, 15° prisms were used to separate the images in trefoil, and bring them back into register again, for demonstration purposes.

An improvement upon this device is shown in my British patent, No. 5800, of 1897, in which swinging lens fronts, coupled to pivoted silvered reflectors, and operated by a lever, are substituted for the revolving prisms for separating the images upon the screen. I have also recently improved the construction and adjustments of this instrument.

It is obvious that, by adapting three condensers and three sources of light to any photo-chromoscopic apparatus, projections can be made, and this idea has been patented more than once; but it is far too wasteful of light to be worthy of consideration from a practical point of view. A single source of light is as efficient with the "lantern kromskop" as three sources of light can possibly be with any transparent mirror direct-viewing device, for reasons which should be obvious to anybody who knows enough of optics to trace the reflections in both instruments.

Having described the most successful and important methods of positive synthesis with three images, I now come to the idea of analysis and positive synthesis with a single image, which may be a sort of linear mosaic of the three separate images heretofore considered.

This idea belongs to Louis Ducos Du Hauron, and is a brilliant conception, although of doubtful, or at least very limited, practical importance. As a clever invention it ranks as high as anything that has been done in trichromatic photography.

The principle of this method was fully set forth in Du Hauron's 1868 patent, coupled, however, with his failure to recognise the correct triad of primaries, and the principle of colour-curve analysis, and pure-colour synthesis. He proposed to make a single negative image through a screen made up of fine juxtaposed coloured lines, alternately red, yellow, and blue, and then to view a positive from this negative through the same screen, making the red lines of the screen cover the lines which were made in the negative through red lines, and so on. It is evident that, with lines fine enough not to be separately perceived by the eye, the result should be a complete coloured picture requiring no special viewing device to see it in its perfection.

Years after I had demonstrated the principle of colour-curve analysis and pure-colour synthesis, Dr. Joly applied the principle to this process, until then unknown to me. McDonough, in America, also revived the process, with red, green, and blue-violet colours, but not with a full recognition of the true principles of colour selection.

This process is exceedingly difficult to carry out successfully with coloured lines fine enough not to be offensive to the eye, and, when the images are made stereoscopic and magnified in the stereoscope, the line structure is positively distressing. It is best adapted as to effect for large window transparencies, to be seen from such a distance that the coloured lines are not separately perceived; but it is said, that when so exposed the colours fade considerably in a little while.

It is very difficult, if not practically impossible, to make a correct selective line screen with from 300 to 600 lines to the inch—it is diffi-

\* U.S. Patent No. 338,074, published March 16, 1886.

cult enough to make such screens with superposed coloured films and glasses in separate squares—and it is doubtful if there are any suitable dyes for this purpose which are permanent. Such records can, however, be made by successive exposures through an opaque line screen, employing the same selective colour screens that are used in the kromskop cameras.\*

In 1895, I thought of a method of making such negatives which permits of a single exposure for all three colour lines, with an opaque line screen, but I had no use for it until last year, when I also devised a means of synthesis for such pictures without the coloured line screen, and I then applied for patents for both inventions.† I afterwards learned that Jan Szczepanik had applied for a patent for the camera in France, No. 287,709 of 1899, and that J. A. C. Branfil published a somewhat similar idea in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, February 26, 1897. It is really, however, an application to this process of my original principle (1886) of screen "pin-hole images" of the lens diaphragm in the half-tone process.

#### FOREIGN NEWS AND NOTES.

**Orthochromatic Photography.**—Dr. E. Vogel, the Editor of the *Photographische Mittheilungen*, cautions his readers against the use of dipped plates, according to the formula recommended by Oscar Pöhwert for oil paintings, in which green, yellow, &c., predominate. This formula was published in the *Atelier des Photographen*, and consisted of 300 c. c. of water, 10 c. c. of uranin solution (1:200), 3 c. c. of ammonia, 5 to 10 drops of nitrate of silver solution (1:10). Ordinary plates to be dipped therein, washed with distilled water and exposed wet. Dr. E. Vogel remarks that not only do plates exposed in the wet state give less sharpness, but that uranin is the worst colour sensitiser of the eosine group, and cannot be compared with erythrosine for practical purposes. Another formula for dipped plates to be exposed after drying, which consists of a solution of acridine yellow, chinolin red, and eosine, is likewise condemned. The screen recommended, consisting of aurantia and brilliant green, is also unfavourably regarded by Dr. E. Vogel, who asks why a green screen should be selected, for oil paintings above all things. It reduces the action of the orange and red, the effect of which rays should be favoured. In conclusion Dr. E. Vogel remarks, that it would be better for the photographic world if it were not favoured with such doubtful recommendations, which only serve to discourage beginners from further experiments with colour-sensitive plates.

**An Artificial Spectrum.**—At the October meeting of the Vienna Photographic Society an artificial spectrum was exhibited, which had been sent by Dr. E. Greebe of the Carl Zeiss Optical Works at Jena. The spectrum was composed of four coloured glass prisms, which together formed a thick plate. These may be roughly described as an obtuse-angled yellow prism with a right-angled purple prism on the left, and a blue rhomboidal prism on the right. A right-angled purple prism on the right of the latter completes the plate. The colours selected for the prism correspond with the ideal colours for trichromatic purposes. By suitable combination any shade of colour may be produced. The artificial spectrum may be practically applied as a test in orthochromatic photography.

**Preparing Zinc Plates.**—The *Moniteur de la Photographie* quotes from *Le Procédé* the following process of preparing zinc plates for the albumen or bichromated mucilaginous processes. The plate should be carefully polished with polishing felt and tripoli, then rinsed in running water, and whilst still wet impressed in the following bath:—

Water .....	1000 c. c.
Alum .....	50 grammes.
Strong solution of gum arabic .....	50 c. c.
Nitric acid .....	20 c. c.
Sulphuric acid .....	5 c. c.

Rock the dish and keep the plate in the bath two or three minutes. Wash the plate in running water for ten or twelve minutes, and let it

\* U.S. Patent (Macfarlane Anderson) No. 559,051, April 28, 1896, and U.S. Patent (F. G. Harrison) No. 578,147, March 2, 1897.

† U.S. Patent No. 648,784, published May 1, 1900, and another not yet published.

ry spontaneously by exposure to air. The badger should not be used, as the slightest friction will spoil the extremely fine grain of the surface thus prepared.

**Platinum Toning.**—The *Deutsche Chem. Zeitung* gives the following formula for toning matt chloride papers:—

Water.....	1000 c. c.
Chrome alum.....	10 grammes.
Salt.....	40 „

For use take 50 c. c. of the above solution, and 1 gramme of sodium platonic-chloride in 950 c. c. of water. The bath should have a temperature of 20° C. The tones range from reddish-brown to black. As soon as the prints have reached the desired colour they should be transferred to a bath of water rendered alkaline by the addition of a little ammonia or soda. The fixing bath should also be alkaline.

**Chloride of Gold.**—The following method of testing chloride of gold is given by H. Reeb, in the *Bulletin de la Société Française*. One equivalent of chloride of gold is deprived of its colour by four equivalents of hyposulphite of soda; but, in order to determine the reaction more readily, a few drops of saturated solution of iodide of potassium are added to the solution of gold to give it a dark brown colour. Dissolve 1 gramme of the chloride of gold in water and dilute to 100 c. c. Prepare a fresh solution of hyposulphite of soda, (1:1000.) Take 1 c. c. of the solution of chloride of gold and add 2 to 3 drops of the saturated solution of iodide of potassium. From a burette add drop by drop sufficient of the solution of hyposulphite of soda to the gold solution to discharge the colour. Read off the quantity of hypo solution used, multiply it by 4 and the product is the percentage of gold contained in the solution of gold chloride. Thus, if 12 c. c. of hypo solution are used, there is 48 per cent. of metallic gold in 100 parts of the gold chloride. Pure brown chloride of gold should contain 64.79 per cent of gold.

**Affixing Paper to Metal.**—The *Photographische Chronik* gives the following hint to those who may wish to attach labels or mount photographs upon metal. Thoroughly cleanse the surface of the metal from all traces of grease by washing it with hot water in which soda has been dissolved. Rub dry with a clean duster and prepare the surface with the juice of an onion. The photographs may then be mounted in the ordinary way upon the metal, and will adhere to it firmly.

**The Trials of an Enthusiast.**—Our Belgian contemporary, *Helios*, has a good story of a young solicitor's clerk, who formed the idea of making a collection of photographs of monstrosities. Thinking the Paris Exhibition would be a favourite field for snap-shooting extraordinary types of human beings, he took advantage of the permission given by the authorities for using the hand camera on Sundays. A portly dame, whose face was adorned with whiskers, and whose eyebrows formed a continuous line above her nasal appendage, allured his photographic instinct. No sooner had he pressed the button than the stately figure swung round and landed a vigorous blow with an umbrella upon his head. The intrepid young man defended himself as best he could, but the infuriated dame seized him by the throat, and would have strangled him had not the police rescued him from her grasp. Both were taken to the police station, and the indignant lady was there informed that the amateur had not exceeded the privileges enjoyed by every citizen within the precincts of the Exhibition, and that she must take proceedings against the photographer before a justice of the peace if she felt herself aggrieved.

## OZOTYPE.

[A Paper read before the West London Photographic Society.]

THE advent of a new process, or a notable modification of an old one, seldom fails to attract the attention of photographers—especially those who, in the practice of their hobby, endeavour to infuse into the records and souvenirs of their wanderings as much pictorial quality as possible.

If it be conceded that a photograph, possessing the combined qualities of beauty and truth, is preferable to one having the latter characteristic only, it seems obvious that every effort to secure these united qualities is to be commended and encouraged. It also follows that

any new process which lends itself to this combination, either by affording a means of obtaining better results than are possible with any other process, or one giving equally good results with greater facility and certainty, must be accorded the photographer's hearty welcome.

Without wishing it to be inferred that the present well-known permanent processes are considered deficient in the principal desirable qualities, it is undeniable that the photographer, however skilled he may become, is more or less confined, within certain rigid limits, by the materials and apparatus at his disposal, for giving effect to any artistic or pictorial ideas he may possess.

That many photographers chafe under this restraint, and strive after greater freedom and means of expression, has surely been abundantly demonstrated at the principal exhibitions held during the present year.

It would be beyond the scope of the present paper to discuss the merits and failings of the many revivals, and improvements, of the various printing processes, or, to point out in detail the limitations to which brief reference has just been made; they will be only too vividly in the minds of all who have consistently tried to keep in touch with the latest products of the tireless experimenter.

In a general way one might repeat the well-known axiom, that it is desirable, for any and all printing processes, to obtain as perfect negatives as possible. Further, whilst it may be fairly true that a perfect negative will yield a good print in any process, it seems a very general opinion that a thoroughly good negative for carbon printing is not of necessity an equally good one for platinum, and vice versa.

Assuming, then, that the photographer has obtained the best negative that the subject itself permitted, or that was possible under the existing conditions or circumstances, the next desideratum would appear to be a printing process of great plasticity, and susceptible of very considerable modification and control, which, in the hands of a careful and fairly skilled worker, would enable him to give expression more freely to the ideas of beauty that the subject impressed him with, in spite of a certain amount of shortcoming on the part of the negative.

It will be for you to form your own opinion, whether anything you will see and hear to-night constitutes an advance, however slight, towards the realisation of your hopes, making due allowance for the very brief acquaintance of the lecturer with the process, and his consequent inability to do it full justice.

It seems probable, bearing in mind the almost invariable experience of the past, that prolonged trial, accompanied, as usual, with much vexation of spirit, will in due course prove whether ozotype in its present form, or with possible improvements, is to be one of the chosen processes for displaying the pictorial possibilities of photography.

Instead of making comparisons with other printing processes we proceed, perhaps the better plan, whilst avoiding the quicksands of theory, will be to lay before you the working technicalities of ozotype, and at the same time draw your attention to some of the claims made on its behalf, leaving those who are well acquainted with other processes, to institute comparisons for themselves, and thus pave the way for an instructive discussion.

The ozotype print may be said to resemble one in carbon in the constituents composing it, that is to say, the final image consists of insoluble pigmented gelatine supported on paper of suitable or desired surface and texture. The method of producing it—at any rate in the earlier stages—is essentially different.

The requisite materials are:—

1. A supply of suitable sized paper, free from alkaline substances.
2. A bottle of sensitising fluid—to be obtained from the Ozotype Company, or dealers.
3. A small bottle of Lepage's fish glue, for sizing paper that may be bought in the unsized condition, but otherwise suitable.
4. A broad flat brush of soft bristle.

The other apparatus, required in the after treatment and production of the print will probably be in the possession of all photographers—at any rate, carbon workers.

Since very full and explicit instructions for working the process are given in Mr. Thos. Manly's book, the operations will be only briefly touched upon; a few results put before you, and, finally, one or two illustrations given of the methods of working.

In the first place, then, if a suitable sized paper is not readily obtainable, any other paper of good quality and surface—fairly smooth to be preferred for sizes up to whole-plate—may be sized in the following manner.

First prepare the sizing solution. A convenient and very satisfactory one consists of one ounce of Lepage's fish glue, dissolved in nine ounces of water; when cool it is ready for use. Having pinned a piece of paper, say 30 in. x 22 in., to a clean drawing board or table, pour a small quantity of solution on to the paper, and brush it rapidly backwards and forwards, and again crosswise, to produce as even a layer as possible, and to avoid using an unnecessary quantity of size. A very little practice enables one to judge where best to pour the size on the paper, and about how much will be required to

comfortably cover the surface when well brushed. The drawing board may be then stood on edge, and the paper left to dry, or the paper may be removed and hung up by the two top corners. If the paper is of open texture or an absorbent nature, a second coating of size may be given with advantage when the first is surface dry.

When the final sizing has become surface dry, but not hard, the sensitising solution should be applied. It is probably unwise to perform this operation in full daylight, but it may be done with perfect safety by the aid of a comfortable amount of artificial light. The sized paper is again pinned down as before, and a small quantity of the sensitising solution applied in a very similar manner to that adopted in sizing, but with this difference, that the amount of sensitising mixture may be accurately measured, and waste avoided. The amount required for the size 30 in.  $\times$  22 in. before mentioned, will vary from three to three and a half fluid drachms, according to the texture of the paper used. A useful figure to remember will be one drachm to one and a half square feet of surface.

When this solution has been carefully brushed all over the surface so as to cover it evenly, the paper may be hung up to dry, the time for which will be from 15 to 60 minutes. It will be found that complete success with this process will depend largely on the care with which the paper has been sized and sensitised. If there are any serious inequalities, they are apt to show in the print and ruin it.

The drying of the sensitised paper must unquestionably be carried out in a non-actinic or a very subdued artificial light. When dry it may be at once cut up to desired sizes, being careful to leave an inch or so of margin at each end for handling. A slight margin at the sides will also be found an advantage.

In this state the paper is ready for printing, and will keep in good working order for a long time if cared for in the same manner as platinum paper, and for some weeks if put in a dry drawer under slight pressure. The operation of printing is conducted in the same manner as with platinum paper; the time required is perhaps somewhat less, and the appearance of the image almost identical. Any difference will be in the direction of a stronger print, having more of the fine details visible.

The next operation is to thoroughly wash the prints, and in order to economise time a number may be operated on at once. Place them, one at a time, in a large dish of cold water—in any convenient place and in any light—and keep them moving for ten minutes. Pour all the water away and refill with clean water for a second and third bath of 10 minutes each. The prints are then ready to be hung up to dry. With very thick or absorbent papers, an increase in the number of baths or in the time will certainly contribute to better results—indeed, there seems no objection to a fairly prolonged washing to ensure the removal of all chemicals unaffected by light.

The surface moisture may be blotted off without injury to the prints, which, when dry, may be kept indefinitely, or until a suitable occasion presents for pigmenting them. They are, of course, no longer liable to injury from light.

When about to pigment the prints, we proceed as follows:—A bath is made up of water 40 ounces, glacial acid 60 minims, hydroquinone 15 grains, and pure sulphate of iron 5 grains. The ingredients are added to the water in the order given, and thoroughly dissolved before using the bath, which will remain in good order for two or three weeks.

It is stated that this bath should be used at a temperature of from 65° to 75°, but the reason is not given; presumably, it is to be sure of getting the gelatine—with a definite time of immersion in the bath—into a suitably soft condition for making close contact with the whole surface of the paper print, when the two are squeezed together.

Having prepared the acetic bath with, say, an inch and a half depth of solution, and warmed it to the required temperature, take a piece of the pigment plaster and place it face downwards in the bath. After about half a minute's immersion, turn it over and brush the face gently with a flat camel's-hair brush to remove air bells, &c. In about another half minute the plaster will be soft and limp: then take a print and bring it into contact with the plaster under the surface of the solution, taking care to lower it into the bath in such a way as to avoid air bells if possible. Lift the two out of the bath together, lay them down on a flat surface, plaster uppermost, and firmly squeeze them together. After removing the remaining surface moisture with blotting-paper, hang the prints up to dry.

When the pigmented prints are dry, or have been hanging in a dry place for not less than three hours, they are ready for development. In this state, also, the prints will keep a considerable time without deteriorating.

The process of development will present no novelties to the carbon worker, and no difficulties to the beginner.

A large tray to contain hot water is almost the only thing necessary, with some means of keeping the water at a temperature of about 105°. While the hot bath is in course of preparation, place the prints in cold water, and let them soak for 20 or 30 minutes—depending on the time of year—colder weather requiring the longer period.

If a large number of prints are being dealt with, it may be necessary

to remove some of them after half an hour's soaking, and place them on blotting-paper to await development.

Take one of the soaked prints and plunge it under the surface of the warm water; allow it to remain from one to one and a half minutes, then take hold of one corner of the paper backing of the plaster, and gently, but firmly, strip it. Care must be taken not to stop during this operation, which should be performed quite under the water or quite out of it. The objection to a stoppage in the act of stripping is that the print is liable to show a mark at the point where the delay occurred. The print may now be developed, or, if a number are to be done, it may be placed, face upwards, on blotting-paper until all are stripped.

To develop the print, place it face downwards in the hot water and leave it for about a minute to soften; turn it over and draw it on to a piece of zinc or glass to form a flat support, and then lave or splash water over it with the hand, or pour from a cup or mug until development is deemed complete. Sufficient experience will soon be gained to enable the operator to decide whether the print requires more or less soaking, in addition to the laving or pouring operations.

When development is complete, the print may be placed at once in a cold alum bath, and then, with a final rinse in cold water, hung up to dry. If the alum bath is postponed until after drying, to permit of slight local development, the prints should always be put into cold water for a few minutes—just to chill the gelatine—before hanging up to dry, or there is great risk of the image running in beads and ruining the print.

When finally dry, after the alum bath, the prints may be mounted or handled in the usual way, the image being no longer soluble.

It would be presumption on the part of a beginner to speak of defects in the process, but there can be no objection to his pointing out where he has failed to get the desired results, or where the prints fall short of his ideal.

Practically, the only difficulties met with have been to acquire a correct judgment of the correct depth of printing with various negatives, and to get the plaster to adhere evenly on rough papers.

The prints shown to-night indicate clearly that the former difficulty is soon overcome; the latter, it is confidently hoped, will disappear with a little more practice.

One peculiarity may be mentioned, as it seems difficult of explanation, viz., the failure of the pigment plaster to adhere to the print outside the edge of the negative, and where the greatest exposure to light had taken place.

The points of superiority over other processes appear to lie with the means of producing the prints, rather than with the results.

The claims may be briefly stated as follows:—

1. The resulting print is permanent.
2. Paper with a variety of tones and surfaces, at the choice of the worker, may be used.
3. Various coloured pigments are available, giving definite and invariable results as regards tone or colour.
4. Modifications may be made in the sizing and sensitising of the paper, and in the composition of the bath used for pigmenting; all of which are said to give control over the final print.
5. By means of the above modifications, various grades of negatives may be used to produce satisfactory prints.
6. All the materials will keep—almost without exception—for an unlimited time without risk of injury.
7. The only operation that cannot be performed in ordinary daylight is drying the sensitised paper.
8. A delay of a week or two between any two consecutive operations will not injuriously affect the result. This quality is, of course, invaluable to the amateur.
9. It is to all intents and purposes a printing-out process, no actinometer or print meter being required.

Nearly all the prints attempted are shown to-night with notes upon them indicating the probable or supposed causes of failure.

With an illustration of some of the principal operations, the subject is at your disposal for free discussion and liberal criticism.

Mr. Manly has been kind enough to send some particulars of his latest practice, with permission to place them before you. He says, "I find it a good plan to dip the washed and dried prints in a glycerine solution (glycerine 1 part, water 2 parts) just before applying them to the plaster in the acetic bath. This prevents air bells from accumulating, and causes the gelatine to adhere properly to the paper. If you have no glycerine, sugar will do as well—loaf sugar 1 part, warm water 4 parts—draw the prints over the surface of the solution. The acetic bath I find best for good negatives is

Water .....	40 ounces.
Glacial acetic acid .....	60 minims.
Hydroquinone .....	20 grains.
10 per cent. solution of sulphate of copper...	60 minims.

The sulphate of copper (which can be left indefinitely as a 10 per cent. solution) I find more convenient than the ferrous sulphate. For cartridge paper (which should be good), or for Whatman's hot-pressed

coat the washed prints, with a camel's-hair brush, with the following sizing solution:—

Fish glue .....	2 drachms,
Glycerine .....	1 ounce,
Water .....	6 ounces,

and put them in the acetic bath without drying. The paper used not be sized previous to sensitising, and the plastered prints can be developed two hours after the acetic bath, whether wet or dry."

G. F. BLACKMORE.

THE NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY'S EXHIBITION.

IN our review last week of the Hackney Photographic Society's Exhibition we spoke in emphatic terms of the neglect by that Society of portraits and figure subjects, and we also remarked upon the improvement, not only in photographic skill, but in the general taste displayed in the selection of subject and the mounting and framing of the pictures by the junior members. The Hackney Exhibition happens to be the first of the winter series of exhibitions held by the metropolitan photographic societies, and, as we have often stated, we have found, and expect to find, there the dominant tone of the series. That our theory is correct is supported by the Exhibition at present under review. The Exhibition, as a whole, was better than that of last year, but the improvement was mainly due to the better quality of the work of the less-known members. Of course, we could hardly hope to find any great advance in that of the leaders of the Society. The small proportion that portraiture and figure studies, and, indeed, all other branches of photography, bore to the landscapes was quite remarkable. At a society exhibition in bygone times one generally found it the case that attempts were made by the same individuals to excel in many branches of photography. Over and over again we have had to deprecate such attempts, and to preach the doctrines of specialisation. We never contemplated, however, that the time would come when whole societies would specialise in the same direction. Landscapes, treated pictorially, are perhaps the most interesting of all subjects to the general visitor to an exhibition of present-day standard, but that is mainly because the average quality of the landscapes is superior to that of other subjects. No one can dictate to a body of photographers who individually practise photography for their own amusement what branch each individual shall take up, and in the earlier days in a society's career it is a sign of strength that those members who are in a state of pupillage should choose to follow the steps of those who are capable of leading them. In a well-established society it is not a sign of strength that all should elect to follow the same lines, for it suggests the idea that the many are simply mere copyists of the few. To tell the truth, that is the impression we often get in viewing the work at an exhibition.

The North Middlesex Exhibition was held, as usual, at the Jubilee Hall, Hornsey-road, N., on the 3rd, 4th, and 5th inst. It was entirely confined to the work of members, and the awards of the judges, Messrs. Chas. Moss and J. B. B. Wellington, were given on the same principle as those at the R.P.S. Exhibitions, for distinctive excellence of work.

The awards were made to H. Stuart for "On an Essex River," R. Child Bayley for a portrait, A. Herbert Lisett for "A Private Corner," and J. C. S. Mummery for "Pagglesham Port;" and the following append was made by the judges to their awards:—

"In addition to the above, the judges wish to mention 'The Beach Road, Tangiers,' by R. Child Bayley, and 'A Girl's Head in Profile,' by A. Herbert Lisett. The work of J. C. S. Mummery shows a high standard of excellence throughout. Much of the landscape work generally would have called for recognition had more care been exercised in the selection and printing in of the clouds; in many cases were altogether wrong and unsuitable. Speaking generally the works showed evidence of much care and no little pictorial knowledge."

While we agree with the criticism of the judges absolutely, we did not find the reference to the badly-chosen and unskilfully-printed clouds more deserved here than at most other exhibitions. It is a very common fault, and one that men with even great reputation are not innocent of. The judges' impressions on this point were probably influenced to a great extent by one picture, "A Bit of Hampstead," by S. E. Wall, which certainly would have been one of the most admired pictures in the Exhibition but for its unfortunate sky. It had every desirable quality except that what were intended to represent detached masses of clouds were apparently masses of something pendant from the branches of the trees.

With redundant modesty Mr. F. W. Cox has labelled his pictures "not for competition." They were in bichromated gum, and were as good examples of translating a negative by that process as any we have seen. We unhesitatingly express our admiration of many of them as pictures, but we are in doubt whether we ought to compliment Mr. Cox as a skilful photographer or as a skilful handler of a brush. Mr. R. Child Bayley's "A Portrait" seemed to us to have a most

infelicitous title. We can hardly imagine that any self-respecting young lady could assent to the woe-begone, bedraggled-looking creature that Mr. Bayley portrays as a portrait of herself. We should have felt inclined to ascribe this production to the influence of the American school of photography, but we happen to know that the negative was made some years ago, before there was an American school. We doubt, however, if we shall be far wrong if we ascribe the certificate awarded to it to the influence of the American school on the judges.

J. C. S. Mummery's landscapes would be, most of them, familiar to visitors to the recent great Exhibition. Needless to say, they possessed the characteristics of style and refinement in treatment usual in the work of their author. A portrait study by the same, though not equal to the landscape work, was promising. H. Stuart's chief work was his certificated picture which was hung in the recent R.P.S. exhibition, entitled "On an Essex River." A figure study, entitled "In an Old Garden," was commendable rather for its photographic than for its pictorial qualities. A. Herbert Lisett's work was careful, and, we think, an improvement on that he has shown before. R. R. Rawlings seemed to have allowed his ambition to run to quantity. His work was, on the whole, good; but there was nothing that specially riveted the attention. S. E. Wall, one of whose pictures we have already referred to, seemed to have been afraid to use a full range of gradation in most of his pictures. In "Derelict" he had a pictorial subject, and his method of treatment was obviously good; but it was not quite satisfactory. "Bosham Creek" was another good subject, but as a picture it was marred by a weakness at one of the margins which led the eye out of the picture.

W. Taylor's most interesting pictures were views in "Cloth Fair, Smithfield," and "Staple Inn, Holborn." They bore testimony to the possibility of obtaining views in London equally valuable as pictures and as records. H. W. Bennett was represented by some of his fine architectural work. J. W. Marchant's work was not so striking as some we have seen, but his views were well selected and the photography was good. Among the other exhibitors whose work pleased us were H. Smith, T. Pring, E. R. Mattocks, A. G. Lawson, F. A. Haylett, F. A. Bishop, and J. J. Armitage.

The lantern slides were fairly numerous and the average quality was good, as far as we could judge them in the exhibition frames.

DR. RUDOLPH'S IMPROVEMENTS IN LENSES.

[Patent No. 24,089 of 1899.]

THE photographic objective hereafter described has been devised for purposes which require a large aperture and an anastigmatically flattened field for a comparatively large angle. The advantage of this objective, as compared with combinations hitherto known for similar purposes; for instance, the objectives described in specification No. 6028, A.D. 1890, and, like anastigmatic constructions, is that the choice of glasses is hardly limited, and less lenses are necessary to obtain good spherical correction even in types of high aperture.

This double advantage of the new objective is due to the use of two pairs of glass surfaces, each pair consisting of two surfaces, which face one another, that is to say, which belong to two consecutive lenses,

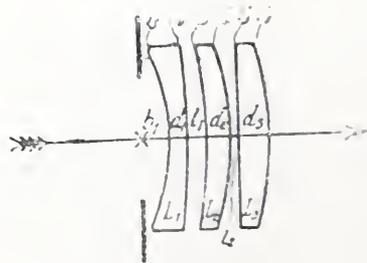

Fig. 1.

and are separated by an air-space, but not by the diaphragm of the system, and the powers of both pairs being of opposite sign.

If  $n_1$  and  $n_2$  be the refractive indices of the two consecutive lenses,  $r/i$  and  $r/k$  the radii of curvature of the glass surfaces facing one another, the power of such a pair of surfaces is given by

$$\phi_{1,2} = -\frac{n_1 - 1}{r_i} + \frac{n_2 - 1}{r_k}$$

the axial thickness of the air-space between both "facing" surfaces being supposed to be negligible.

There exist already several photographic objectives having two pairs of facing glass surfaces separated by air, but the powers of these pairs

are both positive or both negative. It may be inferred from fig. 3 of Specification No. 27,635, A.D. 1896, relating to the so-called Planar, that the two pairs of facing glass surfaces are the surfaces  $r_4, r_1$  and  $r_3, r_2$  of the lenses  $L_1, L_2$  and  $L_2, L_3$  respectively. The sign of the power of each pair is positive. Another construction of this kind has been described in Specification No. 12,859, A.D. 1898. This objective is composed of four separate parts and contains—according to the data given in M. von Rohr's "Theorie und Geschichte des Photographischen Objectivs," p. 392—two pairs of facing glass surfaces, each of which pairs has a negative power.

The effect of combining two pairs of facing surfaces of opposite power is similar to the result obtained in the objective described in Specification No. 6028, A.D. 1890, by the opposite sign prescribed for the difference between the refractive indices of the crown and flint-lenses in the cemented components of a doublet. The pairs of facing surfaces produce, in accordance with the signs of their powers, astigmatic differences of opposite character, so that, in addition to spherical correction of the whole system and flattening of the image, astigmatism may fully be corrected. In the former objective the maximum differ-

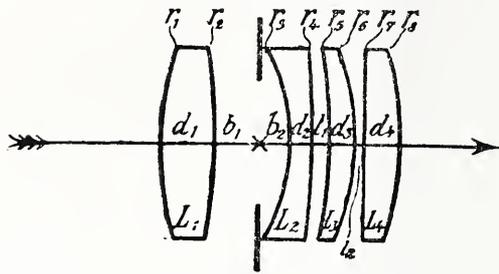

Fig. 2.

ence of the refractive indices of the lenses cemented together was (with regard to practical usefulness of the glasses)  $1.63 - 1.50 = 0.13$ . In the present objective, however, the difference of the refractive indices belonging to each of the facing glass surfaces will amount to  $1.50 - 1.00 = 0.50$  even in the most unfavourable case. It is further to be considered that when the present objective has the same number of lenses as the former, its number of elements available for correction is increased, so that the present objective when consisting of four lenses presents a surplus of two radii and two air-spaces. From the foregoing it will be understood that the adoption of the new type of objective will result either in larger apertures, the spherical corrections remaining of the same quality, or—when the apertures are unaltered—in improved spherical corrections.

Besides the two pairs of facing glass surfaces of opposite sign the well-known means of correction may be employed at will, and in consequence thereof the new objective may consist of single lenses as well as of cemented lens systems. Moreover, it is an essential feature of the invention that the selection of kinds of glass is nearly unlimited, so that glasses which diminish the secondary spectrum may be used, although their optical properties vary in very narrow limits only.

The features of the invention may be realised either in "simple

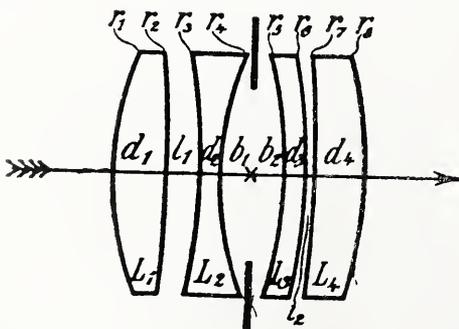

Fig. 3.

objectives" (objectives having their diaphragm behind or in front of them), or in "doublets" (objectives in which the diaphragm is placed in the system).

In the annexed drawing:

Fig. 1 represents a simple objective constructed according to the invention.

Fig. 2 represents a doublet, one of the two components of which is constructed according to the invention.

Fig. 3 represents a doublet constructed according to the invention.

Fig. 4 represents another doublet constructed according to the invention.

Fig. 5 represents a third doublet constructed according to the invention.

The most primitive simple objective consists of three single lenses  $L_1, L_2, L_3$  placed separately as shown in fig. 1. One pair of facing glass surfaces is formed by the surfaces  $r_2, r_3$  of the lenses  $L_1, L_2$  and the other by the surfaces  $r_4, r_5$  of the lenses  $L_2, L_3$ . For each of the single elements  $L_1, L_2, L_3$  a compound lens or a non-cemented lens system may be substituted, whereby the construction of the simple objective becomes more or less complicated.

Such a simple objective may also advantageously be used as a component of unsymmetrical as well as hemi- or holosymmetrical

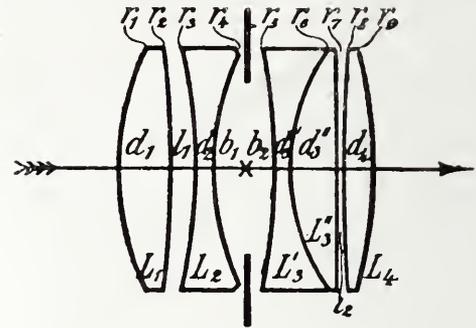

Fig. 4.

doublets. The most primitive kind of an unsymmetrical doublet, a component of which is a simple objective constructed according to the invention, is shown in fig. 2. It consists of four lenses  $L_1, L_2, L_3, L_4$ , the back component  $L_2 + L_3 + L_4$  being the simple objective shown in fig. 1. But it will be understood that the simple objective may also be used as the front component of the doublet.

The most primitive doublet, which in its totality is constructed according to the invention, has two lenses in front of the diaphragm and two lenses behind it as shown in fig. 3, the two pairs of facing surfaces being placed on different sides of the diaphragm. The surfaces  $r_2, r_3$  of the lenses  $L_1, L_2$  form the one pair having positive power, and the surfaces  $r_6, r_7$  of the lenses  $L_3, L_4$ , the other pair having negative power. The lenses  $L_1, L_2, L_3, L_4$  may be single lenses, as shown, or compound lenses. It will be preferable to substitute compounds for some of the single lenses either for the purpose of remaining within certain limits as to the choice of glasses or for obtaining certain effects as regards the correction of chromatic or spherical aberrations. According to the particular purposes of each doublet the elements of such a composite lens may be made of glasses having the same refraction and different dispersion, or the same dispersion and different refraction, or different refraction and different dispersion.

In fig. 4 a more complicated doublet is shown, which has been developed from the doublet represented in fig. 3 by substituting two elements  $L_3$  and  $L_3'$  cemented together for the lens  $L_3$ . Example

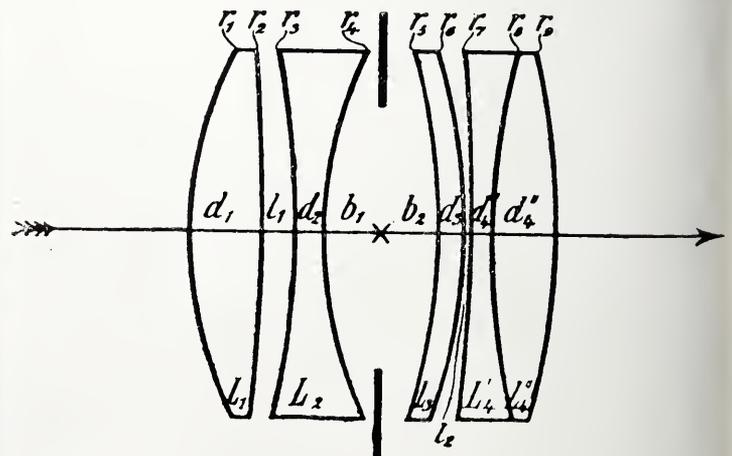

Fig. 5.

3 given below, and showing detailed data of construction, refers to the same fig. 4. In this example  $L_3$  and  $L_3'$  are ground from glasses having the same refraction, but different dispersion, so as to chromatically correct the whole system.

Finally, in fig. 5, a construction is represented in which for the lens

$L_4$  of fig. 3 a compound consisting of  $L_1^1$  and  $L_1^2$  has been substituted. In the example 4, which gives detailed data of construction in reference to fig. 5, glasses of different dispersion and different refraction have been selected by means of which the chromatic correction as well as the diminution of the spherical zones are obtained.

In the following numerical examples of objectives constructed according to the invention the letters  $L_1, L_2 \dots$  denote the lenses;  $l_1, d_2 \dots$  their axial thicknesses;  $r_1, r_2 \dots$  the radii of curvature of their spherical surfaces;  $b^1, b^2$  the distance between the diaphragm and the adjacent lens vertices;  $l_1, l_2$  the axial thicknesses of the air-spaces between two lenses (the distance between two lenses). The radii, thicknesses, diameters and distances are expressed by proportional numbers, the unity of which is the focal length of the entire objective. By simply multiplying these numbers with the focal length required in each case, the data of construction for any objective wanted will be obtained. The different kinds of glass are determined by their refractive indices  $n_D, n_F, n_G$ , relating to the D-line and the F-line of the solar spectrum and to the H $\gamma$  line of the hydrogen spectrum respectively. The value of  $\frac{\Delta n}{n_D - 1}$  indicates the relative dispersive power of the kind of glass,  $\Delta n$  being given for the interval between D and H $\gamma$ , whereas by the quotients

$$\frac{n_F - n_D}{n_G - n_D} \text{ and } \frac{n_G - n_F}{n_G - n_D}$$

the increase of the dispersion in the considered interval is shown.

## Our Editorial Table.

### OUR BIRD FRIENDS.

By R. Kearton, F.Z.S., with 100 illustrations from photographs by Cherry Kearton Crown 8vo.; cloth gilt; 6s. London: Cassell and Co., Ltd.

In the last of his bird books, Mr. R. Kearton has written not by any means the least entertaining of the delightful series of volumes with which the names of his brother and himself are associated. He talks to us in simple language, which young people will enjoy, and their seniors not rebel at, of the bird at home—of his "tricks and his manners," as Dickens's Jenny Wren puts it. To quote from the Publisher's note: "The wonders of feathers and flight; remarkable nests of different styles of architecture; eggs and the value of their shape, size, colour, and numbers; the care and protection of young; feeding habits; and remarkable songs and call notes," are lovingly touched on in Mr. Kearton's chapters. His keenness of observation and his sense of humour stand him in good stead in enabling him to penetrate with wonderful zest the charm, the interest, and the beauty of bird life. We cannot imagine any hitherto heedless person taking up this book and reading it and failing to become at once a lover of birds. The hundred or so illustrations are from photographs by Mr. Cherry Kearton, who has made this branch of work a speciality. He is to be congratulated on the really wonderful skill and patience he must have expended in order to secure his negatives. For example, an opening in the book at random we light upon photographs showing "A Baby Jackdaw's First Peep into the World," "Merlin's Nest with Newly-hatched Chick," "Blue-tit feeding on suspended kernel of nut," and so on. The combination of photographic skill with a perfect genius for seeking such subjects, or, indeed, for conceiving them, is a dual gift of which we sincerely envy Mr. Kearton. We thank both author and photographer for a fascinating work, which is full of the well-recorded results of efforts in the service of a part of the world of nature upon which the human eye invariably rests with delight. As a Christmas and New-year's gift-book "Our Bird Friends" will, no doubt, be immensely popular. It well deserves to be.

### THE RAINBOW PLATE.

Manufactured by the Warwick Dry Plate Co., Warwick.

GOOD-KEEPING qualities are claimed for the Rainbow Plate, which is made in two rapidities, Fast (Wynne's Meter 90) and Slow (Wynne's Meter 45). Some of the plates have been in our possession for several months, and on recently testing them we found that they worked quite cleanly, and without any degradation of the deposit. As a means of testing their colour sensitiveness, we chose the following plan: In place of the lens on the front of the camera we fixed a small pocket spectroscope, and, pointing the camera to a clear part of the sky, photographed the spectral band so obtained. This rough and ready method of testing showed that the "Rainbow" plates had been made fairly sensitive to the red, a region of the spectrum which uncorrected plates do not, of course, render so satisfactorily as could be wished. We might mention that this method of spectroscopically testing the sensitiveness of plates is a very useful one for purposes of making comparisons, especially with non-corrected plates whose rapidity it is desired to ascertain. Again, in place of the spectrum itself, an arti-

ficial spectrum made of selected pieces of glass and photographed by transmitted light, as one copies a negative or transparency, also affords a system of testing plates, by which a very good idea of their adaptability for translating colour may be obtained. The Rainbow plates appear to be carefully prepared, and are very fine in the grain.

### THE AGFA REDUCER.

Agents: A. and M. Zimmermann, 9 and 10, St. Mary-at-Hill, London, E.C.

THE samples of the Agfa reducer which Messrs. Zimmermann sent us reached us in the form of 10 gramme cartridges, the salt itself having a slightly greenish tinge of colour. We found the quantity named freely soluble in 100 c. c. of water (about 3½ ounces). In order to test the reducing powers of agfa, we selected a negative of a church interior, the highest lights of which—windows—were excessively dense. The reduction proceeded slowly, but harmoniously, and in the result we found that it had taken off sufficient of the deposit in the windows to make the detail hitherto buried in them printable and recognisable, without unduly diminishing the remaining parts of the negative. We noticed that agfa—which is said to be a combination of a ferric salt and an alkaline thiosulphate—had no staining effect. This reducer is also recommended by the manufacturers for bromide prints and lantern slides. It is directed that the salt, as well as the solution, should be protected as much as possible from the daylight. To the occasional worker the agfa reducer in cartridge form should be of very great use, for the convenience of the latter obviates the necessity of making up and retaining special solutions of mercury or other substances for purposes of reduction.

### THE PAGET HANDBOOKS.

Published by the Paget Prize Plate Company.

WE have received from the Paget Prize Plate Company a set of the series of the little handbooks issued to users of their plates and papers. These are entitled Paget Prize Plates, and how to use them, by Mr. W. J. Wilson, F.C.S.; Paget Prize Lantern Plates, by Mr. S. Herbert Fry, F.R.P.S.; and Paget Prize P.O.P., by Mr. Wilson. There is also a list of exposure tables for use with the plates. These little books are written by men of sound practical knowledge, and, as they are issued gratis, they should be in the hands of all users of the Paget Company's world-renowned productions.

## Studio Gossip.

OUR bright contemporary, "M.A.P.," prints the following two photographic stories in its last issue:—The Queen and the Photograph. Here is a new and characteristic story about the Queen. She commanded the young widow of a certain major of the Artillery, who had fallen in South Africa under peculiarly sad conditions, to visit her at Windsor; she also asked to see the baby—a posthumous child—to whom she had consented to act as godmother. When her visitors were leaving, the Queen expressed a wish to have their photographs, with that of the deceased officer. The widow, with extraordinary lack of taste, had her photograph taken in full evening dress. It was returned by Her Majesty.—The Cost of a Duke: My Northern correspondent writes: "I have lately come across a little story of the Duchess of Montrose, whose beauty is no less renowned than her philanthropy. The scene was a bazaar where the Duchess was selling photographs. One old Scotch 'buddy' of the more frugal sex was very anxious to secure a photograph of the Duchess; but the price asked was five shillings. The old woman hesitated; she wanted the photograph, but she could not well afford so much. 'You can have my husband,' said the Duchess, with an amused glance at the Duke standing near, 'for two-and-sixpence.' The would-be purchaser looked at the Duke and then at his photograph contemptuously. 'Half-a-crown!' she blurted out, 'I wouldn't give a silver sapphire for him. But,' she added insinuatingly, 'I'm right willing tae give hauf-a-crown for your bonnie sel.' The Duchess was unable to resist this, and herself added the other half-crown to the bazaar coffers, or, as another version of the story goes, the despised Duke proffered the balance.

## News and Notes.

ROYAL Photographic Society.—Ordinary Meeting, Tuesday, December 11, at 8 p.m. The Atmospheric Gas Company will demonstrate a new method of lighting. Mr. H. Snowden Ward will show some recent results by the McDonough-Joly colour process.

A LANTERN explosion of acetylene gas recently took place at Austin, Illinois. An entertainment was being given in the First Presbyterian Church, and the operator, who had recently returned from missionary work in India, lost his right hand and sustained other injuries. The gas was in cylinders, and one of them sprang a leak, and the light that was in the lantern ignited it, causing the explosion. The middle tier of seats, where the tanks had been placed, was wrecked, and the large windows were blown out. The fire was extinguished.

**LORD KELVIN on Polytechnics.**—Last week Lord Kelvin presented the awards at the Birkbeck Institution, and afterwards spoke briefly to the students, the distinguished scientist disclaiming any intention of "delivering an address." The primary object of the institution, explained the great physicist, was not to teach men and women how to earn a livelihood, but rather to make life more worth living to those who were already earning a livelihood. The example of Dr. Birkbeck had led to the formation of polytechnics and athenæums throughout the country, all seeking to feed the mind of their students with wholesome food, and to render the possessor of the food happier and better and more useful to the world. Such a marked change, he urged, could not fail to be beneficial to England and her vast Empire.

**BOROUGH Polytechnic Photographic Exhibition.**—The Sixth Annual Exhibition of the Borough Polytechnic Photographic Society will be held at the Institute, 103, Borough-road, S.E., on Thursday, Friday, and Saturday, December 27, 28, and 29, 1900. As previously announced, this year's exhibition will consist solely of the work of members of the Society. With a view to popularising photography, it is noticed that the whole of the exhibition will be thrown open to the public free, and, as a further appeal to the lay mind, a large number of side attractions are being introduced. These include a good show of photographic apparatus and accessories by the trade, a special exhibit of natural colour photographs, lantern entertainments, and frequent displays of animated photographs, X rays, wireless telegraphy, &c., whilst a special feature will be made of short popular demonstrations of photographic processes. The judges for the exhibition will be Messrs. John A. Hodges, H. Snowden Ward, and Chas. H. Oakden.

**PHOTOGRAPHY and Modern Illustration.**—In the making—in the manufacture, we may say—of handsome "Art" books the publisher of the present day is exceeding skilled. Lacking the "flair" that might enable him to discover original talent and the sympathy necessary to utilise it, he plunges, says a writer in "The Outlook," camera in hand, into the storehouses of the past, returning with an album of beautifully printed blocks, pieced out by a running accompaniment of more or less critical appreciation. Thanks to this practice, the demand for illustration of serious artistic quality is as small as its supply, and even picture-buyers of limited means have come to prefer photographs of famous pictures by Velasquez or Rembrandt to "the real thing" by artists of more modest merit. To an admirer of a famous picture the first sight of its photograph revives the memory of the thing itself almost to illusion. Unfortunately, as the experiment is repeated the illusion weakens, and, if the thing be persisted in, it has this effect, that when you next go to see the painting itself you are irresistibly reminded of the photograph. This preference for photographs of the art of other centuries over real art of one's own is a characteristic of our generation, which always prefers its sensations let down, which will pay a shilling to see a jerky, colourless cinematograph of something a hundred miles away, though by so doing it misses the full-blooded reality at hand—nay, will often stop to see a photograph of what if seen in nature would be passed by unheedingly.

## Commercial & Legal Intelligence

**MOUNTS for Christmas and New-year Cards.**—As usual at this time of year, Mr. Jonathan Fallowfield, of 146, Charing Cross-road, London, W.C., is issuing a special illustrated price-list of motto mounts for Christmas and New-year.

We are informed that H.R.H. the Grand Duke of Hesse has conferred upon Dr. Louis Merck the distinction of "Geheimer Commerzienrat," in recognition of his great services to the chemical industry of Germany. H.R.H. has further conferred upon Dr. E. A. Merck the distinction of "Medicinalrat," in recognition of his services rendered in connection with the Chemical Exhibition at the World's Fair of Paris, 1900.

AN effort is to be made to employ colours in the illustration of sporting subjects in the "Badminton Magazine," says the "Daily Chronicle." At first these must be in the nature of an experiment, but the hope is that in time it may be possible to employ colour whenever a picture needs it. As the editor remarks, "The plumage of a bird, the skin of an animal, the scales of a fish cannot be realised from any monochrome representation, colour being one of the most essential elements." The difficulty in the past has been that all known processes of colour printing have been too elaborate and expensive for the periodical press, if carried out in really artistic style. Recent inventions in printing and photography have cheapened the cost, and, moreover, good results are now more certain.

At the opening of the series of eight special evening lectures at the handsome premises of "Kodak," Limited, at 96, Bold-street, Liverpool, a very popular innovation was initiated by their manager, Mr. J. Phethean, M.P.S. In the lecture and demonstration on Eastman's platino-matt bromide paper enlargements were made from the visitors' own negatives and afterwards called for. Owing to the number of visitors who could not be accommodated at the first lecture, it had to be twice repeated. Many hearty expressions of interest and thanks were tendered. Another interesting feature was the exhibition of choice lantern slides at the conclusion of the lecture. The free lectures and demonstrations are proving extremely popular, and show that "Kodak," Limited, goes beyond mere business considerations and is doing good work by providing these interesting and educational lectures and demonstrations.

### ROYAL PHOTOGRAPHIC SOCIETY.

NOVEMBER 27,—Technical Meeting,—Mr. J. J. Vezey in the chair.

#### ANALYTICAL PHOTOGRAPHY.

Mr. Francis Galton, F.R.S., delivered an address upon the subject of some experiments which he has recently made to isolate the particulars in which one photograph differs from another of a different aspect of the same original. As the object in view is the separation or analysis of the expressions or variations of the subject of the several photographers, he has called the process "Analytical Photography." The principal results of his experiments were published some few months ago in "Nature," and the article was reprinted in THE BRITISH JOURNAL OF PHOTOGRAPHY for August 10 last. Mr. Galton's lecture was delivered extempore, and, as it was of a somewhat discursive character, we prefer to refer our readers to that issue for a succinct and detailed account of his investigations and their outcome. In his opening remarks, he explained that when, in 1881, he submitted to the Royal Photographic Society his now well-known method of composite photography, the idea occurred to him that a converse process might be contrived. In composite photography a number of different portraits are impressed successively upon the same sensitive surface, giving to each only a proportionate fraction of the total exposure, the result being that what is common to all is retained, while that which is individual—or is seen in one of the several portraits—is lost. In analytical photography, on the other hand, the object is to dissect a composite so as to show what is individual. For this purpose the starting point is the fact that "the superposition of a rather faint positive upon its rather faint negative produces an approximately uniform grey when they are viewed together as a single transparency." If, then, negatives and positives are made of different aspects of the same subject—for instance, a sitter with a serious expression and the same subject with a smile—and if the transparency of the latter is superposed upon the negative of the former, the characteristic lines of the smile will be isolated from the whole of the features. That is to say, what is common to both will be blended in the uniform grey, while the "smile," which differentiates one from the other, will be separated out. Mr. Galton exhibited the very ingenious apparatus which, with the aid of Mr. T. R. Dallmeyer, the President of the Society, he had devised for working the process, and he expressed the opinion that it would be of value to artists and physiologists in the determination of the great changes which really occur in apparently trifling differences of expression or development.

#### COMING EVENTS.

On Dec. 11, the Atmospheric Gas Company will show a new system of artificial lighting for portraiture, which members are invited to test with their cameras; and Mr. H. Snowden Ward will read a paper upon, and give illustrations of, the Macdonough-Joly process of colour photography. At the Technical Meeting, on Dec. 18, Mr. H. C. Shelley, war artist of "The King," will read a paper on "Photography in Warfare."

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 29,—Mr. R. J. Kinson in the chair.

Mr. Philip Everitt said that it would be remembered that Mr. T. R. Dallmeyer showed, on the occasion of the first Traill-Taylor Memorial Lecture, which was delivered by him two years ago, an instrument for measuring the focus of a lens. Mr. Everitt had recently made use of the focometer, now installed at the Royal Photographic Society's rooms,

and had measured a Zeiss Unar lens of 210 mm., or 8.2679 inches focus, and a Steinheil orthostigmat of 9 cm., or 3.5434 inches focus. He found that the Unar measured on the focometer 8.235 inches—showing a difference only of 1.30th inch; and the orthostigmat 3.5184 inches—showing a difference of 1.40th inch. It was interesting, he thought, to note that opticians should send out lenses marked so very nearly to the exact focal lengths as proved by the two tests described.

Mr. A. Haddon sketched on the board, and explained a condensing apparatus new to him, and possibly also to many of the members. It must have occurred to many at times that alcohol of a little greater strength than that usually obtainable would be very useful, or a means of removing impurities, and if this could be done without infringing any of the laws of the realm so much the better. Stills, whether they consist of a worm or Liebig's condenser, are usually cumbrous; but this apparatus was very small, yet condensed well and rapidly.

Without an illustration, a perfect idea of the condenser cannot be given. It consists of two glass tubes, one within the other, fused together at their upper edges. The vapour of the liquid to be purified is introduced by means of a branch piece between the tubes, and cold water is allowed to play upon the condensing surfaces. The condensed vapour then trickles through an outlet at the bottom, while the water is conveyed away in another direction. The condenser is supplied by Messrs. Baird and Tatlock.

Mr. H. C. Rapson, remarking that a great deal had been said and written against the permanence of sulphur-toned prints and slides, showed some lantern slides to disprove assertions that of necessity sulphur toning was unreliable. The slides shown for comparison were gold toned and sulphur toned respectively. They had been exposed for twelve months in the studio, and the sulphur-toned slide was still good, while the gold-toned slide had gone off somewhat.

Mr. A. Mackie agreed that it was not at all a matter of course that sulphur toning was unreliable. Want of permanence could easily be contrived in sulphur toning, but, on the other hand, excellent results could as easily be secured. The usual method of sulphur toning, by decomposition of hyposulphite of soda, was not calculated to afford permanent results.

Mr. P. Everitt said that years ago Sir W. de W. Abney had pointed out that there was no reason to suspect the keeping qualities of images composed of silver sulphide.

Mr. J. E. Hodd spoke of some trials of the developed P.O.P. process with which he had succeeded very well. He promised a demonstration of the method, and said that he employed the following formula for development:—

Hydroquinone .....	12 grains.
Citric acid .....	30 grains.
Acetate of soda .....	6 drachms.
Water .....	15 ounces.

The paper was not bromised prior to development, but must, of course, be fresh and not exposed to strong daylight before putting in the frame. He printed until detail was just visible in the high lights; short of this the prints would be hard.

Mr. Haddon remarked upon the better quality of the half-tone developed prints compared with printed-out images, and instanced the fine prints shown some time ago by Mr. Bullen and Mr. Mayall.

A discussion ensued on gold toning, relative to the quantity of gold per sheet required, and the time in which large batches could be finished.

#### PHOTOGRAPHIC CLUB.

NOVEMBER 28.—Mr. Geo. E. Brown in the chair.

Mr. John Gunston gave a very interesting lantern lecture on Switzerland, as seen by the tourist in contradistinction with the mountaineer. With a start from Lucerne, he took his audience over the Brunig railway, through Brienz and the lake of that name, calling at the many delightful little waterside villages on the way to Interlaken. Here views of the famous Jungfrau were obtained, and the journey resumed into higher altitudes. From Murren some fine mountain views were obtained, the snow and ice and cloud effects being particularly well rendered. The Rhone glacier and the great Matterhorn received considerable attention by the lecturer, whose series of pictures was such as to convey an excellent idea of the magnitude and grandeur of Swiss mountain scenery. Mr. Gunston subsequently stated that for snow views he invariably used Edwards' isochromatic plates, with a light yellow screen. For some of the views films were employed. The exposure for a view of snow-clad landscape with foreground and sky at *f*-22 would under these circumstances, with the slow plate be about one-half to one second, the yellow screen increasing exposure about three times. With the instantaneous brand a sixth or a quarter of a second would be about right.

A vote of thanks was passed to Mr. Gunston.

**Liverpool Amateur Photographic Association.**—The ordinary monthly meeting of the Society was held on Thursday, 29th ult., the President, Mr. John H. Welch, in the chair.—The business of the meeting having been disposed of, Mr. Richard F. Soper was called upon to deliver his lecture, "An Easter Pilgrimage to the Shrine of St. Lawrence," being an account of the Society's Easter excursion to Ludlow. The lecture was illustrated by slides contributed by members of the party, and was greatly enjoyed by the large audience assembled. A vote of thanks to the lecturer, proposed by Dr. Thurstan Holland (one of the pilgrims), terminated the proceedings.

**Newcastle-on-Tyne and Northern Counties Photographic Association.**—On Tuesday night, November 27, Mr. W. Parry read a paper on "Instantaneous Photography" before a large audience of members of the above

Association, their friends, and members of the Young Men's Christian Association. He began with a short sketch of the history of photography, tracing it from its earliest conception, almost from the time when it was first noticed that the human skin was darkened by exposure to the sun, to the present day, when such rapidly-moving objects as bullets after being fired, and torpedo-boats travelling at 41 miles an hour, were portrayed on the screen. The lecture was pithily interspersed with humorous remarks and anecdotes, and the majority of the slides being shipping views, were relieved with those of babies, both laughing and crying, showing some of the trials of a portrait photographer in spite of quick plates. Many of the slides shown were those of Mr. Parry's famous "Warships going at full speed," and were magnificent examples of instantaneous work, whilst those made by combination printing were marvels of technical skill, the join between the two negatives not being visible even when Mr. Parry showed where it was. Some of the portraits shown, where the background had been removed to give a statuesque effect, were most pleasing. Several examples of shutter work by other members of the Association brought a most enjoyable and instructive evening to a close. The slides were shown by the Rev. J. W. Ogden, F.R.G.S., with his magnificent triunal lantern.

## Patent News.

THE following applications for Patents were made between November 19 and November 24, 1900:—

- FOCUSING DEVICE.—No. 20,860. "An Improved Focussing Device for Photographic Cameras." H. HOLMES and G. HOUGHTON.
- RETOUCHING DESK.—No. 20,861. "An Improved Photographic Retouching Desk." P. F. COGGIN.
- CAMERAS.—No. 20,862. "Improvements in Photographic Cameras." F. H. SANDERSON.
- VIEW-FINDERS.—No. 20,863. "An Improved Adapter for Photographic View-finders." G. HOUGHTON and W. A. EDWARDS.
- ELECTRIC LAMPS.—No. 20,868. "Improvements in Electric Lamps for Use in Photography." J. SCHMIDT.
- CAMERAS.—No. 20,932. "Improvements in Roll-holding Cameras." Complete specification. P. RUDOLPH and O. NÄTHER.
- SHUTTERS.—No. 20,933. "Improvements in Photographic Shutters." E. DÖNITZ.
- PRINTING-FRAME.—No. 21,034. "Apparatus for Printing Photographs from Negatives." F. W. SUTER.
- CAMERAS.—No. 21,239. "Improvements in or relating to Photographic Cameras." E. S. SHEPHERD.
- HAND CAMERAS.—No. 21,279. "Improvements in and relating to Hand Cameras." Complete specification. A. C. JACKSON.

#### FORTHCOMING EXHIBITIONS.

1901.

- January 14-19..... Blairgowrie and District Photographic Association.  
The Hon. Secretaries, Blairgowrie, N.B.
- February 16-March 9 Edinburgh Photographic Society. Secretary, J. S. McCulloch, W.S., 10A, George-street, Edinburgh.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### C.I.V. PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—I noticed in your JOURNAL soon after the S.A. War started that some photographer in town had taken the C.I.V.'s free of charge, and presented them with copies of their photos. This I did directly the war started to all who were going to the front, and advertised same in the local papers. The sequel came last Friday, when all our local C.I.V.'s and Sergeant Engleheart, V.C., were entertained at a banquet in the Town Hall, Barnet, when I prepared and gave away to each of the diners and guests a souvenir in the shape of a photograph containing all their photos, and suitably inscribed. In all there were about 250. The guests and C.I.V.'s, &c., numbered 50, and they had photos 8x6, and the others cabinet size. I enclose you a rough copy of the small ones. I think you will be pleased to hear that I was complimented on having given them, and received a vote of thanks at the dinner.—I am, yours, &c.,

ALBERT ENGLAND.

The Studio, Triangle, New Barnet.

[The copy enclosed includes ten named members of the C.I.V. It is an excellent print, and, no doubt, the souvenir will be prized by those to whom it was presented. Eds.]

## Answers to Correspondents.

\* \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPH REGISTERED:—

A. J. Lovell, 27, Wellington-row, Brackenthwaite, Whitehaven.—*Photograph of pencil drawing of the Earl of Lonsdale.*

FERROTYPE.—W. BILLING. Ferrotypes plates for the wet collodion process, and all the necessary materials for working it, can be obtained from Fallowfield's, Charing-cross-road.

JOHN ROBINSON.—Yes; an advertisement in the JOURNAL would best suit your objects. The Continental and American journals would, we think, not be of much use to you.

CANARY MEDIUM.—S. ROME. A fish tail burner, shielded by two thicknesses of canary medium, will form a perfectly safe dark-room light. But it will not be sufficient if orthochromatic plates be employed. With them a ruby light is necessary, and even with that the plates should not be exposed too close to it until the image is well out.

THE COPYRIGHT UNION.—"COPY" writes: "Can you give me particulars of joining the Copyright Photographic Union, or could you put me in communication with the Secretary of the society?"—In reply: Address the Secretary of the Photographic Copyright Union, Mr. H. Gower, London Chamber of Commerce, Botolph House, Eastcheap, E.C.

DISPUTED AGREEMENT.—"IN DOUBT." We have read through the copy of the agreement you enclose, and from it we opine that your reading of it is correct. But, as the whole business seems somewhat complicated, we should advise you to submit it to some solicitor in your neighbourhood. Take his opinion, and act according to it, as, to us, one or two of the clauses seem somewhat vague.

RENDERING CALICO NON-INFLAMMABLE.—"BOBS" writes: "I have some calico hanging in the studio, which is liable to catch fire. Can you tell me in what solution to steep it, and thereby render it non-inflammable?"—In reply: Steep the calico in a solution of tungstate of soda and hang up to dry. A solution of alum will also render the fabric non-inflammable, but the tungstate of soda is the best.

SPOTS ON FILMS.—"A. C. W." says: "Herewith please find three negatives made on a rollable film. You will see that, though much under-exposed, the skies are covered with spots. The camera was carefully dusted before the film was used, and it was dusted again before it was developed, so I am pretty certain that the spots were not due to dust."—In reply: We have little hesitation in saying that the spots are due to the emulsion. Send one or two examples to the makers of the film.

COPYING PAINTINGS.—J. WARDLOW asks the following question: "In copying an oil painting, using orthochromatic plates, is it necessary to use so deep a yellow screen, when the light itself is yellow, as when there is a bright summer light. Because, if a lighter tint could be used, and the same result obtained, the exposure would, of course, be shortened."—In reply: If the light is very yellow a paler yellow screen will suffice. Indeed, if the light were yellow enough, no screen at all need be used.

THE ELECTRIC LIGHT IN THE STUDIO.—"INQUIRER" writes: "I am having electric light fitted in my studio, and should be greatly obliged if you would inform me which is the best system, the incandescent or arc lamp. Is it expensive to work after fitted?"—In reply: Both systems are good. The arc is best adapted for a continuous current and the incandescent for the alternating. The light, when installed, is not very expensive in working, but that, of course, depends upon the price charged for the current.

WINTER SNAPSHOTS.—"RUSTIC" says: "I am going to spend a few weeks in London shortly. Will you please say whether, if I bring a hand camera with me, it will be possible to get a few snapshots of London streets."—In reply: Well, all depends upon circumstances. If the light is good—exceptionally good for this season in London—and the plates used are very rapid ones, and the lens will cover with a large aperture, the thing is quite possible. But the work, even then, must not be attempted with extremely rapid exposures.

MUDDY PLATINOTYPE PRINTS.—GEO. MERTON sends some platinum prints, and asks the cause of their muddiness, adding that he has followed the instructions to the letter.—In reply: The cause of the trouble is that the paper has been exposed to damp, and so absorbed moisture. At this season of the year the atmosphere is very moist, and greater precautions against it are now necessary than was the case during the dry summer weather. The remedy is obvious—don't expose the paper to the air, and keep the pads of the frames perfectly dry.

FAULTY LIGHTING.—"A. L." says: "I send herewith six cabinet portraits, which are of the general average of my work, and I am not pleased with it because it is not so good as that done by another photographer in the town. His portraits all look rounder and seem to stand out more than mine do. I shall be obliged if you can give me a hint or two."—In reply: The fault with the portraits is that they are all illumined with too much direct front and top light. Subdue both, and use a stronger side light. If you do that the pictures will be much improved.

CENTRING LIGHT IN LANTERN.—C. WATSON writes: "I have one of —'s lanterns (limelight), but with it I cannot get an evenly-illumined disc on the screen. A friend, from whom I bought it, got excellent results. Can you tell me how to do the same?"—In reply: In the first place, see that the point of light is exactly in the optical axis of the optical system. That being secured, move the light backward and forward until the disc is evenly lighted. Cannot you get your friend to give you a practical lesson in the use of the instrument? It would help you more than any written instructions we can give you.

COPYRIGHT.—"S. O. L. D." writes: "Last year I was commissioned to take a dozen views of the district to illustrate a small history of the place. I supplied prints which have been used for the work. Nothing was said about the copyright. Now the one for whom I did the work has sold his business, and the block with it. Can I prevent the purchaser from using them if I now make the pictures copyright, as I was the author of them?"—In reply: No, you cannot. You were paid for your work, to enable the blocks to be made, and, of course, they are the property of the purchaser to do what he likes with them.

PHOTOGRAPHS ON WATCH DIALS.—"J. R. S." writes: "I shall feel greatly obliged if you or any of your readers will kindly supply me with particulars regarding the process of transferring photos on to watch dials."—In reply: We presume our correspondent means fixing the photographs into the enamel. If so, there are two or three different methods of doing it. The powder process is the one that is generally followed. Space in this column is, however, too limited for giving working details of the process. A pamphlet on the process is published by Dawbarn and Ward, Farringdon-avenue, which gives full working details. Better get that.

SCRATCHED MIRROR.—G. CROSS writes: "I have been trying to do some process work, and the other day, in re-polishing the mirror, which had become tarnished, I managed to get two or three small scratches upon it. They run longitudinally, and are very fine; probably they were caused by a particle of grit on the polishing pad. Will they, as they are very fine, materially impair the working of the mirror, as I do not care to go to the cost of re-silvering it unless it is absolutely necessary, as I am only experimenting at present?"—In reply: The scratches will do no harm whatever. They will only cause a small—very small—loss of light. The quality of the mirror is not impaired at all, as you will find in working.

COPYING TAPESTRY.—"PUZZLED" writes: "I am wanted to copy two pieces of tapestry. They are about ten feet by seven, but they must be done as they are, fixed to the wall. One end of them is more strongly lighted than the other. The pictures have to be ten inches long. Can you tell me of any means by which the light on the two ends can be better equalised in the negative than it seems to be on the originals?"—In reply: In a similar case that we know of, the difficulty was overcome in this way: The plate was exposed for the time necessary to get the best lighted portion fully exposed, then some magnesium was burnt, after the blinds were pulled down to sufficiently light up the darker portions, and the result was good.

PRINTING ON SILK.—"ENTERPRISE" asks: "What is the reason of the outer edges of the sensitising on a silk handkerchief stained by silver marks, although it has not been exposed to light? I followed somewhat the instruction given in your issue a fortnight since. I think it a very beautiful process and very simple to work, but this is a drawback. Would a solution of cyanide of potash remove the stains? If so, what strength?"—In reply: The cause of the staining is that the silk contained some matter that reduced the silver. It was not washed perfectly clean to begin with. The stains may, possibly, be removed by treatment with a solution of cyanide of potassium. Its strength is not very material. The stronger it is the quicker it does its work. Try twenty grains to the ounce of water.

MRS. CAMERON'S PHOTOGRAPHS.—J. G. WILLIAMS writes: "Reference was recently made in THE BRITISH JOURNAL OF PHOTOGRAPHY to the late Mrs. Cameron's photographs. I know an old gentleman here who has shown me two prints (about 12 x 10) by this lady, and incidentally remarked he had several more somewhere. After your remarks on the subject, I have wondered if they are of sufficient value to warrant my approaching the gentleman on the subject; also if there is any society who would take care of and exhibit such pictures, as it might be to advantage to point out that they might be loaned or given to such a body, so as to be useful to the community. If the matter is of sufficient importance, the favour of your advice would be a valuable assistance."—In reply: We thank our correspondent for his letter. The Royal Photographic Society, 66, Russell-square, W.C., might be willing to accept the photographs, which are probably of no commercial value.

\* \* \* We have been obliged to hold over till next week many answers to correspondents, reviews, reports, and other matter.

Information," and "Practical Notes and Suggestions of the Year," there will be found much useful matter, which, with the large collection of formulæ, tables, and other data for photographers, places at their disposal for daily reference a mass of information not to be found in any other photographic annual.

\* \* The 1898, 1899, and 1900 editions of the ALMANAC (20,500 copies) were each sold out within a few months of publication.

\* \* Of the 1901 Edition, just issued, over 18,000 were disposed of on the day of publication—an increase of more than a thousand as compared with last year.

## EX CATHEDRÀ.

We have been asked to announce that a fund is being raised on behalf of Mrs. and Miss Warnerke, who were left in straitened circumstances by the late Mr. Leon Warnerke, whose death we recently recorded in the columns of the JOURNAL. The Committee having charge of the fund consists of Sir W. de W. Abney, C.B., F.R.S., Sir H. Trueman Wood, M.A., Mr. James Cadett, Mr. Thomas R. Dallmeyer, F.R.A.S., Mr. George Davison, Mr. F. Ince, and Mr. H. W. Teed. Mr. Ince has undertaken the duties of Treasurer, and subscriptions may be addressed to him at 15, Netherhall-gardens, Hampstead, London, N.W. This movement has our heartiest support, and we hope that the Committee's appeal will meet with a liberal response. For a quarter of a century the late Mr. Warnerke was intimately associated with photographic progress in this country, and he will long be remembered for the kindly readiness with which he always placed his great store of knowledge at the disposal of those who sought it. A casual study of Leon Warnerke's photographic career must serve to show that, had he addressed himself to the task of securing material reward for his work, he might have easily provided his own opportunities for so doing. But he was quite unselfishly devoted to photography, and it is in that light that we desire to present his character to the photographic world, which is now being appealed to on behalf of those

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1901.

Edited by THOMAS BEDDING, F.R.P.S.

THE Fortieth Annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC is now published. The total number of pages in the 1901 ALMANAC is 1552, and the volume is the largest yet produced. The text portion of the book occupies about 500 pages. It is, as hitherto, issued in paper covers, price 1s., or cloth bound, 1s. 6d.

The frontispiece is a bromide print by Messrs. Morgan and Kidd, of Richmond, Surrey, from a negative by Mr. W. Croke, of Princes-street, Edinburgh. A number of other illustrations will also be found in the text matter. Over eighty articles on practical subjects, contributed by well-known photographers, form a feature of the volume. The principal advances of the year are synopsis in the "Epitome of Progress During 1900," and in the other sections, "Patented Inventions of the Year," "Miscellaneous

to whom, by his premature death, he bequeathed a sorrow of no common poignancy. A list of subscriptions will be published in due course, and we ourselves shall be happy to receive and acknowledge any sums that may be sent to us. Cheques should be made payable to the Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY, and crossed "to account of the Warnerke Fund."

\* \* \*

By the courtesy of Mr. J. Craig Annan, we have received a copy of the circular relating to the photographic branch of the Fine Art Section of the Glasgow International Exhibition, which will be opened in May 1901. This circular, which has been addressed to prominent photographers at home and abroad, states that "the desire of the Committee is to secure the finest and most important works of the leading pictorial workers of this and other countries, both deceased and living." The General Prospectus enters fully into the scope of the Fine Arts Section, of which photography forms a division. Mr. Craig Annan is Convener of the Sub-Committee on Photography, and among the General Committee we perceive the names of John Stuart, George Davison, James Paton, and others that will be familiar to our readers. The Arts Section will be placed in the new Art Gallery and Museum building, "which is of stone, with concrete floors, and consists of a central hall, 125 feet by 56 feet, with two courts, each 102 feet by 60 feet, east and west of this hall. The galleries are twelve in number, arranged in two floors around the courts, with eight pavilions at the corners. The galleries average 100 feet long by 28 feet wide. The upper galleries and pavilions are roof-lighted, and specially adapted for showing pictures." Photography, we understand, will be placed in one of the galleries here referred to. Mr. Craig Annan and his colleagues are working assiduously in the interests of the photographic section, which, it may be anticipated, will be the most comprehensive of its kind ever organized. It may be noted that the invitation circular asks for the loan of specifically-named photographs, but adds: "In the event of these works not being available, the Committee will be glad if you will suggest others which you could place at their disposal." This is really a wise provision, for, as the photographs are not to be delivered till March 30, there is quite time for the birth and growth of a new school of photography—so quickly are these things managed nowadays—and it would be a pity if it were not represented at Glasgow. But, seriously, we shall watch with deep interest the effect on other great exhibition executives of the notable action of the Glasgow authorities in giving pictorial photography a place in the Fine Arts Section next May.

\* \* \*

A COPY of a distinctly fresh and novel "Christmas number" has recently reached us. It is called "New Zealand Illustrated," and it is issued from the offices of the "Weekly Press," Christchurch, N.Z. Our distant confrère shall himself describe the principal features of his annual: "The pictures total over 180, and, except about thirty, duly acknowledged to various successful New Zealand photographers, amongst which is the beautiful photograph of 'The Pikau,' by Iles, Auckland, which adorns the cover, the negatives used have been made by Messrs. J. N. Taylor and Walter Burke, F.R.P.S., both of our staff. The whole of the process work, the printing, and the elaborate litho-

graphing of cover and supplement was done in our office and by our own staff." Beyond its sub-title of "Christmas number," there is nothing of a seasonable character about this admirably-produced publication, which, by the aid of its well-made phototypes, gives us, it would appear, a glimpse of the chief features of life in New Zealand. Dunedin, Auckland, Napier, Wanganui, and Nelson look to be delightful places, and so many, so varied, are the beauties of New Zealand pastoral life as shown in these sunny photographs that, writing as we do in the midst of December gloom, we are tempted to envy those who are privileged to live their lives where Nature is more gracious than here at home. It is a most interesting number, which we shall preserve for future reference; the blocks are well printed, and the original negatives have obviously been made by skilful photographers. In future issues we shall expect three-colour photography to be substituted for chromo-lithography in the production of the cover and presentation-plate. Meanwhile, let us say that we have been exceedingly pleased at the receipt of this very unconventional Christmas number, upon which we congratulate our Christchurch brethren.

\* \* \*

THE "Majority" dinner of the Photographic Club, which was held last week, was a pleasant little festivity, and amongst the fifty or sixty gentlemen present there were some whose photographic experiences extended back thirty or forty years. We are betraying no secret in saying that the Club passes into the twenty-second year of its age with some misgivings as to the tenure of existence which lies immediately before it. With a past career of great usefulness to look back upon, an excellent library, meeting-room, dark room, apparatus for projection, a good sum of money invested, and some men of first-rate photographic knowledge still on its books, the Club, nevertheless, has to face a diminishing membership and dwindling interest in its meetings. The full causes of this are beyond our present purpose to inquire; we may, however, offer the friendly hint that in these days an annual subscription of one guinea is too much to expect from new-comers in photography who in suburban London can find plenty of useful photographic societies whose dues are considerably less. Mr. Bridge, the Chairman of last Saturday's dinner, made an appeal to members to help revive interest in the Club, and we hope it may be found practicable to do so, although, with the Royal Photographic Society nowadays occupying such a powerful position in the estimation of London photographers, we confess that we are not sanguine that it can be done. Still, the experiment is possibly worth attempting though it will be a task of no slight difficulty to destroy an impression, which we have found to prevail, that the Club has accomplished its mission. We sincerely hope, as we wrote some weeks ago, that the word "Finis" will not be written to the Club's record so long as photography itself exists, and nothing would please us more than to find that with the new year it entered upon a new lease of life. Twenty-one years ago, however, when the Club started, gelatine photography was a fresh and absorbing subject of experiment and discussion, and, great as photographic advance has been in the meanwhile, we fear that London photographers have no longer anything so much in common as the revolution in negative processes provided them with in the

years from 1878 to 1884 or so. And it is this fact which, perhaps, will most baulk whatever efforts are made to replace the Club in its former position of influence.

\* \* \*

DURING the past week a considerable number of letters have appeared in the London "Standard" from victims of the "Société Artistique de Portraits, Paris." From the letters it seems that this enterprising firm of swindlers now make it a practice to send their alluring circulars to the relatives of persons whose deaths are advertised in the English newspapers, offering to send free of all charge a "beautiful crayon portrait," and, from the letters referred to, it appears that this new game has "caught on," for the writers of the letters have sent photographs of the departed with the result that they cannot get them back, unless they remit for the "beautiful crayon portrait," or the frame for it, or, failing that, the eight shillings, for the packing, &c. A professional friend, anent this subject, remarked to us a day or two ago that it served the victims right to expect that they would receive from a foreign firm a handsome picture for nothing. Why should they, especially after all the exposures of the swindle in the photographic press and the daily papers? It is almost inconceivable that English people are so easily gulled as to send "priceless portraits" to a foreign country expecting to receive enlargements from them "free of all charges." They can, of course, for a very modest sum now get them from the local photographer. "A Mother" writes, amongst the letters referred to, that she sent "a photograph of her little son, who had only just died, which photograph I would not lose for worlds." She ultimately sent, she says, five shillings, to which the Société finally reduced the charge, but had not succeeded in getting either the photograph back or the beautiful crayon portrait. Another letter, from "A Son," says: "I sent my father's photograph—the only one I had—with the usual result." Another writer says he had sent a portrait of a deceased son, also with a like result. "A Father" complains that he has sent "the only photo I had of one of my daughters," and because he refused to remit the eight shillings he has not heard any more from the swindlers. There are several other letters to the similar effect. It does seem surprising that a certain section of the British public are so easily duped by the offer of something of value for nothing; but while this is so, swindlers, however barefaced, will flourish.

### SEPIA PLATINUM PRINTS AND THEIR PERMANENCY.

THE brief note in a recent issue on this subject has raised a question of considerable importance, and on which very little work has been done, practically, in fact, the only work recorded being by Hübl, of Vienna, before entering upon which it would be as well to consider the means that are employed for obtaining sepia and brown tones generally.

The most reliable method of obtaining sepia tones is undoubtedly by the use of the special sepia commercial paper, and the agent which it is said gives the sepia or brown tone is the addition of a palladium or mercury salt to the sensitising solution. On the other hand, there is not the slightest doubt that the sizing of the paper has some in-

fluence on the tone, for Hübl<sup>1</sup> says that animal-sized paper tends to give bluish-black tones, whilst papers sized with vegetable matters give brownish-black tones.

Another method of obtaining sepia tones is by using a mercury salt, mercuric chloride in the developer, as was done by Rowland Briant<sup>2</sup> and Strakosch.<sup>3</sup>

The third method is by the use of uranium, in the form of the well-known uranium intensifier, a process which seems to have been independently worked out by Rowland Briant<sup>4</sup> and Mr. Fitz-Payne,<sup>5</sup> the difference being that the former intensified his prints first with acidified gallic acid and silver nitrate, and thus obtained a red brown image, which could be further modified by the use of uranium; the latter, on the other hand, stated that black platinotype thoroughly freed from iron could be toned at once with the uranium. Strakosch used precisely the same process.

In 1895 Packham<sup>6</sup> described before the Royal Photographic Society a method of toning platinotypes with a solution or decoction of catechu. Peebles Smith<sup>7</sup> suggested in 1897 a process of obtaining sepia and brown prints with the ordinary black cold-bath paper by the use of a warm mixture of potassium oxalate, cupric chloride, mercuric chloride, and lead acetate, and this process will give an enormous range of colours.

As regards the permanency of the sepia prints obtained by the use of palladium and mercury in the sensitising solution, Hübl's paper<sup>8</sup> is very explicit, and no apology is needed for inserting a literal translation of the same. He says:—

"By the addition of palladium or mercury salts to the sensitising solution of the iron-platinum papers, platinotypes of pure brown tones, the so-called sepia prints, may, as is well known, be obtained. The cause of the brown colour can be explained in two ways; either we must assume that a brown mercury compound or brown metallic palladium is deposited in the black platinum precipitate, or there must be, in the presence of the said metallic salts, the platinum separated in a brown-coloured modification.

"The following behaviour of the sepia prints unmistakably supports the latter assumption:

"1. A print prepared with pure palladium salt disappears completely when treated with hydrochloric acid, and, since all palladium and mercuric prints<sup>9</sup> become brighter in the hydrochloric acid bath, it must be conceded that in developing any deposited palladium or mercury compounds a change in the shade of the colour cannot be noticed.

"2. Neither ammonia nor sulphuretted hydrogen alters the colour of the mercury image.

"3. Bromide vapour bleaches the brown image without altering the colour.

"4. Sepia prints, copiously treated with hydrochloric acid, cannot be toned in a uranium bath without a reducing agent, and it would appear that any observations to the opposite must be ascribed to insufficiently acid-treated pictures. If with prints thus toned with uranium the ferrocyanide of uranium be removed with ammonia, the original brown image is obtained again.

<sup>5</sup> Camera Club "Journal," vol. vi. p. 161.

<sup>6</sup> "Photo News," 1895, p. 108, Patent No. 24,963, 1894; abstract, "Brit. Journ. of Photography," 1894, p. 798.

<sup>7</sup> "Amer. Amateur Phot.," 1897, March.

<sup>8</sup> Eder's "Jahrbuch," 1895, p. 264.

<sup>9</sup> It is obvious that here Hübl speaks of platinotype prints from paper sensitised with these salts.—Eds.

"From these phenomena it must be concluded that the sepia print, assuming that it has been sufficiently treated with hydrochloric acid, consists actually only of pure metallic platinum, which under the said conditions is separated in a brown modification. That metallic precipitates can be precipitated in various shades of colour is a well-known fact, as without palladium and mercury brownish-toned platinotypes can be prepared.

"The assumption stated is finally supported by the behaviour of platinotypes to silver intensification. Black prints intensify with silver nitrate and a reducing agent into black; sepia prints, however, into a brown colour. This peculiarity can only be explained by stating that the depositing silver settles down in a molecular structure corresponding to that of the platinum precipitate."

If these arguments can be accepted, and we see no reason against the same, one might assume that all sepia platinotypes produced by the addition of various metallic salts to the developer are equally permanent, though we are not aware of any experiments with prints produced by Peebles Smith's process, a process which is valuable in that it enables any tone to be produced, from deep blackish-brown to quite a red having been recorded.

As regards uranium toning, the general consensus of opinion and experience go to prove that the results cannot be depended upon as regards permanency, and we believe that a platinotype thus toned, which was one of the permanent collection of the Royal Photographic Society, showed after about two years considerable change of colour where exposed to the light.

As regards the catechu toning process, the only statement that we know of on this is made by Eder,<sup>1</sup> for he says, "The platinotypes, coloured brown by toning (uranium, catechu, &c.) contain as the lower image metallic platinum; the toning with uranium is quite stable, that with catechu, however, is not quite stable to light." It will be noted that Eder considers uranium toning permanent.

With regard to the catechu toning, a very similar and prior process is that of Liesegang, who obtained brown tones by the oxidised products of pyrogallol, amidol, &c.

**Silver Salts dissolved in Silver Nitrate.**—Herr Karl Hellwig has been investigating the conditions under which various complex silver salts exist in solution, some of which it may be well to place on record. At 25° C. in nitrate of silver solution, silver iodide, bromide, chloride, cyanide, and thiocyanate respectively, were soluble to the extent of 9.4, 2.13, 5.6, 9.1, and 2.6 millimoles per litre.

**Action of Chlorine on Metallic Silver in the Light.**—V. von Cordier has been investigating this subject, and finds that blue and violet light favour the combination of silver and chlorine, while red light seems to be inoperative. If light before being allowed to act be made to traverse a sufficiently thick layer of chlorine, it behaves similarly to red light, but the actual result depends upon whether the gas was dry or moist. If the gas was dry, the action was partly much the same as when white light is used, but, if passed through moist chlorine, a considerable diminution in the activity of combustion is observed. If a little hydrogen be added to the chlorine the difference is still more noticeable. Röntgen rays do not influence the action of combination in the slightest degree.

**Velocity of Light.**—The figures generally considered the most trustworthy are those of Professor Newcomb made at Washington

<sup>1</sup> "Handbuch der Photographie," vol. iv. Heft 2, p. 232, 1899.

in 1882. He employed Fizeau's mirror system and arrived at 299,860 miles per second as being the correct velocity. This Fizeau method involves the use of a fixed and revolving mirror, Professor Newcomb in his experiments separating them by a distance of 2550 yards in one set and of 3720 in another. It is obvious that the greater the distance apart of the two mirrors the more accurate are the figures obtained likely to be. Recently an experiment has been made increasing the distance of separation to an unprecedentedly large degree. M. Perrotin described to the Paris Academy of Sciences his arrangements, the separating space between the mirrors being no less than twelve kilometres. To ensure the utmost accuracy possible, fifteen hundred separate estimations were made and the mean of them all was but slightly different from Newcomb's, 299,900.

**Examinations and Studies.**—Dr. Oliver Lodge, in his address to the students of the University of Birmingham, enunciated some novel views in regard to the time examinations should be held with regard to the preceding period of study. Virtually he proposed that the examinations should not immediately follow the teaching, and that a vacation interval should intervene for private study and revision, quiet thought, assimilation, and digestion. Students should not be taken straight from the lecture room into the examination room so that they might tell the examiner what the lecturer had said before they had time to forget it. So he wished to urge that a long vacation should be left between instruction and examination; that the examinations be held in September instead of the end of June. If no interval for rumination was afforded during student days, if the unrooted ideas were pulled up for inspection by the examiner at the end of each session, the students turned loose in the holidays, empty, swept, and only partially garnished, for a period of complete idleness before another filling-in process began, the last state of that man was liable to be little better than the first. These are novel but weighty words, and deserve consideration by all examining bodies.

**Corona Photographs.**—At the last meeting of the British Astronomical Association much time was given to the question of the best way to photograph the sun's corona. It is naturally desired to obtain a view of the whole phenomena presented to the eye at one time; but, if sufficient exposure be given to bring out the corona, the chromosphere itself would be overdone beyond redemption; while, if the latter be snapshotted, the corona is lost. Then again, in view of the discrepancy between the results of photography and sketching by hand there would seem to be a probability that the actinic picture of the corona may greatly differ from the visual one. Professor Burckhalter some little time ago devised a method of so graduating the exposure given to each part of the image that one consistent uniform whole was produced. This method was described by Mr. Nelson at the meeting, and Mr. Crommelin praised it highly, and stated that he considered it the process of the future for obtaining a good picture of the whole corona. Mr. Thorp, whose work with diffraction gratings is so well known, made an excellent suggestion, which he considered simpler than Professor Burckhalter's—to place a vignette arrangement in front of the plate during exposure.

## THE OPTICS OF TRICHROMATIC PHOTOGRAPHY.

[The Third Traill Taylor Memorial Lecture.]

### IV.

THE negatives are made through an opaque line screen in combination with a party-coloured lens diaphragm. The opaque line screen is placed within the focal plane, and so adjusted with respect to the parti-coloured diaphragm as to make a line record of the same character as with a coloured line screen, but with the advantage that the selective colour screens can be made up of superposed films and glasses with the same precision as kromskop camera screens, and the ratio of exposures can be perfectly controlled without the use of compensating screens. This method has one disadvantage as compared with the use of the selective coloured line screen, and that is, that it

akes longer exposures to make the negatives, and it gives slightly separated view points for the three elements, introducing colour rings on the edges of out-of-focus objects.

The most remarkable novelty is the method of synthesis without coloured line screens. For this purpose a simple optical device is employed, containing at one end three bits of coloured glass, and in the middle a pair of plano-convex lenses. Between these lenses is glass, on the surface of which has been moulded in gelatine a series of prismatic lines. Right-hand prismatic lines refract to the eye light coming through the bit of red glass, left hand prisms' light coming through the blue glass, and flat spaces between transmit light from the green glass directly. To the eye, at the other end of the instrument, this prismatic surface has exactly the appearance of a coloured line screen, but the lines can be made finer, and the colours as pure as in the kromoskop.

The positive line record, when brought into register upon this surface, shows the colours with all the vividness and accuracy of the kromoskop image,\* and the whole outfit is simple enough to be made and sold as a superior scientific toy. I call this instrument the kromolinoskop.

Louis Ducos Du Hauron proposed to make prints on paper by the coloured line tint processes, and MacDonough and his successors have tried to carry out the idea commercially. It should be evident that if the coloured line tint is made up of pure colours, as it must be for accurate results, the "whites" of such pictures would be much nearer black than white, as compared with white paper in the same light. In practice, very weak colours are used, and the result suggests a tinted photograph with overcast whites. Those examples which I have seen cannot be compared for quality with good trichromatic prints from three half-tone process blocks, and the practical difficulties of the process are far greater.

Another and very ingenious method of positive synthesis is Professor R. W. Wood's "diffraction process." Professor Wood commences with an ordinary trichromatic positive colour record, such as a kromoskop "kromogram," and prints the three images in register upon a bichromated gelatine or albumen film in diffraction-line tints, in which the lines are so spaced that the deviation for red in the print from the red positives corresponds to the deviation for green in the print from the green positive, and blue in the print from the blue positive. The resulting composite print is colourless, but, when viewed in a simple device suitably adjusted with respect to a single small source of light, diffracts to the eye a mixture of coloured lights which, theoretically, should be equivalent to the kromoskop image.

By disposing the diffraction lines horizontally, which I suggested in order to readily permit of binocular vision, Professor Wood has been able to obtain stereoscopic reproductions, and the most serious defect in the picture at present is a tendency to crudity of colour, due to the fact that diffraction-line prints do not ordinarily show correct gradations of light and shade. I have proposed to overcome this difficulty by breaking up the diffraction lines by casting V-shaped shadows across the plate when making the diffraction print by means of an opaque line screen used according to my principle of gradating the lines in the half-tone process. I believe that the rendering of gradations of light and shade in the diffraction-line print can be perfectly controlled in this way. The prints can be made by placing the diffraction tints (on pellicles) in contact with the bichromated film, the kromoskop positive over this, and the opaque line screen over the positive, with the direction of the lines at right angles to the diffraction lines. The opaque line screen may be so fine that the graduated breaks in the diffraction lines will not be noticeable in the result. Mr. Thorpe, of Manchester, has made diffraction prints with a single diffraction grating by disposing the lines at three different angles, and employing three sources of illumination.

The principles of trichromatic printing I have already set forth.

\* One condition of perfect purity of colours in this reproduction is a "structureless" positive image. A fine ground glass laid upon the positive so mixes the coloured rays that the picture is converted into a perfect monochrome, and a very granular positive image degrades the colours by introducing a small amount of the same action. By supplementing the prismatic screen with an opaque line screen adjusted as in the camera, this defect can be remedied, but chloride of silver positives toned black should give perfect results with the prismatic screen alone.

It remains to make a few remarks about various methods of producing such prints.

The most perfect results have been obtained by printing in bichromated gelatine, either pigmented or afterwards coloured by immersion in dyes. Louis Ducos Du Hauron made prints in pigmented gelatine and superimposed them in register upon a single support. With "colour-curve" negative records and correct printing colours, very good results should be obtained in this way, provided that the printing, and development, and pigmentation of the films are all in perfect harmony—conditions extremely difficult to secure.

In 1889 I made such prints by sensitising commercial gelatino-bromide celluloid films with bichromate, printing the three images as one, developing as one, dissolving out the bromide of silver, and then cutting them apart and dyeing by immersion in aqueous solutions of the dyes. This method offers the important advantage that the prints are equal in printing and development, and the colouration can be controlled. The finished prints were cemented together with Canada balsam between glasses. I communicated this method to others before publishing it myself, and it has since been credited to others, but I believe I was the only originator of it.

Lumière Brothers published a method which is an adaptation of the principle of the gum-bichromate process, and they have shown some excellent results in lantern-slide and stereoscopic transparencies, but the opinion has been expressed that most of their work was not done by the method which they published, but possibly by Woodburytype printing.

Dr. Gustav Selle has adapted a principle which had previously been employed for making monochrome prints upon fabrics. He prints in thin films of bichromated gelatine, washes out the free bichromate, and colours with dyes which are fixed in the film by the chromium oxide, which has been produced by the action of light. Reimmersion in water dissolves out the colour not fixed by the chromium oxide, and leaves a positive colour print, which is sometimes very good, but it is apt to be rather too feeble for transparencies and to be tinted in the whites.

Attempts to reduce collotype trichromatic printing to successful commercial practice have wasted much time and money for a dozen printing houses since I uttered a warning and showed why the method is unsuitable. I do not know of anybody who is trying to do it now.

Trichromatic printing with half-tone process blocks was first carried out by me in 1881, and is now developing considerable commercial importance. Its development has been slow, partly because suitable paper, inks, and presses were not at first available. The almost universal adoption of the half-tone block process for typographic illustration has gradually brought about the necessary improvements in machinery, materials, and methods, so that, with correct principles to go on, improvement should now be rapid.

I now come to the consideration of some special methods and modifications, which at present appear to be more interesting than important, and must be treated briefly.

Dr. Hauron, some years ago, proposed the production of colour records in an ordinary camera by employing three transparent sensitive films superposed, one sensitive to violet light, another to green light, and another to orange light, with interleaved films of colour to control the action. The idea is a very ingenious one, and theoretically feasible; but, in practice, it will hardly be possible to make three transparent films of different colour sensitiveness which will either give the same scale of gradations in the developed images or require similar exposures. The problem of working to colour curves is also greatly complicated by this arrangement of superposed films. I am of the opinion that the production of colour records by my camera with the rhomboidal prisms will prove not only much less troublesome, but incomparably more reliable and satisfactory.

Mr. J. Wallace Bennetto has proposed a semi-dyalitic system, in which the sensitive films for the green and blue images are superposed, and the plate for the red image exposed separately, in a camera having a single transparent reflector of red glass. This system has, to a lesser degree, the defects of Du Hauron's dialytic system, but with the added defects of uneven illumination across the plates, due

to the use of a transparent mirror in a camera with a single objective, and the polarisation defect.

Charles Cros, in 1881, proposed a composite black film, made up of three or more fugitive colours, each of which would be bleached out by the action of light of the colour complementary to itself.\* This is, theoretically, the most rational basis for a direct process of pigimentary colour photography that has ever been suggested, but it is doubtful if it can ever be practically developed and the colours fixed. This method has been reinvented several times, and I gave it out as a new idea myself in 1891,† together with some observations upon developing and fixing the prints. Otto Wiener has since elaborated the same idea.

In conclusion, although Maxwell's colour measurements furnished the key to a proper realisation and exposition of the principles of trichromatic photography, acknowledgment is especially due to Sir William Abney for his more complete investigations along the same lines, for many helpful observations, and for new methods of selecting and measuring colours, all of which are most valuable to the student, and should be taken at first hand. I give none of the references, because everybody who is interested in this subject should read everything which bears Sir William Abney's name as author.

Acknowledgment is also due to Mr. Thomas Bedding for his appreciation of the importance of this subject, which led him to pay close attention to it for years, and finally to publish it in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, the best editorial review of the progress of trichromatic photography which had ever appeared in photographic literature.

I am aware that the incorporation of so much controversial matter in a scientific lecture is not generally to be commended, but the circumstances are, perhaps, somewhat peculiar, and I believe its bearings upon the subject will make it helpful in this instance. I am trying to promulgate what I believe to be important truths by the most effective means which I can command, and, if I have erred in judgment or in statement, I shall be only too glad of an opportunity to make all necessary corrections.

FREDERIC E. IVES.

## THE PHOTOGRAPHER'S YEAR.

### DECEMBER.

OF late years there has not been much distinction between the weather of November and December, nor, consequently, as they are consecutive months in the deadest time of the year, of the appearance of things in general in one and the other. This is a change of recent years, for November, in popular estimation, is par excellence the dull and dismal month, December being regarded as brighter and altogether more cheery. Whether this continuation into so mouldy a decaying length of autumn, and the delay in the coming of winter, are merely features of a recurring cycle of weather, or whether the present order is permanent, we cannot as yet say. We would certainly wish it were the former, for crisp cold in the season we have been trained to expect it in is pleasanter than an extension of raw damp, dull skies, and fog. As something in support of the hope being justified by past records, it has been widely noted that there are cycles in weather, a succession of years of one kind being followed by a somewhat equal length of a different kind. Pharaoh's seven full and seven lean years—in which, by-the-way, Egypt would have given most telling contrasts to the photographer had he been then existent—are a well-known instance that will readily appeal to all. Herbert Spencer, our leading living philosopher, also lends incidental support to the view in his generalisations that throughout all nature there is a law of rhythm, a kind of ebb and flow, as it were. But, however interesting such a field of broad inquiry would prove, we are more concerned at present with the weather and the photographic aspect of things in December. Even if the weather of the last few years has come for good, winter has a more successful snatch at an occasional day in December than in November. There are some clear and frosty days, and he who has

\* *Moniteur de la Photographie*, 1881, p. 67.

† *Anthony's Photographic Bulletin*, 1891, p. 93.

held on to his camera in November is not likely to give it up now. The light in quantity is less, but other conditions, by which a fuller amount is made available, are more favourable. So much is not absorbed by fog, and, although hedge and landscape are bare, they are not so damply bare as they were, but show a crisping touch of frost. The same lighter touch of December cold brings what is more likely to generate an enthusiasm strong enough to reach working point, a light fall of snow. To most photographers snow is undoubtedly snow "in the abstract." They are satisfied with it in an artist's sketch, or on a Christmas card, and hesitate at meeting the discomfort of the closer acquaintance meant in getting a picture of their own. These discomforts are much reduced in the light fall, and, fortunately, the light fall is the more suitable to the purpose. In the heavy fall that comes later, there is too complete an obliteration of all the features in the landscape. Distinctive character is lost, and the picture acquires instead the characteristics of the regions of normally heavy snowfalls. An English village too completely under snow looks too much like a Russian or Norwegian village, and its representation loses point. The mind is not inclined to wrench itself free from general conclusions and impressions, strongly, though unconsciously, gained from observation and reading, in favour of the exceptional in any one picture. The more accurately a picture can represent something typical the better and stronger it is. Artists recognise this, and give a sufficiency of detail, spite of snow, to keep interest fully alive. It would not be difficult oftentimes to prove the artist's pictures of snow to be incorrect, for as he feels the cold quite as much as the photographer, and must be longer in it over his work to boot, much of it must be done from memory, and where that fails, by the aid of imagination. Still, in nine cases out of ten his picture is more pleasing than a photograph. The artist knows what he likes, and expresses it, truly inferring that other men probably like much the same thing. This all-important discriminative faculty can never be made up by a selective one, however good, on the part of the photographer; but the conditions are far more closely equalised between the two workers in representing a light than a heavy fall. A photograph under these circumstances would not only show more to advantage, but also gain strength in the hiding of the excess of detail constituting the general drawback to all photographic pictures aiming at being artistic. The plate should be a fairly rapid one, the stop large, and exposure, spite of the prevailing whiteness, moderately long. From personal experience, rapid development with pyro ammonia has proved very satisfactory, although quite as good results have been noted from a lengthier and more cautious use of pyro soda by a friend. No opinion is offered as to the merits of other developers, as they have not been tried fully enough with this type of work to justify it. Probably strong individual liking for a particular developer would, in closer knowledge of its best mode of action, so control its use as to pretty much equalise results. A slow "platino bromide" paper, fully developed, gives a good print.

A powdering of snow adds much to the value and suggestion of the Christmas pictures with which December is full. If there is no snow the photographer is, of course, out of it; but there are, fortunately, other things that strongly suggest Christmas, and it is worth some effort to incorporate them in a picture, even with the valuable touch of snow. It had better be, indeed it cannot but be, if it aspires to any height in stirring emotion, anything but an apt suggestion. Every one's mental picture of Christmas is so vague and inexpressible, made up as it is from bits that have strayed from masterly word-pictures and sympathetic descriptions, such as those of Dickens and Irving, and from scraps of remembrances of many celebrations, that nothing like a complete actual picture will meet and satisfy it. This very vagueness is really a strong help to a suggestion, and the scrappier it is the better, for more room is given to the fancy and imagination to exercise themselves in.

The celebrations and associations being mainly indoor, photographic effort is much restricted. The Christmas tree and decorations can be got, it is true, but they lack the vivifying touch of human presence and interest. Not that it is impracticable to take the Christmas tree being loaded, or the decorations being nailed up, but the exposure is too long, and if there be no movement there is certain to be a fatal woodenness in the result. The figures lack spontaneity and crispness, and the picture takes a third-rate place. The out-of-door possibilities are better; the woodman chopping down the Christmas tree, or carrying it on his shoulder in the lane; children carrying mistletoe and holly; the yule log, still an institution in many out-of-the-way corners, being hauled towards the house. Children's parties and fancy dress

walls are also a pleasing feature of the season. It would do the little ones no great harm if taken out, even bare-headed, for a minute, to be posed against the prepared background in front of a camera ready focussed, and taken. The dress is the matter of an hour, and the child will only too soon grow up past its most interesting stage, but the picture remains for good to call up pleasant reminiscences.

The Christmas picture, generally, is measured more by sentiment than any severe rules of art, or the wealth published by the illustrated magazines would not find so ready and appreciative a sale. This is a concession falling in with the general unbending of stricter rules and laws at Christmas. The season is a kind of wise and necessary safety-valve for emotion that cannot well find expression at ordinary times. It is a splash of colour demanded by the better side of human nature across the prevailing greys of life. The children that we relegate to the care of others at ordinary times are now truly our own, and we recognise their particular claims by making the world as far as we can, in toys, tales, and pantomime, a child's world for their pleasure. The poor, again, are always with us in hospital, workhouse, and overcrowded slum. We recognise that we cannot be always attending to them personally, and possibly do our alternative best in arranging matters for, and subscribing towards, their well-being. But Christmas brings an instructive desire for a closer and personal touch; dinners and suppers are provided as pleasant extras, and individual effort made to make accompanying entertainments bright and successful. Whatever religious value may be attached to Christmas, if the founder who gave his name to the season had done no more than generate so keen an acceptance of the feeling of common humanity with the less fortunate, and the desire to brighten their less happy lot, he has done incomparable good to human nature and its moral evolution.

As bearing upon our point, this enlarging and softening of sympathetic feeling can be helped out by the photographer, and he himself gain in doing so. Reference has already been made to the possibilities of the picturing of children in social mood. In the general social character of the season these are enlarged. There is no compliment more highly felt by any member of an assembled family than the offer to take his or her photograph. Apart from the little excusable touch of vanity that every one feels at having his picture taken, a father or mother's enjoyment must be much heightened by the evident desire of a son or daughter to gain a pleasing picture of them. The time of the year is certainly about the worst, but this must be accepted, and the gain in a willing subject at his best far more than compensates for inevitable drawbacks. The picture taken when technical difficulties were at their lowest, and skill at its highest, in the studio of the professional in June, was not regarded as particularly good. Individuality was lost in the frock coat, the pose, and the unaccustomed accessories. Although it will not be now an indoor picture, father in his top-coat ready for a walk, with a portion of his own house, lawn, or garden as background, is quite as much father as though he were seated at the residence, and infinitely more so than in a strange studio. The gist of the argument is the value and further accentuating of those conditions making for true and broad success, as opposed to the subsidiary ones making merely for technical excellence. The former will probably be their best in every way under the benign and mellowing influence of Christmas.

In December, as in the preceding and following wintry months, there is much work that can be done to fill up dull evenings. Photographic dealers offer a bewildering variety of papers upon which printing of the highest excellence can be done by gaslight. As the print must always be the final desideratum, and negatives yield such varying results with different papers, experiment sufficient to formulate broadly the best results to form working rules could with advantage and interest be carried out. The "personal equation," indeed, makes this a necessity, for it is rarely that two men will agree as to the merits of a paper, even though both have closely followed the maker's directions and formulæ. This makes any definite detailed statements upon the subject of little general value, did space permit of their discussion.

At the close of this series of articles that throughout the past year we have gone to make up "The Photographic Year," the same reason is offered as a reason for their scrappy and discursive character. It is hoped, however, that readers sufficiently interested to have followed them, although possibly from their particular and personal points of view, are inclined to question the value of many of the statements made, may yet have to acknowledge having gained occasionally a fresh outlook that would not otherwise have suggested itself. If so, the writer most cordially hopes it may find practical fruition in many pleasing pictures.

## BELGIUM—A RETROSPECT.

### II.

I HAD many times visited this picturesque old treasure house, but hitherto had not been able to obtain permission to take any photographs of the interior. Now, however, I had succeeded in doing so, and went to avail myself of the privilege, accompanied by the friend recently alluded to. The arrangement between us was, that I was to take my pictures while he wrote his articles. Unfortunately, when he had finished his paragraphs he seemed to consider I ought to have finished my exposures, and we ought to "move on." It was an instance of theoretical versus practical photography. However, eventually, we each got "through," and were content. I have been there many times since. The position of a few of the objects has been slightly altered, otherwise it is exactly the same as it was when I photographed it; but I always seem to miss that familiar figure who on that memorable occasion, sixteen years ago, sat in out-of-the-way corners making notes.

It was on this journey I made my first series of the Ruins of Villers-la-Ville, an old Cistercian monastery founded in 1147. It came to our knowledge that "billets circulaires" were to be obtained which would take us from Antwerp to Brussels, Ottignies, and Villers, and from Bousval to Nivelles, Braine l'Alleud (Waterloo), Brussels, and back to Antwerp for 3f. 30c., and we availed ourselves of these. Similar tickets are still issued, and at the same fares. The only condition is that the journey must be completed in two days, otherwise you are at liberty to stop anywhere on the route. It is a very enjoyable journey, and through some very pretty country. We had admired and photographed the abbey, walked through the wood between Villers and Bousval, and travelled from Bousval to Nivelles when a curious incident occurred which caused the stationmaster of the latter place some anxiety. We were on the platform consulting the time-tables, and, having ascertained there would be no train to Brussels for about an hour and a half, we decided to go for a stroll, but lo! and behold, all the doors leading from the platform were fastened, and the stationmaster (who appeared to be "Lord High Everything Else") had left us alone in our glory! In an old city like Nivelles there are many more interesting places than the platform of the railway station; but, how to get out? that was the question. While thinking this over we heard the sounds of a steam organ, and the usual shouting, singing, and noise which denotes a kermesse or fair. Doubtless this was where the combined station-master-porter had gone to while away the interval between the trains. We tried several of the doors without success; at last we came upon one with a piece of moulding broken off which allowed the bolt of the lock to be seen; the blade of a pocket-knife "did the rest," and in a couple of minutes we were through the waiting-room and out into the street. Having carefully closed the doors after us, we went up into the town, took some photographs of the old church and other buildings, and returned to the station just in time for the train. The expression of the official when he saw us was a study. He tried to open up a conversation on the subject of our "vanishing trick," but we simply stared at him (one of us with a stolidly blank expression, and the other with a pleasant smile), and professed perfect ignorance of either French or Flemish. We entered the train, and, looking out of the window as we departed with a polite "Bon jour, Monsieur," left him standing bewildered on the platform, evidently wondering at the eccentricity of "les Anglais."

Arrived at Brussels, another episode awaited us. At that time a Mr. Van der Perrenboom was very unpopular; whether he had been trying to "stagger humanity" in Belgium, and failed, I do not know; but there was no question about his having rubbed somebody the wrong way. Bands of students and others paraded the streets singing either the "Marsellaise" or a lugubrious chant which had been composed "pour la circonstance." As we emerged from the railway station we suddenly found ourselves forming the advance guard of a revolutionary mob, and in imminent danger of being "run in." We had no alternative but to accept the situation, but at the first opportunity slipped down a side street, and found our way to the North Station by a more peaceful route. It was an exciting experience, but fortunately not of long duration.

When I visited Belgium in September 1889, I was accompanied by another light of literary photography, viz., the late J. Traill Taylor. It was his first visit to Belgium, and we made the most of the time. At Antwerp, after the churches, I think the thing that astonished our friend most was the great number of jewellers' shops in the Klapdorp,

his opinion being that the extent of the jewellery business in a city might be taken as a sort of a thermometer indicating its wealth and prosperity; hence, it need scarcely be said, Antwerp, from a commercial point of view, rose considerably in his estimation. The thing attracting the most attention there at the time of our visit was the terrible catastrophe of September 6. Everybody was talking about it, everybody was more or less suffering from it. Everywhere (especially on the north side) there were evidences of its severity, if only as revealed by the broken windows and cracked walls. Collections were being made in every part of the city in aid of the sufferers. The village of Austruweel was a wreck; not a house remained; whole families were annihilated. Portions of human bodies had been blown to the other side of the river, and sailors belonging to various ships trading to Antwerp came home to find their houses destroyed and themselves the sole survivors of a family.

The large petroleum stores of Messrs. Reith and Co. at that time were reported to have contained about 80,000 barrels. One of the large tanks (about the size and shape of an ordinary gas-holder) was battered in, and thousands of gallons of petroleum escaped and flooded the place; everything that would burn had been destroyed. Railway waggons were merely a mass of bent iron, and steel rails were twisted into the most remarkable shapes; and all this through a want of proper supervision on the part of the authorities.

It appears that a man who rented one of the warehouses in the vicinity of Austruweel bought 51 millions of cartridges from the Spanish Government solely to break up and sell for gunpowder, copper, and lead. He employed a large number of girls at a small remuneration (65 centimes per day), and they had picked to pieces more than 25 millions of cartridges when the explosion occurred. Only 700 pounds of gunpowder were supposed to be on the premises at one time. What the quantity really was on the day of the accident will never be known, but the surrounding property was simply annihilated and hundreds of lives had been lost. Everything possible was done by the Belgians to aid the sufferers and survivors of this terrible misfortune, as much as £24,000 having been collected in a few weeks.

Of course, friend Taylor and I went to visit the scene of the disaster, and obtain, if possible, some photographic record of it. This latter was not easy, for two reasons: firstly, there was little remaining to photograph; and, secondly, the soldiers on duty would not allow any one to go near the little that remained. I had taken one picture, and my companion was very anxious to get a nearer view of the ruins. "Point the camera to that soldier over there," said he, "that's where we want to get." The soldier saw us, and straightened himself up. After I had capped the lens, we saw him coming slowly towards us. We had a chat with him, and asked if he would like a print of the photograph we had taken. He was graciously pleased to favour us with his name and address. Then he asked if we would like to go over the ruins; if so, he would go with us. This he did. The ground in many places was still saturated with petroleum, the terrible ruin we beheld and the sad stories we were told, made "la catastrophe" the subject of our conversation for a long time afterwards.

The Zoological Gardens of Antwerp are among the best in Europe. The collection of animals is very comprehensive, and there is an absence of that malodorous state of things which exists in, at any rate, one other European collection I could allude to. The old railway station, which was by the side of the gardens, and on a level with them, has during the last few years been improved away. The trains now run on the high level; a magnificent glass-roofed new station now terminates at the end of the Avenue de Keyser, and the space so many years occupied by the temporary station is being rearranged to include (among other improvements) an imposing new entrance to that happy hunting ground of the "snapshotter" and lover of good music, the Jardin Zoologique.

Mr. Traill Taylor and I had been "doing" the gardens one afternoon, when my companion made a dead stop before a shop window a few yards from the old entrée. American Cake Tobacco at 25 centimes "per stuck" was more than he could resist. We entered the establishment, and he bought enough to fill a pocket of his long overcoat. In vain I pointed out there might be some difficulty at Dover. "Sufficient for the day," &c., said he; "Sufficient for three months," said I. And he carried about his stock of tobacco with evident gratification, as the prospect of many a pipe full free of duty crossed his mind.

About halfway between Antwerp and Brussels is the little town of Malines. About ten minutes walk from the station will bring us to the Grande Place, where, within a few hundred yards, are all the

objects of interest. The Cathedral (St. Rombold), with its lofty tower and skeleton clock-face more than twice the diameter of Big Ben; the Town Hall; the Schepenen Huis; the statue to Margaret of Austria and other good subjects can all be photographed within a couple of hours. Any one liking old bits has only to find his way back to the station by the Rue de l'Empereur, and ask for the old Palace of Margaret of Austria (now the Courts of Justice). If the concierge is a good temper, and the courts are not sitting, some very good subjects may be found in the older portions of the place.

The attractions of "Petite Paris," as Brussels is so often called, have, from the photographer's point of view, been considerably added to during the last 35 years. The old parts of the city are much the same, and it is a matter for congratulation that the Guild House in the Grand Place (one of the finest mediæval squares in Europe) have been restored and rebuilt from time to time in the old style of their predecessors. No attempt has been made to modernise or improve them, and the result is that the beautiful Hôtel de Ville and its surroundings make the square one of the chief attractions of the city.

Of the cathedral I have already spoken. The new churches in the outer portion of the ever-increasing city are not very remarkable. Some of the older ones have been restored; but Notre Dame des Victoires (dating from about 1550) has just donned a new front, and the incongruity is anything but satisfactory. The Porte de Hal still rears its head with a kind of a sort of a "don't forget me, I am the sole remnant of the old fortifications" about it. The monument to Counts Egmont and Hoorn, notwithstanding the addition of ten years ago, is as ineffective as ever. But the little Mannekin Fountain behind the Town Hall is still one of the curiosities of Brussels.

F. A. BRIDGE.

#### LONG FOCUSED LENSES.

[Received too late for the ALMANAC.]

"ALWAYS use the longest focussed lens possible" is a piece of advice often given, and it is wholesome advice, because it tends to counteract the inclination that so many have to use the shortest possible focussed lens they can, without the appearance of dark corners on the plate with the object of getting in as much as possible of the view.

But it must not be supposed that the use of a very long focussed lens is generally possible or desirable. One photographer I knew asserted that for landscape work no lens of shorter focus than 30 inches should ever be employed when using  $\frac{1}{2}$ -plates, that is to say, that the maximum angle allowable was about  $15^\circ$ . He had a camera constructed to take such a lens, with a rigid body about 28 inches long, and a few inches of bellows at one end for focussing purposes. It was supported by two legs attached to the front and one at the back, and with it he did some most excellent work. A landscape painter, however, of whom the question was asked, "Do you in your paintings never include an angle of more than  $15^\circ$  or  $20^\circ$ ?" said: "I frequently take in much wider angles than that." And it seems reasonable that the photographer should do the same. The result of the use of such abnormally long focussed lenses is that very little foreground can, as a rule, be included—the picture will consist for the most part of middle and extreme distance. A wide angled lens does include objects so close to the tripod feet that they appear too large for pictorial effect, a lane, for instance, may often be seen stretching from each side of the plate; and in photographing buildings in order to get the objects large enough the camera is brought so close that horizontal lines in planes not perpendicular to the axis of the lens converge much too strongly for pleasing effect, and the result is what is known as exaggerated perspective, though, as a matter of fact, there is no real exaggeration about it. But, on the other hand, if a very long focussed lens is used, the camera must be taken so far off from the building that the lines above mentioned are so nearly parallel that the resulting picture does not give the effect of perspective relief. I have seen a picture of a church taken with a tele-photo lens from the N.W. at a distance of about half a mile, in which the west front and the north wall look as if they were in one plane; moreover, when the camera is so far from the object, the intervening atmosphere has the effect of reducing the depth of the shadows and rendering the picture flat from lack of contrast between light and shade.

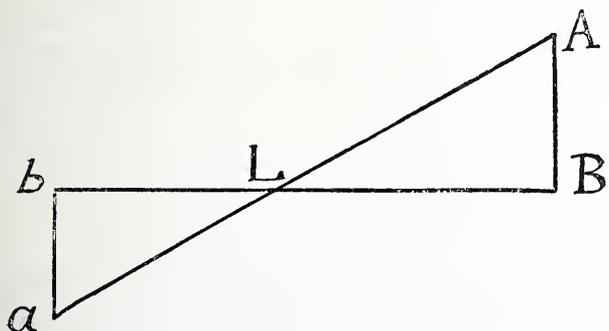

I propose to work out a few examples of the connection between size of object and image, distance of object and focal length of the lens, by means of simple geometry and arithmetic, which will show the limit that are practically put on the length of focus. To make matters as simple as possible, the lens will be treated as if it were a pinhole, so that the height of the image bears the same ratio to the focal length that the height of the object bears to its distance from the pinhole. That this is the case will be seen from the accompanying diagram.

First, for portraiture. If a 30 inch focussed lens is used, and it is desired to represent a standing figure, five inches high on the plate, that is one-sixth of the focal length, then the man must stand at a distance from the camera equal to six times his own height. That is if he is six

feet in height he must stand twelve yards off. In like manner, if we wish to represent a church tower 100 feet high by an image four inches in height, then the camera must be taken to a distance equal to  $7\frac{1}{2}$  times the height of the tower from it, or 750 feet, or 250 yards, more than a furlong. This would in most cases be impossible owing to intervening objects, and when possible would scarcely be desirable.

In interior work the use of a long focussed lens often gives a wrong impression. I saw a photograph of an aisle of a ruined abbey taken on a whole-plate with a 16-inch lens. The result was that only the distant parts of the aisle were included, and the effect of the long aisle—a great charm in the original—was wholly lost.

I will now assume that we are using a  $\frac{1}{2}$ -plate camera for the purpose of taking vertical pictures, that it is placed five feet from the ground, that the swing back is not used, and that the rising front allows the lens to be raised so that its axis cuts the plate in a point 4 inches

from its longer side, *i.e.*, 4 inches below the top of the picture that is taken with it. Let  $AB$  be that part of the object above five feet from the ground,  $ab$  its image, and  $L$  the lens. Then from similar triangles

$$L : B :: L : b :: a : b$$

but  $Lb$  is the focal length in inches, which we will represent by  $f$  and  $a : b = 4$  inches. Hence  $AB \times f = 4 LB$ . Suppose ourselves inside a church the ridge of whose roof runs in a straight line from end to end at the height of 55 feet from the floor, that is 50 feet above the camera, and suppose the length of the church to be 200 feet, and that the camera be planted against the west wall.

**Problem I.**—What focussed lens will allow us to just get the top of the east wall on the plate? Let  $A$  be the top of this wall,  $AB = 50$  feet  $LB = 200$  feet, and the equation becomes  $50f = 4 \times 200$ . Whence  $f = 16$ , or a lens of 16 in. focus will just enable us to do what we require.

**Problem II.**—What focussed lens must we use to include exactly half of the ridge of the roof? In this case  $AB$  (which represents a vertical line dropped from the middle point of the ridge) is still 50 feet,  $LB = 100$  feet, and the equation becomes  $50f = 4 \times 100$ . Whence  $f = 8$ ; or a lens of 8 in. focus must be used.

Probably in most general views we should want to include this amount of roof, and should seldom be able to get away from the east to a distance greater than four times the height, so that seldom can we use a lens of a longer focus than eight inches. In French Gothic churches the height of the roof ridge is often a third, or even more than a third, of the length of the building, so that shorter focussed lenses have to be used. In some recent work in French churches, by no means the most lofty, I found that I had to use a five inch lens in order to get a sufficient portion of the roof in to show the character of the groining.

I find it advisable not to use the swing back if it can be avoided, for this necessitates extra stopping down to secure sharpness, and this entails increase in the exposure, often sufficiently long, owing to want of light, even when the largest possible stops that can be used when the axis of the lens is horizontal are employed.

To sum up the results, I find that for interior architectural work, save for details of carving, it is rarely possible to use a lens that much exceeds in focal length the longest side of the plate, and for exterior architecture one whose focal length is about one and a quarter times the length of the longest side, for landscapes and for portraits one whose focal length is double that of the longest side of the plate is usually amply sufficient, but in all kinds of work I find it often necessary to use shorter focussed lenses than those just enumerated.

REV. T. PERKINS.

#### A POINT ABOUT BROMIDE PAPERS.

[Received too late for the ALMANAC.]

THERE is one point to which I have never seen reference made with regard to printing on bromide papers. There may not be much in it, but my own experience is that there is something in it. It has reference to the making of prints from negatives of varying density. We know perfectly well that in dealing with carbon paper we have the power to vary our results not only by using hotter or colder water in

developing, or by placing the printing frame nearer to or further from the window, but also by altering the strength of the bichromate in the sensitising bath. So in printing on bromide papers we can not only produce different results by varying the distance of the negative from the light or altering the constituents of the developer, but there is another way in which we can assist ourselves in getting the best results from negatives which err in one or other direction, either in too great density or the opposite extreme.

I refer to the use of different brands of paper. I have no doubt that this point has been observed by other workers. To myself it has for several years been very noticeable. If I have to deal with a negative which errs in the direction of too much weakness as regards density, I have found that I have been able to get better results by the use of Eastman's permanent bromide paper, and, conversely, that with negatives with an excess of density I get the best possible results with Wellington and Ward's tinted papers. It may be said, and with truth, that better results can be obtained from thin negatives by printing on white papers, of whatever make, but I am sure that Eastman's papers are more adapted to thin negatives than are those of Wellington and Ward's, and, conversely, that the papers of the latter firm are better suited to dense negatives than are those of Eastman's. I have no doubt that varying effects are producible by using other makes of paper, if only the worker will experiment with them. Of course, these varieties in effect can be obtained equally well by the use of a variety of developers, but when one works entirely with one form of developer, as I do, say with oxalate and iron, it is a convenience to be able to get the equality of results from such a variety of negatives, as one is sure to get in one's work, without tinkering about with half a dozen different developing formulæ. H. SELBY.

#### THE CAMERA CLUB.

THE "Journal" of the Camera Club for December gives publicity to the following: At a general meeting of the Camera Club Company, Ltd., held on Monday, November 12, 1900, to consider the proposal of the Board to increase the subscription of members, the Chairman announced that the replies to the circulars sent to members showed that the appeal had not been answered with sufficient unanimity, and, consequently, that no resolution for the increase of subscriptions would be put to the meeting.

The replies sent in showed that 222 members were in favour of the proposed increase of subscription, and 65 against it.

He then, in conformity with the notice contained in the circulars, proposed a resolution that the Club be closed on December 31, 1900, and that proceedings be taken to wind up the Camera Club Company, Ltd. This was seconded by Mr. W. Asbury Greene, the Vice-Chairman.

Mr. E. J. Humphery proposed, as an amendment, that a Committee of Members be appointed to consult with the Board and devise a scheme for the carrying on of the Club. This amendment was carried, and, subsequently, Mr. E. J. Humphery, Mr. E. W. Pulling, Dr. D. G. Thomson, Mr. H. H. O'Farrell, Mr. R. M. Cocks, Mr. J. W. T. Cadett, and Mr. J. Wallace Godfrey were elected members of this Committee.

The Chairman tendered the resignation of the members of the existing Board, but, at the request of the meeting, these gentlemen agreed to continue in office until the end of the year.

#### REDHILL AND DISTRICT CAMERA CLUB EXHIBITION AND SOIREE.

THIS plucky little Club held its second Annual Exhibition in the spacious room of the Market Hall, Redhill, on Friday, Nov. 30. The Club numbers now some 75 members, and it has barely been established two years, and its weekly meetings are well attended. The President for the year is Mr. W. Brooks, of Reigate. The meeting was arranged for 7.30 p.m., and by eight o'clock a large and brilliant gathering had assembled. The first hour was occupied in the reception by the President, and what might be termed side shows, *viz.*, tele-photography, microscopes, and some very interesting experiments with soap bubbles by Mr. W. F. Burgess, F.C.S., F.I.C., &c. This demonstration was given on the large stage. The Mayor of the borough of Reigate (Mr. F. C. Barnes) was present, wearing his badge and chain of office, accompanied by the Mayoress.

At 8.30 p.m. a concert was given, lasting about one hour. Previous to that, the President was engaged in giving explanations of tele-photography with apparatus lent him by Mr. T. R. Dallmeyer. The President had also on exhibition some of Thorp's diffraction gratings and a small direct vision spectroscope. Mr. F. Martin-Duncan had charge of the microscopes, which interested many of the visitors. In one of the microscopes was shown a micrometer 2526 lines to the inch made on Brooks's collodion emulsion by Mr. Johnson, of Manchester. There was a large display of members' work on the walls, some of

the work being exceedingly good, being a great improvement on last year. The room was badly lighted, and did not do justice to the pictures. There was good competition for the certificates, which were presented by the Mayor to the successful members, viz., Dr. Blackler, for a Surrey cottage, a very artistic production; Miss S. E. Duncan and R. Wyn Rucher, for landscapes; Mr. J. O. Grant, for animals; Mr. T. P. Padwick, for marine study "Anchored;" Miss Mabel Pelly, for "An April Evening;" Mr. A. H. Dunning, for stand camera negatives; Captain B. Marr Johnson, for enlargement of "The Silent Pool;" Mr. F. Martin Duncan, for photo-micrographs of special merit. Messrs. F. Martin Duncan, A. H. Dunning, J. O. Grant, and T. P. Padwick also scored for lantern slides. Mr. F. Martin Duncan's micro-photo slides were superb. There were several non-competitive members, viz., the President, who was represented by some two dozen exhibits, mostly printed in carbon, ranging from 12x10 up to 24 x 18, and a frame of tele-photo examples taken by him in Cornwall during the past summer, fully illustrating the capabilities of Mr. Thomas R. Dallmeyer's system. Mr. and Mrs. Ralph Robinson were also well represented. Mr. Henry Speyer was represented by two exquisite examples of his Alpine work above the snow line, which are perfect masterpieces. Specially noticeable were the photo-micrographs by Mr. F. Martin Duncan, which were as near perfection as they possibly could be.

After the distribution of the awards by the Mayor, the President gave a short address in respect to the Club, pointing out its advantages to those who joined; this year the Club was in possession of a certain amount of apparatus for demonstration, and a club lantern, &c., and a library, which was growing.

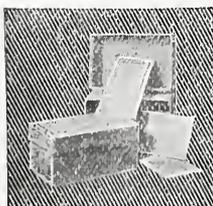

At 9.30 followed the lantern exhibition by the President, who manipulated the lantern from the gallery, some 70 feet from the screen. First were shown the members' competition slides. Mr. J. O. Grant's animal studies were greatly admired; next followed four slides by Mr. Padwick—snow scenes; following him came Mr. A. H. Dunning with four slides (general views). Mr. F. Martin Duncan's photo-micro lantern slides were the last of the competition slides shown, and were extremely fine. The above were the successful competitors, and received a certificate of merit. Then followed one dozen of Mr. Henry Speyer's Alpine slides, which are always welcome, and his name was received with a round of applause. It need not be said that his slides are of the highest possible excellence. This gentleman described his own slides. Following were a series of slides illustrating tele-photographs taken in Cornwall, which were put upon the screen. The first slide was a picture taken at one mile distant of a fishing village with the ordinary lens, without Dallmeyer's tele-photo attachment; then followed the same scene with the tele-photo attachment, which brought forth loud applause. Some similar pictures were shown of boats, &c., and St. Mawes Castle, taken at three miles distant. These were described by the President as they appeared on the screen. Most noticeable in the examples were the non-dwarfing of the distant houses and the non-dropping of the hill line—giving the whole a more natural appearance than if taken in the ordinary way, making the system most valuable to the artist. Mr. Brooks then put on the screen a small selection of his own slides made on collodio-bromide, which included some animals from the Zoo taken on one of the Club outings, some Cornish pictures, the Hotel Cecil, and Thames Embankment. To finish, a series of one dozen of Mr. Sanger Shepherd's photos in natural colours by the three-colour process (a short description of which process was given by the President). A portrait of Her Most Gracious Majesty the Queen was shown, after singing the National Anthem, bringing a most successful and brilliant evening to a close, and which the company appeared very much to enjoy.

## Our Editorial Table.

### THE M. Q. MIDGET DEVELOPER.

Manufactured and sold by John J. Griffin and Sons,  
20-26, Sardinia-street, Lincoln's Inn-fields, W.C.

FOR the convenience of those who may have occasion to use the Velox developers in small quantities, Messrs. Griffin are now sending out

packets retailing at 2d. each, or 10d. the box of six. Each packet, of course, contains the reducer and the accelerator, and in sufficient quantity to make 2 oz. of solution. They are distinguished from the

larger M. Q. packets by the designation M. Q. "Midget" Developer, and the solution may be used for plates as well as paper. Messrs. Griffin draw our attention to the following useful note on the subject of brush development for small prints on Velox: The materials necessary are a piece of clean glass (or, as a convenient substitute, a sheet of cardboard) and a pad of cotton wool or a soft badger's-hair brush. The M. Q. Developer should be mixed up just prior to use, or, if kept at all (which is not recommended), stored in tightly-stoppered bottles filled to the neck. To develop, take sufficient for immediate needs, using a small open vessel to hold it, and apply the solution evenly and rapidly to the paper by means of the pad of wool or brush. After the development of each print, squeeze the pad or brush (or, better still, dip in clean water and squeeze dry) before recharging same with fresh developer. Under no circumstances must any portion of the used solution be returned to the vessel.

### THE "SOHO" BROMIDE PRINTING MACHINE.

Manufactured and sold by Marion and Co., Soho-square, London, W.O.

As a means of making consecutive exposures on rolls of bromide paper, this little machine, as we can testify from practical trial, is a simple piece of apparatus to employ. It is very portable, for its extreme measurements are only 26 x 13 x 6 inches. In use the roll of unexposed paper is placed in position at A, the end (plain paper) passed under the negative-holder, B, which is easily raised for the purpose, then between a grip, C, and finally attached to the receiving-spool, D. With a left to right movement of the lever, F, the paper is properly straightened under the negative, and, this being accomplished, F is

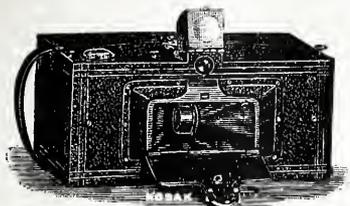

pushed to the extreme left, and all is ready for exposing. The exposures having been made, the paper must be changed, and here we quote from the succinct instructions: Grasp the lever, F, and press it to the right firmly and quickly as far as it will go, then bring it back again to its original position. What takes place by this movement is, as soon as the lever is moved, the negative-holder, B, is raised, leaving the paper free. Grip, C, moves along, pulling the paper with it, which at the same time is rolled up on the spool, D. On the return movement spool, D, does not move; the grip, C, releases the paper, and as soon as the lever has reached its first position the holder, B, comes down again into contact. The frame, E, is on springs, which keeps the whole in position. The exposure is, of course, made to an artificial light. The Soho machine is very easily worked, and it should be found of great practical value by professional photographers who have occasion to obtain a number of bromide prints identical in quality at a minimum expenditure of time and trouble.

### THE NO. 4 PANORAM KODAK.

Manufactured and sold by Kodak, Ltd., 43, Clerkenwell-road, E.C.

THIS instrument is similar in construction to the No. 1 Panoram which was placed in the hands of photographers some months ago, but it gives a much larger photograph, viz., 12 in. x 3½ in. The camera takes the ordinary Bull's-eye spool, and its price is £3 10s. An excellent specimen of work done by the newest Kodak has been kindly sent us by the Company. For the information of any of our readers who may be practically unfamiliar with this system of hand-camera work we append a few descriptive particulars of the No. 4 Panoram: Its capacity is five exposures without reloading; the size of the camera, 4½ in. x 5 in. x 10 in.; weight, 2 lbs. 10 oz.; and the length of focus of the lens, 5 in. In use: When taking the pano-

amic pictures a lever is set, and, on pressing the discharging button, the lens swings round; the film, arranged in a curve at the back of the camera, receives the impression. The view taken includes an angle of 142°. The No. 4 Panoram Kodak has a two-speed shutter, spirit

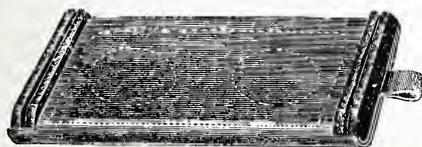

level, a bright finder, and is fitted with socket for tripod screw. V-shaped lines on the top of the camera show the scope of the view. The camera is finished in black morocco leather, with nickel-plated fittings.

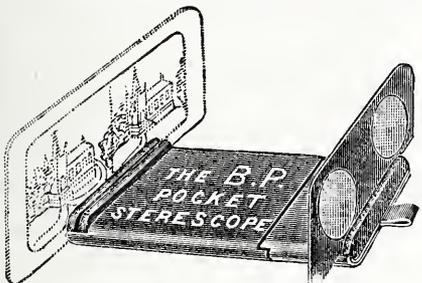

#### THE "BEST PORTABLE" STEREOSCOPE.

Manufactured and sold by W. Tylar, 41, High-street, Aston, Birmingham.

THIS form of stereoscope which Mr. Tylar aptly calls the "B.P.,"

is so portable enough when closed to be carried in the coat pocket without inconvenience, for it measures only 7½ in. × 4 in. × ½ in., and weighs

4 oz. In fact, as it is pointed out, it "looks like a cigar case, only a little longer." The illustrations show how the instrument is packed or set up. It costs only 1s. 9d., and quite answers the purpose of enabling stereo slides to be examined binocularly without inconvenience.

#### CATALOGUE RECEIVED.

The City Sale and Exchange, 54, Lime-street, E.C.

SEVENTY-FOUR pages of this catalogue are devoted to illustrated descriptions of optical lantern apparatus and about 200 to sets of slides. We are asked to state that a copy will be sent post free on application to any part of the world. The firm's lantern-slide library contains over 100,000 slides for hire, and a glance through the list before us shows that a very great variety of subjects is stocked.

#### PHOTOGRAPHISCHE BIBLIOTHEK.

No. 11, "Das Arbeiten mit Films." Martin Kiesling. No. 12, "Stand-Entwicklung." E. Blech. Berlin: Gustave Schmidt.)

THESE two works form part of a series of handbooks written in a popular style for the amateur upon various branches of photography. The present volumes deal with the use of films and stand development. The former subject is placed before the reader by Herr Martin Kiesling concisely and comprehensively, and should be a useful guide to those who are directing their attention to the popular substitutes for glass. Herr Blech's treatise on stand development will be read with interest by many. The method of developing negatives with very dilute baths has not received the attention it deserves. It has considerable advantages for the amateur, and we trust that Herr Blech's volume may excite further interest in the subject.

#### KNOWLEDGE DIARY AND SCIENTIFIC HANDBOOK FOR 1901.

528 pp. Price, 3s. London: "Knowledge" Office, 326, High Holborn, W.C.

OUR esteemed monthly contemporary commences the new century by the publication of a diary and handbook which should find a place on the desks of all those interested in astronomy and cognate scientific work. The diary space takes up about 400 pages, and the general contents include a calendar of notable scientific events, twelve star maps, showing the night sky for every month in the year, a monthly astronomical ephemeris, an account of the hundred brightest stars and of the astronomical phenomena for the year, with various astronomical

notes and valuable tables; an original essay on the uses of knowledge; many original articles, including one on "How to use an Equatorial Telescope," &c.; an historic summary of the advance of science in the nineteenth century, and other items. In reading the various ably-written summaries in the book we are struck by the immensity of assistance which photography has rendered to astronomical science in recent years. This diary and handbook is really a well-conceived idea ably carried out, and we welcome it as a distinct gain to the list of useful annual publications.

## News and Notes.

ROYAL Photographic Society.—Technical Meeting, Tuesday, December 18, at 66, Russell-square, at 8 p.m., "Photography in War," by H. C. Shelley, the War Correspondent.

JUVENILE Lectures at the Society of Arts.—The usual short course of lectures adapted for a juvenile audience will be given at the Society of Arts on Wednesday afternoons, January 2 and 9, 1901, at 4.30 o'clock, by E. Walter Maunder, F.R.A.S., Superintendent of the Solar Department, Greenwich Observatory, on "Eclipses."

A CORRECTION.—Mr. J. A. Reid writes: In the matter entitled "Photographers, the Public, and the Illustrated Press," published in your issue of November 23, the following sentence occurs: "In the case of photographs of Royalty and of distinguished personages, however, the supply is much less limited." The word "less" should obviously have been "more."

THE Royal Society will begin a work of great magnitude and importance on the first day of the new century—no less than an International Catalogue of Scientific Literature. It is to be issued in seventeen volumes, relating to seventeen different sciences. The Government have given a guarantee of £1000 a year for five years, "to make good to the Royal Society a part of any loss which may be incurred by the publication of the proposed catalogue." It is hoped, however, that it will not be necessary to ask for the sum guaranteed, or, at most, for more than a small part of it.

THE Croydon Camera Club's Fourth Exhibition will be held at the Art Gallery, Park-lane, Croydon, from Wednesday, February 20, to Wednesday, February 27, 1901. The following are the open classes—Landscape and Marine; Figure Studies and Portraiture; Architecture (exterior and interior); Any subject (open to amateur photographers resident in the borough of Croydon); Lantern slides (sets of six slides). One silver and one bronze medal will be offered in each of the open classes. Entry forms and further particulars can be obtained from the Hon. Secretary, Mr. W. H. Rogers, 46, Bensham Manor-road, Thornton Heath.

THE Amateur Photographic Field Club.—The Camera Club "Journal" states that the Annual Exhibition of lantern slides, by members of the Amateur Photographic Field Club, took place at the Camera Club on November 7. In the unavoidable absence of the President, Mr. Alfred Deed, the chair was taken by Lieut.-Colonel Gale. Slides were exhibited by Lieut.-Colonel Gale, Major Lang, and Messrs. Seymour Conway, T. Bright, W. G. Harrison, B. E. Lawrence, H. H. P. Powles, Reginald Belfield, and A. C. Beard. The hundred and forty slides exhibited were fully up to the reputation of the oldest photographic club in existence, and showed that the Field Club is as vigorous as ever.

UNIVERSITIES and Polytechnics.—The relation of the polytechnics and technical institutes to the newly-constituted University of London was the subject of an address delivered last week by Sir Michael Foster, K.C.B., M.P., at the Northern Polytechnic Institute. In the struggle for existence between man and man and race and race, he said, the knowledge called "useful" was becoming more and more an important factor. Therefore, polytechnics were regarded with the greater favour by universities for the reason that in their handling of useful knowledge depended the prosperity of industry and commerce of this great country; they could, in fact, help England to win back that trade which she had lost!

WE are informed that, after a lapse of a number of years, the Sheffield Photographic Society is proposing to have a public Photographic Exhibition. At a recent meeting of the Society a suggestion to that effect was brought forward by the Council, who were requested to give further consideration to the matter, and bring forward a definite scheme for a suggested Exhibition. At a subsequent meeting of the Council the whole matter was, with the assistance of Mr. Ezra Clough, Secretary of the Yorkshire Photographic Union, fully discussed, and certain suggestions adopted, which were placed before the monthly meeting of the Society. When, after considerable discussion, it was resolved that an Exhibition be held next year, and a guarantee fund formed in connection therewith.

MORE Disappearing City.—Soon there will be very little of the old City of London left. All the ancient buildings are fast being demolished for improvements that become imperative by modern requirements. It has now been decided to pull down the four old houses and shops now standing before the Church of St. Giles, Cripplegate, to widen Fore-street. With the shops, the old gatehouse will be removed. This quaint-looking edifice dates back to 1660. This ancient gate, we learn, will be carefully taken down and re-erected some distance further back, but the old houses, with their antiquated frontages, are to disappear for ever. Although the old gateway will be photographable in its new quarters, the pictures taken under the modern conditions will not have

the same interest in the eyes of archæologists as will those taken in conjunction with its ancient surroundings. It is for that reason that we call attention to the subject, so that those of our readers who desire to secure photographs of the block while it is intact may obtain them before the opportunity is lost. The City authorities are slow to move, but when once they start they proceed quickly.

**ROYAL INSTITUTION.**—The following are the Lecture Arrangements at the Royal Institution, before Easter:—Sir Robert Ball, six lectures (adapted to young people) on Great Chapters from the Book of Nature; Professor J. A. Ewing, six lectures on Practical Mechanics (experimentally treated), first principles and modern illustrations; Dr. Allan Macfadyen, Fullerian Professor of Physiology, R.I., four lectures on The Cell as the Unit of Life; Dr. Arthur Willey, three lectures on The Origin of Vertebrate Animals; the Rev. H. G. Graham, three lectures on Society in France before the Revolution; Sir Wyke Bayliss, two lectures on Shakespeare in Relation to his Contemporaries in Art; Professor R. K. Douglas, two lectures on China; Mr. F. Corder, three lectures on Vocal Music, its Growth and Decay (with musical illustrations); the Right Hon. Lord Rayleigh, six lectures on Sound and Vibrations. The Friday Evening Meetings will begin on January 13, when a discourse will be delivered by Professor Dewar on Gases at the Beginning and End of the Century; succeeding discourses will probably be given by Dr. A. W. Ward (the Master of Peterhouse), the Right Rev. Monsignor Gerald Molloy, Professor G. H. Bryan, Professor J. J. Thomson, Sir W. Roberts-Austen, Mr. H. Hardinge Cunynghame, Mr. W. A. Shenstone, Dr. Horace Brown, the Right Hon. Lord Rayleigh, and other gentlemen.

A New Photographic Club for Great Yarmouth.—One of our Yarmouth contemporaries gives the following particulars of the formation of a new photographic club at Great Yarmouth. For some time past the town has been unable to boast, amongst its heavy list of clubs and societies, an organization devoted to the interests of local followers of the entrancing science of photography (unless we make an exception of one or two somewhat nebulous and moribund societies) which, seeing how strong are the ranks of amateur photographers in this locality, is undoubtedly a reproach. This has evidently occurred to several enthusiasts, prominent among whom is Mr. T. J. Wigg, a gentleman already engaged in so many useful and diverse enterprises that it was only natural that on his shoulders should fall the burden of the preliminary arrangements in the formation of a new club. In his busy, but never too busy, hands, matters proceeded smoothly and expeditiously to the desired consummation, and recently the Great Yarmouth and District Camera Club was duly constituted, Mr. Bruce Leach presiding over a full and representative meeting of the riders of this pleasant and instructive hobby. The following officers were elected after the necessary preliminaries were gone through:—President, Fleet-surgeon S. T. O'Grady, R.N.; Vice-Presidents, Messrs. B. Leach and G. Rumbold; Hon. Secretary and Treasurer, Mr. T. J. Wigg; Committee, Messrs. C. Rumbold, W. Wigg, — Simpson, H. E. Ebbage, C. W. Moss, and the Rev. D. Harford-Battersby. Mr. Wigg, the Hon. Secretary, whose address is Holland House, North-quay, will be glad to hear from those desirous of joining the club.

## Commercial & Legal Intelligence.

THE Taber Bas-Relief Photographic Company, 141, New Bond-street, W., have been awarded a silver medal for their exhibit at the Jubilee Exhibition which has just been held at Frankfort-on-Maine.

WALTER D. WELFORD v. Walter Grubb (trading as the Camera Construction Co.).—In a previous issue we referred to this County Court case, in which Mr. Welford claimed damages for delay in executing orders, a counter claim being entered for loss of profit on an unfulfilled contract. On Friday last the Judge gave his decision, awarding Mr. Welford £5 damages, the counter claim being dismissed with costs.

MESSRS. Newton and Co., of 3, Fleet-street, E.C., ask us to state that they are now making lantern slides from Mr. Douglas English's negatives of British reptiles, such as snakes, frogs, toads, lizards, &c., showing their various stages of evolution. Dr. Spitta has just completed a set of negatives of malarial diseases, a subject that is of much interest just now. More slides will be ready directly. We also understand that Messrs. Newton's Ether Saturator is also attracting very great attention.

THE London, Brighton, and South Coast Railway Company are issuing an illustrated handbook to "The Riviera for a £10 note." A series of inexpensive Riviera tours are given via Newhaven and Dieppe. By a ticket costing £10 first-class, and £7 7s. second-class, it is now possible to visit the whole Riviera coast, including Marseilles, Cannes, Nice, Monte Carlo, San Remo, &c. The journey can be broken at Paris in both directions, thus saving the fatigue of the long through journey between London and the Mediterranean.

DISSOLUTION OF PARTNERSHIP.—The co-partnership hitherto existing between Andrew George Adamson and Graham Cochrane Kirkwood MacLennan, carrying on business at 22, Christopher-street, Finsbury-square, London, E.C., as Adamson Bros., Electrical Engineers and Experts in Artificial Lights for Photography, has been, by mutual consent, dissolved as from the 5th ult. All debts due by and to the firm at that date will be paid and received by Andrew George Adamson, who will continue the business as before, at the same address, for his own behoof.

THE Tella Easy-Payment System.—For the convenience of their clients and others, the Tella Camera Co., Ltd., of 110, Shaftesbury-avenue, London, W., are adopting the easy-payment system, applicable to any make of photographic apparatus. The following are among the principal conditions:—The payments for goods are extended over six months for purchasers under £6, over nine months for purchasers over £6 and under £9, and over twelve months for purchasers over £12. A deposit of not less than a sixth part of the value of the goods ordered must accompany each order, which will be considered to be the first monthly payment. Goods may be selected from any maker's list approved of by the company. A pamphlet giving full particulars of the system may be obtained on application to the company at the above address.

RE George Thatcher and Eleanor Louisa Somerset, trading as E. Hawkins and Co., Artist Photographers, Preston-street, Brighton.—The public examination of these debtors came on for hearing at the Brighton County Court, before the Registrar, on Thursday, Dec. 6. The debtor Thatcher stated that the statement of affairs disclosed liabilities amounting to £384 8s. 9d., and assets estimated to produce £325 13s. 9d. The business was formerly carried on by a Mr. Hawkins, who died in 1889. Witness then acted as manager, and subsequently he put £600 into the business, and took it over. In 1892 he got into financial difficulties, but he could not remember what dividend in the pound was paid to the creditors. In 1898 he again became involved in difficulties, and paid his creditors 10s. in the pound. Some of the money to pay that dividend was provided by Miss Somerset. Some of the debts due under that arrangement were still outstanding. In 1899 he took Miss Somerset into partnership, but the business was not profitable.—Miss Somerset stated that she kept the books of the firm. The business would have paid its way but for the old debts.—The examination was closed.

THE Trade Poisons Bill.—A third and final meeting of the Chemical Trade Section of the London Chamber of Commerce was held on Tuesday afternoon last week to consider the above Bill (which has been formulated by the Traders in Poisons and Poisonous Compounds for Technical and Trade Purposes Protection Society of 5, Clement's-inn, London, W.C.), which has for its object the alteration and amendment of the law relating to the sale of poisons and poisonous compounds for agricultural and other trade purposes in Great Britain and Ireland, and to decide what action, if any, should be taken by the Chemical Trade Section in the matter. There was a very full attendance of members and others interested, and after considerable discussion the following resolution was proposed by Mr. Thomas Bennett (Messrs. Bennett, Lawes, and Co., Ltd.), and seconded by Mr. J. J. Bowley (Messrs. F. Bowley and Sons):—"The Chemical Trade Section recommend the Council of the Chamber of Commerce to actively support in Parliament the proposed Bill to alter and amend the law relating to the sale of poisons and poisonous compounds used for agricultural and other trade purposes."—The resolution was carried.

THE Alliance between Science and Industry.—Last September Prof. Carhardt communicated to the American Institute of Electrical Engineers a very complete account, which has recently been printed in "Science," of the Reichsanstalt at Berlin. He had worked there as a guest for some months in 1899, and had thus gained an insight into its management and organisation. The details he gives of these are very interesting, and the proof of the value of the work done, and of its consequences to German industry, most striking. The cost of the Institution, we may note, was about £200,000; the annual expenditure amounts to about £15,000. After mentioning these figures, he continues: "A very pertinent inquiry is, what are the results of all this expenditure?" and a careful analysis leads him to the conclusion that "the results have already justified, in a remarkable manner, all the expenditure of labour and money. The renown in exact scientific measurements formerly possessed by France and England has now largely been transferred to Germany. Formerly scientific workers in the United States looked to England for exact standards, especially in the department of electricity, now they go to Germany." And, again, "Germany is rapidly moving toward industrial supremacy in Europe. One of the most potent factors in this notable advance is the perfected alliance between science and commerce existing in Germany. Science has come to be regarded there as a commercial factor. If England is losing her supremacy in manufactures and in commerce, as many claim, it is because of English conservatism and the failure to utilise to the fullest extent the lessons taught by science."—"Nature."

## Patent News.

THE following applications for Patents were made between November 26 and December 1, 1900:—

CINEMATOGRAPHS.—No. 21,339. "Improvements in Apparatus for Photographing and Exhibiting Cinematograph and Mutoscope Ordinary Pictures." H. W. H. PALMER.

APPARATUS.—No. 21,537. "Improvements in or relating to Photographic Apparatus." A. SALMON.

CINEMATOGRAPHS.—No. 21,545. "Improvements relating to Cinematographs." L. GAUMONT.

SHUTTERS.—No. 21,594. "Improvements in Denoting Speeds of Photographic Shutters." A. L. ADAMS.

DEVELOPING DISH.—No. 21,711. "An Improved Photographic Developing Dish." E. B. FOX.

PHOTOGRAPHING IN COLOUR.—No. 21,817. "A Process for Photographing in Colour." B. ACRES.

# Meetings of Societies.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

December.	Name of Society.	Subject.
.....	Doncaster .....	{ <i>Some Typical Subjects and their Treatment.</i> A. Horsley Hinton.
.....	Glasgow and West of Scotland .....	{ <i>Demonstration: Velox Novelties.</i> Makers' Demonstrator.
.....	Aintree .....	{ <i>The Norman Castles of Wales.</i> E. E. Thorpe.
.....	Birmingham Photo. Society .....	{ <i>Social Evening and Exhibition of Members' Christmas Cards.</i>
.....	Bootle .....	{ <i>Annual General Meeting.</i>
.....	Croydon Microscopical .....	{ <i>Ordinary Meeting.</i>
.....	Gospel Oak .....	{ <i>Demonstration: Lantern Slides by the Carbon Process.</i> H. H. Morgan.
.....	Newcastle-on-Tyne .....	{ <i>Films v. Plates, and the New Thornton Film.</i> W. D. Welford, F.R.P.S.

### ROYAL PHOTOGRAPHIC SOCIETY.

DECEMBER 11,—Ordinary Meeting,—Mr. T. R. Dallmeyer, F.R.A.S. (President), in the chair.

#### NEW MEMBERS, AUDITORS, &c.

A large number of new members (about 25) were elected, and nine candidates for membership were nominated.

Messrs. H. Vivian Hyde, Frank Seary, and W. E. Dunmore were elected as Auditors of the Society's accounts for the current year.

It was announced that the Blairgowrie and District Photographic Society had been admitted to affiliation.

The President acknowledged the receipt of several gifts to the Society, among them being a Daguerreotype stereoscopic slide, presented by Mr. Duncan Robertson, which had been given by the late Mr. Walter Woodbury to Mr. Louis Woolf. It was in a wonderfully good state of preservation.

#### AN ISOCHROMATIC-SCREEN ATTACHMENT.

Major-General Waterhouse, I.S.C., on behalf of General Tennant, showed a Thornton-Pickard shutter to which had been fitted a very simple and effective attachment for an isochromatic screen. The attachment consisted of two rectangular slips of ebonite so arranged as to form a groove in which a glass light-filter could be placed without interfering with the ordinary use of the shutter.

#### A NEW ARTIFICIAL LIGHT.

Mr. Chapman, of the Atmospheric Gas Company, gave a demonstration of a new system of artificial lighting, and exhibited prints from negatives taken by this illuminant. The negatives were on Barnet medium plates, and the exposure was five seconds with a portrait lens (aperture not stated), three burners being employed. The prints were on P.O.P. and had been printed out in half-an-hour at a distance of ten inches from one of the gas-burners, the light from which was said to be 125 candle-power, as shown by a photometer. The burners were fitted with ordinary Welsbach mantles, and the only necessary apparatus was a carburetter and some means of producing half an inch of air pressure, the gas being derived from a mixture of 75 parts of the crudest benzoline with 25 parts of the purest paraffin. An analysis of the gas as burned showed that it consisted of oxygen 24.46, nitrogen 77.68, and only 1.86 of combustible gas. There was no smell or smoke; and, to show that there was no danger, even if the taps were left open in the presence of naked lights. Mr. Chapman played with the apparatus in a manner which one would have expected to result in the rapid and complete demolition of No. 66, Russell-square, and the dispersal of the audience in a multitude of small and undistinguishable fragments. But nothing happened.

#### THE MACDONOUGH-JOLY COLOUR PROCESS.

Mr. H. Snowden Ward read a paper on "The Macdonough-Joly Process of Colour Photography," and showed a large collection of lantern slides to demonstrate the capabilities of the method. He disclaimed any commercial interest in the subject, and regretted that it had no commercial aspect at present, as there was, consequently, no immediate prospect of

members being able to purchase the necessary apparatus and materials with which to pursue their own investigations. He added that he was informed on the best authority that the public would not be asked to subscribe to any scheme or company for exploiting the Macdonough-Joly process. As the archives of the Society contained very little information upon the subject, he proceeded to give some details of the work which had been undertaken with a view to devising a natural colour process for the production by means of one negative and one print, and without complicated labour on the part of the photographer, of either transparencies or photographic or photo-mechanical prints. The first man to suggest a practical method of achieving this result was Louis Ducos du Hauron, but, owing to the want of plates sufficiently sensitive to red and green, his ideas were not practicable. Mr. James Macdonough, who in 1892 applied for a patent in the United States, claimed the invention of a method in which specks of coloured transparent matter were scattered under or over the film of a gelatine dry plate, but its practical difficulties were apparently sufficient to cause him to abandon it in favour of the scheme suggested long before by Du Hauron, and which had occurred almost simultaneously to Dr. Joly, of Dublin. The same idea appears to have been independently evolved by both Dr. Joly and Mr. Macdonough, and without knowledge of the work of Du Hauron, and also by a Mr. Anderson, who carried it a stage further. The outlines of the Macdonough-Joly process, as it now exists, are tolerably well known, and Mr. Snowden Ward's paper comprised a consideration of the problems which it involves—the mechanical, chemical, and optical difficulties in connection with the ruling of the taking and viewing screens, the selection of colours and plates, and of dyes having the correct absorption, the production of paper prints, &c. The slides exhibited—some of which were very fine—included examples from negatives taken in London by the author of the paper, and others by the Ohio Colour-Photo Company, Mr. Gavton A. Douglass, Professor Peterson, Mr. C. N. Crewdson and Mr. S. L. Stein (of Milwaukee). The apparatus used by Mr. Snowden Ward, and the special plates required, had been lent to him by Mr. D. K. Tripp, of Chicago.

A very brief discussion ensued.

#### COMING EVENTS.

"Photography in Warfare" will be the title of a paper to be read, at the Technical Meeting on December 18, by Mr. H. C. Shelley (war correspondent of "The King"), who will exhibit slides from negatives taken by himself during the campaign in South Africa. There will be no meeting on January 1.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 6,—Mr. R. P. Drage in the chair.

Mr. W. D. Welford showed a gas-stove useful for carbon printing, and to which allusion was made by Mr. Watmough Webster in a recent article in these pages. Its construction fits it very well for suspension on the wall-bracket system, and this is how the speaker made use of it, a piece of zinc preventing damage to the wall by heat. Cold water is introduced by a rubber pipe from the supply tap connected with the stove, the gas is lit, and boiling water comes out at the rate of a quart a minute. The water passes along two tubes fitted outside with a number of heat-radiating metal discs. The stove is made by Fletcher, of Warrington, at a moderate figure.

Mr. T. E. Freshwater showed on the screen the result of a further experiment with the Joly process. The subject was a dish of apples, but the reds were a little too prominent in the slide. The difficulty he had previously referred to of getting the lines of the positive to correspond exactly with those of the viewing screen, still troubled him, and he thought that there must be some variation in the widths of the ruling of the taking and viewing screens he used. In addition to a number of miscellaneous old slides, he showed a series, from negatives by a friend, depicting life and customs in the neighbourhood of Darjeeling and Kurseong, in India. Tea-planting is the principal following in these parts, and many were the views showing the fields covered with the tea-plant, the natives picking the leaves, the drying and fermenting of these in the houses, and, finally, the cases of finished tea ready for despatch to the retailer and consumer. Landslips have caused much damage in these regions, and abundant testimony to the extent of the devastation was given in some of the photographs of hillsides denuded altogether of what was a fine crop of the plant. Other photographs presented the curious effect of railway lines and sleepers suspended in mid-air, the heavy rains having washed away the supporting earth in their torrential descent from the mountains. From Darjeeling, fine views of the Himalayas are to be had, and one of the slides depicted the lofty Mount Everest at a distance of very many miles. The series was completed with a selection of photo-micrographs of parasites peculiar to Indian creatures—flying foxes, fireflies, &c. The photographs and the descriptive notes given by Mr. Freshwater were received with considerable pleasure and attention.

#### PHOTOGRAPHIC CLUB.

DECEMBER 5.—Mr. H. Snowden Ward in the chair.

Mr. Geo. E. Brown said he had been dealing lately with two or three gross of plates, and had put to the test Mr. J. R. Williams's assertion that spirit baths used to accelerate the drying of plates could be kept active in an easy way by the immersion of some dry gelatine in the bath. The effect of this was said to be that the water abstracted from the gelatine plates by the spirit was taken up from the spirit by the dry gelatine at the bottom of the bath, thus maintaining the spirit bath for a longer time in a condition of efficiency. The speaker found

that a bath so furnished with a dry gelatine absorbent acted just about as well as the spirit bath usually did, but was not appreciably better, and the bath worked slowly in course of time owing to the excess of water taken up by the spirit. On the face of it, he thought that it was incredible that the spirit should remove water from one mass of gelatine to give it up to another, unless a difference in the nature of the two gelatines was sufficient to bring the result about.

Mr. A. Mackie did not attach much value to the suggestion, saying that a piece of dry gelatine placed in the spirit bath came out as dry as when it went in.

Mr. E. W. Foxlee said that over and over again during the past thirty years these instructions had been published. He had taken some Nelson's fine photographic gelatine, and thoroughly dried and digested it in 830 spirit for a week, taking the specific gravity of the bath before the addition of the gelatine and at the end of the week. He found that the spirit was of exactly the same strength as when he began. If the spirit contained a great deal of water, and dry gelatine were introduced into it, time might show that water was absorbed, he thought, but with spirit of any pretence to strength he thought not.

A discussion took place regarding the best developer for bromide enlargements, having in view considerations of permanence and colour of the image.

Mr. F. A. Bridge said that ferrous oxalate was his preference. The nature of the developer had no influence upon the permanence of the print. Ferrous oxalate gave as many variations of black as any developer. For these reasons, in his opinion, ferrous oxalate was an excellent developer.

Mr. E. W. Foxlee held that, theoretically, ferrous oxalate was not a good developer. It was usually acid, and the print, after development, was treated with acid, but he was sure that this acid was seldom washed out before fixing, thus risking the liberation of sulphur with the decomposition of the hyposulphite.

Mr. Bridge could show prints made years ago which never received more than five minutes' washing. So long as they were thoroughly fixed there was thus, apparently, little to fear.

**Croydon Camera Club.**—One of the great nuisances which beset the go-as-you-please photographer is without doubt the trouble and uncertainty which accompany the toning of silver prints. Two courses are open. One is the sweet simplicity of the "combined" bath, in which a delightful tone is quickly and easily obtained, but sub-sulphides, lurking in the image are apt, in a very few days or weeks, to bring about all kinds of extraordinary changes, which serve to ruin, if not destroy, the print. The other alternative is the sulphocyanide—or other gold toning bath. This is not only wasteful, but is tedious, uncertain in action, and unreliable in the tone which ensues. No wonder, then, that there was a goodly gathering at the club rooms on Wednesday, December 5, when Mr. E. G. Ley introduced, for the first time in England, a new make of print-out paper which requires no gold toning. We need not enter into details of manufacture except to indicate that the paper holds in its gelatine surface the silver salt which forms the visible image, and also the gold salt which tones the image. When printing is complete—the time taken being about the normal—about two minutes' immersion in ordinary salt and water causes the print to assume the customary photographic purple-brown hue. A subsequent hypo bath, to dissolve out the unacted-upon silver, followed by the usual washing, completes the operation. Mr. Ley showed the simplicity and certainty of the process by manipulating a number of prints.

**Southsea Amateur Photographic Society.**—The most popular and effective means of encouraging the development of photography and of raising the standard of work throughout the country is the holding of exhibitions with classes open to all competitors, and Southsea is not behindhand in taking her share in the responsibility. The arrangements for the Annual Exhibition, which the Southsea Society is to hold on January 29, 30, and 31, 1901, are rapidly progressing, and now the committee have secured the services as judges of such experts as Messrs. H. Snowden Ward, H. Simonds, and W. West, this now well-known Exhibition must certainly repeat the success that has attended those held in preceding years. All information can be obtained from the Hon. Secretary, Mr. Gilbert Wood, 10, Pelham-road, Southsea.

**Leicester and Leicestershire Photographic Society.**—The Annual Exhibition of this Society will be held in the Co-operative Hall, Leicester, on March 19 to 22, 1901. There will be open and local classes, silver and bronze medals being offered in each, also a championship medal for the best picture in the Exhibition. There will be a large number of other attractions, comprising lantern displays and specimens of early work in photography, &c. The names of the judges will be announced later. Entries close March 13. Pictures must be delivered not later than March 15. Entry forms and full particulars may be had from the Exhibition Secretaries: H. Walker, Glen Burn, Ashleigh-road, Leicester, and E. W. Bush, 19 Equity-road, Leicester.

#### FORTHCOMING EXHIBITIONS.

1901.

January 14-19 ..... Blairgowrie and District Photographic Association.  
The Hon. Secretaries, Blairgowrie, N.B.  
February 16-March 9 Edinburgh Photographic Society. Secretary, J. S. McCulloch, W.S., 10A, George-street, Edinburgh.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE BLAIRGOWRIE EXHIBITION.

To the EDITORS.

GENTLEMEN,—I will be obliged if you will kindly notify your readers that entries for the Blairgowrie and District Photographic Association's Third International Exhibition close on the 20th inst.

Particulars and entry forms will be gladly sent on application to yours truly,  
JOHN B. MACLACHLAN, Joint Secretary.

Blairgowrie, December 6.

### THE LATE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

To the EDITORS.

GENTLEMEN,—That the Photographers' Benevolent Association is dead there is no shadow of doubt; but I don't think it is yet time to give up all hope of its resuscitation.

I have been waiting an opportunity of making one more effort in that direction, and, with your permission, would ask all photographers (employers and assistants) who are earnest in their desire to have some such a society attached to the profession to write me at the address below; then, if the response is in any way encouraging, a preliminary meeting will be called on an early date.—I am, yours, &c.,

W. T. WILKINSON

(Original Founder of the Photographers' Benevolent Association).  
63, St. John's-hill, S.W., December 3.

[We do not wish to discourage Mr. Wilkinson in his well-meant desire to revive the Benevolent Association, but in our opinion the calling and holding of such a meeting as he proposes can serve no useful purpose. If a good number of the principal professional photographers, and their assistants, in London, were to join forces and arrange for a *personal canvas* of their brethren in all the large towns, something might be done towards arriving at a practicable scheme; but not otherwise, we are afraid. The initiative must come from those more directly interested in the scheme; and, failing that, in our opinion it will be sheer waste of time on the part of Mr. Wilkinson or anybody else to attempt to make photographers self-helpful against their wills or inclinations. Eds.]

### THE THORNTON FILM COMPANY'S COMPETITIONS.

To the EDITORS.

GENTLEMEN,—We have pleasure in announcing that we have commenced a Monthly Prize Competition for the best negatives taken on the Thornton Film. The prize given is a folding pocket Kodak, and the results will be announced every month.

Competitors may enter as often as they like, and are not restricted as to the number of negatives. All negatives remain the property of competitors, but we are willing to purchase them by arrangement afterwards.

Entry forms and full particulars will be found in each packet of films. We are, yours, &c.,  
THE THORNTON FILM Co., LTD.

Altrincham, December 4.  
The following are the full particulars and conditions of the competition:—

The prize consists of a Folding Pocket Kodak, value £2 2s. Suitable for lady or gentleman.

The prize is given every month in the year for the best negative sent in during the preceding month.

#### CONDITIONS.

1. Competitors may enter as often as they like. No competitor is disqualified if he or she happen to have secured a prize before.
2. Negatives may be any size and any subject. Several negatives may be entered by one competitor, if desired.
3. All negatives entered must have been developed during the preceding month, or, in the case of competitors abroad, during one of the two preceding months.
4. Negatives must be on Thornton Film (any of the different kinds quoted in the price list).
5. The negatives, together with a print from each, and accompanied by the entry form, duly filled in and signed, must be sent by post direct to the Thornton Film Company, Ltd., Altrincham, Cheshire, not later than the 3rd of the month in which the award is to be made. They may be protected between pieces of cardboard in an envelope.

6. A stamped and addressed envelope must be sent for return of the negatives. Every care will be taken of them, but the company accept no responsibility.

7. All prints become the property of the company, but all negatives remain the property of competitors. Thus every one receives the negatives back. In the case of the winning negatives, however, the company will be glad to purchase same by arrangement afterwards.

### THE WATKINS SYSTEM OF TIME DEVELOPMENT.

To the EDITORS.

GENTLEMEN,—From time to time I have seen a great deal written about Watkins' system of time development, and one thing struck me forcibly, viz.: In order to note the time at which the image commences to appear on the plate, it is necessary to keep the plate exposed to the red light in order to do this. How does Mr. Watkins get over the fact that (especially when using fast plates) the plate is pretty certain to become fogged? I watched for somebody else to ask this question, but nobody has, so I am compelled to do so myself.—I am, yours, &c.,

WALTER KEATING, Jun.

61, Dawson-street, Dublin.

[Having submitted the foregoing letter to Mr. Watkins, the latter gentleman has been good enough to send us the following reply. Eds.]

Mr. Keating appears to criticise without having tried the plan. The necessary exposure to the red light involved in my method is less than in the older plan of having to judge the density of the negative by taking it out of the dish and holding it up to the light. After the image has appeared the plate can be covered up and not looked at again, and, as the total time of development is at least five times the appearance, the necessary exposure to red light is quite short.

But, if Mr. Keating will refer to THE BRITISH JOURNAL OF PHOTOGRAPHY for July 28, 1899, he will find details of that modification of my method by which all dark-room light is done away with. The developer is first tested with a standard strip of exposed plate, and the time of appearance of this decides the duration of development of the negative. The negative is then developed in complete darkness.

For the last three years I have used this method with great comfort in developing Cadett spectrum and other isochromatic plates, using no bromide and never getting a trace of fog, with the great advantage of never having to trouble about the "safety" of my dark-room light.

Let me take the opportunity of giving a slight modification of my timing method, which tends to simplicity of working.

It is to always adhere to the multiplying factor six, and to control the steepness of gradation (density) of the negative by the degree of dilution of the pyro-soda developer. The advantage is that the number of seconds' appearance is translated without mental effort into the number of minutes' development. Thus 40 seconds' appearance requires a development of four minutes. The developer may contain from  $\frac{1}{2}$  to 2 grains of pyro to the ounce, according to the negative required, with the usual quantity of bromide.

If it is desired to use this new plan with a developer other than pyro, metol-hydroquinone should be used, the contrast of the negative being decided by the proportion of metol to hydroquinone, the latter in any case being in larger proportion.

ALFRED WATKINS,

### WILL STEREOSCOPIC PHOTOGRAPHY REVIVE?

To the EDITORS.

GENTLEMEN,—There are unmistakable symptoms that it will. One of them is that it is beginning to engross the attention of many photographic societies, as witness the papers read before them, and the excellent examples shown and the approbation they meet with. But the resuscitation of anything that has become extinct, or partially extinct, for the stereoscope has never become really so, is a slow procedure. At the November meeting of the Edinburgh Photographic Society I notice that Mr. William Goodwin read an admirable paper on the subject, an abstract of which you gave a fortnight ago. In his paper Mr. Goodwin made some remarks as to one reason why the stereoscope at one time fell into disfavour, and that is a reason to which you have more than once referred in your columns, namely, the vulgar character of some of the slides that were put upon the market at the time, which almost amounted to indecency. I regret to see some of these slides are now being offered for sale on stalls in the streets, evidently printed from the old negatives, and similar ones—though of more modern production—are to be seen in some of the penny-in-the-slot machines which are to be found in London and other large towns. Some of these pictures—vulgar in the extreme—become something more than that when coupled with the titles given to them. It is sincerely to be hoped that these so-called "comic" slides will never again be introduced into drawing-room collections,

as they were at one period, otherwise I fear that our old friend the stereoscope will not find much favour in good society. It is also to be hoped that some of the subjects that have been shown as "art work" in the nude or semi-nude in some one of our recent exhibitions of photographs will not be essayed for the stereoscope, as that will, certainly, anything but conduce to its popularity.—I am, yours, &c.,

CYCLOPS.

December 10.

### WINTER EVENING PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—The long winter evenings are now with us, and many enthusiastic photographers are no doubt speculating as to how they can best turn them to photographic account. The ways they can do that are numerous indeed, though some of them seem to be quite neglected. One is photo-microscopy. Many are no doubt deterred from essaying this branch of photography from the mistaken idea that costly apparatus is a *sine qua non*. It is nothing of the kind, unless we go to the higher divisions of it. For large and popular subjects a microscope, or even a microscopic objective, is not a necessity, for a short-focus photographic lens, if of good quality, will answer the purpose quite well. Every one knows how to enlarge from a small negative, and most amateurs have the necessary appliances for the work. Now the principle of photo-micrography is precisely the same as that of enlarging from a small negative. If, for example, instead of a photographic negative we place, say, the wing of a butterfly, mounted on glass, in the place it would occupy in the enlarging apparatus, we can make an enlargement of it in exactly the same way, and just as sharp as we should get from a negative had one been used, and amplified the same number of diameters. For such things as a butterfly, dragon-fly, large moth, &c., an ordinary quarter-plate lens will answer very well when somewhat stopped down to ensure good definition. For smaller objects a lens of shorter focus will be better, and found more convenient in use. With one of the small lenses of the Petzval type that used to be supplied for postage-stamp portraits, of about one and a half inches focus, I have made very successful pictures of such objects as the proboscis of the blow-fly and similar ones which showed every minutia in the enlarged picture. In using the lens for this purpose it is scarcely necessary to say that the posterior element was placed towards the object to be enlarged. I have said enough to show that amateurs need not be deterred from entering the field of photo-micrography on account of the cost of apparatus, that is, when the operations are confined to such subjects as I have alluded to. I enclose my card, and am, yours, &c.,

PHOTO-MICROGRAPHER.

December 8.

### THE INTENSIFICATION AND AFTER-MANIPULATION OF CARBON PRINTS.

To the EDITORS.

GENTLEMEN,—As the reader of the paper under the above title, referred to in your leader on pages 769 and 770, December 7, 1900, permit me to make some few remarks on your statements.

1. Your assumption that negatives and transparencies only were referred to and treated is altogether wrong. As a matter of fact, I showed, during my paper, negatives, transparencies, and paper prints.

Your statement that the dyes would also dye the paper support is certainly correct, so far as regards single transfer; and I can only think that for the time you had forgotten that there is such a thing as double transfer in the carbon process. If I use the waxed paper temporary support, and use my dyes before the final transfer, I get good, clear whites in my final. This also applies to the use of opal or plain glass coated with collodion, provided your dye is not too strong and that your coating of collodion is not too thick.

The last paragraph of my paper, which reads as follows: "As to their permanency I cannot say. At the same time, I see no reason why they should not stand, providing, of course, that your dye is not a known fugitive, or, at any rate, made to do so by treating with a mordant, chrome alum, or tannic acid, for instance." I quote from your own report, page 729, not 725, as you have it.

To your question as to what the result of using a "fugitive" dye for a window transparency would be after a more or less brief period, I opine, as the carbon process is of itself one of permanence, and the dyeing only affecting the gelatine, that, after the dye had vanished, you would still have your print retained, but, of course, in the original colour. You mention various methods, most of which were known to me. What I sought for was something of a more simple and cheaper nature.

Again, the fact you mention was the first mentioned in my paper and the only one demonstrated to the meeting. I refer to the potassium permanganate process. Is this permanent, as you state? I think not, unless you after-treat it with a solution of gallic acid, of which you make no mention.

Here I leave the matter for the present, pleased in the fact that my paper has answered its purpose well in bringing before the photo-

graphic public new methods and old methods, even the old, many very aged photographers of my own acquaintance did not know of.— I am, yours, &c.,

ERNEST HUMAN.

[In his paper Mr. Human spoke only of *carbon prints*, which we assumed were prints in their finished state, before the dyeing. Every tyro would know, we should have thought, that if the dyeing was done while the pigmented image was on its temporary support there would be no dye transferred from that provided that the picture was reasonably washed. How could this be? With regard to the fugitiveness of some of the coal-tar colours, Mr. Human says that, "after the dye had vanished, you would still have your print retained, but, of course, in the original colour." Yes, but *plus* the tint left behind by the faded dye, because the fugitive coal-tar colours when they fade leave some tint (usually an unpleasant one) behind. Mr. Human asks if the permanganate method of intensification is permanent unless you treat the print with gallic acid. We say yes, speaking from experience. We have both carbon transparencies and negatives intensified with the permanganate of potash more than twenty years ago, and were not treated with gallic acid, that are as good as when first done. Oxides of manganese are permanent pigments to all intents and purposes. Eds.]

## FORMALIN AND FORMALDEHYDE.

To the EDITORS

GENTLEMEN,—Amongst the editorial lucubrations of one of your weekly contemporaries, dated December 6, is an article on the above, which is calculated to terrorise the users and would-be users of this most useful and beneficial body.

Inasmuch as a bath of formalin is an effective operation amongst the manipulations recommended for my new film "*Cristoid*," it seems necessary that your readers should have the benefit of my somewhat extensive personal experience of its use, and you will place me under a great obligation by finding space for these lines.

I have used the formalin bath (1 per cent. solution) now practically daily for over two years, and the physiological effects described by the editor are conspicuous by their absence, the finger-tips and hands generally are absolutely normal, although freely immersed in the bath whenever used. The pungent effects of the gas liberated during the operation (an infinitesimal quantity) were slightly noticeable on first making its acquaintance, and then they were not to be compared to the inconvenience experienced whilst the domestic onion is being sliced. Not a trace of pain has been felt in the finger-tips, neither have the nails become brittle, whilst the exfoliation of cuticle has proceeded at no greater rate than in the case of any user of developers or other astringent and caustic solutions. I am inclined to think there must have been some mistranslation of the article in the "*Photographische Zeitung*," or possibly the German article was inspired by some opponent of the celebrated chemical firm who has brought the use of formaldehyde for the hardening of gelatine to the fore. I am of opinion that our friend the Editor would have been better advised to have obtained the experience of workers nearer home.

It would have been more useful to dilate on the noxious effects of ammonia; nitrous and nitric fumes, or even spirits of salts, leave alone bichromate of potash or bichloride of mercury, or possibly he may have drawn attention to the presence of the terrible cyanogen in the poor, odorous, but grateful bulb already mentioned, and the much-wasted mustard. Yet, still better, on the stomach-tanning properties of the teapot.

Formaldehyde ranks now as our best and most useful antiseptic because of its diffusive properties. It is largely used in the hospitals. This would scarcely obtain if the doctors feared the injurious effects on nose, eyes, or lungs. As a matter of fact, the microscopic amount which reaches the membranes must be promptly resolved by the ammonia salts present into formates, which are normal constituents of the blood. The regular user of formaldehyde may, at least, take to himself the satisfaction of knowing that he has perfect immunity whilst in its presence from all diseases depending on an atmosphere-borne germ for their initiation.

Apologising for this trespass, I am, yours, &c., J. T. SANDELL.  
December 11.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

A. McH.—A letter addressed to the gentleman named, care of the Savage Club, London, would, no doubt, find him.

THE ACETYLENE LIGHT.—"CYCLIST" writes: "Will you kindly inform me if it would be possible to take a photograph at night by the help of several ordinary cycle lamps burning acetylene gas?"—In reply: The thing would be quite possible, but a large number of lamps would be required to produce successful pictures.

WHITE INK, &c.—"L. M." asks: "(1) How can I make this? Chinese white, in water, won't flow properly. (2) What is the most suitable kind of commercial dry plate to use for making enlarged negatives?"—In reply: (1) If a little prepared oxgall, as sold by artists' colourmen, be added, the colour will flow well. (2) Any of the ordinary, or slow, plates on the market are suitable for the work.

ARTISTS' CANVAS.—T. A. HEATHCOTE writes: "Could you let me know how to make artists' canvas; I have been using whiting and size, but it is not waterproof, and the paint sinks in the canvas?"—In reply: Making artists' canvas is difficult when doing it on a small scale, and the result is not equal to that which can be purchased. We should advise you to purchase it ready prepared. It may be had in rolls of different widths from those who supply artists' materials.

PHOTOGRAPHING ON SILK.—W. THOMPSON writes: "Would you kindly let me know the cause of the marks on the enclosed piece of silk? I only get this happen now and again. The silk seems to saturate itself evenly with the silver solution, so I cannot account for it. Should be glad to know how to avoid this in future."—In reply: We can only suggest that the silk was not perfectly clean and dry when it was salted, or the salting was uneven. We have not met with such marks ourselves.

BURNISHING PRINTS.—R. HENDRIE writes: "I have got a new burnisher, 10 in. Hanover, but I cannot get the desired polish. Am I to let my cards get completely dry, or what is the best way to prepare them for the bromide? I use Ilford P.O. paper."—In reply: Possibly sufficient pressure is not applied, or the heat is not great enough. The prints should be moderately dry, but not too dry. The prints should be lubricated. A good lubricant is a gram, or so, of Castile soap to the ounce of methylated spirit.

COPYRIGHT.—"R. J. P. S." writes: "A customer has left two illustrations of a weekly paper, bearing date 1862, to be copied, and has ordered several dozen for re-sale, but, before going on with order, would be pleased to know how to proceed in the event of our infringing the Copyright Act?"—In reply: If there is any copyright existing in the prints you would certainly be infringing it. But without knowing more particulars we can give no opinion in the matter.

A QUESTION OF COPYRIGHT.—W. F. WILSON writes: "Two little girls here in an entertainment represented the 'Dirty Boy' of Pears' Soap, and had a large bowl with Pears' name printed thereon. As the original is copyright, is it wrong to make up as such, and can I photograph these little girls as such?"—In reply: It would not be an infringement of copyright to make a "living picture" like the painting. That was decided in the case of *Hanfstaengl v. The Empire*. But if the living picture were photographed it would seem that that would be an infringement, according to a case decided some years ago in the north.

DARK ROOMS.—"M. J. W." writes: "I am about to make a dark room inside another room. The space I have at disposal for its width is 6 ft. 6 in. I wish to economise space as far as possible, yet not so as to limit unduly my dark room, which I wish to be large enough to permit of using an enlarging camera, and for general work. Will you kindly suggest what you think would be the best length which would suit the above requirements?"—In reply: Twelve feet would be a convenient length for working. But if it were a little longer it would be still more convenient, especially if the enlarging is done with the lantern.

COPYING DAGUERRETYPE.—"C. and Co." say: "We have a Daguerreotype brought to us to copy, and, as we have never had such a thing to do before, we shall be glad if you can give us any information as to how to proceed. We know the thing is very difficult, and we have been told that it is impossible to get a presentable copy of a Daguerreotype."—In reply: There is no difficulty whatever in getting a good copy of a Daguerreotype; indeed, as a rule, they yield excellent copies if they are properly lighted. Place the picture so that it is lighted by a strong direct side light (stopping off all front light), so that all reflection from the surface is away from the lens. Under these conditions an excellent result may be obtained.

\* \* Many answers to correspondents are unavoidably held over.

### THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1901.

Edited by THOMAS BEDDING, F.R.P.S.

*What some readers think of the book:—*

- "A splendid ALMANAC."
- "A handsome present."
- "Grows bigger and better every year."
- "More interesting than ever."
- "More copious and more useful."
- "A necessity to the busy worker."
- "Better than all its predecessors."
- "I congratulate you heartily on issuing such a good book."
- "Most acceptable and useful."
- "Grows more valuable and interesting every year."
- "A capital issue."
- "Excellent in every feature: the letterpress, diagrams, tables, and illustrations are most helpful."
- "A first-rate and exceedingly cheap publication, fully up to, if not beyond, the standard of former years. . . . A combination that must mean continued and strengthened life."

\* \* \* The 1898, 1899, and 1900 editions of the ALMANAC (20,500 copies) were each sold out within a few months of publication.

\* \* \* Of the 1901 Edition, just issued, over 19,000 have already been disposed of.

### EX CATHEDRÂ.

THE position and future prospects of the Camera Club have recently engaged the serious attention of the members of that body, and, as some misapprehension has arisen in connection with the precise state of affairs in Charing Cross-road, we think it desirable to make public the following details. A few weeks ago the present Executive intimated to members an inability to carry on the Club after December 31 of this year unless an increased subscription were agreed to. The responses to the Committee's suggestion of a raised subscription were not numerous enough to meet the requirements of the case, and consequently, at a largely-attended meeting of the members, the Committee intimated their intention of winding up the Club at the end of the year. This decision, however, was in no way binding on the members of the Club, and those present at the meeting referred to, in number about eighty, unanimously appointed an Advisory Committee to take into consideration the best means of carrying on the Club. On Friday evening last a second general meeting, as largely attended as the first, was held at the Club house, and the report of the Advisory Committee was adopted. From this report, a private document of great length, we, of course, do not feel ourselves at liberty to make any extracts, but we may say that its suggestions are of such a nature that, if properly carried out, they should assure to the Club a successful and remunerative future.

THE position of affairs, then, is roughly this: The old Executive of the Camera Club is preparing to shortly terminate its responsibilities of administration, whilst the sponsors of the new scheme are perfecting its details with a view to taking over the control of the Club at an early date. Meanwhile, the Camera Club, as such, goes on as usual, and, although the transition period of the next few

weeks or months is bound in the nature of things to be a time of uncertainty and anxiety, we have the best reasons for confidently expecting that the interruption thus made in the Club's career will be of a temporary kind only. We have good grounds for saying that hundreds of members of the Camera Club are concerned to assure and improve its future. There is no question whatever of discontinuing the Club. That is a subject upon which there has been no discussion at all. The whole aim of the general body of members is to place the Club's future existence on a solid foundation. A general scheme of reformed administration has been adopted. In carrying it out great changes in detail may be safely anticipated; but the exact nature of such things it is impossible to forecast. Of one thing, however, we can speak with the strongest confidence. It is this, that within the Club there exists a large body of able and influential men with the power and the will to carry on the Club successfully in the future, and, in our mind, there is no doubt whatever that they will succeed in their object.

\* \* \*

A KNOWLEDGE of the Camera Club, for about ten years, a considerable part of which period we have enjoyed the honour of membership, has given us exceptionally good opportunities of forming an opinion of the chances of the Club's future success as a social centre for those interested in photography. We, for our part, have no hesitation in predicting a new career of the most marked prosperity for the Camera Club, if that institution be administered in a business-like and alert manner, and the responsible officers, whoever they may be, are imbued with broad-minded and progressive notions of management. Most emphatically do we affirm, from knowledge and observation, that there is more room for the Camera Club than ever there was. We sometimes hear it said that the photographic craze of 1885, when the Club started, has died out, and with it the necessity for such an institution as the Camera Club. We quite distinctly recollect the growth of the amateur photographic "craze" of the years 1883-1885, if craze it could be properly styled. We do not think it could. For every amateur photographer of that time there are probably at this day scores. We are asked to believe that the photographic "craze" had come to a head well before hand-camera times, before cheap plates, rollable films, radiography, animated photography, the Lippmann, Ives, and Joly processes of colour photography, before photo-typically illustrated newspapers were produced, before the photographic industry was half its present size, and when THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC was only about a fifth of its present dimensions—300 pages, instead of 1500! Absurd! In reality, the so-called "craze" of 1885 was nothing but a tardy realisation of the great power which gelatine as an emulsifying vehicle had previously placed in the hands of photographers. The "craze" for photography, if we must use the unsatisfactory term, is at this time much keener than ever it was, and we, at any rate, expect to be many years older before its limits have been reached.

\* \* \*

FROM its original standpoint of a centre for amateur photographers, the field before the Camera Club is, we think, broader, not narrower, than it was fifteen years ago. Professional men and members of the leisured classes, men of science and investigators, travellers, naval and military officers, and others to whom a club is a necessary part of

social life are now more numerous, if our opportunities of observation do not mislead us, than in 1885. Men of this kind, in London and the country, who do not know of the Camera Club and the social and photographic facilities it affords, would probably join in considerable numbers if some means of reaching them were devised. The Club premises are centrally situated, all the usual conveniences are at the disposal of the ordinary club man, and the photographer may have the use of dark rooms, studio, and so forth. We have heard it said that such a combination of facilities as this does not exist anywhere else in London, if in the world. We most gladly add our testimony to the excellent spirit of gentlemanly good feeling which invariably pervades the Club. The lectures, held twice a week, are attractive and varied in subjects, and are always well attended. Of how many West-end clubs can it be said that interesting lectures are made a feature? It is not necessary further for us to dwell on the pleasant features of club life that may be enjoyed in Charing Cross-road. We write of them from intimate personal knowledge and experience, and in the belief, as we have already said, that if the Camera Club were more widely known it would not suffer from lack of members, but would probably find it difficult to accommodate those who had gained or were seeking admission. Our sole object in writing these lines is to encourage those who contemplate taking upon themselves the future task of conducting the Camera Club, and we sincerely trust that no other interpretation will be put upon our remarks. As the leading social club for photographers in the world, there appears to us to be a fine field of usefulness before the Camera Club, and we wish the utmost success to those who have made up their minds to stand by the Club and "see it through" what we are convinced is merely a temporary and by no means acute difficulty.

\* \* \*

THE last number of the "Journal" of the Photographic Society of Philadelphia contains a report on "Etching Matte," a recently-introduced print-out platinotype paper. The report was presented by Mr. C. Yarnell Abbott, an able photographer, with whose work we have for some time been familiar, and it will be seen that he met with only partial success with the new paper:—

"The directions furnished with the paper state that printing, which should be done in the sun, should be continued until 'the image is well defined and the shadows assume a deep canary colour.' Practically, I found that the image printed out very little more than with Willis and Clements or Bradley paper. The printing time is about twice as long. Development is absolutely simple. The print is immersed in clear water which may be of almost any reasonable temperature, although I fancied I got best results at about 74°. The prints flash up very quickly, but there does not seem to be any danger of over-development as with the 'development' papers. They are then cleared in a weak acid bath—about one drachm of hydrochloric acid to the quart of water. Five minutes' clearing and ten minutes' washing in running water are said to be sufficient.

"The circular claims that, by the use of water of different temperatures applied locally in development, great latitude is obtained, the rule being, 'the deeper the printing the colder the water,' and vice versa. Theoretically, therefore, warm or hot water may be applied locally to force detail in the whites of the print, as in bringing out clouds. Along this line, however, I had very little success. As you will

see by some of the prints, there is a tendency to chalkiness in the whites, and no amount of hot water applied locally seemed to affect this, or to bring out detail."

\* \* \*

MR. Abbott goes on to testify to the simplicity of the process and the durability of the results, but, on the whole, he does not seem to have been more successful with this print-out platinum paper than English photographers with similar picture-making surfaces that have been introduced into this country at intervals during the last twelve or thirteen years. At the same meeting of the Philadelphia Society, Mr. G. D. Firmin presented a report on Eastman's sepia paper, which he said is almost a "printing-out paper," as the image is quite distinct before development. The reporter furnished the following details of this process, which may interest some of our readers:—

"The paper prints somewhat more quickly than platinum. Development is as with blue-print paper, with water, which washes out the unaffected salt. Three changes of water will suffice. The print becomes yellow in the water and paler as the sensitive salts are washed out. The regular proceeding is now to *tone* the print in weak hypo solution. It is not, however, necessary to do this, and various modifications may be employed, as hereafter described. The instructions accompanying the paper say, Wash in two or three changes of water; then immerse in hypo solution  $1\frac{1}{2}$  grains to the ounce. I believe a still weaker solution gives more control and therefore better results. In the hypo bath the print changes to a pinkish brown, becoming eventually a rich chocolate-brown. 'The tone depends upon the time in the hypo bath,' i.e., from 'pink' brown to dark brown." Eastman sepia paper has been on the American market for some time. An absolutely new photographic printing process would be a difficult thing to desire nowadays, but it is interesting to note the great amount of attention which the introduction of modifications of old printing processes invariably excites amongst photographers. There is a constant demand for an "ideal method," which in all probability will never be forthcoming, for the simple reason that the matter of printing affords scope for the exercise of such a wide variety of tastes that their gratification under one head is neither practicable nor possible.

#### THE PRESERVATION OF CAMERAS AND SLIDES.

WE should not like to hazard a guess at the number of millions of pounds sterling invested, in the hands of amateur and professional, in various kinds of photographic cabinet ware, including even nothing beyond simple cameras and slides. Though the Americans are beginning to run us closely, Great Britain still enjoys pre-eminence undoubted in this manufacture, and is responsible for the finest examples the world can produce. We saw the other day in a letter from one of our best makers, in reply to some laudatory words from a customer, a very pregnant sentence. "Yes," wrote the maker, "I suppose you will want me to do it up again in another thirty years." The camera and slides which were in question had just been "done up"—to adopt the maker's phrase—after daily hard use for thirty years, and we learnt that it would not have been sent at all but for some alterations and additions that were required. Yet how many of these millions of pounds' worth that we speak of are there in good order after ten years' possession, or after five, or even after two years? Naturally, as

changes in mode of work take place, and improvements are instituted, there is a tendency to throw aside the old and take up new patterns, relegating the discarded ones either to the lumber-room or the auctioneer's hammer. Making all allowances in this direction, there still must remain a vast store, both of British and foreign, that have been in the owners' possession for a long time, and to these more particularly is our query pertinent. There can be no doubt whatever as to the large proportion of those falling in this category being out of order, in one way or another, camera or slide, or both, and mainly through want of a little care and attention at the right moment. Damp, from one source or another, is responsible for most of the cases, careless exposure to dust and sun ruin many, while abroad, especially in tropical regions, we have, in addition to these, the evil wrought by insect pests. In a country like our own damp is a difficult enemy to fight, however good the instruments employed may be. It is not always damp per se that does the injury, it is the pulling and straining of the camera or slide after damp has been absorbed. The very highest class of woodwork is liable to absorb moisture if laid aside in a damp place, the shutters of the slides jam, or the sliding portions of the camera stick, and then the inevitable main force is called into play, with the result of a strain or a break. This is the simplest instance that occurs even when a fair amount of care has been taken. We have seen a camera left in a room in a newly-built house that appeared dry, but which had sufficient moisture to cause every one of the slides to jam. When, however, an accidental shower has caught a camera, and it has been packed up wet, and never attended to when brought home, when slides are taken into the dark room and handled with wet fingers, or splashed with developer or other solution, and left for it to dry on, when they are stored away in winter time, the season's work being over, in any out-of-the-way place, dry or otherwise, and on bringing into use again it is found that the woodwork has sprung, the leather is peeling away, we think it by no means undesirable that the whole set should go wrong and need replacing. The owners of beautiful examples of the cabinet-maker's art who will treat it no better than that deserve no pity, but rather to be compelled to buy another outfit. Every day after a camera has been used it should be most carefully dusted and dried, and occasionally all the woodwork most carefully rubbed and polished to remove accidental finger-marks, &c., and to polish off that deposit from the air which attaches to every polished object after a time. The thrifty housewife knows that her furniture keeps all the better for constant cleaning and rubbing, and a similar need exists with regard to camera work, though it has to be attended to more deftly and carefully.

The exercise of the greatest care will not always suffice to prevent the effects of damp in causing woodwork to swell, and to avoid this all metal cameras have been designed, but never had much vogue, though some of the recent popular Kodaks are mainly metal. But we think that if British conservatism could only be overcome great improvement would be found possible by adopting some of the more recently-invented means of treating wood to render it damp-proof through and through. We have seen stores of mahogany more than thirty or forty years old, and no self-respecting maker would use any but the driest of wood for cameras or slides, seg-dried being considered the best. Obviously, this ageing must add to the cost of the wood, and any process

which, without interfering with the ease of working or detracting in any way from the strength, elasticity, or other needful qualities, if fairly put upon the market, ought to receive every consideration from the camera maker, and, if found good, be adopted.

When we come to consider the ravages wrought by insect pests in tropical regions we trench on a topic which perhaps might be better treated by local experts. It is, however, obvious that an air-tight metallic case would have the double effect of keeping out insects and preserving the camera from damp, the hot, damp air of the tropics having a deadly effect upon glued work, ruining woodwork generally. With regard to that particular pest, the white ant, we have been informed by a large exporting camera-maker that if Russian leather be selected as a covering it will keep these ants away altogether as long as the special odour of the leather remains. We give this hint for what it is worth. If any reader should test its value, and communicate the result through our columns, it might be of assistance to his brother workers. But, ants or no ants, in tropical or temperate zone, let every one possessed of a camera pay some respect to it and handle it tenderly, and look after its continued well-being.

#### The Connection between Electricity and Light.—

The *Photographisches Wochenblatt* draws attention to a discovery Lenard has made, which may be of importance. In view of the fact that ultra-violet light possesses the power of discharging electrically charged bodies, Lenard has endeavoured to ascertain what becomes of the electricity, and finds that it is converted into cathode rays, which pass into space. It is remarkable that a charge of negative electricity is only once converted into cathode rays by violet light, and that cathode rays may be generated and transmitted in a vacuum such as may be produced by the best air pumps of the present day. It has hitherto been considered impossible that an electrical discharge can take place under such conditions. Lenard has also discovered that cathode rays generated in such a manner have only one-thirtieth the rapidity of light. They are in fact the slowest rays known to us. The speed of transmission of induced electricity surpasses very considerably that of light. It is to be expected that Lenard's discovery will explain many photo-electrical phenomena. The connection between light and electricity indicates prospects of great technical importance.

**Awards at the Paris Exhibition.**—Exhibitors who have been awarded a "grand prix," gold, silver, or bronze medals, will receive a diploma and a bronze medal, which has been designed by M. Chaplain of the "Institut de France." Exhibitors who have received "honourable mention" will be given a diploma, and those who are "hors concours" will receive a diploma to that effect and a bronze medal. Workmen, engineers, artists, and others, will receive similar honours to the exhibitors. The medals are 63 mm. in diameter, and those entitled to gold or silver medals may obtain them from the Paris mint by paying 710 francs and 22 francs respectively. The fineness of the silver medals is 950:1000, and of the gold 916:1000. The silver medals weigh about 130 grammes, and the gold about 200 grammes.

**Enlarging.**—The *Photographische Chronik* refers to the question, which is often asked, as to the lens with which an enlargement should be made. The reply is frequently given, that the same lens may be used with which the negative was taken. But it is evident that the best results may not be secured by such means, for a lens may have had to be stopped down considerably to obtain sharp marginal definition, in which case the inverted process of enlargement will be rendered much more difficult. The best lens to use is one of modern type, corrected for astigmatism, and with large aperture.

Such lenses have greater covering power, and, as this favours the use of a large aperture and a shorter focus, the work of enlarging will be greatly facilitated.

**Weighing small Quantities.**—We also notice another remark in the *Photographische Chronik*, that is worth remembering, in case small quantities of chemicals have to be weighed off for photographic purposes, which is frequently the case. We suppose few photographers are possessed of a good chemical balance, and the usual dark-room method of obviating the difficulty, to which we have referred, is to make a solution of considerable bulk and measure off a small quantity representing the amount required. But there are many substances that deteriorate rapidly in solution, and the method may thus become rather expensive. The *Chronik* recommends that such substances be intimately mixed with pumice powder, silica, or some other substance indifferent to the action of water or other fluids. By using such mixtures small quantities may be weighed off in a fairly accurate manner.

**Palladium Toning.**—The *Photographische Wochenblatt* contains an article by J. Joé giving details of a palladium toning process for silver prints. Plain salted paper is recommended as the most suitable, but commercial gelatino-chloride and collodio-chloride papers may also be used, in which case sepia tones prevail, unless combined palladium and gold toning is resorted to. There is much similarity between palladium and platinum toning, with regard to colour and other characteristics. The prints do not lose so much in fixing as when toned with iridium, and they should be printed to about the same depth as for platinum toning. It is very important that the prints should be thoroughly washed before toning and before fixing. Insufficient washing before fixing is followed by yellow stain, a fact which may be taken advantage of if the effect of an engraving upon toned paper is aimed at. It is also important that the bath should be acid. A strong bath favours black tones, and a weaker bath sepia and brown. Joé recommends the following formula:—

Potassium palladio-chloride .....	1 gramme.
Table salt .....	10 grammes.
Citric acid .....	10 "
Water .....	2 litres.

After taking the print from the frame, immerse it in salt and water, thoroughly wash it before toning, and again thoroughly wash before fixing.

The following bath gives very agreeable chocolate brown tones:—

Potassium palladio-chloride .....	1 gramme.
Molybdate of ammonia .....	10 grammes.
Citric acid .....	10 "
Water .....	2½ litres.

Palladium is an expensive toning process on account of the high price of the metal, but there is some compensation in the fact that more prints may be toned with a given quantity of it than with gold.

#### ON THINGS IN GENERAL.

SOMETHING for nothing; that is what the gulls in the Tanqueray swindle expected, now they are whining because if they are to get something they have to pay for it! Tanqueray is evidently a keen student of human nature, and he knows how deeply implanted is the desire to "pick up a bargain," to get something "on the cheap," as it is often tersely, if vulgarly, put. Traps without end for hundreds of years past have been set with the same bait, and with constant success; but naturally the bait has to be changed from time to time to keep it from getting stale, though a considerable lapse of time is often needed before that comes about. The free portrait bait is a good one, undoubtedly, and one could almost forgive its originator if he would only return original photographs when his bait was not swallowed; but the admiration that might otherwise be felt for the ingenuity of the trick vanishes when it is seen that the fellow is only a common cheat clever enough to escape the meshes of the law. But I should like to put a question on this matter, "Are photographers

entirely blameless." Time was when they stood upon their dignity; but nowadays there are so many who teach the public the small value they attach to their own productions by reason of free sittings offered under specious pretences; unlimited number of proofs to select from, unlimited free "retakes," that there is, after all, not much to be surprised at when a foreigner offers to do just the same thing, something for nothing."

When platino-bromide prints were first introduced I objected wrongly to the name, as it lent itself to either deliberate fraud or unconscious misrepresentation. It will be scarcely credible to the more scientifically educated photographers, but it is, nevertheless, a fact that some photographers are under the impression that platino-bromides contain platinum; little wonder then that we should at least have a case brought into court where it has been advanced that bromides "may not be exactly quite the same, but they are identical as regards appearance," as platinotypes. I do not remember having before this seen a case brought into court to remedy the fraud of bromides supplied in lieu of platinotypes, and it is very remarkable that such a case should not yet have been brought, for the evil is rampant. I know of a case of a well-known photographer in a large way of business who carries on this fraud systematically, if all I hear is true: I do not doubt it. It is not merely that the purchaser is defrauded—*caveat emptor*—but the process of true platinum printing is brought into disrepute, and reputable photographers are apt to be told platinotypes are not permanent. The evil is so great that it becomes a question whether some endeavour should not be made to stamp out such fraud by concerted measures taken by photographers generally. If photographers are to hold their own, and too many find it hard enough to do so of late years, some steps should be taken to prevent a slur being cast on the profession by such fraudulent practices as these.

While discussing platinotype matters, one naturally turns to a recent discussion at the L.P.P.A. upon sepia platinotypes, and sundry further discussions thereon. This is all very like flogging a dead horse. True, there is no harm in talking of platinotypes of other days; but why not go back to the very first platinotypes with their lead salts if we are to discuss platinotypes as they were? Surely most users of this beautiful process are aware that there is no mercury employed in sepia platinotypes at the present time; if not, they ought to be, and they had better peruse the booklet issued by the Company with full instructions. The only difference between a sepia and a black tone developer is that acid is added for the former colour. A special solution used to be sold, but there is no need of it now. The real difference lies in the paper employed, that chosen for sepia is of entirely different manufacture from that used for black tones.

The "permanent processes" have been to the front of late, in an unusually strong fashion, and the Editors have given a useful and timely lesson on making reversed negatives which do not require the trouble of "double transfer" for printing in carbon. There is one little point when making reversed negatives, by taking the picture through the glass, and that is—take special care that the springs of the dark slide back do not scratch the surface of the plate! This can easily be avoided if the need for care is remembered—a piece of brown paper doubled up three or four times is springy enough to take up the pressure and prevent it reaching the film itself. Some films are much more readily scratched than others; but all alike need some precaution taken. Double transfer is liable to an inconvenience not often referred to: when the print is taken off waxed glass, sufficient of the wax adheres to it to render it most difficult to paint upon, and a good deal of benzole is needed before this film, which is surprisingly repellent, is removed. A little prepared oxgall is a great help, and when colours are used it is better to employ the colourless prepared oxgall for artist's use, it is almost as colourless as water.

In reading the account of the Croydon Club Meeting, I note a reference to a new print-out paper requiring no toning, and it is stated that the occasion was the first time it had been used in England. Doubtless the remarks were intended to apply to this particular kind of self-toning paper, and not such papers in general, for during the last few years quite a number of self-toning papers have been placed upon the market, all "requiring no gold." The rationale of the "toning" is pretty obvious, especially when we read the in-

structions of many of them—hypo fixing at a maximum strength of five per cent. It is very unfortunate that such modes of printing should be recommended, every one knows of the evils which lurk in the path of very weak fixing solutions.

With regard to Mr. J. A. Reid's comments on what I wrote with reference to the illustrated press, I take it that there is a very great point of difference between us, but as he speaks of traversing my statements I might perhaps add a further word or two, though, the tone he takes is one no one could take umbrage at. He refers to editors and proprietors of papers. "As a matter of fact, in many cases it is the editor—the proprietors may not be consulted." Well, I think we both have the same paper in view, and certainly in that case, the proprietors are not only consulted but have a lively ultimate voice in the matter. I could give some lively examples if necessary. "The point was that there are people who do not think photographs of Royalty, especially of Her Majesty, should be exploited for the benefit of one particular paper." But is it so? I think Her Majesty has sat to several photographers. A weekly retaining fee is not suggested as being paid to all. I never said that the degradation of the illustrated press came from the portrait department, nor did I mean to infer it. "If we cannot prevent the force of circumstances why shed aimless tears." I don't know that there was anything particularly lachrymose in my remarks; and as to preventing the force of circumstances, well, if we cry "*Delenda est Carthago*" long enough we may perhaps not destroy those editors, but bring them to a proper sense of their relations to photographers, and stop the fire-shillingidea. As to there being no compulsion in the matter, is there not? Is there a photographer living who if asked to go and take a photo of Her Majesty for an illustrated paper would not gladly do so? He would be glad of the kudos to aid his business, but the papers won't recompense him now to the extent that would have been possible in the 80,000 order days. I may say that as to the papers worth while sending photos to, there are very nearly a score now. However, as I said, I don't think there is much real difference of opinion between me and Mr. Reid, so I will say no more.

FREE LANCE.

## REDUCERS.

THE operation of reducing the intensity of the silver image may be effected, as is well known, by various processes, which may be divided into two classes according to their results:—

1. Reducers acting uniformly on the different parts of the image.
2. Reducers acting on the most opaque parts of the image.

To the first class belong the peroxide salts of cerium, the mixture of potassium ferridcyanide, and hyposulphite of soda, and a certain number of other metallic salts of which we have already pointed out the properties.

This method of reduction is used in every case when one wants to increase the contrasts of an over-exposed negative. On the other hand, the second method is employed when an under-exposed negative has been over-developed, for then one wants to reduce the image without losing any of the details which may be insufficient in the more transparent parts of the negative.

This method of reduction may be effected either by an indirect process, or by means of peroxide compounds, endowed with similar properties to oxygenated water.

In the first process, which was suggested by Eder, the whole of the silver of the negative is transformed into chloride by the action of ferric chloride, and then developed by a slow-acting developer, the development being stopped before the negative has become too opaque, the chloride not reduced is dissolved out by hyposulphite of soda.<sup>1</sup>

This method which is based upon a very interesting principle, is extremely delicate in application, because it is difficult to determine the exact moment to stop the action of the developer.

<sup>1</sup> Eder's later method is by the use of a mixture of hydrochloric acid, bichromate of potash, and water, and alum, and this is preferable to the use of ferric chloride. McIntosh suggested an improvement upon this in the use of bromide and bichromate of potash and nitric acid.—Eds.

In the second process, the persalts such as the persulphates, and especially ammonium persulphate, are used, which can play at the same time the rôle of an oxidiser or a reducer according to the conditions under which it is used. Besides ammonium persulphate ( $\text{NH}_4\text{SO}_4$ ), the uses of which we were the first to point out, and to give a detailed method of its use,<sup>1</sup> two other substances have been pointed out which give precisely the same results as does ammonium persulphate.

One of these is oxygenated water or hydrogen peroxide in an acid solution, suggested by Dr. Andresen<sup>2</sup> the other is the permanganate of potassium in acid solution which was suggested by Prof. Namias,<sup>3</sup> in the following formula:—

Potassium permanganate.....	0.5 parts.
Sulphuric acid (strong).....	1 part.
Water.....	1000 parts.

It is admitted that ammonium persulphate and hydrogen peroxide in acid act in an analogous manner on the silver of the negative, the former in giving a double sulphate of silver and ammonia according to the equation

and the second in giving also a silver sulphate if sulphuric acid be added to the hydrogen peroxide, and according to the equation

To explain the peculiar action of ammonium persulphate which reduces more rapidly the dense parts of the negative than the thin, we have to take into account the secondary reducing action which ammonium persulphate possesses in the presence of the double sulphate of silver and ammonia, a reaction which may be represented by the equation

An exactly analogous reaction may be obtained with acid hydrogen peroxide:—

We have thought that this inverse action of the principal reaction tended specially to take place on the outside of the gelatine film; where the double sulphate of ammonium and silver exists in the presence of an excess of persulphate, whilst in the interior of the film the persulphate is only used to dissolve the silver of the negative, the inverse action taking place with much more difficulty owing to the absence of any excess of ammonium persulphate. This hypothesis, which is equally applicable to hydrogen peroxide, may, to a certain extent, explain why the dense portions, which include a much greater portion of the thickness of the film than the transparent parts, are more rapidly dissolved than the latter by the persulphate of ammonia.

Our theory has been discussed by various authors, but up to the present time no one has given a satisfactory explanation of this curious phenomenon.

The action of permanganate of potash in the presence of sulphuric acid may be equally explained by reactions analogous to the foregoing.

We may, in fact, suppose that the solution of the silver takes place according to the following equation:—

As regards the inverse reaction of the permanganate on the silver of the transparent parts which is on the surface of the film we may assume that it has a tendency to deposit silver on these parts according to the equation:—

as in the case of ammonium persulphate or of hydrogen peroxide.

Finally we may point out the negative results which we have obtained with a whole series of peroxidised bodies, which we thought *à priori* ought to be substitutes for ammonium persulphate. We recognised that a small number of these substances tended to trans-

form the silver of the image into oxide, and gave a slight intensification, others had no action on the image when employed in a neutral or acid solution.

The compounds we have tested are: periodates, iodates, iodic and periodic acid; perchlorates, chlorates, perchloric and chloric acid; bromates, permolybdates, pertungstates, pervanadates, alkaline perborates.

In conclusion we may sum up by stating that substances capable of reducing negatives, by attacking the opaque parts more rapidly than the transparent, appear to be small in number, and only act in an acid solution. This class of substances seems to be limited to the persulphates, to hydrogen peroxide, and permanganate of potash in acid solution.

Therefore, these are compounds, which, although peroxidised, differ very notably, from the point of view of their chemical properties, from reducing substances acting simultaneously and uniformly on all parts of the picture.

MM. LUMIERE and SEYEWETZ.

## BELGIUM—A RETROSPECT.

### III.

Of the important buildings erected in recent years, first place must be given to the Palais de Justice. It is true that it took nearly 20 years to complete, and that it cost about two millions of money; but the people of Brussels have something worth looking at for the money and worth waiting for. A magnificent structure 400 feet high, and of both elegant and substantial proportions, is more in accordance with the object of its erection than our Royal Courts of Justice in London, the design for which, to the casual observer, seems to have been specially prepared with a view to using up a conglomeration of second-hand building materials.

Another fine building is the New Exchange on the Boulevard Anspach. The most recent new Post Office opposite the Théâtre de la Monnaie is a great improvement on the old Jesuits' Church, where the postal business was carried on for many years. This old church was demolished a few years since, and an elegant fountain now occupies the site.

Of the many museums in Brussels, perhaps the most astonishing is that of the eccentric painter Anton Joseph Wiertz. This should certainly be seen, as it is far removed from the "usual thing" in Continental paintings as it is possible to imagine.

The environs of Brussels contain many spots well worth seeing. Laeken, with its Royal Palace, monument to Leopold I., and prettily laid-out cemetery, where will be found the grave of the celebrated Madame Malibran. The quaint old church of St. Mary adjoining has recently been pulled down, leaving the unfinished new church with its octagonal east end in all its glory.

The Bois de la Cambre is easily reached by tramcar from the Place Royale, and many excellent pictures may be obtained there without let or hindrance.

The field of Waterloo still has its attractions for English and American visitors, although 85 years have elapsed since the memorable battle. I paid a visit to it in 1863, but have felt no inclination to repeat the experience. I understand the relics still hold out, although not so plentiful as at one time; the same old stories are related, and have lost nothing by repetition. I thought years ago, it would be better if the incident of Waterloo were forgotten, and, possibly, no one would regret it but the guides who kindly meet you on your arrival. Latterly, however, I have come to the conclusion that perhaps a reminder of the victory of June 18th, 1815, on that side of the Channel, is not altogether undesirable.

Mr. Taylor and I had been talking about the new Waterloo Monument which had recently been unveiled at the cemetery at Evere, and when at Brussels thought we would like some photographs of it. So one fine morning we took the steam tram from Josse ten Noode, and in due time arrived at the cemetery. Here, however, we received a check, the gatekeeper politely, but firmly, declining to allow us to take our cameras with us. We explained that we only desired to photograph the new monument towards which the English people had subscribed so much, but it was no use. "You cannot photograph it," said he. He kindly offered to take care of our cameras while we went to see it, however; and this offer we accepted. He pointed out the direction in which we should find the interesting monument, and after some difficulty we discovered the spot. Here we found an

<sup>1</sup> *Bulletin de la Société Française de Photographie*, 1898.

<sup>2</sup> *Photographische Correspondenz*, 1898.

<sup>3</sup> *Bulletin de la Società Fot. Italiana*, 1899.

erection covered with canvas, and, on looking inside, the object we had come so far to see was carefully wrapped up in dirty cloths, closely tied round with rope. We looked at each other for a moment or two, and then I'm afraid we forgot our surroundings and laughed long and loudly. When we returned to the gate the porter politely handed us our cameras. I thought I detected a twinkle in his eye as he did so, but that may have been fancy on my part. We often spoke of this episode afterwards, but were never quite sure whether the man misled us intentionally or unconsciously. Why there should have been so much difficulty placed in the way of obtaining photographs of this monument I do not know; but, although I took considerable trouble to do so a year or two afterwards, it was only by a ruse that I succeeded.

During the last twenty years few places have changed much less than Ghent, more especially in the older parts of the city. The Town Hall is still smothered up by comparatively narrow streets. The belfry still wants repairing; the cathedral, with its fine pulpit of oak and marble; the front of old St. Nicholas; the corn market; and the old Marché du Vendredi, are as interesting as ever, and the beautiful statue of Jacques van Artevelde (erected in 1863) is still considered one of the most lifelike in Europe, although the accumulated dust of nearly 40 years might be removed with advantage. By the bye, the study of this naturally-posed statue might be a lesson to some of those sculptors whose inanimate-looking effigies stand solemn sentry in our English open spaces.

The great Béguinage has always been considered one of the attractions of Ghent, and a visit to this religious lace-making community is generally regarded as indispensable to those taking any interest in such institutions. The entrance gates, the little church, and quaintly-arranged buildings make a capital little series of views, and if the interior of the church, with its dimly-lighted aisles and hundreds of nuns and novices at vespers, could only be reproduced, it would form one of the most effective and devotional pictures possible. In 1884 I tried to obtain a photograph of the sisters as they left the church after their early morning service. The weather was propitious, and I took up my position and waited. I had ascertained the hour the service usually concluded, but it was some time after this, and still no Béguins appeared. At last, getting somewhat hungry and impatient, I went over to the church and looked in. It was empty; they had all departed by the little back-door near the altar.

The ruins of the ancient Abbey of St. Bavon, dating from 1179, are always worth revisiting. But the Lourdes (about two miles from the Pays de Waas Station), with its new church and enlarged hotel, is a comparatively new institution. It was after a visit to the Lourdes (in order that Mr. J. Traill Taylor should snapshot some of the grottoes and piles of crutches and sticks left there by believers in the curative power of the Holy Well) that my companion espied in the window of a little shop in the Rue d'Anvers a fine piece of Gorgonzola. "Now for some fun," said he; "see me talk French." I followed his burly form into the small establishment, where a buxom woman stood smiling behind the counter. "S'il vous plait?" said the lady, inquiringly. Mr. Taylor pointed to the cheese with his right hand, and in the other held up two 10 centime nickels; "Tippence," said he. "Pardon, monsieur," said the lady. "Tippence, tippence," reiterated Mr. Taylor. Then the lady suddenly comprehended what was desired. "Ah! oui," said she. In almost less time than it takes to relate, she had taken the cheese from the window, cut off a piece which she wrapped up carefully and handed to him in exchange for his "tippence;" and he came out of that little shop beaming with pride and satisfaction.

One of the most interesting cities in Belgium is Bruges. It is now only a shadow (so to speak) of its former self. In the fourteenth century we are told it was the commercial centre of Europe. In the sixteenth century its population was 200,000, and the pride and arrogance of the Flemings at that time is well exemplified by the following anecdote. A repast was given by one of the Counts of Flanders to certain Flemish magistrates, and the chairs they occupied were unfurnished with cushions. The proud burghers not being satisfied with the bare seats, folded their valuable cloaks and sat upon them. After the feast they were retiring, apparently forgetting these costly articles of dress, of which a courtier begged to remind them; but the Burgomaster of Bruges replied, "We Flemings are not in the habit of carrying away the cushions after dinner!" and the whole of the cloaks were left behind.

During the present century Bruges has always been noted for the number of paupers it contained. Sixty years ago, out of a much

reduced population of 43,000, it was estimated that 18,000 were practically paupers during the winter time. The population at present is about 54,000, but quite 20 per cent. are paupers. Ordinary visitors would not suspect such a state of things, for there is little or no mendicancy, and, although the inhabitants are certainly a "slow going" lot, they appear to be fairly prosperous. The city abounds in photographic subjects, the Grande Place alone furnishing several. This square was remarkable years ago for the number of estaminets and restaurants contained in it; one side alone had 13 such establishments. In 1887 a very fine monument was erected in the centre of the place. The ancient "Lion" house still remains, but several old houses have been removed to make room for the new Post Office and other buildings. The famous belfry is, of course, the great attraction of the square. How many times this has been photographed during the last few years, either from the square or the well-known spot, Quai de Rosaire, it would be rash to hazard a guess. The chimes are said to be the best in Belgium, and when in good order are certainly very fine. A few years ago they were in a terrible condition, and it was difficult to make out what the tunes were intended for. They reminded one of a transposing pianoforte gone wrong.

The cathedral is very fine internally, but the outside is dull and heavy, notwithstanding the addition of the spire in 1871. The Hôtel de Ville is a small but elegant Gothic building, and the two-storied Chapel St. Sang is very interesting. There is one thing, however, at Bruges which should on no account be missed, viz., Memling's paintings in the Hospital of St. John. They are wonderful; the groups on the medallions of the Shrine of St. Ursula are said to be his finest work, and these splendid examples of fifteenth century painting are certainly among the most interesting works of Flemish artists. The old hospital (which dates from the twelfth century), apart from itself, contains many noteworthy objects well worth the franc charged for admission.

#### A NEW COMBINED TONING AND FIXING BATH.

[Translated from the *Camera Obscura*.]

The combined bath used for toning and fixing collodio-chloride papers generally contains much less gold than that used for gelatino-chloride papers. The difference between the two baths is marked by the presence of alum in the latter under normal conditions, whilst it is absent from the former.

Having observed that a bath containing alum showed less activity in toning collodio-chloride paper than when this ingredient was absent, it occurred to me that the presence of alum in the bath used for gelatine papers might be connected with the difference between the two varieties of papers to which I have referred.

Why should alum be added to the bath? The emulsion is prepared with a considerable quantity of potash alum, much more being used than for dry plates. Nevertheless the latter, even in warm weather, do not suffer much from softening of the film. Moreover, it is unusual to add alum to the fixing bath when prints are toned with an alkaline gold bath.

The presence of a hardening agent seems to be rendered necessary principally through the preparation of the normal bath with sulphocyanide of ammonium, and the occasional addition of salts of lead. Both are solvents of gelatine, if the solutions are concentrated, and they soften the gelatine when used diluted. I tried a bath without either of these additions, and used only half the normal quantity of gold recommended for gelatino-chloride paper. It was composed as follows:—

Water .....	1 litre.
Hyposulphite of soda .....	150 grammes.
Chloride of gold .....	$\frac{1}{2}$ gramme.

The toning proceeded slowly, and only to a red-brown, without a bluish tinge. Notwithstanding the hot summer weather, there was no softening of the film.

The addition of sulphocyanide of ammonium was immediately followed by increased activity of the bath, and the tone was bluer. At the same time the film suffered.

I have recently found that thiosinamine is more favourable in its action upon the toning bath than sulphocyanide of ammonium, and, likewise, has less influence upon the gelatine. If 5 to 10 per cent. of a saturated aqueous solution of thiosinamine is added to the toning bath mentioned above, it will be found to work well. If the weather

is not too warm, it will be found unnecessary to add any alum, but in the height of summer it is desirable. The fact that the prints scarcely turn yellow, and begin to tone as soon as immersed in the bath, shows that it is much more energetic than the solution to which no thiosinamine has been added. For the same reason thiosinamine may be used instead of sulphocyanide of ammonium in the ordinary gold bath.

It is a matter of interest that a bath may be prepared with hyposulphite of soda and thiosinamine which will tone without any gold. It is only necessary to add a little alkali, as, for instance, carbonate of soda. Although I most emphatically condemn the use of such a bath, I will give a few particulars concerning it. (Notwithstanding all the warnings that are given, so many combined baths poor in gold, and perhaps even destitute of it, are used, that very little harm can be done by giving information concerning another.) It is well known that thiosinamine, in combination with salts of silver, forms soluble double salts. If these solutions are made alkaline, sulphide of silver is formed. The reaction between the silver nitrate of the image and the alkaline thiosinamine is retarded by addition of hyposulphite of soda. By due adjustment of the three components a bath that will act well may be made. Under such conditions the thiosinamine will, of course, be deprived of its natural function as a fixing agent. Compared with an acid hypo bath, such a solution has the advantage of not destroying the half-tones.

Other experiments, for the purpose of obviating the disadvantages of alum in toning, were unsuccessful. Sulphocyanide of aluminium and formaldehyde caused a heavy deposition of sulphur in the fixing bath through acid reaction, and were consequently no better. The addition of 10 grammes of tannin to the first-mentioned bath rendered the solution turbid (but without depositing sulphur). Upon warming the bath to study its action more closely, the film became rather puckered. The outer skin of the gelatine film, which is of a certain thickness, was already tanned, but the underlying portion of the film was still quite unaffected. What I had thought possible for various reasons had taken place. The tanning agent had diffused in the gelatine more slowly than water, or the solutions of those salts, which have a softening action, probably because the combination of tannin and gelatine had formed a membrane very impervious to the tannin.

I have frequently observed that a saturated aqueous solution of citrate of potash has a precipitating action upon a 10 per cent. solution of gelatine, but my anticipations were not realised that this salt might have similar properties to alum for hardening a gelatine film. On the other hand, like thiosinamine, its influence is favourable to toning. Whilst a print was still red after immersion for twenty minutes in a bath composed of

Water .....	1 litre,
Hypsulphite of soda .....	120 grammes,
Chloride of gold .....	$\frac{1}{2}$ gramme,

after ten minutes' immersion in a similar bath, to which 200 c. c. of a 50 per cent. solution of citrate of potash had been added, the tone had reached a deep black.

R. E. LIESEGANG.

### SOME THOUGHTS ON PHOTOGRAPHY.

[Abstract of paper read at the November Meeting of the Photographic Society of Philadelphia.]

PHOTOGRAPHY bears a resemblance to nature in this,—the enormous amount of material thrown broadcast on the world, very little of which is fit or expected to survive. An immense lot of energy and stuff are apparently wasted in order that there may be a very special choice as the evolution of the creature goes on. It has been very easy to make numberless photographs without thought, but what now is required is special skill, endless patience, and more knowledge and study than most of us have been able to obtain. Then, perhaps, a master would be able to make two or three pictures and several portraits in a year which would be worthy to live as works of art. I am speaking very seriously of great works. Sketches and studies are part of the daily exercise of picture-makers, and much material, interesting and profitable to look at, can be shown which need not be mistaken for masterpieces nor shown as such.

We are suffering just now—we always have been—from influences, and, though the influences are better than they used to be, the dis-

position to imitate proclaims that photography still is young. Perhaps in its youth it could not do better than to imitate good things, but I think it could. It could do better by studying them. The painters enjoy some of our "painty" effects, and misunderstand others. They recognise our imitations, but hurt us by identifying our small resemblances with schools of painting, ignoring our identity, calling a strongly-lighted subject a Rembrandt, a hand and glove means Titian, a long, sweeping line indicates Alexander. Prints are classified as Corots or Constables, Whistlers or Holbeins, and we've been feeling flattered—in one sense we should—but it is a false compliment. In spite of all this the individuality of the man is claiming recognition. This is acknowledged on every side. The personality of the photographer is felt in the trivial French character of Puyo's prints, in the strong awkward compositions of the Hoffmeisters, and, above all, the supreme evidence of personality is seen by reflection, for instance, Mr. White's influence so unmistakably stamped on the charming prints by Mr. Edmiston shown in this year's Salon. This personality is not to be worked for; it is the inevitable sign of life, the unconscious expression of the man in his work. We look at pictures on the exhibition wall, a Dyer, a Eugene, or a Steichens, and feel the personality of the man through his special feeling or the shape of his idea, and far from our thoughts is the question whether it is a Voigtlander lens, Seeds 27x plate, platinum, or gum-bichromate print.

Any means that is photographic should be used; the skill of the hand in manipulating plates and prints is not illegitimate. Foreign methods, such as working up in water colour, are destructive of the purity of the art, as the introduction of gems and tinsel into painting and sculpture, and foreign phrases into a piece of English literature, are acknowledgments of unskilfulness or the disinclination to work.

There is an idea about that we see as the lens does. It is a very great mistake; we do not, either mentally or physically. The eye cannot focus on more than one spot. The lens focuses on one entire plane, and with persuasion can be forced to give equal sharpness to everything within its range, from the distant horizon to the near foreground. The difficulty of avoiding this stupid and uninteresting aspect of things is probably the reason why there has been more successful indoor than outdoor work, although that is due partly to the fact that the light, at least, can be concentrated in an enclosure. A feeble admission of this difficulty in mechanical photographs is the usual habit of dragging a figure into a landscape which has no sympathy with it, with the firm conviction that it "introduces life," as they say, into something thus acknowledged to be dead. The only reason the figure introduced draws attention from the general monotony is that it is an intrusion, usually a self-conscious one.

I do not mean to say that the indoor work is better than the outdoor work, that is, pure landscape, but there is more good work in which figures are used. I am compelled to say that the worst things done in photography have been with figures, deliberately planned, posed, and exhibited as "artistic." The deadly self-consciousness of models, the unfitness of objects and clothes used, and the poverty of imagination on the part of the man behind the camera, gives one a sense that one sees a straight photograph of a tableau, a living-picture arrangement, or the misfits of the grand opera choruses with calcium lights. A painter said to his pupils: "Art is an animal not to be caught by detail." The idea is good enough to be remembered by photographic students. Perhaps the commonplaceness of many photographs is mainly due to the absence of any definite intention at the start. We soak our plates and our paper, but we do not soak ourselves enough in our subject. We should follow up a picture, visit it often in many lights and seasons, carrying it about in our memory to its final completion. We may over-expose our plates, but we cannot get too strong a mental impression. It is good practice to sketch with the camera, using no plates, but studying on the ground glass, becoming familiar with the disposition of our lens, so that it may not surprise us, finding out and avoiding what is impossible, while it is impossible, studying how to work the camera to get our point of view, as well as to adjust our eyes to the lens as to new spectacles.

A photographer needs a special training for quickness of perception. It is his advantage to be able to retain by instant exposure of a plate some things which could not or would not enter his mind to conceive, and to do this his judgment and keenness must be constantly under his control. We cannot afford to lose the suggestions of the happenings, which, like the conjunctions of some planets, a man may be able to see only once in his life, and in instances where it is some

line of beauty, or some expression or sentiment, or intense feeling, there is no way of repeating the effect. But the camera can catch it if the man recognises what he wants, and by his memory he can work the material into rare pictures. Such material is, like nuggets of gold, likely to contain much dross because stuff is there which also happens and is not by choice, and the royal right of elimination must be used to dispose of whatever detracts from the value of the thing. Good judgment and a sense of abstract beauty, the realisation of the embodiment of ideas in forms and lines, in light and sound, make that quality called "feeling," which is the personality, the "temperament" of an artist, a painter, photographer, writer, or musician.

EVA LAWRENCE WATSON.

### THE ORGANIZATION OF PHOTOGRAPHIC LABOUR.

AFTER the subdivision of labour\*, the most important consideration in the economy of production is the organization of the workers, the system upon which they are applied to their various duties, so that each member may fill the position in which his capacities find their fullest scope, and are made most productive. Necessarily this means that to a certain extent each worker becomes a unit, a detail, in a mechanism designed expressly to employ his productive powers to the best advantage, and with the minimum waste. The primary requisite in such a system is the concentration of the workers into as small a space as possible consistent with the demands of the particular activities about which they are occupied. Here we find the reason of the factory, the busy hive, where large numbers of workers are placed within a confined area.

In the early days this concentration was carried to such an extremity that the health of employees suffered through overcrowding, nor was it remedied until governmental action was taken, and various Acts of Parliament to regulate the management of factories were passed. The principle underlying this injurious action on the part of factory owners is right enough, provided due attention is given to the health of the workers. Taking this precaution, concentration can be enforced in all cases with every advantage in aiding successful production.

Examining photographic workshops in the light of this principle, it is found that the majority defy it in every particular. Thus we have operators at the top of a house, retouchers on the second floor, mounters and spotters on the ground floor, and printers in the next street, or several miles distant from the main establishment. Even in the single department of operating it is no unusual thing to find the studio on the housetop, and the dark room in the cellar; or again, the printing done at the end of a long garden, and the toning, mounting, and finishing in the front premises. When assistants are so distributed loss of time and waste of labour power in passing from one department to another must occur, besides delay in handing negatives from operator to retoucher and from retoucher to printer. When workrooms are separated the actual time occupied in going from one to the other may be small, but, even though small, it will amount to a check on the course of work. Practically it comes to paying operator, retoucher, or printer £2 or £3 per week for running up and down stairs and passages, which is too high a wage for labour that is not directly productive. Even supposing a messenger is employed for this service, it still remains unproductive labour, and therefore his wages represent a loss. These few instances may illustrate the importance of concentration of skilled labour as a factor in economic production.

Another advantage arising from the close union of assistants is that the charges upon management are thereby reduced. When various departments are scattered the supervision cannot be so close as when combined, and, especially in large factories, this becomes a matter which makes a difference in the cost of management. Even in a small photographic establishment the principal spends much time merely in making inquiries of, and giving orders to, his employees, and all time thus wasted means that his services are taken from productive to perform unproductive duties that yield no profit.

It follows from this that the arrangement of a photographic house of business is a question worthy of attention, since it may exercise a great influence in determining whether the balance at the year's end is on the right or the wrong side; at the least, it is economically unsound to carry on photographic production in premises where separation of the various branches is compulsory. The workers properly related, the next essential is to direct their energies in the most profitable channels, and to allow no deviation which would tend to disorganise or throw the whole machinery of production out of gear. The first point to insist upon is that the highly skilled and highly paid assistant should be put to labour requiring such skill, and that the less skilled and less paid be allotted and kept to functions in accord with their capacities and rate of pay. To occupy operators, retouchers, or printers, in performing inferior services that might be done by a lower type of mechanic, or by unskilled labour, cannot lead to an economy, but is rather inviting

a financial loss. On the other hand, it is also wasteful to reverse their positions, allowing printers to retouch, retouchers to act in the studio, and operators to exercise the privileges of management. These perversions are contrary to the orderly conduct of business; in the first case it implies a loss to the employer who cannot find sufficient work to fully occupy the time of an operator and retoucher in those duties for which they are trained and paid wages in accordance with the high skill demanded; in the second instance it is not economical to pay employees for services which are inefficient, since by doing so they are overpaid. The principle to bear in mind is that a worker should be allowed to do only that at which he is thoroughly competent, otherwise, whatever his salary, he is overpaid.

Next to knowing what a man can accomplish is the question of how much, that is, of gauging the amount of produce he can be expected to finish daily. Evidently, if a worker does less than his powers are capable of, he is employed at a loss, but it is not so obvious, though none the less true, that when his powers are over-strained he becomes unprofitable as a factor in economic production. It is a common fallacy with employers to believe that the working capacity of a man can be indefinitely increased either by persuasion or compulsion, and thus by bringing sufficient pressure to bear the output of one man can be made equivalent to that of two men. Man to man, perhaps, the working powers vary, though, taking men in the mass, the maximum that can be expected from them is a fairly constant quantity. To give an example: In a photographic printing establishment employing some 30 printers, working under the same conditions, it was found after repeated observation that their capabilities ranged as under:—One printer marked 500, two printers marked 400, 24 printers marked 300, three printers marked 200. From this it is seen that whilst the best printer could produce two-and-a-half times as much as the worst, the larger proportion, 24 out of 30, fell under the same head as regards their powers of production, indicating a limitation of capacity. They were, as a matter of fact, incapable of doing more. Supposing, however, compulsion were tried to compel them to reach the 500 limit, by lengthening hours or by closer supervision, little would result, for it has been proved in other industries that long hours do not mean an increased output. Extra supervision also fails, because, though the output may increase, the gain is outbalanced by the added expense of the overlookers. In the end it is better to recognise that the producing power of men in the main is a fixed quantity, and that it is essential in the economic organization of labour to estimate this average capacity, to apportion the work, paying wages in accordance.

Another requisite in the profitable employment of labour is a regular and systematic method of working; this demands stability of management, leading to steadiness of occupation, and uniformity of output. Instability of management reacts on the employee, weakens his power, and reduces his efficiency. Owing to the numerous processes now used in the photographic trade, a breaking of the continuity of production has become quite customary, an operator, for example, being changed almost hourly from enlarging to outdoor operating, then to studio work, and again to making gelatino-bromide prints. With such breaks as this implies the productiveness of a worker must be curtailed, and the value of his services much less than if the whole day were spent in pursuing a single object, the effect on a business being that wages are made a greater charge on cost of production, and, consequently, profits are lower.

Steadiness of purpose, though at variance with the notion of a servant, is a powerful aid towards the successful conduct of employees. It is a wrong policy to be continually altering the course of work, methods of manipulation, or rearranging meal times and hours of working. Many employers also contract the habit of taking a worker from an unfinished task to commence another, repeating this again and again until at the day's end nothing marketable has been produced. With a sound economy, continuous effort until a given task is completed should be the rule in place of the indecision and feebleness characteristic of the management of many photographic houses.

An action that destroys systematic procedure is frequent experimenting with the numerous plates, papers, &c., now manufactured. Photographic labour is an expensive commodity, and when added we have the cost of plates, &c., used in the experiments, it is evident that some solid advantage should be in view, or otherwise a serious loss in wages and material must be met. In all cases the photographer needs to distinguish between what is experimental and what is productive work. To facilitate the organization of assistants the employer should have every confidence in them, that is to say, their work allotted to them they should be left to execute it: if workmen cannot be so left, then production will never be profitable, because the cost of excessive supervision, as with slave labour, outbalances what profit is made on their labour.

At the present time the employer undertakes the sole responsibility of the organization of labour: as manufacture increases in complexity it will be thrown largely on the workmen themselves. In a trade union this is admitted, and one of its duties is to classify and fix the capacity and functions of its members. Assuming that trade unionism became general, the productive power of the nation would increase, since the employer must find it more economical to deal with employees already organized than to perform the task himself.

JOHN A. RALDALL

\* See THE BRITISH JOURNAL OF PHOTOGRAPHY, Sept. 28, 1900, p. 168.

## THE "POLYSCOPE."

THE polyscope is the invention just patented of Mr. Baskett, one of the members of the West Surrey Photographic Society, and shown by him in the last demonstration at the Society's rooms, Railway Hotel, Battersea Rise. It is a much-improved and developed kaleidoscope, dear to our childhood, but now capable more than ever of rendering symmetrical designs from all kinds of irregular foundations, with the addition that, by raising the mirrors parallel, continuous repeats of any original pattern are obtained. As in the kaleidoscope, the changes seem endless, with the great difference that once the pattern is determined it can be photographed from the viewing end of the apparatus, and a permanent record secured—which, if desired, may be made the start of a fresh series of patterns. Mr. Baskett showed, by means of a few sprigs of ragwort, a bootlace, random scribbling, a bent wire, a piece of printed pattern, &c., the wonderful variety of effects obtainable—squares, octagons, polygons, fan shapes, cylinders, friezes, belts—all being given by the polyscope in rapid succession, altered by every change in the object used, or of its position or change in the angles of the mirror. Simple lines entangled were followed by combinations of bewildering mixture, beautiful, fantastic, and as fascinating to watch as a conjuring trick. Even humour had a place, for by means of some Dutch faces in the library copy of the "Studio" Mr. Baskett produced a series of grotesques—two faces that quietly merged in one, with separate eyes, but a common nose—or, rather an uncommon one—for roars of laughter greeted its appearance, or, again, the faces combined, and created a new face altogether, and then dwindled away to wooden-looking knobs much like the pawns of chess. The mode of photographing having been shown, and an exposure made, Mr. Wilshire, the Hon. Secretary, next passed through the lantern a series of slides prepared from polyscope photographs—mostly lovely lace patterns—derived from an original piece about an inch square. Beautiful lamp-shade designs from parts of an ornamental letter in a book were succeeded in intricate devices from a photograph on which a fly had accidentally settled in the polyscope. The evening ended with two votes of thanks to Mr. Baskett, one for the demonstration, and a second one for the gift to the Society, which the Secretary announced, of the polyscope used that evening.

## PERMANGANATE OF POTASH AS A REDUCER.

[Received too late for the ALMANAC.]

I HAVE found permanganate of potash a first-class reducer for negatives that (1) require general reduction, and (2) those in which the contrasts are too harsh. In fact, with the exception of the case of veiled shadows in which ferriocyanide of potash is to be preferred, I consider the permanganate is the best reducer available. I find in practice that its action varies according to degree of dilution, and, secondly, according as the negative be wet or dry on applying the reducer. A wet negative to which a dilute solution is applied is evenly reduced all over; the same solution applied to a dry negative gives a slight excess of action on the denser deposits. By rapidly immersing and removing a dry negative, with instant washing, the action is confined absolutely to the high lights, and this action is proportionate, within limits, to the strength of the reducing solution. To treat a negative that is very much too harsh, it is better to use a solution of medium strength, and to do the needful in stages, i.e., washing and drying the negative after one flowing, and then treating the dry negative again till sufficiently reduced. If a negative is treated a second time with the permanganate before drying, the action will not be confined to the high lights, but be more general. H. HANDS.

## LUMIERE'S CERIUM REDUCER.

[Patent No. 470 of 1900.]

MESSRS. Lumière remark that the reducing agents of photographic images obtained by silver salts hitherto employed to reduce over-exposed and over-developed negatives were primarily formed of two solutions, such as the perchloride of iron and the hyposulphite of soda, into which the image to be reduced was immersed successively, after preliminary washing, to obviate the formation of a precipitate.

The inconvenience resulting from the necessity of immersing the image successively in two baths has brought about the employment of substances, such as the ferrocyanide of potassium and the hyposulphite of soda, acting in a manner analogous to the perchloride of iron and the hyposulphite of soda, but capable of being mixed without producing a precipitate.

The reducing agents, formed of a mixture of peroxygenised salt and hyposulphite of soda, could not be preserved in aqueous solution with-

out the two salts reacting somewhat rapidly on each other, and at the end of a short time the reducing agent was not usable.

Further, the mixture of ferrocyanide and hyposulphite of soda, which is the reducing agent ordinarily employed, frequently acts in an irregular manner if the precaution is not taken of eliminating the excess of reactive by immersing the image in water before examining it by transparency to ascertain the progress of the operation.

The patentees have observed that certain peroxygenised salts alone, without the addition of hyposulphite of soda, can be utilised as reducers, provided the acids of these salts give a silver salt sufficiently soluble in water.

With the ferric salts, this property, although fulfilled by the sulphate, the nitrate, the lactate, &c., is not practically utilisable, as the washing in water colours the film yellow, probably because of the formation of a basic salt. The communicators have well succeeded in avoiding this inconvenience in a manner practically complete by the addition to the ferric salt of a considerable quantity of an organic acid, or even of an alkaline salt obtained by an organic acid, but another inconvenience which the employment of ferric salts presents is that, whilst reducing the image, it modifies its colour, which becomes more yellow.

Messrs. Lumière have found that the aqueous solutions of salts of peroxide of cerium, and more particularly the sulphate of cerium, have the property of very regularly reducing images produced with silver salts, either on glass or on paper, without producing any of the inconveniences of the ferric salts.

Their great solubility enables concentrated solutions of them to be made which do not affect the gelatine at all, and they are diluted with water as necessary at the moment when they are required.

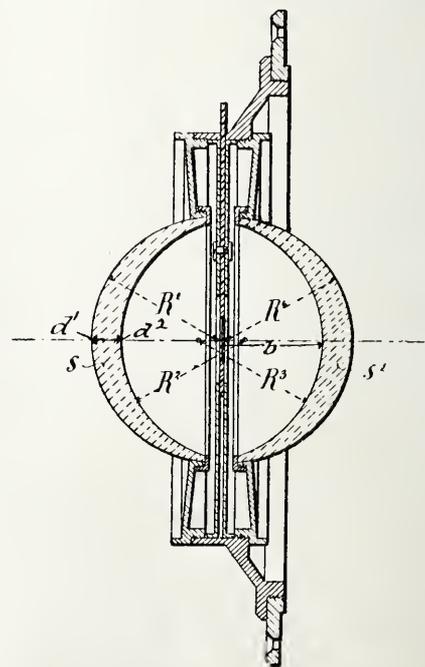

In order to prevent these solutions being separated by a large excess of water, there is added to a 10 per cent. solution, for example, which may be considered as the normal concentrated solution, a few cubic centimetres of concentrated sulphuric acid.

The solutions thus prepared are very stable, do not affect the gelatine, and remain in solution even in the light. To reduce negatives the 10 per cent. solution is diluted as required. For paper a much more diluted solution is employed, for example, a 1 per cent. solution. The communicators have discovered that other peroxide salts, such as those of titanium, have analogous properties, but less useful than those of cerium.

## GOERZ'S IMPROVEMENTS IN ASTIGMATICALLY CORRECTED LENSES FOR PHOTOGRAPHY.

[Patent No. 14,487 of 1900.]

THE object of the present invention is a photographic lens astigmatically corrected for taking photographs under as wide a picture-angle as possible. The correction of spherical and chromatic aberration

being neglected, it is possible to produce an even picture of almost unlimited dimensions free from stigmatism of the oblique pencils.

The new lens belongs to the class of spherical lenses. All the constructions of these lenses hitherto known show great deviations from an astigmatic correctness and are only useful for picture-angles of at most 90°. Even if the lens frames or openings of the object-

glasses were to allow of rays passing under an inclination angle greater than  $45^\circ$  to the optical axis, astigmatic curves will show that a sharp image cannot be the result owing to the rapid increase of astigmatic aberration.

Through investigations given in the treatise by E. v. Hoegh in *Archiv für Wissenschaftliche Photographie* (Archive of Scientific Photography), vol. ii., part 4, Halle a.d.S. 1900, p. 86, it has been proved that astigmatic correction of the picture field or narrow pencils for any given direction of the rays can be produced in the simple meniscus. In a lens of 6.09 mm. thickness it was, for instance, found that at an inclination of the pencil to the optical axis of about  $30^\circ$  a strictly anastigmatic correction was produced, but that for all other rays (except those at an angle of  $0^\circ$  to the axis) astigmatism remained, which attains a certain allowable maximum between the axis and corrected rays, but continually increases beyond the latter.

Thus with a view angle of  $60^\circ$  astigmatic errors will occur which are so large that the sharpness of the picture will be insufficient.

If, however, astigmatic correction has to be done for a larger view angle, such as  $90^\circ$ , the maximum of astigmatic difference between the optical axis and the corrected principal rays will surpass the measure allowed for the non-sharpness and produce a useless picture. These so-called intermediate errors form consequently determinate limits to the extension of the useful picture-field.

By means of calculation the applicant has found that the intermediate errors have a certain connection with the thickness of the glass meniscus employed, and that they become less in proportion to the diminished thickness of the glass. The result of this observation is the present improved construction of lens.

The annexed drawing represents a form of construction of the improved lens in section through the axis.

The lens is composed of two cup-shaped meniscuses  $s$  and  $s^1$  arranged symmetrically having their concave sides towards each other. The convex and concave surfaces of the meniscuses have approximately the same radius of curvature and the thicknesses of the glass are very trifling.

For instance, for a lens with a focal distance of 100 mm. the following constants may be employed:

Radius of curvature of the convex surfaces: =  
 $R^1 = R^4 = 8.47132$  mm.

Radius of curvature of the concave surfaces =  
 $R^2 = R^3 = 8.51034$  mm.

Greatest thickness of the glass of the lenses =  
 $d^1 d^2 = 2.206$  mm.

Half distance between the concave lens surfaces =  
 $b^1 = 6.7961$ .

Index of diffraction of the glass used for the lens in relation to the line  $G^1$  of the spectrum =  
 $n G^1 = 1.52053$ .

Calculation shows such small results for the intermediate errors owing to the trifling thickness of the glass that a decrease of sharpness is unnoticeable with a view angle of  $135^\circ$ . The principal rays leaving under an inclination to the axis of  $53^\circ$  will show astigmatic corrections, whilst the astigmatic error at the place of its maximum between the centre and the edge amounts only to 0.133 mm. and consequently can be quite neglected. The astigmatic difference of the rays leaving under an inclination angle to the axis of  $72^\circ$  which angle is now practically useless will likewise only amount to 0.641 mm.

Further, it results from calculation that the amount of the index from diffraction of the glass material used for the meniscuses has no great effect on the nature of the picture, in consequence of which glass as pure as possible and of as small a colour-destroying capacity as possible should be chosen, since with the trifling thickness of the glass achromatising is not feasible.

## Studio Gossip.

At the Royal Aquarium, Westminster, the second Gas and Allied Trades and International Acetylene Exhibition will be held from Friday, December 21, 1900, till Tuesday, January 22, 1901. A great feature will be the acetylene section, where it is proposed to demonstrate the strides this new illuminant has made during the past twelve months. Gold, silver, and bronze medals, and diplomas will be given for the most efficient apparatus for the manufacture and distribution of acetylene gas. The Exhibition will be principally devoted to the showing of all kinds of apparatus for the generation, storage, purifying, measuring, and distribution of gas; all kinds of apparatus used in cookery and heating by gas; gas traction and power, including the latest types of of gas engines; apparatus for showing the different systems of gas lighting, including compressors, mantles, burners, and art metal fittings; apparatus for showing the adaptability of acetylene for railway lighting, burners, fittings, &c. In the acetylene section it is proposed that a committee shall test the working of the various apparatus during the Exhibition, and award gold, silver, and bronze medals for the most efficient apparatus.

WINTER Precautions.—We are now within a few days of Christmas, but, up to the present, we have had, with one slight exception, no indication of winter—the weather has been quite springlike. In this fickle climate of ours there is no telling when winter—and a good, old-fashioned one, too—may be upon us. Are we all prepared for one if it does come? Is our water supply, for example, securely protected against frost? Few of us but know the inconveniences we suffered a few years ago during weeks through our water supply being frozen and photographic printing being practically stopped for want of water for washing the pictures, burst pipes, &c. Most, when the pipes were frozen, realised how easily the trouble in most instances might have been avoided had a few timely precautions in securing the pipes both within and without the house been taken against frost reaching them. The trouble involved in protecting the pipes is but slight, even if events should prove that it was unnecessary. When once the pipes get frozen there is very little prospect of them getting thawed again till the weather changes, and that may not be for weeks, as was the case in the year to which we have just referred. An old proverb says, "A stitch in time," &c., and this may well be borne in mind by photographers at this season with regard to their water supply.

PORTRAITS with Winter Surroundings.—It may seem a little anomalous to direct attention to the subject of portraits taken under wintry aspects when there is no immediate prospect of our having any actual winter. In some countries where the winter is severe and lasts long, as in America, Canada, Russia, and elsewhere, a special feature is made by professional photographers of portraits taken with winter surroundings, and a considerable business is done in them. Why should this not be done here if we have a long spell of cold weather and some snow? At present, while the weather is so mild, it is true, there would not be a demand for them, but the case would be different if we happen to get some "real" winter later on, and portraitists were ready with specimens to show at once; but they should be taken beforehand, and so as to be ready to exhibit. Furs and winter clothing generally are very effective in portraits, but they are still more so when the surroundings are in unison with them, such as snow-clad accessories and backgrounds. We have on more than one occasion in back volumes indicated how they can easily be extemporised without delay, except for a little trouble with what is to be found in almost every studio. Why we call attention to the subject here is to remind our friends that there is a possible way of bringing some little extra "grist to the mill" during the dull winter months, which many quite overlook in this country.

THERE exists a microbe which, when properly fed, will grow and multiply enormously, emitting during its development a strange phosphorescent light. In the past we have been wont to look upon phosphorescence as a phenomenon due essentially to the presence of phosphorus somewhere. We now know that this is a mistake, says "The Lancet," for phosphorescence occurs in a very great number of instances in the entire absence of phosphorus. Phosphorescence is undoubtedly a manifestation of chemical or physical change, but the change, of course, may not always be due to the working of countless microscopic organisms. It certainly is in the case of the phosphorescence of the sea. In this case the phosphorescence is best when the sea is disturbed, and the maximum of light is emitted from the crest of a short, rapid wave or in the foam produced by some disturbance. This is due to the fact that the phosphorescent bacteria or photo-bacteria are much more active in the presence of an excess of oxygen. Indeed, the respiratory exchange or oxidation of the bacteria is the cause of sea phosphorescence, since if the micro-organisms be killed or oxygen be excluded the light is quenched at once, while on adding an abundant supply of combustible food-stuff, such as sugar, the light is intensified. The glow of ordinary yellow phosphorus is, of course, due to direct oxidation without the agency of micro-organisms. The peculiar greenish glow seen upon stale haddocks and other sea fishes is produced by this remarkable photo-bacterium, and is in no way connected with the presence of phosphorus. It is possible to cultivate the phosphorescent bacteria so as to obtain a fluid which is very strongly phosphorescent. Thus by placing the flesh of fresh haddocks or herrings in a two to three per cent. solution of common salt and keeping at a low temperature—about seven degrees above freezing—it will be found that after a few days not merely the fishes, but also the whole of the liquid in which they are immersed, give off a pale greenish light which becomes much more brilliant if a little sugar be added. Pure cultures may thus be obtained exhibiting such a strongly phosphorescent light that by protracted exposure they may be photographed by their own light.

## News and Notes.

THE Madras Amateur Photographic Society ceases to exist on December 31.

WE are sorry to have to announce the death of Mr. G. Higginson, photographer, Bowdon, Cheshire, which took place on Sunday, December 16. He was much respected in the photographic profession.

THE Borough Polytechnic Photographic Society's Sixth Annual Exhibition of Photographs and Lantern Slides will be held at the Borough Polytechnic Institute, 103, Borough-road, S.E., on Thursday, Friday, and Saturday, December 27, 28, and 29, 1900, from seven to 10.30 p.m. on Thursday, and six to 10.30 p.m. on Friday and Saturday. There will also be large displays of photographic apparatus accessories by the trade, popular lantern entertainments, war pictures by the animatograph, special

exhibit of natural colour photographs, X rays, chromoscopes, wireless telegraphy, photography popularised by short practical demonstrations. Admission will be free.

**The Exhibition of Modern Illustration.**—The Board of Education has decided to open this Exhibition on Monday, January 7 next, in the galleries of the Indian Section of the Victoria and Albert Museum, South Kensington. A private view will be held on Saturday, January 5.

**The New Physical Laboratory.**—It is now notified that the Queen has granted to the Royal Society Bushey House, Bushey Park, which was formerly occupied by the Duc de Nemours, for the purposes of a National Physical Laboratory. It will be remembered that some months ago the good people of Richmond, or a certain section of them, were up in arms when it was proposed to have the National Physical Laboratory in the old Deer Park, while others were much in favour of that location. We had some comments on the affair at the time. We wonder if the inhabitants of Twickenham and Hampton will raise a similar objection to the presence of the Laboratory in their district that the Richmond people did? We should imagine not, but that they would be only too pleased to welcome its presence.

**The Thornton Heath Polytechnic Photographic Society** announces a Photographic Competition, open to members only, in which two silver and four bronze medals are offered for competition. The following are the classes:—Hand-camera work (direct prints only, from negatives taken with the camera in the hand): One silver medal, presented by Mr. F. O. Bynoe, Vice-President, and one bronze medal, presented by the Society. Landscape, seascape, and river scenery: One bronze medal. Any other subject: One bronze medal. Lantern slides (sets of four): One bronze medal. The award will be made to the best individual slide. A silver medal, presented by the President, will be awarded to the best picture entered for competition. The pictures in the competition will be exhibited at a conversazione, to be held at the Public Hall, Thornton Heath, on Saturday, February 9, 1901. Mr. R. Child Bayley, F.R.P.S., will act as judge.

**EXHIBITION of Kodak Pictures of the Transvaal War.**—At the new branch premises of Kodak, Ltd., at 59, Brompton-road, London, S.W., Knightsbridge, near top of Sloane-street), a collection of 180 enlargements of Kodak records of the South African war is now on view. The pictures have been taken by Mr. H. C. Shelley (War Correspondent of "The King" and "The Westminster Gazette"), Captain Archibald, U.S.A., Major F. A. B. Daly, R.A.M.C., Lieutenant and Adjutant T. Matheson (1st Battalion Coldstream Guards), Lady Sarah Wilson, Mr. Dan Albone, Captain F. J. Bowker (2nd Battalion Hampshire Regiment), Lieutenant J. C. Halahan (1st Battalion Royal Dublin Fusiliers), Major Hill (2nd Battalion Royal Irish Fusiliers), Mr. W. D. M. Cotts, Mr. R. Dunsmore, Captain E. Radcliffe (2nd Battalion Devon Regiment), Mr. W. Pott, Lieutenant Claude A. Lafone (2nd Battalion Devon Regiment), Sapper H. Stormer, T.D., R.E., Miss M. C. Fair, Mr. H. C. Causton.

**MARKS on Porcelain and Pottery.**—At a meeting of the Auctioneers' Institute of the United Kingdom, held last week, a paper was read on "Marks on Pottery and Porcelain." It is, we believe, a recognised fact that auctioneers, dealers, and connoisseurs are frequently deceived by fraudulent marks on both pottery and porcelain. The lecture, we read, was illustrated by drawings of the chief marks known. It occurs to us that the illustrations would have been still more satisfactory and reliable had they been photographs instead of hand drawings, and possibly the better recognised by connoisseurs. Marks on porcelain, like the labels on violins, are frequently imitated with fraudulent intent, and purchasers are often deceived, and so sometimes are honest dealers. But if there were a complete collection of photographs of the genuine old makes available it would alike be some protection to dealers and to the public generally, much more than would be one of hand drawings. Some such protection is desirable when the prices that old porcelain realise are considered. For example, during the lecture it was mentioned that there was a dessert service of old Sèvres at Windsor Castle that was valued at £100,000.

At the last meeting of the Roentgen Society, Dr. Mackenzie Davidson gave some demonstrations with his stereoscopic fluoroscope, on which shadows cast by the Roentgen rays are shown upon the fluorescent screen in three dimensions, instead of, as is usually the case, in only two. Since this fluoroscope was exhibited at the Royal Society's soirée in June last improvements have been introduced into the motor mercury break (which can be used with any coil), and also in the eyepiece through which the operator looks at the shadows on the screen. This break is arranged to work any current from 12 up to 100 volts, and by its use the brilliancy of the image on the screen is greatly increased, and the flickering is done away with. As is well known, two tubes are sparking alternately, and the automatic eyepiece, which consists of a shutter moving backwards and forwards over an opening, allows the image from the first tube to be seen by one eye, and immediately after the image from the second tube is presented to the other eye. The movement of the shutter synchronises with the sparking, and is sufficiently rapid to make the image stereoscopic, with the result that the location of a foreign body, or the diagnosis of injury or disease, is immensely simplified. By the use of the Mackenzie Davidson break the time of exposure is also greatly lessened if high voltages are used.

**STOLEN Relics.**—The theft of the Nelson relics from the Painted Hall, Greenwich, is now exciting great surprise, not to say indignation. This is not the only theft there has been from museums of late, for it now comes out that some objects which were lent by the Science and Art Department to the borough of West Ham were missed more than a month ago. Some months back several valuable articles were stolen from the Victoria and Albert Museum, South Kensington, and we now

learn, by a Reuter's telegram, that a similar robbery to that from Greenwich has been effected from Toulon Museum, when some historically interesting relics of the late Admiral Baudin were stolen. It is difficult to imagine where thieves can dispose of these relics. One would think they would be white elephants on the hands of the thieves, for they could not be offered for sale, as, being what they are, they can only be marketable for the precious metal they contain. One would surmise, however, if all the relics and other articles of interest in our National museums were photographed, and a photographic record of them kept, it might at times lead to the detection of the culprits if they offered them for sale. At Windsor Castle, for example, all the pictures have been photographed and the negatives kept systematically, also any new ones acquired are immediately photographed and added to the other copies. By this arrangement, in the case of theft, copies could at once be circulated with every prospect that the thief would soon be found out. Why should not a similar practice be followed with the priceless objects in our museums?

## Commercial & Legal Intelligence

The Directors of Kodak, Ltd., have declared a dividend of 1½ per cent. on the Preference issue, making 6 per cent. for the year ending December 31, 1900, and an interim dividend of 2½ per cent. on the Ordinary shares, which dividends will be payable on or after the 31st inst. They have further resolved that the transfer books be closed till the 31st inst.

Messrs. Thom and Wiggins, of 15 and 16, Giltspur-street, London, E.C., write: "We have been appointed the sole representatives of Messrs. Trapp and Münch, Berlin, the well-known manufacturers of pure photographic mounts, &c., and have established ourselves at the above address under the style of Thom and Wiggins. We shall also supply all articles appertaining to the photographic trade, viz.: Cameras, lenses, shutters, plates, papers, blottings, backgrounds," &c.

RE Edgar Albert Willis, of 20, St. John's-road, Scarborough, and Alfred Alexander Willis, of 1, Stepney-avenue, Scarborough, carrying on business as E. A. and A. A. Willis, landscape photographers, at 31, Londesborough-road, Scarborough.—The first meeting of the creditors interested under this failure took place at the offices of the Official Receiver, Scarborough, on Friday last. The statement of affairs filed by the debtors disclosed gross liabilities amounting to £320 16s. 11d., of which £308 6s. 1d. was expected to rank against the estate for dividend. The deficiency, after allowing for the claims of preferential creditors payable in full, was returned at £126 12s. 5d.

**THE Austin-Edwards Monthly Competitions.**—The following is the list of awards in the Lantern-slide and Film-negative Competitions for the current month: Lantern-slide Competition: £3 cash prize, F. W. Gregg, Brixton, S. W., "Norman Arches, Peterborough;" £2 cash prize, F. J. Mortimer, Portsea, "Watching the tide rise;" £1 cash prize, H. Holt, West Kirby, "Bishop Reginald's Gateway, Evesham;" £1 cash prize, Miss G. F. M. Hopkins, Oxford, "A Greengrocer's Shop, Laignueglia;" £1 cash prize, W. Riley, Coventry, "Treking Home;" £1 cash prize, R. R. Rawkins, Canonbury, N., "A Canal Lock;" £1 cash prize, H. G. Brierley, Huddersfield, "In the Kasbab, Tangier." Film Negative Competition: The Frena Camera given each month for the best negative on an Austin-Edwards Film has been secured by J. H. Williams, Worcester, for his negative, "Interior of a Conservatory."

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

December.	Name of Society.	Subject.
27-29 .....	Borough Polytechnic .....	Sixth Annual Exhibition.
27 .....	Oldham .....	{ Demonstration: <i>Thornton Films</i> . Walter D. Welford.
28 .....	Croydon Microscopical .....	Conversational Meeting.

### ROYAL PHOTOGRAPHIC SOCIETY.

DECEMBER 18,—Technical Meeting,—Mr. Thomas Bedding, F.R.P.S., in the chair.

### PHOTOGRAPHY IN WARFARE.

Mr. H. C. Shelley, who had been announced to read a paper on the subject, "Photography in Warfare," explained that he had had no time to prepare a special paper, but was delighted to have the opportunity of delivering before the Society the lecture which he was now giving throughout the country on the war in South Africa, and illustrating it with slides from some of the photographs taken by himself in the course of the campaign as War Artist of "The King." He proposed to tell the story of his personal experiences, and the pictures, whatever their merits or demerits as photographs, were, at any rate, truthful representations of the scenes and incidents which they purported to depict, and not sketches made in a comfortable studio in St. John's Wood under the

inspiration of liquid and nicotian refreshment. At noon, on October 12 last year, Mr. Shelley received instructions to start for Cape Town, and, as he had to leave England two days later, he had very little time in which to get together any special photographic outfit. No particulars were given as to the apparatus which he took with him, but we are able to state that it included a half-plate stand camera with tele-photo, R.R. and W.A. lenses, and a Thornton-Pickard shutter, quarter-plate and half-plate Shew Cameras, two Kodaks with rolled films, and a 5 x 4 cartridge Kodak, which he bought at Cape Town. We believe that most of the slides exhibited were from negatives taken with the last-mentioned instrument, it having been found impossible to carry a glass-plate camera about a battlefield. He, however, took a supply of plates from England, and used a large number of them on suitable occasions. Many negatives were developed during a halt of two months at the Modder River. "Modder" means "mud," of which Modder River water chiefly consists, and it is surprising that such excellent results could have been obtained with a developer of which this commodity formed a considerable proportion. The tele-photo lens could not be employed at a greater distance than about half a mile, as the heat haze was so intense as to hopelessly blur the picture. Leaving Southampton by the "Dunottar Castle," Mr. Shelley had as a fellow-passenger Sir Redvers Buller, and succeeded in getting a very good snapshot of him, in spite of his strong antipathy to the camera. After staying at Natal for a fortnight, the lecturer decided to follow the fortunes of the force which had started for the relief of Kimberley, and travelled by rail to De Aar. The railway journey was illustrated by some views of the dimly monotonous veldt, and reference was made to the very large number of men who were required for the purpose of guarding the lines of communication, which extended over about a thousand miles. So many had to be allocated to this essential duty that, out of the 200,000 men who were sent out, probably not more than 70,000 were available for active service in the field. On reaching Lord Methuen's base at Orange River, Mr. Shelley and other correspondents were told they could not be allowed to go further. The relief force had started for Kimberley with a certain number of press-men, and they must not even go beyond the bounds of camp without permission. After some days the lecturer got out of this difficulty by securing a pass to Hoptown "and back," but the return halves of that pass are still in his possession, for from Hoptown he started off across the veldt to try to overtake Lord Methuen. The battle of Belmont took place at this time, and some pictures of the hospital trains arriving with parties of wounded gave Mr. Shelley an opportunity of stating his experiences of the work of the ambulance department. He was on several battlefields with the Royal Army Medical Corps, and he expressed the emphatic opinion that, considering the facts that the operations were conducted at a distance of a thousand miles from the base and in the heart of the enemy's country, and that the army had gone to South Africa, not for a picnic, but for war, the hospital arrangements and the service of the R.A.M.C. were magnificent. No other word would adequately describe them. Having overtaken Lord Methuen's force, the lecturer accompanied it to Kimberley, and afterwards proceeded to Bloemfontein. The photographs exhibited were throughout excellent, technically and pictorially, and showed no evidences of the very difficult and dangerous circumstances under which most of them were taken. They included many views of camp life and typical bits of scenery, pictures of the Boer trenches, groups of prisoners, incidents of the battles of Magersfontein and Modder River, and, in fact, everything that was necessary to bring before the audience in a most striking and vivid manner the realities of the campaign. Photographically, one of the most interesting slides represented a banquet given at Bloemfontein by Lord Roberts to the foreign attachés who accompanied him: it was from a negative taken by the aid of a flashlight apparatus extemporised by the lecturer, who ransacked the town in order to obtain the necessary materials. Mr. Shelley is a capital lecturer, and told some good stories, sometimes with a touch of dry humour which was much enjoyed by his audience, and with simple and eloquent pathos when relating some of the tragic incidents which are inseparable from such a subject. The applause with which he was frequently rewarded reached its climax when a most cordial vote of thanks was tendered to him.

COMING EVENTS.

On January 2 Mr. Frank Sutcliffe will open an exhibition of his photographs and will give an address. At the Ordinary Meeting on January 8 Mr. C. H. Bothamley, F.I.C., F.C.S., will read a paper on "Some New Methods of Intensification and Reduction."

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 13.—Mr. T. K. Grant in the chair.

Mr. J. E. Hodd gave a demonstration of the "Development of Printing-out Paper." This process, he said, was looked upon and taken up by the average amateur photographer with a great deal more trepidation and fear than the real difficulties warranted. Wilson's process he had worked very successfully, but the process he now used presented no difficulties whatever. The formula used was that adopted by the Kodak Company for solio paper, but modifications could be easily contrived. At this stage a series of prints produced from partially-printed impressions and finished by development was passed round. Different makes of paper had been employed so as to make it clear that it was not difficult to successfully deal with several of the papers on the market. It was mentioned that most of the matt prints were on the new Carbona paper, a paper that developed very well. Mr. Hodd wished to impress upon

the meeting that with any given negative the prints resulting by development were, as a rule, far better than those produced completely by printing out. Prints were passed round showing the tone of the paper given by development; they were neither toned nor fixed. The negatives in many cases accompanied the prints. It was advisable to carry the initial printing out to the stage when all detail was well out, but to nothing like the stage required for toning and fixing in the usual way. The printing should be followed as soon as practicable by the development, long delay not being conducive to excellence of result. As giving an idea of the depth of printing required, he passed round a couple of prints, both of which had been printed that morning in twenty minutes, before 8.30 o'clock, when the light was certainly not powerful. The developer used was composed of

Quinol .....	12 grains.
Citric acid .....	30 grains.
Sodium acetate .....	6 drachms.
Water .....	15 ounces.

Air bells must be carefully avoided in flooding the paper with the developer. Development should be followed by ten minutes' thorough washing, and then toning can be effected. Mr. Hodd used a bicarbonate bath. The whole of the operations were clearly described and shown, and the prints made during the evening were passed round. Mr. Hodd said that fresh paper should be always used. If printing were carried to a stage short of that prescribed, the result would tend to hardness but if well printed a nice, pleasing softness is obtained.

PHOTOGRAPHIC CLUB.

DECEMBER 12.—Mr. F. A. Bridge in the chair.

Mr. H. Snowden Ward passed round some selected examples of recent additions to the collection in the hands of the National Photographic Survey. The work by Mr. A. R. Hogg, depicting the inside and outside of Dowth Mound, in Ireland, was excellent; and Mr. R. W. Dugdale's contributions were likewise of a meritorious and valuable character. Amongst the batch of prints about to be deposited at the British Museum was a series of prints from an old collection of negatives taken in Highgate. Many of the subjects have vanished or changed, so that this find is an interesting one. There are now in the British Museum 1550 subjects, and they may be seen in the Print Room, where they are stored in the order of counties.

Sir J. Benjamin Stone, M.P., who was present, spoke of the great progress being made by the Survey, the interest in it being distributed throughout the whole of this country and Scotland and Ireland. He believed that the many references to its work by public men, who he was pleased to see had grasped the importance of the movement, was something to be proud of. The Association was firmly established, and its influence was spreading. He considered that many of the photographic societies in small provincial districts could add interest to their work and strength to their position if they took up the Survey scheme. As a stimulant to activity he could safely recommend this course.

Mr. F. H. Evans, whose reputation and skill as a photographer, specially of cathedrals and churches, is well known, gave a pleasing chat and exhibition of pictures taken at Ely, Wells, and some of the French cathedrals. One of the earliest pictures was a unique view of the Octagon at Ely, the whole of which had been cleared of its benches specially at his desire. Mr. Evans had with him several views of this portion of the edifice, giving glimpses between pillars and through arches, all of which were much admired. There were several pictures taken at Middleburg, in Holland, recommended by Mr. Evans as a delightful spot for a week-end holiday, amongst them two of the Rathaus. The French cathedrals represented were those of Amiens, Chartres, and Bourges, the last of which afforded Mr. Evans particular enjoyment. Altogether, the slides proved a source of much pleasure to the meeting, and as creditable to Mr. Evans as his former work.

Mr. Harold Baker confessed a preference for the simplicity, dignity, and strength of the English cathedral structures to the more florid and gorgeous, though beautiful, French buildings.

Sir Benjamin Stone remarked that the impressions that these pictures created in his mind were, to his thinking, more important than the actual pictures. The photographs wanted life—they wanted the story of the creation of the great buildings which represented the religious fervour that animated the country in days past. He thought that a knowledge of these things added so much to the value of pictures such as these, and commended to the Club the suggestion that the "story" told by a picture should not be dominated by the purely spectacular merit of the view.

North Middlesex Photographic Society.—December 10, Mr. E. R. Mattocks in the chair.—Mr. F. W. Cox gave a lecture on "The Life of Constable." The work of John Constable, R.A., was the first definite departure in English landscape painting from the conventional treatment of earlier painters, and was the result of direct and personal impressions of nature. The exhibition in France of his "Hay Wain" and "White Horse" exercised a powerful influence upon the art of landscape painting in that country. His work was not appreciated save by a few until late in life, and he supported himself by painting portraits. On the death of his father-in-law he came into a fortune of £20,000, which enabled him to devote himself entirely to his beloved landscapes. He was born at East Bergholt, Suffolk, and most of his well-known paintings were

done in the neighbourhood. Three of his most important pictures, "The Valley Farm," "The Cornfield," and the "Hay Wain," are in the National Gallery, and his "Salisbury Cathedral" is at South Kensington.

**Croydon Camera Club.**—The fifty-second Lantern Show of the Croydon Camera Club was held at the Public Hall, George-street, on Wednesday, December 12, with the usual indications of success. The first part was devoted to a visit, made by members of the Club to the Paris Exhibition, the pictures being by Messrs. S. Carley, Stokes, and Beck. These proved to be an unusually even set, notable for good gradation, sharpness, and general interest. They provoked much approval, and Mr. Carley, who described the 60 pictures, received a well-merited round of applause on stepping down from the platform. The above were followed by a series of pictures illustrating the life of the Handy Man. Next on the list were a number of mixed scenes by members, described by the President. Mr. Stanley illustrated some places visited last Easter by the Club, including Cuckfield House, better known as the "Rookwood" written of by Harrison Ainsworth. Mr. Paice showed figure and cattle slides, and Mr. Maclean and Mr. Noaks also contributed a few studies. But best of these series were a number by Mr. A. E. Isaac, the Hon. Lanternist, to whose untiring labours the Club is so much indebted for the appreciation of these shows. Mr. Isaac's slides included some capital scenes of old and picturesque portions of York, and several striking and curious bits of Knaresborough. The peculiar spiral spire of Chesterfield Church provoked much interest, and the series was brought to a brilliant ending with a striking picture of a storm cloud. The third portion was devoted to a lecture founded upon an excursion made last June by the Club to Rochester and district, when some forty or fifty pictures were obtained which illustrated many points closely connected with the life of the late Charles Dickens, and with the places described in several of his novels. The lecturer was the Rev. Cecil H. Fielding, of West Malling, who gave the audience a strong dose of "Dickensiana," with a goodly ingredient of early English history thrown in as a kind of make-weight. Some lecturers there are who know too little about their subject. Mr. Fielding is not of that sort; indeed, he is almost like the gourmet who, asked how many roast larks he could eat, answered, "I could go on eating them for ever." So many things connected with Rochester and Dickens were spoken of that we can find space but for a tenth of a tithe of what fell from the lecturer's lips. As regards the cathedral, it was melancholy to be reminded of the ruthless removal of the ancient spire, and its replacement by the present debased tower which ordinary folk in their innocence no doubt take to be an object deserving admiration and veneration. The old building known as Eastgate House was shown as the one where "Pickwick" hid behind the door of the young ladies' school, and which is also made to figure in "Edwin Drood." Of course, the "Seven Poor Travellers" came in for many remarks, some interiors of it, which had been lent by Mr. Snowden Ward, being much admired. The Bull Inn, associated with "Dr. Slammer," "Jingle," "Pickwick," and other of Dickens' characters afforded much scope for talk. Cooling Castle was glanced at, and Cooling Church also. This is the scene of the interview between "Pip" and the escaped convict in "Great Expectations." Of course, Gadshill was visited, and afforded a number of apropos anecdotes. Time was short for all that Mr. Fielding would have liked to say, or no doubt we should, inter alia, have heard more about Dickens' pet books, of which he has an imposing array in his library, as we noted on the occasion of a recent visit. Here are just a few of their titles:—"Abernethy on the Constitution," Toots' "Universal Letter Writer" (two vols.), Adams' "Precedents," Kant's "Eminent Humbugs" (ten vols.), "Mag's Diversions" (four vols.), Catts' "Lives" (nine vols.), "History of a Short Chancery Suit" (21 vols.), and others which show that our great novelist had a very catholic taste as regards his reading. The Sir John Falstaff and Cobham Hall were also illustrated and described. We should add that the lantern slides, with the exception of half-a-dozen interiors lent by Mr. Snowden Ward, were taken by the following members of the Club:—Messrs. Maclean, Rogers, Noaks, Stanley, Watson, Frost, Carley, and Sandell.

**Glasgow Eastern Amateur Photographic Association.**—The Annual Meeting of this Association was held on Thursday evening, 13th inst.—The reports showed that the membership paid up was 75, and that, while last year's balance was under 20s., the income of £74 during the year had left the Association with a balance of over £11. Satisfaction was expressed with the reports, especially as the expenditure on equipment of the rooms had been very heavy. Office-bearers were elected as follows:—Hon. President, Mr. W. R. Malcolm; President, A. D. Inglis; Vice-Presidents, Robert M'Millan and James Kennedy; Secretary, George R. Johnstone, 166, Slatefield-street, Dennistoun; Lanternist, John Gillespie; Treasurer, Alex. M'Intyre, 6, Craignestock-place; Council, Matthew Crosbie, John Gardner, W. S. Crockett, A. Allan, jun., Matthew Wilson, and D. Johnstone.

**Ardrossan Camera Club.**—Annual Exhibition.—The Second Annual Exhibition and competition of this Society was opened last week, and will remain open till the first week in January. There was keen competition in all the classes, and the judges, Mr. W. M. Warneuke and Mr. Matthew Ballantine (of Mr. Lizars) had some difficulty in coming to a decision in several cases. The pictures of outstanding merit were almost entirely the work of Mr. W. Fotheringham and Mr. J. M. Comrie, in both of whom the Society has members capable of setting an exceedingly high standard. Mr. Warneuke and other friends have lent a number of pictures for exhibition. The judges made their awards as follows, a silver and bronze medal being given in each class:—Class I. Half-plate and over: 1, W. Fotheringham; 2, J. M. Comrie; 3, J. C. Guthrie. Class II. Under Half-plate: 1, J. M. Comrie; 2, J. S. Barbour; 3, Thos. Guthrie. Class III. Hand Camera: 1, J. M.

Comrie; 2, G. C. Guthrie; 3, Arthur Craig. Class V. Set of four Lantern Slides: 1, J. M. Comrie; 2, Arch. Ritchie; 3, G. C. Guthrie. Class VI. Enlargements: 1, W. Fotheringham; 2, J. M. Comrie; 3, G. C. Guthrie. Class VII. Set of three pictures taken with "Challenge" Camera: 1, W. Fotheringham; 2, Thos. Guthrie. Beginners' Class—Set of three pictures: J. Macdonald.

#### FORTHCOMING EXHIBITIONS.

1901.

- January 14-19..... Blairgowrie and District Photographic Association.  
The Hon. Secretaries, Blairgowrie, N.B.  
February 16-March 9 Edinburgh Photographic Society. Secretary, J. S.  
M'Culloch, W.S., 10A, George-street, Edinburgh.

### Patent News.

THE following applications for Patents were made between December 3 and December 8, 1900:—

- FOCUSsing.—No. 21,840. "An Improved Method of Ascertaining when the Sensitised Plate or Film of a Camera is in Focus." A. COATS, JUN.  
CAMERAS.—No. 22,200. "Improvements relating to Photographic Cameras." N. CONTI.  
STEREOSCOPY.—No. 22,246. "Improvements in the Method of and Means for obtaining Stereoscopic Effects." C. A. BURGHARDT and A. V. HUNT  
FILMS.—No. 22,385. "Improvements in the Preparation of Films for Photographic Purposes." Communicated by Bunt & Luxuspapierfabrik, Goldbach, Germany. P. A. NEWTON.

### Correspondence.

- \* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE PERMANENCY OF SEPIA-PLATINOTYPE PRINTS.

To the EDITORS.

GENTLEMEN,—I have been greatly interested in your recent notes on the above subject. It may interest you, and possibly some of your readers, to know that I have used the method suggested by Peebles Smith for obtaining sepia and brown prints with the ordinary black cold-bath paper. The process was first tried in the summer of 1898, and I find the prints then developed have not apparently altered in the slightest degree, although some of them have been framed, and no particular care taken of the others. Since then this method has been used many times to obtain particular effects. I do not, however, find this process gives really brown or sepia prints, but rather very warm blacks, and half-tones ranging from sepia to brown. I should be glad to send you, for examination and return, prints developed by this process, and, if any of your readers are sufficiently interested, to give them my method of developing the prints, for which I do not claim any originality.—I am, yours, &c.,  
HARRY QUILTER.  
St. Martin's, Leicester.

[We should be very pleased to examine the prints referred to by Mr. Quilter. Eds.]

#### THE WATKINS SPEED LIST.

To the EDITORS.

GENTLEMEN,—In sending the latest edition of our speed list, permit us to draw attention to a point regarding the Watkins speed numbers which has not been previously noted. It is that the numbers indicate without calculation the hand camera exposure (half the full exposure) with mid-day summer sun, and the lens at *f*-8, thus 100 Watkins requires 1/100th second exposure under these circumstances, 50 Watkins requires 1/50th second, and so on.—We are, yours, &c.,  
THE WATKINS METER COMPANY.

Hereford, December 11, 1900.

**PATENT.**—H. BEAUCHAMP. "I see that a patent has been taken out for a contrivance that I and one or two of my friends have had in use in our studios for some years past. It is not of my invention, but that of one of the others. Shall I be infringing the patent if I continue to use it?"—In reply: Certainly not, if you were using it before the date of the patent. What is more, if you had, the patent is of no value whatever.

**SILVER STAINS ON NEGATIVES.**—"SILVER-STAIN" writes: "During the winter months of the past few years I have been greatly inconvenienced by my negatives silver-staining. I take all precaution, such as drying the negative, the paper (P.O.P.), pads, &c., before printing, and also have the printing room heated, but though I take this trouble my negatives get marked all over with a slight red silver stain."—In reply: This should not occur if the negatives were thoroughly washed and varnished and all was perfectly dry. It should be borne in mind that if cold negatives are brought into a warm room moisture will condense upon them, as dew. Possibly this may be the source of the trouble.

**OLD NEGATIVE GLASSES—EXPOSURE.**—"F. H. S." writes: "(1) I would be obliged if you could tell me what can be done with useless negative glasses? Is the glass of value, if so, how can it be disposed of? (2) I have a 10×8 camera and lens (Dallmeyer) to take a 13×11 plate. In using these, should the exposure be longer in proportion to the size of plate used? or is it only when stops are used that the exposure (for portraits) is required to be longer?"—In reply: (1) Practically the glass is of no value whatever. It is not worth the trouble of cleaning off the films, unless, indeed, it be of large sizes. (2) The size of the plate makes no difference in the exposure—that is governed by the size of the stop used.

**VALUE OF BOOK ILLUSTRATED WITH PHOTOGRAPHS.**—A BAKER writes: "I notice in your last issue a short notice on "Photography and Modern Illustrations." I have just bought a book called "The Home of Santa Claus," and I find it illustrated with over 100 photos, some being good combination photos. It must have taken a great deal of time to arrange and think out the different subjects, and I was wondering whether the photographer was well paid, as I thought of advertising to do such work. I would be pleased to loan you my copy if you have not one, so as to obtain your advice."—In reply: If our correspondent will let us see the book referred to we will let him have our ideas on the subject.

**TEMPORARY SUPPORT FOR CARBON PRINTS.**—T. M. FORD writes: "Can you inform me if there is temporary support for carbons that will give more of a matt finish to them than the usual Sawyer's temporary support? What I want is a dull matt surface, and I know I can get it with opals coated with collodion, but, as I do a great number, it would come very expensive. The support I am using gives a slight shiny surface, which I would like to avoid, if possible, as I think it spoils the beauty of the carbon."—In reply: So far as we know there is no temporary support sold that will give a matt surface. If the print, after stripping from the support, be soaked in water for an hour or two, much of the gloss will disappear on drying, particularly if it be squeegeed upon as a piece of ground glass.

**MAGNESIUM POWDER; INTENSIFICATION.**—"H. H." writes: "(1) Would you kindly let me know whether the magnesium powder by itself is dangerous to use in an ordinary room for taking a portrait, and would you let me know the quantity to use to take an instantaneous photograph with an Ilford Impress plate and a R.R. lens working at f-8? (2) Is it possible to make a fair printing negative from an over-exposed plate which has been intensified with mercuric chloride and blackend with sulphite of soda, which takes hours to print in the sun, and when it is printed it is very flat, with very little contrast?"—In reply: (1) The magnesium powder, by itself, is not dangerous. The quantity necessary to take the portrait will depend upon the distance it is burnt from the sitter. The farther it is away the more will be required. Better make one or two trials from where it is to be burnt—say, commencing with thirty grains. (2) Only by reducing the negative. Try putting it back again in the mercuric chloride. That will usually reduce the image sufficiently.

**DISCOLOURED PRINTS.**—"AJAX" writes: "I should feel obliged if you would give your opinion as to the cause of failure in the production of enclosed prints. They were, apparently, all right when taken out of the fixing bath, but were all discoloured the next morning, in the condition of those enclosed. The toning, fixing, and washing was done in an outhouse, and on this occasion only a coke fire was kept burning in a perforated pail in the centre of the room, which gave off sulphur fumes. Do you think the fumes would impregnate any of the solutions used or washing water, and so cause this deep yellow appearance?"—In reply: Although such a stove is very undesirable in a photographic workroom, we do not think, in this case, that it had anything to do with the stains, otherwise there would not be some parts of the prints with pure whites. The cause of the stains is that the prints are not fixed. They were not long enough in the hypo bath, or it was too weak, also that the prints were allowed to stick together while in it. Where the solution had free action the whites are pure. There are well-defined marks where the prints overlaid each other.

**CARBON PRINTING BY ELECTRIC LIGHT.**—B. ASHBURN puts this question: "How long will it take by electric (arc) light to make a print direct from a negative?"—In reply: This is a question that it is impossible to answer, because it would depend upon the power of the light, the density of the negative, the distance of the negative from the light, and the sensitiveness of the tissue, &c., all of which are important factors in the case.

**ALUM IN THE FIXING BATH.**—"PREMIER" writes: "I should be glad if you will inform me whether the use of the following fixing bath is likely to affect the permanency of bromide prints:—Hyposulphite soda, 8 ozs.; alum, 1 oz.; water, 40 ozs. The hypo is first dissolved in hot water, the dry alum then being added to the solution, which is well stirred the while. The precipitate is then left for a day or so to subside, and the clear liquid only is used. The advantages of using such a bath I find to be clear whites in the 'fixed' prints, and a hardening of the gelatine surface, which is a great comfort in mounting. Another point is, this bath keeps clear for a long time, and it is in this particular one may be likely to do wrong in using it after its 'fixing' powers are exhausted. Could you give a rule for knowing when exhaustion has taken place?"—In reply: We are no advocates of acid fixing baths for paper prints when permanency is a consideration. There is "no rule for knowing when exhaustion has taken place." The only thing to judge by is the amount of paper that has been fixed in the solution. The fact that the solution keeps clear is no criterion whatever.

**A WAGES QUESTION.**—H. BISHOP writes: "I belong to a London firm who make a large number of drawings, maps, and other line subjects, and who are desirous of engaging a photographer. 1. Is there any trade rate of wages paid such men? 2. If not, would you give one some idea of the salary we ought to pay a good, capable, all-round man, as we only require one man? Please note the words 'some idea.' 3. The work we want done is the reproduction or reduction of plans to 15 × 12 or larger by the dry-plate process, producing negatives suitable for making photo transfers from. The man must be able to do all the work, from taking the negative to making a photo-litho transfer or printing from the negative on a metal plate direct, retouching the same and the negative; also large prints by Velox or other gaslight papers; also to make large sun prints from tracings, by the blue, black and white, and other processes, all to be so that it can be done with precision."—In reply: 1. There is no regular trade rate. 2-3. You require a skilled operator in all the processes you require him to work, and we should say about three guineas a week would be a fair salary to pay him for his services.

**A QUESTION OF PRICES.**—"BHOUSE" writes: "I am in charge of a local studio. Some months ago I was asked to come and photograph some machinery inside a mill, which I did do. The mill is about a mile from my place of business. Owing to the light on the machinery, of course I had to give it a long exposure. The light was also changeable, and, to make certain, I had to expose two plates, which took me over an hour and a half, all the time of which I had to stand at one place without being able to get out, as my way lay in front of the camera. The size of the photograph was whole-plate. The order was for an enamelled print unmounted, and negative to be given up. I was, furthermore, forbidden to make any use whatever for myself of that photograph, and was to keep that as a secret, owing to personal reasons of party concerned. Then, after my complying with all his wishes, and giving satisfaction in every way, the party concerned objects to the price charged by me, saying that it is too much. I do not like to have any bother with that gentleman, and should therefore be obliged if you would say what you think is a fair charge for a job of this kind, taking, of course, everything in consideration?"—In reply: Prices for this class of work vary considerably, and we are scarcely in a position to give an opinion on a question of prices. We should say, under the circumstances, that from a guinea to a guinea-and-a-half would be a fair charge.

**SNOW-SCENE PHOTOGRAPHY.**—"WINTER" writes: "Please be kind enough to reply to the following in next week's paper: 1. For snow scenes in bright sunshine do you advise slow, medium, or special rapid plates? Should the plate be chromatic or ordinary? If the former, should a pale yellow screen be used? What stop would you suggest? and, approximately, what exposure and developer? 2. For snow scenes in dull, foggy weather what kind of plate and speed would you advise? 3. What is the most suitable kind of plate for catching the effect of a sunbeam striking through the trees in a forest? Should it be slow, medium, or special rapid, and, if a chromatic, should a screen be used? 4. Do you believe in a brown paper or cardboard shade, projecting about six inches beyond the lens hood, to assist in producing brilliant negatives; and, when working in a dull and unfavourable light, would such an arrangement be an assistance in helping the lens to concentrate such poor photographic light as there happened to be?"—In reply: 1. A plate of medium rapidity we should prefer, and chromatic. If the light is yellow a screen is not necessary—the largest stop that will give the desired definition with the lens you employ. The exposure will, of course, depend upon the light at the time, and the aperture at which the lens is worked. Use the developer with which you are most familiar. 2. A rapid or a medium rapid plate. 3. Either will do. A screen is scarcely necessary if a chromatic plate be used. 4. Yes, it would shield the lens from instantaneous light.

## THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1901.

Edited by THOMAS BEDDING, F.R.P.S.

*What some readers think of the book:—*

- "A splendid ALMANAC."
- "A handsome present."
- "Grows bigger and better every year."
- "More interesting than ever."
- "More copious and more useful."
- "A necessity to the busy worker."
- "Better than all its predecessors."
- "I congratulate you heartily on issuing such a good book."
- "Most acceptable and useful."
- "Grows more valuable and interesting every year."
- "A capital issue."
- "Excellent in every feature: the letterpress, diagrams, tables, and illustrations are most helpful."
- "A first-rate and exceedingly cheap publication, fully up to, if not beyond, the standard of former years. . . . A combination that must mean continued and strengthened life."

## *Some Press Opinions:—*

- "A mass of useful information for all photographers, professional and amateur."  
"Shrewsbury Chronicle."
- "Invaluable to all who have to do with photography."  
"Bedfordshire Times and Independent."
- "This monumental work."  
"Pharmaceutical Journal."
- "An annual of the greatest interest."  
"Dundee Advertiser."
- "Any one interested should make a point of getting a copy."  
"Sussex Daily News."
- "As a reference book for photographers it is probably unrivalled."  
"British and Colonial Druggist."
- "There is enough to learn in it till the next ALMANAC appears in 1902."  
"Invention."
- "Bigger and more useful than ever."  
"Oxford Times."
- "The ALMANAC should commend itself to all interested in the use of the camera."  
"Oxford Chronicle."

\* \* The 1898, 1899, and 1900 editions of the ALMANAC (20,500 copies) were each sold out within a few months of publication.

\* \* The 1901 Edition, just issued, has been entirely sold out in less than three weeks from publication. This result is a record without parallel either in the history of the ALMANAC or any similar publication.

## EX CATHEDRÂ.

ONE of the most marked signs of the close of the century is the extent to which at last the public mind has become open to the fact of the length to which British industrial supremacy is being threatened by German competition. In our manufactures and chemical products alike the vast strides made in Germany have tardily been recognised, and the marvellous phenomenon of a country which a quarter of a century ago was little more than an agricultural community coming to the very forefront in industrial work has really awoken alarm. In one special direction German products have a particular interest for photographers—the Jena glass, which, we need scarcely now inform our readers, is not, as some yet suppose, one, but many. Twenty-four years ago the finest optical glass was made in this country, but in a report of the London Exhibition of that date Pro-

fessor Abbe pointed out the need for improvement, if improvements in microscopes were to be made, and showed where attempts in that direction by Harcourt and Stokes had failed. There the matter rested, so far as we were concerned, but not so in Germany. Abbe, in connection with a glass manufacturer, Schott, conducted an elaborate and laborious series of investigations, in which they were aided by extremely substantial pecuniary help from their Government. The result was the production of a large number of new kinds of glass, which, by reason of varying dispersive powers for similar refrangibilities rendered possible the construction of optical instruments with hitherto undreamt-of possibilities, powers which once were said to be contrary to the laws of science to produce. Photography has concurrently with microscopy been the gainer, and the manufacture of photographic lenses has been revolutionised. In 1888 Germany made nearly the whole of the glass it required for optical instruments, and very soon it began to export this glass. In 1898 the trade had so grown that no less than thirty thousand pounds' worth of what we might term the raw glass was exported, while in the manufactured form microscopes, photographic lenses, &c., no less than a quarter of a million pounds' worth was sent out of the country. With the dawn of a new century we may hope that our own country, thoroughly awake to the needs of the situation, will show the world that it cannot be beaten on this ground. Already some of the finest objectives of the day have been invented and made in this country, and we may hope still for advance.

\* \* \*

OVER the signature of A. S. Herschel there appears in last week's "Nature" a long and interesting letter embodying mainly the results of Mr. Herschel's experiments in electricity of stripping. He finds that when using solio and P.O.P. generally there is too great a tendency to too complete adherence to the glass, and he has chiefly made use of albumenised paper. When observing the separation of the print from the glass surface he noticed strong electrical attraction between the glass plate and the freshly-separated paper. The glass best adapted to show the effect is very hard unhygroscopic, and the print must not be squeegeed, but merely laid on wet, and the superfluous water freed by swinging, then the back gently padded with a soft cloth. It should then be left to dry spontaneously, back upwards. In a damp atmosphere the paper remains adherent, but in a warm room it separates spontaneously with audible clicks as the tension gives way. If the paper be rubbed at the back just before it is ready to separate it will remain adherent through electrical attraction. After vainly trying to observe a luminous effect, he at last observed a light flash. "The momentary gleam of the electric light play can be very easily observed by holding an albumen paper print thoroughly well self-dried on glass, proper side downwards, in a perfectly dark room over a hot room stove to produce the paper's separation, and by stripping the print off downwards as soon as some edge of it has grown loose enough—probably with some degree of light—to allow it to be taken in the fingers. I have by this means now seen those brush and glow lights flitting beams a second time, and there seems to be no difficulty of producing them in varied form and brightness by this method of proceeding."

\* \* \*

POSSIBLY because of the great distance to be travelled to get a proper observation, the eclipse of May, 1901, does

not attract much attention; but we may say that those who desire to visit the Malayan Archipelago and observe the eclipse at the same time will find all the information they need in a pamphlet issued by the Government of Batavia.

### THE UP-TO-DATE PROCESS-MONGER.

THERE is little doubt that during the last ten or fifteen years many gentlemen, who it is only fair to class as amateur workers, have, in pursuance of their delightful hobby, been able to discover numerous ways in which photography may be applied to aid them in their particular line of business; and it is only reasonable to state that in numerous instances several fresh departures in the method of preparing and producing various articles in commerce have been introduced as a result of even the slight acquaintance such gentlemen have had as amateur workers. Very many of these fresh applications of photography are, no doubt, entitled to be classed as original ideas, for, were it not for the special knowledge on the part of some individual connected with a particular profession or trade, very probably the casual photographer might never have hit upon the idea of applying photography to such purposes. On the other hand, it is surprising how much that is as old as the hills is re-discovered by those whose limited experience of photography does not enable them to really discern when a bonâ-fide fresh discovery has been made. It would be perhaps too much to expect that, from among the vast ramifications of photography, as applied to trade and even scientific purposes of the present day, every now and then certain individuals should not herald forth, in some particular line of business, the discovery of a valuable application of photography, by means of which improved methods in working as well as probably some fancied saving in cost of production can be effected. The secret process-monger, it may be truly said, has been in evidence ever since the early days of photography, for at that distant period of time when our baby was a nursling in arms doubtless there was a very wide field for fresh discoveries, much more so than really exists at the present day. There is, however, a noticeable difference between the process-monger of years ago and that of to-day. In the early days of photography, whenever a really fresh discovery was made, the custom was for the inventor to offer its advantages to photographers generally, and by persuading them to adopt such, and by bringing the same prominently before their customers, many photographers recouped themselves for what little outlay they expended in the way of premiums for making such. Then, however, the practice of photography was a very different matter to what it is at the present day, and the "process-monger" had practically no alternative but to offer his discovery to those only who were capable of working it, viz., professional workers. All this has been changed in recent years, for photography has been placed in the hands of every one, on account of its simplicity, until it is really difficult to find in any place of business the individual who is not possessed of more or less knowledge in photography.

The process-monger has, therefore, a wider field to work upon, and it would appear as if we are about to witness what may be termed a revival of this method of doing business in the hope of earning a livelihood. To attempt to enumerate a tithe of the valuable discoveries that have from

time to time been trotted out by those who honestly believed they had discovered something new, but which in point of fact was not so, would be difficult indeed. As a rule, so long as such discoveries were offered to professional workers only, there was little difficulty in the matter, for it was at once apparent, in the trade or profession, that a fresh departure of a genuine character had been introduced and invariably there followed an admission from professional workers, when a thing *was* really new; but, on the other hand, there is no doubt that very much that was as old as the hills was from time to time being hawked around by unprincipled individuals in the hope of deriving a benefit from the same. At that distant period of time it was, therefore, less difficult to discern what was "genuine" from false. But, in the present day, by reason of the fact that process-mongers have a wider field to work upon, and not infrequently confine their attentions to the application of photography to certain articles of trade, they succeed in many instances in extracting a mere nominal fee of a guinea or two. Simply by reason of the fact that the sum asked is not a large one, and as there may be something in the matter after all, people are induced to have a deal on the score that the risk is not a heavy one, even supposing there be little or no advantage in what is eventually disclosed to them. To say that much of this sort of thing does not exist at the present day would be stating what is really not fact, for within the past year or two several trades have been subjected to attacks from individuals anxious to divulge some secret method of working, of which photography may be termed the base, and it is only fair to state that injury to the bonâ-fide professional worker can be traced to the operations of such people. Take any trade in which from time immemorial photography has played an important part. Here we find the work has been well and truly performed either by the business firm or by a professional worker of good standing, who in return receives a fair remuneration for his work, keeping his method of performing the same to himself, just as any other professional worker would do. The up-to-date process-monger comes along with his fancied discovery, both as regards its being something new, and at the same time seeing that the party knows a little about photography), the implicity of doing the work being so great, sees nothing to prevent his doing his own part of the same.

Now, to many minds, there may at first sight appear nothing imprudent or anything liable to injure the professional worker in all this, but on closely examining this line of procedure it will be seen that very much injury is done to the respectable professional by such people. First of all, as is well known, there are numbers of cases, in which special work is performed for special trades, in which not only the material employed by the professional is kept secret to himself, but also the method of using the same; and in cases of this kind, by reason of such knowledge being a purely professional secret, and unknown to those even who employ and pay for the work produced, the moment the process-monger comes along and divulges what is really a well-known method, and one regularly used by the photographer, the temptation is very great on the part of the employer of such, seeing he has a slight acquaintance with photography and has now been placed in possession of the knowledge of the proper material to use, to try himself to do what the professional photographer has hitherto been engaged to perform. In one high-class trade quite recently

this sort of thing has been practised, to the injury of both the professional and the tradesman. In the case of the latter, for years the professional was doing a special class of work, the method being unknown to his employer, and so long as the latter kept his orders regularly in the same channel the method of producing these results was not imparted to any one else in the trade, so that the tradesman had virtually an interest in keeping the photographer's method of working a secret. The moment the process-monger comes along he does not rest satisfied with imparting the information to one only, but he makes it broadcast over the whole trade, and injures the professional and tradesman alike, who to perfect the method of working may very probably have spent a considerable sum of money, and is therefore justly entitled to some preference in the matter. During the last twelve or fifteen years there has been a great outcry by professional workers regarding the injury they receive at the hands of thoughtless amateur workers, and much has been written as to how such might be protected so as to secure immunity from loss to their business. No doubt many good cases of where injury has been done to honest, hard-working professionals could be shown, but hitherto no possible plan of protection seems to have been devised, and photographers have just had to grin and bear it. It would appear now that a fresh danger threatens the profession by an outbreak of secret process-workers, who in reality in many cases are divulging nothing that is unknown to the professional, but who, by reason of imparting certain information in circles where such is likely to be of interest and value, do an incalculable amount of injury to professional and tradesman alike.

**Intensifying and Toning Platinum Prints.**—In Eder's *Jahrbuch* the following means of modifying platinum prints are given by Raimund Rapp, of Vienna. To intensify a print, wash it thoroughly and immerse it in the following bath:—

Cold saturated solution of gallic acid	....	50 c. c.
Water	.....	50 "
10 per cent. solution of silver nitrate	....	2 "
Glacial acetic acid	.....	10 to 20 drops.

The print will intensify slowly, and, when it has acquired sufficient depth, wash it in two or three changes of water to which a little acetic acid has been added. The silver, which has been deposited on the image, is then converted to platinum by using the following bath:—

Potassium chloro-platinite	.....	1 gramme.
Phosphoric acid	.....	15 c. c.
Water	.....	600 "

Wash the print once more.

As the process is based upon physical development, by the introduction of various modifications other tones may be secured after the print has been treated with the gallic acid and silver bath. For reddish tints use the well-known uranium intensification formula very much diluted. The bath may be reduced to one tenth of its ordinary strength. Green tones may be obtained by treating a red or brown uranium toned print with a twenty-five per cent. solution of sulphate of iron. If a print toned green in this way is immersed in water acidulated with hydrochloric acid, it will acquire an intense blue tone. Less pronounced green and blue tones may be obtained by immersing the silver intensified print in the following bath:—

Water	.....	50 c. c.
Ferricyanide of potassium solution (1:50)	.....	20 "
Ammonio-citrate of iron solution (1:50)	.....	10 "
Uranium nitrate solution (1:50)	.....	10 "
Glacial acetic acid	.....	10 "

The prints gradually acquire a green tone, but, if the subsequent washing is too prolonged, they turn blue. A very fine deep blue tone may be obtained with the following gold bath:—

Water .....	1 litre.
Nitrate of lead .....	15 grammes.
Sulphocyanide of ammonium .....	40 "

After filtration add:—

Chloride of gold solution (1:50).....	20 c. c.
---------------------------------------	----------

The prints may remain several hours in the bath, during which time intensity of the tone increases. Wash for about an hour.

**A New Pigment Process.**—The Actien-Gesellschaft für Anilin-Fabrikation, of Berlin, have just patented a new pigment process, which strikes one as being very simple and likely to be of value, in that prints in very many different colours may be obtained without the necessity of transfer, and, further, which has the advantage of giving a printed-out image. As an example of the process they give the following directions. Paper is soaked for a minute in the following solution:—

Soft gelatine .....	6 parts.
Ammonium bichromate .....	16-20 "
Water .....	100 "

Dissolve by the aid of a gentle heat, and dry in the dark. Expose under a negative for about half as long as is required for a gum bichromate print, and then wash quickly in frequently changed water to free it from the undercomposed chromate; the last washing water should be acidulated with 0.1 per cent of sulphuric acid. Development is effected at ordinary temperatures in solutions of which the following is typical:—

P.-phenyldiamin .....	1 part.
Sodium bisulphite .....	1-2 part.
Water .....	600 "

The picture quickly appears in a dark brown colour, and is then washed in acidified water and dried. If instead of using p.-phenyldiamin one of the following be used, all possible colours may be obtained:—dimethyl-p.-phenyldiamin, toluene-p.-diamin, 1.5 naphtholendiamin, p.-amidophenol, methyl-p.-amidophenol, o-p.-diamidophenol, β-triamidophenol, pyrogallol, 1.5-dioxy naphthaline, p.-amidodiphenylamin, p.-diamidodiphenylamin, aniline, dimethylaniline. The theory of this process is that the chromium dioxide which is left in the image after the prints have been washed is a strong oxidising agent, and converts certain colourless organic compounds of the aromatic series by oxidation in colouring matters of various shades.

**A New Iron Printing Process.**—Messrs. A. and L. Lumière have patented the use of ferric saccharinate as a light-sensitive salt for an iron printing process, which has the advantage of greater keeping power, a property which is conspicuous by its absence in most of the iron processes. A solution of saccharinate of barium is added to ferric sulphate, in the proportion of the molecular weights and an insoluble precipitate of barium sulphate is formed which can be filtered out leaving a clear solution of ferric saccharinate. Gelatinised paper is painted with this solution and then dried in the dark, and then exposed in the ordinary way. The image is developed by using ferrid or ferrocyanide of potassium or other salts which will give coloured compounds with the ferrous salt produced by light.

#### The National Photographic Record Association.

We are informed that at the last Council Meeting of the Association 366 photographs were presented from all parts of the kingdom, forming a valuable addition to the collection, recording, as they do, some of the most interesting subjects, both from an antiquarian and historical point of view. The President, Sir J. Benjamin Stone, M.P., sent in 100 prints taken in Warwickshire, including a series of

Stratford-on-Avon, and an interesting record of collecting the "wroth money" at sunrise at Ryton-on-Dunsmore. Mr. Sulman gave a set of the old historical houses of Hornsey and Highgate, many already removed. The following were also included: One hundred and three from Mr. Geo. Scamell, Hon. Secretary, of the historical houses of London, and the old Sussex churches, including Bosham, Sompting, Shoreham, &c.; some of Old Newgate by Mr. T. Bolas; Canonbury Tower and other contributions by E. Scamell; Worcester Cathedral by F. Littledale. Many especially interesting records of Irish life and antiquities by Mrs. Muriel and A. Hogg, the latter sending a particularly fine series of the Tumulus of New Grange, the interior views being splendid specimens of flashlight work. The Rev. A. C. Harvey contributed an interesting set of photographs of the old parish register, showing extract of Act for burying in woollen—affidavits that such had been done—and another page certifying that certain families had paid the penalty of 5*l.* that their friends might be buried in linen. Mr. Clark forwarded a set of old crosses at Llantwit Major. Mr. Calcott an interesting record of many of the old houses of Bristol, several of which have been already removed. Mr. Felce a fine series of Norman capitals and misereres in the Northampton churches. Mr. Hodgson a long record from Kingston-on-Thames, and Mr. F. Parkinson a very complete set of the Easter sepulchre at Heckington Church. These photographs have now been forwarded to the British Museum, and together with those already deposited make up a collection of nearly 1600 prints contributed by members of the Association.

#### JOTTINGS.

It should strengthen the hands of those gentlemen who have undertaken the task of carrying on the Camera Club in the new century to know that a great many persons outside the Club who might, with favourable circumstances, be disposed to seek membership, are sympathetically interested in the successful accomplishment of that task. Amongst my own acquaintances I can count several who are in this category. The times are favourable to new departures of most kinds. Sooner or later all mundane institutions tend to slacken on the journey of progress, and then it becomes necessary to apply the first law of nature, in order to avoid total stoppage. Quoting the words of the amiable Mrs. Chick, we all occasionally, in the affairs of life are compelled to "make an effort;" and, in the case of the Camera Club, it is just a little "effort," and nothing more, that is needed to quite completely vitalise it. Socially and photographically the world is still all before it, and, with modern and vigorous methods of administration, it should be a comparatively easy matter to put it in a financial position on a permanently satisfactory basis. That this will be done, readers of this paragraph may take it from me there are the best possible reasons for believing. I have had an extensive and peculiar experience of British photographic institutions—the R.P.S., the Convention, the Benevolent, the extinct Central Photographic Club, and several small societies. They have brought me many pleasures and friendships, but I look back almost lovingly upon the last few years, during which I have had the happiness of taking mine ease at the Camera Club. In photographic society matters I fear I am a difficult person to please; yet, if there is one thing which I hope and believe the mysterious new century will not rob me of, it is my favourite corner in Charing Cross-road. So, gentlemen of the Advisory Committee, the best of luck attend your efforts.

THE McDonough-Joly process of colour photography has lately excited much interest amongst photographers; less, perhaps, on account of the system itself or the nature of its results, than of the part which Mr. Snowden Ward has taken in bringing it to the notice of the public. Mr. Ward, a responsible journalist, has, in my hearing, been adversely criticised for so prominently associating himself with an enterprise which appears to be nothing more nor less than a commercial speculation, but it has evidently escaped general notice that he has not neglected the earliest opportunity of clearly defining his position in the matter. At the meeting of the Royal Photographic Society, on December 11 (see the JOURNAL, p. 797), Mr. Ward, before commencing his address, "disclaimed any commercial interest in the

ject." This is a phrase upon which the very broadest inter-  
 etation should be put, and it is to be hoped, in justice to Mr. Ward,  
 at those—and I have heard many—who have expressed doubts on  
 e subject will fully accept his disclaimer. So much for one aspect  
 a matter which is of acute importance to press and public alike.  
 r. Ward went on to inform his hearers that the McDonough-Joly  
 ocess "had no commercial aspect at present, and there was con-  
 quently no immediate prospect of members being able to purchase  
 e necessary apparatus and materials with which to pursue their  
 n investigations. He added that he was informed, on the best  
 thority, that the public would not be asked to subscribe to any  
 heme or company for exploiting the McDonough-Joly process." I  
 aw attention to these statements for the benefit and information of  
 ose persons who have hastily criticised Mr. Ward's association of  
 s name with the McDonough-Joly process, or rather with the  
 mpany not unnaturally assumed to be about to exploit it. I offer  
 comment on these points beyond saying that, in company-  
 omoting schemes which take colour photography as their bases of  
 erations, the intervention of a photographic journalist is a matter  
 at carries with it the very gravest risks of misconstruction.

HAVING detached the name of a *confrère* from a matter with which  
 seems it has been improperly associated, "I should like to make one  
 two remarks," as the speakers at meetings fall into the habit of  
 ying. I have the authority of an American friend—an expert in  
 ch things—for stating that the McDonough-Joly process was  
 ken up tentatively in the United States by a few professionals, who  
 oduced some very pretty portrait transparencies indeed, only to  
 scover that there was no demand for them amongst their sitters.  
 y informant also averred that he only knew of one amateur who  
 d succeeded with the process. Against these statements, however,  
 ust be set the undoubted fact that some very pleasing pictures indeed  
 various American workers have been, and are being, shown in this  
 untry—also some others which are scarcely so satisfactory as colour  
 nderings. Nearly three years ago the Natural Colour Photograph  
 mpany had an exhibition of transparencies by the Joly process at  
 e Crystal Palace Exhibition, and some of the results were strikingly  
 od, *sui generis*. Between that process and the one with which the  
 e Mr. McDonough's name has been linked the points of difference  
 e slight indeed. They consist in the main—so far as can be dis-  
 vered—of closer rulings of the taking and viewing screens. This  
 ay be an improvement, but it can scarcely be called an advance.  
 ose responsible for the exploitation of the McDonough-Joly  
 ocess in this country appear to be acting in entire ignorance of what  
 s already been done here. It is only right they should be told that  
 ey are late in the field. With regard to the adaptation of the process  
 paper: the superposition of a black image on paper ruled in three  
 ours produces effects that can only be described as sombre. It is a  
 ethod that might suit some subjects; but generally I should think  
 dinary three-colour block printing would be considered preferable.  
 en we have the brilliant suggestion to coat paper ruled in coloured  
 es with gelatine chloride printing-out emulsion, so as to get tri-  
 romatic results in an ordinary frame—an idea which I should very  
 uch like to see put into practice.

THE whole of this business is "wropt in mystery." If no appeal  
 to be made to the public for financial support, why all these  
 monstrations and exhibitions? There has been an exhibition at the  
 ew Gallery; a demonstration at Glasgow fully reported in the  
 al papers, one of which (in my possession) distinctly states that a  
 rge company is to be formed; and the transparencies have been  
 own at the Cleveland and Ashton-under-Lyne Exhibitions. There  
 ve also been the papers and exhibitions at the Royal, the Camera  
 ub, the Photographic Club, and the Queen's Hall. A sheaf of  
 wspaper cuttings about the process lies before me, and from time  
 time communications on the subject have been published by the  
 our Photo Company of Birkbeck Bank Chambers. I find it hard  
 reconcile all this activity with the pronouncement that the usual  
 mpany is not to be formed. The latter course is what one might  
 aturally expect to be followed. Why should it not? The whole

matter is purely one of business. The science of the process could  
 be perfectly well provided for by the reading of one paper at one  
 meeting. Driven into a corner by the denial that a public company  
 is to be formed, one is really puzzled to account for these  
 many meetings and exhibitions. Can it be that the Colour Photo  
 Company, Mr. Tripp, and the other gentlemen are disguised philan-  
 thropists banded together for the blessed purpose of entertaining the  
 public with pretty pictures, free gratis, and for nothing? But  
 seriously, there are many things in connexion with the McDonough-  
 Joly process and its presentation to the British public which require to  
 be cleared up in the interests of those directly concerned. If it is  
 really the case that it is not contemplated to attempt the flotation of  
 a company on the process, the Colour Photo Company is happily  
 absolved from the necessity of listening to advice which in the cir-  
 cumstances of the case is superfluous. And that advice is simply,  
 Don't. For in my humble opinion the McDonough-Joly process of  
 colour photography on glass or paper stands very little chance indeed  
 of being taken up by professionals, amateurs, or the trade, to such  
 an extent as would warrant the formation of a public company  
 having the smallest hope of resulting in financial success.

THE Editors of *The Photogram* send me the annual bound volume  
 of that elegant publication, together with a pretty calendar for 1901  
 for which I tender them my best thanks. The former makes a very  
 handsome and at the same time useful gift-book, and as I glance  
 through its carefully filled pages of instructive photographs—not  
 grams—and judiciously chosen matter, I am struck by the wide  
 field of photographic service which *The Photogram* sets itself to  
 occupy. The illustrations in particular seem to give me at a glance  
 a kind of panoramic impression of British photography during the  
 closing year. To the monthly issue of *The Photogram* for January  
 1901, which lies before me, a special interest also attaches. For  
 months past many references have been made to the "New American  
 School of Photography." In the nature of things only a minority of  
 photographers can secure the opportunity of examining these  
 photographs. The next best thing, of course, to do is to study  
 reproductions of them. In the January *Photogram* there are some  
 eight phototypes of examples, that were hung in Russell-square in  
 October last. Mrs. Kasebier; Mr. Clarence White; Mrs. Sears;  
 Mr. Steichen; Mr. Watts Lee; Mr. Eugene; Mrs. Russell and  
 Mrs. Devas are represented in this collection, which gives one an  
 excellent idea of the style of work of which the 400 American  
 photographs consisted. The reader, too, will have the inestimable  
 privilege of perusing an article by Mr. Eduard J. Steichen, on the  
 "School," of which he is a member, and of seeing a most wonderful  
 portrait of himself by himself. On no account should this or Mr.  
 Eugene's *Adam and Eve* be missed. Emphatically *The Photogram*  
 for January 1901 should be bought, conned, and treasured, by  
 everybody interested in modern pictorial photography.

WRITING as I do, within a few hours of Christmas Day, 1900, I  
 thank with all my heart the many friends from near and far who  
 have sent me reminders of the Season of Goodwill. In a few days a  
 year and a century will close, and I suppose there is not one of us who  
 between this and Tuesday next will not wonder in silence what the  
 New Time holds in store for us. May it realise for all who read these  
 lines the very best they can desire for themselves! Nearly half my  
 life has been passed in pleasant association with THE BRITISH JOURNAL  
 OF PHOTOGRAPHY and its friends and readers, and I hope that in the  
 new century it may long be my happiness to wish them all what I  
 sincerely wish them now, *A Happy and a Prosperous New Year.*

COSMOE.

#### LIGHT FILTERS.

[Translated from the "Photographische Correspondenz."]

A LIGHT filter may be described, generally, as any medium which  
 absorbs light and allows any of the various kinds of light (wave-  
 lengths) comprised in the entire spectrum to pass freely. The trans-  
 mitted rays are called filtered light, and may belong to widely differing  
 regions of the spectrum.

In its restricted meaning, however, only those media are called light filters which have desirable selective qualities, or, in other words, which may be used for definite purposes. It is a well-known fact that the selective properties of certain media are undesirable and even injurious. We need only mention the troubles due to absorption by the atmosphere, and various kinds of glass, minerals, &c. To all appearances they are colourless, yet they underlie certain problems in astronomy, and more especially astro-photography, micro-photography, spectro-photography, and other photographic processes.<sup>1</sup>

These absorptions mostly concern the very valuable region of the ultra-violet, on account of its great chemical activity, and we are much indebted to the classic work of Schumann,<sup>2</sup> Eder, and Valenta,<sup>3</sup> and H. C. Vogel<sup>4</sup> (and likewise to Buss<sup>5</sup> for his examination of dye-stuffs), which supply us with valuable conclusions, as well as the means of avoiding, as much as possible, the undesirable qualities of light filters.

The following remarks are restricted to light filters of desirable characteristics, and refer to their peculiar properties and applications.

According to the various methods of examining light, light filters may be classified as follows:—

1. Photographic.
2. Visual.
3. Bolometric.

A large part of the ultra-violet region of the spectrum (about  $100\mu\mu$ — $370\mu\mu$ ) is very suitable for photographic examination, also the whole of the visual region (about  $370\mu\mu$ — $750\mu\mu$ ) and a small portion of the ultra-red.

Ocular observation by direct means is, of course, confined to the visual part of the spectrum, whilst the bolometric method (developed by Langley and Rubens), in addition to the visual portion, also comprises an extensive tract of the ultra-red (about  $750\mu\mu$ — $2800\mu\mu$ ).

Absorbents of the ultra-red have hitherto been of little practical value.<sup>6</sup> For this reason we shall omit them from further consideration. We will give a short description of the visual light filters, but our principal attention will be devoted to photographic light filters, which at present have become of the greatest practical importance.

### 1. VISUAL LIGHT FILTERS.

The history of visual light filters is connected very closely with the history of the theory of colour, and especially with the theory of colour absorption. The Egyptians were acquainted with coloured glass, but not till later was the preparation of transparent glass successfully accomplished. The properties of various media as light filters have since been applied in numberless forms in manufactures and the arts, as shown in various branches of dyeing, ornamentation, painting, &c. They are especially exemplified in the application of stained glass to the decoration of churches, to theatrical purposes, and to signalling. Coloured lights have also been invented, as a substitute for light filters, for many purposes (Bengal lights, &c.).

So far as I am aware, the first conscious scientific application of light filters was made by the many-sided Florentine artist, Leonardo da Vinci (1452-1519),<sup>7</sup> who used coloured glasses for the analysis of mixed colours.

Light filters have since been used for scientific purposes, especially in the study of the theory of colour. I may mention as modern applications the use of filters for purposes of physical optics, and for spectro and polarimetric measurements. In physical optics they are used in studying the laws of light sensations, and for the selection of certain physiologically active light rays, &c. (coloured spectacles, chambre rouge, &c.).

Light filters are also used extensively for technical purposes. From numerous examples we select a few which are mentioned as being peculiarly interesting.

Monochromatic filters are recommended for use with imperfectly

<sup>1</sup> We include here many cases in which too much dye has been used in preparing the photographic film, thus inducing screen action.

<sup>2</sup> Unfortunately, Schumann's numerous works are widely scattered, and difficult of access. Much may be found in Eder's "Jahrbuch," which is an invaluable record, and I have used it extensively for this paper.

<sup>3</sup> "Denkschriften der math.-naturw. Classe." Vienna, 1894, vol. lxi.

<sup>4</sup> Ibid. 1896, vol. xlvi.

<sup>5</sup> Reference in the "Photographische Correspondenz," p. 368. An original contribution to the spectrum analysis of some dye-stuffs, &c.—"Forschungsberichte," Munchen, 1896. See also Krues: "The Absorption of Coloured Rays by Glass, and table of absorption of coloured glass." Eder's "Jahrbuch," 1890, p. 45. Eder's "Rec. und Tabellen," 4th ed. p. 70.

<sup>6</sup> Such filters have special application to micro-projection, where the heat rays must be eliminated as much as possible as a safeguard. Further details may be found in the recent works of Rubens.

<sup>7</sup> "Trattato della Pittura," Paris 1651, chap. xxxi

corrected lenses (secondary spectrum) in order to focus the image sharply. In such cases coloured focussing discs are specially recommended (Francotte),<sup>8</sup> or, preferably, monochromatic spectacles. Beck<sup>9</sup> recommends green spectacles (phototone) for landscape photography, to facilitate a better estimation of the relative values of light and shade. Yellow filters are much liked as an adjunct to telescopes, field-glasses, &c., and agreeably modify the image. In America blue glasses have been inserted in field-glasses for the detection of the slightly yellow gases of smokeless powder, but I do not know with what success.

For viewing the so-called anaglyphs, spectacles with glasses of different colours are used. The anaglyphs consist of two images printed one over the other in complementary colours. Upon examination through spectacles of corresponding colours, each eye perceives but one image, that is to say, for each eye one image is eliminated. As both images are stereoscopic, they are united and seen in relief.<sup>10</sup>

Extensive application is also made of light filters in the synthetic methods of producing mixed colours. These are very numerous, and I mention the following:—

1. Additive three-colour projection (Maxwell 1861, Ducos du Hauron 1869, v. Bezold 1885, Ives 1888, &c.).
2. Additive four-colour projection (Scott, 1891, &c.).
3. Additive methods with party-coloured screens (MacDonough 1892, Joly 1894, Brasseur and Sampolo 1897, &c.). (Additive printing process, Intern. Colour Photo Co., 1899.) (Textiles, Szepanik, 1900.)
4. Subtractive methods for tri- and poly-chromatic positives (Ducos du Hauron and Cros 1868, Vidal 1891, Ives 1895, Selle 1895, Lumière 1895, &c.).
5. Subtractive methods of tri- and poly-chromatic printing: Ducos du Hauron 1869, Kraus 1890, Hofmann 1900, &c.; colour printing (Scholler, Kuhn, Henneberg, Watzek 1898, &c., gum bichromate; Vallot 1896, bleaching process; Vaucamp 1897, three-film process; Noack 1897, diazo process).
6. Subtractive methods of three-colour photo-mechanical printing: Le Blon 1735, Gauthier 1745, &c. (Intaglio); Weishaupt 1835, Collen, Ransonnet 1865 (lithography); Husnik 1870, Albert 1786, Ulrich 1890, &c. (collo type); E. Vogel-Kurtz 1892, &c. (typographic).
7. Subtractive three-colour processes in dyeing and ceramics: Du Farg 1737, &c.; Vidal 1890, &c.

The colouring materials in all these synthetical mixed processes are to be regarded as light filters, although they are not usually so described, because their action depends exclusively upon their properties of absorption.

### 2. PHOTOGRAPHIC LIGHT FILTERS.

The ortho-, iso-, or pan-chromatic process has evolved from the efforts which have been made to render coloured objects photographically in their natural tone values. Nevertheless, the name only indicates the end which these processes have in view. We do not know of any process, yet, of a *purely* photo-chemical nature, which in its qualities of colour sensitiveness perfectly corresponds to the photo-chemical processes of the normal human eye. The curves of sensitiveness for the spectrum show considerable elevation in the blue and violet in the case of all modern photographic preparations, without any exception. In order to obtain a correct, orthochromatic curve we must generally use a yellow filter as a means of compensation.

### 3. COMPENSATING FILTERS.

Fig. 1 is the schematic representation of the action of the compensating filters,  $C_1$ ,  $C_2$ , and  $C_3$ , the sensitiveness of the process being  $x y$ .

The selection of the best possible compensating filter depends upon the nature of the process curve, as shall be shortly described. The process curve, as might be expected, also depends upon the quality of the light used.<sup>11</sup> This may be selected in such a manner that a compensating filter becomes superfluous.

Good compensating filters should not entirely eliminate any visible zone of the spectrum, as, for instance,  $C_2$  and  $C_3$ , in fig. 1; they should only subdue, as in the case of  $C_1$ . On the other hand, the ultra-violet should be quite eliminated.

There are many known absorbents of ultra-violet, and they are

<sup>8</sup> "Journal of the Royal Micro. Soc." 1892, p. 270. Eder's "Jahrbuch," 1895, p. 380.

<sup>9</sup> Eder's "Jahrbuch," 1895, p. 358.

<sup>10</sup> The process was worked out in 1853 by Rollmann for drawings (1858), by d'Almeida for projection; and, later, by Ducos du Hauron for photo-mechanical printing. Instead of light-filters, polarisers have been used for projection by Anderton, Boys, &c. For various applications of polarised light in photography, see Eder's "Jahrbuch," 1895, p. 406.

<sup>11</sup> Abney. Eder's "Jahrbuch," 1896, p. 128.

partly characterised as very active fluorescent media. We enumerate a few:—

1. Solution of sulphate of quinine.
2. Solution of aesculin,
3. Solution of fluorescein,
4. Bisulphide of carbon (Miller, "Phil. Trans.," 1862, p. 861).
5. Petroleum.
6. Solutions of nitrates of alkalis. (Ervera, Eder's "Jahrbuch," 1900, p. 22).
7. Various kinds of glass, especially uranium glass, &c.<sup>13</sup>

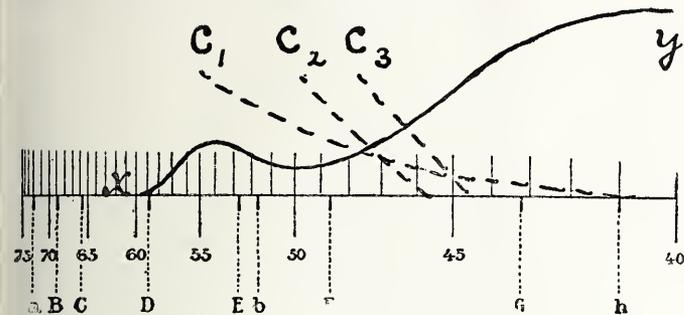

FIG. 1.

There is an exceptionally comprehensive literature relating to compensating filters. For nearly every one of the numerous organic yellow dyes some special preference is claimed. I give the names of some which are more especially recommended:—

Acridin yellow, auramin O, aurantia, aurin, brilliant yellow, chrysoïdin, dimethyl-orange and methyl-orange, martius yellow, picric acid and alts, primulin, tropäolin, Victoria yellow. (As a handy guide to the organic dyestuffs, see "Tabellarische Uebersicht über die künstl. org. Farbstoffe," Schultz and Julius, and Formanek's "Spectralanalytischer Nachweis künstl. org. Farbstoffe," Berlin, 1900).

Among the inorganic media, special mention should be made of the use of solutions of bichromate.

Ready-made yellow screens, yellow glass, &c., have been sold commercially for some time. C. Zeiss, of Jena, supplies them in three shades.

Cadett and Neall, Ashted, Surrey, supply screens of two shades for their spectrum plates. The "Absolutus," or darker screen, gives the nearest possible correct rendering, whilst for shorter exposures the "Gilvus," or planer screen, is supplied, but is less correct.

Compensating filters are used for the reproduction of paintings, landscapes, portraits,<sup>13</sup> and scientific purposes (spectrum photographs, &c.).

Several filters may be used in combination, viz.:—

1. Simultaneously in superposition (subtractive combination).
2. Successively (additive combination).

Both methods have been recommended for purposes of compensation. Burchett<sup>14</sup> combines green and yellow, as a subtractive method, in front of and behind the lens. Vidal<sup>15</sup> and Hruza<sup>16</sup> use additive combination by changing the filter. It is evident that the field for combination is very extensive.

4. CONTRAST FILTERS.

If certain colours of the object are to be brought out and accentuated in the photograph, a filter complementary to it in colour must be selected. This is called a contrast filter.

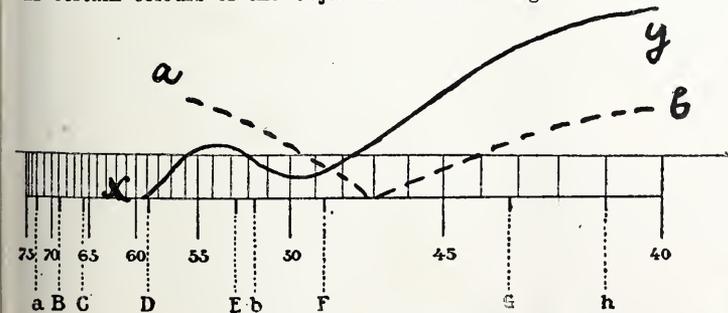

FIG. 2.

tuated in the photograph, a filter complementary to it in colour must be selected. This is called a contrast filter.

<sup>12</sup> Eder's "Handbuch," i. p. 281.  
<sup>13</sup> Bergheim recommends yellow studio blinds. Eder's "Jahrbuch," 1897, p. 303.  
<sup>14</sup> Eder's "Jahrbuch," 1895, p. 382.  
<sup>15</sup> Eder's "Jahrbuch," 1891, p. 437. Duchocôis, ib., 1895, p. 437.  
<sup>16</sup> Eder's "Jahrbuch," 1894, p. 53. Hruza combines in a cumbersome way three selective filters. See following reference.

These are mostly used in micro-photography, where very delicately-coloured objects frequently present themselves, and they are likewise used in photographing clouds, when the blue sky has to be shown as a black background.

Fig. 2 shows the action of a contrast filter, combined with the process, x, y, the curve of transmission of the colour to the contrasted being b.

The literature of contrast filters is also exceptionally comprehensive. The discussion constantly turns upon the point indicated above.<sup>17</sup>

5. MONOCHROMATIC FILTERS.

In the strict acceptance of the word there are no monochromatic filters, but for the sake of simplicity filters have been so called that only transmit very narrow bands of the spectrum. According to the process used, very different filters will exhibit the same monochromatic action.

Monochromatic filters are mostly used for photographing with lenses forming a chromatic image (micro-photography,<sup>18</sup> astro-photography, &c.).

We enumerate some of the most important filters:—

1. Ultra-violet. This would be valuable for many purposes (Schumann), but none yet recognised.
2. Violet. Zettnow, iodide of copper, Eder's "Jahrbuch," 1893, p. 262; Gifford, methyl-violet + gentian violet + blue glass; methyl-green + blue glass, Eder's "Jahrbuch," 1896, p. 303.
3. Blue. Fehling's solution, ammonio-oxide of copper. In 1888 Lohse did not know of any blue filter that did not simultaneously transmit red, and concluded it was theoretically impossible to make one. Now many such are known.
4. Green. Zettnow, chromate of copper filter, Centralblatt für Bact., &c., 188, p. 51; Gifford, benzaldehyde green + picric acid, Eder's "Jahrbuch," 1895, p. 217.
5. Red. Zettnow, oxide of copper glass, "Phot. Corr.," 1889, July. Nagel gives a complete list in the "Biol. Centralblatt," xviii. p. 649.

This short statement shows how extensively the subtractive combination filters have been explored. Their use is of much value for the transmission of small bands of the spectrum. Landolt<sup>19</sup> makes extensive use of this method of polarimetric purpose.

6. PROTECTIVE FILTERS.

Protective filters are used for regulating the light of rooms where preparations have to be preserved from the action of light. Such filters, generally speaking, should only transmit light which has no effect upon the preparations in question, or only affects them after

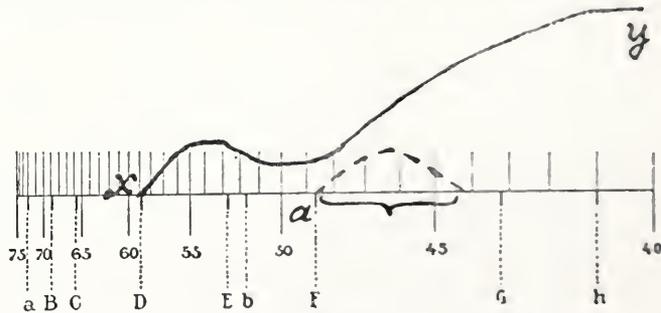

FIG. 3.

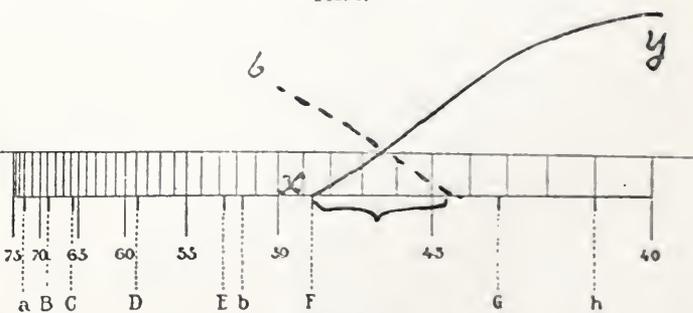

FIG. 4.

exposure for a considerable length of time. The colour of the filter should therefore be complementary to the actinic colours.

<sup>17</sup> Exhaustively treated by W. Gebhardt, "Phot. Rundschau," xiii. p. 43. "Intern. Phot. Monatschrift," vi pp. 49, 73, 95, 113.  
<sup>18</sup> See Neuhaus, "Lehrbuch der Micro-photographie," 2nd ed., pp. 66 to 74.  
<sup>19</sup> Method of determining rotary dispersion by means of light filters. "Ber. der deutsch. chem. Ges.," vol. xxvii pp. 2872 to 2887.

For most printing processes very pale yellow filters suffice; for Daguerreotype and the albumen process, the filter should be deeper; for the wet-collodion process, a pale orange filter; for the ordinary dry process, a deep orange filter; for the ordinary orthochromatic plate, a red filter; for Lumière's panchromatic plates, a dark-green filter. Cadett's spectrum plates (deep red) should only be exposed to the extreme red.

Cadett offers commercially "safe glasses," which are a subtractive combination of several dyestuffs.

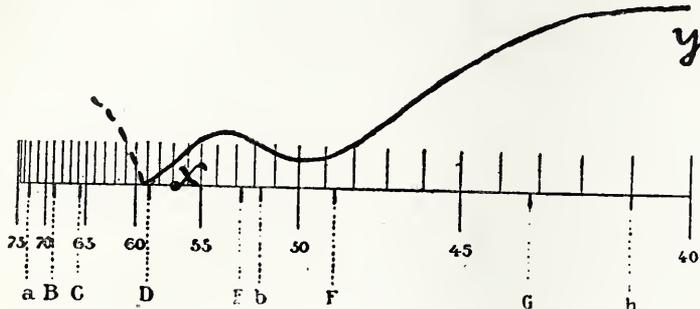

FIG. 5

Fig. 5 shows the action of a protective filter in the case of process x y.

Much has also been written upon this subject.

As subtractive combinations H. W. Vogel has recommended massive copper ruby + gold ruby glass; Miethe<sup>20</sup> copper ruby + cobalt glass.

#### 7. SELECTIVE FILTERS.

Combination filters, used in the indirect method of composite colour photography are called selective filters. Their purpose is for the selection of certain groups of colour from the object to be photographed. This process is called optical colour selection<sup>21</sup> (analysis, separation of colours, decomposition), in contradistinction to manual colour selection, which has been much used since Le Blon's investigations. Selection is generally supplemented by the second process of optical synthesis (colour reconstruction), the object of which is to reproduce the colour of the object as correctly as possible.

The optical synthesis may be done by two independent methods of admixture:—

1. The additive method of admixture (actual light mixture). The primary colour system of the three-colour synthesis, red, green, and blue-violet.

2. Subtractive method of admixture (mixture of colour substances). The primary colour system of the three-colour plates: pale blue, purple, and yellow.

The various synthetical processes are already mentioned under the visual light filters.

The history of optical colour selection has been traced back as far as the year 1861.

The English physicist, James Clerk-Maxwell, made the following statement on May 17, 1861, in a paper read before the Royal Institution:—

"Three photographs of a coloured ribbon, taken through the three coloured solutions respectively (three glass troughs, containing, respectively, sulphocyanide of iron, chloride of copper, and ammoniated copper), were introduced into the lantern, giving images representing the red, the green, and the blue parts separately. When these were superposed, a coloured image was seen, which, if the red and green images had been as fully photographed as the blue, would have been a truly coloured image of the ribbon. By finding photographic materials more sensitive to the less refrangible rays, the representation of the colours of the objects might be greatly improved."<sup>22</sup>

Twelve years passed before anything more was done in the direction of solving the problem enunciated by Maxwell. Meanwhile others occupied themselves with the process of selection set out by Maxwell.

The English miniature painter, Collen<sup>23</sup> and Baron Ransonnet,<sup>24</sup> of Vienna, in 1865, selected red, yellow, and blue filters, but worked upon Brewster's incorrect theory of the three physical primary colours.

<sup>20</sup> Eder's "Jahrbuch," 1895, p. 380. For complete information concerning dark-room illumination, see Baynton, "Process Photogram," 1900, p. 142.

<sup>21</sup> In France, trichromatic photography is called "triple selection." Monpillard, "Bull. Soc. Franc.," 1898, p. 535.

<sup>22</sup> Proceedings of the Royal Inst., "British Journal," 1861, p. 270.

<sup>23</sup> "Brit. Journ. of Phot.," 1865, p. 547.

<sup>24</sup> "Photo Corresp.," 1860, p. 199.

Ducos du Hauron<sup>25</sup> in 1868, Cros<sup>26</sup> in 1869, and Husnik<sup>27</sup> in 1870, on the other hand, used Maxwell's filters, red, green, and violet, which correspond with the Young-Helmholtz theory of the three primary sensations, which was Maxwell's starting-point. Maxwell's synthetic method was additive (tri-chromatic projection), but he also indicated the possibility of the subtractive method upon paper (three-colour printing). The work of Collen, Ransonnet, Ducos du Hauron, Cros, and Husnik was, on the other hand, principally in the direction of the subtractive method of synthesis.

DR. GREBE, Jena.

(To be continued.)

#### BELGIUM—A RETROSPECT.

##### IV.

MOST Flemish cities at intervals manufacture a festival or carnival in honour of some departed worthy, and Bruges is no exception. In 1884 they had a particularly grand show in remembrance of Charles le Bon. The procession was about a mile long, and must have taken an immense amount of trouble to arrange. Unfortunately the first day the cortège perambulated the city the weather was unpropitious, and I am afraid several of the chief performers had an uncomfortable time of it. Two days afterwards the procession was to go over the same route again, and at some inconvenience I went to Bruges and engaged a window in the Grande Place, just where I thought I could get some satisfactory pictures of this unusual festival. The time came. I was all fixed up at the window ready. The band was heard in the distance, and the procession entered the square, only on this occasion, for some unexplained reason, it passed across on the opposite side of it. The waiting crowd easily accommodated themselves to the circumstances by rushing across the large open space, while I—well, I packed up and paid for the window with the best grace I could assume under the trying circumstances.

The interior of St. Sauveur was beautifully decorated for the festival, and I was very desirous of getting a plate of it. I was informed that the only time it could be done was while the priests changed their robes after the first portion of the procession. I arranged to give a certain signal at one of the small doors, and if all was clear the verger promised to let me in. I arrived at the time stated, and gave the signal. The verger stealthily opened the door, and I lost no time in getting to work. After a few minutes a small bell rang, and I had to "clear out." I had got what I wanted, however (so had the verger), and felt to a certain extent compensated for my disappointment in the square.

I might here mention that among the annual festivals in Belgium perhaps the most noteworthy is the great procession of "Notre Dame," which takes place in Antwerp on the Sunday following August 15. Years ago it took place on that date. It was looked upon at that time as an ordinary occurrence, and attracted few beyond the townspeople; then there was little difficulty in obtaining satisfactory photographs of the procession from any window en route, or even near the altar in the Place de Meir. Now this festival is more noised abroad; immense numbers visit the city on the occasion; every coign of vantage is crammed with sightseers, and two years ago a friend of mine counted 90 cameras in and around the Place de Meir.

From Bruges the next halt is usually Ostend. If any class of school children were asked what this port was noted for, the answer would most likely be "Rabbits." If the question were asked of a lady who had been there, the reply would probably be, "Varieties in bathing costumes." If the inquiry were made of the father of a family of grown-up daughters, who had spent the season on the Digue, he might reply, "The number of times it is possible for a lady to change her costume between the hours of ten and five o'clock." With the reply of the children, I'm afraid I could not agree, as I have never seen a rabbit in Ostend; but the other answers I should regard as tolerably right, and it may therefore be taken for granted that Ostend is (during the season) a place where the snapshotist will find plenty of opportunity for getting through his stock of plates.

The difference in the state of Ostend in season and out of season can only be understood by those who have seen it under both conditions; and when Mr. Traill Taylor and I were there, in the early October of 1889, my companion could scarcely credit this was the place of whose festivities he had heard so much. We had arranged

<sup>25</sup> Privileg. 23 Nov., 1868, No. 83,061. Eder's "Handbueh," vol. 8, p. 443.

<sup>26</sup> "Les Mondes," 1869.

<sup>27</sup> "Phot. Mitth.," 1870, p. 2, and "Phot. Corresp.," 1878, p. 1.

to spend our last day here, and a quiet day it undoubtedly was; that is if the wind were left out of consideration. The Digue, which only a few days before had been all gaiety, was now deserted. Well I remember standing under the shelter of the Kursaal while my genial friend discoursed on Yankee experiences, and warbled the old American revival song—

“Roll, Jordan, Roll;  
Oh, Brudder, you ought to be dere,  
A-sittin’ in de Kingdom,  
To hear Jordan Roll.”

We had arranged to leave Ostend next morning by the early boat (5 a.m.), but by that time the wind had increased to a gale, and we decided to postpone our departure until 10.45, on the chance of better weather. After breakfast the wind had moderated a little, and, as I had an important engagement in London that evening, there was no alternative but to risk it, and on board we went. It poured in torrents, and the sky was black with angry-looking clouds. It was the worst crossing I ever experienced, and the boat arrived at Dover so much behind time that all hand luggage (such as ours) was allowed to pass unexamined by the Customs. We were just settling down comfortably in the carriage as the train steamed out of Dover when I noticed a sorrowful expression on the face of my companion. “Ah, lad!” said he, “if I had only known our luggage would not have been examined, I’d have brought over another couple of pounds of that ‘American cake tobacco.’”

We arrived in London only just in time for my appointment, and, although the sea between Ostend and Dover had treated us “the north side of friendly,” I always look back upon that tour as one of the most enjoyable I ever spent in Belgium.

I have occupied so much space with the attractions of Antwerp, Brussels, Bruges, Ghent, and Malines that I am afraid I shall have to group many other places, interesting both historically and photographically. Those of my readers who have time will do well to visit Louvain, with its richly-decorated fifteenth century Town Hall; Liège, with its many churches, statues, gun and sword factories, and vast iron works founded by John Cockerill, occupying nearly 300 acres of ground, and employing about 10,000 hands; Chaudfontaine, with its charming views; Namur, with its excursion down the Meuse (a river in many respects equal to the Rhine) to Dinant, with its market place; Roche Bayard, Anseremme, Chateaux Walzin, and Freyer; Hastiere, and the grottoes of Rochfort and Han; Huy, with its fine old gateway; and several villages between Namur and Dinant, where a most enjoyable time may be spent at a comparatively trifling cost.

Innumerable snapshots may be obtained everywhere, and the little carts drawn by dogs are all over the country. In many districts the wooden shoes are being gradually displaced in favour of leather, but, in the majority of the villages, more especially on the Dutch side, the sabots, white caps, and bright brass milk cans are still to be found as of old.

There is one thing in which the Belgians are as bad as the English. They allow advertising boards by the sides of the railway lines, and even in some cases the sides of the cottages are painted with gaudy advertisements. In our photographic journals from time to time we see complaints of “disfiguring the landscape” by such malpractices. But I wonder what would happen if some of those who cry out on this subject became possessed of eligible property where these eyesores already existed? Would they remove them; or would the complaints of “disfiguring the landscape” cease?

In the old days the Belgians were contented with their own time, and it was a little awkward to find you had gained 20 minutes on the journey. Now Greenwich time is used on all the railways there, which greatly facilitates matters, although their time-tables with trains from 1 minute past 0 to 59 minutes past 25 are a little confusing until you get used to them.

Were I to relate all the odd experiences I have had among the French-Flemish people I should occupy more space than is at my disposal. Latterly, I have heard of English tourists not having been treated courteously in Belgium, and this may, of course, be true, as I am rather sorry to see that a misguided few of King Leopold’s subjects are forgetting the terms of a certain treaty signed in London in November, 1831, and do not seem fully to understand the meaning of the word neutrality. Still, the little mistakes of a handful of discontented people must not be taken as a fair sample of a nation. Personally, I have always received at the hands of the Belgians the

greatest courtesy and consideration, and I am sure I can promise the same treatment to any one else, who during his visit abstains from discussing political and religious matters, recognises that it is quite possible for an Englishman to be a foreigner, and that the possession of a thirty shilling tourist ticket does not entitle the holder to “boss” the country.

Finally, if any of your readers think of going to Belgium, I hope they will not allow the photographs which appear in some of our English railway carriages to upset their plans. These illustrations are intended to act as an inducement to would-be tourists, and many of them are excellent. But, had Belgium not been more attractive than some of these smudges represent it, this article would never have been written.

F. A. BRIDGE.

#### THE NEW AMERICAN SCHOOL FROM AN AMERICAN PHOTOGRAPHIC POINT OF VIEW.

WRITING of the recently-held Exhibition of the Philadelphia Photographic Salon, our contemporary “Anthony’s Bulletin” remarks that those who rule the destinies of “high-art” photography in America have sat in solemn council and have chosen some 120 prints as worthy of being admitted to public view; a number of photographers whose qualifications are beyond cavil, or who do not approve of being judged, have contributed almost as many more; and these 204 photographs, hung in the gallery of the Philadelphia Academy of Fine Arts, constitute the third Philadelphia Photographic Salon.

Much has been said, proceeds the article, as to the wonderful advance which has been made by these men, as compared with the professional photographers of America; and this Exhibition affords an opportunity of judging the value of the statements made.

Of the 200 prints exhibited, only 80 can, by any stretch of courtesy, be called portraits, the remainder are figure studies or outdoor scenes. From these 80 we can learn the strength and the weakness of the new school.

These advanced workers evidently prefer revolution to evolution, and in endeavouring to create an “art” have succeeded in creating an extreme, and at times a crazy, fashion. They have decided that professional photography is beyond salvation, and have never discovered that its salvation has actually been achieved—and from within. It is so very easy—flippantly easy—to find cause for fault, and those who have condemned the professional photographer have no excuse except crass ignorance. There are lots of bad professional work—but there is good. And there is much good. The idea that professional photography is “bad” has led these workers into strange blunders. They have gone on the idea that the reverse of bad must be good, and that therefore, if their work is totally unlike the usual thing, why, then it must be “artistic.” Therefore, as cardinal sins in a photograph are likeness, and clearness, and detail, and retouching, they get rid of these. Never mind about likeness; instead of calling it a portrait, it can be termed a “study,” and will be the better for it. Clearness and detail, with half a dozen other possible beauties, are sacrificed at one fell swoop by the choice of a paper. By sensitising his own paper the photographer can get any degree of roughness or texture or colour for his support. By the use of gum bichromate he can get any extreme of granularity or indistinctness. So we have little prints, not larger than a cabinet, formed of such big splotches of gum that three of them will make a nose, or a dozen of them will cover a face. It is no question of being critical; it is a simple impossibility to escape from the texture. Step back from the photograph, as though it were a fragment of a great enlargement, and the grain follows you as far as you can see any meaning in the picture. We hear of brush development; subordinate detail, so that the “motif” of a picture can be seen. Motif! save the mark! They give us pictures with an eye and a nose, a forehead and a chin. The mouth is a smudge of black; and sometimes, too, the eye. The hair and background and coat are all one vast mass of daub. The hair blends into the background, and there is no suggestion of any dividing line. It is mounted on a patch of brown wrapping paper to make a mat a quarter inch all round the picture, and this mat is in turn mounted on a much larger one of some green or grey tint. A fancy signature is appended, and maybe it is framed.

To speak plainly, it is so very, very easy to make an “artistic” picture. A print is made, from an execrable negative, and the artist fakes, and dabbles, and restrains, and coaxes; and at last he has got some-

thing. He did not know exactly what he was after; but he knew he was after "something." And by the time he has got it he has pored so long over it that really he does not know how to judge it. So it is mounted, and some kindred soul comes along and says, "I like that; it appeals to me"—and off it goes to the Salon and to fame.

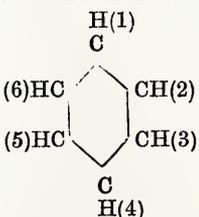

There is good work at the Salon; work which is sound photography and good art. And there is work that would give hints in pose, &c., to the wide-awake professional. But any one, from a dozen of our leading photographers, could choose six—or twenty—of his best portraits, and they would hold their own—and more—with the best of the Salon work. Francis Watts Lee has two lovely things, one of them a portrait of two little sisters. Miss Watson—whose work is all good—shows one of the daintiest and most delicate—withal strong—heads that photography has produced. The "Portrait of a Baby" by Alfred Stieglitz is a delightful bit; and he has one of a mother and child looking out of a window, which should gladden the heart of any photographer who can appreciate a good thing.

A longer list could be made of the bad work than of the good. But the good—from two or three workers—is very good, and that because they are not in the immature stage of revolt against "photographic quality." But the chief hope for the new school is in its utter weakness. So much has it gone off the track that it will only save itself from utter grief by a thorough recantation. It has been said—and hoped—that the amateur would raise the level of the best professional work. He must, instead, if he would live, reap his wild oats by a course of humble discipleship under the leaders of the men he has despised.

### PHOTOGRAPHIC DEVELOPERS.

[A Paper read before the Andersonian Chemical Society in the Glasgow and West of Scotland Technical College.]

THE number of photographic developers is nowadays so great that a proper knowledge of their properties and suitability for various processes requires a long practical acquaintance with them. The knowledge of their chemical constitution and properties is of great assistance in the proper understanding of the action of developers and their application. The behaviour of a developer is in some way connected with its constitution, though at present it is not very well understood. A developer consists of two amido (NH<sub>2</sub>), or two hydroxy (HO), or an amido and a hydroxy group at least united in a certain way. They may be quite simple, as in hydrazine (NH<sub>2</sub>.NH<sub>2</sub>), or hydroxylamine (NH<sub>2</sub>.HO), or hydroxyl (HO.HO). They may be united by benzene, or a benzene derivative, in which case they displace one of the hydrogen atoms. They must also be in the ortho or para relation

to each other. In this benzene ring  the hydrogen atoms, 1 and 2, are in the ortho, and 3 in the meta, and 1 and 4 are in the para relationship. When they are in the meta relationship the substance does not develop. In naphthalene derivatives it is not known whether meta compounds are developers or not. In benzene compounds the groups must be joined to the same nucleus as in diamido

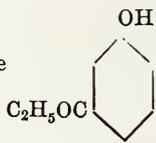

oxydiphenal (NH<sub>2</sub>)C<sub>6</sub>H<sub>4</sub>.C<sub>6</sub>H<sub>3</sub>. In this compound the first amido compound takes no part in the developing action. The association of the benzene nuclei in naphthalene is more intimate than in diphenal, thus it is that the groups in the case of naphthalene need not be in the developers, and are not much used as such. The amido group works well in conjunction with a hydroxy group, and some of the most powerful developers consist of benzene derivatives having such compounds. The substitution of hydrogen atoms of the amido groups by alkyl radicles, such as CH<sub>3</sub> and C<sub>2</sub>H<sub>5</sub>, has given some very useful and powerful developers. Such substitution produces compounds like

dimethyl-phenylene-diamine  $C_6H_4 \begin{matrix} NCH_3 \\ | \\ NCH_3 \end{matrix}$  and dimethyl-para-amido-phenol  $C_6H_4 \begin{matrix} NCH_3 \\ | \\ OH \end{matrix}$ . These derivatives are easily oxidised, and are good developers. When the hydrogen of the hydroxyl group is replaced by an alkyl radicle developing power is destroyed. Thus quinol

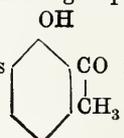

monoethyl ether  $C_6H_4 \begin{matrix} OH(1) \\ | \\ OC_2H_5(4) \end{matrix}$  does not develop. If one of the groups, whether amido or hydroxy, be in the side chain of a benzene derivative, the substance possesses no developing power. Such a com-

compound is represented in para-amido-phenol  $C_6H_4 \begin{matrix} NH_2 \\ | \\ C \begin{matrix} OH \\ | \\ CH_3 \\ | \\ H \end{matrix} \end{matrix}$ . The

presence of a carboxylic group (COOH) in the benzene nucleus destroys developing power, even when it is neutralised by powerful alkalies, but when it is etherised the substance becomes a developer. Such a

compound would be . The presence of sulphuric acid

has very little effect on the developing power, but it greatly increases the solubility of the developer in water, the influence of the ketonic group (=CO) is rather curious. In simple

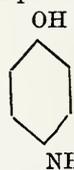

phenols, as  it confers developing power, and thus this deriva-

tive is an exception to the general law. The ketonic group may unite a developing benzene derivative to another body, and, if this other body has no hydroxy groups, the compound possesses developing power, but if a hydroxy group be introduced into what may be called a side chain developing power is destroyed. The developing power of a benzene derivative cannot thus be increased by the joining to it of another derivative which has developing power.

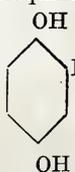

The addition of another amido group to a hydroxy-amido developer increases the developing power, but is liable to cause the developer to become slow in action towards the end of development. This is supposed to be due to production of secondary amines which neutralise the effect of the rest of the developer. Tri-amido-phenol and tetra-amido-phenol, which should be very powerful developers, are comparatively useless for this reason. Tri-amido-phenol will work, however, in conjunction with mono-sodium phosphate and sodium sulphite. This is probably due to the acidic character of mono-sodium phosphate.

One wonders why such simple developers as hydrazine, hydroxylamine, and hydroxyl are not used. This is because the first two liberate nitrogen, while hydroxyl liberates oxygen. These gases cause the bubbles to swell off in small blisters. It is curious that hydroxyl, which is a powerful oxidiser, here plays the part of a reducing agent. Hydroxyl is known to reduce silver oxide with the liberation of oxygen.

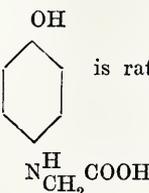

I am enabled, by the kindness of Messrs. A. & M. Zimmermann, the agents of the Actien-Gesellschaft für Anilinfabrikation, to exhibit specimens of developers which I will proceed to describe. Amidol or hydro-

chloride of diamido-phenol  occurs as sparkling white

crystals, which gradually blacken. It is easily soluble in water, and is used in conjunction with sodium sulphite and potassium bromide. The addition of alkalies is not necessary. It gives an image of a splendid blue-black tone. It develops rapidly at first, but soon slows down, and then works very slowly, giving poor density in plates. For this reason it is only used for bromide papers, and is probably the best for this purpose. Its disadvantage is that it will not keep more than a few days. Metol or sulphate of methyl para-amido-phenol occurs as a crystalline powder. Easily soluble in water, it is used in conjunction with NO<sub>2</sub>SO<sub>3</sub>, with alkali carbonates as accelerators. It is a fairly powerful developer, and is well suited for under-exposures. The image comes up very quickly, and density is built up better than with amidol. Ortol or sulphate of methyl-ortho-amido-phenol is similar to metol, only that it is less powerful. It does not oxidise so readily. The same solution may be used over again. I have heard of 48 successive plates being developed in the same solution. A modification of hydroquinone is sold under the name of hydroquinone Br.

Its formula is . It is extremely free from fogging in its

action, and is admirably adapted for the development of over-exposed plates.

Glycin or para-oxyphenyl-glycin  is rather a curious de-

veloper. The peculiarity of it is its very low power. At first sight it should appear slightly more powerful than para-amido-phenol, but it has only about a third the power of that body. This is because it is properly glycin (NH<sub>2</sub>CH<sub>2</sub>COOH), in which one of the hydrogen atoms has been replaced by a molecule of phenol. Glycin is very soluble in water, giving an acid solution which keeps well. It is very free from stain.

Dianine is diamido-resorcin, which I have described. Rodinal is the sodium salt of para-amido-phenol dissolved in a concentrated solution of sodium sulphite. It keeps very well, and is convenient in use, simply requiring dilution. It is the most powerful developer known, and is about the best for extreme under-exposure. After having tried this developer one is not inclined to develop under-exposures for two hours with a pyro-ammonia developer of strength one quarter-grain per ounce when the same result is got in twenty minutes with rodinal.

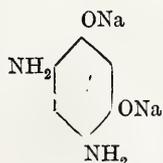

Eikonogen is a developer that has gone much out of fashion, probably because the large amount of 3.5 per cent. in the developer clashes with the average amateur's idea of thrift. This developer is an excellent one for slight under-exposures, and can conveniently be used in a single solution.

Hydroquinone and para-phenyl-endiamine unite in molecular proportion to form brilliant scales slightly soluble in cold water. It is sold under the name of hydramine. It works very slowly as a developer in the ordinary way, but the addition of caustic lithia in a small quantity enormously increases its speed. It is extremely sensitive to the restraining action of potassium bromide. It will develop until the solution is completely exhausted of developer. It requires less sulphite than other developers. Owing to the small quantity of salts in the developing solution the frilling of the gelatine is greatly mitigated.

I have here a sample from Messrs. John J. Griffin and Sons of a dihydroxyl developer sold under the name of kachin, and otherwise known as pyrocatechin or catechol. This developer has slightly less power than hydroquinone, and has to be used in a larger quantity in the developer. It is not so easily oxidised, and is very clean in working. I have here a negative developed with kachin, and you will see the blackness of the image. It has made a very flat scene into a passable photograph. Borax restrains this developer better than KBr. It is curious that borax acts as a restrainer with some developers, while with others it acts as an accelerator. This is noticed with pyrogallol. The reason is borax combines with certain polyhydric alcohols forming energetic conjugated acids. No such action takes place with quinol, eikonogen, or hydroxylamine-hydrochloride, in which case it acts as an accelerator.

Kachin is the only developer that sodium thiosulphite has no restraining action upon, and it may be added to the developing solution in sufficient strength to fix the plate simultaneously with development.

Resorcinal is well known not to be possessed of developing power, but when amido groups are introduced, and suitably arranged, it becomes a very useful developer. Diamido-resorcin (2.4) used in a 1 per cent. solution, with 3 per cent. of sodium sulphite anhydrous, as a developer. It gives very good results. The graduations are even, and the image is clear. The addition of sodium carbonate raised the speed, but not the power. The best is 8 per cent., which is a little in excess of that required to form the theoretical compound:—

In conclusion, I may say I believe that any substance is a developer which is capable on oxidation with silver bromide, especially if it has been exposed to light, forming a quinone-like compound, and the ease with which this takes place, especially in the presence of retarding agents, is a measure of the power of the developer.

ALEXANDER D. LEIPPER.

SOME NOTES ON INTENSIFICATION.

It is curious, even among those who have learned their technical work pretty thoroughly, occasions arise, when developing plates, where, for one or other reason, it becomes difficult to obtain full printing density without risking the introduction of other, and worse, evils.

Small wonder is it those less experienced find this obtaining uniformity of density difficult, if not, indeed, impossible, the main trouble in their case being the plates are not allowed to remain in the developing solution for sufficient time, with the result, after fixation has taken place, what had seemed likely to prove fairly vigorous images turn out but ghostly affairs.

Often enough over-exposure in the hands of a beginner is another cause of unduly thin negatives, unless means are taken at the outset to guard against it.

There can be no doubt to take such steps as may be required for the rectifying of errors in exposure during development is better than having to depend upon any after process, either of intensification or reduction.

Yet, easy as it appears to so adjust development as to nullify any errors, there are numerous occasions when negatives suffer from want of intensity, and in such instances it is well to try improvements.

When development has simply been stopped at too early a stage, the image presents a thin, delicate appearance, free from veil or fog. With such a plate a ready mode of strengthening it is to employ the uranium intensifier.

Before treating with this, or, indeed, most other forms of intensification, the plate should be first subjected to a thorough and effective washing, which, if possible, ought to take place in running water; failing this, changes are made at frequent intervals.

If this is not done, and practically the last trace of hypo eliminated, stains follow, and the negative, instead of being improved, is ruined.

Assuming thorough washing to have taken place, immersion for such time as necessary in a solution made up of—

Potassium ferricyanide .....	1 part.
Uranium nitrate .....	1 part.
Glacial acetic acid .....	10 parts.
Water .....	100 parts.

will result in a change of colour, and at the same time the image is bodily strengthened

When sufficient intensification is judged to have taken place, the plate is bathed in a dilute solution of acetic acid in water, then washed for a short while, dried, and is ready for printing from.

This is a useful method, because, should the result not prove satisfactory, soaking in weak solution of ammoniated water restores it to its original condition.

Again, if but some portion needs additional density, it is so simple a matter to clear away the uranium deposit where not required.

To do this so that no markings shall show needs time spent over it, and plenty of water used to keep the edges softly defined. With care radical alterations may undoubtedly be made, but one cannot help feeling better means are available, either chemical or by stumping with lead or chalk powder.

Uranium, as a means of intensification, is perhaps of most service where the additional density is only required for temporary purposes, as when a negative has purposely been made thin for some particular printing process, bromide or C.C. platinotype paper, for instance, and it is desired to print from it in a medium, such as carbon or rough silver paper, for a time: then the addition light-resisting property is rapidly given by means of this salt, and as rapidly removed when necessity for it has been fulfilled.

Among more permanent means to the same end is that of first bleaching the image in a saturated solution of bichloride of mercury, to each ounce of which should be added one minim of hydrochloric acid, the function of the acid being to prevent any formation of prejudicial compounds.

The plate is then thoroughly washed, and afterwards developed, in daylight, with the following:—

- A. Saturated solution of ferrous sulphate.
- B. Saturated solution of potassium oxalate.

These are mixed in the usual proportion of one part A poured into four parts of B.

After the image is sufficiently redeveloped, it is washed for a time, then subjected to a dilute bath of hydrochloric or citric acid, again well washed, and dried.

The above method is recommended by Mr. Chapman Jones, and perhaps no better authority upon intensification and kindred work exists.

There is one matter well to attend to in commencing such treatment of gelatine plates which have been dried, namely, to thoroughly soak them in clean water, preferably such as has been boiled, otherwise at times a curious reticulation of the film is liable to take place: why, is not so clear, but in practice this trouble does not appear when a preliminary soaking in water has been given.

Many negatives one sees, especially those produced on very rapid

plates, which have had shutter exposures, as when doing hand-camera work, require not only general intensification, but their shadows clearing; in other words, reduction first, followed by intensification.

In such instances, as ready and effective means as any is Howard Farmer's ferridcyanide and hypo, seeing that it is absolutely under control, and may be applied so soon as the plate comes from the fixing bath, and slight clearing up of the shadows is found necessary.

A good washing follows. Then either the plate is dried and intensified at some convenient time, or it may be proceeded with the moment all traces of hypo have been got rid of.

For several reasons it is better, however, to defer this part of the operation, one being, a film of gelatine, undergoing such treatment, becomes exceedingly tender and liable to blister or frill; and yet a further reason, one can better judge the degree of additional density required when examining a plate in a dry condition, its appearance while wet often proving deceptive. It would serve no useful purpose to give but a tithe of the formulæ for intensifying which have appeared from time to time, but one which will give admirable results is that known as the copper process.

The plates being first bleached in the following:—

Sulphate of copper .....	2 drachms.
Ammonium bromide .....	½ oz.
Water .....	10 oz.

When it appears thoroughly white all over, and right through at the back, wash and develop in daylight by means of any developing agent conveniently at hand. On completion, another and thorough washing follows, and after drying the negative is ready for use.

To many who may dislike using mercury, on account of its highly poisonous nature, the copper method of arriving at the same result may prove useful, for it answers perfectly.

So far, consideration has been given to the general intensification of original negatives by chemical means; but, where a little time and trouble is not objected to, it seems a pity, instead of so often trying to patch up a thin, flat image, the end is not obtained by reproduction, it simply means making a transparency on a slow plate, and from that another negative, either through the camera or by contact. By so doing all danger of spoiling the original plate is avoided. Nor have any deadly poisonous chemicals to be handled, while the control one has over the final result is far less restricted, for it may be made pretty much what is desired in regard to contrast and general density.

Many years ago, having exposed a rapid plate, and grossly overdone it, development in due time followed. At that period, being but young in the practice of photography, a normal developer was poured over the plate, and, of course, with the usual effect—the whole image flashed out, and rapidly began to veil. Being little more than a novice, and somewhat terror-stricken at the pet picture behaving in such fashion, the plate made a premature acquaintance with a strong hypo bath, the effect of which may be imagined. Instead of a negative of respectable appearance and density, a muddy-coloured ghost was all that remained to reward the time and money spent in obtaining models, posing them, then going through the needful manipulations of exposing, and so forth.

Time and time again was an attempt made to get some sort of a print from it, but without success, and it remained for years a silent reminder of the folly of commencing photography by using the most sensitive plate obtainable.

Circumstances arose necessitating a clearance being made of all lumber. Among other things, some 200 old negatives had to go, one of them being the particular one mentioned above. Perhaps it was a recollection of the wild hopes it had dashed to the ground which caused its being kept, and a trial made to get a printable negative from it. Any way, a few days later, when making some slides, it was placed in the camera, and a lantern plate received such part of its image as seemed worth keeping. Considering its extreme lack of density a full exposure was given, then development done with strongly-restrained hydroquinone; the result, a slide full of detail, right through from shadow to high light, and of ample density, which afterwards allowed a 12 × 10 enlarged negative being made in the ordinary way.

Where, for special reasons, the defective original may be important and impossible of rectification by other than after-treatment, this method of reproduction seems more safe, and by no means less expeditious, than attempting it by direct treatment on the original negative itself.

Some plates require selective intensification, that is, either the high lights need forcing or the reverse.

In the former condition considerable improvement seems to ensue by taking advantage of light action on bichromate, followed by soaking in a suitable aniline dye.

The gelatine film of a negative is more or less capable of absorption, to greater degree in those portions lightly charged with silver, and less so where partially holding the heaviest deposits. If, therefore, the shadows may be rendered insoluble, the half-tones partially so, the high lights left capable of fully absorbing matter, it follows a striking variation may be brought about if the whole film be subjected to a monochromatic coloured solution. For then what takes place is that greater

absorption ensues just where most needed, viz., in the high lights, to a lesser degree in the lower tones, and practically none in the shadows; this being brought about by first subjecting the negative to a bath of bichromate of potassium for a few minutes, at a strength of 1 drachm of the salt dissolved in 4 oz. of water, after which the plate is dried in the dark, but laid flat, instead of standing in a rack.

When dry, it only remains to expose it to daylight for ten minutes or so, but through the glass, as if printing, and it is better to place some dark or black material behind it to absorb any excess light, black cloth or velvet being convenient for the purpose.

The light, acting most through the thin deposits in the shadows, renders the gelatine in those parts insoluble, the half-tones partly so, and the high lights are left practically as they were.

After washing the plate to get rid of the bichromate, it may then be soaked in some aniline dye of non-actinic colour, red or yellow, when the more soluble parts will greedily absorb the dye, those not so soluble only partially, while the deep shadows, which had been rendered totally insoluble, take up none, and remain free of the foreign colouring matter. After this treatment the plate gives a print of altogether different quality than before, the high lights having been practically intensified and the shadows left in their original condition.

At times negatives suffer from opposite evils to that just dealt with, i.e., full density in high lights, but deficient of strength in the shadows, in which state of affairs, if the absorbing qualities of gelatine be again taken advantage of, but in this instance without calling in the tanning influence of the bichromate salt, we shall have the shadow absorbing the full extent of colour, while the already fully-charged portions of the negative take up but a trifling quantity. The plate, after such treatment, will be found to render the high lights when printing practically as before, but the various steps in gradation down to the deepest point of shadow will print far less deeply, what in this instance has taken place being the deep shadows have been rendered obstructive to the passage of actinal light rays in far greater proportion to the more dense deposits, or, in other words, we have intensified the shadows to the maximum extent, while leaving the high lights in the least disturbed condition.

For amateur workers who but at lengthy intervals may need to intensify a plate or two, no more convenient way of doing it exists than to use the mercury iodide "Tabloids," which are put up in those small glass phials, for at any time a fresh bath may be made up in a moment by dissolving one tabloid in one ounce of water and placing the plate in the solution. Intensification proceeds gradually straight away, and is concluded in one operation, it being merely necessary to take it out when sufficiently dense, wash, and dry it.

This does away with any danger or trouble in keeping mercury solutions, for the bath can be poured away the moment it has done its work and a fresh one made whenever needed.

Perhaps of all methods this mercury iodide has the merit of simplicity of working most marked, the plate merely being soaked in the solution till done, and the operation of intensifying is ended, nor does there seem any reason for its being less permanent than others.

By one or other of the methods mentioned very radical alterations in the printing values of any negative may be brought about; but, after all, they are but making the best of a bad job and only prayed in aid, failing the opportunity to rephotograph the subject and remedy faults by due adjustment of exposure to development.

W. THOMAS, F.R.P.S.

#### NOTES FROM THE NORTH.

THE one topic not considered out of place in Glasgow at the present time is the outlook for our coming International Exhibition, and how it hurts our native vanity to discover that in London scarcely anything seems to be known about it. One of our enterprising dealers went up to the Metropolis last week to make arrangements for a specially good display at his stall in the great Show, but, to his dismay, hardly a soul had heard or knew anything about the primary object of his errand, and the odd one or two who had heard a whisper were by no means sure whether it was not a photographic exhibition on a larger scale than usual. Of course, they were prepared to listen and to assent to propositions holding out a prospect of increased trade, but it surely argues culpable carelessness that important London dealers and manufacturers of optical and photographic goods should not be aware, in detail, of such an important means of reaching the retailer and consumer as this Exhibition will afford.

Since the Czar has practically arranged to pay it a visit, its international character has been more than ever assured, and as the Exhibition, both in extent and importance, promises to be the finest ever held in this country out of London, it cannot be ignored with safety by those who would keep a grip of the home and foreign markets. While there is evidence of the indifference of British manufacturers and traders, the foreigner has been very much alive to his interests, and more is probably known about the prospects of the Exhibition in Berlin and Hamburg than in London and Manchester. Several Con-

tinental firms are already represented by special agents on the ground, and the space secured by foreign exhibitors is out of proportion to what it would have been had our own people been fuller alive to their interests. It is thus trade is wrested from us, and we are being gradually ousted out of the markets of the world. But for the enterprise of the dealer referred to, the probability is that several specialities which can more than hold their own with Continental goods would not have been brought under the notice of the great photographic community.

Photographically, the Exhibition is to "lick creation," as the Yankees say. The photographic section of the Fine Art Department is to excel anything ever seen in this or in the other hemisphere. Mr. J. Craig Annan, the convener, might not say so in these very words, but these are his sentiments, all the same. The leading professional photographers have also come well to the front in applying for space. Time alone will show whether the quarter allotted to them is the best for their purpose. There is just the slightest ground for the suspicion that, in deciding to keep their cases as far as possible in one section, the Space Committee had chiefly in view the decoration of the approach to the Grand Hall in which the concerts will be given. In any case, they are all to be together, with the exception of Mr. W. M. Warneuke, who has secured space in the covered way connecting the Industrial Hall with the Concert Hall.

The dealers' stalls are to be situated in the Industrial Hall. The design which Messrs. Rae Bros. have already in hand will be one of the most striking in the hall. It is said that Kodak, Ltd., do not intend to run a stall, considering that their ends will be adequately served by their new warehouse in Buchanan-street. An early start is to be made with the erection of Messrs. T. and R. Annan's studio inside the Exhibition grounds. The studio is to be in keeping with the general design of the buildings as a whole, and is to be put up at the entire expense of the firm.

Mr. H. C. Shelley has been down lecturing in such small towns as Coatbridge, Kirkintilloch, and Bo'ness, but he has not appeared upon a platform in Glasgow. Many have been disappointed, and surprise has been expressed that one or other of the photographic societies has not secured his services. It may be the old story of a prophet having no honour in his own country, as Mr. Shelley is too well known in Glasgow to require an introduction. He returns this way again in the spring with his Transvaal lecture, when it may be arranged to give Glasgow a chance of hearing his graphic account of his part in the prolonged campaign. I believe Edinburgh is one of the towns on his engagement list.

Weather of the most wretched description has seriously interfered with the Christmas and New-year trade both among photographers and dealers. What avails tempting show-cases and windows as brilliant as electric light can make them when, day after day, the streets are swept morning, noon, and night with wind and rain. Happily, the unpropitious weather has not diminished the gaiety of the citizens, and the lantern and cinematograph have been more in demand than ever at entertainments in private houses.

Rumour has been very persistent of late regarding the intentions of the Glasgow and West of Scotland Society in the matter of new and more commodious rooms. Certain of the office-bearers deny that there is any immediate prospect of new rooms being secured, but a sharp look-out is being kept on all likely premises. A lodging in Blythswood-square was examined a few days ago, but the figure sought was, I understand, much beyond what the Association would be prepared to face. Down Ardrossan way, the amateur photographers of clubbable tastes have been fortunate enough to rent the premises formerly occupied by a professional worker, and, with a small expenditure, have adapted them to their needs. It is not every amateur society that finds itself in possession of a studio in the second year of its existence.

Thanks to the initiative of Mr. W. J. B. Halley, Hon. Treasurer of the Glasgow and West of Scotland Amateur Association, a beginning has been made with the formation of a photographic museum. Recently a very fine collection of Daguerreotypes was offered privately for sale. Mr. Halley had first choice, and purchased five for his Society, who have had them framed in the best manner known for their effective preservation, and hung on the walls of the Association's rooms. It is the intention of Mr. Halley and his fellow office-bearers to secure examples of the progress of photography from the days of the Daguerreotype downwards. In this they are following the course pursued many years ago by Mr. William Lang, F.C.S., and one of Glasgow's most enthusiastic amateurs, in forming what is now one of the finest collections of the kind in the country. The Glasgow Corporation are gradually acquiring a photographic antiquarian collection.

The present session of the Edinburgh Photographic Society has already produced more than one paper of widespread interest. The latest of the series was delivered at the last monthly meeting by Mr. W. E. Carnegie Dickson, B.Sc., on "Photography in Medicine and Surgery." In his opening remarks he dealt with the every-day ap-

plication of photography in affording illustrations of interesting cases, medical and surgical, in which art had no place, and with the annoyance the doctor feels when his best cases turn up in the winter months. He showed how difficulties were overcome in special cases by the use of the inverting or canting table and a tall tripod. He next touched upon the value of stereo-photography in the realm of scientific investigation, and of the importance of micro-photography in the study of histology. The last part of his paper covered the use of radiography. The former custom of the surgeon was never to attempt to remove a foreign substance by an operation unless he could feel it; now it was necessary to see it. Every hospital had now its X-ray department, and the South African war had proved the immense value of the discovery in dealing with bullet wounds and fractures.

A great deal of interest is being taken in colour photography in this quarter. The transparencies which were shown at the Royal Society to illustrate the present stage of the McDonough-Joly process have been on view, and been inspected by many hundreds during the past few weeks, at the Blythswood-square studio of Mr. W. M. Warneuke. Lord Kelvin has been attracted by the process, and at the annual conversazione of the Scottish Natural History Society, at which he presided in the Balmoral Hotel, Edinburgh, on the 15th inst., Mr. Warneuke attended at his lordship's request, and gave a demonstration of the process, the transparencies which were at the Royal Society being supplemented by a much larger number, as well as by a collection of lantern slides. Disappointment having been expressed that Mr. Warneuke's studio was only open in the daytime, it is his intention to arrange a number of evening demonstrations for the convenience of those engaged during the day.

Mr. Charles Reid, of Wishaw, is among the lecturers again with his inimitable collection of animal studies. These studies, I have reason to believe, are not sufficiently well known among those who arrange lantern entertainments for children, or the crudely-coloured, grotesquely drawn, and generally repulsive type of lantern slide so greatly run upon, would soon be consigned to deserved oblivion. There are many admirable lantern sets on the market, but the nightmarish "Jack the Giant Killer" type is still catalogued by dealers, along with other kindred atrocities. There should be an Act of Parliament passed to prohibit their display.

#### AN IMPROVED SELF-ACTING TONING PAPER.

[Patent No. 19,683 of 1899.]

In self-acting toning papers the soluble salt of gold affected the toning in the fixing bath. Hitherto, says the patentee, Herr Raethel, chloride has been added to the emulsions, partly for chloridating the silver salt and partly to influence the tone, of the prepared picture. In all cases the gold merely has been employed for the purpose to accomplish the toning of the picture.

The object of the present application is to provide a paper in which the gold not only forms the toning ingredient, but in which it also assists the production of the picture already before the toning.

The manufacture of my paper is based upon the knowledge that salt of gold in conjunction with or in presence of chloride of barium is very sensible to the action of light, whilst chloride of gold ( $\text{AuCl}_3$ ) alone is insensible to the same. My process is carried out in the following manner:—

I produce two solutions or emulsions sensible to the action of light, the composition of both being the following:

1. The emulsion of silver sensible to the light, for instance, consists of
  - 400 grains collodion (5 per cent.).
  - 16 grains nitrate of silver dissolved in
  - 20 grains of distilled water, and
  - 30 grains of alcohol.
  - 5—8 grains of a chloric salt, for instance, chloride of calcium, lithium, strontium or magnesium, dissolved in 20 grains of water.
  - 3 grains of an organic acid, as, for instance, citric acid, dissolved in 20 grains of alcohol.

2. The gold emulsion sensible to the action of light is produced in the following manner:—

To a solution of 0.1 grain of chloride of gold ( $\text{AuCl}_3$ ), dissolved in 100 parts of ether-alcohol, about 5 drops of a solution of 1 grain chloride of barium in 40 grains of alcohol (40 per cent.) are added, and then the whole is thoroughly mixed with about 200 grains of collodion (5 per cent.).

Chloride of barium in presence of chloride of gold is easily and completely soluble in the mixture of ether-alcohol with pure alcohol (40 per cent.).

Both solutions remain inactive for about 12 hours, and then 80 grains of the gold solution are added to the above quantity of prepared silver emulsion, the whole being shaken thoroughly.

The emulsion thus produced and mixed can now be employed, and the pictures, after having been dried, are ready for printing.

The pictures copied upon this paper are of reddish-brown colour, and for the purpose of toning are placed into water, whereby that quantity of the chloride of gold which has not yet been attacked by the light acts as a toning medium. A repetition of the fixation and of the water bath suffices to obtain reliable pictures of an intense purple colour.

## Our Editorial Table.

The International Annual of Anthony's Photographic Bulletin for 1901 is made up, as in former years, of articles and reproductions from photographs. Most of the latter are not very new in style or treatment, but they are at least intelligible, which many modern American photographs are not. The book is an excellent example of typography, but it is not quite free of error in the section devoted to English photographic societies, the list of which is neither full nor accurate. Messrs. Percy Lund, Humphries, and Co., 3, Amen-corner, E.C., are the publishers of the Annual.

## Studio Gossip.

SIR L. Alma-Tadema on Art.—Sir Lawrence Alma-Tadema, R.A., presented the prizes and certificates to the successful students of the Hornsey School of Art at their annual soirée at the Corbin Hall, Crouch End, last week. Addressing the students, he said the great difficulty of an artist—and one which literary men never quite understood, because they had not learnt it by experience—was excellence of execution. Of course the ideas and feelings must be there to make art complete. Still, excellence of execution and the way of expressing the painter's ideas in such a way that Jack and everybody could understand them at a glance, were very perplexing. Ever since he was a youth he had always been guided by this principle of excellence of execution, and he hoped he would never be satisfied with his work; because people who were satisfied with what they produced had no higher aim, and had better not do any more. Art was many-sided. Everybody could not paint imaginative pictures, nor could everybody obtain the same excellence. If they felt more inclined to devote their artistic bent towards the making of furniture—and there were great masters in this kind of art—he would urge them not to think for a moment that it was less important, because it appealed to the greater masses of people, teaching them that there was beauty wherever it could be seen. People were taught to see beauty when their furniture was made in good taste. If they designed a chair or anything else, their first thought ought to be as to how it was going to be used; because one of the great beauties of a thing lay in its use.

## News and Notes.

THE Röntgen Society's next Ordinary General Meeting will be held on Thursday, January 3, 1901, at 20, Hanover-square. A paper will be read by Mr. A. W. Isenthal on "Continental Progress in Practical Radiography and Apparatus." Before the paper Dr. J. H. Sequiera has kindly consented to show some cases of rodent ulcer treated with X rays, which will be further referred to on the therapeutic discussion evening.

THE South London Photographic Society's Lantern-slide Competition.—The following is the list of awards for the best sets of six lantern slides made from negatives taken on the South London Society's Rhine trip last summer:—Silver medal: T. Morley Brook; bronze, C. J. King, C. Churchill; highly commended, W. Page; commended, A. Bedding, W. Page. Mr. Bedding's slide of the fourteenth century carving at Bonn was adjudged to be the best individual slide. The judges were Messrs. G. J. T. Walford and E. R. Bull.

APOCHROMATIC Collinear Lenses.—Messrs. Voigtlander and Sohn, of Brunswick and London, announce the issue of a new series of apochromatic collinear lenses. It is stated that the glasses used in the lenses have been selected so that the secondary spectrum is completely corrected, consequently the three images for blue, green, and red fall on the same plane and are the same size. By this apochromatic correction the sharpness of the definition has been increased, and is more even over the whole image than with an ordinary objective of the same aperture.

THE Brentford Photographic Society's Third Annual Exhibition will be held in the Large Hall, Public Baths, Clifden-road, Brentford, on Tuesday and Wednesday, March 19 and 20, 1901. The following will act as judges:—Messrs. John A. Hodges, F.R.P.S., J. C. S. Mummery, and James A. Sinclair, F.R.P.S. The following is the Open Section: Landscape and Seascape, Portraiture and Figure Studies, Architecture, Flower and Animal Studies, Lantern Slides. Silver and bronze medals will be awarded, at the discretion of the judges, in each class. Entry forms, accompanied by a remittance, must be sent to the Hon. Secretary, Mr. Hilton Grundy, Brentford, Middlesex, by Friday, March 8.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

January.	Name of Society.	Subject.
1.....	Gospel Oak .....	{ Exhibition and Criticism of Members' Lantern Slides.
2.....	Borough Polytechnic.....	{ Pictorial Lantern Slides. R. R. Rawlins.
2.....	Croydon Camera Club .....	{ A Filmless Cinematograph. Alphonse Courlander.
2.....	Royal Photographic Society .....	{ Opening of Exhibit on of Photographs and an Address by Frank Sutcliffe.
2.....	Woodford .....	{ How to Make a Picture. J. T. Ashby.
3.....	Darwen .....	{ Lecture: Hand-camera Work.
3.....	Hull .....	{ Lantern-slide Making on Kristal Plates by Gaslight. T. G. Ames.
3.....	Oldham .....	{ Lantern Slides.
3.....	Röntgen Society .....	{ Paper by A. W. Isenthal.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 20,—Mr. P. R. Salmon in the chair.

Mr. Rapson passed round several developed chloride prints, being the results of experiments he had carried out on the lines of the demonstration given at the last meeting by Mr. J. E. Hodd. Mr. Rapson had tried for the toning phosphate of soda, which produced a reducing effect; acetate of soda, which made the entire print very dirty; and a combination of phosphate and acetate, which gave a better tone than either used singly, and also the sulpho-cyanide bath, which gave the cold tones Mr. Rapson preferred, and which he could not get by any other. A discussion then followed on the personal likes and dislikes of cold and warm tones.

Mr. E. Human, *re* the stains produced on the dish by this dissolving process, said he had found no difficulty in removing them by the usual reducer of ferricyanide and hypo.

Mr. P. Everitt showed one of the Steinheil lenses which had been brought over to him from Germany, and he thought that this lens was the first of its kind brought into this country, and was not an anastigmat, being nearer to the older series of aplanats, and is known as a Series V. Copying Lens, this one in particular being 17½ in. focus, working aperture 20. During the past few years this series had been very considerably improved, each combination now consisting of three glasses, instead of two, as in the past. Mr. Everitt pointed out that this lens, which was very much smaller than other aplanats of this focus, was listed to cover, for landscapes, a plate, 20 in. × 16 in., and the price £9. F-20 is considered the largest working intensity, but f-15 is the full aperture, and at this it is quite free from spherical aberration. The advantages claimed for this lens are its cheapness, its extreme usefulness for architecture and landscape, and its small bulk compared to the usual R.R. of this focus.

Mr. Cleary, of Montreal, brought up a considerable number of stereo views of South Africa, &c., and which were found to be very interesting, the quality of the prints being more than usually good for trade stereographs.

Mr. Mackie passed a few remarks on the art of photography as we know it now, commencing at the beginning of the present century.

### PHOTOGRAPHIC CLUB.

DECEMBER 19,—Mr. W. R. Stretton in the chair.

Mr. H. Snowden Ward, F.R.P.S., gave a lecture upon the McDonough-Joly process of colour photography, the inception of which in 1862 was credited to Duocos du Hauron. The process would have probably been developed right away had it not been for the fact that it involved the use of plates fairly equally sensitive to different parts of the spectrum, which were not then obtainable. The process was brought out simultaneously in America by McDonough, and in England by Joly, who appear to have been working quite independently one of the other. Mr. Ward said he had been working the process during recent months, and with great satisfaction to himself. Many difficulties had been pointed out by critics, but he could frankly say that, while some of these were real and some fanciful, there were other pitfalls that had not been alluded to. The process was liable to the difficulties attending ordinary photography, and it had others peculiar to itself. It had the virtues also of ordinary work, apart from extreme speed, with the added recommendation of colour reproduction. He did not wish to compare the process with any other—Lippmann, Ives, &c., all of which were interesting in their way. The McDonough-Joly process introduces no novel methods to the photographer, and the additional appliances when obtainable commercially are not likely to be expensive. Mr. Ward outlined the principles of the process as follows:—A plate sensitive to all parts of the spectrum, such as the Rapid Spectrum, in England; and an orthochromatised Seed plate, in America, is exposed in close contact with what is known as a taking screen. This screen is a glass plate ruled with very narrow parallel lines, red, green, and blue-violet. Joly adopted 240 lines per inch, and McDonough 300 lines. The objection to the use of finer lines is in the difficulty of afterwards superimposing the positive and the viewing screen. Coarser lines, on the other hand, become aggressive. Now, every object in the original, which reflects blue light, affects only the part of the plate covered by the blue lines of the screen, the red and green lines preventing action in their preserves by absorption. When the plate is developed the silver is found deposited in lines which fall under the blue lines of the screen. A positive from

his negative placed in contact with a viewing-screen ruled similarly to the taking screen would allow only the blue lines to be seen, thus reproducing the original colours. By this process positives on paper or glass may be made and seen in natural colours. Mixtures of colours are reproduced by partial action through the various lines, but, in viewing the picture, the colour effect is obtained by a visual combination of the colour lines, not a true combination of the colours. A special light filter that is adjustable for special conditions is used, and one was shown to the meeting. For paper prints, paper ruled in a similar way to the green is sensitised with silver emulsion, and an arrangement is made to register the lines of the negative with those of the paper. The silver deposit serves as a stencil, covering up some of the lines and allowing others to remain visible.

Mr. Ward then showed on the screen some lantern slides taken in England by himself and by Mr. C. N. Crewdson, which gentleman also showed a fine series of pictures taken at the Ober-Ammergau play. The examples of the process were received with every sign of interest, but criticism was made of the rendering of the colours in several of the pictures.

**Aintree Photographic Society.**—At last week's meeting, Mr. E. E. Thorpe gave a lecture on the "Norman Castles of Wales," and demonstrated by a series of lantern slides the great possibilities for the camera in and around the large number of ruined castles in the "land of the leek," many of which are scarcely less striking than the splendid and romantic scenery in which they are situated. This, and the fact of them having associations with historical events and traditional legend of more than ordinary interest, affords ample work for the photographer who can spend a lengthened tour in Wales.

## Patent News.

THE following applications for Patents were made between December 10 and December 15, 1900:—

**STUDIOS.**—No. 22,449. "Improvements relating to Photographic Studios." Communicated by C. Bernhoeft. H. H. LAKE.

**PRINTING FRAMES.**—No. 22,633. "Improvements in Photographic Printing Frames." J. WILKINSON and A. WILKINSON.

**TONGS FOR DEVELOPMENT.**—No. 22,669. "Tongs for Photographic Developing Purposes." J. T. PARTRIDGE.

**DEVELOPING "MACHINES."**—No. 22,696. "A New or Improved Developing and Fixing Machine for use in Photography." H. LÖSCHER.

**"COPYING MACHINE."**—No. 22,697. "Improvements in Photographic Copying Machines." H. LÖSCHER.

**CAMERAS.**—No. 22,904. "Improvements in Photographic Cameras." H. SIEWERS.

**CHANGING APPARATUS.**—No. 22,971. "A New or Improved Apparatus for Changing Photographic Plates or Cut Films." P. J. JOB and T. NAYLOR.

**LANTERNS.**—No. 22,981. "Improvements in and connected with Kinetographs and Magic Lanterns." Complete specification. G. W. BROWN and G. R. BEAUMONT.

## FORTHCOMING EXHIBITIONS.

1901.

January 14-19..... Blairgowrie and District Photographic Association. The Hon. Secretaries, Blairgowrie, N.B.

February 16-March 9 Edinburgh Photographic Society. Secretary, J. S. McCulloch, W.S., 10A, George-street, Edinburgh.

## Correspondence.

### GREEN FERRIC AMMONIUM CITRATE.

To the EDITORS.

GENTLEMEN,—I notice that in THE BRITISH JOURNAL ALMANAC for 1901, p. 799, there is an article on the manufacture of blue printing paper with green ferric ammonium citrate. In this treatise the writer made a statement that the green ferric ammonium citrate was not obtainable in this country, which statement I should like to rectify, as I have been some years manufacturing ferric ammonium citrate

green scales, and, as a matter of fact, have been supplying it to this country for a very long time, and I am still doing so.—I am, yours, &c.,

E. MERCK,  
per FREDK. BOEHM.

16, Jewry-street, London, E.C., December 20, 1900.

MR. ARCHER CLARKE also writes:—"Ferric ammonium citrate (green crystals).—'Ons,' in the 1901 ALMANAC, p. 798, throws a doubt on being able to obtain above in England. Let me add this fact that over six months ago I purchased 2 lb. of Elliott, 36, Jewin-street, London, E.C."

## COINS AS WEIGHTS.

To the EDITORS.

GENTLEMEN,—At p. 987 of the ALMANAC for next year you give a table for using coins as weights. All such tables that I have seen are founded on the legal weights of new coins, and are of little use except as a last resource for rough purposes. A very slight use of coins renders them sensibly light, and it would always be better to use such cheap weights as can be readily procured everywhere.

Gold coins (especially sovereigns) are now fairly accurate, as a sovereign ceases to be legal tender when it has lost about three-quarters of a grain of its standard weight, and a half-sovereign when it has lost about half a grain. These coins pass constantly through the banks, and are withdrawn when found light.

With silver coin, the case is otherwise: the law does not prescribe a minimum weight for their currency, and practically they remain in use till the impress on them is barely visible. The weights in the table are the legal weights of new coins, subject to the variation known as the remedy, but they can not apply to the contents of our purses or tills.

I have had the curiosity to examine the contents of my purse, with the following results:—

Five half-crowns weighed in the aggregate 68.17 grammes instead of 70.69 grammes, and the lightest weighed only 12.80 grammes instead of 14.14.

Of seven shillings, which should each have been 5.655 grammes in weight, the lightest only weighed 5.392 grammes; while the whole weighed 37.74 instead of 39.585 grammes. Thus the half-crowns had lost 2.7 per cent. of their weight on an average, and the lightest of them no less than 9.2 per cent. The shillings had, on the average, lost 4.6 per cent., while the most worn was 6.8 per cent. too light: nor were these coins nearly worn out.

Copper, or properly bronze, coins are even more untrustworthy. Ten pence were found to weigh 87.92 grammes, instead of 94.5 like new coins from the Mint; they had fallen off 7 per cent. from their full weight, while the most worn one weighed only 85.1 instead of 94.5 grammes, being thus 12 per cent. below standard. Those who are at all particular about weightings will therefore use even the cheapest weights they can buy rather than trust to the contents of their purses.—I am, yours, &c.,

J. F. T.

## WANTED—A HISTORY OF PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—During the next few days the columns of the general newspapers will, no doubt, give place to many articles treating on the advances in knowledge that have taken place in the century which closes on Tuesday next. Photography, of course, is bound to come in for mention, but the professional journalist will hardly be in a position to tell his readers anything of more than superficial interest on that subject. "The Photography of the Century" would supply an excellent topic for treatment in the pages of a photographic paper; but, here, again, I very much doubt if it would serve any useful purpose, beyond supplying a little agreeable reading. The fact is that photographic history, so far as it has been written in this country, is in a very untrustworthy state. From the days of the Daguerreotype, photography may be said to have been in constant process of evolution, with the result that highly important successions of improvements and advances have taken place. But a correct apportionment of individual credit for the work has never yet been made, and, in consequence, there are many reputations in photography of spurious value, while others, if justice were done to them, would stand much higher than they do. We must look to some undiscovered and competent historian to right all this. Meanwhile, it is safe to say to such a one a most important conclusion will very easily force itself upon him, viz. to no single individual can be assigned the credit of having discovered or invented photography. It is a common error to assign pre-eminence to certain workers without taking into account the assistance they have derived from the labours of others. What is needed is a proper adjustment of credit—in fact, a reliable history of photography.—I am, yours, &c.,

F. R. Hist. Soc.

London, December 22, 1900.

## MR. SUTCLIFFE'S EXHIBITION AT RUSSELL-SQUARE.

To the Editors.

GENTLEMEN,—I beg to inform you that on Wednesday, January 2, 1901, at 8 p.m., the Royal Photographic Society will open at 66, Russell-square an exhibition of photographs by Mr. F. M. Sutcliffe, of Whitby, and an address will be read. The Exhibition, it is expected, will remain open until Saturday, February 16, daily (Sundays excepted), from 10 to 4, Wednesdays 10 to 8. Admission on presentation of visiting card.—I am, yours, &c.,

A. W. W. BARTLETT,  
Assistant Secretary.

66, Russell-square, December 22, 1900.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPH REGISTERED:—

J. Warwick, 82B, Lowther-street, Carlisle.—Photograph of Union Jack taken to Pretoria.

OTHELLO.—In our opinion you are not liable.

D. O. (Treharris). We have no present cognisance of the firm you name.

EXPIRATION OF TENANCY.—"G. H. G." says: "I have my studio and premises on a three years' agreement, which expires in March next. What notice must I give, as I wish to clear out then?"—In reply: No notice is necessary, as the tenancy terminates at the end of the time for which it was made.

PLATINUM RESIDUES.—"BEDFORD CIRCUS" asks: "1. Is it any use to send clippings of platinotype paper to the refiner? 2. Is it worth while to save any washings in any part of plat. printing?"—In reply: Metallic platinum is recoverable from both paper clippings and used developers, but the quantity of these must determine the point whether it is worth while troubling a refiner in the matter.

CERAMIC PHOTOGRAPHY.—W. WALKER writes: "I have an inquiry for a tile with the photo of a lady burnt in for insertion in a granite monument in cemetery. Will you kindly tell me where I could get the same, and oblige?"—In reply: Messrs. Mawson and Kidd, Richmond, would, no doubt, supply a ceramic enamel. We are not sure if tile work is still undertaken in this country; but some reader may help our correspondent in the matter.

ELECTRIC LIGHT FOR PORTRAITURE.—"H. P. G." writes: "Can you, please, tell me what C.P., with an arc light, is generally used for portraiture so that two or more persons can be taken in a group? The current on our mains is a continuous one."—In reply: From six to ten thousand candle-power is what is usually employed. The greater the light the farther it can be placed from the sitters. That is necessary when groups have to be taken.

THE TANQUEREY FRAUDS, &c.—"AMIDOL" asks: "1. Would you advise me or any photographer exhibiting the cutting from your paper concerning the frauds by the foreign firms, Tanqueray, &c? 2. What good book or books can I obtain on the lighting of photographic studios, and where, price, &c.?"—In reply: 1. Such a course might have a good effect. 2. "The Studio and what to do in it," by Mr. H. P. Robinson. It is published by Sampson Low and Co., Fetter-lane, E.C.

COPYRIGHT.—"A. Y. X." writes: "A photographer here has a negative which he has made copyright, and he offers to sell it to me for a certain sum. What I want to know is this: If I buy the negative do I get the copyright with it, or does that still rest with him, as he is the author of the work?"—In reply: The copyright will not pass to you with the negative unless the photographer duly assigns it to you in the ordinary way. See that is done before you complete the purchase.

OBSCURING STUDIO VIEWS.—"S. F. J." writes: "I have taken a studio which is on the ground floor, and any one passing through a side street can see into it and stand and watch while I am taking sitters, which greatly disturbs them. If I pull down the blinds I stop off the light, and if I were to frost the glass I should also lose a lot of light. Is there any other means of overcoming the annoyance?"—In reply: We should recommend that the side be glazed with fluted (white) glass. That will obstruct no light and cannot be seen through.

PHOTOGRAPHING PLATE.—"R. P. J." says: "I expect shortly to have two large challenge cups to photograph. They are silver, and some parts are highly burnished, while others are matt. Would there be any advantage in using orthochromatic plates for the work; also, would there be any good in backing the plates?"—In reply: We do not think any good would accrue from employing orthochromatic plates. But the plates should certainly be backed for subjects of this character.

TONING LANTERN SLIDES.—"C. L. S." asks: "Can you tell me whether there is a pamphlet published on the toning or otherwise altering the colour of lantern slides, or whether such information is only scattered about in the various photographic journals? I have seen slides having different colours in each slide, produced by chemical means, such as brown cows, green trees, and blue sky."—In reply: In Mr. Hepworth's "Book of the Lantern" he gives much information on the hand colouring of lantern slides. Data as to differential toning are very scattered.

"CANSON'S PAPER EXPERIMENTALIST" says: "I have been reading an old work on photography, in which, with one of the processes, Canson paper is recommended above all others. Can you tell me where it is to be bought? I have inquired at several dealers, and they say that there is no such thing, or that they have never heard of it, &c."—In reply: This paper was much in favour in the early days of photography. It was made by Canson Brothers, Annonay, France. It is probably not made now, as we have not heard of it in the market for many years.

VELOX VERSUS PLATINOTYPE.—E. COLE writes: "I am writing to ask your opinion of the relative value of 'platinotype' paper and 'Velox,' also their commercial value one to the other. My reason for doing so is, I am engaged in a photographic firm, whose name, of course, I must withhold, and the Velox is passed for platinotype, which, if their character or value differ, should not be done from matter of principle."—In reply: Quite so. A Velox print consists of reduced silver, a platinotype print of reduced platinum. To pass one off for the other is at least a deception, if not a fraud.

STARCH PASTE.—M. A. BINNS says: "I use starch for mounting our prints. Can you tell me of anything that I can put into it to keep it from going bad, as it is such a bother to make it fresh every day or two?"—In reply: Any antiseptic will preserve the paste from putrefaction, such as carbolic acid, oil of cloves, salicylic acid, and the like. But we should advise the paste to be used freshly made. Surely there is not much trouble involved in mixing a little starch from time to time as it is required. Freshly-made starch paste is more adhesive than that which has been kept for some time by the aid of antiseptics.

THE ROYAL ARMS.—"LOYAL" writes: "Some years ago I supplied some photographs, prints, to the order of the Queen. They were ordered direct from her. I am opening a new branch, and have bought secondhand a coat-of-arms with 'By appointment to Her Majesty' upon it, which I am having repainted and freshly gilt. A friend tells me it will get me into trouble if I put this over my shop front. But the carver and gilder says I am perfectly entitled to use the Royal Arms if I have supplied anything direct to the order of the Queen or any of the Royal Family. Who is right?"—In reply: It will be decidedly illegal to use the Royal Arms in the circumstances detailed. You must hold the Royal warrant to entitle you to put up the Royal Arms.

WINTER PORTRAITURE.—THOS. CONWAY says: "I have a portrait of a lady, taken in America, in which she is represented as in a snow-storm, with the snowflakes falling all around. Can you tell me how the falling snow is managed?"—In reply: There are different ways of producing the effect. The most general one is to splash over the negative some opaque pigment, in the following way: Grind up some, say, flake white on a palette. Then take a tooth-brush and touch the ends of the bristles in the colour, and then, holding it a little distance from the negative, pass the back of a knife over them so as to flirt the colour on to it. If the negative be varnished, as it should be, the colour can be cleaned off, if the first attempt is not satisfactory.

THE INCANDESCENT LIGHT, &c.—"ETUM" writes: "My room is about 14 ft. square, 12 ft. high, with two good windows, north aspect. The windows reach to within 2 ft. of floor and top. There is a gas main on sufficient for 15 ordinary burners, no electric current near. I have a half-circle reflector of wire frame and tinned over, formerly used at a bazaar, 4 ft. diameter. 1. It struck me that if I had a gas bracket fitted to this to take six or six incandescent burners I might manage portraiture at night. Could I? 2. Would six lights be sufficient for 5 in. exposure on fast plates? 3. How should burners be arranged, in straight line or circle? Of course, the reflector would be arranged to face the sitter, and (4) should it be plated or enamelled white? 5. Also, please inform me if the enclosed portrait (not retouched) has been correctly lighted?"—In reply: 1. It is possible, but the exposure will be long, we expect, with such a limited light unless it were placed very close to the sitter. 2. We fancy not. 3. Better arrange them in two rows. 4. Enamelled white. 5. The lighting is not good, there is not sufficient shadow to give rotundity to the face. Too much front light.

### LANTERN NOTES AND NEWS.

ONE hospital in New York has adopted a camera to record minutely the action of patients in epileptic fits and similar afflictions, and many moving pictures have been taken showing the movements in walking of persons afflicted with locomotor ataxia. They are produced slowly on the screen, so that physicians are enabled to study the symptoms carefully. Moving pictures have been taken in Vienna showing operations being performed by great surgeons.

\* \* \* \* \*

IN a memoir recently presented to the Paris Academy of Sciences, M. Berthélot refers to the explosive properties of chlorate of potassium. He finds that, if the chlorate is suddenly placed in a vessel at a higher temperature than that at which decomposition commences, the salt explodes, though, if slowly heated, the chlorate does not explode. The investigation was probably made in consequence of a comparatively recent disaster in Lancashire.

\* \* \* \* \*

AN electrically ignited flashlight apparatus has recently been introduced into the United States. It consists of two cells of a powerful dry battery enclosed in a box suitably connected up in circuit, one part of the circuit being connected to two screws with spring fingers attached, and similar screws at the bottom, at the narrow end. From one screw is a light spring wire, having a loop in its end, to which a spring is attached. From the other screw projects a hook-shaped shorter rigid wire. When the spring wire is pulled forward by the string, it brings both terminals into electrical contact. To the right of the box is a flash card, having two fine wires on the surface arranged in a diamond form, and having in their circuit a minute platinum fuse. The card is placed on the box, and the wire terminals are slipped under the two spring wires, which completes the electrical circuit. The flash powder, in a small round box, is poured out on the card in the diamond-shaped space in such a way that some of it comes in contact with the platinum fuse. To ignite the powder, it is only necessary to close the electrical circuit by pulling lightly on the string, which brings the two wire terminals at the bottom into contact, causing the electric current to heat the platinum fuse to redness and instantly fire the powder. The operation is extremely simple, and enables one to remain at some distance from the flash, and even to be included in the picture, as it is evident that the length of the string can be adjusted to suit the circumstances.

It is stated that with a light of this kind it is an easy matter to take instantaneous interior daylight photographs of children and infants. Placing them near a window, the camera is adjusted on a stand and focussed. The flash light may be located six feet or eight feet from the subject, arranged to illuminate the shadow side of the face. The shutter of the camera may be set a very slow speed. Taking the operating bulb of the camera in one hand and the string of the flash lamp in the other, the photographer can set off both at the same time, compressing the shutter bulb with the right and pulling the string with the left hand. The intensity of the shadow side may be varied by the distance of the light from the subject. Very soft and pleasing children's portraits may be made in this way; but flashlight pictures at night can be made perfectly, and in large rooms duplicate sets of light can be arranged to flash at once and thereby give proper illumination.

\* \* \* \* \*

THE European Blair Camera Company, Limited, of the Mills, Foots Cray, Kent, have issued the following notice to the trade: "In order to meet the largely increased demand for our sensitised cinematograph film, we have found it necessary to enlarge our plant and devote our attention solely to the manufacturing end of the business. We have made arrangements with the Warwick Trading Company, Ltd., 5, Warwick-court, High Holborn, London, W.C., whereby the said Company will purchase our entire output of sensitised cinematograph film from and after January 1, 1900. All future orders for our film should therefore be sent to the said Company. This arrangement, however, applies only to our sensitised cinematograph film, as we still continue to supply our plates, cartridge, and cut sheet films direct from the factory."

\* \* \* \* \*

ACCORDING to a contemporary, the system adopted by M. Boyer in taking flashlight photographs of the Parisian theatres consists briefly of an arrangement for burning several magnesium cartridges in succession. A number of batteries of burners are used and pure magnesium is consumed. The powerful blowing apparatus permits a prolonging of the flash for the time required. The cartridge apparatus is actuated by electricity. In order that it may be possible for the operator to make a series of negatives without being annoyed by the smoke of the preceding flashes, there is installed a ventilating fan actuated by an electric motor. By means of a cloth sleeve the smoke and dust are carried outside of the building.

\* \* \* \* \*

It is stated that experiments with acetylene gas, made by a pine-wood proprietor in France, demonstrated that, by combining it with resin oil, it does not evaporate so quickly, is less explosive, and gives the carbide a pleasant odour. The acetylene light has been adopted by several establishments in Bayonne, the calcium carbide employed being mostly imported from America and Switzerland, and sold at about 17. 4s. per cwt. A number of calcium carbide factories are reported to be in course of

construction in the neighbourhood of Lourdes (Hautes Pyrénées), which, it is expected, will in the course of time effect a considerable reduction in the price.

\* \* \* \* \*

A NOVEL idea has been hit upon by Messrs. Eyre & Spottiswoode, Her Majesty's printers, in the production of a lantern lecture upon "The Boer War Day by Day," illustrated by many absorbingly interesting lantern slides. Messrs. Eyre & Spottiswoode announce, as a unique feature, that, both in descriptive matter and slides, the lecture will be daily brought up to date. It will, in fact, become a "Lantern War News," additions being made up to the latest possible moment.

\* \* \* \* \*

MESSRS. NEWTON & Co., of Fleet-street, have obtained the sole right to make lantern slides from the *Illustrated London News* and the *Sketch's* original drawings of the Transvaal War. This enables Messrs. Newton to bring their list of war slides up to date week by week. They also publish a reading to accompany about 200 slides.

#### LANTERN MEMS.

THE New Year brings new ideas and new resolutions, but an old wish that is always welcome will remain, and that I now give my readers; it is, "Best wishes for a healthful, happy, and prosperous New Year." It seems strange to write 1900 after so many years writing eighteen hundred and something. Many years. Yes! And what changes in that time! Changes and losses among our friends—changes in our business or professions, changes of fashion in hobbies and apparatus, and changes in methods of working.

\* \* \* \* \*

THIS is not the page for moralising, so I will briefly refer to changes in style and form of instruments and apparatus and in their manipulation. The optical lantern in principle is the same as the ancient magic lantern; but what a contrast in detail and improvement in the optical arrangement and the illuminant! A lanternist must be hard to please who cannot find the apparatus he wants for ordinary projection, or have made to his order, without much trouble, one that will meet his *special* requirements. It is really remarkable what an enormous difference can be made when required in a lantern to suit individual tastes, and from this I am forced to the conclusion that finality is not yet reached, and probably it is as well for the popularity of the instrument that it is so.

\* \* \* \* \*

IF a machine or apparatus becomes stereotyped, it loses its charm, and in like manner, if a camera or lantern cannot be made with distinctive points of merit, the owner has not the same pleasure in it. Who cannot recall the pride, and perhaps justifiable pride, with which the points of the same have been emphasised to the select circle of admirers, or enlarged upon at the Club meeting? Most men, and women, too, for the matter of that, like to be distinctive. I saw a play recently where the son's wife thought to please the mother-in-law for once by giving an order for a gown to the same dressmaker, to be made "as mother likes it," and the horror created by both mother-in-law and wife appearing at dinner in similar attire. So it is at a club outing; if B has an apparatus after the type of that used by A, he takes care to have this or that added, "Just a little dodge of my own, you know, which I found so very useful in previous work."

\* \* \* \* \*

GOOD "biz!" I say; let the fresh ideas come along, and put them into practice, and may the results in 1900 justify their adoption. Let it be with a lanternist as it is with a sportsman with his gun; get the best that money can buy, or brains conceive, and skilled hands carry out, and there will be no fear of any want of popularity of the optical lantern, especially if during the summer photographs of a high standard have been taken that can be projected on the screen to the delight of friends or the public.

Now, what are the improvements since I have known projection apparatus? It is a long catalogue I am afraid; but, if it can be put briefly, it may be interesting. As regards the light, first, let me think what choice there is now against that available when I first touched a first-class lantern thirty-five years ago. Then it was Colza or sperm oil lamps, oxycalcium spirit lamp, and oxyhydrogen limelight with gas bags; now we have the arc electric light of any desired power, high-pressure oxyhydrogen limelight, and compressed gas in cylinders, oxyether light, blowthrough jets or injectors, with oxygen gas only under pressure, giving as much light as the old mixed gas jets, acetylene gas light, incandescent gas light, incandescent electric light with focus lamps of 100 candle power, improved paraffin lamps with three and four wicks, giving really good results for small-size disc. The old single combination lenses have disappeared, and now, even with a lantern retailing for about 1*l.*, a good portrait combination front lens is supplied, also a passable four-inch double condenser of plano-convex form, and a three-wick lamp is fitted. This is a satisfactory lantern for those with slender purses, and provides the means of instruction and amusement for the family and for schools.

\* \* \* \* \*

THE higher-class apparatus embraces improvements in steadiness of mounting, convenience of manipulation, extra facilities for centering the light, and superior optical arrangements to secure best possible definition, and the size projection required for the particular distance most suitable for the hall or room where it will be employed. This range of focus has accounted for a great number of plans for altering the front, and embraces telescopic tubes of sliding or rack-work pattern, solid tube with inside sliding jackets, leather bellows front, open fronts on plain sliding mounts, and on lathe beds, according to rigidity required, and box extension of various patterns. The objectives are of various diameters from 3 inches of 16 to 12 inches focus, down by degrees to, say, 2 $\frac{3}{8}$  inches for 10 and 8 inches, 2 inches diameter for 6 inches focus, and slightly less for five inches and 4 inches equivalent focus. The bodies, or light-screening portions, may be as fancy dictates or as County Councils will; but, if one is desirous of avoiding the risk of a burn when a powerful light is employed, an asbestos and Russian iron-lined mahogany or other wooden body is advisable.

\* \* \* \* \*

TRIPLE and biunial lanterns have been so improved in mechanical details that perfect centering and registration of effect slides is ensured, and one operator can now manipulate a first-class apparatus more easily and certainly than two operators used to work a side-by-side pair of lanterns in the old days. Then as to apparatus for the projection of animated photographs, which was scarcely conceived possible at the time I go back to, we have such a list and variety that a purchaser is bewildered what to decide on. He cannot do better than go to a firm he has confidence in, and, after saying how much he is prepared to spend, leave the selection in his hands. Those who have already had experience in exhibiting animated photographs will have found out for themselves what are the difficulties of manipulation, and be able to choose an apparatus that gives them the maximum steadiness with the minimum of trouble, and secure safety in working with the least wear and tear on the films.

\* \* \* \* \*

THE BRITISH JOURNAL OF PHOTOGRAPHY ALMANAC, always so valuable, is again excellent in the editorial and other articles, and the information it places so conveniently for the use of its readers; but there is one subject that is not, perhaps, quite so well represented as usual, and that is the optical lantern, and enlarging by its means. I, for one, owe an apology to the Editor for not having an article in as usual on some subject connected with optics or the lantern. My excuse is, that my hands have been exceedingly full for the last six months, more particularly in connexion with work due to the military forces proceeding to South Africa. No doubt, all my readers join with me in wishing our troops the best of luck in the new year, and a speedy termination of the war, so that our thoughts

may be concentrated on the progress of the arts, and such technical matters as, say the improved power of lantern lights, and advances in optical apparatus, rather than on the development of appliances for the destruction of men.

G. R. BAKER.

### CARBON LANTERN SLIDES.

It is generally conceded that the acme of perfection in slide-making is reached either by the Woodburytype or carbon processes; the former is, as a rule, quite beyond the amateur, and the latter is not very much used, as the preparation of a slide by means of the gelatine lantern plate is so simple. The beauty of the carbon slide lies, as a rule, in the exquisite transparency of the shadows and the perfect rendering of all the tones in the negative, and the general absence of anything like grain, as the pigment in special transparency tissue looks more like a stain than a solid.

For absence of grain there is no doubt that the gelatino-chloride printing-out plate ranks next to them, and then the gelatino-chloride developing plate. It is possible, however, to obtain slides in almost any colour by what is certainly a carbon process, and a modification which has the advantage of requiring no tissue, but in which the ordinary gelatino-chloride printing-out paper can be used.

It is immaterial whether the paper has become yellow through age or whether it is a spoilt print, though in the latter case the printing is a little more difficult.

Allow the paper to darken to a deep rich colour by exposure to daylight, but in no case must it be allowed to bronze; it should then be immersed for two minutes in a five per cent. solution of common salt, then in a four per cent. solution of bichromate of potash and dry it, preferably by squeegeeing it to a piece of waxed plate glass and allow it to dry in the dark. When thoroughly dry, it can be exposed under the negative, allowed to soak in water till limp, and then squeegeed to a lantern plate from which the silver image has been removed by means of potassium cyanide well washed, and then treated with a ten per cent. solution of formalin and rinsed. The exposed paper may be squeegeed to a plain piece of glass without any gelatine, but it requires extremely careful handling.

When squeegeed down, it should be left for at least half an hour and then developed in warm water exactly as an ordinary carbon print, only that the paper should not be pulled off, but merely allowed to float off.

When the image is quite developed, it may be dipped into alum solution or weak formalin, washed, and then toned with any gold bath or platinum, or intensified by any of the ordinary methods as used for negatives. Exquisite results are obtained by merely immersing in a ten per cent. solution of silver nitrate, blotting off superfluous moisture, exposing thoroughly to daylight, and then toning in a combined bath.

A. D. PRETZL.

### LANTERN MATTERS.

#### SINGLE-LANTERN PROJECTION.

Of the objections generally urged against the employment of single lanterns in limelight projection, perhaps the one which has hitherto received most consideration at the hands of lanternists is that relating to the liability of an interruption arising from the breakdown of a lime, and the consequent necessity for a temporary stoppage during the period a new cylinder is being substituted. To many ardent lanternists, no doubt, this objection appears one of almost vital importance, and hence the recourse we so frequently see to the employment of biennial lamps, even for the projection of ordinary sets of lecture transparencies.

The objection mentioned, no doubt, has tended to detract from the popularity of single-lantern work, for, in years past, there is no doubt it was a difficult matter to employ a powerful mixing jet for a period of close upon one and a half hours' time without having to change a lime during that period of working, and in some instances, where bad samples of limes were used, even more difficulty was experienced. The increase of power in modern forms of mixing jets (which, no doubt, have been

more particularly designed for use in cinematographic projection) has, at the same time, called for the production of a more durable species of lime than was obtainable in former days, when what may be termed merely lower-pressure jets were almost solely employed. The results of these high-pressure jets being so much in use is seen in the very marked advance in quality and difference in size of the newer form of lime cylinders now placed in the hands of experienced lanternists; and, although opinions may differ in regard to what is the best form and size of cylinders to employ for ordinary transparency projection (for some authorities maintain that the old size of cylinder—viz., 1½ in. by ¾,—perhaps is in some respects to be preferred to the more modern size of cylinder, which is nearly double the thickness), it is maintained that the smaller size yields less heat with a lesser light spot, and no doubt this assertion is quite well founded. But, on the other hand, when we come to face the difficulty or liability of limes splitting under the action of a powerful jet, then there is no question as to the immense advantage the employment of these larger-sized cylinders confers over that of the smaller limes, and but few operators could now be found who have had much experience in single lantern working, and the employment of these large cinematographic limes or cylinders, who would ever for a moment think of going back to the old ¾-inch size of cylinder, especially where powerful mixing jets are employed.

The introduction of these cinematographic limes will do much to popularise single lantern working, for they quite remove the main objection hitherto held, viz., the difficulty of making one lime last throughout an entire evening's entertainment.

In limes or their substitutes for lantern projection there, of course, will at all times be a variety in quality no matter what the size of the cylinders are, for there are good and bad of both sizes. An operator, however, who is possessed of a really good large lime cylinder need have no fear of his light giving out during a two hours' exhibition with a powerful mixing jet. On the other hand, a ¾-in. cylinder has frequently to be subjected to an extra boring operation to make it fit the lime pin of his jet, and this tends to weaken the already thin enough surface of the lime to such an extent as to make it very liable to fracture under the heat of the blowpipe.

On the score of durability there is no doubt the advantage lies in the employment of the larger-sized cylinders.

It has, however, been urged that these large limes give a much greater heat, and are more liable to cause a condenser to be fractured, than smaller sizes. This objection, however, is easily met by employing condensers of slightly longer foci than those generally in use in single lanterns. The use of such long-focus condensers need not necessarily imply any loss of light as many lanternists are given to understand as likely to follow their employment, for the extra pressure obtainable by modern mixing jets when used in conjunction with the limes that are capable of withstanding the extra blast of the blowpipe enables a much more powerful light to be employed.

The fracturing of a condenser is another very exasperating circumstance during a single-lantern entertainment, and is an event that is liable to happen to any operator.

There is no doubt, however, it is less likely to happen where condensers are carefully selected in regard to their focal length, being slightly longer when powerful jets and larger lime cylinders are employed. It is well known that a jet employed with a twelve-inch objective requires to be worked at a much closer proximity to the back combination of a condenser than is the case where objectives of much shorter foci are being used, and this is another point in favour of the employment of the longest possible focus in a condenser.

To enable a single lantern, therefore, being used with quite satisfactory results for, say, a period of one and a half hours straight on and where powerful mixing jets are required, a distinct advantage is gained by the employment of large, hard lime cylinders, and having the lamp fitted with the longest possible focus condensers that can be used in relation to the focal length of the objective employed.

On the score of comfort and ease of working a single lantern as against a double decker, the advantage is very great with the former, and, when it is used in conjunction with a good mechanical carrier, not the universal right-and-left or sec-saw pattern, but a carrier that not only registers each slide exactly, but at the same time ensures every slide being in exact focus, as well as yielding as nearly as possible a true dissolving effect, then we are in a position to give a single-lantern entertainment of a very high order, and one that need not occasion the slightest fear of a breakdown from any of the causes so much dreaded in former years.

T. N. ARMSTRONG.

## FERROUS OXALATE FOR LANTERN SLIDES.

THE iron developer for lantern slides is seldom recommended so strongly as we find in a recently published article on the subject by Mr. H. A. Van Dusen. That gentleman points out that it is almost universally acknowledged that a first-class lantern slide from a gelatine plate requires much experience and skill on the part of the operator.

There is, he adds, an inherent peculiarity in gelatine which makes it not specially suited for giving clear high lights, which is what one really desires in a slide, despite the artistic twaddle about the beauty of veiled lights.

Brilliance is the great *desideratum* in slide-making if one has any intention of showing his slides upon a screen. The opalescence of the gelatine may, it is true, add to the artistic effect in a window transparency or on a slide intended to be viewed like a transparency in the graphoscope, but any haziness would condemn a slide intended for exhibition.

A gelatine slide ought to be properly exposed and properly developed if you expect it to be considered by a judge good.

Any doctoring in the shape of reduction, or intensification, or even toning, is but a makeshift.

Endeavour, therefore, to get correct exposures, and to do this you must study your negatives, for upon the character of the negatives the tone of the slide depends. True, long exposure is liable to give warmer tones, but there is really very little latitude of exposure allowable in judging time on a slide.

A very light excess of exposure will cause a blurring or slight solarisation in the intense lights, which would amount to *nil* in a negative, but which on projection is greatly exaggerated, amounting to a smudge or smear.

The tone of a properly exposed slide is satisfactory enough without any subsequent modification.

Though there are many developers which act most energetically and beautifully in the making of negatives, he has never found anything equal to ferrous-oxalate developer for slide work.

A.	
Oxalate of potash .....	2 ounces (av.).
Chloride of ammonium .....	40 grains.
Water .....	20 ounces.
B.	
Sulphate of iron (cryst.) .....	4 drachms (av.).
Citric acid .....	2 "
Water .....	20 ounces.
C.	
Bromide of potassium .....	1 ounce.
Water .....	3 ounces.
Sugar .....	1 drachm.

Take equal parts of A and B, and add 5 minims of C to each ounce of mixed developer.

It will be noticed that this oxalate developer is very much weaker than that which was formerly used for negative work, and that the amount of acid is also in excess.

The acid and sugar act as retarders of the developing action, that is, slow it, while the bromide acts as a restrainer.

If the development should need acceleration, make use of a stronger oxalate and iron solution; that is, the above with only one-fourth the amount of water.

Add a little of this strong solution to the developer to expedite the appearance of the image.

Of course, do not presume that you may over-expose, and modify in the development the density on the image, for correct exposure must be aimed at, and the endeavour made to adjust the developer to the exposure, the stock solution of mixed ferrous oxalate being intended as a means to this end. It is only in this way that brilliancy of results may be attained.

It may perhaps be necessary to mention here, that in mixing the developer for use the iron should always be added to the oxalate solution, never the oxalate to the iron. This latter procedure would cause muddiness in the solution and practically ruin the developer.

## SOME SCIENTIFIC APPLICATIONS OF ANIMATED PHOTOGRAPHY.

MR. C. FRANCIS JENKINS, the well-known American authority on animated photography, has published some very interesting particulars relating to the uses which science derives from this branch of photographic production.

For example, he says the U. S. Department of Agriculture is using a new instrument, technically known as the Phantoscope, for the study of plant growth. A description of the first experiment will serve to explain the application. The camera was anchored in front to a tomato plant just sprouting, and for weeks, by means of a simple clock attachment, which closed and opened an electric circuit, an exposure every half-hour, day and night, was made. The resultant ribbon is run through the Phantoscope, and the thousands of pictures are made to appear inseparably on a large canvas. Each onlooker sees the young shoot spring up, sees it grow, sees its leaves unfold, sees it put forth blossom and fruit, all in the space of a few minutes. Many fascinating discoveries are confidently expected by thus being able to accelerate the record of plant growth from three months to three minutes. For example, it is proved that the plant sleeps at night, this being shown by the intermittent growth on the canvas. The effect of stimuli and disease is also shown.

Obviously there are almost infinite possibilities for the utilisation of the method. The entomologist can reproduce the winding of the cocoon by the caterpillar as rapidly as the bobbin in a silk mill, can show the opening of the chrysalis in the spring, and, by combining the X-ray apparatus and the Phantoscope, can show the exact movements of the butterfly in his efforts to liberate himself.

The reverse, retardation, is even more prolific of interesting results. Comparatively little is known of insect and bird flight, because the wing movement is too rapid for the eye to detect the mechanical action. But with the new machine it is possible to take above 30,000 pictures per minute, the while giving to each full-timed illumination. By the synthetic process employed, the wings are reproduced in action at a rate one-twentieth as fast as taken. The flapping of wings can therefore easily be followed and the motion watched. In a study of fast-moving mechanism, soaring and falling bodies, data are procured invaluable in a solution of the problem of aerial navigation. Professor Muybridge did wonderful work in correcting accepted notions of the leg action of a trotting horse, but only partial results were achieved in bird flight, as analysis only, and not synthesis, was attempted.

The instrument, continues Mr. Jenkins, is invaluable in ethnological field work, making permanent records of Indian ceremonies, domestic arts and employments, primitive modes of living, etc., all of which, it will be conceded, are rapidly being lost or contaminated by a theatrical effect introduced for the benefit of the whites. These ribbons preserve in their integrity these ceremonies to all posterity.

The initial and subsequent trials of the battleship models in the experimental basin in the Washington Navy Yard may be made, each record preserved for comparison with the subsequent behaviour of the same model or of other and improved patterns. This method will, doubtless, sooner or later, be adopted by yacht-builders for the same purpose.

Such ribbons are also invaluable for demonstration before committees of Congress to more readily secure appropriations of moneys for desirable purposes. The eye can read in pictures in five minutes what would require hours for the ear to grasp, and with more convincing argument.

These methods of object-teaching prove not only of interest to the scientific investigator, but of inestimable value in the teaching of science to the children. The lantern has long been utilised in public instruction, but is now outstripped in effectiveness by the new device. On a large canvas, before the entire school, can be shown the growth of plants, the opening of flower petals, the passing of the seasons, the diurnal progress of the sun, the birth of the butterfly, the hatching of chickens, snakes shedding their skins, the flow of blood in the arteries, the transit of Venus across the solar disc, and other subjects yet to be arranged for.

The instrument has also been pressed into use in an effort to open up avenues of education for mutes. A hundred assemblies may be addressed by the same speaker, at the same moment, and in as many different places. Thus, one sits before the camera repeating the words of the address, that is, talks to the camera, the latter meanwhile making a permanent record of the lecture in the form of a great number of separate photographs on a long ribbon. Subsequently this ribbon is to be run through a proper projecting machine, which reproduces them on a large canvas in such manner as to appear to the eye a single portrait with lips moving in intelligible speech.

The hourly Weather Bureau reports for the year, when made up into a long ribbon and reproduced on the canvas, show the shifting of the "highs" and "lows," and the making, progress, and duration of areas of humidity, of high winds, cyclones, and the like. It is confidently believed that lessons will be learned therefrom which will guarantee still more accurate weather forecasts, resulting in incalculable benefit to shipping, to maritime, and other interests.

It has even been suggested by a scientist of recognised standing, that in the near future, with a combination of the Phantoscope and improved X-ray apparatus, that human life from conception to birth may be shown, for the possibilities of invention or discovery may not be gauged with cold reason.

By means of special Phantoscopic apparatus and colour filters, much of this work can be reproduced in natural colour and stereoscopic relief, a desirable though somewhat costly process. A water-melon, for instance, is photographed with a compound camera using four ribbons, in front of three of which respectively a red, yellow, and blue colour filter is located. The exposures are made hourly from the time the first shoot springs from the ground until the fruit matures. The positives are projected in a special lantern through colour screens. The composite picture is viewed with the left eye while the right simultaneously looks at the untinted picture, which appears side by side with the coloured pictures. This produces a stereoscopic effect, at the same time the picture appears in natural colour. The colour process is, in reality, the Ives's process, modified to suit the special requirements of the case.

Each onlooker, being provided with a neat little binocular eyepiece for diverging the lines of vision, sees upon the screen a green shoot spring up, sees it grow, sees the leaves unfold along its sinuous length, sees it blossom and develop the melon, the luscious red heart of which is exposed to view by the nocturnal coloured visitor. Not only to the layman is the picture one of beauty in form and colour, but one of great interest to the botanist in determining the periods and rates of colour change.

The perfected Phantoscope is, therefore, simply a scientific mechanism for reproducing the physical phenomena of life and action, by which, in colour, form, and motion, every aspect of a fact may be seized and reproduced at will, with all the depth and atmosphere of stereoscopic vision.

### THE DANGER OF FLASH LIGHTS.

NOTWITHSTANDING the number of serious accidents that have been chronicled, and the cautions given as to the dangerous character of most of the flashlight compositions, mishaps are continually occurring. We read of one that recently happened in a studio at St. Louis, which may serve as a warning to those who compound their own flashlight powders here. Briefly, the facts are these: An operator was using the blade of a knife to mix a quantity of Blitz powder and magnesium together, when the compound ignited, with the result that the man was terribly burnt about the face, hands, and arms, and had to be removed on an ambulance to the City Infirmary, where his condition was found to be serious. It was also stated that some of the white-hot flame had been inhaled by him, which, of course, added greatly to the gravity of the case.

We have on several previous occasions warned those who make flashlight powder, containing chlorate of potash and the like, as to the way that the compounds should be mixed. They should be dried and pulverised separately, then mixed in small quantities at a time, as required for use, on a sheet of paper, using a strip of stout paper or thin cardboard for the purpose. Had this method been adopted in the St. Louis studio, the accident would not have happened. There the operator used the blade of a knife for the purpose, probably because it was more convenient. Here is one more caution we would give: When mixing the ingredients in ever such small quantities, do it at arm's length, because then, if the mixture does ignite, the operator's face will not be injured by the flame, as in the case just cited, for most of these compounds are liable at times to "play tricks," and go off when least expected. Our object in specially calling attention to this accident is to once more impress the necessity of extreme caution upon those of our readers who may not know the dangerous nature of the material they are dealing with when they compound their own flashlight powders.

### PRACTICAL THREE-COLOUR LANTERN-SLIDE MAKING.

[Paper read before the Royal Photographic Society.]

THE subject of photography in colour is one which always seems to arouse some interest, and, although we have had methods of taking photographs in colour for over thirty years, we have seen very little of the actual work, especially in the case of lantern lectures. I want to-night to describe to you a practical method of making slides in natural colour, and of using them in an ordinary lantern.

You know that very much has been done in colour photography by various workers, from the time of Clerk-Maxwell in 1861, Du Haumont

since 1868, F. E. Ives from 1887 to the present time, and many others. Mr. Ives's process, now upon the market as you know, relies on the triple lantern for combining the images; it is a strictly scientific process, based upon Clerk-Maxwell's measurements of 1861, and some of the results that he has shown before this Society would be very hard to beat. But there is one disadvantage of the triple lantern, and that is there is such an enormous loss of light; and what I have been endeavouring to do is to place in the hands of lecturers, and especially of amateurs, a simple means of making natural colour photographs which can be shown upon the screen by an ordinary lantern.

The first thing we have to consider in connexion with colour photography is the nature of colour itself.

*Experiments with White Light and the Spectrum.*—The three-colour process is based upon the fact that all the colours of nature may be counterfeited sufficiently nearly to deceive the human eye, by means of mixtures of three colours of the spectrum itself, a particular red, a particular green, and a particular blue-violet. In order to see a coloured object properly, we have to illuminate it by white light, and white light contains light of all colours. Our first experiment, then, should be to separate white light into its component colours, and then we must find out what colours we are to photograph our object in.

It therefore appears that, if we photograph the separate parts of the picture through colour filters, print from the negatives in transparent pigments, and superpose the prints, we should be able to get a photograph in natural colour, but there complication commences to come in. You know that in the early days all our photographs were taken by blue and violet light, the light of the ultra-violet end of the spectrum. The first step towards making colour photography practical was when Captain Abney, Dr. Eder, and others started sensitising photographic plates for the red and green of the spectrum, and I will now show you two negatives, one taken on an ordinary plate and the other on the latest form of Cadett spectrum plate. You will notice that in the ordinary plate the action of the spectrum ends in the green, whereas in the spectrum plate there is action right up into the red.

The next thing we have to do is to find out what mixtures of the primary red, green, and blue violet reproduction colours will reproduce the spectrum as we see it in the spectroscope. The first actual measurements to this end were made by Clerk-Maxwell in 1861, and various other able experimenters have remeasured his results, the latest being Captain Abney. Actual practice with screens made to match Maxwell's curves has shown that it is necessary to make some slight alterations, and I hope that, when Captain Abney's curves are finally revised and published, we shall find that the alterations that have been made in practice will fall in with his actual measurements, because it is only by actual measurement that we can hope to get really accurate results.

Next I show you Maxwell's primary red, green, and blue-violet, and also the colour filters that we use for taking the photographs. The three photographs of the subject are taken through three of these colour filters. The next slide will show the effect of these filters on an actual object.

Here we have three photographs of a series of colour patches, white, red, green, blue, and yellow. The red patch is, as you see, represented as a dense deposit only in the negative taken through the red filter; the green patch is a yellowish-green, and as we saw just now that the red and green form yellow, we have slight action in the red and most of the action in the green filter negative; the blue is greenish-blue, and we get it represented by slight action in the green and considerable action in the blue filter negative; the yellow patch is represented by full action in the red and full action in the green filter negatives, the white patch being represented by equal density in all three negatives. In Mr. Ives's process he took negatives something like these and from them made positives in black; he then placed the three positives in three lanterns, or in a triple lantern, provided with red, green, and blue colour filters, and projected them on the screen, and in that way he secured pictures in colour by the screening out by the black and white positives of varying amounts of the coloured lights, the three coloured lights combining to form white. When we turn to printing in three transparent pigments, so as to superimpose them, we are doing an entirely different thing; instead of mixing coloured lights we are adding the absorption of one print to the absorption of two others, and for that reason we must not use the colours that Mr. Ives used, but these colours that I show you. They are really the colours used to form Maxwell's reconstituted white light, *minus* one of its constituents, and may be properly called *minus* red, *minus* green, and *minus* blue. By the combined absorption of the blue and the yellow we get green, by the combined absorptions of the magenta and the yellow we get red, by the combined absorptions of the magenta and the greenish-blue we get blue-violet, the absorption of all three gives black, so that, if we can print in those three colours, we ought to be able to secure a reproduction of the object photographed. Here is an actual print stained with the pink dye—*minus* green, one stained with the yellow dye—*minus* blue, and one stained with the greenish-blue dye or *minus* red, and when they are superposed you will see that the object is shown in its natural colours. I will pass through the lantern a few of the slides, and then explain how the prints are made.

[A number of slides in colour were shown.]

I will now show you the three filters through which the negatives are taken. The accurate manufacture of these filters has been made com-

mercially possible by aid of Captain Abney's Colour Sensitometer. I believe that the great impetus which has been given to the correct photography of colour, either as colour or as black and white, is largely owing to this invention. If we attempt to make filters in the way that we did before this instrument was invented, we have to photograph the spectrum through the particular filter under test on the plate we propose to use, and then every negative has to be measured. The measurement of a spectrum negative is a very difficult subject, and even when you have all the apparatus set up you may be two or three hours measuring a single negative, and, as it may be necessary to take several dozen or more negatives with each filter before we get it correct, you will see that the problem of making accurate filters by the old method was out of the question. Captain Abney's method is to accurately measure the luminosities and colour composition of several coloured glasses embracing a large portion of the spectrum in terms of Clerk-Maxwell's reproduction colours, and then to make three sectors to rotate in front of the row of glasses, one for each filter, red, green, and blue-violet, with apertures cut so as to bring the various proportions of one of the standard reproduction colours contained in the various test glasses to a common unit—the smallest proportion of that colour in the series of glasses. Once we have this row of coloured glasses set up and the rotating sectors made, we have a ready means of finding out the perfection of our filters, because we have only to get all the colour patches represented in the negative by equal density upon the particular plate we propose to use to ensure having the filters correct. This invention has enabled the testing of filters for commercial purposes to be carried out in a very short time. The scheme is so excellent, and so little notice seems to have been taken of it, that I do not think we fully appreciate the enormous importance of this invention of Captain Abney's.

Then we come to the question of how to use the filters. The simplest means of using them is, of course, to put them in front of your lens and take your pictures upon plates in the ordinary dark slides; but you will very soon find that this method is impracticable. Changing the filters and changing the slides is a very troublesome process, and you are very liable to get the images shifted in doing it. The first attempt that was made to facilitate matters in this respect was to use the old repeating back; instead of mounting the screens in front of the lens, a long plate-holder was provided for holding all the plates and the screens, and it was shifted along to make each separate exposure. That was a great improvement, because it enabled us to change the screens and the dark slide at the same time, and it is possible with the modern Cadett spectrum plate to get all three exposures made within a minute. Next there were various attempts, principally by French inventors, to get all three exposures made at one time. One of the first of these, and one of the simplest, was a device of Du Hauron's, which he invented in 1868 or 1869, and of which I show you a diagram.

Du Hauron and Cros devised many other means of combination, including a double-step photo-chromoscope with three mirrors, which was afterwards modified by Mr. Ives, by doing away with the third mirror; and I think those who will turn up Du Hauron's and Cros's papers between 1868 and 1879 will find almost all the devices that we know to-day mentioned in one form or another. One difficulty with his camera was that it was necessary to use three plate-holders, and you know how Mr. Ives got over that by means of prisms and transparent mirrors, so as to get all three images on a single plate, and quite recently he has patented another arrangement, of which I will draw a diagram.

I have recently taken the old form of Du Hauron's camera, and got over its worst difficulty. It is necessary that all three negatives should represent white light by equal density, and it is therefore necessary to have some scheme of equalising the light coming to the three images, so that, allowing for the screening action of the colour filters, we shall get equal density for white light in all three negatives. The usual way by which it is attempted to vary the amount of reflection from the mirrors is to vary the amount of silver deposited upon them; but any one who has tried partially silvering glass knows that to make a mirror four inches square, and to get it absolutely free from pinholes, and to reflect a definite proportion of the light, is a very difficult matter. After many attempts in that direction I gave up the idea, and thought of a scheme of using the adjustable diaphragm. I made another colour filter to go in the diaphragm slot of the lens on the plan of the adjustable filter diaphragm I introduced some years ago, some examples of which I see are still hung in a frame on these walls to-night.

I think that with that alteration the old camera of 1868 is as useful and satisfactory an instrument as we could wish for for the purpose.

Having got our three negatives, the next question is to find the easiest way of making transparent prints of the correct absorptions that can be mounted in super-position. One of the best pigments for the blue image is a modified form of Prussian blue. Ordinary Prussian blue toning does not give a particularly transparent image, but by modifying the formula it is possible to get a very transparent greenish-blue image of the right absorption, and therefore an easy way of making the blue print is to make a lantern slide from the red-colour filter negative just the same as you would for an ordinary black-toned lantern slide. It is necessary, however, that the image should be an actual developed image with no "faking" in the way of intensification or reduction, and it is also essential for attaining the correct absorption that the original image

should be a pure black. If you give a long exposure and use bromide and get a warm slide, it is almost impossible to get the correct blue tone, but, by strictly following the development formula that will be given with the apparatus, a good black image will be produced which, upon treatment with the toning solution, will become a rich greenish-blue.

For the pink and yellow prints the best and simplest way is to print upon very thin film by the modified carbon process suggested by Captain Abney. We have made a special film, consisting of pure soluble gelatine containing a small proportion of silver bromide, coated on a very transparent celluloid base, as we did not find the ordinary celluloid films used by Captain Abney a success (the gelatines used for sensitive films being unsuitable for our purpose), and it has to be sensitised in a weak bichromate solution and dried. The gelatine film is very much thinner than that used for ordinary carbon tissue, and the difficulties of drying carbon tissue do not exist with it.

Having the tissue sensitised and dry, we place it in the printing frame in contact with the negative, but instead of putting the gelatine-coated side of the film next the negative, we clean the back of the celluloid and put it in contact with the film side of the negative, so that we print through the thin celluloid film. In that way we get rid of the transfer, and also of the trouble arising from change of size, a further advantage being that the two images are reversed, thereby greatly facilitating the sealing up of the finished prints. All three prints may be made by this method on one long strip of the film. The frame may be opened and the images examined, and after an exposure of about one minute in good daylight you will find that the images are well printed out on the transparent film. The printed-out image is slightly brown, and very much of the same character as the undeveloped platinotype image. No attention should be paid to the strength of the print, but as soon as all the details are out the print is placed in warm water, about 90° F., and in five or six minutes you will find a perfectly developed image. The small amount of bromide of silver is placed in the gelatine film in order, in the first place, to prevent the light getting through and making the film insoluble quite to the back; and, in the second place, in order to be able to see what you are doing, because, if we were printing in colourless gelatine, we should not be able to tell when the image was developed, but the small amount of bromide of silver enables us to see what we are doing. The image being developed, you can place it over a dark surface and see the image in white gelatine.

As soon as development is complete the film is placed in weak hypo, which leaves a colourless cast of the subject. The film is then dried, the three pictures cut apart, and soaked for a few minutes in the staining solutions, which are carefully made up from mixtures of dyes so as to give the right absorptions. The print from the negative taken through the red filter is stained in a greenish-blue solution, or *minus* red; the print from the negative through the green filter is stained in pink solution, or *minus* green; and the print from the negative taken through the blue filter is stained in the yellow solution, or *minus* blue. When the three stained prints are dry, they are placed one over another and you have the final result.

I have mentioned two methods of making the blue print. As you know, celluloid is expensive, and it is economy to make the blue print upon an ordinary lantern plate, because you must have a cover glass, and if you make the blue print on an ordinary lantern plate you have one of the glasses necessary for the finished slide; you then make the other two prints on films, place them in contact and register—they are easy to register—and then fasten them together with binding and a cover glass, and the slide is finished.

That method of binding answers very well where you want to examine the slides in your hand or the stereoscope, or where you are projecting them on a small screen; but, if you want to project them across a wide hall, you will find that the three films will scatter the light considerably. This is easily overcome by cementing the three films together with Canada balsam, and when they are cemented together it is almost impossible to tell whether you have one film or three, the sealed result looks exactly like one piece of glass.

I think this scheme of reproduction is so simple that there ought not to be any difficulty in the average amateur carrying it out; the only thing is to get the necessary materials for it, and these I have endeavoured to supply. The requisite screens, cameras, printing films, and staining solutions will be placed upon the market, and will be obtainable from the usual sources, and I hope that within a short time we shall see a great many of our lectures illustrated by this process. I do not claim that the process is new. I think that we ought all to thoroughly acknowledge the great debt that we owe to the earlier workers in colour photography, and especially Du Hauron and Clerk-Maxwell, Captain Abney, Mr. F. E. Ives, and many others, for it was Clerk-Maxwell who laid the whole foundation of the work we do to-day, and it was only the lax way in which the manufacturers supplied the means that kept back the development of colour photography. I take it that the present increase in the amount of attention that is given to colour photography is due to Captain Abney's colour sensitometer and the endeavours of the plate-makers. The plate-makers have placed in our hands several brands of plates on which we can test these colour photographs, but I do not think that I am going further than I ought in saying one firm have contributed a large share towards this end—

Messrs. Cadett & Neall, of Ashted. All the work that I have been doing lately has been done on the Cadett spectrum plate. With the Cadett spectrum plate and measured colour filters I think that we should be able to make the negatives with very great ease. A good many persons have attempted this work, but the difficulty of working out filters and finding out the exact way of going to work has been so great that very few have cared to take the time and trouble, but I think that we shall see a great deal more of it now.

With regard to the time of exposure, using the Cadett rapid spectrum plate and the repeating back, you will probably find that in a good light you will have to give an exposure of about ten seconds for the red impression, five seconds for the green, and about one second for the blue; but with the triple camera the exposures on an open landscape would be about two seconds for the three, and I am hoping that Mr. Cadett will still further increase the speed of the spectrum plate, which is already more than twice that of any other brand of orthochromatic plate. It only needs a little more speed to enable us to take coloured animated photographs; there is quite a simple scheme for projecting animated photographs in colours, and, as far as I know, the only thing required to make it a success is a still more rapid spectrum emulsion coated on transparent flexible film.

E. SANGER SHEPHERD.

### EXPLOSION AT A CALCIUM CARBIDE WORKS.

SOME time ago an explosion at some calcium carbide works in Ottawa, Canada, took place, and a correspondent of the *Scientific American* has supplied that journal with an account of the circumstances of the accident.

The fire originated in a building adjoining the carbide works, cause unknown.

A hole was cut in the roof of the works directly over a crucible containing about 1000 pounds of molten carbide.

Water from the firemen's hose was poured in through the hole on the upper floor, whence it streamed down into the furnace-room on pigs of carbide lying on the floor, and on a small quantity of broken carbide ready for packing, gas generated from the water dripping on the cold carbide. It was ignited by burning wood falling through the ventilating shaft, and burned quietly as rapidly as it was given off. Suddenly an accumulation of water poured into the crucible on top of the molten carbide. An explosion followed that wrecked the plant and injured eighteen men. The verdict of the jury was that the explosion came from that crucible, but left it an open question as to whether it was caused by the rapid conversion of the water into steam or by water gas formed by the vaporisation of the water on the unfused mixture of coke and lime. The correspondent adds that the expert testimony was all against the possibility of the explosion being acetylene. Such men as Thomas Macfarlane (Analyst for the Department of Inland Revenue), Professor Shutt (Analytical Chemist, Dominion Experimental Farm), Professor McGill (of the Geological Survey), and the men engaged in manufacturing carbide, deposed that it was impossible to generate acetylene from red-hot carbide. Medical evidence as to the injuries from the explosion showed that they were the result of dry heat, not steam. The victims themselves said that the burns came from the hot unfused mixture of lime and coke. Only one injury was serious, resulting in the loss of an eye.

The coroner's verdict has dissipated a great deal of prejudice against carbide. The jury came to the conclusion that its manufacture was not of a hazardous character when conducted in a fireproof building. The City Council, acting on the finding of the jury, have instructed the By-laws Committee to frame a by-law to regulate the manufacture and storage of carbide. They consider this necessary because Ottawa is destined to be the centre of an immense carbide industry. Within the city, and in a radius of forty-five miles, there is over a million horse power in waterfalls, abundance of lime, and easy access to coke and charcoal. In this northern country, where the nights are so long in the fall and winter, acetylene is bound to take a front rank as the poor man's light.

### LANTERN LECTURES ON "FAIR DEVON."

IN the dull days of winter some delight comes to the photographer in mentally going over the ground of previous pleasant exploits and in anticipating fresh fields. Next summer may, from a number of causes, see more travel done within the borders of Britain than on the Continent, where, though British money is appreciated, and is, indeed, the cause of much prosperity, the Briton is not a *persona grata*—just now. As a picture ground, with fine climate and most enjoyable weather from April

to October, the county of Devon is, among its residents and those who know it well, worth consideration. Mr. Chas. R. Rowe, who formerly was engaged editorially for a number of years in connexion with our contemporary *Photography*, will next week be lecturing at the Photographic Club, the Camera Club, and the Polytechnic (Regent-street) upon 'Fair Devon,' illustrating the subject with a large number of lantern views. He has always been an enthusiast upon this subject, and he is none the less so now, when he is giving his whole work, by pen and voice, to the matter. He is quite at the service of any amateur photographer or visitor who may desire to know more about Devon, and his address is 17, Bedford-circus, Exeter. Devon has not been an exploited county, and it has never been over-run with the rushing tourist, but it has a magnificent lot of views—of nearly every sort, woodland, moorland, cliff and shore, river, architectural, and remains of bygone ages. It would satisfy the wants of many, while at the same time being easily accessible and readily got over. Those who are thinking—only just the matter of a few minutes' dreaming now and then, maybe—will do well to turn up at one of these lectures.

### THE DESIGNOSCOPE.

To project upon a lantern screen the operations of sketching diagrams or pictures, so that an audience may enjoy a full view of the draughtsman's work as he proceeds, calls for but slight additions to the ordinary single lantern. To exhibit in the ordinary way caricature slides originally drawn by clever and renowned cartoonists constitutes all that is necessary to ensure a very good evening's entertainment; but giving the audience the opportunity of seeing such work actually delineated before their own eyes must add substantially to the interest of such a show, whilst the applause, that is not likely to be withheld, cannot fail to encourage the artist in his work.

For the purpose of such projections, the optical adjustments of an

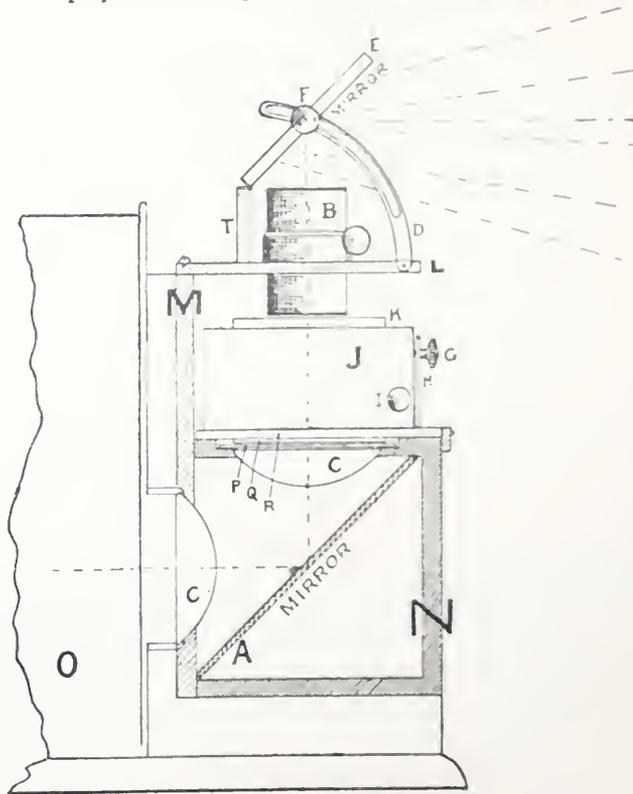

FIG. I.

ordinary single lantern require the following rearrangement: Referring to the diagram (fig. 1) a plate-glass mirror, A, is interposed between the two lenses of the condenser, C C, at an angle of 45°; the light emanating from within the lantern is thus thrown out of its usual course in a perpendicular direction, and then passes through a slide or object-glass situated at P, after which it proceeds through the objective lenses at B, supported by a suitable holder, L. The rays of light finally strike upon a second mirror, E, which is silvered on the front surface, whence they travel to the lantern screen. Hence the slide, instead of being carried through the lantern in a vertical position, as in the ordinary lantern, is laid horizontally upon a suitable framework situated immediately over the second lens of the condenser. By such an alteration in the arrangement of the optical combination it becomes possible to interpose between

the condenser and objective lenses such apparatus necessary to form a desk on which the draughtsman's sketching glasses may be laid, whilst he is enabled to do his work without blocking the course of light by his own person. Thus we have an apparatus, not only useful for the cartoonist, but also for the purpose of demonstrating characters in writing, teaching shorthand, and various scientific facts.

To such an apparatus I propose to add an instrument which I have called the Designoscope, the object of which is to multiply the lines made upon the sketching glass by the draughtsman, and so convert his simple strokes into a beautiful conventional figure upon the screen. All the essential parts of this little instrument are shown in all three of the accompanying figures at G, H, I, J, K, R, and S, fig. 3 showing a view of the instrument as it appears when placed upon the desk and looked at from the under side of the objective lenses.

In each diagram, G, is a thumbscrew for securing at the desired angle the mirror K H is the wing guide, to which the framed mirror is secured by G.

I is a thumbscrew, working in a thread made in the mirror frame, pressing against the back of the mirror glass, and thus keeping it from sliding out of place.

J is a mahogany frame holding mirror, and supported on the base, R, to which it is pivoted.

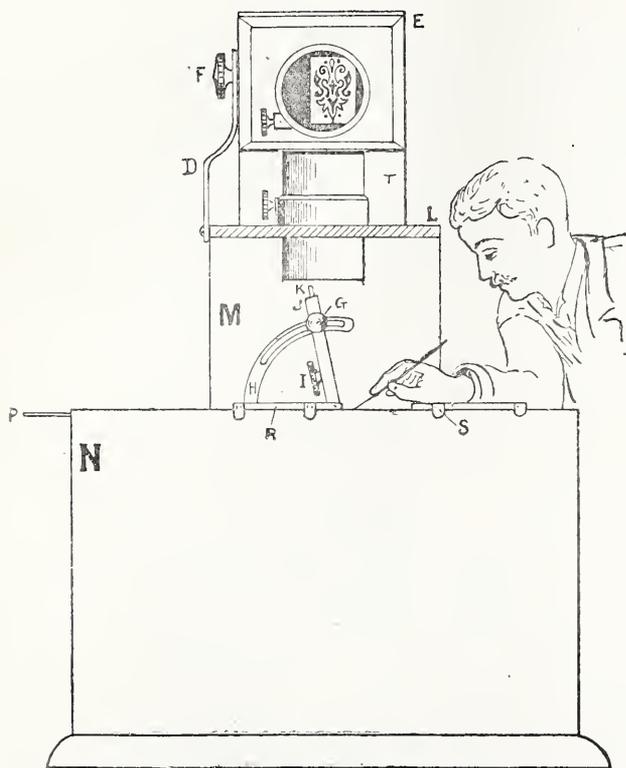

FIG. 2.

K is a mirror made of plate glass with the silver precipitated upon the front surface and burnished.

R is a base, supporting mirror, and acting as a shutter for cutting off superfluous rays, otherwise emanating from a portion of the condenser.

S is an arm rest, forming no part of the instrument itself, but necessary for preventing the operator's sleeves from touching the surface of the sketching glass.

The object-glass, P, consists of a long strip of plate glass, suitably prepared by stippling its upper surface with mountants (Fallowfield's) and allowing it to dry. The ink employed is that usually supplied with rubber stamps, obtainable in red, blue, green, violet, or black. The colour used must be decided by the taste of the operator and also by the subject in hand.

Having adjusted the mirror, J K, so that both sides of the projected image appear equally illuminated, the operator works upon the glass slide, P, from the position shown in fig. 2, with his arm resting upon the bridge, S. In this diagram (*i.e.*, fig. 2) the slide, P, is shown in its position as the artist is drawing his last design. When the first image has been drawn upon the left-hand end of the slide, it is pushed from right to left. This motion will cause the designs upon the screen to fold in the centre and vanish, and a clear space will thus be made for the next design. If, after a series of designs have been completed, the slide upon which they are drawn is pushed from left to right, the designs will appear to spring from the centre, then separate in two, and finally disappear on opposite sides of the illuminated space.

Various effects are produced by using two separate glasses, and, whilst in contact with each other, causing them to move in contrary directions.

A pair of glasses worked in this way, and being painted, one in yellow colours and the other in blue, produces varying shades of green, wherever intersection takes place. Designs etched with a steel point, and removing soot from smoked glasses, produce a very pleasing effect upon the screen. Though in all these operations the draughtsman actually draws but one-half the design, to the audience he appears to be using two hands, drawing both sides of the design at the same moment.

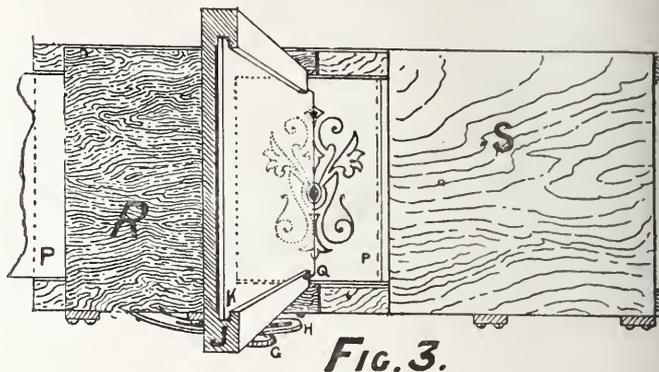

FIG. 3.

It will be remarked that by the addition of a second mirror to the Designoscope, suitably attached so that it has all the necessary adjustable means, a four-sided figure may be projected upon the screen, or figures having even six slides, after the manner of a kaleidoscopic design.

The beauty of the effects obtainable with the Designoscope are not likely to be fully appreciated from a mere description in words, and a practical observation alone can reveal to the reader the great variety of combinations, both in colour and form, that may with advantage be introduced.

THEODORE BROWN.

#### CARBIDE OF CALCIUM.

A RUSSIAN engineer, Orlovsky, of St. Petersburg, has made an improvement in the manufacture of calcium carbide, which has for effect the prevention of the absorption of damp and the more regular and slower evolution of acetylene when in contact with water. He places the carbide just when it comes from the electric furnace, and, whilst still hot, in a mixture of one part of tar and forty parts of petroleum residues. It is also reported that Herr Wolff, of Berlin, has patented a process for its manufacture which entirely does away with the electric furnace. A compound of lime, carbon, and powdered aluminium is mixed together, and then fired by a slow match or torch. The aluminium, it is said, combines with the oxygen of the quicklime, and the temperature thus caused is so high that the lime melts and combines with the carbon.

#### MAGNESIUM PAPER.

THE following method of making magnesium paper may be useful to some, as it is easily carried about, and the intensity of the illumination may be regulated by the quantity of paper burnt. Two sheets of paper should be coated with starch paste, and then dusted with powdered magnesium, and the two surfaces pressed into contact. Two sheets are also prepared in a similar manner with powdered chlorate of potash, and then pressed on the outside of the magnesium sheets.

MESSRS. FUERST BROS.' recent cinematograph films include the following: "Departure of Field-Marshal Lord Roberts for South Africa."—His lordship is seen going on board the R.M.S. *Dunottar Castle*, at Southampton. Episodes of the War in the Transvaal: "Arrest of a Boer Spy."—An English Column are resting near Mafeking after an attack upon the Boers. The sentinel stops some people advancing towards the camp, amongst whom is a spy who, when brought up and searched before the officers, is found to be in possession of some plans; he is taken to the front of the camp, an officer rises and commands a company of men to take him off for execution; the men fall into line and leave with the officer. "The Execution of the Boer Spy."—On arriving at the place of execution the spy is immediately shot; he dies heroically, defying the enemies of his country. "A Skirmish near Glencoe."—A detachment of Boers, trying to pass the English outposts, is surprised by a strong English detachment, who, reinforced by two cannons, repulse the Boers, leaving twelve of the enemy slain on the field. "Episodes of the Modder River Battles."—The Boers seize some English cannon, one of which explodes without, however, doing much damage among the victorious Boers. The Boer women load the guns and pass them on to the Burghers. Severe fighting and heavy losses.

## LANTERN MEMS.

WHAT has become of the lantern business this season? With the exception of a fair demand for lantern photographs of the scenes of the war, portraits of generals and celebrities in connexion with the South African War, and reproduction of the illustrations in the papers of the battle scenes and incidents, there is little or no demand for lantern work. The explanation, by general consent, is, that ordinary business is quite unhinged, and, although many opticians have had a very busy time in supplying binocular field glasses, telescopes, and compasses for use at the seat of war, other branches of scientific work have been at a stand-still.

\* \* \* \* \*

If this explanation cannot be considered adequate, then those interested in the optical lantern will have to bestir themselves to bring about a better condition of affairs, as far as trade is concerned. Is it that some novelty is required? The introduction of animated photography, and the biograph and various other graphs, made a great change in the better class of lantern entertainments, and superseded to a large extent dissolving-view entertainments. No doubt the public like realism, and entertainments illustrated by triple lanterns, properly manipulated, such as used to be done by Mr. B. J. Malden, never failed to draw big audiences, but once the taste for moving photographs had become established the dioramic scenes and effects were at a discount.

\* \* \* \* \*

BEAUTIFUL pictures will always be admired, and, if the effects produced are natural, the audience will always be pleased. Those who have any fine hand-painted and dissolving-view effect slides in their collection will do well to keep them, for they will enhance in value rather than decrease, as the number of first-class slide-painters is very limited, and, from what I can see, will get less. By slide-painters I do not mean those who can colour a photographic transparency, but rather the artist who can draw and paint direct on glass figures in miniature that can be enlarged so as to be seen by a large audience. It is a great gift to be able to draw so that the figure looks real, and not like a doll, or without anatomical form.

\* \* \* \* \*

FORTUNATELY in landscapes and with scenes of travels, celebrated buildings, &c., photography still helps us to a large extent, and many beautiful effects of day and night for dissolving are now published

that never fail to be appreciated. If what lantern-makers and slide-producers are feeling now is not explained by the war scare, then some attractive novelties will have to be added to the optical lantern, and entertainments given with its aid to bring about a better condition of affairs. It is probably only a temporary wave, and, when peace is restored, then the optical lantern will once more take the position it is entitled to, and to which it was exalted some years ago.

\* \* \* \* \*

As many lanterns as ever, if not more, are used for teaching purposes, but what seems to be different is the reduction in the number of private gentlemen who take to the lantern as a hobby. I sometimes think that the institutions, or churches, chapels, &c., which have benefited by the entertainments given by lantern amateurs have not had a representative to give the proper acknowledgment for the trouble and pains taken to bring about a successful result; in fact in some instances, they look upon the operator, who very often gives services voluntarily, as a mere showman. In the case of a singer he has simply to walk into the hall with a roll of music under his arm, and, when the time comes, sing his song; but with the lantern operator it means a great amount of thought, and generally real hard work, to bring about the desired result, besides a lot of preliminary practice. If all this is appreciated at its proper worth, well and good, for, no doubt, a properly carried-out lantern entertainment is a great attraction, and the means of affording pleasure to a large number.

\* \* \* \* \*

ANOTHER way of looking at the business side of the matter is that so many societies have their own lantern: and, in fact, the greater portion of them must be now supplied; hence the demand in that quarter must be getting less, while the members know they have only to take their transparencies to the society or club, and they can have them shown on the screen to their own or the members' edification.

\* \* \* \* \*

WHAT can be done in the way of novelties for the lantern? I should like to see some advance made in the Aphengescope, or opaque lantern, and the lantern microscope brought more to the front; the long-desired and often-tried stereoscopic projection to be perfected and rendered possible or easy of attainment, in ordinary halls and with average audiences, without each having to be provided with special adjuncts, or only such as will be useful for other purposes, such as an opera-glass. The stereoscopic projection by polarisation, so to speak, deserved the praise it received at the time Mr. Anderton invented it and introduced it to the scientific world; but, as a commercial venture, I fear it has not "caught on." It may help towards the ultimate achievement, but the ideal projection will have to be as clear as that of an ordinary photographic view as shown by the single optical lantern, and perfect stereoscopic effect as seen in the hand stereoscope.

G. R. BAKER.

## LANTERN MATTERS.

## LIMES.

BUT few lanternists having any experience will be found who are not alive to the fact that, in every description of limelight projection, the question as to the quality as well as form of the limes employed is one of the first importance.

Since the earlier days of limelight projection when gases were used in a mixed condition under pressure from one bag, and then, later again, when increased safety was assured by storing the gases in separate bags, down to the present almost perfect system of working from high-pressure cylinders, but little alteration can be said to have been effected in regard to the limes employed during these different stages, and very many of the older handbooks and guides to lantern projection are still read as up-to-date authorities in this particular item connected with the limelight, notwithstanding that, during the last five years, quite a revolution may be said to have taken place in "optical projection." That much of what may be termed a distinct advance is attributable to the newer form of mixing jets, which in their turn have been designed by reason of the increased pressure derived by working from cylinders, is a fact patent to every one conversant with lantern displays, for the increased or practically unlimited pressure from cylinders has given us jets quite different in design, as well as those containing chambers packed to such an extent as would have rendered their employment quite out of the question in the old gas-bag days. Yet it is very questionable if a corresponding improvement has been effected in the matter of our limes and the method of using them, for many of our modern powerful jets are sorely handicapped, and seldom seen working to their best advantage, by reason of the failure of the limes employed to withstand the extreme blast from these powerful jets.

Twenty-six years ago, in the pages of THE BRITISH JOURNAL OF PHOTOGRAPHY, under date January 23, 1874, there were given two illustrations of what at that time appeared to be the most serviceable form of lime cylinders to employ, and it is interesting, in these days of high-pressure working, to refer to the form of limes and method of using same advocated by Mr. Noton at that distant date, for the question naturally arises, if some similar method would not at the present day be well adapted for use with the powerful jets employed in cinematographic and other long-distance limelight projection.

Mr. Noton advocated the employment of solid cylinders of lime, one and a half inches in length by five-eighths in diameter. These cylinders, however, were manufactured without any bore down their centre, so that they could not be used with a jet furnished with the ordinary lime pin. This, however, was not his idea of how such cylinders ought to be held *in situ*, for Mr. Noton made a distinct feature of his method of employing solid cylinders by substituting for the lime pin a semi-circular trough or gutter, into which the solid cylinder was laid horizontally in a line with the axis of the lenses. This permitted the ends of the lime being exposed to the flame of the blow-pipe, and, as this trough or gutter was supported on a spindle capable of being rapidly rotated in its socket, either end of the lime cylinder was capable of being exposed to the flame, and Mr. Noton at the time remarked that, when any pitting of a lime at one end took place, by rotating the spindle the back of the gutter brought the used end of the lime into such a position as permitted its being scraped to a fresh flat surface again. Of course, at that distant date, the pressure employed was nothing like we use at the present time, and the limes were manufactured by Mr. Noton himself and, doubtless were of a very soft quality, but in this early experiment have we not the germs of what might be converted into an improvement in connexion with present-day practice?

As is well known, more recent improvements took the form of boring the lime cylinders, so that they could be used vertically on the lime pin, and this for many years has been the form invariably employed, simply because by rotating the screw of the jet a fresh part of the surface of the cylinder is brought opposite the flame, and, so long as the power of the jet employed was such as did not overcome the wall of the lime cylinder, this method of rotating a lime proved quite efficient; but, as has been stated during recent years, the increased power of modern jets becomes very destructive to the older forms of lime cylinders, and those of small dimensions are now found quite useless when used in conjunction with a really high-power jet.

A by no means uncommon size of lime cylinder is that of three-quarters of an inch in diameter, by one inch and five-eighths in length, down the centre of which runs a bore of one-eighth of an inch for attachment on the lime pin, and with this particular form and size of lime cylinder it is claimed Professor Faraday obtained the most brilliant light. The writer,

however, would suggest that, however admirable such may have proved in the past when employed with what may be termed low-pressure jets, the same would not be employed by any practical lanternist who appreciated the difficulty of keeping a steady light, say of one thousand candle power, straight on end in a single lantern for a period of one and a half hours, a requirement by no means uncommon at the present day.

It by no means follows, however, that circumstances would not arise in which such dimensions of lime cylinders would be preferable to those of greater diameter, for there is no question, when it comes to be a matter of selecting the best size and form of lime for use in such a lantern as, say, a bi-unial, where rapid dissolving has to be effected, then these limes, with their thinner walls and smaller heating surface, become very effective, for they unquestionably permit of a more ready response to the incandescent stage, which is a matter of much importance when dissolving effects are being rendered, and, of course, with bi-unial lanterns there is never the anxiety about changing a lime that is the case with single lamps. And here we have just a case in point where an operator's experience will guide him in the selection of the proper form and size of lime for the particular class of projection he is about to undertake.

With the introduction of modern powerful jets, more especially designed for cinematographic projection, it has been found necessary to increase the diameter of the cylinders; and these for some time have been manufactured up to one inch and a quarter in diameter, and this size has worked satisfactorily with powerful jets, the increased thickness standing the strong blast of the blow-pipe fairly well for a considerable time, provided the limes are in good condition, and in these limes the bore is slightly less than in those of former years; for speed in dissolving, however, they do not permit of a sufficiently rapid incandescent spot being reached, but for any single lantern work, where a continuous steady light, is a *sine-qua-non*, they are indispensable.

Against their use it has been urged that they are destructive to condensers by reason of the extreme heat they generate, doubtless by not allowing the flame to pass so readily around them as a lesser cylinder in diameter will permit; and not a few experienced operators decline to use them for this reason alone, preferring an intermediate size of cylinder, viz., those of one inch in diameter, and in which the bore for the lime pin is just sufficient to allow of its being attached to the jet, so that the walls of the cylinder are not weakened to any extent. It is claimed that this size of cylinder yields splendid results, and that such are a distinct improvement over those of one and a quarter inches in diameter.

In using these limes, an operator should never be tempted to tamper with the bores of the cylinder, for the common practice of boring out the hole for the lime pin is one that should be discountenanced at all costs. Such a practice never fails to weaken the walls of the lime, and to this treatment nine out of every ten break-downs during work is attributable.

For many years the lime pins of our jets were too large in relation to the size of the cylinders used, and it was nearly always the custom to widen the bores by means of a penknife or other equally unsuitable tool. Modern jets, however, do not possess this fault to the same extent, and any jet whose lime pin is too thick to permit of the bore of a standard lime easily passing over it should have the pin reduced rather than resort to the opening up of the bore of the lime, which never fails to weaken the walls of the same.

The above remarks, of course, refer to the employment of mixed gases under pressure. In cases where a blow-through form of jet is employed, the question of a lime giving out during an entertainment is quite as important, and seeing, as a rule, softer grades of limes are employed for blow-through work, a good deal of trouble is met with in this form of jet likewise.

Experienced lanternists, however, seldom favour the use of very soft limes, or, for that matter, use a blow-through form of jet at all. They pin their faith to the mixed jet, which is quite as safe and far easier to manipulate than the so-called safety, with its yards upon yards of rubber tubing connected at ever-varying distances, oftentimes over the heads of their audience as well as under their feet and which proves so attractive to many of our juveniles as tempts them to pinch, and, at times, give a show away.

T. N. ARMSTRONG.

## WANTED AN OLD LANTERN: AN APPEAL.

IN the JOURNAL for October 13 last, we printed the following appeal from the Head Master of the Orange-street Board School, Southwark, London, S.E.: "In this large Board school, situated at the very centre of the most poverty-stricken district of London, we find great difficulty in attracting the poor lads and interesting them in their lessons. They

to work before, between, and after school hours, and have no opportunity for relaxation or self-improvement out of school. I have induced the School Board to fit one of my rooms with cased-in black blinds, and am striving to awaken an intelligent interest among the boys by the free use of lantern lessons, but the slides at my disposal are very limited in number and range of subject. I am sure many of your readers have slides (or negatives from which I can make slides) of places possessing geographical, historical, or Biblical interest, or illustrating geographical scenes, industries, &c., for which they have no further use, but which would be of great value for my purpose. I shall be most thankful to receive any which the kindness of your readers may induce them to send. I should also be glad of any discarded lantern large enough to allow the use of incandescent light (my own iron one being unsuitable), or lantern-slide making apparatus, and would gladly pay carriage if desired."

A week ago we were enabled, by the kindness of Mr. J. Bushby, of Penrith, to hand over some sixty or seventy excellent lantern slides to the Head Master of the school, who writes us on the subject as follows:—

"I am greatly obliged by your kindness in giving publicity to my appeal, but regret to say that up to the present the results have been rather disappointing.

"I have only received two packets of slides, and no one seems to have an old-fashioned large-bodied lantern to spare.

"I thought that, as they are of little use for modern exhibition purposes owing to lack of portability, &c., many must be thrown aside as mere lumber, and one would be of the greatest use to me as a fixture in my lantern room.

"I should be glad if you could spare the time to call on me here, to see what great assistance lantern pictures are in my school work and how I utilise them for nearly every subject of instruction."

We are sorry that the appeal met with so little success. It has, however, occurred to us that, by once more making it public, a selection of slides, and an old lantern, may be forthcoming from those of our readers who have no further use for them. In entertaining and instructing the poor children of the Orange-street Board School they would be put to the best possible uses.

RÖNTGEN WORK IN SOUTH AFRICA :

DR. HALL-EDWARDS TO GO TO THE FRONT.

We understand that Mr. J. F. Hall-Edwards, surgical radiographer to the General Hospital, Birmingham, has been appointed X-ray expert and surgical photographer to the hospital of the Imperial Yeomanry at Capetown. Mr. Hall-Edwards was the first to obtain X-ray photographs in Birmingham after the promulgation of Röntgen's discovery, and the first in the kingdom to utilise the rays to facilitate surgical operations. He has devised a portable Röntgen-ray apparatus for use on the battle-field, but his present appointment is for service in the base hospital. The department of which he will take charge at Capetown will not only use the X rays as an aid to surgery, but will keep systematic records, by means of ordinary photography, of the cases treated. These will serve not only for immediate utility, but will be of permanent utility in the literature of military surgery. Mr. Hall-Edwards was sent for to the War Office a week or two ago, and some negotiations had taken place with regard to a possible appointment in connexion with the army hospitals, when he received the offer from Mr. A. D. Fripp, who attended the Prince of Wales after the accident to His Royal Highness's knee, and who is the leading civilian member of the Imperial Yeomanry surgical staff. The appointment was confirmed last week in London, and Mr. Hall-Edwards returned to Birmingham to prepare for his departure for the Cape with the rest of the staff, on February 5, in the *Majestic*. It is understood that the appointment at the General Hospital will be kept open for him until his return. Two sets of X-ray apparatus have already been given for use with the Imperial Yeomanry. An appeal is now being made for ordinary photographic apparatus and material, including cameras, plates, chemicals, and portable dark rooms. Another gift that would be specially welcomed is a dynamo to light the operating theatre.

A COMPACT ENLARGING APPARATUS.

Most of us, during our photographic career, have been seized with the desire to make enlarged prints from some of our negatives. Some have attempted it, with more or less gratifying results. Others probably have hesitated from various reasons, perhaps lack of funds, or imaginary difficulties of the process. To the latter I would venture to dedicate this short article.

I do not intend to go into the principles of enlarging. This subject

has been written upon so many times that it would be superfluous to go over the ground again. I shall therefore simply confine myself to giving a brief description of an apparatus I made for the purpose, trusting it may be the means of leading some reader to try this most fascinating branch of photography.

I do not claim originality for the idea, which is simply this: The negative is placed in the back of the camera, illuminated by gas enclosed in a box, the image being thrown on to a board, which can be moved to and from the lens as required. My way of carrying out the idea may, however, differ slightly from the usual methods adopted. It has, however, the advantage of cheapness, for, beyond cost of the three

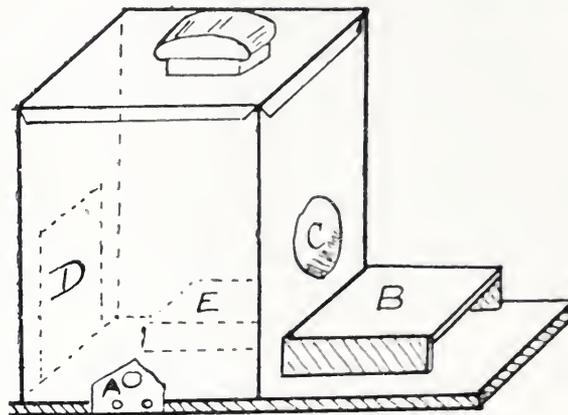

FIG. 1.

articles I shall shortly mention, the expenditure will be found very trifling. It can also be packed away in a comparatively small space, a great desideratum to amateurs who are unable to keep a separate room for their photography.

The most satisfactory way of illuminating the negative, so far as my experience goes, is with a condenser. Of course, daylight can be used, and is perhaps better with a dense negative, but it is so uncertain in its actinic value that it is necessary to test each exposure, whereas, with artificial light, having once ascertained the necessary exposure, any number of copies can be made with more certain results. Moreover, most amateurs have to do their work in the evening, and are therefore compelled to use artificial light.

At the outset I may as well state the principal articles it will be

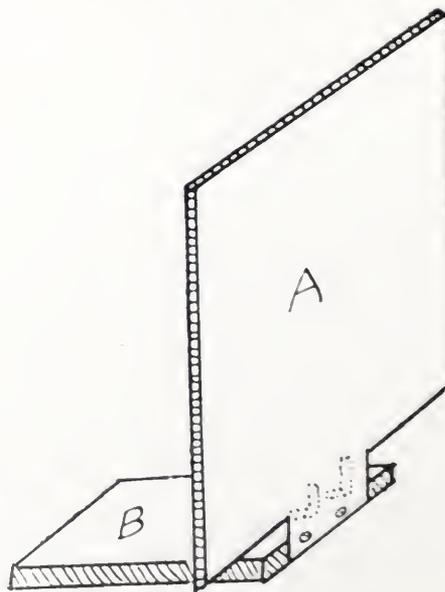

FIG. 2.

necessary to purchase, unless the reader happens to be possessed of a lantern. They are these: A condenser, an incandescent burner, and a lantern tray and jet to carry the burner. Of course a large condenser is preferable, but they cost a considerable sum. The ordinary 4-inch condenser used with the lantern will, however, be found to answer the purpose. If a half-plate view is to be enlarged, it will be necessary to make a reduced negative—a form of procedure which does not seem to have any appreciable effect on the resulting enlargement. The one thing to aim at is to get both the reduced positive and negative with plenty of detail, and not too dense.

We will first of all make the box to contain the illuminant (fig. 1). It

is a great convenience to make this to occupy as small a space as possible. I therefore selected millboard for the purpose, and made the box collapsible. The size is immaterial, so long as it is large enough. A convenient size is about 14 inches high by 12 inches long, and about 9 inches in width. Cut two pieces of millboard  $14 \times 12$  inches, and two pieces  $14 \times 9$  inches. These are for the four sides of the box. Join them together with bookbinder's cloth or some light-tight material in the following order:  $14 \times 12$ ,  $14 \times 9$ ,  $14 \times 12$ ,  $14 \times 9$  inches. In joining, be careful to allow about  $\frac{3}{8}$  inch between each piece of millboard; this will form a sort of hinge, and will allow the box to fold up flat when not in use.

For the top of the box it will be necessary to have a piece of thin tin which must have a hole cut out on which to fit a cowl so as to ventilate the box and carry off the heat when the gas is lighted inside. If the box is made to the measurements named, a piece of tin,  $14 \times 11$  inches will be required. From each corner cut out a square inch and fold over, forming a rim 1 inch wide. The bottom of the box must be made of wood. As it will be necessary to have some support for the camera when placed in front of the box for enlarging, make this piece to measure about  $20 \times 9$  inches.

Place the enlarging box on the board in position, and, in order to keep it in place, screw two pieces of wood on the two edges of the board to fasten the box firmly to when enlarging. A couple of screw nuts will secure in position (fig. 1), A. In front of the box a raised platform must be made to place the camera on. The height of this will depend on the size of the camera used, but will in all probability range from 2 to 3 inches. A piece of wood or millboard large enough to support the

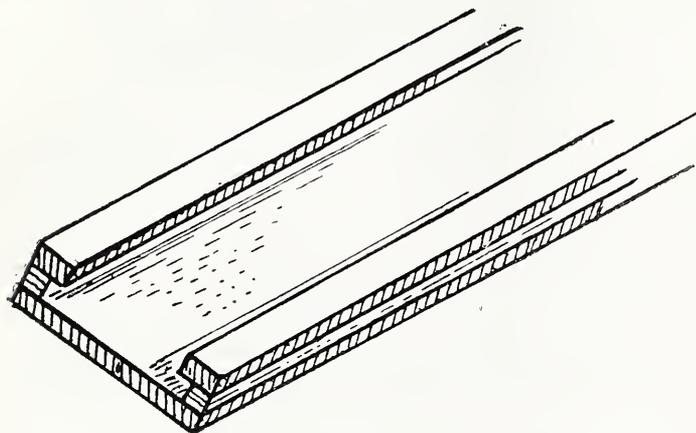

Fig. 3.

camera, and fastened on two pieces of wood the requisite height, will be found the simplest way of doing this (fig. 1), B.

Now cut a circular hole in the front of the box to carry the condenser (fig. 1), C. The position of this should be about 4 to 5 inches from the bottom, so that the centre of negative comes opposite centre of condenser. Now cut a piece out from the back of the box, about  $8 \times 6$  inches. This is necessary for adjusting the light during enlarging, and can be covered over with a small curtain (fig. 1), D.

We shall also require the tray that carries the illuminant raised a little from the bottom. This can be done by making a raised platform, similar to the one in front that carries the camera (fig. 1), E. If two little strips of wood are fastened to the top of this platform to form a groove for the tray to move backwards and forward, it will be found a great help in keeping the tray in position.

We will now turn our attention to the board on which to project the enlarged image (fig. 2), A. It is absolutely necessary that this should be perpendicular and at right angles to the negative. Get a block of wood, 5 inches wide by  $\frac{3}{4}$  inch thick and 6 inches long (fig. 2), B. At one end of this place the board upon which we project the image, fastening it at right angles by two brackets. The size of this board will, of course, depend on the size of the enlargement required, but  $15 \times 12$  inches will be found a convenient size. Be very careful that the brackets are at right angles, or it will throw part of the enlarged image out of focus. Previous to fastening, cut a strip about an inch wide from bottom of board at each end (see illustration).

We now have complete the box to contain the illuminant, and the board to receive the enlarged image. It is, however, necessary that this board should move in a straight line to and from the camera, or the image will be out of focus. To get over this difficulty take a piece of wood about 2 or 3 feet long and 6 inches in width. The length of this will vary with the focus of the lens being used, the longer the focus the longer the board. A 5-inch lens will require a board about the length named. Now cut two strips of wood  $\frac{1}{2}$  inch square, and about 2 feet in length. Screw these on top of the piece of wood at the edges, so that, when the piece carrying the enlarging board is placed between them, it will slide smoothly up and down. Now get two more strips of  $\frac{1}{2}$ -inch wood, this

time 1 inch wide by 2 feet long. Screw these on top of the pieces  $\frac{1}{2}$ -inch square, and we shall have formed a groove in which the enlarging board will move to and fro (fig. 3). If this board is too long, saw it in half, and hinge the two parts together. It can then be folded over and packed away in a smaller space.

Our apparatus is now complete. To use, place the tray with the incandescent burner in the box at the back of the condenser, connect with rubber tubing to a gas-burner, and light up. Put the negative to be enlarged in the dark slide at back of camera, and draw both shutters, placing this on the raised platform with the negative next to the condenser. The grooved board should be placed right up to the board on which the camera stands. (These two boards may be fastened together with hinges if preferred, but it is not necessary. Be careful, however, in either case to cut off both ends where they join at right angles.) The distance between lens and negative, and lens and enlarging board, will, of course, depend on the size we intend the enlargement to be. This is, however, not a difficult matter, and can easily be ascertained. If any trouble is experienced, a glance at the tables of enlargements in the pages of THE BRITISH JOURNAL OF PHOTOGRAPHIC ALMANAC will make it all clear. J. H. BURKE.

### THE PURIFICATION OF ACETYLENE GAS.

A GREAT deal is being said, written, and printed concerning the purification of acetylene.

Every user of the gas is aware of the fact that purification is a necessity if the use of it is to be a comfort, and not a nuisance, from the sanitary inspector's point of view.

When the present writer commenced to use this beautiful illuminant, he was informed that purification was hardly necessary, considering the short time the gas is required in taking a sitter. This was found to be a fallacy, as, with some carbide, the studio soon filled with a thick, smoky haze, which attacked the lungs of both sitter and operator to an extent sufficient to set them coughing, and to render it impossible to obtain another negative until the place had been thoroughly ventilated.

This being thus, he set about him to discover a means of preventing the appearance of these annoying fumes. It was found that they were caused by impurities arising in the generation of the gas, the said impurities being sulphuretted and phosphoretted hydrogen, and also ammonia. Of the latter very little remained, as the gas, after leaving the generating chambers, had to bubble through some forty gallons of water, which practically removed that impurity. There remained for consideration the sulphuretted and phosphoretted hydrogen only.

After making various experiments and seeking further information, it was decided to make a purifier on the plan recommended by G. F. Thompson in his book on *Acetylene Gas and Calcium Carbide*,\* in which he states, in the closing chapter on purifying and drying, that, "under ordinary conditions, the gas will be thoroughly purified by being passed through material saturated with sulphuric or hydrochloric acid, and afterwards drying by passing the gas through calcium chloride."

For the information of the readers of this JOURNAL, a description of a purifier constructed merely to test the utility of the method advised, and found to be so efficacious that it has remained in use during the last three months, and is now working satisfactorily, is here given.

It was constructed from odd material at hand, and any one handy with the soldering iron can make one at a cost of not more than five or six shillings, and the cost of recharging whenever it may be necessary would not be more than a few pence.

The materials required are a 28-pound carbide can, measuring 16 inches in height and 8 inches in diameter, a 7-inch flower-pot and saucer, enough coke broken up to about the size of walnuts and free from dust to fill the flower-pot, a few feet of compo. pipe, three  $\frac{3}{8}$  inch brass unions, a small tap, a piece of perforated zinc about 6 inches square, a sixpenny box of glass wool from the chemist's, a tube of tin about 19 inches high and  $3\frac{1}{2}$  inches in diameter, such as platinum paper is stored in, a small tin box 3 or 4 inches wide and about 1 inch thick—an old harness paste box will do—2 pounds of hydrochloric acid, and  $1\frac{1}{2}$  pounds of calcium chloride.

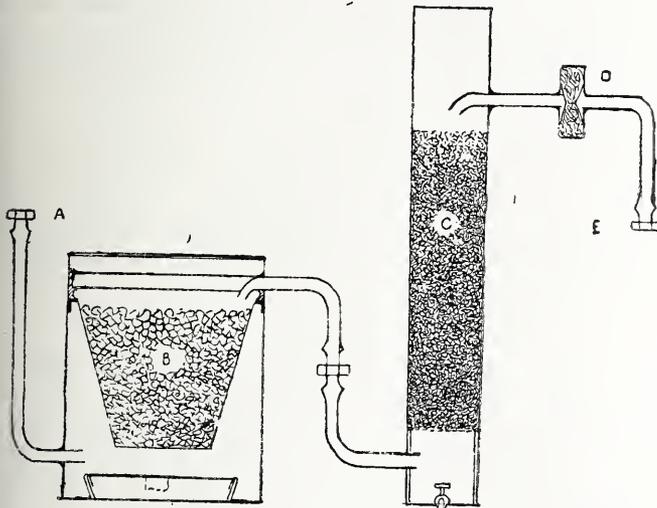

Proceed as follows: Cut the carbide can down to  $10\frac{1}{2}$  inches in height, and pierce a hole about 3 inches from the bottom to take inlet pipe, and another, one inch from the top on the opposite side, for the insertion of the outlet; solder four pieces of tin in the bottom to hold the saucer in place—this is to catch any drip there may be from the flower-pot. Next make a tin collar, the outside to be large enough to just fit in the can, and the inside sufficiently large to take the flower-pot just under the rim. Solder this in the can so as to support the flower-pot at about 2 or 3 inches from the bottom, then take the flower-pot and drill 4 holes round the side at about 1 inch from the bottom—these are to break the gas into streams. Place the flower-pot in the can, the rim resting on the collar; fill in the space between the pot, and the side of the can with plaster of Paris, finishing off smooth all round, and, when dry, give it a coat of any enamel paint that may be handy; measure off sufficient pipe to reach outlet of generator from inlet of purifier when in position, and, inserting

\* *Acetylene Gas and Calcium Carbide*, by G. F. Thompson, Consulting Engineer. Published by the author at Lombard Chambers, Brixton-street. Price, 3s. 6d.

one end of it, about 1 inch into the hole, made 3 inches from the bottom, solder in firmly, making a good joint; next, taking one foot of pipe and passing 2 inches into the top hole of can, solder it in the same manner as before, cut out a top to fit inside the can, and with the edge turned down  $\frac{1}{2}$  inch all round.

Take an old marmalade jar and three parts fill it with hydrochloric acid—this had better be done out of doors, set the jar into an earthenware developing dish, put the coke, bit by bit, into the acid, dousing it under with a piece of stick, turning it out as it is saturated, and adding more acid as required until all is thoroughly soaked; allow it to drain a minute or two, and then transfer it to the flower-pot, filling it to within about one inch of the top; put in the top or lid, and, in order to make its removal easy for recharging, fill the interstices with plaster of Paris, as before. When dry, run solder right round, making it properly gas-tight, and your purifier is ready.

Now for the dehydrator: take the tin tube and punch a hole about 4 inches from the bottom, and on the opposite side a second about 3 inches from the top, to take inlet and outlet pipes, and a third as near the bottom as possible in the front, to take the small brass water-tap which is to allow of the removal of any moisture that may gather at the bottom. Next make a grid of perforated zinc, just small enough to drop down inside the tin, and supported on a tin sleeve or lining, so that the grid when in position is about an inch above the inlet hole. Solder on

A Inlet from Generator.  
C Calcium Chloride.

B Coke saturated with Hydrochloric Acid.  
D Outlet to Main Service pipe.

the tap, and insert the end of a piece of pipe about one foot long in the inlet hole, and a piece about three inches in length in the top or outlet hole, soldering them both in place, take the harness paste box and punch a hole through lid and bottom in the centre, and barely insert the end of the short outlet pipe, solder it round inside; and over the end of the pipe, inside the box, solder a rather obtuse cone of perforated zinc, then take the top of the box and enough pipe to reach to your service main, putting a zinc cone over the end as before, fill the box loosely with glass wool; and, putting the lid on, solder round securely.

The object of the glass wool is to remove any bodily impurities there may be in the gas, and also it forms a strike-back trap. Should the flame from any cause do so, it would prevent the flame reaching the purifier and generator.

Fill the tube with the calcium chloride and solder on the cap or lid, joint your brass unions one between purifier and dryer, and the others between the generator and purifier and wool-box and main service pipe. Give the whole two coats of red enamel paint, and your task is finished.

When the time comes to recharge the purifier, disconnect it from generator and dryer, and run a hot soldering iron round the lid, take out the coke, wash it in a pail of water, resaturate and return it to the flower-pot, solder on the lid again, and recouple the unions. The cost is a mere trifle, and the benefit great. The accompanying sketch will help to clear any doubtful points in the description.

JESSE LANDON.

#### LONG-RANGE PHOTOGRAPHY.

Mr. Ernest Marriage, who is so well known for his unique architectural studies, chanced on a singularly happy moment, as the President reminded the meeting, to deliver his lecture on "Tele-photography," which drew a large audience to the Croydon Camera Club lecture-room last week.

Mr. Maclean, in his further remarks while introducing the lecturer, drew attention to the great interest and discussion which had lately arisen as to the value of long-range photography for military reconnaissance,

and described a number of such photographs taken by Mr. Shelley, special correspondent of *The King*, the negatives of which he had seen, and from which he judged that, by the aid of a lantern, they would give much valuable information. He also alluded to the admirable treatise on the subject by Mr. Dallmeyer, and handed round for inspection a copy of the work in question.

Mr. Marriage, who was received with much cordiality, began by explaining, with the aid of lantern slides, such special forms of apparatus as he found best to use. A strongly made long-extension (but not treble extension) camera, and a very firm tripod, were the main desiderata. As regards length of exposure, it compares with that required for the ordinary image directly as the square of the linear magnification. How to reckon this last was also clearly explained.

Following these technical data, a large and varied display of slides from Mr. Marriage's tele-photo studies were shown. Thus, sets of three or more were displayed to illustrate the magnification of the image obtainable with various "negative" attachments. Others illustrated the difference of definition existing between (a) a tele-photo view of a distant village and (b) a view of the same village taken with an ordinary lens and having the part included by (a) enlarged to the same dimension. The view (a) was considered the best; (b), no doubt, suffered somewhat because of the magnification of the grain in the film, which would accompany considerable enlargement.

#### NATURALISTIC PERSPECTIVE.

The effect of the tele-photographic lens in rendering perspective was next dwelt upon, and, although under certain circumstances there is a considerable gain in employing the above lens, the feeling of the meeting was that the lens is apt to err in a direction exactly opposite that in which the W. A. lens is at fault. A notable example of this faultiness was shown in a cow taken from the rear with its head turned round, so that the latter was seen in profile. In this case the diminishment in size which the eye is accustomed to see in subjects which recede from the picture plane, was not exhibited, and hence the cow's head, although forming that part of the animal furthest away from the lens, seemed to be about one and a half times as large as it should be.

Many other points and uses of this useful lens were illustrated with a number of striking, and, in many cases, charming lantern slides, several of which had been obtained with *The Naturalist's Hand Camera*. Special note may be made of a figure study, and of some botanical pictures exhibiting minute flowers, &c., in their native habitats. Mr. Marriage concluded his lecture with a brilliant series of pictures, illustrating architectural details of quaint and exquisite carvings, mainly of capitals in high positions, which few eyes can see *in situ*, and which the ordinary lens cannot do justice to.

At the close of a lecture listened to with marked attention, a considerable amount of discussion was held, and many questions asked, those taking a principal part in this being Messrs. Maclean (who explained that, when photographing objects over a mile away, the ordinary estimated exposure needful might be reduced to one-third), Rogers, Edwards (who observed that after this lecture he decided to answer the question, "Is Marriage a failure?" with a "No!"), Isaac (who as usual worked the lantern with much skill), Jeffrey, Jewell (who remarked upon the difficulties attending long-distance photography in hot climates, stating he had often seen at Melbourne raccourse the horizontal top of a long wooden enclosure, at a distance of about a quarter of a mile, represented by a dancing serpentine line), Wratten (who spoke of his experiences with tele-photography in 1897), and Salt.

At the instance of the President, a strongly emphasised vote of thanks was adopted by acclamation, accompanied by sustained applause.

#### RECENT ADVANCES IN RADIOGRAPHY.

THE war seems to have, for the present, knocked the interest out of all other subjects, and such engrossing matters as those which advanced photography continually brings forward have to take a back seat. Even at the Camera Club, the last new developer and the most recent isochromatic screen are forgotten, and the members crowd round the fireplace at the end of the big room, where the latest telegrams from the seat of war or the fairy tales from Dr. Leyds are posted every half-hour, or as soon as they come to hand.

It might, therefore, have been anticipated that a discourse on such a recondite subject as the Röntgen rays would have failed to attract a sufficient audience, and that Mr. William Webster would have found in front of him a beggarly array of empty benches; but, happily, this was not the case, and by eight o'clock the members mustered in goodly numbers. There were many visitors, chiefly of the medical persuasion, also present, and these gentlemen took upon themselves the chief

burden of the interesting discussion which followed the reading of the paper.

Mr. Webster commenced with that awkward thing known as an apology. He lived at Blackheath, and the Blackheathens are much belated in the matter of electric lighting. Owing to the fogs, and to the somewhat slow travelling due to the South-Eastern Railway, Blackheath does not get its news very quickly, and therefore it was a long time before it dawned upon these dwellers in Kent that electric lighting was possible. After some years, wires were laid down, but the current which is to flow along those conductors is not yet ready, and therefore the beautiful experiments with the spectrum which Mr. Webster had intended to show to the Club could not be rehearsed, and could not be performed. An experimental lecture without experiments is a futile thing, and the lecturer therefore uttered maledictions upon the Blackheathen absence of electric current, revenged himself by boycotting everybody concerned, and made up his mind to trust to lantern slides alone for his illustrations.

Mr. Webster confined the first portion of his lecture to the consideration of various curiosities in the anatomy of the skeleton of the hand as revealed by radiography. Some years ago he showed several of his pictures to eminent surgeons, and it was acknowledged by them that this new method of showing the bony structure of the living hand must lead to serious modifications of the views held by anatomists as expressed in the text-books. These differences were associated more particularly with the gradual ossification of the structures, which is not complete in the human hand until the adult stage is reached.

Mr. Webster's radiographs, or skiagraphs, which were projected upon the lantern screen showed the gradual process of ossification very beautifully, from the infant hand to that of the adult. In the new-born child the bones are in quite a rudimentary condition, the carpal and metacarpal bones looking like so many ill-formed and detached pieces of limy matter. At two years of age the shape of these bones becomes more pronounced, and the little button-like outgrowths (epiphyses) begin to make their appearance between the shaft bones (phalanges) of the fingers. At four and a half years the buttons are much larger and distinct, and the carpal, or wrist, bones become far more accentuated. At seven years all the bones of the hand can be readily recognised, although their shape is as yet imperfect. The hand may be said to reach its perfect condition, so far as youth is concerned, at about the twelfth year, but we shall presently see that variations come in through external conditions. The button-like epiphyses are still prominent between the phalanges, but in the next few years they gradually join the shank bones until the adult hand is fully formed.

Radiography has taught our anatomists one thing at least that they never knew before, and that is the curious circumstance that the ossification process is hastened by hard work. One of Mr. Webster's photographs showed the hand of a boy of fifteen which was as fully developed as if he had been six years older; he was the son of a blacksmith. But the credit of the first observation of this kind is due to Mr. T. C. Hepworth who, four years ago, recognising that such an effect might be anticipated, radiographed the hand of Master Basil Gauntlett at the age of ten years, and proved that the three hours' daily practice at the piano had caused the same hastening of nature's handiwork. Mr. Hepworth was present at the lecture and called attention to this early observation of his.

Mr. Webster showed a photograph of the first Jackson's X-ray tube, and he rightly pointed out that this was a modification of Crookes' tube. Some of us are apt to forget that, without the early labours of Crookes, Röntgen's X rays would probably have remained undiscovered for a long time to come. With this same tube Mr. Jackson, of King's College, London, had seen the bones of his hand on a screen some time before Röntgen had astonished the world with the same observation. Mr. Webster had also a good word to say of the Apps induction coil. Apps was one of the first makers of these coils, and it is pleasant to know that his efforts have not been superseded by late comers.

Mr. Webster next approached the very interesting subject of the effect of the X rays upon the skin. It would seem that fond parents are very loth to allow their children to place their hands, or other parts of their anatomy, under the influence of these rays, and small blame to them, for reports of the dire injuries resulting from such influence have been rife ever since Röntgen made his first experiments. The lecturer himself had suffered from a kind of X-ray sunburn, and the mischief culminated in the loss of two of his finger-nails; but it is certain that these effects only come about when the skin has been subjected to the action of the rays time after time at frequent intervals. A single sitting, even though it may extend to a quarter of an hour or more, has no perceptible effect upon the epidermis. On the other hand, these mysterious radiations would seem to have a decidedly beneficial action under certain conditions. The superficial tanning of the skin which is brought about renders the surface immune to the bite of such insects as gnats and mosquitoes. A sun-tanned skin is, in like manner, proof against insect attack, and there is reason to believe that the radiant heat from prolonged exposure to the electric arc light confers a similar immunity upon the skin.

It has long been thought that the X rays may be found of therapeutic value in the cure of certain skin diseases, and Mr. Webster brought forward a case which seems to corroborate this view, although count may

not have been taken of diet and other hygienic conditions which prevailed at the time of treatment. It was a case of lupus. First we were shown a photograph of the patient as he was before treatment, with the horrible fungoid growth upon his nose. After some weeks' daily application of the X rays, the patient wearing a mask which protected every part of his face but the diseased organ during the application of the rays, he was, to all intents and purposes, cured. His later state was shown not only by a photograph, but, in still more convincing manner, by the patient himself, who was "on view" during the lecture. The consideration of this interesting case brought Mr. Webster's lecture to a conclusion.

Dr. Abrahams, who occupied the chair, in commenting upon the lecturer's remarks and illustrations, said that abroad, especially at Copenhagen, a number of lupus cases had been treated by exposure to sunlight, and about thirty per cent. of cures had been reported. He had some doubt whether such cures could be regarded as permanent, a thing which time alone could show. There was no doubt that radiography was of enormous service in the study of anatomy, and they all would have to correct the impressions gained from books.

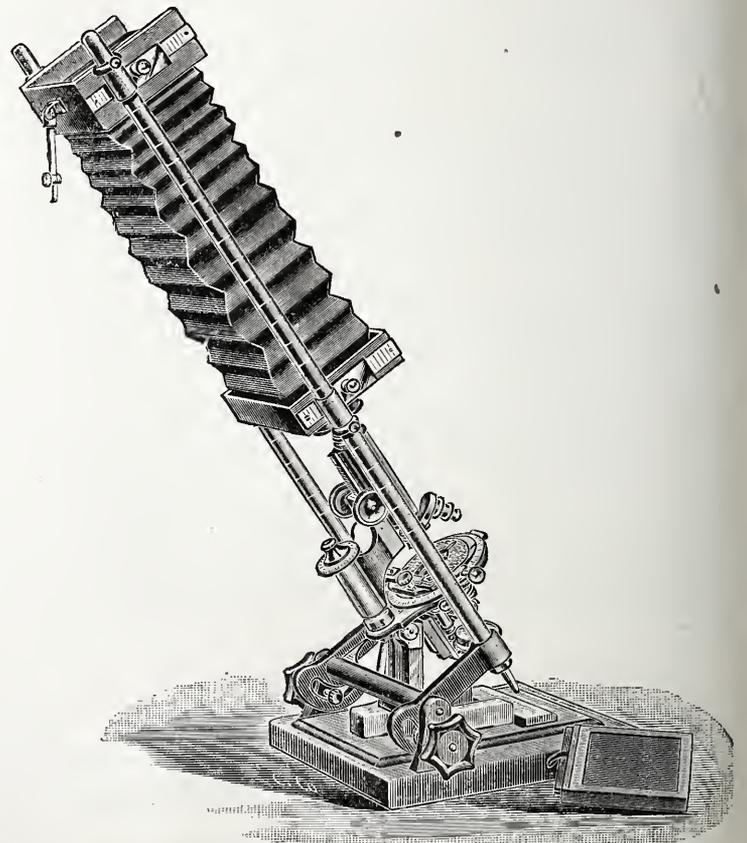

The President of the Röntgen Society said that there is no doubt that the text-books put the ossification of the centres very much too late. He was of opinion that Mr. Webster was wrong in depending so much upon what he might call the snap-shot principle in making his radiographic exposures. As a rule, an extended time could be given to the work with advantage. He also thought that Mr. Webster in his lupus case had used a needlessly powerful current, the same effects being gained in a case which had come under his own notice with a much weaker force. He questioned, too, whether the indiarubber mask described by the lecturer was a real protection to the other parts of the skin. He himself always used a mask of lead, which was quite impenetrable by the rays.

After Mr. Webster had dealt in a brief manner with the several points raised in the discussion, he showed a new form of reflecting lantern or aphengescope, which had been recently introduced by Messrs. Newton for throwing drawings and solid objects on a screen. The lantern body was of the old pattern, and it contained two incandescent (gas) burners, each furnished with a reflector. The projecting lens was a single one of about four inches diameter.

#### THE BAUSCH AND LOMB PHOTO-MICROGRAPHIC OUTFIT.

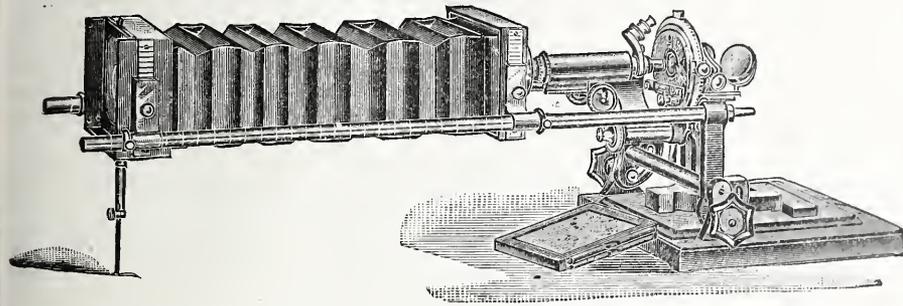

Agents: A. E. Staley & Co., 35, Aldermanbury, E.C.

AMONGST the many specialities of the renowned American house of Bausch & Lomb, for which Messrs. Staley are agents, may be mentioned the admirable photo-micrographic system shown in the illus-

trations. The camera, which takes either quarter-plate or 5 x 4, has all the usual motions; the bellows gives an extension of twenty inches. The stand is solid, enamelled, with nickelled fittings; there are double clamping

screws for vertical or horizontal positions; adjustable supporting arm for camera, and double dark slide. The light-tight metal connexions between microscope and camera are blackened inside and out. The microscope supplied is Messrs. Bausch & Lomb's newest model, with two eyepieces, and one-inch, two-thirds, and one-sixth objectives; sub-stage, with iris diaphragm and ray filter; triple nose piece; con-

densing lens, on stand; and Welsbach gas lamp, with metal chimney and iris diaphragm. The entire system is beautifully finished throughout, and we have much pleasure in bringing it to the notice of our readers, who will gain a clear idea of its external appearance from the illustrations.

COMMERCIAL SAMPLES OF CALCIUM CARBIDE.

The following is a translation from the *Annales de Chimie et de Physique* of a paper by M. Henri Moissan, the discoverer of electrical carbide:—

Although it may appear an extremely simple thing, yet the manufacture of calcium carbide in large quantities presents not a few difficulties. The precautions to be observed in the preparation of the mixture, the choice of suitable lime and carbon, the heat of the furnace, the arrangement of the large electrodes between which the current passes, have been in turn considered, and at the present time the best conditions are pretty clearly understood. The withdrawal of the large volumes of incandescent gas produced is still a difficulty, but one which, according to the most recent technological experiments, is on a fair way to solution.

At the outset of this industry, the materials used—the lime and carbon—left much to be desired. The earliest manufacturers of carbide used, as a source of carbon, coke containing much mineral matter as well as sulphur and phosphorus. The lime, too, was anything but pure, containing almost always silicate of aluminium and phosphates and sulphates. It is not surprising, therefore, that such a mixture, after ignition in the electric furnace, should have furnished a most impure carbide. It contained phosphide of calcium, sulphide of aluminium, and silicides, decomposable even by water. In the presence of a small quantity of water, this compound produced an extremely impure acetylene, containing phosphoretted hydrogen and sulphuretted hydrogen.

In order to increase their profits, or perhaps through ignorance, these firms produced a very impure carbide, and therefore a very impure acetylene. This low-grade product was the cause of the early difficulties in the application of acetylene to lighting, but it was soon understood that a pure lime and carbon, as free as possible from all mineral matter, must be used, and at the present time the manufacture is done under much better conditions. Carbides are now obtainable in commerce which have been thoroughly fused, are homogeneous, and exhibit the sharply crystalline fracture, with reddish-brown reflections, characteristic of the pure product.

It is to carbide answering this description that the acetylene manufacturer must give the preference. Although its appearance is so characteristic, the analysis of carbide is advisable. Many methods have already been given, and that of MM. Lunge and Cedercreutz, in which they let fall a certain weight of carbide into water, appears to me to give good results. The great difficulty is to secure an average sample, the hardness of the material making this very difficult. Theoretically, one kilo of carbide gives 349 litres of acetylene (*i.e.*, one pound gives 5.6 cubic feet.—*Translator*).

In decomposing samples of carbide with milk of lime, saturated with acetylene, we obtained the following results, expressed at 0° C. and 760 mm. (= 32° F. and thirty inches).

	1.	2.	3.	4.	5.	6.	7.
Vol. (a)	292.81	294.10	301.30	304.61	307.72	316.41	318.77
(b)	4.70	4.72	4.87	4.88	4.94	5.08	5.12

*a* gives litres per kilo; *b* gives cubic feet per pound. If, on the other hand, the carbide is not the fused and crystallised variety, if it is porous and greyish, the yield is always less. With such samples we obtained the following figures:—

	1.	2.	3.
Vol. (a)	228.6	250.4	260.3
(b)	3.67	4.02	4.18

Without dwelling further on the impurities in acetylene gas, we will pass to consider the form in which the impurities exist in the carbide. We may, however, point out a fact already mentioned by M. Chuard, that acetylene contains ammonia. He found the percentage in the gas to vary from .03 to .06, and the nitrogen in the residue from .24 per cent. to .40 per cent. In four samples which we analysed we found total N.:— .02, .12, .15, and .31 per cent. Several of these carbides gave a small quantity of hydrogen phosphide, whilst others were free from it; but we have studied in particular the composition of the insoluble residue which the carbide leaves when decomposed by water.

In order to obtain this residue we decomposed the carbide with a solution of sugar in water, in this way keeping the lime in solution as saccharate. The small residue thus remaining (we used ten grammes of sample) was thrown on to a filter, washed first with sugar solution, and then with pure water, both liquids being free from carbon dioxide. It was then treated with alcohol and ether, and dried *in vacuo* at 40° C.

Examined under a microscope, this residue shows calcium sulphide, calcium and iron silicates, and white particles rich in lime and sometimes a little sulphide of calcium and graphite. It loses weight slightly in hydrochloric acid (1 in 10), iron, lime, and alumina passing into solution. Silicide of carbon and graphite remain unaltered, whilst calcium sulphide disappears. By treating with hydrochloric acid (concentrated), a certain proportion of lime, iron, and silicon passes into solution, but there is no relation between the insoluble matter and the yield of acetylene. The following are the results obtained by treating the samples as above described:—

	Per Cent. of Residue.				
	1.	2.	3.	4.	5.
Sugar solution	3.4	5.3	3.9	3.9	3.4
Hydrochloric acid (1 in 10)	2.1	1.9	2.4	2.4	1.4
Hydrochloric acid (concentrated)	1.7	1.7	2.2	2.2	1.1

By a use of this method, coupled with an examination of the residues under the microscope, we have gained much information as to the form in which the impurities exist.

*Silicon*.—This is present mainly as silicide of carbon. This compound is easily recognised under the microscope, its hexagonal crystals, green or blue, being extremely characteristic. Owing to its great density (3.12) and its equally great stability, it can be easily separated from other substances. If the carbide residue be treated alternately with boiling sulphuric acid and hydrofluoric acid, only graphite and carbon silicide are left, and the latter can be readily separated by means of bromoform (*sp. gr.* 2.9). Silicon sometimes occurs, as Le Chatelier has shown, as calcium silicide, tiny globules, showing a metallic fracture and consisting of iron, carbon, and silicon, being sometimes observable. Crystals of silicon, as described by Marsden, are also to be found. We have never come across any samples of carbide which, when treated with a small quantity of water, exhibited the spontaneous inflammability of hydrogen silicide, but it has often occurred that this gas was evolved when the calcium silicide in the insoluble residue was treated with strong hydrochloric acid.

*Sulphur*.—In the samples which we have examined the sulphur was present as calcium sulphide or aluminium sulphide. We detected the presence of calcium sulphide in some of the residues from treatment with sugar solution by means of a solution of lead acetate, solution acidified with acetic acid. Under the microscope the white particles of calcium sulphide became completely black. Calcium sulphide does not evolve hydrogen sulphide by the action of water in the presence of hydrated lime. This we proved by finely powdering a small quantity of calcium sulphide prepared in the electric arc, agitating with milk of lime and testing the filtered liquid with a lead salt. No black precipitate was produced. It is to be noted that all the carbides which we have examined give, with excess of water, a milk of lime, the clear solution from which gives a black precipitate with salts of lead containing sulphur and traces of phosphorus, a result due to the decomposition of the calcium sulphide in the presence of the milk of lime. Hydrogen sulphide does not, however, occur in acetylene when the carbide is decomposed in a plentiful supply of water, the lime produced tending to retain the gas.

In the preparation of carbide the sulphates contained in the lime are reduced, forming calcium sulphide, which is not decomposed by water. If, however, the lime contains aluminium silicate, silicate of carbon is formed, and, if there is sulphur, as sulphate or sulphide, sulphide of aluminium, decomposable by cold water with evolution of hydrogen sulphide.

M. Mourlot, by heating sulphide of antimony and aluminium in the electric furnace, has indeed obtained a fused sulphide of aluminium of crystalline fracture and perfectly stable at the high temperature. Carbide prepared under these conditions can therefore contain aluminium sulphide, and will give rise, in presence of cold water, to the evolution of

hydrogen sulphide. The sulphur cannot exist in the state of silicon sulphide, as we proved by heating to redness impure aluminium containing silicon in a tube in a current of hydrogen sulphide. The  $Al_2S_3$  melted and a ring of sulphide of silicon sublimed into the tube. Hence it could not occur in "electrical" carbide.

When a carbide contains a certain quantity of calcium sulphide, it gives, on decomposition with water, traces of an organic compound containing sulphur, and differing from hydrogen sulphide. This can be shown as follows.—

The acetylene produced by acting on the carbide with excess of water is passed through potash bulbs containing a solution of copper nitrate, or potash, or lead acetate. It is then burnt, and the products of combustion led into an aspirator and agitated with a little water, kept at  $0^\circ C$ . In three experiments made thus, a small quantity of sulphuric acid was detected. The potash bulbs had retained the hydrogen sulphide, and had allowed a sulphided compound to pass over. An experiment made in the same way, but aspirating the air of the laboratory, gave no sulphate. In this experiment the first Liebig tube containing copper nitrate or lead salt blackened under the action of hydrogen phosphide, but contained after the experiment only traces of sulphur, and often none at all. The gas was therefore perfectly freed from hydrogen sulphide.

The weight of the total sulphur in the carbide gave us a percentage of sulphur in the three samples: .37, .43, .74.

Iron is in the state of silicide or carbo-silicide. Its percentage is very variable, and depends almost entirely on the purity of the carbon used.

Phosphorus is the most difficult impurity to deal with. The greater part exists as calcium phosphide, which is decomposable by water, but it exists also as tiny globules, metallic in appearance, and containing iron and silicon.

Carbon.—Some samples of carbide contain notable quantities of graphite. The graphite which we isolated was in thin scales, sometimes hexagonal, but most frequently of round, irregular shape. It exists in only small quantity, and retains silicon and calcium with great tenacity.

Lastly, as the existence of diamonds in commercial samples of carbide has been asserted, we made special experiments upon this point.

After treatment with water, followed by hydrochloric acid, the residue was subjected to the process, which we have already described, for the separation of diamonds in presence of all kinds of other substances. We isolated some transparent particles, round in form, and with no apparent crystalline structure. They were incombustible in oxygen in the platinum boat described in our memoir on artificial diamonds.\* None of the samples contained diamonds.

### THE "BIOKAM."

At the meeting of the London and Provincial Photographic Association, on January 25, Mr. Walter D. Welford showed and described the Biokam apparatus for animated photography. It is remarkable for its small and compact appearance. The film is twenty-five feet in length, giving 700 exposures. Used as an ordinary hand camera, the same number of single views can be secured. The films are contained in drums, which are attachable to the apparatus as required. The exposed films may be rewound into the drums if desired, enabling any number of films to be exposed without recourse to a dark room. The film is pierced with one slit-like perforation in its centre between each exposure. After exposure the film is wound upon a frame studded with upright pegs, of a size capable of accommodating twenty-five feet of film. Twenty ounces of developer is named as enough solution, but sixty ounces is nearer the mark. The dish supplied was also, Mr. Welford considered, too shallow. Printing is done by passing through the apparatus the negative and an unexposed film in contact, and developing as before. The camera is then quickly turned into a projecting apparatus. There are two lenses—one for taking and one for the projection of the pictures—both of very short focus. Used with the incandescent gas light, for which the apparatus is intended, there is every safety, but, of course, only a small picture is given.

Mr. Welford subsequently showed on the screen a number of pictures, including four by himself taken in Belgium, and others of street scenes—conjuring, &c.—supplied by the Company.

### SPECTROSCOPES AND GRATINGS FOR COLOUR PHOTOGRAPHY.

In a recent number of *Nature* Mr. C. P. Butler, of the Royal College of Science, draws attention to the fact that Mr. T. Thorp, of Manchester, who has so successfully reproduced copies of Rowland's gratings, has been able to make an "echelon" grating on the principle suggested by Professor A. A. Michelson last year, but stated to be well nigh impossible on account of mechanical difficulties. The success of the operations,

\* *Le Four Electrique*, p. 174.

adds Mr. Butler, depends on the shape, depth, and spacing of the grooves, and after many calculations and preliminary trials Mr. Thorp finds he can produce echelon films throwing the *whole* of the light into the first, second, or other requisite order, the direct image being practically suppressed.

In order to show us the perfection to which his films have attained, Mr. Thorp has forwarded us a small spectroscope with fixed slit, selling at 10s., a small grating selling at 10s., and a large grating (mounted films) which he purposes disposing of cheaply to purchasers of his spectroscopes for experiments in colour photography diffraction methods, the method being quite distinct from that of Professor Wood, to whom, however, adds Mr. Thorp, we are all indebted for the inception of the process.

Professor Wood, Mr. Thorp points out, cannot use rulings of more than about 3000 or 4000 to the inch, whilst by Mr. Thorp's method lines of any closeness can be successfully used. He has *only one* ruling, yet he is enabled to show diffraction pictures in most brilliant colours, natural or otherwise, and has already exhibited the spectroscopic apparatus, which he has made for experimental purposes only, before several societies in the North of England. Mr. Thorp has been working at the process for some twelve months, and believes he sees his way to a very simple and efficient form of apparatus for exhibiting the pictures, as well as a simple means of reproduction. The latter process is *un fait accompli*, but, as the principal point in connexion with the idea is the subject of a patent, he cannot for the moment go further into the matter. He is at present investigating a new form of ruling, which promises to be quite an advance, as its spectrum is almost as brilliant as a prism one, nearly all the light being thrown into one order.

We have found the little spectroscope Mr. Thorp has kindly sent us of the greatest use. It is well worth the 10s. charged for it. All those of our readers who are interested in the allied subjects of spectroscopy and colour photography, should procure Mr. Thorp's list from him at Whitefield, near Manchester. It refers in detail to his transmission diffraction gratings, prism gratings, spectroscopes, dynamometers, polarising solar eyepieces, and other instruments.

### PHOTOGRAPHIC CLUB'S ANNUAL LANTERN ENTERTAINMENT.

The Annual Lantern and Musical Entertainment and Ladies' Night took place on Wednesday, January 24, at Anderton's Hotel, Mr. H. Snowden Ward in the chair. The entertainment was under the capable direction of Mr. E. A. Newell, who had provided an excellent programme, which was admirably carried out by Mr. Fred. W. Stephens, Mr. R. B. Hopkins, Miss Annie Swinfen, Mr. Chas. Volcard, Mr. Ager Grover, Mr. Musgrave Tufnail, and the other members of the Euterpean Quartette, with Mr. Thos. F. Noakes, accompanist. Lantern exhibitions were provided to vary the programme, slides being contributed by Mr. and Mrs. Welford, Mr. W. R. Stretton, Mr. Lewis Medland, Mrs. Catherine Weed Ward, Messrs. Chas. Reed, G. W. Tottem, J. R. Williams, and others. The entertainment was an unqualified success, credit for which must be given to the untiring efforts of Mr. Newell, seconded by the labours of the stewards.

### REDHILL AND DISTRICT CAMERA CLUB'S LANTERN EVENING.

ON January 24, the Club gave a most interesting lantern exhibition on a very large scale, at the Market Hall, Redhill, the subject being "Round about the Matterhorn and Aletsch Glacier." The lecture was given by Mr. Henry Speyer, a member of the Club. The Mayor of Reigate (Mr. F. E. Barnes, J.P.C.C.) took the chair, accompanied by the Mayoress. Mr. William Brooks (President of the Club) acted as lanternist, the lantern being in the gallery at the end of the hall, some seventy feet from the screen. The lecturer handled his subject in a very masterly manner; he has a very pleasing voice and a good style of delivery; his pictures show that his work (as an amateur) is of the highest possible order, and he knew his subject well, being an enthusiastic mountaineer. The lecture was interspersed by bits of dry humour. He took his audience from the Lake of Geneva in the lowlands, up to the highest peaks, and his cloud studies were perfect masterpieces of photographic art, and were loudly applauded by the audience; from start to finish the interest never flagged. The audience was one that any lecturer might be proud of, and was composed of the *élite* of Reigate and Redhill. A large number of reserved seats had been provided, which were soon filled and had to be largely increased. The lecture was in aid of the funds of the Club to purchase apparatus, &c. The services of both lecturer and lanternist were entirely free, and the whole was looked upon as a grand success.

After the lecture the Mayor proposed a vote of thanks to Mr. Speyer, the lecturer, and also to Mr. Brooks for acting as lanternist. The Club numbers nearly sixty members, and is still increasing. It is considered that an evening of this kind is the best thing to help a society on.

## LANTERN MEMS.

PHOTOGRAPHY in colours will always be a fascinating subject, and, though the discovery of the philosopher's stone in this respect is still in the dim distance, some advances have been made towards it during the past five years. Ives's name will always come to the top as one of the most earnest workers in the art of producing photographic representation in the colours of nature on the principles enunciated by the late Professor Clerk-Maxwell. The lecture by Professor R. W. Wood at the Society of Arts recently was full of interest, and the appreciative audience made up in enthusiasm for its comparative smallness in numbers. Previous lectures on this subject have taxed the resources of the attendants to find seating accommodation for those desirous of seeing the results of recent experimenters' work, and I quite thought I should have to be content with an odd corner in the lecture-room of the Society when I arrived just before eight o'clock.

\* \* \* \* \*

THE lecturer had his subject at his fingers' ends, and could tell us in straightforward language what he knew himself about colour photography. He was not slow in giving credit to Mr. Ives and Dr. Joly for what they had done, and also to M. Lumière for his system of colour printing, but each of these was different in principle and method of working to the process he had developed, namely, the diffraction process. The results of this process, although very beautiful, could not claim to out-distance those mentioned, for it is not practical to project the result so that a large audience could see at once the beautiful coloured subjects, as was done by Professor Lippmann, Mr. Ives, Dr. Joly, and others.

\* \* \* \* \*

THE essence of the success of the diffraction pictures lies in having the right number of lines to the screen to form the diffraction grating, and viewing the result from the exact point of view where the eye receives the rays representing the red, green, and blue-violet sensations in their proper positions. To obtain pure colours, lines from 2000 to 3000 to the inch have to be drawn. The former give red rays, while 2400 lines to the inch give green and 2750 blue. Pictures are taken of the same subject through screens of these different gradations of lines, and the film positives obtained from same put in superposition to make one transparency. In practice it was found that bichromated gelatine was too coarse in the grain to

give the best results, and so a solution of celluloid was poured on each of the positives, and, when dry, the very fine strip pulled off, and all three placed in contact above each other in exact register.

\* \* \* \* \*

THE cost of ruling screens with such a number of lines is very great, and the risk of damage in using same is considerable, so it is interesting and satisfactory to know that excellent, if not equally good, results can be obtained from a photographic print from these refracted lines. In fact, a positive can be obtained from a positive, and so can be duplicated many times. The technical working of the process will be best understood by reading the article *in extenso* in the Society of Arts Journal, but it may be here interesting to state that the results shown justified all that was claimed for the examples.

\* \* \* \* \*

DIFFICULTIES of manipulation in working out the process occurred to Professor Wood, as is invariably the case with inventors, more particularly in getting screens ruled fine enough and of perfect regularity; but this seems to be surmounted now by screens ruled by Professor Rowland's engine at Baltimore. The examples shown in the library of the Society of Arts were most interesting and fascinating, the colours of the subjects being particularly brilliant. The device for seeing the transparencies stereoscopically was very ingenious. The two designs were each placed in front of a double convex magnifying glass, and at the focus of these lenses two horizontal slits in an opaque substance were made, and through this the positives were viewed. These slits were long enough to permit of persons of various interocular widths using them and in front of the slit two thin prisms are mounted to combine the two pictures, and so get stereoscopic effect. With all these pictures the light has to be in such a position that the rays fall at a certain angle on the design.

\* \* \* \* \*

FROM the experiments made by Mr. Thomas Thorp of Manchester, it is possible to get diffraction gratings, or rather grooves of a saw-tooth section, of  $\frac{1}{20000}$  of an inch in depth and  $\frac{1}{10000}$  of an inch from ridge to ridge, and these, which are produced by a kind of steam-hammer process, are utilised by being copied in a celluloid casting, which then acts as a diffraction grating. The possibility of getting a suitable transparency for projection on the screen is now likely, for the work to this end depends on getting the light concentrated in one spectrum, and this much has been accomplished in verification of Lord Rayleigh's theory.

\* \* \* \* \*

AN interesting subject has been thrashed out by Professor S. P. Langley, of Washington, U.S., viz., the percentage of light reflected from different surfaces, and taking black velvet as the most absorbent and a mirror as the least, and therefore highest reflective surface,

we have the percentages of reflected illuminant expressed as follows:—

*Black*.—Velvet, 0·4 p.c.; cloth, 1·2 p.c.; paper, 4·5 p.c.  
*Blue* (dark), 6·5 p.c.; *Green* (dark), 10·1 p.c.  
*Red* (pale), 16·2 p.c.; *Yellow* (dark), 20 p.c.  
 Blue (pale), 30 p.c.; *Yellow* (pale), 40 p.c.  
*Green* (pale), 46·5 p.c.; *Orange* (pale), 54·8 p.c.  
 White (pale), 70 p.c.; *Mirror*, 92 p.c.

HENCE the purity of whiteness on lantern screens is a necessity to get the best results, and for certain special purposes and effects the silvered screens of Mr. Anderton's are beneficial; the table is also useful in connexion with photographic work, colours of walls, &c., it being stated that glossy or varnished paint is better than dull, and incandescent gaslight with a white varnish on the wall is the most economical illumination for a room.

\* \* \* \* \*

ONE of the leading weekly illustrated papers has "broken out in a new place," and now supplies lantern slides of the war pictures they publish at 1s. each, or hire them at 5s. a dozen. They also have a complete set with lecture that they hire out for 35s., and certain reductions for extension of time if more than one lecture is to be given. Dealers will be pleased to see there is no cutting of prices here, and the "penny per slide" scale, which can scarcely be worth while for a tradesman to bother with, does not apply in this case.

G. R. BAKER.

#### LECTURE SIGNALS.

THAT much of the success in limelight lecturing is attributable to a well and pre-arranged system of signalling between lecturer and operator is a fact well known to any one possessed of even a moderate amount of experience in limelight procedure. No doubt there are exceptions, in which signalling may be entirely dispensed with, such as where a lecturer has, by continuous practice with one and the same operator, made his subject and slides so familiar to the lanternist as will enable him to run through the entire lecture without requiring any change of signals from the platform; but with the general run of lecturers this will seldom be possible, and it is one of the greatest mistakes imaginable for any lecturer to attempt to discard the use of a signal of some kind or other when working with a strange operator. A glaring case of this kind recently came under the writer's notice. A gentleman prided himself that he had his lecture off by heart, having delivered it over a hundred times, and so modelled that any lanternist could, by merely paying attention to his words, know just when to make a change. Yet, notwithstanding the operator was a man of wide experience, the usual breakdowns, resulting in the recall of several slides, had to be made. This is just a case in point, and goes far to prove that, no matter how conversant a lecturer may be with his subject, it is impracticable to attempt delivery without adopting some method of signalling when a strange lanternist is operating.

Lantern signals, as a rule, may be divided into two classes, viz., those which appeal to the sense of vision, and those which are heard by the operator, and each of these methods can be carried into effect by a variety of means.

Speaking generally, the methods employed under the latter system embrace quite a number of devices whereby sounds are conveyed to the lanternists, such as the knock on the floor from the butt end of a pointer, and in the hands of some lecturers this proves a very effective method, for, when cleverly practised, the attention of an audience is seldom distracted from the subject, as is more or less the case when a noisy heel, or, what is even worse, a distracting "cric, cric," or castanet, be employed. How such a system of signalling ever became so much in use has puzzled many, for it has fatal drawbacks, as witness the exuberance of mischievous boys when they possess a signal of the same description as the lecturer. Another method that has, within recent years, become very popular, is an electric signal from the platform to the lantern, but of these there are good and very bad systems. It is by no means uncommon, where such is in use, for the signal to be so noisy as to make a fair resemblance to the whirring of a covey of partridges; whilst, on the other hand, it is possible to so arrange the system as to merely raise and lower a small arm, or semaphore, contained in a small box on the lantern stand. This is absolutely devoid of any noise, and is, all told,

far and away the best method yet devised for signalling a change of slides, its one and only drawback being that, except in fixed positions or halls where a wire can be permanently laid, some trouble is experienced in arranging to run a wire for one night's use in, at times awkward situations. Several of our best lecturers in former years preferred to dispense with any special provision for signalling, and a favourite method with the versatile Andrew Pringle used to be the mere tapping with the blade of his penknife on a glass tumbler. There are, of course, several other methods coming under the category of sound signals, which it is quite unnecessary to mention.

On the other hand, perhaps by far the better system is where a lecturer so prearranges matters that his signal for a change of slide is only known to the lanternist, the audience being unable to detect the cue. This method has for many years been the one adopted by the writer, and it has invariably worked satisfactorily with every lanternist, be he strange or familiar with the lecture that was being delivered. In silent signalling of this description, one of the easiest and surest signs to convey an intimation that a change of slide is desired will be found in merely raising the right hand and seizing or touching the right lapel of the coat. Any lecturer trying this simple dodge will be surprised at the ease and naturalness of the motion, which at times may be termed even graceful. It has also the advantage of keeping a lanternist's attention engaged upon the lecturer during his delivery, and this is the method the writer now invariably adopts; and he has never met with even a strange operator but who was favourably impressed with its effectiveness and simplicity. Some lecturers who likewise prefer a silent method of signalling make a practice of having ready at hand a sheet of ordinary writing-paper, and by merely turning the same, or slightly wafting it, thereby attracting the lanternist's attention. Others, again, make a rule of standing somewhat erect and placing the thumb of the right hand in their waistcoat pocket, or against their watch-chain buttonhole. Of the more mechanical methods of silent signalling by vision mention may be made of using a reading lamp having a red signal disc; but this may be said to be obsolete, except in cases where the entertainment takes more the nature of a lantern reading than a lecture. If a method of silent signalling be desired, there is no better sign than one or other of the two dodges previously mentioned; their great advantage lies in the fact that the right hand can be used to give the signal, no matter in what attitude the lecturer be at the desired moment, and it never attracts the attention of the audience from the subject.

Operators, as a rule, have a great deal to put up with at the hands of those lecturers who imagine they know more than any one else in limelight lecturing; and I often think there is no more conceited individual in the world than the half-fledged limelight lecturer, who knows far less than the man at the lamp, but who poses as one possessed of a deep knowledge of this class of entertainment. Over and over again have I witnessed fiascoes clearly attributable to the lecturer, or rather reader, himself, and which would never have occurred at the hands of an experienced speaker. It is safe to assume that any one who knows his part will never so recall a slide, or draw the audience's attention to any misplaced picture or mistake, for which he himself is invariably responsible, but which a greenhorn will take care to lay at the door of his operator. Such mistakes will occur with the best men; but they know better than to pay attention to such trivialities, and therefore go on with their lecture, and speak to the picture or subject on the screen. This is just one case in point where an inexperienced lecturer gives himself away before his audience, and at the same time acts unfairly by his operator. A ready speaker will at all times be able to turn such little mistakes into their proper groove in such a way as never to draw an audience's attention to them.

T. N. ARMSTRONG.

#### PHOTOGRAPHY AS AN AID TO SPECTRUM ANALYSIS.

In the current number of the *Photographisches Centralblatt*, Dr. E. Haschek gives an extremely interesting sketch of the above subject, which we abstract somewhat fully.

Newton had used prisms to prove that not only could light be refracted, but that it could also be dispersed, and, further, that the spectrum thus formed could be again combined into white light, and that the individual colours were no longer compound, but simple, and could not be further split up. He merely used a hole in a shutter through which the rays of light fell on to the prism. The renowned optician, Fraunhofer, was the first to improve on this simple arrangement by using a slit instead of a hole, and projected the image of this by means of a lens on to a prism and thus obtained a sharp spectrum.

When using the sun as the source of light, he noticed numerous dark lines crossing the spectrum, and further argued that they were independent of our atmosphere in that they were the same independently of the height of the sun. He then sketched the spectrum, and to the most prominent lines he assigned the letters of the alphabet, and they have always been called Fraunhofer's lines, and by these letters ever since. He further noticed that, when examining some artificial lights that one considered colourless showed a brilliant yellow line, which was coincident with the particular dark line in the solar spectrum, which he had called D. These dark lines were subsequently frequently noticed, and various explanations of their cause given, and many spectra of coloured flames were also examined.

This, then, was the position of the question when Kirchoff and Bunsen attacked it, and to them may be ascribed the foundation of spectrum analysis. Kirchoff enunciated the statement that a body absorbed those lines which it emitted at the same temperature, and that glowing solid and liquid bodies gave continuous spectra, but that gaseous substances gave line or banded spectra. He further stated that any body brought in the gaseous state to incandescence gave a discontinuous spectrum peculiar to itself, by means of which it could be recognised. If, moreover, we had a mixture of luminous gases, each constituent would give its spectrum, and the composition of the gases could be determined.

These facts were applied by Kirchoff to the solar spectrum, and he argued that we have in the sun a solid or liquid body, the light of which is stopped by an atmosphere of vapour. The question which Kirchoff now attacked was, Are there present in the solar atmosphere the same substances as we have on earth, or are they others? This question could naturally only be examined by means of the elements, as their compounds must, at the temperature of the sun, be disassociated. In order to settle the question, he examined numerous terrestrial substances, and found their lines coincident with the solar lines. Thus hydrogen, sodium, iron, nickel, cobalt, magnesium, and many other substances were found in the sun.

Spectrum analysis does rather more than this, for, if we examine a terrestrial substance, we shall find numerous lines which may be ascribed to known elements, but there may be lines present of unknown origin, and they then prove the existence of a new element. Thus, in 1860, Kirchoff and Bunsen discovered the elements rubidium and cesium in certain water, and these lines were to be seen when only one drop of the liquid was placed in a gas-burner, but it was necessary to evaporate no less than 44,000 kilogrammes of the liquid in order to obtain 16.5 grammes of the mixture of the chlorides of rubidium and cesium, which gave the characteristic lines. This is a striking proof of the sensitiveness of the new method and of its value to chemistry. In a similar way Brookes, in 1862, found thallium, in 1863 Reich and Richter found indium, and in 1875 Lecoq de Boisbaudran gallium. The work of Kirchoff and Bunsen was continued by numerous investigators, and, amongst others, Huggins examined the spectra of the fixed stars, and proved that in these some of the earthly elements, and especially hydrogen, were present, and thus was proved the common chemical composition of the universe.

Kirchoff and Bunsen had drawn all their measurements of the lines to the empiric scale of the apparatus they used, and it was extremely difficult to reduce all the readings of other instruments to this. It was therefore extremely desirable to adopt some definite standard, and the wave-length was chosen. Fraunhofer had measured wave-lengths, but Angström was the first to make its use general, and after him is called the unit by which wave-lengths are measured, which is the ten-millionth of a millimetre, Angström's unit. He measured, by means of a grating, a series of standard lines, from which he reduced all others, and chose as the normal spectrum the grating spectrum, because in this the relative distribution of the colours is independent of the apparatus, and the distance of two lines is simply proportional to the difference of their wave-length. Unfortunately, the measure that he used was false, and it was necessary therefore to undertake a new estimation of the wave-lengths, and this was done by Thalén, and more recently, by Müller and Kempf. Here, however, was a great trouble, for, beyond errors of measurement was a variation in the standard lines used.

Now Rowland appears on the scene, and, rightly recognising that it was not of so much importance to know the absolute value of the wave-lengths as to know their exact relative numbers, he took the mean of the best known measurements of the wave-lengths of the sodium lines, and on this number based his system. If his numbers were once proved wrong, they could be put right by simple multiplication with a factor which was the same for all wave-lengths. With the aid of the values

of the wave-lengths for the sodium lines, Rowland estimated the wave-lengths of numerous lines of the solar and electric arc spectra, and these are the standard wave-lengths of all modern measurements. The apparatus he used, and which he had made, was the concave grating.

Possibly it would be as well to explain what the optician means by a grating. If we imagine grooves cut in a flat, transparent surface, so that equidistant transparent and opaque lines result, the incident rays of light will be bent by the opaque lines, and this in proportion to the wave-length; thus the light is again resolved into its coloured constituents, and with this, in opposition to the prism, the violet is dispersed the least and the red the most; thus there is formed not only one spectrum, but, symmetrically to the direct image which is caused by undispersed light, a whole series of spectra, which are called of the first, second, third, &c., order. There is thus a certain weakening of the light of the grating spectrum compared to that of the prismatic spectrum, and it is obvious that it is immaterial whether the grating be used in reflected or transmitted light; the case is the same, as there are accessories, such as mirrors or lenses, required to produce real images of the slit, which is what the spectrum lines actually are, therefore there is again a loss of light, and whole parts of the spectrum may be actually absorbed, as, for instance, the ultra-violet by glass. Rowland ruled the grating now direct on to a concave mirror of speculum metal, and thus made the concave grating, which, without any accessories of lenses or mirrors, formed real images of the spectral lines. By perfecting his machinery he has been able to rule 14,438, and latterly 20,000, lines to the inch.

With such a concave grating he has measured the standard wave-lengths and the Fraunhofer lines in the solar spectrum to the number of about 20,000, which are given to seven places of decimals. The accuracy of this is about 1000 of Angström's unit, or up to the 10,000 of a millionth of a millimetre, which, for a line in the violet with the wave-length of  $4000\text{\AA}$ , is accurate measurement up to 0.02 Angström with an error of 0.00005 per cent., an accuracy which has never been attained in any other measurements. To make this quite clear, it would mean that a distance of 40,000 kilometres would be accurately measured to within 50 centimetres, which is the exact measurement of the circumference of the earth on a meridian to half metre. Not only has Rowland accurately measured the wave-lengths, but also the intensity of the lines and their character, and compared them with the emission lines of nearly all known elements, so that we now know the composition of the solar atmosphere almost as well as though we had analysed it in the laboratory.

This work of Rowland was rendered possible not only by his excellent grating, but also by the employment of photography as an aid, particularly in the ultra-violet and for very faint lines, the measurement of which is extremely difficult. All the work since his, such as that by Kayser and Runge, as well as the work of Eder and Valenta, has been done by using photography.

All this work is done as follows: Two exposures are made on one plate, one of the substance to be examined, the other the standard spectrum, which is usually that of iron. It is best to make these exposures so that the two spectra partly overlap. Now, how are the measurements made? There are two methods, one of which we may call the subjective, the other the objective method. The first is measurement by means of a comparator. On a slit which passes along a ruled measure a microscope is fastened; the slit is, by the aid of a screw, moved along the spectrum; in the microscope the cross wires are focussed on the line, and the position read off on the measure. The position of the standard lines and that of the line to be measured is read off on the divisions of the comparator measure; the wave-lengths of the standard lines are known, also the difference of the wave-lengths in ratio to the distance of the lines, and inversely, assuming that the spectra have been taken with a grating, and the value of the wave-lengths can be reckoned from the numbers measured direct. But this work takes up an enormous amount of time, and Rowland has had a screw cut which moves his slit at one revolution two lines of the wave length difference of Angström's unit. This, however, does not do away with all reckoning, as the actual coincidence cannot be absolute.

The second method, the objective, is that which has been used by Professor Esner and Dr. Hasehek, and it is simply a projection method. The spectra are projected on to a screen and enlarged, so that the lines which have the difference of the Angström's unit wave-length are exactly at 1 cm. from each other. For measuring, the standard lines are focussed on those parts of one of three millimetre scales affixed to the screen, which correspond to their wave-lengths and the wave-lengths of the strange lines can then be simply read off. The accuracy attainable with one measurement amounts to  $0.02\text{\AA}$ , thus about one-tenth of the

accuracy of Rowland's measurements, which it must not be forgotten are the mean of several readings, so that errors are reduced. By the objective, during the last five years, the lines of sixty elements have been determined in the Physico-chemical Institute of the Imperial University of Vienna. The total number of lines ascribed to individual elements amounts to about 50,000, the total number of those measured is at least double that. Already all the metals, even the rarest have been investigated, and only arsenic and the metalloids have now to be examined.

What, now, are the results that have so far been learnt from spectrum analysis? The merest superficial glance at the spectra teaches us that the number of lines varies from element to element. These numbers of lines, which have been determined for any element, are a periodic function of the atomic weight of the kind that, with increasing atomic weight of the elements, there are found at tolerably regular distances spectra very rich in lines and spectra very poor in lines. Those richest in lines are uranium, with 5270; tungsten, with about 3000; molybdenum, with 2800 lines in the ultra-violet region between the wave-lengths, 4700 to 2000A. These numbers apply to spark spectra. The number of lines of the arc spectra, which one can learn from the work of Rowland, Kayser, and Runge, & Hasselberg, are generally smaller; and only about two-thirds of the spark spectra follow the same law.

As a further result, we have learnt the difference between the arc and spark spectra. Even from the above it is clear that there are in the spark spectrum lines which are wanting in the arc spectrum, and not always the weak ones, and *vice versa*. Frequently the strong lines of one spectrum are weak in the other, or wanting altogether, so that their character may be entirely altered. It is obvious, therefore, that for examining substances by the aid of spectrum analysis it is always necessary to work in that method in which the elemental basis was made.

The alteration of the intensity of the spectrum lines is not, however, the worst thing to be contended with; much worse is their change of position. It was for a long time a moot point whether such could be the case, and this could not be settled with the incomplete prismatic apparatus. Rowland, again, settled this point. Michelson had suggested the wave-length of light as the unit of length, and tried to express the length of the metre in wave-lengths. The measurements made for this purpose showed differences to Rowland's—differences which could not be ascribed to errors in working—and the reason was that Michelson had used the spark, whilst Rowland had used the arc spectrum. Humphreys and Mohler examined the question, and they found that under pressure the wave-lengths were increased—that is, they were displaced towards the red. This displacement is proportional to the pressure and the wave-length of the line in question, and is, moreover, different for different elements.

Displacements of the lines also take place without pressure from causes inherent in the source of light itself, as in the fixed stars. It was pointed out by Doppler for sound waves, that, if we approach a wave centre with a certain velocity, we shall pass more waves in a certain unit of time than if we were in relative rest, or even if we were moving away. If the wave-centre approaches us, the same happens, and we get the tone of the sound, becoming gradually shriller; and, in the case of light, as the wave-centre approaches us, there will be a shortening of the wave-length, and *vice versa*; and from the amount of this displacement and the wave-length of the line we can estimate the rapidity of the procession or retrocession of the source of light, so that by spectrum analysis we learn not only the nature and composition of the fixed stars, but also their rapidity of movement in our line of sight.

#### DENSITY IN LANTERN SLIDES.

THE lantern-slide man has a tendency, most likely in his endeavour to get (using gelatine lantern plates) a satisfactory tone, or rather colour, to pile up the density of his slide. He is aware probably, from experience, that no very rich tones are to be had unless the initial deposit, from action and the developer, is fairly dense. This desire for colour is the reason, no doubt, why gelatine slides are so often unsatisfactory when subjected to the lantern test.

In comparing densities of slides by the various processes—gelatine, collodion, or carbon—it must not be forgotten that the gelatine film, be it ever so thin, will never equal collodion; also, that a "carbon" slide may have the appearance of being dense and yet be very transparent when viewed through the lantern. In the preface to my little book on *Lantern-slide Production*, Mr. J. P. Gibson cautions the worker against over-density. There is more in this than meets the eye. The slide

which looks extremely well as a transparency for decorative purposes will be far too dense for the lantern.

Lately, when making a set of slides for a lecture, I noticed this matter of density very particularly. The negatives themselves presented a respectable variety. There were negatives taken in the summer, bright and pleasing, and others of the "grey-day" order, and some woful, thin. Well, from the usual average negative I got the usual average slide, clean and of good colour; from the thin greyish negative I made the best possible positive, and that best was what one would expect from a short exposure, developed up strongly, the film then cleared, and the picture toned—in short, a slide clear and clean, but very far from dense. Then, again, there were a few slides from dense negatives, which displayed their origin, being strong, so far as concerns the principal objects the distances having been allowed to take their chance. The slides were handled by several men of average experience, and generally voted "far too thin." Now, this all depended on the way you looked at them. My way is to select the slides by means of the light afforded by an ordinary paraffin reading lamp, with opal shade, and it will be found that, if the detail, under such conditions, is all clearly visible, *we may safely disregard mere detail*, as such. As a matter of fact, the slides were, when shown in the lantern (oxyhydrogen), a very good lot, and those with the thinnest deposit were by no means the least satisfactory. I may remark here on the desirability of a perfectly *clean screen*. It is not such a difficult matter to get *clean slides*, and it is hard to have them shown, as they are sometimes, on a screen which exhibits all the marks of rough usage.

There is no doubt the *thin* slide, by the gelatine process, shows up the best on the screen, but I can imagine that the objection to a thin deposit will be mainly on the score of colour.

J. PIRK.

#### WHY LANTERN EXHIBITIONS ARE NOT MORE POPULAR.

BEING a somewhat old lantern amateur, I always read your *Lantern Notes* with much interest, and sometimes wish I could be present at the lantern evenings of the photographic societies, as, no doubt, some very fine slides are to be seen there; but the very indifferent quality of the usual commercial slide, such as I often exhibit for lecturers, schools, missionary meetings, &c., is, I think, a full answer to the often-repeated question why lantern exhibitions are not more patronised. Most of the slides that come into my hands are hired from the stocks of London houses, who make a business of letting slides on hire, and it is quite safe to say that seventy-five per cent. of such slides are rubbish. If of the old hand-drawn and painted order, they are most crude and rough, so that, when exhibited with a modern lime light and lenses, which really define, they are anything but pictures; and, if of the newer kind, produced by photography, the bulk of them are badly at fault from over or under-exposure or development; some are heavy and muddy, others thin and flat, and many of the sets from life models are most clumsy and unfinished; as a rule, flesh is rendered dark and heavy, and colours of the draperies taken on the ordinary plates are rendered too dark and heavy also, and then, when the slides are attempted to be coloured, the effect is worse still. This is particularly noticeable in the slides of soldiers of the line, of which I have seen several lately. Perhaps worst of all are those slides which are bad photographs of the wash drawings from the illustrated papers, with no vigour or contrast about them, roughly coloured in some cases, in others simply poor, grey photographic transparencies, which are no pleasure to exhibit, and I should think are largely the cause of the lack of interest so much complained of. But given a good set of slides, with a good narrative and a good speaker to deliver it, I believe that now a lantern lecture is one of the surest means of drawing a good congregation. If I knew where to obtain a really fine set of slides illustrating the present war with a good interesting reading, I believe that good work might be done in this Weald of Kent towards the relief fund, but such slides as have passed through my lantern at present are not nearly good enough.

Hawkhurst.

#### ACETYLENE—THE ORDER IN COUNCIL.

THE following is the text of the Order in Council prohibiting the admixture of air or oxygen gas:—

Whereas acetylene when in admixture with air or oxygen is specially dangerous to life or property by reason of its explosive properties. Now, therefore, be it ordered and declared as follows:

Acetylene, when in admixture with atmospheric air or with oxygen gas, in whatever proportion, and at whatever pressure, and whether or not in

admixture with other substances, shall be deemed to be an explosive within the meaning of the said Act.

And whereas it is in the judgment of Her Majesty expedient for the public safety that acetylene, when an explosive within the meaning of this order, shall be prohibited. Now, therefore, be it ordered and prescribed that acetylene declared to be an explosive by this order shall be prohibited from being manufactured, imported, kept, conveyed or sold.

Provided that nothing in this order shall apply to acetylene in admixture with air when such admixture takes place only in a burner or contrivance in which the mixture is intended to be burnt.

A CHAPTER FOR AMATEUR LANTERNISTS.

I TRUST that the following brief description of one or two articles, I find very useful in giving lantern exhibitions, may prove of service to some reader who may have a lantern but has not the requisite means wherewith to purchase such articles on the market.

Moreover, there is always a certain amount of pleasure in making our own apparatus, and, if it is not always finished off in such a workmanlike manner as things we buy, still it often answers the purpose quite as well, if not better.

I have found it very necessary, in giving an entertainment to children, to have the lantern fixed firmly, so that a chance kick from some troublesome youngster did not wreck the whole apparatus. The ordinary three-legged stands are rather expensive, and also not so firm as they might be, so I therefore set about making one that would stand rough usage without being too cumbersome. I will endeavour to give a short description of it, so that any reader, if he desires, can make one like it.

Get two pieces of wood, 20 inches long by 8 inches wide. One of these should be an inch, and the other  $\frac{1}{2}$ -inch in thickness. Place the thin one on top, and fasten together with a couple of hinges at one end. Purchase a strong thumbscrew, about 6 inches long (fig. 1, A). Bore a hole

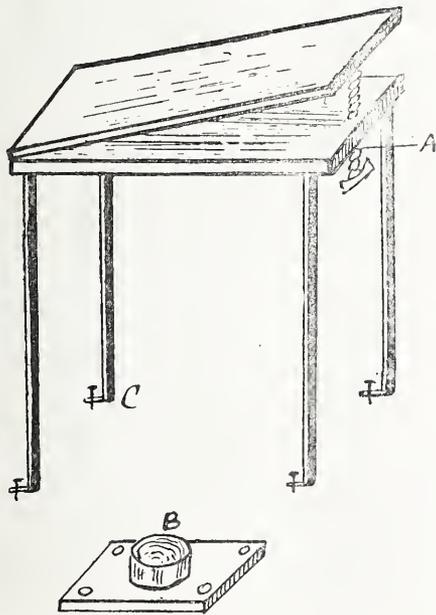

FIG. 1.

in the bottom piece of wood and sink in the worm of the screw. These two pieces of wood are to serve for a platform on which to screw the lantern, and by turning the screw underneath it will enable us to raise the lantern to any required height. The lantern can be kept in position by fastening with a small thumbscrew through the hole that is usually provided in the front of all lanterns, of course having previously sunk the worm of the screw in the exact position in the top piece of wood.

And now for the legs, the length of which will depend somewhat on the illuminant used in the lantern. If limelight is used, they can be made shorter, as the lantern can be tilted much more than if an oil lamp is used. I find also that the acetylene light will not allow so much tilting, as the flame is liable to damage the condenser if raised too much. A convenient height when limelight is used is about 4 feet 6 inches, but, if an oil lamp is used, about a foot longer. If the lantern box is made of wood, the legs may be still further shortened by fastening the box on to the lantern platform, and then screwing the lantern on to the box. By this method the length of the legs can be reduced about a foot.

The next thing is to get a gas-fitter to let you have four pieces of gas-piping, and at one end of each piece make them to screw into four sockets. On the end of each socket get him to braze an iron plate with four screw

holes (fig. 1, B). Screw these four sockets underneath the thick piece of wood forming the platform at the four corners. Have the other end of the gas-piping flattened out, and about  $1\frac{1}{2}$  inches turned out to form a sort of foot to stand on. In these pieces have a small hole bored large enough to take a small screw or bradawl (fig 1, C). Our stand is now complete. To erect, screw the four legs into the sockets on the lantern platform, and either screw or fasten with small bradawls the other ends into the floor. Fasten the lantern on to the platform with the small thumbscrew, and the apparatus will be found quite firm and stable, and can be left without coming to grief. The expense of all this will be found very small, the gas-piping and work only costing a few shillings.

Another very necessary requirement is the possession of a good screen. Of course, if the lanternist travels about, he is compelled to have one that will fold up, and the best substance for this is good white linen. The brilliancy of the picture is, however, much increased by using an opaque screen. These are rather expensive to buy, and are also rather cumbersome to carry about, and, unless the exhibitions are given in the same hall, I should hardly like to recommend the purchase of one. Should, however, the reader be in the habit of using the same place for his entertainments, it will be worth the trouble of making one. They are usually made of linen, faced with white cartridge paper (fig. 2, A). Unless the screen is to be only a few feet square, it is not advisable to attempt to paste the paper on to the linen, but buy it already done. I purchased mine at a wholesale map-mounter's. It is apparent to all that this cannot be folded up, so it is necessary to mount it on a roller the requisite length. At the other end a good stout lath will be necessary. If it is intended to hang the screen up from the walls or rafters of the hall, nothing further will be required, but very often this cannot be managed. It is then absolutely necessary to make some sort of stand to erect the screen on. There are

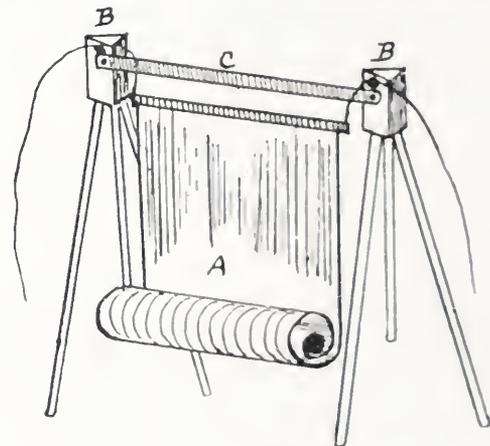

FIG. 2.

several ways of accomplishing this, but I will here mention one that seems to me to meet all requirements without being too cumbersome.

Cut two pieces of wood about 4 inches long in a triangular shape (fig. 2, B). These pieces should be about 2 inches in thickness. Now get six long pieces of good hard wood about 1 inch square. The length of these pieces will depend on the size of the screen. A screen 8 feet square would require these pieces about 9 feet long. Three of these should be fastened with hinges on the three sides of each of the triangular pieces of wood. The reason for this is, no doubt, apparent to the reader.

By opening the legs we have an arrangement similar to the ordinary tripod used for supporting the camera, but on a much larger scale. To prevent the legs slipping, fasten a small spike on each leg, or else place a piece of rubber at the bottom. To keep the stand firm, fasten a piece of wood about 1 by  $1\frac{1}{2}$  inch on the two triangular pieces (fig. 2, C). The length of this piece will depend on the width of the screen, which it should slightly exceed. This should be fastened with two thumbscrews.

The next business is to fasten the screen to the support in such a manner so that it will pull up and down at will. The best plan is to fix two small pulleys on to the triangular pieces of wood. Fasten two long pieces of thick cord each end of the top of the screen (viz., the end with the lath fastened on), and pass the cord through the pulleys; erect the supports, pull both cords, and the screen will be raised into position, unfolding itself during the operation.

The foregoing remarks have been confined to the making of necessary apparatus, which I hope will render the task of the lanternist who has not too much money to spend on apparatus a little easier. As this article is written for those with little experience, perhaps a hint or two on the best way of getting over a few difficulties may not be out of place. It sometimes happens that the hall in which the exhibition is to be given is a long, narrow one. If the apparatus is placed in the centre of the room, the screen is partly eclipsed by the operator and lantern. This is more especially the case if an oil lantern is used, as with this illuminant the lantern cannot be tilted too much, and it is therefore necessary to have rather a high stand. To get over this difficulty, place the lantern and

stand on either side of the hall, and throw the pictures on the screen from that position. In order to get the pictures in focus, place the screen sideways a little, so that it is at right angles with the lantern. By doing this the operator does not in any way obstruct the view of the audience, and the difference will be hardly noticeable.

Another little hint: When tilting the lantern, always alter the screen in a corresponding degree, so as to get it at right angles, viz., move the bottom further back and fasten in the position required.

J. H. BURKE.

### ACETYLENE.

PERADVENTURE it is winter time, and on the wrong side of the shortest day; there looms before you some months of almost endless nights, with murky days of the shortest duration sandwiched in between.

The number of sitters who have been just too late are on the increase, and, of course, you are too honourable to perform upon them with an empty dark slide.

You scratch your head—that is, if you are addicted to the habit—and hum a line or two of "The Absent Minded Beggar;" you look, perhaps, down the columns of your day-book, and think that if you had been able to have taken the last three sitters, you might have turned a middling day into a passably good one. The post comes in, and, amongst your letters, returned proofs, and re-orders, you find an illustrated price-list of acetylene gas apparatus; you scan it through eagerly, and have a vague remembrance of paragraphs in the JOURNAL on the subject.

The list will probably tell you that acetylene gas is far ahead of any other illuminant; in fact, equal to sunlight, and almost as cheap; the exposure required to take a negative is only two to four seconds, moreover, it is so portable that you can take the apparatus about with you in your waistcoat pocket to balls and parties, and earn a mint o' money in next to no time; in addition to your ability to use it in your studio, you can light up your shop, your reception room, your dark room, your every room; you can copy and enlarge with it, and work miracles generally.

No new fittings required; the old ones will do, with new burners. All you have to do is to buy a generator and studio outfit, send for the gas company's man to take their meter away, fix the generator, put in the new burners, light up, and you will have your place one blizzy-blaze of light at a cost of far less than coal gas, that is—ahem!—candle power for candle power.

To continue, you decide to go in for it; you send an order for the generator, the studio light, and a supply of nipples and carbide, not forgetting a cheque for something like twenty pounds, more or less. Meanwhile you call in the carpenter to erect a small house some distance from your insured buildings to contain the generator, and the plumber to run the pipes into the studio, and wherever else you fancy you would like the gas; you send your fire-insurance policies to the head office to get them endorsed, permitting you to use acetylene gas in buildings they cover; also to the local authorities for a licence to keep more than five pounds' weight of carbide on the premises. The inspector will call to see where you intend to store it, you will pay 5s., and get your licence.

When the generator, &c., arrives, you are like unto a little child with a new toy, in a dickens of a hurry to try it. The plumber is fetched poste haste, and unpacks and fixes the apparatus while you carefully read the directions, after filling it up with water and mixing a Winchester of glycerine with the water to keep it from freezing. You charge the carbide holders, turn on the taps as directed, and the gas-holder begins to fill. Rushing into the studio, you turn on all the taps to burn out the air in the pipes, and presently the light comes up bright, white, steady, and beautiful; you long for night to come, so that you can begin making negatives and a fortune.

Well, slowly but surely, and only too quickly for the printer, the night does come. You light up your window, your shop, your reception room, your studio, your dark room, your every room, and there is no mistake about the light, it is an illumination. You place your assistant in position, and propose to take his picture; you focus it up, put in the plate, giving it three seconds' exposure, proceed to develop, and you get—what? Nothing; that is, nothing of any use.

You stick up a couple of spare reflectors, and expose again, giving double exposure, with almost the same result; nothing daunted, again you try, giving an exposure of ten seconds, and the result is a negative of the soot-and-whitewash order; and, in desperation, you try again, giving a seemingly never-ending exposure of twenty seconds, and at last you have a printable negative, but nothing like a daylight one.

Next you try a head and bust, and, by putting the reflector close up to the sitter, the light nearer to his head, and exposing for fifteen seconds, you get a negative which, after retouching, could not be distinguished from one taken by daylight.

But what's all this smoke? Your model is coughing his head off, you commence to do the same yourself, and you see that the studio is full of a thick penetrating haze that plays on your lungs. You open the ventilators, turn out the lights, and go into the shop, to find that it is in the same condition; also there is a strong smell of onions or something pervading the atmosphere; you hold a taper to the taps of your gas brackets that you never knew to leak with company's gas, and find that

they catch fire round the tap in almost every case. Clearly, old fittings will not do. You make up your mind to call in the plumber in the morning. Later on a friend comes in, and you are explaining the light to him, when all at once the burners commence to send up a dense cloud of black smoke, which deposits soot on everything. Taking a lantern, you place it outside your generator house, so that its rays are cast inside, and, on opening the door, you find that the charge is exhausted and the holder empty. Being too tired to do more, you close for the night, only to find in the morning that the frost has done its work, and your generator frozen up in spite of the glycerine.

Disappointed and annoyed, you wire to the makers regarding the haze and the black smoke, and a reply reaches you to the effect that you omitted to order a purifier, and that you ought to use nothing but non-carbonizing burners.

The assistant is despatched by train for the purifier and purifying material and a dozen or two of non-carbonizing burners, and, while he is away, you swaddle up your generator house in sacks and matting, and, by gentle degrees, with warm water contrive to thaw the ice, and so unlock the machine. This done, you wash out the carbide-holders, which you find to be a dirty business, and, if your nostrils are delicate, an offensive one. You dry and recharge them, and hope for better times. By-and-by the assistant returns, and the plumber fixes the purifier and burners into their places. The day wears on, and, as it draws to a close, customers, who have been few during the bit of sunshine during the fore and afternoon, come in a bunch. There is perhaps a group of two for three-quarter cabinets, a gentleman, in khaki for the first time, who requires full-length ten by eights, and a lady who desires fancy-lighted head and bust whole-plate plats. They are booked, and you say to yourself, "Now for it."

There is still a little daylight left, but certainly not enough to take a negative. You proceed to place your group of two in position, and, on looking at the focussing screen, you cannot see to focus nicely; so the acetylene is turned on, and by its aid you can make it painfully sharp if you wish. Everything being ready, you expose, and, as there is a certain amount of daylight left, you give six seconds; on developing, you find the negative to equal a summer negative of good quality. You next take the gentleman in khaki, with just as good a result. By this time it is quite dark. The fancy-lighted head delights you by the excellent effect of light and shade, and you find that, by moving the light around, almost any effect can be obtained. Moreover, the long exposure does not seem to inconvenience your customer one bit, and you think your money well spent, after all.

It takes some little time to find out what the light will do, and what it will not do; and, if you attempt only the possibles, you can have nothing but praise for the excellent illuminating powers of acetylene gas.

It will, on dull days, help you to get bright, clear, crisp negatives of anything, by assisting the daylight; when the day is drawing to a close, you can go on for at least another hour; and, when the daylight has quite gone, you can continue taking head and bust, and some three-quarter figures, when they happen to be favourable to the light, till morning if you choose; you can copy by it, and it is also very useful in the lantern.

It will not, by itself, take a group or full-length figure, that is if you want them equal to daylight work; and, of course, babies and animals are out of the question on account of the long exposures necessary.

Ten minutes' instruction will be sufficient to enable your man-of-all-work to relieve you of all trouble with the recharging of the generator beyond the drawing of a cheque occasionally for more carbide, which, although it rarely gives the five feet per pound, as stated in the lists of the various manufacturers, is still fairly cheap, as the cost of your light per sitter will be found to average about one penny; and, when once you are used to it, you will have nothing but words of praise for your installation of acetylene gas plant.

JESSE LONDON.

### ON THE PART PLAYED IN PHOTOGRAPHY BY THE ACCOMMODATION OF THE EYE.

[Abridged from a paper before the Union Nationale at Rennes.]

THE eye accommodates itself to every object which it sees in turn, according to the distance by which this object is separated from it.

In looking at a picture or a photograph this accommodation is the same for all the planes represented, and depends only on the distance of the surface from the eye. It is the principal cause which militates against the illusion which the artist seeks to create.

This illusion of space represented on canvas would have no existence at all but that the picture falls within a zone of constant ocular accommodation, a region the depth of which varies with the distance of the eye.

The eye, in fact, resembles every other optical instrument in having a certain depth of focus, and therefore, at a given distance, a certain depth of field in which the accommodation of the optical organ is practically constant.

In order to obtain the maximum effect of relief in the different planes of the subject it must be placed in the position so that the foreground coincides with the picture, the distance depending on the distance away of the point of view of the observer. The depth of this region corre-

sponding to a given foreground can be easily calculated in terms of the physiological qualities of the eye. Its mean value is about 1 millimetre (.04 inch), for a distance of 5 centimetres (2 inches); 8 millimetres (.3 inches), for 20 centimetres (7.8 inches); 5 centimetres (.2 inches), for 40 centimetres (16 inches); after this it increases rapidly. At 1 metre (practically a yard) it is 50 centimetres, at 2 metres (2 yards), 3 metres, 50 centimetres (19½ inches). It is infinite at a distance greater than 3 metres.

As in photography, lenses of comparatively short focus are always used; these regions of accommodation are very small. The objects which make up the foreground are always considerably reduced in the image. This reduction is one-fiftieth if the apparatus is placed fifty-one times the focus of the lens from the subject. The eye sees them in the print as if they were objects of one-fiftieth the size, photographed at a distance equal to the focal length of the lens. The region of constant accommodation of nature is fifty times the depth of that which corresponds to this focal length. Hence the further off the foregrounds are, the more truthful will be the relief of the planes of the picture. The eye, however, will replace nature itself by a reduction of nature on the scale of the foreground.

In the case of a portrait, the illusion of relief is perfect if the portrait is obtained life size (either directly or by enlargement), and, if the focal distance is such that the zone of constant accommodation is at least ten centimetres (four inches), otherwise our imagination cannot reveal to us anything but the picture of a doll.

The part which accommodation plays in stereoscopy is still more important. Here the complete illusion of relief is possible when the foregrounds are of natural size, the two points of view separated as are the human eyes, and the lens of such focal length that the whole of the scene falls within the zone of constant accommodation corresponding thereto. Otherwise than has been described, the relief of natural objects can only be obtained in the case of objects smaller than life, as the foreground is more distant; in the case of objects larger, as it is nearer than the focus; and in all cases, in order that the effect may be natural, there must be a proportion between the focal length of the lenses and their distance apart on the one hand, and between scale of reproduction of the foreground and the depth of the region of constant accommodation corresponding to the planes of the subject on the other.

RECENT PATENTS IN COLOUR PHOTOGRAPHY.

DR. SELLE'S PROCESS FOR PHOTOGRAPHS ON FLEXIBLE SUPPORTS.

[No. 4290 of 1899.]

THE following is Dr. Selle's own description: "I take a rigid waterproof plane of desired size, for instance, a glass plate, preferably somewhat larger than the finished print is to be by at least half an inch each way. One surface of this plate I coat around the edges to a width of, say, a quarter of an inch, with a solution of gelatine of, for instance, ten per cent. strength. I now take a sheet of paper, one side of which, at least, should be covered with a waterproofing material, and, after cutting it to the size of the glass plate, I place it on top of the latter (a waterproofed side being uppermost), applying pressure so that the edges of the paper may adhere firmly to the gelatine on the glass, care being had to expel any air from between the paper and the glass plate. If a non-waterproofed paper is used, then the latter should be cut slightly smaller than the glass, and should be placed for a few minutes in water prior to being put on the glass support. The paper being quite dry, and adhering to the glass plate, I cover it with a thin layer of an impervious material, which is as transparent as possible, for instance, collodion. On this film, when dry, I spread a very thin layer of plain bichromat. d gelatine, and allow it to dry. I then expose this plate to the action of light under either of the three negatives, say, for instance, the 'red' negative. The transferring of the image from the negative to the paper beneath it, *i.e.*, the printing having been accomplished, the plate is washed in cold water, and is then placed in a bath consisting of the appropriate solution of, for example (if the 'red' negative was used first), five per cent. methyl blue, until the image is fully developed. The plate is then taken out of the bath and allowed to dry. When quite dry, the aforesaid coating operations with collodion and bichromated gelatine (which are here termed 'sensitising') are repeated. The plate is then printed under another negative, for instance, the 'green' negative, then washed, and placed in a bath consisting of the appropriate solution, say a three per cent. solution of fuchsin (red) until the image is fully developed. I thus have the red image on top of the blue image. The plate, after drying, is sensitised for the third and last time; it is then printed under the 'blue' negative, washed and developed in a bath consisting, for instance, of a seven and a half per cent. solution of helianthin (yellow). When dry, the photographic colour print on paper is finished; it is then cut all round within the edges of the gelatine, which was applied to the glass as first mentioned. The paper carrying the print will then come clear off the glass, and can be mounted like any ordinary photograph. The superimposition of the three negatives during the three printings is easily accomplished for the second and third negatives by holding the plate up

to the light, and making the contours on the negative coincide with the contours of the image on the plate beneath it; the plate and negative are then, during printing, held together by means of strong spring clips, instead of being placed in a printing frame. In case where thick opaque paper is used, it is desirable, as is done in multi-colour printing, to make corresponding register marks on the negatives, which will become subsequently reproduced on the positives, and serve to remove the difficulty of obtaining a true register."

CAPTAIN LASCELLES DAVIDSON'S THREE-COLOUR CAMERA.

[No. 3550 of 1899.]

The camera is constructed with a front plate, *a*, having the three lenses, *b*, *b*<sup>1</sup>, *b*<sup>2</sup>, all of the same focus. These lenses are each provided with the colour screens, *b*<sup>1</sup>, *b*<sup>2</sup>, *b*<sup>3</sup>, arranged behind the lenses, the colour screens being of the requisite colours to give the three photographs in the proper colours required, for three-colour photography. The camera is completed by means of the bellows body, *c*, and the movable back plate, *d*, adapted to receive the dark slide holding the photographic plate and being provided with a hinged ground-glass screen, *e*, which can be turned up out of the way when the dark slide is in place. For the purpose of dividing the camera into three compartments flexible partitions, *f*, are provided, having a certain amount of springiness, so that, when released, they will collapse and allow of the colour screens, *b*<sup>1</sup>, *b*<sup>2</sup>, *b*<sup>3</sup>, being got at easily. These partitions, *f*, are provided with rigid bars, *g*, each fitted at their ends into slots upon the back plate, *d*. These partitions, *f*, being of

Fig. 1.

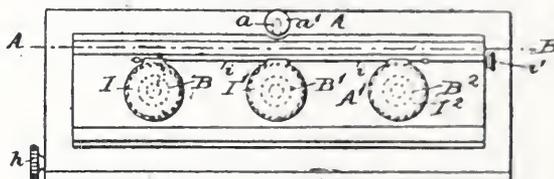

Fig. 2.

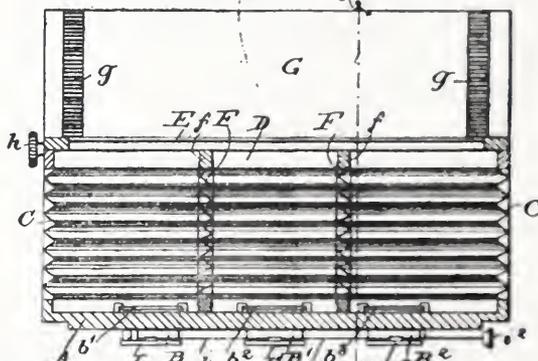

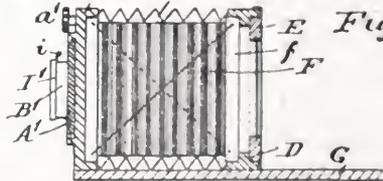

Fig. 3.

a flexible character, will therefore extend or collapse in accordance with the movements of the bellows body, *c*. The front, *a*, of the camera is attached to the baseboard, *g*, and the focussing is effected by the movement of the back, *d*, which is operated by pinions engaging in the racks, *g*, upon the baseboard, *a*, the milled head, *h*, serving for rotating the pinions. In order to effect slight adjustments of the lenses, *b*, *b*<sup>1</sup>, *b*<sup>2</sup>, they are mounted on a sliding frame, *a*<sup>1</sup>, fitting in grooves in the front, *a*, of the camera, and the longitudinal slot, *a*, in which a milled screw, *a*<sup>1</sup>, engages, allows of a slight vertical adjustment.

Shutters, *r*, *r*<sup>1</sup>, *r*<sup>2</sup>, are fitted to the lenses, *b*, *b*<sup>1</sup>, *b*<sup>2</sup>, and are connected together by means of a rod, *i*, operated by a milled head, *i*<sup>1</sup>, so that all three lenses can be exposed simultaneously.

These lenses are provided with differently sized apertures and with stops, in order to allow for the differences required for the particular colour screen in use in each lens.

COLONEL OSBORNE POLLOCK'S THREE-COLOUR CAMERA.

[No. 14,364 of 1899.]

The instrument consists of a rectangular body, *a*, with a removable inner body, *b*, which fits into place with a sliding fit. *c* are guides for the inner body, and *c*<sup>1</sup> is a guide frame at the back of the main body, *a*.

$d$  is the usual ground-glass focussing screen; it is only shown at fig. 3.  $e, e^1, e^2$ , are three lenses arranged at the front of the camera, the lenses  $e^1$  and  $e^2$  being arranged one beside the other, and the lens  $e$  above and intermediate of the other two.

The inner body is divided into three boxes or chambers,  $f, f^1, f^2$ , divided off from one another by means of division pieces,  $g, g^1$ . It will be seen that the arrangement of the chambers corresponds to the arrangement of the lenses, that is to say the chamber,  $f$ , is above and intermediate of the other chambers,  $f^1, f^2$ . At the front end of each chamber is a colour screen, and these colour screens are fitted removably in place, the colour screen,  $h$ , for the upper chamber,  $f$ , being passed through a slot at the upper side of the chamber, and held in place by means of a button,  $i$ , whilst the colour screens,  $h$ , and  $h^2$ , for the chambers,  $f$ , and  $f^2$ , are passed through a slot at the side of each chamber, and are held in place in a similar manner to the screen,  $h$ . The screens consist of coloured glass, the screen  $h$  being red, the screen  $h^1$  blue, the screen  $h^2$  green.

What is claimed for this camera is that in colour photography three exposures can be made at the one time without the intervention of a

its guest, which closed, on Tuesday last, the lectures for the month of February.

There is only one man who is entitled to grumble, and that is the individual who is mad on photography, the man who button-holes you on the staircase and asks how many grains of bromide you put into your developer when the temperature is something below 32° F.; the photographic bore that you flee from as you would from the wrath to come. There is method in his madness, at least, when he points to the programme and howls out in his agony, "Is this a photographic club, or is it a ——" You wait not for the completion of the sentence, but suddenly remember that you have an appointment in the billiard-room upstairs, and find yourself presently in the midst of a discussion with the marker as to the merits of the new pockets which have been fitted to the table.

Perhaps it was in deference to the aspirations of the mad photographer that one of the announced items of the February programme was postponed, and Professor R. W. Wood, of Wisconsin, was asked to give an account of his new colour process. Anyhow, the Club found itself, on Monday last week, listening with great interest to a lecture which embraced more than one subject, and with another Wood—Sir H. Trueman Wood—occupying the chair in his customary tactful manner.

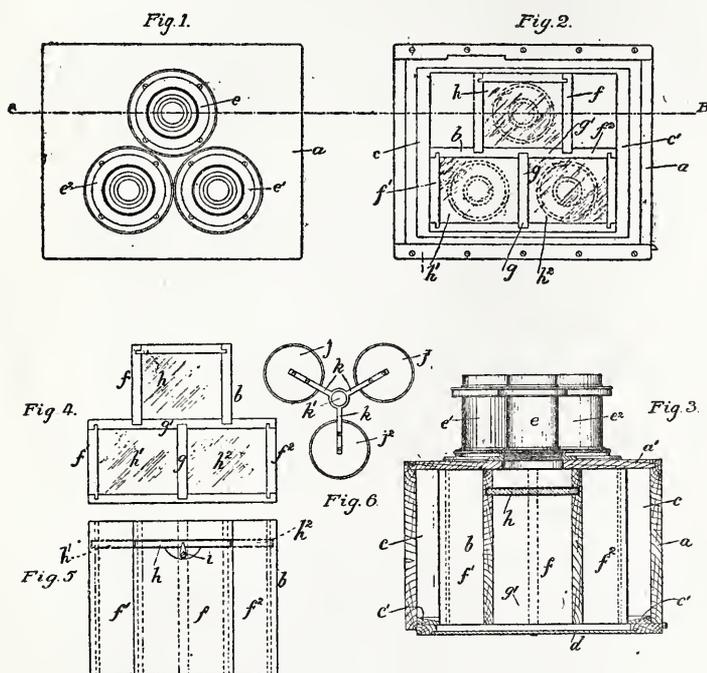

The main subject with which Professor Wood dealt was his colour process, and as this has elsewhere been described in detail—for it is not the first time the lecture has been delivered—we need not enter into particulars. But we must say a word of acknowledgment as to the happy manner in which the lecturer presented his remarks. It was a clear exposition of a very difficult subject. Although the lecturer was not a good draughtsman, as he himself confessed, he handled coloured chalks with such deftness that he was able on the blackboard to make his meaning apparent even to those who knew nothing about the vagaries of diffraction gratings. Never at a loss for a word, he spoke rapidly, and was always ready with some apt and homely illustration which helped to point his remarks. There was also a piquancy in the unconscious introduction now and then of an unmistakable Americanism, as, for instance, "I shall be glad to answer any questions when I'm through."

In addition to the colour process, Professor Wood showed a zone plate, which he had obtained by copying by photography the concentric rings ruled upon a large sheet of cardboard. He explained the rule for making such a diagram, and showed how the zone plate could be used instead of a lens, both in the telescope and in the camera. In the former instrument it was possible to see details with it in the lunar craters, and with the latter he had taken some photographs with a zone plate which were projected upon the screen. These pictures of marshy ground and wintry trees were interesting curiosities, and he pointed out that, in consequence of the zone plate possessing two foci, the detailed images of the twigs were accompanied by a blurred image which looked as if the design had been rubbed in those places by charcoal and stump. Barring this peculiarity, the pictures had much the appearance of pinhole photographs, and the method may commend itself to those who are seeking something of a smudgy character for the next exhibition of advanced art.

But perhaps the most interesting, and certainly the most wonderful, pictures which Professor Wood showed were in connexion with a recondite subject which he originally brought before the Philosophical Society a year ago, namely, the photography of sound waves.

It is easy enough to photograph waves and ripples in water which are comparatively slow in movement and evident to the sight. With waves and ripples in the ambient air, which no man can see, and which travel at a rate of a thousand feet per second, it is very different. Professor Boys was, perhaps, the first to photograph anything of the kind, and he did so unwittingly. In his marvellous pictures of flying bullets can be seen the wave of compression bowed out in front of the missile, and the wave of rarefaction behind it, in addition to the beautiful ripple in the rear. Sound waves are of much the same character, only they are spherical in form, and Professor Wood set out with the expressed intention of securing them in his camera. The apparatus was simple, and consisted of an electric spark apparatus to give the sound or snap, and another spark to give the necessary light by which to secure the image. Nor was he content with the simple wave. His photographs showed the phenomena of reflection and refraction, and some showed how the wave was retarded by being partly sent through carbonic acid gas, or hastened by transmission through hydrogen. A beautiful example was that in which the photograph showed the wave striking a series of steps, and bounding off each so as to meet the ear with the periodicity necessary to produce a musical note. Professor Wood's lecture aroused much interest, and the vote of thanks passed at the conclusion of the evening was something more than a mere formality.

THE Paris Exposition will be brilliantly illuminated at night. There will be 3116 incandescent lamps at the great entrance gate in addition to twelve very large arc lights; on the cupola and minarets there will be eight search lights, and sixteen simple reflector lights upon the pylons. The Alexander III. bridge will be lighted by 508 incandescent lamps of 117 candle power. The electricity building will be lighted by 5000 incandescent lamps, eight search lights, and four plain arc projectors. On the water palace there will be 1098 incandescent lamps.

reflector as has hitherto been practised, and also that the camera can be used either for colour photography or ordinary photography as desired.

The front board,  $a^1$  (see fig. 3), of the camera is removably fitted in place in the usual manner with cameras having movable front boards, so that, when it is desired to use the camera for ordinary photography, the front board with the three lenses thereon can be removed and replaced by a front board with a single lens thereon. The inner body is, in such cases, also removed, so that the camera can be used in the same manner as an ordinary camera.

Owing to the law of parallax, the camera, with its three lenses, is always in focus, that is to say, no focussing is required, as the camera can only be used for objects situated beyond a definite point, the point varying with the focal length of the lenses used.

The three simultaneous exposures are made by means of three caps,  $j, j^1, j^2$ , for the lenses. The caps are connected together by radial bars,  $k$ , which are connected together at the centre, and provided at this point with a knob or handle,  $k^1$ . If so desired, a shutter may be used instead of the caps.

The necessary difference in the duration of the exposure for each of the colours is regulated by the size of the aperture of each lens.

#### PROFESSOR WOOD AT THE CAMERA CLUB.

THE February lecture programme at the Camera Club has been crowded with good things, and was of such a varied character that it may safely be said that he must be a man of singularly barren mind who could not find in it something to arouse his interest, if not enthusiasm. If he had no liking for "the discharge of electricity through gases," he could revel in "Niello work," and, if he did not like that, he could linger over "Some Aspects of Ancient Egyptian Art." If his tastes were not with pyramids and mummies, he was sure to discover something more to his palate in one of the other lectures announced, and, when all failed, he could secure a ticket for the Club House Dinner, with Sir William Abney as

## LANTERN MEMS.

WHAT would the lecturer do without photography? This is the more emphasised every time one attends a scientific or technical meeting, for diagrams, no matter how skilfully drawn or produced, can never portray so faithfully as photography the salient points, and, even if details that are hidden from view in an apparatus have to be explained, a photographic projection is always more satisfactory than a diagram. This being a truism, some will say, Why refer to it?

\* \* \* \* \*

If the actual apparatus, machine, or instrument, cannot be shown to the audience or its size prevents its being seen by a large number of persons, the optical lantern and a photographic transparency then provide the necessary means, and, although some affirm that photography "can deceive," the majority will be perfectly satisfied that the view before them is correct and enables them to see the general design or examine details.

\* \* \* \* \*

At a lecture I recently attended at the Auto-mobile Club, I was impressed, from the photographs shown, by the wonderful progress that has been made in the design and construction of motor cars and carriages since I saw the demonstration organized by Sir David Salomons some two or three years ago at Tunbridge Wells; and, having seen the cars at Brighton that took part in the first trial run, I was doubly interested in Mr. Sturmeys capital paper on the subject of Motor Locomotion. That the auto cars have come to stay there is no question, and photographers will be adopting this method of travelling wherever something more has to be carried than can be comfortably placed on a bicycle or pedal tricycle. The trial of auto cars in the 1000 miles run at the end of the month, and the Exhibition to be given, before and after the same, in London and in the provinces and large cities during the actual progression from Bristol to the north and back to London, should create an interest in them and make still more popular.

\* \* \* \* \*

I COULD not help contrasting the comfort of such places as the Auto-mobile Club and the Camera Club with some of the meeting places where scientific papers are read, and, although for a strictly technical meeting, lasting from one hour to an hour and a half at the outside, one can put up with the straight-back seat, cold rooms, or other discomforts, it is this sort of thing that is distinctly a draw-

back to a society that caters for the social as well as the technical side of a section of the scientific world. Enthusiasm is a good thing in new societies, and one ought not perhaps to find fault with having too much of a good thing; but certainly I had, and I think many others had, too much of two good things the other evening. Either of them by themselves was a feast, but both together after ten hours' ordinary business was too much.

\* \* \* \* \*

A SOCIETY has been formed called the Optical Society, and Dr. R. M. Walmsley, F.R.S.E., gave a Presidential address which reviewed in a most interesting manner the work accomplished by opticians and in the optical world with its many allied branches, and particularly dwelt on the wonderful scope in what he called the "borderland of optics." This included photography, electricity, and X-ray work, and quite a long list of sections that the optician had to be versed in, or in which it would be wise for him to be well informed; while the modern requirements of military men and travellers enabled him to dwell on the improvements in prismatic field glasses, range-finders of various types, and other instruments—altogether a most useful *résumé* of work done, and which will be of value, not only to the optician, but all who are interested in scientific matters.

\* \* \* \* \*

A MOST useful paper was read by Mr. Dixey on "The Centering of Spectacle Lenses," and illustrated by diagrams and apparatus. The technique was interesting to all, and the information given for the benefit of the junior members of the optical industry should be of great value to them. Opticians who make photographic lenses know the value of perfect centering, but spectacle-sellers often do not pay that attention to the correct centering of spectacle and pince-nez lenses that is so essential, for it must be borne in mind that for the best results a different centre is required for lenses used for looking at near objects to that for distant objects; in fact, when the higher powers or shorter-focus glasses are used for near work, a great gain is obtained, not only as regards the improved definition, but also in the comfort of seeing, by having the lenses decentered.

\* \* \* \* \*

THOSE who, like myself, have had over thirty years' experience in all branches of a scientific optician's, and had some thousands of cases of eyesight-testing, can endorse this, and emphasise the necessity for all who have eyesight that is not perfectly normal to be most careful in the use of glasses. Nearly every case has some peculiarity, and must be taken on its own merits and arranged for separately. A glance at a file of prescriptions, arranged after a series of refraction tests, both with the optometer and Snellin's types, show what a wonderful diversity there is in the human eyesight.

\* \* \* \* \*

THE *Globe* says, in its "Echoes of Science," that Professor Raoul Pictet, of Geneva, whose name is identified with the early lique-

faction of air, has now discovered a means of separating oxygen from nitrogen in air at ordinary pressure. It is a practical application of "liquid air," and the commercial apparatus can supply 500,000 cubic feet of oxygen, and over a million cubic feet of nitrogen, for an expenditure of 500 horse power. In addition, there will be a by-product of 1500 pounds of liquid carbonic acid, which, we may add, is now made by brewers for the market. Oxygen will be useful instead of air for heating up coal furnaces. It can be stored in steel tubes and transported to consumers. Nitrogen can be employed for the production of nitric acid and ammonia. The Pictet process is to be introduced into New York." Will this affect the supply of oxygen for lanternists' use? is the natural question asked.

G. R. BAKER.

### LANTERN MATTERS.

#### A PLEA FOR LONG-FOCUS OBJECTIVES.

WHEN arranging for a lantern exhibition one of the first questions to arise is, What size of disc would be the most suitable for the occasion? and, seeing that the size of disc, or, what is practically the same thing, the size of the picture is controlled by two factors, viz., first, by the distance the objective is from the screen, and, secondly, the focal length of the objective employed, it follows that there is always more or less margin at an operator's disposal provided he has plenty of floor space at his command; and, this being the case, a large amount of useful work may be conducted with an outfit which possesses only one objective. It is generally admitted, however, that the most pleasing effects in lantern projection are obtained when matters are so arranged as to provide a disc which is as nearly as possible in size a fourth of the longest distance of the hall, and this standard of proportion will be found to apply to large and small rooms alike, and is one that nearly every lanternist of note has accepted as the proper one to work up to. A little thought will enable any one to see how nicely the rule will apply to both public halls and private rooms alike. Take, for instance, a small public hall of, say, fifty feet in length. Here a twelve-foot disc would be the most suitable; while, on the other hand, a private room of, say, sixteen feet in length, would be nicely suited with a four-foot picture.

In working up to this standard of one-fourth the greatest length of the room, it stands to reason that, if very or moderately short-focus objectives be employed, the lantern must be placed at a short distance from the screen. On the other hand, with lenses of longer foci, an operator must arrange his lantern at a greater distance; and here, again, a most important question arises, viz., What is the most suitable focal length of objective to employ in all-round working?

To answer this question, consideration must be given as to the most suitable distance to place a lantern in the room or hall.

When lenses of short focus are employed, it nearly always happens that the lantern has to be placed in a position where it is surrounded by the audience, and this is objectionable in more ways than one, for not only is much discomfort experienced by those spectators sitting in the rear of the lantern, but much useful floor space is taken up at what is nearly always the best point of sight, and which would be better placed at the disposal of the audience. On the other hand, when long-focus objectives are employed, they will permit of the lantern being placed at the back of an audience, and allow of a much greater amount of ease and comfort to an operator, as well as not interfering in any way with the point of sight of any of the spectators.

An idea prevails that a better light is provided when the optical arrangements of a lantern are such as permit of the disc being projected from a point somewhat near the screen. This opinion, no doubt, was held by a goodly number of operators several years ago, when gas bags were almost universally employed in lantern projection; but, with the introduction of compressed gas in cylinders and greatly improved forms of mixing jets, these old-fashioned ideas have ceased to exist, for, with the enormous pressure from cylinders, there is certainly no reason why the utmost brilliancy should not be attained when working from a standpoint at a considerable distance from the screen.

In the days of gas bags a good portrait combination of about six inches focus was looked upon as a most useful lens to employ in lantern projection, and one of our leading authorities on limelight matters is found expressing it as his opinion that, where only one objective finds a place in a lantern outfit, a lens of six-inches focus will probably be found the most useful for any one to employ.

Others, again, who do a large amount of professional work and whose opinion is equally worthy of consideration, simply by reason of their being expert lanternists, seldom think of employing an objective of such

short focus as six inches, and these are found steering what may be termed a middle course in preferring an objective of about eight-inch focus, and it is with either one or other of these objectives most lanterns are now supplied to amateur operators, notwithstanding they but seldom allow an operator to work so as to conform to the standard of yielding picture in size proportionate to a fourth of the room without inconvenience to spectators. In what may properly be termed "Home Working," for instance, a by no means uncommon size of dining, sitting, or drawing-room will be found to consist of twenty feet in length or thereabouts, a fourth of which would be five feet, and to yield this size of picture in such a room a lens of nearer twelve-inches focus will be found necessary; although much shorter-focus lenses are regularly found doing duty in such places, of course yielding much larger pictures, which are too often specially noticeable by the inferior definition which those short-focus lenses yield. Speaking generally, if pictures are to be provided that approach in size a fourth of the longest part of any hall or room, then it will be found that a twelve-inch lens will come nearest yielding the same with the least amount of inconvenience to spectator of any size of objective, simply by reason that it will permit of the lantern being placed at a considerable distance from the screen. A very little calculation will show how nearly a twelve-inch lens fulfils the requirements of the rule laid down, viz., providing a picture a fourth of the size of any hall. Take, for instance, a large hall of, say, eighty or a hundred feet, and when either of these distances is multiplied by three and divided by twelve in conformity to the standard formulae, in each case working from behind an audience, we get a disc always in a proportion to one-fourth the longest distance. The larger the hall, of course the larger the picture necessary, and, no matter what be the size of the room in which an exhibition has to be given, a lens of twelve-inches focus will be found to work almost exactly to the standard size so long as transparencies of three inches in dimensions are being projected, and for many years I have found a good portrait combination of twelve inches focal length the most generally useful of all projective lenses.

Circumstances will arise in which, owing to obstructions in the line of sight, as well as peculiarities in the shape of a building, a shorter focus lens would be desirable; but this objection holds good in the same degree with short-focus lenses as with long, and it often happens a long focus objective enables an operator just to cut clear of some obtruding object, such as gas bracket, &c., where with only a shorter focus the same would yield nasty eyesores on the screen. With, however, a really good long-focus portrait objective an operator has the power of manipulating the combination as will enable the objective to be utilised as a shorter-focus objective. In most treatises on lantern projection the information is given that, when an objective is required of longer focus than the entire portrait combination is yielding, the front lens may be utilised by unscrewing the back lenses of the combination and using in their place the front lens only, convex side next the slide. This generally provides a fairly good single-lens lantern objective of nearly double the focus of the entire combination, and when used with a suitable stop at the proper distance in front of the lens, so that the stop merely cuts off the more oblique rays, very fair definition is obtained and also very good illumination; few, however, if any, of these handbooks on lantern projection give the information *how to manipulate a portrait combination so as to shorten its focal length without adding an auxiliary lens to the same*, and, when the entire combination is of about twelve inches, can with the greatest ease be reduced to a focal length of about eight inches or so.

To accomplish this shortening of focus, unscrew the back portion of the combination and then remove entirely the inner portion and use the lens with the front and back lenses in their regular place without the flint concavo-convex, which has been removed from the back. Exception may be taken to this procedure on purely optical reasons, but in practice it will be found to work remarkably well, and my twelve-inch objective has often been so used, giving really good definition without any stopping down even.

A twelve-inch portrait combination is therefore probably the most serviceable lantern objective any one can acquire. It should be borne in mind, however, that, when long-focus objectives are employed, care should be observed in seeing that the condensers are of rather long focus than are generally fitted to lanterns carrying six-inch objectives.

T. N. ARMSTRONG.

### THREE-COLOUR PHOTOGRAPHS APPLIED TO THE CORRECT DELINEATION OF NATURAL HISTORY SUBJECTS.

THE above is the title of a most interesting paper read before the Croydon Microscopical and Natural History Club by Mr. Saville Kent, F.L.S.

U.S., of which the following is an abstract. The three-colour process, as its name implies, involves the employment of three-colour printing only in conjunction with a proportionate abbreviation of time occupied in its mechanical accomplishment, compared with the older and more elaborate system of chromo-lithography.

It is, moreover, an essentially photographic method, three separate negatives of diverse but scientifically gauged intensities being taken of each subject, and the combined colour printings or positives from these negatives having a corresponding but complementary colour ratio.

The scientific principle upon which the very remarkable colour reproductions now obtainable have been rendered possible owes its origin to the late Professor Clerk-Maxwell who, as long since as the year 1861, demonstrated the fact that all the colours of the solar spectrum, and concurrently all those of nature, are the equivalents of an admixture in varying proportions of the three primary colours of the spectrum, viz., red, green, and blue-violet; and it is only of late years that Clerk-Maxwell's discovery has been found capable of practical commercial application. Among those who have contributed most extensively to both the theoretical and practical utilisation of this three-colour photographic process, the names of our own countryman, Captain Sir W. Abney, Frederick Ives, of Philadelphia, Professor Joly, of Dublin, and Lumière, of Paris, are most eminently notable.

Mr. Ives's investigations led to the production of that ingenious instrument the photo-chromoscope, or kromoskop, as it is most popularly called, by which negatives taken through red, blue, and green-coloured glasses are viewed by means of reflectors through glasses of the same tint, with the most realistic fidelity. Mr. Ives has also invented a kromoskop lantern, by which through coloured glasses similar realistic images can be projected on the screen; but, after all, these are but intangible images, which cannot be represented without the aid of the complex and costly instruments devised by their inventor. To meet popular requirements and general application, natural colour pictures or lantern slides that are available, like monochromes of the ordinary type, for individual handling and examination or for projection by any ordinary optical lantern, have been the desideratum.

Substantial progress has now been made towards the achievement of this much-desired goal. Ives himself was among the first to produce such tangible natural colour lantern pictures. Mr. Bennetto, of Cornwall, has produced noteworthy results; in both cases the positives are printed on three transparent primary colour carbon tissues, which were then superimposed in correct register. Lumière, of Paris, has employed stained collodion films consecutively printed in correct register on top of one another with the accomplishment of the same object. There yet remains to be mentioned the very ingenious adaptation of the three-colour process invented by Professor Joly, of Dublin. In accordance with his system, the three primary colours are all included in alternating microscopically minute parallel lines ruled on a single original or *taking* screen, and, in the reverse or complementary order, in a corresponding or *viewing* screen, which has to be bound up in perfect register with each resulting positive. But the aggressive prominence of the ruled colour lines is undoubtedly a fatal obstacle to the utilisation of the Joly process for the colour registration of subjects requiring scientifically accurate reproduction of their minute details.

Neither of these systems, however, fulfils the requirements of easy practical application and scientific accuracy that is in demand, but the following process, according to Mr. Saville Kent's personal experiments and experience, does appear to hold out the most encouraging future prospects. Modifications of the Ives transparency system have been devised by Mr. Sanger Shepherd, the essential details of whose process will be found in THE BRITISH JOURNAL OF PHOTOGRAPHY for December, 1899. The practical applications of this Sanger Shepherd lantern-slide process are so far assured, that all the materials and instructions for its employment are now obtainable through all the ordinary commercial channels.

Mr. Saville Kent then proceeded to illustrate his subject by means of slides thrown on the screen, which were the outcome of his own experiments with this process, explaining first that the negatives from which they were produced were all taken in trifolia colours through a set of coloured screens as shown, and the positives printed from the three consecutive negatives taken have, in corresponding order, to be printed in or stained the complementary colours of blue, red, and yellow, and are then carefully superimposed to produce the natural colour replica.

The slides now shown will demonstrate the practical utility of this process for the correct delineation, or perhaps, rather, counterfeiting, the natural aspect of the objects photographed, and these slides, fifty in number, illustrate all the leading branches of national history. Among

floral objects, the orchids come largely to the fore, dendrobium, masdevallia, cypripedium, and cattleya being specially noteworthy. Various tropical butterflies associated in nature with these orchids were included in this series. More ordinary floral types, including a bright crimson bloxinia, associated with a brilliant blue morpho butterfly, a vase of lilac, and several groups of tropical waterlilies, of abnormal plant form, two typical species of the genus *stupelia*, or so-called passion flowers of South Africa, the one, *S. variegata*, resembling a spotted star-fish, and the other, *S. psomoensis*, clothed with brown furlike hair, were of special interest. It was explained by Mr. Saville Kent that the carrion-like odour of these flowers attracted flies, who in that last-named species more particularly deposited their eggs freely upon them, apparently under the impression that the malodorous blossom with its hairy clothing was the skin of a defunct quadruped. A group of scarlet-and-white spotted fungi from the Shirley Woods, for which the exhibitor was indebted to Dr. Franklin Parsons, concluded the botanical series.

Among the various forms of butterflies and moths, that of our familiar Red Admiral, *Vanessatalanta*, complacently resting on a cabbage-leaf, was more particularly admired.

Mr. Saville Kent then showed some lizards from Australia, Algiers, and Egypt, of which he has an extensive collection, and also the so-called Deguxin from Central America, which he has demonstrated has the habit of running bipedally, after the manner of a bird.

Fish were found to lend themselves very appropriately to this three-colour photographic process, and very fine examples were shown of gold and silver carp, a red-spotted plaice, and a john dory in the act of engulfing a small rock fish. A very successful group, called *A Spring Idyll*, consisted of a bank of primroses with a couple of brimstone butterflies toying over them, while, ensconced in a sheltering corner of fern leaves, a young leveret was inquisitively watching the sporting butterflies.

Bird life too was well illustrated. The so-called Australian wren, showing brilliant blue, black, and scarlet coloration, and the little emu wren, of a more sober brown, formed appropriate subjects for this process. These were photographed in connexion with Australian acacias and other flowering plants indigenous to their native habitats. A justly admired peacock's feather, in which the characteristic tints were most realistically reproduced, brought Mr. Saville Kent's highly appreciated lecture to a close.

#### ORTHOCHROMATIC PHOTOGRAPHY AT THE PHOTOGRAPHIC CLUB.

ON March 21 Mr. E. Sanger Shepherd gave a lecture, under the auspices of the Affiliation, upon the subject of "Orthochromatic Photography." He commenced by showing upon the screen a glaring example of a difficult subject for reproduction by photography in its true values, namely, a picture coloured in crude yellows, reds, and blues. For the ordinary plate no more difficult subject could be chosen. The next slide showed the best out of eight negatives taken on ordinary plates in an attempt to photograph the test object, and this, as might be expected, was a ghastly failure looked at as a representation of the luminosities in the original. The reason so bad a translation is obtained lies in the fact that the ordinary plate is sensitive to only a very small proportion of the spectrum. A comparative slide was shown in which at the top was a rough imitation of the spectrum, under this a photograph of the spectrum representing the luminosity of the spectrum of white light to the human eye, the maximum being in the yellow, decreasing rapidly towards the red, and gradually the other way to the violet end. Under this was a representation of the preceding negative in the form of a curve. It is very difficult to illustrate in a book, by half-tone or varying densities, the differences in the density of different parts of a negative, so that, as a rule, a curve is plotted to convey the desired information. The enormous intensity of the yellow of the spectrum in comparison with the blue and violet was plainly shown. The next slides showed comparative results on the spectrum plate and an ordinary plate, greatly to the advantage of the former, which gave a far nearer approximation to correct rendering of luminosities than was possible with the ordinary plate.

The principle underlying orthochromatic photography is that certain dyes added to the emulsion alter the spectrum sensitiveness of the plate. The dyes fluoresce and render the emulsion capable of being influenced by light which would otherwise fail to affect it. The new Cadett plate is practically sensitive through the whole length of the spectrum, and that evenly. At this point a most instructive series of plates was shown. Against the spectrum plate, which, as mentioned before, has an almost

even sensitiveness throughout the spectrum, were matched various commercial brands of plates. In one there was a gap in the green, where no action had taken place, but a high red sensitiveness, so high that red light was unsafe for development and a green light was substituted. In most of the tests shown the blue was far more intense than it rightly should be for its luminosity. One plate showed red and green sensitiveness fairly, but too strongly in the blue. It becomes necessary in such cases to lower the action of the blue to allow the red and green to catch up. This would be done with a colour filter, and the whole brought into harmony. It was seen from the experiments and explanations that the Cadet spectrum plate provided the best means with which to begin experimenting for the perfect rendering of colour values in nature according to their luminosities. Mr. Sanger Shepherd then went at length into the method of adjusting screens and measuring the results advocated by Sir W. de W. Abney, which was of great service.

By these and other means it becomes comparatively easy to make filters which will give action in any part of the spectrum. Mr. Sanger Shepherd then showed the method of measuring the luminosities of any colours by means of adjustable sectors of black and white card, the relative quantities of which are adjustable, mounted with the colour to be tested on a spindle and rapidly rotated by an electro-motor. The black-and-white blending produce a grey, the depth of which can be altered by increasing or decreasing the white sector, until it matches the luminosity of the test colour. Mr. Shepherd then projected several single slides, made by superimposing three dyed films representing the three primary colour sensations, naming the screens used and the complementary colours in which they were printed.

In answer to several queries, he strongly warned those taking up orthochromatic or colour photography against the use of hydroquinone for development. It possessed the peculiar property of bringing up the parts of the image formed by blue light at an early stage, and, although the other colours caught up in time, there was the disadvantage that the time of development, which was important in this work, was materially altered. The question of dark-room illumination was rather a bogey. Plates would not be appreciably affected by the use of a fairly bright light if one followed the custom he now adopted, namely, of developing all negatives for colour work inside of three minutes.

Where a proper safelight is used, the plates may be exposed to it for fifteen or twenty minutes during development if conditions so require. As a rule, his negatives were completely developed in forty-five seconds. Metol was used, and with it anhydrous carbonate and anhydrous sulphite of soda. The latter being rather difficult to obtain, crystals may be substituted, but each batch of developer should then be tested, because the amount of water in the salt varies considerably with different samples. For colour work he never used bromide. The amount of sulphite used had a bearing upon the time of development, and the influence of different quantities was enormous, as does the amount of water it originally contained. Two samples from the same firm, recently used, gave in one case a negative of full density in one minute, while the other gave only a ghost of an image.

Some discussion ensued respecting the origination of the principles of orthochromatics, and Mr. Mackie gave credit to the late Dr. H. W. Vogel. The tale was that Col. Stuart Wortley had an idea that, by staining the plate, halation might be overcome. He sent some plates so dyed to Dr. Vogel, who noticed that they showed quite a different colour sensitiveness to undyed plates. Following this discovery to a logical conclusion, he laid the basis of orthochromatic photography, and he only regretted that his due reward had not been received from all quarters.

A vote of thanks to Mr. Shepherd concluded the meeting.

#### PHOSPHORESCENT SULPHIDE OF STRONTIUM.

ACCORDING to a French contemporary, M. José Mourello has presented to the Académie des Sciences an account of his method of preparing a phosphorescent sulphide of strontium. The same experimenter has previously shown that certain substances, such as carbonate of manganese and sub-nitrate of bismuth, in small proportions, have the property of exciting the phosphorescence of strontium sulphide. In his recent experiments with sulphate of manganese he has succeeded in obtaining a brilliant phosphorescence. The method of preparation is as follows: A mixture is made of 100 grammes carbonate of strontium, 30 grammes sulphur, and 0.2 gramme sulphate of manganese, pure and anhydrous; these are well mixed and put into an earthen crucible, well closed. The crucible is heated to a bright red for three hours. In this manner a sulphide of strontium is formed which is almost white, hard, and

possessed of an intense yellow-green phosphorescence, which may be excited by the exposure of a few seconds to diffused light. The experimenter describes several other methods of preparation, by which he has progressively arrived at results even more satisfactory. He takes, for instance, 100 grammes carbonate of strontium, adding 50 c. c. of water in which has been dissolved 2 grammes of dry sodium carbonate and 0.5 gramme fused chloride of sodium. After desiccation the mixture is calcined, and to the impure strontia resulting is added 30 grammes of sulphur and 0.2 gramme sulphate of manganese. By submitting this mixture to an intense heat a sulphide of strontium is obtained whose phosphorescence is more brilliant than in the former case, and it is excited with less exposure to light. The experiment which has given the best results is the following: With 100 grammes of carbonate of strontium is mixed a solution of 0.2 gramme sulphate of manganese in 50 c. c. of water; to the mixture is added 30 grammes of sulphur, 0.5 fused sodium chloride, and 2 grammes sodium carbonate. This mixture, heated in a crucible to bright redness for three hours, gives a sulphide which is rather white, hard, and granular, possessing a very great phosphorescent power, it being excited by the smallest exposure to diffused light.

#### CURATIVE PROPERTIES OF LIGHT.

ACCORDING to a contemporary, Dr. Mount-Bleyer, of New York, is of opinion that pure air, sunlight, and concentrated electric light will improve any case of tuberculosis. The best thing a man dying of tuberculosis can do is to buy an old greenhouse, put some blue glass in the roof, and walk around naked in the sunlight. But even this treatment can be improved upon. I was led to my electric-light cure, proceeds the Doctor, by my experiments on animals. Then I took men and women who had tuberculosis, and placed them in houses especially constructed with blue glass roofs; in fact, I built a solarium at Liberty, N.Y., a great glass building, which looks like a horticultural conservatory. My patients were drooping plants, which I attempted to nurture. They walked around in the rays of blue sunlight, and improved wonderfully. Most of them got well. Then, I argued, if blue light was so beneficial to consumptives, why not provide it for them artificially and in concentrated form? I procured a powerful arc-light concentrating lantern. Its candle power must have been 10,000. I used it on my consumptive animals, sending its rays through blue glass. The effect was remarkable. The beasts were made well much more quickly than in blue sunlight. It was equally beneficial to human patients. Next I dispensed with the blue glass. Instead, I caused the light to pass through large jars filled with chemical fluids, which absorbed all the light rays in the lower end of the spectrum, for I found that only the blue, the indigo, and the violet rays exert an influence on the movement of the spores. If a vessel containing a deep coloured solution of ammoniated copper oxide, which transmits only blue or violet rays, be placed between the source of light and cultivated spores, the spores are seen to react, just as they will when placed in contact with ordinary white light. On the other hand, they do not react at all to light which has passed through bichromate of potassium solution, through the yellow vapour of a sodium flame, or through ruby or red glass. I am able, therefore, to control the reaction of spores under light rays merely by interposing various solutions in the path of the light. Now, there is no difficulty in passing the rays through the human trunk to the lungs. We know that the cathode rays force their way through opaque bodies that ordinarily arrest the transit of sunlight. Röntgen has told us that, unlike sunlight, these cathode rays do not undulate in waves, but pass, as it were, backward and forward. To this, probably, is due their penetrating power. So we have the means of projecting the rays, with all their therapeutic properties, right into the lungs of the consumptive; in other words, it is possible to operate on his lungs without opening his body. Light is inimical to the development of the harmful organisms. The action of light entirely destroys the bacteria or reduces them to a condition of torpidity which they require months to overcome. A 22,000 candle-power light has been built for the doctor, with which to treat persons suffering from tuberculosis.

#### PRACTICABLE PHOTO-MICROGRAPHY.

[From the *Journal of Applied Microscopy.*]

By "practicable" the writer means simply possible and successful day in and day out—with all kinds of objects, tissues often miserably stained, thick sections lacking contrast, bacteria or the evasive *Amphipleura P.*, or even that *bête noir* of a generation gone by, the podura scale.

Photographic annuals, text-books, and even catalogues are sounding the praises of cheap and simple apparatus to the unwary victim, who begins to believe "any one can do it," and wastes time, money, &c., and then declares the whole thing a failure, and sticks to "diagrammatic drawings" for ever as the correct thing. So that, after many years of work, with many failures and a few successes, the writer will not be thought over-conservative if he advises only the *best* in the way of work room, apparatus, luminant, and technique.

Van Heurck may have done good work in photographing diatomacea with a vertical camera, but Nelson has far surpassed him in the same field with a horizontal apparatus.

The writer possesses a vertical camera, made from Van Heurck's model, but it has only 420 mm. space possible between plate and ocular, so that various magnifications can only be obtained by high-power objectives or, what is worse, high eye-piecing. One recent experience will illustrate, the writer being called upon to photograph a specimen of "hydatid mole" cut at 25 micra, poorly stained, where only high magnification (400 diameters) would satisfy the author of the article—and the syncytium cells alone well differentiated, the rest of the section a myxomatous tangle. High-power objectives and oculars would do nothing in such a case, but a 12 mm. 65 n.a. apochromat, with No. 3 projection ocular and 1800 mm. camera extension, gave a fair negative, and was published.

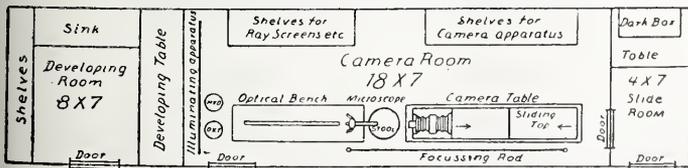

While fairly good work has been and will be done by our best workers with comparatively poor apparatus, it does not pay in these days of nerve stress for a valuable worker to sacrifice himself trying to do the impracticable when it is not necessary, and an occasional success does not compensate for many sad failures, with loss of time, money, and vitality.

What the writer means by "best" will be explained most simply by a brief description of his own work place, apparatus, light, and technique, as he possesses them.

Work place: a cellar with cement floor, brick walls, plastered ceiling, and running water; no vibration. The room, or rooms (three in number) are arranged side by side, 30 feet long, 7 wide; the first, plate-loading room, 4 x 7; next, camera room, 18 x 7; and last, the developing and printing room, 8 x 7, with no communication except from plate-loading room to camera. The developing and loading room are usually combined, but we find it better to have separate rooms and avoid possibility of hypo dust, &c., on plates. The rooms are all built with hollow walls of dull black paper on a wooden frame, ensuring perfect ventilation and being light-tight. The temperature does not vary 15° the year through, and no frilling or fogging of plates occurs because of excess of temperature.

As to apparatus, we have already given our decided preference for horizontal table and camera, so only need give brief description: two tables end to end, 18 inches apart, one, 5 feet long, carrying light, optical bench, and microscope; the other, 6 feet long, carrying only the camera, fastened rigidly together after proper alignment.

The optical bench carries illuminating medium—either Welsbach gas lamp or oxyhydro zirconium light, as the case may be, the first for low-power work and careful arrangement of microscope and object to be photographed, preliminary to high-power work and use of more powerful illuminant; the oxyhydro light can be slipped on in place of the Welsbach, and in a minute we are ready for exposure.

PLAN OF PHOTO-MICROGRAPHIC LABORATORY.

While we have a very fine heliostat, most of our work is done at night for various reasons, and oxygen and hydrogen under pressure are all that are needed—far better than electric arc lamp for our work. Hard limes are used for some ordinary work, as the zirconium is very expensive and breaks easily.

The optical part of the bench consists of the usual collecting lenses of Jena glass, with light filters, cooling cell, iris, diaphragm shutter, &c., all movable on the rail.

The microscope, which is used for no other purpose, sits on a sole plate, which is rigidly attached to the table, and is adjustable in all directions—English model, tripod foot, made by Watson & Sons, especially for this work, having mechanical stage and all possible improve-

ments. Between this table and the camera table is a stool at the proper height for easy observation and manipulation of the microscope. The focussing rod runs at the left side, independent of the camera, the full length of the camera table, moving the fine adjustment of the microscope by means of a loose leather pulley running on a grooved wheel 3 inches in diameter, without the slightest strain on the microscope. The camera table proper is 6 feet long, with a sliding top 7 feet long, to which the camera is fastened, running on its own rails—the whole top sliding smoothly on wooden runners to and from the microscope as needed, so that one can sit down comfortably at the microscope, select the desired area to be photographed, then move the camera up to the tube of the microscope, clamp all rigidly together, and proceed.

Before describing the camera, we will bring before our readers a simple piece of apparatus, possibly original with the writer, which has been found such a help that we are glad to publish it.

Running on the camera rails back of the entire camera is a wooden frame carrying an 8 x 10 photographic plate, exposed for a minute to white light with a white paper before it, in other words "fogged white," left undeveloped, giving a pure white surface with just enough grain to show details exquisitely. The top of the table carrying the camera is marked off carefully, showing various magnifications with different objectives, with and without oculars, and to use this screen the whole camera is closed up close to ocular of microscope, plate-holder and inside diaphragms of camera removed, the screen moved to the mark showing desired magnification and the image projected upon it in far less time than it takes to write.

The only light in the room coming through the microscope, the section can be studied, rearranged if necessary, cells accurately measured, as the screen is ruled to mm., equality of illumination guaranteed, &c., then this screen is removed, and the camera back with plate-glass focussing screen slid into the same mark, the final focussing done with achromatic focussing lens on plate-glass focussing screen, plate-holder substituted and exposure made—no failures, simplicity in every detail, with fullest assurance that one knows just what is being photographed, having seen its actual details projected on just the same surface as the sensitised plate which is to be made into the negative.

The Camera proper is the large "Complete" horizontal one, made by Messrs. Bausch & Lomb, with several improvements kindly made at our suggestion, giving a camera extension from 400 mm. to 2000 mm., more than answering any demands that can possibly be made upon it.

The plate-holder is perfect, and with a plate-glass focussing screen cross-ruled to mm. can be used for the most critical work, magnifications being obtained with a fairly complete battery of objectives from 25 to 400 diameters, using no higher than 2 mm. immersion objective and No. 6 projection ocular.

To the question arising in the mind of our reader. Why is such a camera extension necessary? we reply simply that high magnifications (all over 200 diameters of some objects can only be obtained by the use of low-power (12 mm. and lower) objectives of best n. a. with long camera extension, for in photo-micrography "depth of focus" or "penetration" means everything, and as this valuable quality (absolutely necessary in sections over 5 micra thick) decreases with increase of n. a., we must compensate by special technique in other ways.

CHAS. H. POTTER, M.D.

## POLARISED LIGHT.

In the course of a recent lecture on this subject at the Royal Institution, Lord Rayleigh said that double refraction, the first phenomenon that led up to the discovery of the polarisation of light, was observed by Erasmus Bartolinus. A crystal of Iceland spar or a thin slice of tourmaline is generally employed in order to get double refraction of a beam of light. If, for experiment, a thin slice of tourmaline be arranged in a lantern so that it allows light to pass through perpendicularly, two images may be obtained. If another thin slice be now added, the light passes through partially; but, on turning round the second at right angles to the first, the part where they overlap is quite dark. This experiment shows the many sided character of polarised light. In considering wave-motion, three main characteristics have to be borne in mind: (1) the wave-length, which has nothing to do with the direction of the light or the distance traversed, but is applied to the distance from the crest of one wave to the crest of the next; (2) the velocity of propagation; (3) the periodic time, the distance which a wave advances in unit time.

The vibrations of light are transverse, and not like those of sound, longitudinal. This statement is seen to be correct, because otherwise

the phenomenon of polarisation would be unexplained. When the refracted and reflected ray together make a right angle, then the best conditions are obtained for getting polarised light. Brewster formulated a law which is of great importance, the angle of incidence of light on water must be such that the tangent is equal to the index of refraction. Light may be oppositely polarised; it should be mentioned that in this connexion the opposite of north and south is east and west, and not south and north.

In order to demonstrate the polarisation of light, a board about thirty feet in length may be placed in a vertical position. At a distance of about three feet from the top a bar is fixed transversely at about three inches from the board, so as to allow a long rope hanging from the top of the board to pass between it and the bar. The rope may be manipulated from the ground; on giving it a succession of shakes at right angles to the board, waves are set up which are stopped by the bar; but when the rope is shaken in a direction parallel with the board, from side to side, the waves pass beyond the bar. By shaking the rope in a circular manner, a compound wave runs along it, part of which, the perpendicular component, is stopped by the bar, but the remainder, which is a horizontal wave, travels beyond the bar. Again, if the bar be replaced by a grating of parallel bars arranged at right angles to the board, and the rope similarly shaken, it will be found that waves perpendicular to the board pass through the grating, and horizontal waves are stopped by it.

These preliminary experiments form an introduction to the subject of the polarisation of light. Just as a circular motion set the rope vibrating with a compound wave, so light may vibrate transversely in two directions—say, north and south, and east and west. Light, on passing through one Nicol's prism, vibrates in one direction only; on passing it into a second Nicol's prism arranged at right angles to the first, no light passes through, since that which was vibrating in the second direction is now cut off.

#### THE LATE PROFESSOR PEPPER.

PROFESSOR PEPPER, who recently died at his residence, Colworth-road, Leytonstone, is best known to fame as the exhibitor of "Pepper's Ghost," which, when it was produced at the old Royal Polytechnic, realised 12,000*l.* in the first six months. He was not the inventor of the idea, which was brought to him by an engineer named Dircks, but he was responsible for its popularisation. The mechanism of the idea was as follows: A stage was used on which living actors walked. Underneath the stage was an arrangement of mirrors fixed at certain angles which threw a phantom representation of a real man upon the stage above. This phantom was cast on a sheet of transparent plate glass in front of the stage, so that, when the real actors passed behind the phantom, they gave the effect of passing through it and yet not obscuring it, the most creepy sensation in ghost-land. When this novelty first came out, it was a huge success; but it has already been supplanted by newer and more up-to-date methods. Professor Pepper was for many years a lecturer at the Royal Polytechnic Institution; he travelled with his show in America and Australia, and became public analyst in Brisbane.

In an interview with Mr. J. N. Maskelyne, published in a daily contemporary, that gentleman said he knew Professor Pepper very well. "He was the first person to bring ghost entertainments before the public. The scenic ghost was not his own invention, though, as many people imagine. We owe that to a civil engineer named Dircks, who took the idea to Professor Pepper, and he, seeing its possibilities, at once patented it. Being the first to bring the ghost before the public, he made a great deal of money out of his displays. He used to license travelling showmen, who all placarded their caravans, as some do to this day, with gilded letters announcing 'Pepper's Ghost.' Pepper himself did not travel with caravans, as is popularly supposed. He gave his entertainments in public halls. Originally he had been a chemist, and for many years he was a lecturer at the Polytechnic. He tried his hand for a time with ghost shows at the Egyptian Hall, but he seems to have lost heavily over the transaction. Afterwards he went over to Australia with his scheme for creating rain by throwing explosives into the clouds. That also was an unsuccessful venture. When he returned to England, he asked me whether I could find him anything to do here, but by that time he was too much out of date to be of service as a public entertainer. The fact is, Pepper's methods for creating illusions are quite obsolete, and could never hold their own for any time before an intelligent audience. He simply got his ghosts by a simple arrangement of glasses and mirrors, but now we never use glass to get illusions, for the most ingenious effects which can be produced by glass could be detected at once by any one in the audience acquainted with the principle of optics. There is no doubt Pepper's ghosts in their day were very successful. They were novel and could be made very amusing. In fact, I enjoy them myself to this day, but, you see, too many people know how it's done to make such shows of any use nowadays. When Pepper first began, speculation was very free

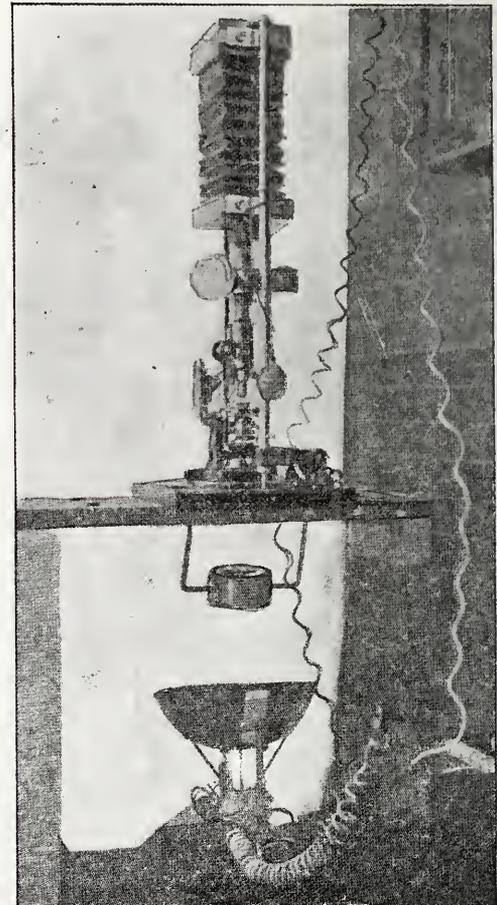

as to how he got his effects, and, as Spiritualism was then very much talked about, it used to be said that the ghosts had something to do with spirit media."

#### A NEW APPARATUS FOR INSTANTANEOUS PHOTO-MICROGRAPHY.

THE subject of photo-micrography is alike important to both biological and physical science. It involves not only accurate and interesting work with microscopic organisms, but from the physical, which includes the photographic side, much care is required in the selection and manipulation of the proper microscopic lenses, in connexion with the source of light employed, stain used upon the subject to be photographed, if a mounted slide, and the chemistry necessarily connected with the handling of the photographic plate itself, in order to obtain the best results, says Prof. A. C. Scott, in *The Scientific American*.

The different general methods employed in this work, together with proper magnification for certain forms, kind of illuminant, with ray filters, exposure, and character of plate, require separate treatment, as the chief object of this article is to describe a new apparatus for making instantaneous photographs of living microscopic animals.

After having worked upon photo-micrography for some time for the

Apparatus for Instantaneous Photo-micrography.

purpose of obtaining photographs of microscopic slides for illustration with the optical lantern, and having determined the conditions requisite to the production of good results with mounted slides, the thought occurred to the writer that, if an instantaneous photograph of a living organism could be made, it might be valuable to the biologist and instructive to the physicist.

It will at once be apparent to those who have worked along this line, that a powerful light is necessary for instantaneous work; in my own work with the apparatus an arc light consuming 2200 watts is employed, which gives, in the position used, about 4000 c. p. This light, as will be seen from the picture of the apparatus entire, is placed at a distance a little greater than the focal length of a condensing lens, so that the intensity of light upon the object and objective is considerably greater than would be the case without the lens. Of course a different position of the lens and light would magnify the intensity of the light greatly, but that is undesirable beyond a certain limit, as the heat would be detrimental to the microscope objective.

With the proper arrangement of the light the essential feature in making instantaneous photographs is the combination shutter and

view tube, which is made to be clamped by means of three thumb-screws to the draw tube of the microscope. This apparatus is fastened on after the ocular has been inserted in the draw tube. The mechanism of the apparatus is as follows:—

Upon a movable brass plate inside a light-tight box (shown in fig. 1, just below the camera bellows) is a 90° prism, mounted in such a way that all of the light which passes through the microscope is projected upon a piece of ground glass at the end of a cone, which may be lengthened or shortened in order to give correct focus to the object here, when it is properly focussed upon the ground glass of the camera directly above the microscope. Next to the prism is a hole in the brass plate for allowing light to pass from the microscope directly to the photographic plate, when the prism is moved by means of a spring and pneumatic release, and finally a sufficient amount of the solid brass left to cover the opening when exposure has been made.

To take a photograph, the microscopic animal is placed in a drop of water upon a suitable glass plate, the light is turned on, and the shutter so set that the object may be focussed upon the ground glass of the cone. The plate-holder is inserted and the dark slide drawn, leaving the plate exposed inside the camera bellows. The movements of the animal are easily seen upon the ground glass, and, when the desired position is obtained, the shutter is released, the prism moves out of the way, and the light passes to the plate. Cramer's isochromatic plates have given the best satisfaction with this instantaneous work. Although the apparatus is not perfected to the writer's complete satisfaction, exposures as short as one-fortieth of a second have been very satisfactory. Neither of the negatives whose prints are shown with this article had more than one-thirty-fifth of a second exposure. It seems perfectly possible, with good microscope objectives and the best arrangement of illuminant, to obtain thoroughly satisfactory negatives in one-hundredth of a second.

The apparatus may be of some value other than photographic to biologists from the fact that it allows one to study the movements of a living microscopic organism with both eyes with perfect ease, instead of the common one-eye method, which is apt to be tiresome.

### THE JOLY, WOOD, AND LIPPMANN PROCESSES FOR PRODUCING PHOTOGRAPHS IN COLOUR.

[*Transactions of the Edinburgh Photographic Society.*]

It has long been the ambition of photographers to produce pictures that will bear towards their subjects the same relation as regards colour that ordinary photographs do in respect to form, and they have spent endless labour in their efforts. Whether the goal towards which their energies are directed is, from an artistic standpoint, likely or desirable to be attained is not a question to be discussed here; but that such a process, if perfected, would, at all events, be useful as a record of things as they were, is self-evident. The results hitherto, in spite of the ingenuity that has been exercised, are only partially successful, and are probably not final, though they may represent finality along the lines on which they have been produced. It is not, however, to the artistic or utilitarian aspect of the case, but to the physical theories on which the processes are based, and upon which only it is possible to work with success, that I wish to draw your attention to-night. As exemplifying the main lines of attack, I have selected three processes, viz., the Joly process, depending on the three-colour theory of vision, and requiring the selection of properly tinted filters and screens; the Wood process, also depending on the three-colour theory, but in which the final picture owes its colour to the diffraction of white light, and not to pigments or dyes; and, lastly, the Lippmann process, in which no act of selection or pigment is required, but where the colours are impressed by themselves according to a process of interference.

Light is believed to be a wavelike disturbance of the all-pervading ether, the waves spreading in all directions from luminous bodies being excessively small and of various lengths. When these waves fall on the retina of the eye, they cause a sensation which we call colour, the different lengths of waves producing different colours. The sensation of white light is, as shown by prismatic decomposition, ordinarily produced by the action of light waves of all the lengths, or, in other words, by a mixture of the different colours roughly called red, yellow, green, blue, and violet.

It has long been known that it is possible to produce to the eye the effect of all colours without having recourse to light of all the wave-lengths, but by using appropriate mixtures of light of three wave-lengths only—a red, a green, and a blue-violet. For example, an excellent yellow that contains no yellow rays results from mixing the red and green, whilst white light is produced by mixing all three. Further, if black is added to the three colours, i.e., if the light is more or less dulled, any shade or tint of colour can be produced, e.g., emerald green can be produced from sixty-three per cent. green, fourteen and a half per cent. blue-violet, and twenty-two and a half per cent. black, whilst peacock-blue is four and a half per cent. green, eight and a half per cent. blue-violet, and eighty-seven per cent. black, and so on.

Working on this theory, Clerk-Maxwell invented the three-colour pro-

cess of photography, which he described and exhibited in 1861. His method, which has been elaborated by Ives, is as follows: Three negatives are taken, each through one of the appropriately coloured screens, and give a record of the rays of those colours that can pass through the screens. Thus one screen allows those rays to pass that will afterwards be expressed as red; another, those that will be represented by blue-violet; and a third, those that will appear as green. Taking the plate exposed under the red screen, those rays that pass cause a blackening on development at the places where they fall on it, and similarly with the other two plates. When the positives are made from these negatives, more or less clear spaces are left wherever the original coloured rays struck, so that, if lights of the right colours are passed through each of the positives and then combined, they will produce the tints and shades of the original, if the screens are well chosen and the plates duly sensitive to the different colours.

It should be noticed, in passing, that the "taking screens" or colour filters through which the negatives are taken must be of somewhat different tint to the screens giving the colours to the positives which are combined to form the finished picture, on account of the fact that, whilst all the spectrum rays assist in producing the colours of the object, their effect is to be reproduced by the combination of three only. Thus, the red and green-tinting screens must each pass some spectrum yellow, or light of this wave-length will not be represented, as in the finished photograph it is formed by the combination of a pure red and green. Again, the red light has a slight effect in producing a sensation of green, and so must be represented in the "green negative" to some extent.

Unfortunately, Clerk-Maxwell had neither the photographic nor the colour facilities available now, or the production of photographs in colour would have been in almost as forward a state forty years ago as it is to-day, for, in spite of the ingenious apparatus of Ives for making the three negatives and combining their effects, the process is difficult to carry out and the apparatus cumbersome and expensive.

Joly, who works on identically the same theory, seeks to avoid these difficulties by taking only one negative, which is exposed in an ordinary camera, but behind a screen composed of the red, green, and blue-violet, in stripes about  $\frac{1}{30}$  of an inch wide, thus producing a record of the light passing through the different colours in similar stripes. The positive from this negative, when seen through a viewing screen similarly ruled in red, green, and blue-violet, gives the coloured picture. Thus, in the photograph of a red object, the negative is black at the red lines, and clear at the blue and green, whilst the reverse is the case in the positive, which, being clear opposite the red lines, and nowhere else, transmits red light from the viewing screen only.

Again, with a colour that is reproduced by combination, such as yellow, the lines in the positive that will be opposite green and red will both be clear, and so red and green stripes are transmitted, which, being so narrow and close together, blend and appear as yellow, and not as red and green. Dull colours are reproduced by the particular lines on the positive being only partially clear, whilst for white all the lines are unobstructed, and the result, which from the loss of light, though not pure white, is at all events a delicate grey.

An almost identical process has been brought forward by M'Donough in the United States, which presents some improvements. The ruling is finer (300 or 450 lines to the inch), and mechanically more perfect, whilst the light filter, which is necessary to aid the isochromatism of the plates in all these processes, is made so as to be variable with the quality of the light. The colours in the lines in M'Donough's screens are paler than in Joly's, which to a certain extent reduces the loss of light inherent in these processes, but probably at the expense of richness of colour. The loss of light, which can be obviated in transparencies by brilliancy of illumination, is very marked in the application of this process by M'Donough to printing coloured photographs, where a process block of the positive is superimposed on a screen printed on the paper; but, owing to the imperfect transparency and purity of the pigments, white and the high lights are represented by rather dull colours.

In order to get over the difficulties arising from using coloured viewing screens, i.e., their costliness, cumbrousness, and liability to fade, Professor R. W. Wood, of Wisconsin University, makes use of the phenomenon of diffraction to produce the colours in the positive, though his process still requires colour filters, as in the Ives process, to make the negatives.

It is necessary, in order to understand how colours are produced by diffraction, to refer to the theory that the difference between different coloured lights lies in the lengths of the waves of which they consist. Now, if a coloured light, say red, passes through a very narrow slit and falls on a screen, that which meets the spot directly opposite the slit will appear as a red band, as the waves from both sides of the slit arrive at the same time and in the same phase, but with light that falls obliquely on the screen it is different, as the light from one side of the slit has farther to travel. If the extra distance is half a wave-length farther on one side of the slit than on the other, the crests of one series of waves arrive at the same time as the troughs of the other set, when they neutralise each other, and darkness results. Still farther to one side, when the extra distance becomes a whole wave-length, the waves get into step again, another band of red light is formed, and so on. With blue and green rays the same thing happens, but nearer the central band, as

their waves are shorter, so that, if white light is used, the red will appear at one place, the green at another, the blue at a third, and so on, so that a spectrum is formed. If, therefore, you look at such a slit from one point, it will appear red; if from another, blue; and of other colours according to position.

Now, the narrower the slit, the farther to one side must the rays be diverted in order to get half a wave-length out; so, by having slits of appropriate width, it is possible to have red, blue, or green light directed to the same point. Instead of single slits it is better to use a grating of many slits side by side, when the same thing happens, but more light is transmitted and the colours are more brilliant.

Wood's process depends on this. He takes three gratings, one of which, with 2000 lines to the inch, when looked at from a certain point, appears red; whilst another, with 2400 lines, appears green; and a third, with 2750, appears blue. He exposes a plate coated with bichromated gelatine under the 2000 grating and a "red" positive obtained as in the Ives process, and then under the "green" positive and the 2400 grating, and finally under the "blue" positive and the 2750 grating. The gelatine is then washed in warm water, and appears as brilliant gratings of 2000 lines to the inch in the red parts of the picture, of 2400 in the green, and 2750 in the blue, whilst, in the colours that are produced by mixture such as yellow, two or more gratings are superimposed.

If this plate is looked at from the appropriate position, the picture appears in its natural colours, red where the grating is 2000 lines to the inch, and so on. At the places where the gratings are superimposed, the effects seem to vary; sometimes they act as required—*e.g.*, for a yellow part produce red and green, which blend and appear as yellow; but occasionally this is not the case, probably on account of a grating of 2000 + 2400 lines being formed which would not transmit yellow to the point of view.

The photographs can be reproduced by simple contact printing on bichromated gelatine plates, each of the copies being a positive, as also are their reproductions, and require no added "viewing screen" in order to see the colours. Though not strictly producing colour photographs, Wood's process is half way on the road to it, especially as it is theoretically possible to produce the positives directly in the camera by exposing a plate successively behind red, green, and blue colour filters, if these are ruled with the appropriate gratings.

Wood's process is thus an advance in some respects on the processes based on that of Clerk-Maxwell; yet it still requires the selection of appropriate colour filters and gratings.

Lippmann, however, avoids such trammelling complexities, and, though his process is extraordinarily difficult to carry out, yet the results are genuine colour photographs produced by the action of light alone without any mechanical assistance whatever. The method on which he works depends on the following considerations: If light waves are made to return exactly on the course by which they come by reflection from a plane surface, the advancing waves blend with the returning waves, and produce a disturbance which resembles an ordinary wave in rising and falling, but differs in that it does not advance. Now, if these "stationary" waves of a particular coloured light are formed in a photographic film which, as a rule, is thick enough to hold about one hundred of them, they affect the sensitive material mainly at their crests, and so, on development, a series of blackened layers are obtained in a sort of ladder-like formation. Finally, on supplying a film with this structure with white light, only those rays that fit in as regards wave-length with the distance between the deposits will continue to exist, all others sooner or later "getting out of step" and being extinguished, so the original colour is reproduced. The same sort of thing will result with rays of other colours, the only difference being the distance between the steps of the ladders, and, though it is rather difficult to form a mental picture of the complex state of affairs when a mixture of coloured rays falls on the plate, yet experiment shows that order, and not confusion, results. Thus, if a plate with a transparent film is exposed in a camera with its glass side towards the lens and with its film backed with a mirror of mercury, a photograph is produced that shows the object in its natural colours. Such a photograph cannot be reproduced by printing, as might be expected from a consideration of the theory, and can only be seen in colour by reflected light. However imperfect the result, however difficult the process, the fact remains that such a photograph reproduces the colours of nature without having recourse to pigment, and shares, with the other processes I have mentioned, the proud position of being elaborated by following the one sound line of research on which success can be expected or deserved—I mean, by working on and developing the consequences of theory.

J. TUDOR CUNDALL, B.Sc.

### ENLARGING CAMERAS.

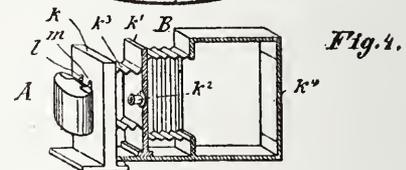

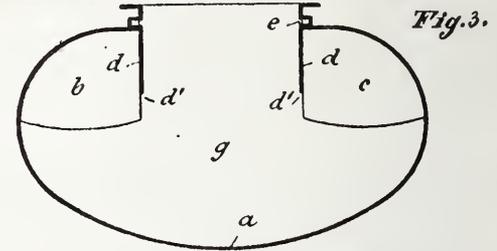

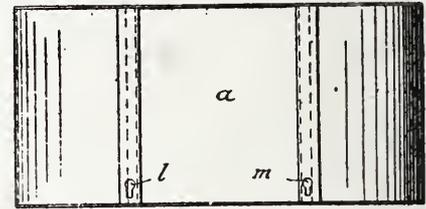

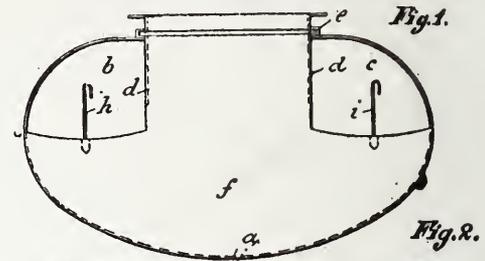

[Patent No. 6583 of 1899.]

THE invention of Herr Stalinski,, of Baden, who says:—

The illuminating apparatus, *A*, is made of a curved, or somewhat reniform, shape, the inside of the front, *a*, of which forms a reflector. At the back and laterally there are provided light chambers, *b*, *c*, whilst in the middle there is a flat neck, *d*, having an internal groove or fold, *e*, which serves for the insertion of a disc when the apparatus is to be em-

ployed for thin negatives, in order to properly subdue the reflected light. The cover, *f*, and the bottom, *g*, of the apparatus leave openings to the light chambers, *b* and *c*, free (see fig. 1), and the neck only extends partially into the apparatus, that is to say, as far as *d*<sup>1</sup>, *d*<sup>1</sup> (fig. 3), in order to allow as many light rays as possible to fall upon the mirror without passing directly into the said neck.

Any strong light can be employed in the light chambers, *b*<sup>1</sup> and *c*, as the sources of light. Where electric light is not available, I advantageously employ magnesium light. For suspending the bands I pro-

vide suitable hooks, or the like, in the chambers, such as *h*, *i*, shown in fig. 1.

To connect the illuminating apparatus to the negative carrier, *k* (fig. 4), of the camera, the former can be furnished with two eyes, or the like, *l* and *m*.

The apparatus is employed as follows: that is to say, assuming that the negative carrier, *k*, the lens-holder, *k*<sup>1</sup>, and the lens, *k*<sup>2</sup>, are fitted in position, and the bellows, *k*<sup>3</sup>, secured to the lens-carrier, *k*<sup>1</sup>, the negative (with the film side turned to the lens) which is to be enlarged is pushed under the springs of the negative-carrier, *k*; the illuminating apparatus, *A*, is suspended by means of the two eyes, *l*, *m*, to the hooks provided on the negative-carrier, *k*, and the apparatus is then ready for use. After the necessary magnesium bands or strips have been suspended in the hooks, *h* and *i*, in the illuminating chambers, *b* and *c*, and the silver bromide paper to be employed arranged in the back, *k*<sup>4</sup>, of the camera, the two magnesium bands are ignited from below, the rays of light proceeding from the light chambers, *b* and *c*, striking against the reflector, and being reflected evenly upon the negative, so that a regularly illuminated picture is obtained.

IN the Photographic Section of the Bath Century Exhibition, now open, the highest award, the gold medal and diploma, has been won by Mr. Graystone Bird, of 38 Milsom-street, Bath, who also received a symmetrica anastigmat lens given by Ross, Ltd., of London.

MESSRS. NEWTON & Co. ask us to note that they have some very fine Scripture slides for the Easter services. The newer series of slides are a set of fourteen "Stations of the Cross," from some finely executed examples of wood-carving. The figures are cut in very bold relief, and stand out almost stereoscopically on the screen. They have also a large number of Scripture slides for Lenten services, which at this time of year are used in many of the churches to illustrate services of sacred song. They have also eighty-eight slides from the well-known pictures of the Passion by J. J. Tissot, as well as 150 from pictures by other famous artists.

## LANTERN MEMS.

Photographic lantern slides have played an important part in national development during the last thirty years, and one of the authors deserving of the utmost credit for the thorough manner in which the subject has been tackled is Mr. F. York, who, with his in recent years, has produced hundreds of sets of slides on photography, history, physiology, microscopy, and the sciences of light, and heat, while history and entertaining subjects have been overlooked. The figures represented by the output are so remarkable that I think they will be of interest to lanternists.

\* \* \* \* \*

In the space of twenty-seven years the number of slides produced reached a total of 2,103,555, and the glass used for them, if each end on end, would reach 215 miles, or about the same distance as London to Plymouth. The weight of this glass would be 4 tons, and, if carried by rail, would require 13 trucks with a carrying capacity of 8 tons each. Placed one on top of each other, a column would be formed 4 miles high, or 21,120 feet. This height can be better understood when it is stated that Mont Blanc is 15,242 feet, or 3 miles high.

\* \* \* \* \*

The secret of this firm's success is due, after the comprehensive nature of the selection and arrangement of the photographic proposition, to the lectures or readings published to accompany the sets of slides, for not only do they save the time of those giving lectures and entertainments, but provide useful information in a readable, and, I speak, palatable, form that assists the amateur photographer who has gone over similar ground and taken snapshots or photographs of the places visited. They thus form the foundation for a lecture in which personal experiences are introduced.

\* \* \* \* \*

Another old and earnest worker in the lantern-slide world is Mr. I. N. King, who for as many years as I can remember has produced photographic prints and transparencies of the Royal palaces and old English homes, and was honoured a few years ago by being granted the royal warrant of appointment as photographer to Her Majesty the Queen, having worked for Her Majesty for over 20 years. Recently I have had the pleasure of inspecting some of his stereoscopic transparencies, and very beautiful they are. There are thousands of people at the present time who have never seen

through a stereoscope at all, and tens of thousands who have not had the advantage of viewing a glass stereograph through a stereoscope. There must be quite a fair percentage of the rising generation who would like to possess some of these beautiful and realistic records of historical buildings, cathedrals, and palaces and artistic works contained in the latter that can only be seen on rare occasions.

\* \* \* \* \*

Mr. HORATIO NELSON KING has had privileges that few others have ever had, and the consequence is that he has been able to photograph rooms in palaces and show places to which the public never have admission, so that those who purchase photographs from Mr. King's negatives get something unique as well as artistic. The stereoscope and stereoscopic slides if properly pushed should be popular again; any way, I know of nothing that gives so much enjoyment to a party of friends as a nice selection of stereoscopic slides, and at a *soirée* one of the most popular exhibits is a revolving stereoscope with 50 glass stereographs inside properly lighted by a good lamp placed behind the ground glass. The oh! of the firework night at the Crystal Palace is reproduced with the addition of "how beautiful!" "how real!" and "how splendidly everything stands out."

\* \* \* \* \*

Mr. KING and his son have taken up in recent years the ever-popular subject of the "Soldiers of the Queen," and have a number of very good examples of the cavalry and infantry of the Household Brigade, and many typical slides of military life, some showing "Tommy" at work, and others at play, while a good one represents a Lifeguardsmen, in full home service regimentals, shaking hands with a comrade in khaki "ordered south." The demand for generals and soldiers who have become famous or popular during the present war is still considerable, and will be until the much-desired ending comes by the occupation of Pretoria. Next season should also be a good one for lantern-slide dealers, as the officers and war correspondents and others that are at the front will want to give their friends illustrated lectures of their doings and experiences. Such, however, was the case after the Egyptian and Soudan wars, and no doubt it will be with the Boer War.

\* \* \* \* \*

THERE has been nothing very new in the lantern world this season, and all invention seems to be stopped, as far as ordinary apparatus is concerned, the optical lantern and dissolving-view apparatus being eclipsed by the cinematograph and apparatus for showing animated photography. It is not to be wondered at, when one sees representations of scenes from the war and popular events portrayed by the biograph and other good apparatus, and the reception given to them by the audience. At a recent visit to one of the halls of variety at the West-end, the only word that could express the applause that followed the exhibition of the pictures was "enthusiastic."

FOR educational work at colleges and schools the lantern is largely used, and now and then the projection microscope and polariscope, but I should like to see these two latter adjuncts of the lantern more popular among amateurs, for nothing could be more wonderful than the microscopic beauty of all nature, whether insect life, botany, or biology, and the best way for the audience to see this is with the projection microscope, or, failing that, by photographic transparencies taken from the actual object by means of the microscope.

G. R. BAKER.

## LIMELIGHT MATTERS.

### MODERN JETS.

DURING the last ten years many improvements have been effected in the construction of limelight jets, and, although it can scarcely be said that any change of principle governing the manner in which the gases are burned, or the heat from the blow-pipe generated, has been introduced in the modern forms of jets, still it may fairly be said that almost a revolution in their form and construction has been introduced. No doubt these changes are attributable, first, to the universal employment of high-pressure gas cylinders; and, secondly, to the adoption some years ago of "saturators" in lieu of hydrogen or coal gas; and, although the life of the saturator has been a short one (for but few even of our best limelight operators are now found using them), still there is no doubt their introduction, to a certain extent at least, had much to do with the radical changes introduced into some of the forms of our more modern jets.

When the convenience attending the use of the earlier form of saturators began to be appreciated, there soon followed numerous experiments in regard to the best form of jets to use in conjunction with them, and it was soon apparent that there was room for improvement by reason of the different densities of the two gases, a more complete system of mixing the two gases being necessary where a saturator was employed than would be the case where coal gas or hydrogen was being utilised. This soon led to the manufacture of jets having much larger chambers, and in one particular form of jet an entirely different form of chamber was introduced, a design—to a certain extent, no doubt—found necessary to enable these large mixing chambers being used in ordinary lantern shells.

It is well known that with all mixing jets it is essential to employ a larger mixing chamber if it is desired to employ a really large bore; for, if an increase of light is desired, it can only be obtained by increasing the heat from the blow-pipe upon the lime, and this increase in heat in turn can only be attained by burning more gas. In the earlier forms of mixing jets the size of the mixing chambers was seldom larger than a half-inch in diameter, and the bore of the nipples used in conjunction therewith somewhere about the one-twenty-fifth of an inch, and during the days of gas bags, where pressure may be said to have been limited as well as constantly varying during an exhibition, these old-fashioned jets were considered to be working very well when they were yielding a light of from 350 to 450 candle power. Experimenters soon grasped the fact that, if large bores in the nipples were to be employed, not only must the mixing chambers be increased in size, but their form required special consideration also, so that a fairly continuous and uninterrupted flow of gas was allowed to pass to the orifice of the jet; this led to the abandonment of the earlier form of box chamber with small circular cavity for the larger, round, and upright form of chambers in which all square corners were rounded off, and by means of which a more silent light was procured even when a considerable increase of gas was put through the jet. The outcome of these experiments was soon seen in the round upright chambers which have been employed up till the present time. In the passing of more gas through a jet, of course there must be a corresponding increase of pressure, and in many of these what may be termed improved forms of jets with an increase of pressure beyond, say, twelve inches, as was the case in the days of gas bags with such jets, they were very prone to become "roarers." This defect in even the best jets soon led up to what is termed the packing of a mixing chamber, whereby the two gases were mixed in the most perfect manner. Of the numerous devices employed for a thorough mixture of the gas before the same is emitted from the nipple of a jet, perhaps none have ever surpassed, if indeed equalled, that devised by Mr. Lancaster, and which is still largely employed, even in the best of our most modern jets.

Mr. Lancaster's method consists in employing a large number of alternate rings and perforated metal discs and circular pieces of gauze; these occupy the entire space of the mixing chamber, and, if ordinary care be

bestowed upon the form and finish of the nipple, a silent light is assured, and this packing enables, in fact requires, a considerable increase of gas pressure to employ such jets to their full advantage. In the days of gas bags it was sometimes difficult to obtain this pressure, but with the introduction of the compressed cylinder with its unlimited pressure there is no doubt that the form of packing employed in a jet is a matter of the first importance, provided those jets are to be made to yield their utmost power without becoming noisy. The difficulty of roaring or hissing in limelight jets may be said to have been entirely overcome in the form of our more modern jets, and, whenever this is found in a really high-class jet of quite recent construction, it can nearly always be traced to some defect in the nipple or its orifice. I can well remember having my attention drawn to a particular jet that was made by one of the very best makers of the day. This jet had worked well for a time, but, owing to some carelessness on the part of an inexperienced operator, the original nipple was ruined, and a new one, on being substituted, proved a roaring jet indeed. On close examination the new nipple showed no signs of being in any way deficient, yet it would not, under a good pressure, yield a silent light. A closer examination revealed the fact, however, that the friend had been tampering with the thread of the screw inside the nipple; this had been increased. The thread for the screw of the connecting pipe reached down the pipe only about three-eighths of an inch, the thread of the nipple inside extended to three quarters of an inch, so, when the nipple was screwed home on the connecting pipe, there was a distance of three-eighths of an inch of clean-cut corrugation, that in use was cepted and churned up what ought to have been a perfectly smooth surface of gas. Of course, the jet was blamed, and the maker also, while in fact the time the fault lay entirely with the user himself. On the nipple being adjusted so that there was no roughness inside to intercept the flow of gas from the mixing chamber, the light quieted down nicely under the full pressure. In mentioning this circumstance it will be seen that what a very little suffices to upset the even balance of a good jet; the nipple in question is one and a half inches in length, and, since the defect has been made good, I have obtained easily a light equal to fifty hundred candles with it. With a much shorter form of nipple the same defect is also liable to occur, and, in every case where a well-made jet is prone to be noisy, it should be examined at this point, and, if the connecting pipe does not deliver the gas up and beyond the screw thread inside the nipple, it should be made to do so.

It has been pointed out that, if increased light is desired, more gas must be burned.

This brings into consideration the most useful size of aperture to employ in a nipple. Speaking generally, all high-power modern jets have much wider apertures than is really required for ordinary lecture lantern projection. These jets are, no doubt, designed for cinematographic work, and hence are required to yield a very great amount of heat upon a small lime, so as to produce the utmost amount of incandescence where so what dense films are being projected on the screen; hence the bore of what may be termed a powerful jet will range from the fifteenth to the eighteenth part of an inch, and in some other forms even wider apertures are used. Competent operators, however, generally shirk a large bore, and rather coax a jet with a somewhat smaller aperture, by reason of the increased comfort a smaller aperture will yield in all-round work. The heat that is generated when even a fifteenth of an inch bore is employed is very great indeed, in fact, often uncomfortably so, and so large bores cannot be practically employed in the small shells so much in vogue in lanterns a few years ago; in fact, most of the modern form of jets cannot be used in these shells at all. The increase in size of the mixing chamber, and in some forms of the newer jets the length of the pipe from the chamber to the nipple, preclude those jets being used in any but specially suited lanterns. In the one case this may mean that the length of pipe does not permit the jet being placed in the conjugate of the short-focus condensers generally fitted to those lanterns; in the other, the height of the nipple will not permit of the light being centered through the condenser.

In ordinary lanterns it will be found the centre of the condenser is about four and a half inches from the floor of the shell, and nearly all the high-power jets (with perhaps one single exception) are so constructed that the nipple is much higher than that distance. This fact ought to be borne in mind by any one who contemplates using a new jet of this class in an old form of lantern. I have known a serious breakdown from this cause alone when a trial had not been made beforehand.

The heat generated by a high-power jet is very different from that given off by the older patterns, and larger shells in the lanterns, as well as longer-focus condensers, must be provided if they are to be used with any degree of satisfaction.

Of course, nipples of different sizes can at all times be kept at hand, only to a slight extent will these smaller-sized nipples alter the force of the jet inside the lantern. A very useful aperture to have is a bore of about the twentieth of an inch. This yields, with a packed chamber, a light of great intensity, and where a short supply happens to be, or where only a moderately small disc is required, a nipple with a bore of the one twenty-fifth of an inch, or even less, will prove a friend in need. All jets ought to be so finished as to permit of the nipples being easily screwed off and on without escape of gas at their junctions, even when red lead is not used.

Another noticeable factor in modern jets is the increase in their weight and size, and it seems as if there is really no need for the great weight of metal that is now employed in their construction. This increase in weight has brought about an increase in size of the pin as well as the methods of attachment, and in one form of jet the maker has hit upon a happy idea of making the upright attachments movable. By this the jet can be beautifully balanced on its upright pin at any angle, according to the length of the body of the lantern, or can be fixed altogether if it be desired. Another manufacturer makes a feature of having his jet supported in the centre only at a fixed point.

In all cases rigidity is well provided, either by the improved method of upright pin or by the entire absence of it in some of our

improvements. In providing for a silent light, manufacturers are now enabled to give a much greater resistance to the flow of gases than was formerly the case, and the packing of different chambers varies considerably. In some times, when a pressure of, say, nine to twelve inches was common, the chambers were either but slightly packed or contained no gauze at all. Now, with fine adjustment taps, which permit of the full pressure being applied to the cylinder, if desired, being utilised, or, as in the case of regulators, the common pressure of two and a half pounds, all kinds of material are employed to pack the chambers. These in some cases embrace mica, stone and asbestos; in others, small shot and such common materials, two and a half pounds pressure on the regulators being a working limit with most of the modern forms of jets. With a certain form of jet, however, if regulators are to be used, they must be carefully weighted to about fifteen pounds pressure, and, of course, a corresponding increase in the strength of the rubber tubing employed is necessary. Under proper conditions these new jets give a fine light, and a

Among the newer form of jets there falls to be noted those fitted with two nipples on one mixing chamber, and much ingenuity has been directed to bring this double jet to its present state of perfection. Somewhat other, it has never been largely employed, but, where the nipples are made in pitch and aperture, a very powerful light is obtained.

It seems strange that during recent years almost all the improvements that have been worked on the mixing form, for but little, if any, attention has been bestowed upon the blow-through jet, which stands practically as it did years ago, this being a strong proof of the superiority of the mixing type. Nowadays there is, happily, no talk of danger with these jets, it being impossible, with the back pressure of cylinders, for an explosion to take place of any moment, even when it is purposely regulated with rubber tubing between the cylinder and jet.

All forms of modern jets a reliable cut-off movement is provided, the older form of taps has given place to a fine adjustment movement. These alone form improvements of great value, and it is only those who have worked with both methods that are enabled to appreciate the advantages of the modern tap. True, these fine adjustments can be applied to any of the older patterns, and their old wing taps utilised as cut-off movements, in which case the improvement upon an old jet is great indeed; but a perfect cut-off attachment should work both ways at the same movement, which is not possible when old jets are provided with new taps.

Really good, high-class jet supplied with varying sizes of nipples is a boon to a lanternist, and, when care is taken that every joint and attachment is gas-tight, it confers a degree of pleasure to work with it that is not known years ago.

T. N. ARMSTRONG.

#### THE CINEORAMA AT THE PARIS EXHIBITION.

We are indebted to the Paris correspondent of the *Daily Telegraph* for a description of the Cineorama, which is intended, when finished, to be one of the great attractions of the Paris Exposition. It is to be a moving picture, but not one of the ordinary kind. The appearance of motion is given to the scenes environing the spectator, not by the primitive

method of a revolving series of ordinary panoramic pictures, but by an ingenious application of the biograph to panoramic views. The experimental operation, which half Paris seemed to have gathered together recently to watch at the Tuileries, consisted of the ascent of a balloon fitted with cinematograph cameras. The views obtained will constitute one of the shows at the cineorama. It must be explained that the object of the latter undertaking is to provide spectators installed in a car, but seated on *terra firma* in a building near the Eiffel Tower, with all the sensations of a balloon voyage in various parts of the world. Travellers, on getting into the car, and on the word "Go!" being given, will, to all intents and purposes, slowly rise from the earth, leaving the crowd standing round the balloon behind them. Hats will be waved, handkerchiefs fluttered, and the throng of onlookers will slowly disappear from view. The horizon will widen, and the earth be hollowed out into a gigantic basin, in which all the variety of scenes which the globe provides will be unfolded to the sight. There will appear the ocean crossed by unceasing lines of steamers, and the desert, traversed by winding caravans or furiously galloping hordes of Tatars; army manoeuvres in full action on the plains of Eastern France, the mad gaiety of carnival crowds in Italian cities, quieter scenes in the ancient towns of Flanders, more furious animation in the bull fights of Spain—such are a few of the bird's-eye views promised at the cineorama. All these views will be in motion; the ocean will be no painted sea, the crowds in the cities will be alive, and, of every scene which he visits, the traveller will feel that he is a part.

All these wonders will be worked by a combination of the panorama and biograph. The views used for the latter will be photographs taken in a real balloon ascent, by means, of course, of special cinematograph cameras. These views, which will thus give the succession of scenes visible to a spectator rising in the air, will be projected upon a circular, or, more accurately, a decagon-shaped sheet, surrounding the imitation car in the centre of the theatre. The novelty of the show might so far be considered to consist only in the idea of taking cinematograph views, not merely of scenes in motion, but also from a moving point—an ascending balloon. But the realisation of this idea also offered various interesting problems, which can only be solved by great perfection in the instruments employed. To obtain cinematograph pictures, not of a scene viewed from a single standpoint, and unfolding itself, so to speak, past one spectator's line of vision, but of the entire horizon at once, as viewed by a number of spectators standing in a circle in an ascending balloon, it is, of course, necessary to use several photographic apparatus simultaneously focussed, so that their combined lenses exactly take in the complete circle. As may be imagined, great nicety in the disposal of these cameras on the balloon car, and of the machinery by which the films are revolved, is required for the experiment to succeed. A similar and equally great difficulty, moreover, is encountered in the projection of these pictures, supposing them to have been successfully taken, on to the panorama sheet. The utmost exactness is necessary in the machinery revolving the slides simultaneously, it being quite understandable that the slightest relative inaccuracy in the revolutions of the various views would produce the direst results in the general picture. One spectator would find himself near to earth, while his next-door neighbour was soaring over mountain peaks; or, in the horizontal direction, two travellers side by side in the car might be journeying one over Madrid, with bull fights going on, and the other above peaceful Bruges, with the fish market in progress. The organizers of the cineorama, by expending the greatest care on the photographic and on the revolving machinery, hope to avoid anything which would probably produce among the visitors balloon giddiness in a peculiarly acute and abnormal form. They have arranged the cameras for taking the photographs in a circle of ten. The pictures will be afterwards shown by ten revolving machines on each side respectively of the Decagonal Hall, the revolutions being at the rate of thirty-five to forty thousand a minute. Thus each of the ten planes of the decagon severally will be a biograph show of the usual kind, the originality of the cineorama being the idea of combining these ten sets of views together to form the circular horizon, and the difficulty of the enterprise lying in the need for absolute synchronism of the ten revolving machines.

Balloon journeys in various parts of the globe are promised in the programme of the cineorama. Last week's experiment, however, was of course confined to the taking of photographs of Paris and the Exhibition, which will, it is stated, be the scene of one of the cineorama journeys. The balloon, a very large machine, was announced to rise from the Tuileries at two the following day, but by that hour the silk covering had only just been filled with gas, the latter being of the ordinary lighting kind. While operations were in progress, opportunity was afforded to

scrutinise the car. On the top of this were mounted the ten cameras, placed in a circle. The name on the apparatus, Raoul Grimoin Sanson, is that of the inventor of the cineorama, the balloon being managed in the ascent by the Count de la Vaulx and M. Mallet, two well-known aeronauts. After various incidents, rather of an alarming kind, as the machine showed a disposition to cast its moorings before its gear had been properly adjusted, the balloon, at a few minutes past five, amid the cheers of an enormous crowd, with which the Tuileries terraces were densely packed, was let off, and rose swiftly, bearing at once to the south-east. Immediately on the word "Go!" the machinery revolving the camera films was set moving with a wild whirring sound, so that the first scene which visitors to the cineorama show will view on their balloon journey over Paris will be in the foreground the friends of the aeronauts and many members of the Tero and Automobile Clubs waving their hats and handkerchiefs, and on rising a little higher the surging crowds round the terraces, with the Place de la Concorde equally thronged, and the Exhibition beyond. What the subsequent scenes will be cannot, of course, yet be ascertained. The balloonists intend, if possible, to cross over the entire Exhibition premises to the Champ de Mars and the Trocadero, so as to obtain views of the whole World's Fair, but, owing to the direction of the wind, it is rather doubtful whether they will be able to carry out this programme entirely. Another difficulty which must have stood in the way of the photographer was the waning light, owing to the late hour of departure. One of the organizers, impatient at the delay, jocosely suggested taking a magnesium light apparatus. Fortunately, however, the afternoon was cloudless and particularly bright, and this will probably have enabled the photographer to get in a good half-hour's work in sufficient daylight.

#### STEREOSCOPY AT THE SEAT OF WAR.

MR. H. F. MACKERN, stereoscopic photographer for Messrs. Underwood & Underwood, writing on the subject of binocular photography at the seat of war, says that, firstly, without the most exceptional credentials it is absolutely impossible to obtain the many permits necessary to get to the scenes of action, and, even with both of these, every step has to be taken with tact and diplomacy.

Secondly, the natural conditions are such as to almost discourage the greatest enthusiast. A sun that burns as though through a magnifying glass, dust that compels one to wear glasses most of the time, and a hot wind sweeping over the bleak kopjes and barren Karroo, blistering the face and cracking the lips, make life almost unbearable.

Lastly, but by no means least, the expense attached to an undertaking of this kind is enough to appal the most enterprising, but his firm have not allowed this to hinder them. Consequently, if the fates should favour his own personal efforts, Messrs. Underwood & Underwood will be able to place before the public a collection of views of the British-Boer War second to none of the best illustrated papers.

Some two hundred negatives of scenes about Capetown—disembarking, entraining of troops, &c., are already in the hands of Messrs. Underwood & Underwood, and some four hundred more are now on the way; these latter are all from the front so far as his field of operations has been conducted.

"I got as much as I desired at Modder River, and then came in for the best 'scoop' I have had yet. The prisoners, some 4700 taken by Lord Roberts, were to be marched into camp. I saw the General at Modder; he flatly refused to allow me or anybody to take photographs. This may have seemed very disappointing, especially as General Cronje, the Boer General, and party were coming in that day, and would depart from headquarters by train to Cape Town. I can't tell you all the details of how I got at it, but I made a negative of General Cronje and party leaving headquarters for the train, negatives of the 4700 marching in, on the road and in camp, and, lastly, a group of all the chief Boer commandants, and with the General's permission. I was glad to get the only stereographs made.

"Besides these most interesting subjects of General and Mrs. Cronje and their son, escorted by General Douglas to the train for Cape Town, the chief Boer commandants who acted under General Cronje, and Boer prisoners on the march from Paardeberg which will speak for themselves when you see them through the stereoscope, you will have in your set some of the most remarkable stereoscopic photographs ever made. These are the titles of only a few: The fearless Suffolks storming the kopje. Montmorency's scouts finding Boer position near Dordrecht. Worcesters skirmishing with Boers near Colesberg. The Gloucesters

charging a kopje and facing death. "The last drop"—a scene on battlefield at Dordrecht. A desperate stand at Modder River, w Methuen was defeated. British scouts firing on a Boer patrol. Zealand Hill defenders and distant hills held by the Worcester Slingersfontein."

#### THE JOLY PROCESS PRACTICALLY APPLIED.

BEFORE the Leeds Camera Club last week, Mr. C. B. Howdice, A.R.I.B., delivered an interesting lecture on "Some Experiments with the Joly Process of Colour Photography." After giving a short description of orthochromatic photography, and the necessity of employing color sensitive plates and yellow screens to secure correct luminosity values he exhibited a "colour chart," showing yellow, blue, green, and red regular gradation according to their luminosity values, and a negative upon an ordinary plate, without screen, of the same. From this it can easily be perceived how inaccurate was the monochromatic rendering of colour values thus made, but another negative, made upon an orthochromatic plate, through a suitable light filter, reproduced these colours in wonderfully correct gradation, according to their luminosity values.

He briefly described the principles of the Ives, Lippmann, Wood, and Sanger Shepherd processes of colour photography, and stated that he had selected that of Professor Joly on account of its comparative simplicity. One feature which strongly recommended itself to him being that special apparatus in the shape of cameras, slides, or lenses, are not necessary.

After explaining at some length the working details of the process, with which our readers are already acquainted, Mr. Howdice gave his own experience of the process, which contained many valuable hints, that should prove of considerable assistance to other workers in colour photography. Mr. Howdice's primary object in employing the Joly process was for the production of lantern slides in colours to illustrate his lecture on "Yorkshire Minsters" and other architectural subjects, but principally for the reproduction of stained-glass windows.

First, as regards plates. After trying almost every brand of color sensitive plate, he now uses only Cadett's special rapid spectrum registering about 120 on Hurter & Driffield's sensitometer. One important reason for keeping to one brand of plates is that the light filter or "interceptor," must be exactly suited to the particular plate used, correct colour-rendering cannot be secured. The makers recommend the ferrous-oxalate developer, but, personally, he prefers metol, which, in his hands, not only works quicker, but yields better results. On account must hydroquinone be used, as it produces density in the blue very early in development, and accentuates them to the detriment of other colours.

Tinkering with the developer is utterly useless in colour photography, for, unless absolutely correct exposure be given, no modification of the developer will produce a negative that will yield a transparent giving correct colours. If any mistake has been made in the exposure which, sometimes, is only revealed with certainty after a positive has been made from the developed negative, it is best to smash the latter once, that procedure being the quickest and cheapest in the end.

When developing "spectrum" plates, which are extremely sensitive to yellow and red, it is advisable to work at some distance from the run light and keep the dish covered, only exposing the plate for a moment to observe the course of development. With the plates named, Mr. Howdice considers sufficient density has been secured when the image is distinctly visible upon the glass side. The lecturer exhibited a number of failures, most of which were due to incorrect exposure, and explained that the method now was to expose for the yellows in the subject, these being a combination of the red and green; the latter, being the laggard, rendered the colour somewhat brown if a full exposure be not given.

Working through two colour screens the necessary exposure is comparatively long one, one minute and upwards being required for outdoor subjects, and up to several hours for interiors. A sunset effect which Mr. Howdice projected on the screen had received two minutes with lens working at  $f/8$ ; a view at Bishop Bickersteth's grave at Ripon had had five minutes at  $f/8$ ; another of the cathedral at Ripon, taken from the south-east, was given twenty-five minutes with  $f/16$  at 5.30 in the morning in July. A portion of the reredos at Beverley at  $f/16$  had ninety-three minutes' exposure, and a portion of the old glass in the east window of the same minster, taken with a tele-photo attachment (magnification six times) at  $f/16$ , received two and a half hours' exposure. Mr. Howdice also showed a large number of "easier" subjects, including flower and fruit studies, birds, botanical sections, shells, butterflies, portrait, china, coloured prints and drawings.

THE X RAYS IN PEACE AND WAR.

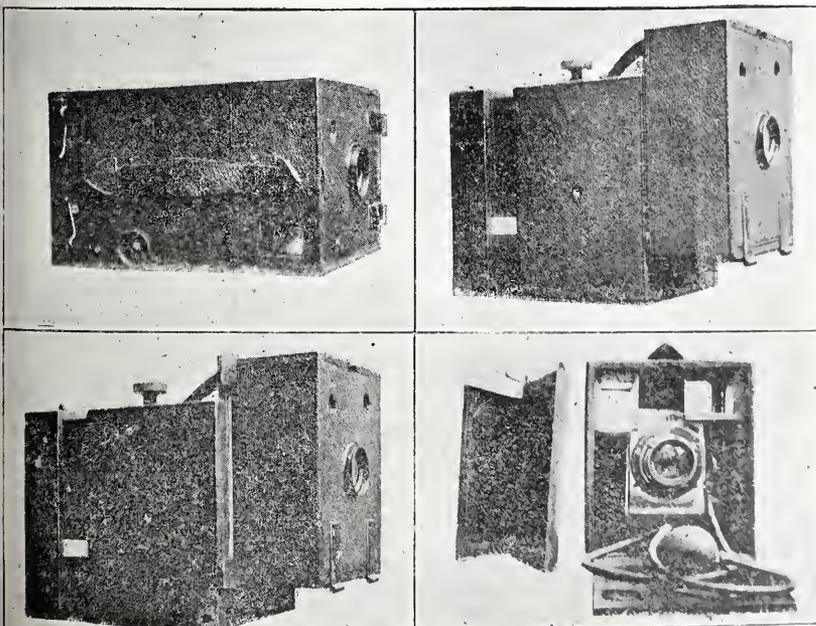

ON Tuesday evening, April 24, under the auspices of the Croydon Microscopical and Natural History Club, Dr. Chisholm Williams and Dr. F. S. Pepperdene delivered a lecture on the above-named subject. The remarkable developments which late years have seen in the adaptation of electricity to the requirements of practical surgery and the especial appropriateness of the subject to the present circumstances of the nation, with so many of its young men falling wounded on the battlefield, together made it a happy thought to promote such a lecture in Croydon, where interest in science and in the war is so keen. The proceeds of the lecture, moreover, were to be devoted to the X-ray department of the City Orthopædic Hospital, in Hatton Garden, and the benevolent purpose of the promoters constituted another strong appeal. The platform was furnished in the centre with a large screen for the display of lantern slides, and one end of the platform had been fitted up as an electrical laboratory for the purpose of practical demonstrations.

Mr. W. Whitaker having, as Chairman, introduced Dr. Williams and Dr. Pepperdene to the audience, Dr. Williams proceeded to read an interesting paper, in the course of which he rapidly sketched the advance of electrical research from the time of Otto von Guericke, the distinguished German natural philosopher who, in the middle of the seventeenth century, invented the air pump, onwards through the labours of the Abbé Nollet, Snow Harris, Faraday, Geissler, Sprengel, Crooke, and Röntgen. The effects of electrical discharges in air and *in vacuo* were explained, and were illustrated with a number of beautiful demonstrations by Dr. Pepperdene, who took charge of the electrical apparatus. The fluorescence of calcium, tungstate, dolomite, sea shells, coral, rubies, Iceland spar, and other minerals under the influence of the rays was similarly demonstrated, the extreme beauty of the demonstrations evoking cordial applause. The penetrability of the rays through various opaque substances—wood, cardboard, aluminium—was shown by photographs on the screen, many curious examples being exhibited. Interesting radiographs of human bones, healthy and diseased, were also displayed on the screen; and foreign bodies—usually needles or bullets—in the flesh of living persons, broken bones, and the effects of wounds received in battle were also shown in the same way, and formed a highly instructive series. The negatives from which the lantern slides were prepared were taken on the Sandell Cristoid films. Thanks were due to Mr. D. P. Roberts, of North End, for the loan of coil and accumulator. Mr. J. H. Baldock manipulated the lantern with gratifying efficiency.

At the close Mr. Whitaker expressed the thanks of the audience to Dr. Williams and Dr. Pepperdene, and this was cordially endorsed by the audience themselves.

THE WELFORD NO. 1 HAND CAMERA.

Manufactured and sold by W. D. Welford, Warwick Lodge, 166, Romford-road, E. THE principal characteristics claimed for this hand camera are that it

combines great efficiency with great simplicity. There are no hidden parts to get out of order, and, as dark slides are used, there is no plate-changing mechanism to go wrong.

The dimensions of the instrument when closed are  $7\frac{1}{2} \times 4\frac{1}{2} \times 5\frac{1}{2}$  inches, and the weight 2 pounds 6 ounces. The dark slides measure  $3\frac{1}{4} \times 4 \times 2$ , and weigh 4 ounces each. The camera has two finders, and a rapid rectilinear lens with iris diaphragm, Thornton-Pickard time and instantaneous shutter, dark slides which open inside the camera, ground-glass focussing screen, rackwork focussing, rising and falling front, cross movement front, is covered with black leather, and has two bushes for fixing to tripod. The lens, specially selected, works at *f*-8. The finders are readily cleaned, every part being accessible for dusting purposes. In focussing, the ground glass springs into position upon withdrawing the dark slide, the insertion of which again brings it to the back. The rising and cross fronts are clearly shown in the illustrations. The cross front serves as a rising front when the view is taken the other way of the plate. Double dark slides are of wood with metal shutters, and open inside the camera after the manner of a small door. Focussing by scale is also provided for, with a powerful rack-and-pinion movement. Considering the many good points of this hand camera, the price is very moderate indeed.

“LA PETITE” LIVING PICTURE CAMERA AND PROJECTOR.

Manufactured and sold by W. C. Hughes, 82, Mortimer-road, Kingsland, N.

THIS skilfully designed instrument is well named, for within the compass of an ordinary sized hand camera you have the entire apparatus for taking and projecting animated photographs. It is remarkably well made, and the mechanism for passing the film across the focal plane is ingenious and simple. A very good idea of the construction of “La

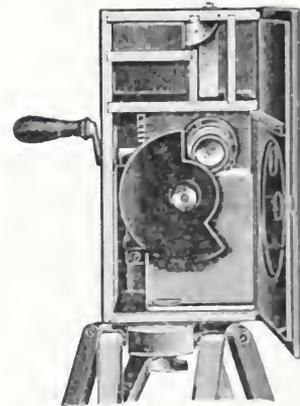

FIG. A.

Petite,” and the manner in which it is worked, will be obtained from the following condensed instructions for its manipulation:—

*Taking.*—Set the camera tripod on firm ground, so that it is perfectly rigid, and, by means of a piece of plain matt celluloid placed in the film race, focus the object to be cinematographed.

Now open the front, and place the cardboard film box into the recess (fig. A). Pass the end of the film over the brass stay, then shut the door

FIG. B.

in front; turn the camera round (fig. B), then pass the film through the race, and again over the brass projection at the bottom of pressure plate, so that the end is outside (fig. B).

Next pass the film into the receiving box (fig. C), and attach the end of the film to the hook on the brass revolving winder, then lock into position by the lever, care being taken not to buckle and catch the film in so doing.

When this is ready, stretch the rubber band on to the pulley, and the machine is ready.

The correct speed for all ordinary subjects is two turns per second.

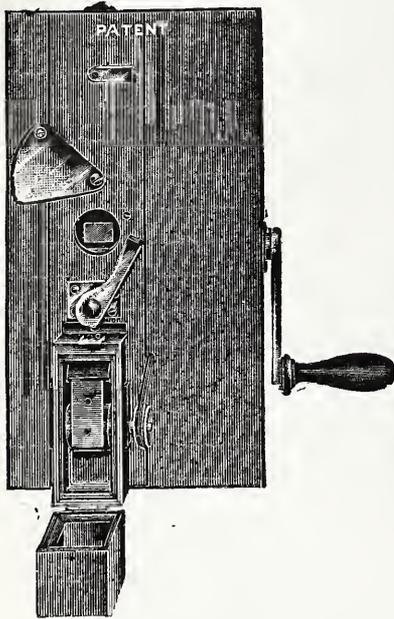

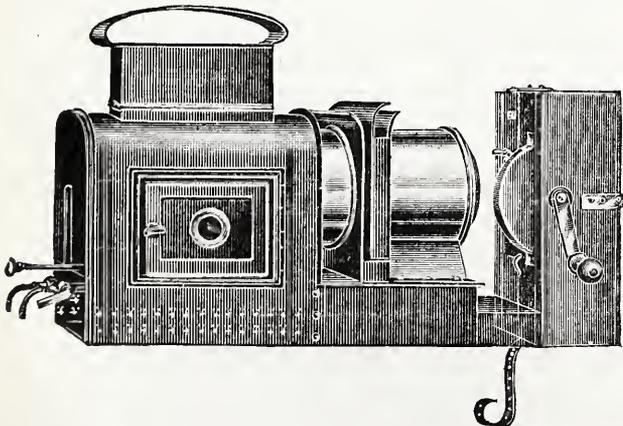

FIG. C.

**Developing.**—The film is wound on to a frame which is supplied with the outfit, the ends being attached by drawing pins in a 12 x 10 inch dish. The following developer is recommended :—

- |                        |            |
|------------------------|------------|
| A.—Pyro .....          | 1 ounce.   |
| Water .....            | 70 ounces. |
| Nitric acid .....      | 12 drops.  |
| B.—Soda sulphite ..... | 10 ounces. |
| Soda carbonate .....   | 8 "        |
| Water .....            | 70 "       |

For use take equal parts.

Take sufficient developer to cover the frame, which is placed into the dish. Before pouring on the developer, it is advisable to first soak the

film in plain water, thereby ensuring even development. When this is done, pour on the developer, care being taken to thoroughly immerse the film.

The image should appear in about five minutes, and full development be completed in ten to fifteen minutes.

After again washing in plain water place in the fixing bath, 1 part hypo, 5 parts water, and thoroughly fix for ten minutes, after which wash in running water for about one hour.

After the film is washed, to prevent it curling when dry, place it in the following bath for five minutes :—

- |                 |            |
|-----------------|------------|
| Glycerine ..... | ½ ounce.   |
| Water .....     | 20 ounces. |

Then place the frame in a warm room till dry.

**Printing.**—Place the "La Petite" on a firm support, and adjust the light from an oil lamp until central with lens.

Fill in the sensitive film in exactly the same way as for taking, and place the negative in the recess, direct in line and underneath the positive, as the film is printed through the lens, both surfaces towards the lens.

After a few experiments no difficulty will be experienced in hitting the correct exposure.

To develop, proceed in exactly the same way as for negatives, only use the following developer :—

- |               |            |
|---------------|------------|
| Rodinal ..... | 1 ounce.   |
| Water .....   | 20 ounces. |

**Projecting.**—Before starting see that the "La Petite" is quite central with the sheet, otherwise a distorted picture will appear.

The stand must be rigid, preferably screwed to the floor, so that there is absolutely no shake.

First adjust the light and throw a disc on to the sheet, then draw the light backwards or forwards until there is even illumination ; if the size of picture is too small, draw the machine farther back from screen until the size required is obtained.

If the oxyhydrogen light is being used, it is necessary to use an alum trough between the condenser and "La Petite" thus absorbing all the heat rays and preventing a possibility of firing.

Now place the film in position on the holder, and thread through the race, and through the bottom of machine, so that it can drop into a box or other receptacle, close the door and turn the handle.

Should the film show the perforation at top or bottom of picture, alter it by means of the lever on door.

"La Petite" gives a half-inch image and a roll of film 25 feet long costs 2s. 6d. The instrument itself is priced 5l. 10s. We have carefully examined the clever little machine and some photographs taken with it, and can strongly recommend it to those of our readers who require a cheap and practical camera for taking and projecting animated photographs on a small scale.

THE USE OF MIRRORS IN PHOTOGRAPHY.

THE article on page 179, under the above title, is one that should prove of great value to all workers in photography, for not only does it "give away" a few very good tricks of the trade, but it offers numerous suggestions to those who have the time for experimenting and proving to themselves—and to others if need be—the inestimable value of mirrors.

Personally speaking I have used mirrors in some form or other for nearly all kinds of photographic work, but it was not until I went to work in the Louvre picture galleries in Paris that I saw mirrors rendering what I believe to be their greatest services. Needless to say, they were used in the work of copying some of the many beautiful paintings in that building, and by an operator who had been practising that particular branch of work for twenty-nine years. It was my good fortune to be sent to the Louvre as his assistant, for we both at that time were working for the same Parisian firm. His easy manner of working and his

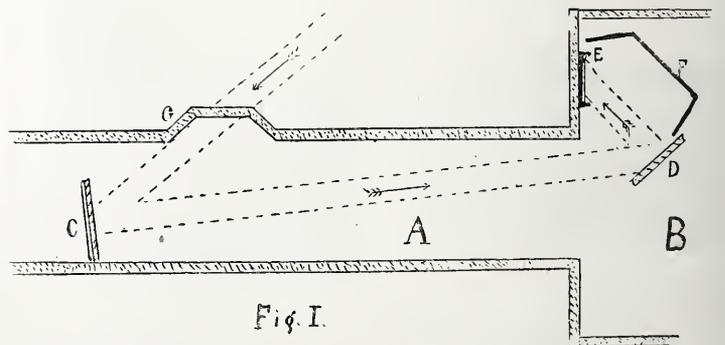

Fig. I.

accurate estimation of exposure brought forcibly to my mind the truth of the old adage, "Practice makes perfect." It was indeed a pleasure to develop his negatives (size about 15 x 12 inches), they were so perfect. Unfortunately, his methods look much more difficult on paper than they were in actual work, but by the aid of two diagrams I hope to be able to give an idea of how he managed to successfully light, and so secure two valuable negatives of two of the most difficult subjects in the Louvre. At the moment of writing I am some hundreds of miles from home and my note-books, or I would give the names of the pictures and the rooms in which they are hung.

Many of the galleries in the Louvre are—as many of my readers are perhaps, aware—lighted entirely from the roof, with the result that, when a camera is placed opposite pictures that are nailed in contact and level with the wall, some ugly reflections can be seen upon the ground glass, more especially if the painting be very much cracked or shiny, as were

the two about to be described. Under ordinary circumstances it was absolutely impossible to obtain even a passable negative of them.

Fig. 1 illustrates the position of one of these pictures, A is a long corridor quite 100 feet long; B is the room in which the picture, E, was hung about 6 feet from the floor. The operator first of all focussed the picture, and then placed round the camera and picture a large folding black screen, F, possibly 12 feet in height, this screen shut out nearly all the light from the picture; in fact, when I stood inside the screen beside the camera, it was almost impossible to see what the picture represented. The corridor, A, was lighted from the roof, but at the extreme end was a large window, G, reaching to the floor, and through this window the sun was shining very brilliant. A large mirror was placed at C, and the sun's rays thrown down the whole length of the corridor on to another mirror

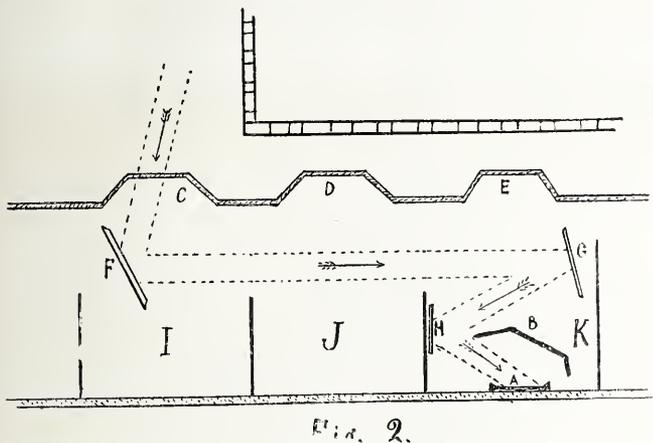

Fig. 2.

at D, which I held, and reflected the rays on to the picture at E. I kept the mirror, D, moving for about two hours, the length of time given for exposure, and a good negative on a Lumière's orthochromatic plate was the result.

We worked on the same principle in copying a picture as shown in fig. 2. In this particular case there was no light coming from the roof, but through very high windows, which was as bad, if not worse, for lighting the narrow corridor in which were three recesses, I J K. The picture we were to copy was at A, in recess, I. Fortunately, some adjoining buildings stopped the sun pouring in at windows, C and D, but at E the sun shone brilliantly. The picture was focussed, and the large black screen, B, placed before the picture. The sun's rays were caught on a mirror at F, reflected on to another mirror at G, then again on to a large screen made of silvered paper, H, and then on to the picture, A. The mirrors, F and G, were set up on chairs at the proper angle, whilst the screen of silver paper was held and kept on the move by myself. Time of exposure about three hours, and a good negative was the result.

We copied some hundreds of pictures and frequently used mirrors, large and small, little and much, but in the two cases cited they were of the greatest use.

RICHARD PENLAKE.

### AN ACCOMMODATION SLIDE FOR THE LECTURER.

It is one thing to acquire knowledge, and quite another to impart it, and the latter is the work of the lecturer.

To be successful, the means employed should be convincing rather than elaborate, and to convince an audience I suppose the first essential is clearness. Simplicity here applies alike to words and experiment with apparatus.

Lecturing recently on the subject of "Our Eyes and their Use," I found that apparatus previously constructed expressly for the purpose afforded me the means, not only of securing undivided attention, but also of illustrating in a most convincing manner the statements I found occasion to make.

This demonstrated usefulness induces me to give a brief description of one of the appliances I found especially handy, with the hope that it may prove of service to others.

The apparatus in question is shown in figs. 2 and 3; but, before fully describing this, let me direct the reader's attention to fig. 1. It is a well-known fact that, in order to see an object clearly, its image must be brought to a focus upon the retina of the eye, and this cannot be accomplished without that change termed accommodation.

If the object of attention be situated at B (fig. 1) with its image in focus upon the retina at B<sup>1</sup>, the image of an object situated closer to the eye, at C, will be brought to a focus behind the eye at C<sup>1</sup>, whilst the image of an object situated at A will be brought to a focus too soon for distinct vision, and will be within the eye at A<sup>1</sup>.

By accommodation the eye is capable of bringing each of these objects in focus upon the retina in succession. The objects out of focus, however, are not entirely lost to view, and their varying degree of clearness, according to their distance from the eye, contributes to that visual combination produced in the mind of the observer, so essential to a general knowledge of his situation in relation to his surroundings.

Although the object of this article is not to point the changes in the

optical combination of the eye when viewing objects at different distances, it may be interesting to note that, if the aperture of the iris and curvature of the lens be such as shown in the diagram, on turning the attention to the foreground object, C, the iris will contract, the pupil

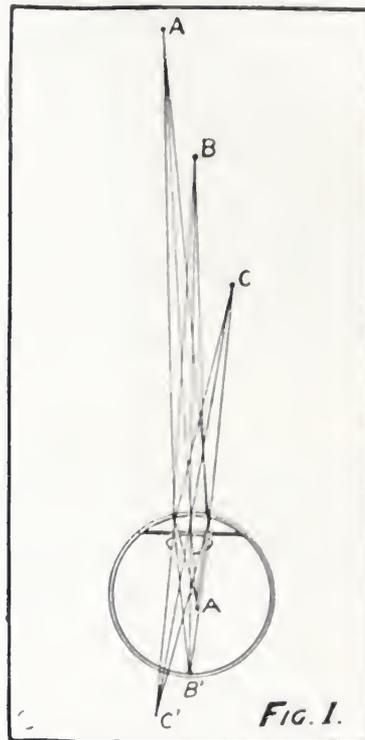

FIG. 1.

become smaller, whilst the lens will take a more convex form. The order of such changes will be reversed if the attention be turned from the nearest object, C, to the remote object, A.

Now, it is obvious from these facts that the picture projected upon the retina, must be an ever-changing one, with regard to the focus of objects

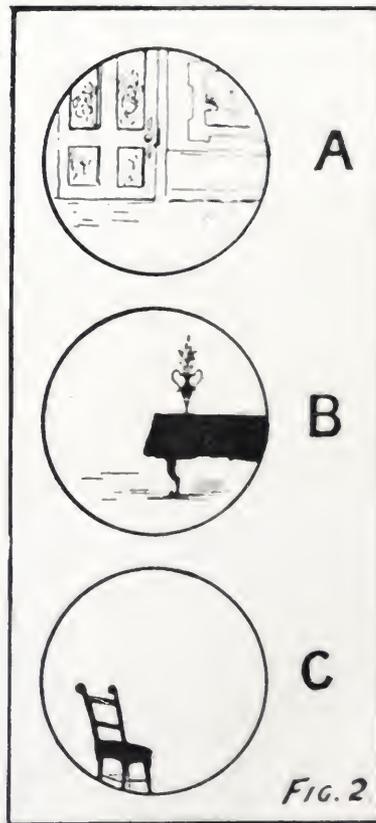

FIG. 2.

in the view, to say nothing of their varying position caused by divergence and convergence of the axes when both eyes are used.

Were it possible, then, to view the ever-changing picture on the retina of a person's eye under the changes of accommodation, what kind of a picture should he see? This question is fully answered, and the effect demonstrated by means of what I have called "an accommodation slide."

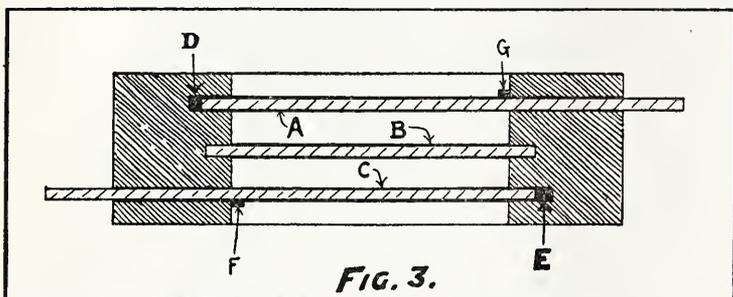

This slide is to be exhibited in an ordinary single optical lantern, and the projection upon the screen will be a representation of the retinal picture when the eye is brought under the influence already mentioned.

Objects situated at three different planes, A, B, C (fig. 1), are painted upon three separate pieces of glass. Reference being made to fig. 2, suppose the remote plane to be occupied by a door, wall, and picture frame, A. The nearest plane occupied by a chair, c, and half way between the chair and the opposite side of the room, a table stands, upon which is placed a vase of flowers, B.

These three glasses are now fitted into suitable framework, such as shown in fig. 3. The middle glass, B, is fixed, but the two outside ones, A and c, have space to move backward and forward along the groove, the object of which will be pointed out presently.

The objects are painted upon those surfaces of the glasses indicated by the arrows. The distance between A and B should be about a quarter of an inch, whilst the distance between B and c should be rather more. This slight difference in separation of the objects will, in use, correspond with the greater change in accommodating the eye from two distinct near planes, and that necessary for accommodation when directing the attention successively to and from two distinct remote planes.

If the slide is now placed in the lantern in the usual way, it is clear that only one of these objects will be in focus upon the screen at the

same moment, and that either chair, table, or wall, may be brought into focus at will.

The combined effect will thus be similar, if not identical, to that produced in the eye under natural circumstances, the attention of the observer always supposed to be directed, or adapted, to that object or plane which happens to be in focus upon the screen.

Needless to say, to ensure the best results there should be some intelligent communication between operator and lecturer.

If accommodation is all that the lecturer desires to illustrate, the three glasses may be fixed; but, should he wish also to show the dissimilar pictures of the retina of each eye under conditions of binocular vision, he may do so by leaving the spaces, E and D (fig. 3), so that the two outside glasses may be shifted. This movement will, of course, alter the relative position of the objects situated at different planes.

When demonstrating this difference in binocular pictures, the operator should first make B his focal plane, so that a fair amount of clearness may be distributed over the three dimensions of the view. Then, with the three glasses in the position shown in the diagram, the objects as situated from the left-eye standpoint will be shown, and, by pushing the two outside glasses to the end of the grooves, a representation of the right-eye view will be obtained, the movement of the shifting glasses being regulated in the first instance by the stop blocks, F and G, glued to the surface of the glasses; and, in the second instance, by the depth of the grooves, E and D.

THEODORE BROWN.

#### A BINOCULAR PROOF OF A BLIND SPOT.

By examining the black-and-white diagram in a stereoscope, the presence of a blind spot in both eyes may be very clearly demonstrated.

The action of the prismatic lenses of the instrument will, of course, present to the mind of the observer a single set of three white circles, and, if the attention be directed to the small centre ring, the observer will be conscious of the presence of two white spots, one on either side of the second ring.

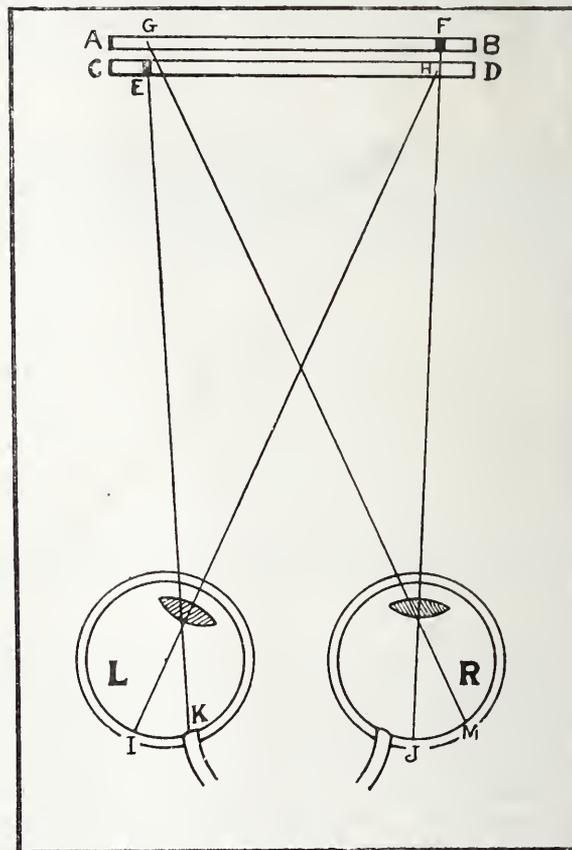

Now, if the axes of both eyes be turned towards the left-hand side spot, the other one will immediately vanish from view, and if, on the other hand, the eyes are directed towards the right-hand side spot, the left-hand spot will vanish.

The phenomenon, if such it may be called, may be explained by reference to a diagram having two sets of rings and viewing it in the stereoscope, they are, of course, seen at the same place, presenting for observation a combined image. Let us suppose the left-hand picture to be situated at c and D, and the right-hand picture A and B, the eyes of the observer at L and R. The diagram shows the axes of both eyes

turned to the same place, *i.e.*, H, in the left-hand picture, and F in the right-hand picture.

Under such circumstances the spot on the right-hand side only will be visible, and this only in the right eye, R, at J, the other spot, E, on the picture, c D, being invisible, because the rays which emanate therefrom fall upon the base of the optic nerve in the left eye, L, at K, the surface of which is insensible to light.

Now, suppose the attention be turned towards the opposite side of the combined image, rays emanating from F will at once fall upon the base of

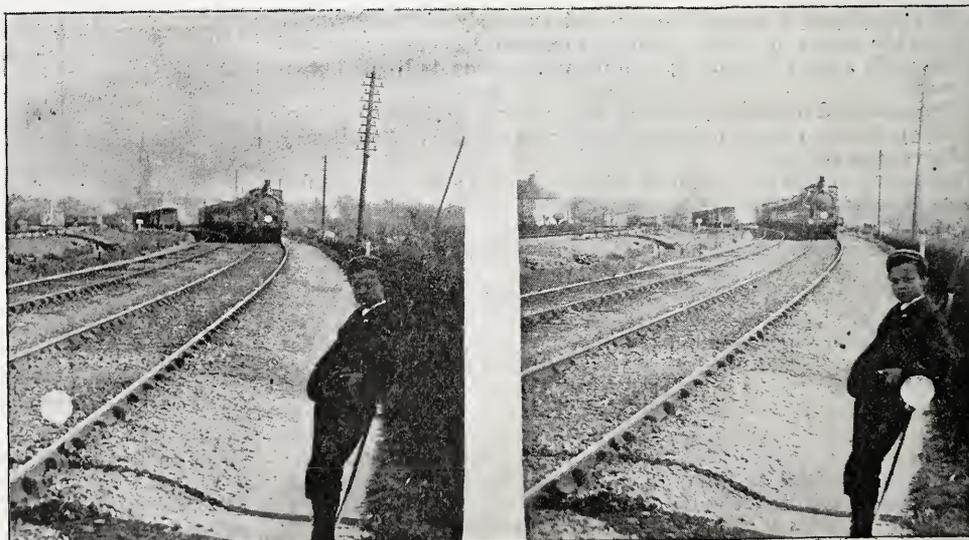

the optic nerve in the other eye, R, with the result that the spot, F, will vanish, and the other spot, E, come into view.

If a white spot be painted on the dissimilar pictures of a stereoscopic pair in the positions shown, the phenomenon will be still more clearly demonstrated. By examining the combined image in the stereoscope, and directing the attention to either spot, the one on the opposite side will vanish, whilst, by turning the attention to the train, both spots will be seen obliquely, and appear one on each side.

According to the separation of different persons' eyes and their focus, I have found it necessary to vary the separation of the two white spots, but a separation of  $4\frac{1}{2}$  inches is found correct for most persons.

## THE SOLAR ECLIPSE.

TUESDAY'S newspapers contained many accounts stating that the solar eclipse of Monday, May 28, had been observed under favourable conditions. A telegram from Ovar reported that the expedition from Greenwich met with perfect success, so far as was then known. A fine day gave promise of a successful eclipse, and, except for some haziness in the atmosphere, the sky at the time of totality was all that could be desired. The scene was, apparently, not so much darkened during the total phase as is sometimes the case. Venus and Mercury, which were quite near the sun, were seen by the naked eye, but no stars were visible, although there were some bright ones in the neighbourhood. The corona, as was expected, proved to be of the type represented by streamers from the sun's equator, which to the naked eye looked short, and with the short plumes at the poles, but it is necessary to wait until the plates are developed before this point can be definitely stated. This fact is very interesting, as it very much strengthens the evidence for the theory that the form of the corona is associated with the sun-spot cycle. At the eclipses of 1867, 1878, and 1889, which were all within a year of a minimum of sun-spots, the corona was seen of this form. On four other occasions—namely, in 1860, 1870, 1883, and 1893, which were near epochs when the spots were many—the corona was of quite a different type, the streamers in these cases being much shortened.

From New York it was announced that the eclipse of the sun was observed with great success at several places in the path of totality. Satisfactory observations are reported from Siloam in Georgia, and Wadesborough in North Carolina. At Wadesborough there were more astronomers and scientists staying than at any other point of observation, the visitors including, among others, observers from the Smithsonian Institute, Princetown College, and the Yerkes Observatory. Amongst the English visitors were Miss Bacon, Miss Woolston, Mrs. Dixon, and Mr. Maskelyne. The equipment of the British Astronomical Association was perfect in every detail. At Thomaston, Georgia, the conditions were ideal, and the results of the observations exceeded what was hoped by the most sanguine watchers. Data of immense importance were secured. The eclipse began at 6 hrs. 31 mins. 24 secs. a.m., and ended at 8 hrs. 55 mins. 46 secs. The Lick Observatory party of observers was most extensively equipped with apparatus for covering the whole range of phenomena, including spectroscopic, telescopic, and photographic work. The spectroscopic observations included analyses of the phenomena of light preceding, attending, and following totality. A thin black wedge first became visible on the outer edge of the sun, and gradually overspread the whole disc. The resulting spectacular effects were almost startling to those who had not previously seen a total eclipse. Before totality the usual curious twilight began to prevail, and became intensified as the dark moon spread over the entire surface of the sun. The darkness was then relieved by the radiance from the corona,

which extended in two beautiful streams of light from each side of the sun's equator. Innumerable photographs were obtained by the observers, among whom were Messrs. Wilterdink and Nyland, from Holland, and Mr. Lumsden, of Toronto. The darkness which accompanied totality threw the negro population into a state of frenzied fear. Many prostrated themselves on the ground and prayed in loud voices, while others shrieked hysterically. Animals, too, were frightened, and the alarmed barking of dogs and lowing of cattle contributed an indescribable weirdness to the gloom. At many other places the eclipse caused similar alarm among negroes, who, in some instances, were convinced that the end of the world was at hand.

The eclipse was observed at Plasencia under most favourable circumstances by a large party of British and Spanish astronomers.

Both visual and photographic observations were successfully made. The shadow band was seen both before and after totality, lying in a north-easterly direction, and travelling south-east, for the moon's shadow was not seen either on the ground or on the sky. The corona was of the typical sun-spot minimum appearance, with large extensions in the direction of the sun's equator, which were traced to about two diameters' distance from the sun. Two large prominences were seen on the sun's western circle.

Neither cloud nor mist was in the Algerian sky during the eclipse, though, perhaps, the atmosphere was not entirely free from dust. The corona was of the minimum type, and the western wing of the well-known fish-tail form were distinctly visible to the naked eye, while the eastern wing seemed a single streamer.

The largest party of Algerian observers were encamped on the roof of the Hôtel de la Régence, where they were happily inaccessible to the mixed native population, who greeted the total phase in the most approved Eastern manner. Here Mr. and Mrs. Maunder again attempted to get focussed on the coronal streamers, and with Mr. Davies took a photograph of the partial phase. Probably the success of both of these depends on the clearness of the atmosphere. Messrs. Cromlin and Davies also took a photograph of the inner corona. Meteorological observations were made by Mr. Brook, and a most important shadow-band observation by Mrs. Brook. These bands travelled in the same direction before and after totality, and were not unbroken lines, but a series of suns and of shadow patches, the patches moving faster along the suns than the suns themselves moved forward.

From Algiers we also learn that the effect as the eclipse approached totality was inexpressibly weird. As darkness crept over the earth, the sea lost its deep blue and became of a spectral grey, while the vivid green of the sub-tropical foliage turned to a funeral purple hue. Just as the last sun-ray faded, the corona instantly shone forth unusually large and brilliant, extending as far as the planet Mercury, which was shining with an intense white lustre about two degrees away from the sun's disc. The shape of the corona was almost exactly that of the eclipse of 1878, as seen in the United States, with two great wings, one shooting almost vertically upwards, the other downwards, both almost exactly on the solar equator. It was a corona typical of the time of sun-spot minimum.

The weather at Tripoli was splendid, and the Lowell University Eclipse Expedition, under Professor Todd, of Amherst College, United States, America, made complete and successful operations with twenty telescopes and photographic apparatus. One of the telescopes used had an object-glass of twenty-four inches. The corona was seen for fifty-two

seconds. It was an exact duplicate of the corona observed in January 1889, thus completely confirming the theory of the eleven-years' period of the corona and its variation with the sun-spots.

At Wadesboro, Georgia, observations were taken by experts from the Smithsonian Institution and the British Astronomical Society of London, and by other scientists, who all unite in describing the conditions as being perfect for observing the eclipse. Professor Barnard, of the Yerkes Observatory, stated that the period of totality was slightly shorter than had been calculated, which proved the tables to be slightly incorrect.

The results obtained in the observation of the eclipse at Barnesville exceeded the most sanguine expectation. The corona flashed out in a double fanlike form of great beauty. Several solar prominences were distinctly observed on both the following and advancing limb. Those on the approaching limb, however, were more distinct and continuous.

#### LIMELIGHT LECTURING TO THE DEAF AND DUMB.

To many there may appear insuperable difficulties in the way of any lecturer, unacquainted with the manipulation of the deaf and dumb alphabet, in being able to convey to an audience composed of mutes anything like a satisfactory description of his set of transparencies, or make his lecture in any way interesting. The fact is, however, that any lecturer can, with the greatest of ease, give lectures or limelight entertainments to audiences composed of mutes without his having the slightest knowledge of the deaf and dumb alphabet, or the numerous signs connected therewith, and this form of entertainment is fast becoming highly popular with many of our deaf and dumb institutions, for but few weeks are seen during the winter months in which a limelight lecture is not found forming a part of the instruction provided for their special benefit. It has been remarked that mutes, somehow or other, pay more attention to the instruction they receive from those teachers who have all their faculties than they do to such of their brethren as are afflicted like themselves, and it is a noticeable fact that those classes presided over by mute teachers are never so well attended as are those otherwise provided. This, doubtless, accounts for the large attendance which always welcomes a popular lecturer when he is announced to give a limelight entertainment, for there are few, if, indeed, any, absentees from among the mutes at such functions. The enjoyment they derive must be seen to be realised, and any one who has never lectured to such an audience can form no idea of the zest and rapt attention which pervade these poor people, and the manner in which they pick up some desired information is truly marvellous.

Although the arrangements for functions of this description differ but slightly from lecturing under ordinary circumstances, there are one or two points which any one having no experience of this kind of entertainment would do well to observe.

The first is, that such audiences are extremely critical, and they can discern the good from the bad in the matter of the quality of lantern slides shown more keenly than another ordinary audience would do.

Secondly, there must be plenty of views provided. An ordinary set of about sixty to seventy slides would go no length with an audience composed of mutes, for lengthy descriptions of the different views are quite out of the question, so that a quantity more nearly approaching two hundred will be found none too many to fill in a good night's entertainment. Any ordinary lecture set can be used, provided there be added thereto a number of slides containing printed or written matter. These will be found exceedingly useful when the lecturer desires to convey some special point or information regarding his subject, such, for instance, as would be the case in describing an old advertisement, or showing a facsimile of an important letter or document to which it is desired to refer minutely. The providing of numerous slides of readable matter is a very important feature in lectures of this description, and go a long way to make much understood which would otherwise fail to be comprehended. An example of slides of this description may be briefly described as follows: "The next six slides will convey to you such-and-such information." In providing slides of this description, it does not necessarily follow that they should be produced by means of photography; they can be prepared in a very few minutes' time by writing on clean cover glasses with the aid of a clean pen and a modicum of Indian ink, and by their means it will be found that quite a lot of interesting information can be conveyed, and it will be soon apparent that such slides are much appreciated by the audience, simply by reason of the

fact that the deaf and dumb are not slow to observe that they have been expressly prepared for their benefit.

The lantern arrangements should be such as will provide a sufficient large disc, and will permit of slides of readable matter being easily read at the back of the hall. In general practice it will be found that a disc that is in size one-fourth the greatest length of the hall will suit nicely in this respect.

With nearly all well-appointed deaf and dumb institutions there are always associated some one possessed of all his faculties who at all times is only too willing to act as interpreter, for it is really only by the aid of such that lectures of this description can be given.

During the past season the writer delivered a lecture before an audience of mutes in the Royal Institute for the Deaf and Dumb, at Glasgow; and a brief description of the manner in which it was carried through may be read with interest. In this institution, it may be stated, the optical lantern is taken advantage of to its fullest extent, and every season see quite a long list of lectures by gentlemen who know absolutely nothing about "finger language," but who are enabled, nevertheless, to afford much instruction and pleasure through the medium of the chaplain, the Rev. Mr. Henderson, who invariably acts as interpreter. The method adopted on that occasion was as follows: The lantern was manipulated from the back of the hall, at a distance of about fifty feet from the stage. A twelve-inch objective was employed, and it was found that slides of printed matter were easily readable at this distance when the lettering was not too small, and all the written slides appeared quite large upon the screen. The writer took his position on the platform to the right of the screen, armed with a long pointer. On the other side of the screen the Rev. Mr. Henderson took up his position, being furnished with an electric lamp enclosed in a cone-shaped reflector, so placed as to concentrate the entire light from the lamp on his hands and chest only. This prevented any light striking back upon the screen and interfering with the brilliancy of the picture.

In lectures of this description reading from a text-book or other written matter is quite out of the question. The lecturer must have his subject off by heart, and speak entirely from experience. This naturally leads into a pleasant conversational turn between him and his interpreter, the lecturer speaking somewhat slowly. His remarks are conveyed by signs and grimaces in a marvellously rapid manner to the audience, who seem to know by instinct what descriptions are to follow; and the signs of the faces of the mutes during such a lecture is one never to be forgotten. To say that they are "quick in the up-tak" is putting it mildly, and, should it so happen by chance that any one in the audience has failed to grasp some point or portion of desired information, he immediately appeals to one of his brethren near to him by means of signs or mysterious grimaces until the desired information is obtained, and this passing of information from one to another is perhaps the most striking of the many interesting features connected with entertainments of this description. A few seconds will suffice for any information being passed through the audience from one end of the hall to the other. Nor are the mutes slow to show their appreciation of what is being submitted to them; this they do with their feet, and but seldom use their hands otherwise than for speaking purposes; in fact, during the entire course of the lecture, it may be said, they kept up amongst themselves a dropping silent conversation by means of their hands and lips. Nor on the other hand, are they slow to express their approval by "thumbs up" or "thumbs down" when anything strikingly good or bad happens to be brought before them. Somehow or other it would appear that beforehand they always look out for a brother mute who is known to possess some special knowledge of the subject that is going to be dealt with, and to him they appeal during the lecture by signs if they are at any loss to understand what the interpreter is communicating, or desire more information regarding the matter being described.

Some may imagine that this continuous passing of signs among the audience would prove somewhat disconcerting; but, in reality, it has no such effect upon a lecturer, a few minutes will suffice to set him quite at his ease. Now and again it is quite possible he may somewhat forget the circumstance he is placed in, and, from force of habit, find himself speaking to some one at the back of the hall instead of only addressing his interpreter; but he soon picks himself up, and gets into a more reasonable strain of voice. From this it will be seen that flowery declamation of any particular part of a subject is quite thrown away upon such an audience. On the other hand, a few jokes and conundrums, conveyed by means of specially prepared slides and thrown upon the screen, always tell well.

At the close of entertainments of this class the mutes are never slow to show their appreciation of what has been done for them, and, were

more of such lectures provided for these afflicted members of the community by the numerous limelight lecturers, who can well afford to give their services for nothing, much pleasure and comfort would be bestowed upon a deserving class who are too seldom thought about.

T. N. ARMSTRONG.

### BINOCULAR VISION AND ITS RELATION TO STEREOSCOPIC PHOTOGRAPHY.

There is a close relationship between the laws which govern binocular vision and those controlling the perception of relief in the stereoscope. There are, however, certain modifications in the latter which must be recognised if success is to be ensured in stereoscopic photography.

It is a well-known fact that in nature we correctly appreciate all objects in the view before us by a continual change, not merely of the axial direction of our two eyes, but also by a change in each eye separately, known as accommodation.

As already mentioned in a previous article on the subject, this adaptation of the optical combination in the eye produces upon the retina a picture which is ever changing as regards the focus of images of objects situated at various distances from the observer.

As these facts have an important bearing upon the subject of picture-making in general, it will be of some value to us if we first consider the nature of the picture upon the retina of a single eye, and then observe

the most desirable arrangement, as the attention is, of course, intended to be directed to the sitter, and not the surrounding objects.

When I look at some of the pictures which have hung upon the walls of the Royal Academy I am inclined to believe that the physiological education of some of our most eminent artists has been sadly neglected, at any rate with regard to those branches of the science pertaining to the optical structure of the human eye. One picture especially comes to my mind at this moment. Naturally the attention is turned towards a group of females lounging in the foreground. They are sharply outlined (and this is well), but when one finds, on looking over a low fence behind them, that the mountains, supposed to be miles away, are also clearly defined, we are strengthened in our belief of this lack of optical knowledge on the part of some men of the brush.

But it must not be supposed that a thorough knowledge of natural optics would enable the artist to paint his picture so that accommodation would be called for. It is obvious that such a change is only demanded when objects are *actually* situated at different distances from the observer, and not merely represented to be by the agencies of proportion, perspective, and shading. It is herein we find that paintings and photographs lack *that something* which, did they possess, would impart to the mind of the observer a sensation yet to be realised.

The foregoing remarks apply to single pictures, photographic or otherwise.

Now let us proceed a little further, and consider how much we have

FIG. 1.

wherein it differs from that image projected upon the retina when examining a single photograph.

In the first instance, as already stated, in nature we are continually altering the focus of the eye to suit objects situated at different distances, with the result of an ever-changing retinal picture. The reason of this necessary change will be clearly understood by any reader possessing but little knowledge of light, sight, and optics.

Contrary to this natural demand, in looking at an ordinary photograph there is no change in accommodation called for. Once having placed the photograph at a suitable distance from the eye, with all objects, whatever their supposed distance in the view may be, and however true the proportion, perspective, and the shading of the whole composition may be, there is still no demand made upon the senses of the observer to focus his eye for distinct vision of various parts. In other words, those parts which happen to be in sharp focus in the photograph will likewise be sharply focussed upon the retina of the eye, whilst other portions of the view more or less out of focus will likewise be seen to that particular degree indistinct.

Hence we see that natural accommodation of the eye will never be called for from the face of a single picture, whether it be a painting or a photograph, and this raises the question, What plane ought to be sharply focussed in a view, or what object in a picture should be most clearly defined? This is a very wide question, the answer of which would vary according to the subject. In portraiture I observe the general rule to be, background out of focus, subject in focus, and, to my mind, this seems

gained by the introduction of a pair of dissimilar pictures such as we prepare for the stereoscope.

We have seen that natural accommodation will never be called for from the face of a single picture, inasmuch as only one plane is presented for observation. We are next led to inquire, Does this double presentation to the mind in the stereoscope create this demand and produce the desired effect? The answer is still in the negative. Though we have gained much, our double pictures requiring convergence and divergence of the eyes' axes before they may be properly blended in all respects, our combined image still lacks that essential to a natural demand for accommodation.

Again, our double proportion, perspective, and shading may be correct, yet we are bound to admit we are far from that ideal sensation nature seems alone able to impart.

Though we have gained relief and created an artificial demand for axial change of the eyes, though the two pictures projected upon the two retinæ of the eyes are dissimilar combinations, each possessing a perspective peculiar to itself, though we use our best means, presenting these two dissimilar pictures in natural colours, we have at last to confess our combined coloured image is not a binocular presentation to the mind such as seen with a pair of good eyes.

By a thoughtful reflection on what has already been said, we note one point in particular where the perception of relief in the stereoscope differs from the perception of relief under conditions of binocular vision, namely, that, in the former case, all objects are *actually* situated at one

distance from the eyes (the surface of the photograph), whereas, in the latter instance, an indefinite number of different planes are presented for observation.

This difference is of greater importance than it at first appears, and indeed, by a careful examination of some of the distracting effects which occur in some stereoscopic slides taken under certain circumstances, we are led to value the knowledge of these facts, and by their recognition avoid in practical work much which to the stereoscopic expert must ever be a source of annoyance.

One of the undesirable effects I have in my mind is that of floating images, or perhaps it would be more correct to call them portions of images, which, in the stereoscope, the observer finds difficult to locate, the cause of which I have anticipated in the foregoing observations.

Although fig. 1 is not a very glaring example possessing the peculiarity referred to, it will serve to illustrate the truth of my remarks.

From a technical standpoint, this stereoscopic picture is a beautiful piece of work, the credit of which is due to Messrs. Seaman & Son.

But there is just one thing which unfortunately mars the whole composition, and which might have been avoided by photographing the subject from a slightly different standpoint.

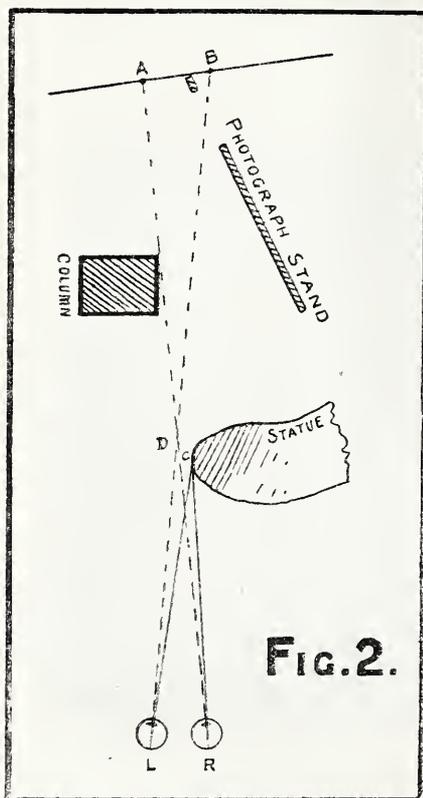

FIG. 2.

On examining this slide in the stereoscope, the attention is, of course, directed especially to the mother and child, the chief figures in the view. Whilst the axes of the eyes are crossed at this plane, and the attention fixed here, oblique rays emanate from the surrounding objects quite in an agreeable way to the eyes, except at one point, namely, just off the end of the mother's body. Here we find a little white patch, apparently at the same plane as the mother and child, but floating in mid air. It is most noticeable if, after looking for a few moments at any portion of the statue, the attention is turned to this point. Now, this effect spoils rather than adds to the beauty of the composition, and it is an effect which occurs in a far more conspicuous manner under similar circumstances in other views.

I have a stereoscopic view in my collection of a rabbit in a box with wire netting in front. By a slight movement or change in the focus of the lenses of the stereoscope, I am able to make the animal spring out of his box, so that he appears outside with the wire netting behind it.

I have another view in which, unavoidably, the sleepers under the rails over which a train is passing appear, not as they should be, below the metals, but on a level with the foot plate, giving a most peculiar and distracting effect in the stereoscope.

These and many other examples which I could give, did space permit, present such odd appearances in the combined image in the stereoscope, from the fact that, when photographs are viewed, no accommodation is

called for, and therefore it becomes an easy matter for the eyes to be deceived, and appreciate objects which in nature would be almost invisible to the observer.

This will be better understood, perhaps, by making reference to fig. 2. This is a diagram showing the position of various objects in the slide (fig. 1). As we have noted, the white patch appears floating in mid air, at the same distance from the eyes as that plane at which the statue is situated. The reason of this is, that when the statue is being looked at the eyes cross their axes at the point, c. Oblique rays, A R and B L, emanate from the nosing of the steps (see photograph), and fall upon agreeable parts of the retina in each eye, so that, if the eyes are turned to the left, the point, D, falls upon the axes of the two eyes, and the images, A and B, are appreciated as one object situated at D, whereas the retina is really being ramified by rays emanating from two entirely separate parts of the distant object, the nosing of the step.

In this particular instance the column, statue, and the leg of the photograph stand play an important part in bringing about the phenomenon by hiding from the eyes certain parts. The right eye, R, is prevented from seeing the image, B, by the statue intercepting; the left eye, L, is prevented from seeing the image, A, by the column, whilst the leg of the photograph stand splits up into two white patches the nosing of the step.

From these facts it is obvious, if such distracting effects are to be avoided, thoughtful care must be exercised in deciding from what point of view a subject should be photographed in order to prevent results of this character in the stereoscope. It has been impossible in this short article to do more than intimate the reason of certain defects in stereoscopic work. Unless the reader has a thorough knowledge of optics and binocular vision in relation to the perception of relief in the stereoscope, he should avoid photographing stereoscopically views with railings in them, or fences where patterns repeat themselves, or troubles of the sort mentioned must be anticipated.

THEODORE BROWN.

#### A PLEA FOR PICTORIAL LANTERN SLIDES.

AMONG a very considerable section of photographic workers there exists an idea that the making of a lantern slide is one of the easiest of photographic manipulations. Of a certain kind of slide this may be true, yet it is, nevertheless, a fact that the production of a slide technically excellent, and at the same time possessing artistic merit of a high order, is by no means an easy matter. An examination of any fairly large collection of lantern slides will at once show that only a small proportion can claim the possession of real pictorial excellence. This may be due, to some extent, to the fact that many workers of great ability seldom attempt to produce their pictures on any medium other than paper; but there is no doubt that many workers who are capable of producing the highest class of work on paper fail altogether to do their pictures justice when they attempt to show them through the medium of the lantern slide.

Now, why should this be? In the first place it must be admitted that very little encouragement is given by the general public to the worker who strives to give his slides something like real pictorial quality. There seems to be an impression abroad, that unless a lantern slide is very brilliant—black and white, in fact—it is of inferior quality. It is a little difficult to say why this feeling should exist; probably its origin may be traced back to the days when the oil lamp was so very much used, and the necessity existed for a very clear slide.

On account of the weak light a slide of great brilliancy was required, and, although methods of illumination have changed, the quality of the lantern slide has not altered correspondingly, people have become accustomed to the extremely brilliant, not to say harsh, effects so often seen on the screen, and anything different is not appreciated as it probably deserves to be. The natural result, then, is that the majority of workers aim at the production of that which will please, hence so many slides of the clear glass and shadows order. Every one who has attended a lantern show will have noticed how a slide of excellent quality, but, perhaps, portraying some subject which presents no very strong effect of light and shade, may be received almost with silence, while another of the black-and-white order, perhaps showing a waterfall as a streak of pure white, and trees as having received a shower of snow, may be loudly applauded.

But lack of appreciation on the part of the public is not the only reason for the want of artistic excellence so often observed in slides. It may be that many workers, having been so long accustomed to the ordinary run of slides, conclude that as a means of real picture-making this is an unsatisfactory method, and never give the lantern slide a trial; or, possibly,

hey consider that a lantern slide is a very small affair into which to put their best efforts, and accordingly the picture does not receive the attention it deserves, and would get, were paper the medium employed. This last reason is very likely to be a common one. We must allow that there is very little to show for our work, so far as bulk is concerned, in a lantern slide, yet we must not lose sight of the fact that the pictures to be viewed on a very much larger scale than any one would ever dream of showing work on paper. The inevitable disappointment comes as soon as the picture is projected on the screen, and then the process is sure to be blamed. The prevalence of so much indifferent work has brought about the idea, among some workers, that the lantern slide is not a suitable means for pictorial representation, that the capabilities of the process are quite inadequate for the requirements of the pictorial photographer. It is rather unfortunate that such an impression should get about, because, if we look carefully into the matter, we find that the lantern slide seems peculiarly fitted for pictorial work.

We sometimes hear the question asked in all seriousness, "Should a lantern slide have any clear glass about it?" Such a question is, of course, absurd; we might as well ask if a picture on paper should show any white lights. The slide must be treated as a picture, and, if the subject represented demands clear glass, then clear glass there should be; while, if the subject be one in which brilliant high lights would be objectionable, then a lower-toned picture should be aimed at.

The lantern slide seems peculiarly fitted for pictorial work by reason of the long range of gradations we can get with it. One of the greatest obstacles the landscape photographer has to encounter lies in the difficulty of rendering on paper the extreme brilliancy in sunshine we see in nature. This sparkle can in some measure be rendered by means of the lantern slide without loss of transparency in the shadows of the picture, an effect we are so apt to produce on paper when striving after great brilliancy.

For pictorial purposes it is sometimes of advantage to raise or lower the key in which a picture may be rendered in the negative. This is often done in enlarging, and it is quite possible to adopt the plan in producing a lantern slide.

In lowering the key of a picture, over-exposure must necessarily be resorted to; but over-exposure need not mean flatness. Some of the very best slides are secured by means of a generous exposure, followed by slight over-development, and a subsequent short immersion in the ferricyanide reducer. By this means only the highest lights of the picture are cleared, the rest being left beautifully subdued.

Some one may say "that is all very well when we wish to lower the general tone of a picture; but, if it is desired to raise the key, to get, say, a strong slide from a rather over-exposed negative, then a lot of high lights of about equal value will be produced, and we cannot sun down where we would like as in the case of a paper print." The same objection would be raised in every case where undesirable high lights presented themselves; but, if the following plan be adopted, even this difficulty may be overcome. There is nothing new about the method; the last time the writer heard the plan advocated was by the President of the Edinburgh Photographic Society.

Let us suppose we have a slide which, in the matter of technique, is satisfactory, but which requires one or two obtrusive high lights toned down. The slide must be placed film to film with an unexposed lantern plate and an exposure of a few seconds, only sufficiently long to affect the high lights, made on the plate through the slide. The plate must now be developed, and the result will be a negative image. This negative image is prepared with a view to being placed in contact with the slide, acting as a cover glass, when it will be obvious that the negative image will coincide with the high lights of the slide, and in this way lower their brilliancy. It will not be desirable, however, to have all the lights toned down, and, in order to prevent this happening, it will be necessary to remove the negative image from the parts which are to be left clear. This is easily done with the ordinary reducer of ferricyanide and hypo. The negative image must, of course, be very weak—more or less so according to the amount of toning down required—and it is very necessary to see that the cover glass carrying this image is in perfect register with the slide.

This method is a great power in the hands of lantern-slide makers; it means, perhaps, some little trouble, but the result is ample recompense, the difficulty of subduing objectionable high lights being one of the greatest hindrances to pictorial lantern-slide making. As a rule, lantern slides are made too hurriedly. It would be a far better plan to spend a long time and a lot of trouble over the making of one really fine slide, a slide which, when finished, would probably be a picture of first-class merit, and would give its producer pleasure whenever projected on the screen.

J. B. JOHNSTON.

## PRACTICABLE PHOTO-MICROGRAPHY.

[Reprinted from the *Journal of Applied Microscopy*.]

**OBJECTIVES AND CONDENSERS.**—Scientific research in optics, improvement in optical glass, with gradual elimination of errors sometimes seemingly trivial to the ordinary laboratory worker, have made possible the present advances in photo-micrography during these more recent years, until we who are reaping the benefit of these improvements can photograph the most difficult objects with comparative ease, our obstacles being mainly those of technique in cutting and staining tissues.

Some manufacturers, who have been unwilling to sacrifice some pet theory, are still working to prove these theories, in spite of laws now well known and obeyed by those who have reaped that certain reward of obedience to law which is called by some "success"—by many, too often, "chance."

Those whose names to-day are recognised as worthy of honour and gratitude have worked almost unrewarded in many cases, and in the face of violent opposition.

Whether the front system of an objective consist of crown or flint glass, or be single or double, means comparatively little to the worker with an ordinary microscope; but these things mean everything to the photographer of microscopic objects, who needs all possible aperture suitable to the power used and all possible correction of spherical and chromatic aberration.

What wonders have been accomplished since Leuwenhoek, in 1672, published his observations of bacteria with a simple lens, a glance into any of our laboratories will show, but only partially, until some veteran worker proudly exhibits to you his favourite lenses, expatiating now on the lighting of the field, now the exquisite definition, keeping you till the wee small hours, until, after breathless manipulation of light and collar correction, he triumphantly shows the striations on *Amphipleura pellucida*, or the nineteenth band of Nobert's plate.

The writer well remembers his first lessons as a boy back in the sixties, looking with awe and interest through the microscope owned by one of the pioneer physicians and scientists of the Western Reserve, the stand of the queer model of those days, a still queerer French triplet lens with dividing fronts of varying powers, from one inch to one-quarter inch.

There were strange iridescent rings around the outside of the field and "dishing" of the object, which we now condemn as chromatic and spherical aberration.

The microscope and objective were made by a famous French optician, but our ordinary student microscopes of to-day far surpass them.

Since those days we have seen the advances step by step, in which our American opticians were always to the front in spite of lack of means and encouragement, and we do well to honour our Tolles and Spencer.

We have seen the colour fringes disappear, the field grow flat, and the aperture increased, until to-day our best dry lenses give better results than the water immersion lenses of that period.

Powell and Lealand in England, Hartnack and Nachet on the Continent, and Tolles and the elder Spencer in this country, were gradually improving their lenses until, in 1873, Tolles produced a fine glycerine immersion objective of 1.23 N. A.

But during this period further advance was checked by the false theory that all that was needed was "power" in order to see minute objects. Indeed, even to-day, almost the first question asked of the possessor of a microscope is, "How high will it magnify?" and, unless one claim at least 5000 diameters, the shoulders are shrugged, and no further interest is manifested.

Even in 1880, three years after the publication of Dr. Abbe's discovery of the diffraction theory, it was common to see  $\frac{1}{2}$  and even  $\frac{1}{4}$ -inch objectives, and Tolles once made (although under protest) a  $\frac{1}{4}$ -inch objective, and that to study a tooth!

Dr. Abbe's untiring labours were finally rewarded by the almost universal adoption of his theories, which, together with the equally zealous labours of Dr. Schott in optical glass, have practically revolutionised the science of lens-making, especially for photo-micrography, and Zeiss apochromatic lenses are within the reach of every earnest worker.

To-day we recognise the fact that the numerical aperture of an objective, and not its power, governs the definition, the limit for the practical worker being about 1.40 N. A. for an immersion objective, although Powell and Lealand in England and Herbert R. Spencer of this country are making  $\frac{1}{2}$  immersion objectives of 1.50 N. A., and the famous Zeiss Company has made four  $\frac{1}{3}$  immersion objectives of 1.63 N. A.; but these can only be used with special slides, cover glasses, and mounting media not accessible to the ordinary worker.

A single example will suffice from our own experience. A few years ago, while buying "everything in sight," we were tempted into purchasing a  $\frac{1}{8}$ -inch immersion objective of 1.20 N. A. of a first-class maker; two years later a  $\frac{1}{8}$  inch immersion objective of 1.35 N. A., by the same maker, was bought at a bargain, almost reluctantly; but we have proved many times, to our own and others' satisfaction, that the  $\frac{1}{8}$  would resolve far more difficult tests than the  $\frac{1}{8}$ , although of only one-third its power.

The  $\frac{1}{8}$  was long ago got rid of at a bargain to the purchaser; the  $\frac{1}{8}$  still remains the gem of our collection, and unequalled in defining power by any we have seen of its N. A.

Still, the best objectives of fifteen years ago, although of sufficient N. A. and well corrected, failed in one very essential point for photography, viz., correction for various rays of the spectrum, lenses for visual work being corrected for yellow-green rays at one end of the spectrum, and lenses for photography corrected for blue-violet rays at the other end of the spectrum, and neither were well fitted for any but their own special work.

In July 1886 the Zeiss Optische Werke, under the guidance of Dr. Abbe introduced the apochromatic lenses, which simplify our work to a marvellous extent.

These lenses, while not necessary for ordinary work, possess two special essentials for photo-micrography, viz., "the union of three different colours of the spectrum in one point of the axis and correction of the spherical aberration for two different colours," thus eliminating secondary spectrum and securing sharp definition for all parts of the field.

A first-class achromatic objective by a good maker will give fairly good negatives of some objects if especially stained and the proper colour screen and plate be used; but if we are called upon to photograph objects which are unstained, with no contrasts, resolved with difficulty with diaphragm nearly closed, *i.e.*, cilia in the bronchi or Fallopian tubes, then even with best of apochromatics we shall need all our technique and patience.

The writer has been the past two weeks fighting a specimen of a rare tumour on which a scientific friend is writing an important article, in which some considerable part of the success depended on defining and photographing a few striæ on muscle fibres—unstained except nuclei, and cut with a freezing microtome at twenty micra.

The result was attained with a Powell and Lealand  $\frac{1}{8}$ -inch apochromatic immersion objective of 1.40 N. A. with a condenser equally well corrected, Zeiss No. 3 projection ocular, 1720 diameters, light yellow screen, ortho plate, and five hours' exposure, and our best achromatic objective failed to yield any result.

Condensers have come to us in their present form about abreast with the gradual improvements in objectives, the English opticians and workers being the first to recognise their value, until now we realise that for the best performance of our best objectives the condenser should be as perfectly corrected and of almost the same N. A.

The ordinary Abbé condenser, even if of equal N. A. with the objective, introduces grave errors, as shown most lamentably in an otherwise fine photograph of *Amphipleura pellucida* reduced to dots with a Zeiss apochromatic 2 mm. of 1.40 N. A., used with an inferior condenser, by Fraenkel and Pfeiffer in their *Atlas of Bacteriology*.

Very good achromatic condensers are now made by the leading manufacturers, but the best we know of and use in every-day work are the Zeiss of 1 N. A., one of 1.43 N. A. oil immersion made especially for us by Spencer, and an apochromatic oil immersion of 1.40 N. A. by Powell and Lealand which gives pure images unexcelled by any we have seen.

By this time our unfortunate reader has begun to despair, and imagine that one must be a multi-millionaire to go in for photo-micrography; but we hasten to correct the impression, for four first-class objectives with an achromatic centering condenser make a fairly complete battery with a projection ocular.

The objectives should be apochromatic, if possible, a 24 mm. of not less than 0.30 N. A., a 12 mm. of 0.65 N. A., a 6 or 4 mm. of 0.95 N. A., and a 2 mm. oil immersion of not less than 1.30 N. A.

If all of these are not obtainable, we should say by all means choose the 12 mm. of 0.65 N. A. and the 2 mm. oil immersion apochromats, and the other perfectly corrected achromatics.

With such objectives and a good camera the best of work can be done by earnest workers.

The writer is well aware of the magnificent work done by the late Surgeon-General Woodward with Tolles and other achromatic objectives, having some of his photographs in his collection, and having more than once handled with reverent care the splendid collection of lenses at the

Army and Navy Medical Museum, including a  $\frac{1}{8}$ -inch by Tolles, probably the first homogeneous immersion objective made.

But we are not all Woodwards, nor have we such facilities as he had, and he would have surpassed himself if he had worked with some of our present objectives.

We have in our own collection five of the best immersion lenses made, including a  $\frac{1}{8}$  and  $\frac{1}{10}$  of 1.35 N. A., and  $\frac{1}{8}$  and  $\frac{1}{10}$  apochromatic of 1.40 N. A., and a  $\frac{1}{10}$  of 1.43 N. A.; also a full set of Zeiss apochromatic dry objectives, viz., 24, 12, 6, and 3 mm. of highest possible N. A.; but we use two of these 99 times in 100—the Zeiss 12 mm. dry apochromatic of 0.65 N. A. and the Powell and Lealand  $\frac{1}{8}$ -inch immersion apochromatic of 1.40 N. A.

The 12 mm. Zeiss apochromatic of 0.65 N. A. is our most useful dry lens, being capable, with proper illumination, of almost any amount of magnification without breaking down, and gives a far better negative with No. 3 projection ocular at 1000 mm. camera extension than any achromatic  $\frac{1}{8}$  or  $\frac{1}{10}$  at the same magnification.

Any one can satisfy himself of this by making two negatives at 300 diameters with full cone of light, using this objective and any  $\frac{1}{8}$  of any good maker, and the apochromat will reveal details of structure that are impossible to the less well-corrected objective.

In regard to condensers, our readers will remember that many objectives can be used as condensers; we have just been making some negatives of *P. angulatum* with 6 mm. apochromatic of 0.95 N. A., using the objective above named as a condenser.

We need also to sound a note of warning in regard to the other optical parts of the apparatus, lest some errors should creep in and offset the advantages of fine objectives and condenser.

The large collecting lenses on our optical bench, with cooling cell and ray filtering trough, should all be of best construction and glass, as also an achromatic lens for rendering the rays parallel before they enter the substage condenser.

This last-mentioned is of great value, almost a necessity for equally lighted fields.

With these conditions realised in all parts of our optical apparatus, we shall need only special methods of technique and experience. Of the former we may write later; the latter comes with time, oft with failure, but ultimately crowned with success. CHARLES H. POTTER, M.D.

#### A TEMPLE OF SCIENCE.

AMONG the many museums and galleries, filled with the priceless treasures of past generations, with which Florence abounds, and which render the city of Dante a veritable Mecca alike to the artist and the student, perhaps none offers a greater interest to the scientific, and more especially the astronomical, visitor than that Temple of Science known as the "Tribuna di Galileo." This richly decorated hall, says Mr. W. Alfred Parr, in *Knowledge*, in which are worthily enshrined some of the most interesting and valuable scientific relics relating to the life and work of Galileo, and which vies in point of interest with the picturesque old tower known as Galileo's Observatory, described by me in a former number of *Knowledge*,\* forms part of the Museum of Physical Science, and was inaugurated in 1840, on the occasion of the assembly at Florence of Italy's principal scientific men. Dedicated, as it is, to the memory of the great Tuscan astronomer, it was but fitting that the structure itself, as well as the paintings, sculptures, and mosaics with which it is so richly adorned, should be representative of the best talent of Tuscany; and that the artists intrusted with the erection and decoration of this memorial to their illustrious compatriot succeeded in worthily acquitting themselves of their task may be seen from the accompanying photograph.

On every side are depicted interesting episodes in the life of Galileo, from the time when, as a young student, he watched the swinging lamp in the Cathedral of Pisa, to the time when, old and blind, and in the retirement of his villa at Arcetri, he dictated the account of his researches to his two celebrated pupils, Torricelli and Viviani; while in the centre of the apse, dominating the whole, stands Professor Costoli's statue of the great astronomer. The painting in the ceiling immediately above the statue, and plainly visible in the photograph [reproduced in *Knowledge* for May], represents Galileo in the act of demonstrating the merits of his newly constructed telescope to the assembled Senate at Venice.

Ranged along the walls are glass cabinets, containing many valuable instruments dating from the time of Galileo and his School; but it is in the two cabinets on either side of the statue that our chief interest

\* See *Knowledge* for July 1899, p. 157. The tower is now the property of Count Paolo Galletti.

centers. In the one to the left of the spectator is preserved, carefully mounted in an elaborate hexagonal frame of worked ivory and ebony, the object-glass which Galileo fashioned with his own hands. This precious bit of glass, if one may believe the Latin inscription on the frame, afforded the great astronomer his first glimpse of Jupiter's satellites, and thus enabled him to announce to the world the great discovery which firmly established the Copernican doctrine, and which elicited Kepler's famous message of congratulation to his fellow-worker, parodying the last words of the Emperor Julian, "Galileo, vicisti!" \* The little lens, barely an inch and a half in diameter, which sufficed to reveal the four "Medicean Stars" to the eyes of the "Tuscan artist," compares strangely with the great thirty-six-inch object-glass on Mount Hamilton, which, 282 years later, added a fifth member to the little group forming the Jovian system. Preserved in this same cabinet, and just discernible in the photograph above the frame containing the object-glass, are two of the first telescopes which Galileo is said to have constructed.

A somewhat gruesome relic of the great man is preserved in the cabinet to the right of the spectator. Mounted on a short marble pillow, adorned with the usual allegorical Latin inscription, is a crystal vial containing the index finger of one of Galileo's hands. It was severed from his body just before the latter was consigned to its last resting-place beneath the grand monument prepared for it in that Westminster Abbey of Florence, the Church of Sante Croce.

The remaining cases contain a valuable collection of astronomical, nautical, and geodesical instruments, formerly belonging to the Accademia del Cimento, the famous institution which, rising, as it were, from the ashes of Galileo, counted among its members such men as Borelli, Viviani, and Redi, and which chose for its motto the significant words, "Provando e Riprovando."

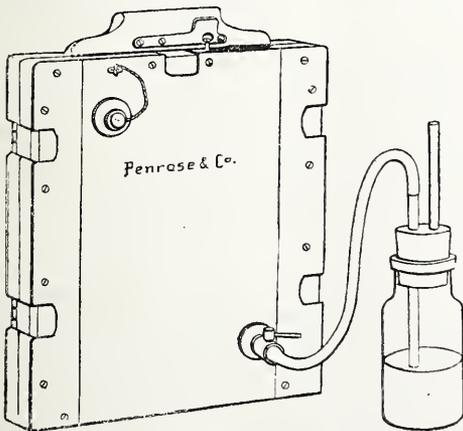

Some old telescopes with wooden "bodies," by Torricelli of Florence, dating from the year 1644, together with others in quaint leather coverings, embossed with curious gilt ornamentations, constructed by Campani of Rome in 1666, are also preserved here, and serve to complete a collection which, alike to the student and the antiquarian, is of absorbing interest throughout.

#### A DARK SLIDE FOR THE LIPPMANN PROCESS,

Manufactured and sold by Penrose & Co., 8 and 8A, Upper Baker-st., London, W.C.

THIS Dark Slide has been designed for working the Lippmann process of photography in colours, and the construction follows the lines suggested by Professor Lippmann, with some improvements tending to greater compactness and security against leakage of the mercury. It has been used and commended by several advanced workers in this process.

Messrs. Penrose have furnished us with the following details:—The slide is slightly larger each way, and somewhat thicker than an ordinary

dark slide, and it only takes a single plate. It is made exceptionally strong to withstand the pressure of the powerful springs which made the holder mercury-tight. The essential feature of the construction is a steel plate, fitted at the back with a number of springs. To this plate are attached two tubes, passing to the outside of the slide. One is provided with a small stop-cock, to which is attached the rubber tube of the mercury bottle. The other is provided with a plug, and forms an air vent, which must be opened when the mercury is running in. The second tube of the mercury bottle also acts as an air vent when the

\* "Galilean, thou hast conquered!"

mercury is returned to the bottle. On the surface of the steel plate is laid a frame of thick chamois leather, forming a margin of about  $\frac{1}{4}$ -inch width, and on this is laid the prepared plate, sensitised side downwards. There is thus a space between the steel plate and glass plate, which can be filled with mercury. In the operation of filling, the slide should be held vertical, and the mercury bottle held above the top of the slide. More mercury than is required to fill the slide should be contained in the bottle in order to get a good "head" to force the mercury up the slide. The flow must be steady and without intermission, or markings will occur on the plate. For the same reason the slide must be held steady.

A focussing frame is sent out with each slide, with the ground glass coinciding with the surface of the sensitive plate. Messrs. Penrose state that they cannot make their dark slide to match existing dark slides, which are generally much too small and light to compare with the Lippmann slide. It is usually best to adapt the latter to a camera next size larger.

Messrs. Penrose inform us that they have just supplied a half-plate slide to Dr. J. H. Smith of Zürich, who has succeeded in producing some successful plates for the process. Plates are also supplied by Chéret of Paris, and may be obtained through Messrs. Penrose.

#### THE "VOLO" DEVELOPING APPARATUS.

Manufactured and sold by George Houghton & Son, 89, High Holborn, W.C.

THIS simple piece of apparatus should be of great assistance to those photographers who employ rollable film for negative work. Its applications and method of use are so obvious from the illustrations that very little description is called for. The printed instructions, however, may conveniently be quoted for the benefit of those not conversant with the principle of rotary development.

"Cut off from the spool the number of exposures that are to be developed, and attach the film, sensitive side outwards, to the wheel by means of a fixed clip, on the wheel. Pass the length of film round the

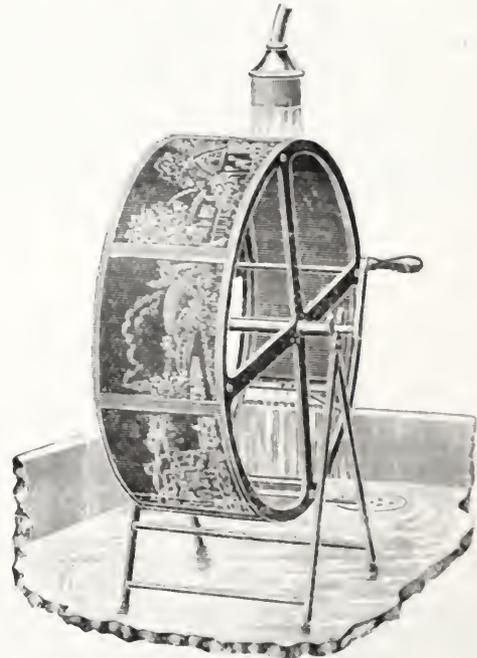

FIG. 1.

rims of the wheel, and attach the other end to a loose or sliding clip. Any number of exposures can be developed at one time up to the number that the wheel will take, as this clip is movable, and can be fixed in any position on the wheel.

"Developing.—The film is now in position for development, and the wheel should be placed on the stand provided and revolved, the film passing through the developer with a gliding motion, which is most desirable for the avoidance of spots and streaks.

"Fixing.—This can be done in the same manner as for developing, or the handle and axle can be removed, and the wheel, with film upon it, placed in a bath of hypo. With the aid of another wheel the operator can then proceed to develop another set of exposures.

"*Washing.*—This can be done by placing the wheel on the stand in a sink, and allowing a stream of water from a tap, preferably fitted with a rose, to play upon it, causing the wheel to revolve, as shown in fig 1; or, if preferred, the handle and axle can be removed, as explained before, and the wheel placed in a bath of water.

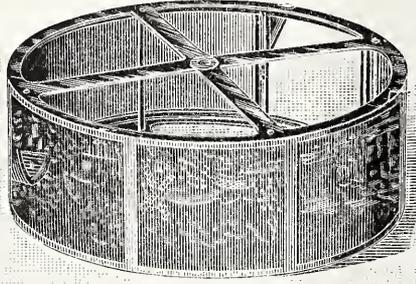

FIG. 2.

"*Drying.*—The wheel can be placed on its side, (Fig. 2), and the film left on until dry, when it can be removed and cut up for printing."

When we inspected the Volo we were much struck by its ready adaptation to rollable-film manipulation, and we have little doubt that it will secure a considerable degree of appreciation.

#### SOME REMARKS ON LIGHT AND LIGHTING.

To enumerate them multitudinous systems of lighting for studio purposes as applied to the photographic art would indeed be a hard task. I suppose every operator has his own special ideas as to producing certain effects which he or any one else may call "artistic." The lighting for one sitter is, or perhaps ought to be, quite different to that of another, and there is no doubt the student of posing and lighting does his level best to produce this variety. There is, however, a kind of limit in most cases, which will, upon a little thought, become apparent. The lighting which best suits the face becomes inappropriate to the dress, which may have heavy folds or a quantity of dark-coloured lace or other trimmings. You get the light so arranged that you observe the delicate embroidery or trimmings of the dress, but then the complexion would be ruined, the character of your sitter would be lost, and instead of a nicely modelled face you produce a mere eyes, nose, and mouth, but a very pretty and delicate dress effect. Such is one of the troubles to be met with in studio lighting. Another, and one not unseldom met with, is the lady or gentleman with white (grey) hair, which has a great tendency to get over-exposed, whilst the somewhat ruddy complexion hangs back, so to speak, and you wonder

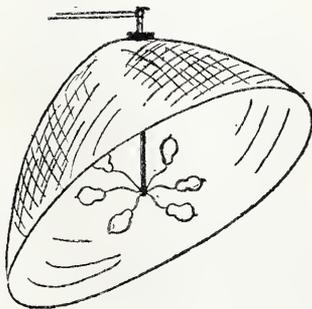

FIG. 1.

if there is really any means of getting a reasonable result without having to resort to isochromatic plates. Then, again, we have the red—yes, decidedly of a strong non-actinic tint—hair, and our old-time friends' faces covered with non-actinic spots, or better known as freckles, which require our retoucher to go so carefully over his or her negative; but, still, we have much to be thankful for, inasmuch as nature has been very considerate in making these the exception and not the rule. Now, these colour cases are best dealt with (if it is worth your while) by the use of those modern inventions of colour filters and plates, as I firmly believe much better work can be done and time saved in the after-operations of faking the negative. Take the case of red hair. We might require the exposure considerably prolonged to get a reasonable effect from the hair, and that would mean over-exposure for the rest of our negative. A colour filter which will give the hair a more neutral tint will also have the advantage of prolonging the exposure for the dress, hands and face, and of thus getting rid of the violent contrasts which stand in our way, and I suppose it would not be difficult to find the sitter whose inappropriateness to a bright clear light would be at once seen had he or she (generally she) come on a dull or hazy morning; or, again, the sitter whose combination

is such that an evening exposure of twenty seconds would produce better results than a middle-day exposure of one second.

I believe the careful operator has all this sort of thing in his notebook; but, still, he has to face these difficulties from day to day, and do the best he can under the circumstances which limit his operations. How much better it would be if he had some means of changing the whole of his light to the tint required. This, however, would be a very difficult thing to arrange; but, still, these are little suggestions which might be utilised in some cases. One might have a number of hoops, upon which could be stretched various tinted gelatines suited to the colours of dress or complexion, and these could, when occasion required, be placed against the principal source of light, and so moderate or control the source of light falling upon the sitter. I think it is fairly admitted that exposure is the principal factor in producing an effective gradation or contrast in a negative, and not any arrangement of development; although one may modify, one cannot altogether compensate for bad exposure. A correct exposure, therefore, means success, and a correct exposure cannot be given on two or more colours (blues and yellows or reds, or modifications of same) without some special plate or filter. Colour-sensitive plates have been on the market now for some time past, and have been used largely for landscape and copying purposes, and there is no reason at all why a more popular use might not be made of them in your studios. The colour filters which are made, or can be made, very conveniently to fit the lens, may be used when focussing, and so the operator can see the modification produced. As a rule (violent colours not being very much worn), very light tints would be sufficient for portrait work, and a set of filters would not be a very formidable task.

Whilst on the subject of light and lighting, I would like to say a word or two with reference to a system of lighting brought out and perfected for all practical studio work by Messrs. Adamson Bros. Many photo-

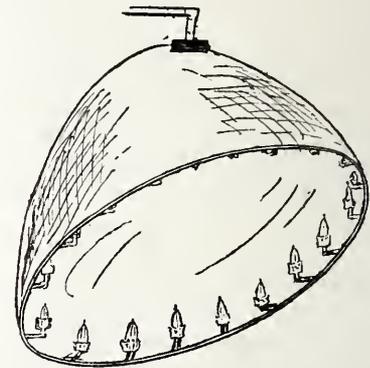

FIG. 2.

graphers who are entirely dependent upon daylight, and constantly have sitters coming late in the evening, would do well to give artificial light a trial. I speak more generally to provincial photographers, and would remind them that there are London photographers who never use daylight at all.

I was in a studio a short time back just off Cheapside, E.C., and, on being shown up, was surprised to find what would have made a better dark room than a studio, until the daylight was let in through, I believe, a solitary window, and the artificial arrangement demonstrated. I do not think I am in any way misleading when I say that some of our very best West-end photographers are using electric artificial lighting for portrait work. This generally consists of one or more large parabolic-shaped reflectors, with a number of incandescent electric lamps in its focal centre, the direct rays being shielded by a small diffusing screen; or the lamps are arranged around its outer edge just within the bowl or parabola. The accompanying rough sketch may assist. Here fig. 1 is arranged for lighting large backgrounds of from twelve to fifteen feet, whilst fig. 2 is for all ordinary purposes—so far as a provincial photographer requires, or, indeed, any photographer—used for small groups and portrait work in general. An apparatus of this description gives one an immense advantage. The source of light can be moved to any point of the studio—a regular and constant factor of exposure; sitters are accommodated, no matter what the weather be, and a good negative available even after dark. This apparatus is always ready for use, and one I had the pleasure of testing, supplied with ordinary house gas, is one to which a rubber tube is attached at its base, and fills up from any ordinary gas-bracket or burner, without having recourse to the main. You just quietly press a small lever for two or three seconds and make your exposure; as you release your lever, the apparatus immediately refills. The cost of an exposure is one-third or one-half a cubic foot. I may just add that the makers have a special mantle constructed for them as used in this apparatus, which seems rather inclined to melt than break, so that the wrecking of mantles is reduced to a minimum.

## LANTERN MEMS.

THE cinematograph has now established itself as a scientific assistant, and animated photography has become a necessity for the recording of natural phenomena as well as historical events, fashionable functions, and pastimes. Mr. Cecil Hepworth has been fortunate in securing a continuous record of the various phases of the recent total solar eclipse, and, on his return from Algiers, has not been slow in giving the public the opportunity of seeing, as near as possible, a lifelike representation of the wonderful sight that comparatively few of the scientifically interested were able to see visually.

\* \* \* \* \*

THE London Hippodrome now show nightly this interesting film, as well as many others in connexion with the war in South Africa, and the appreciation of this and other entertainments at this place of amusement is proved by the fact that at eight o'clock the other evening, when I went, every seat in the house had been sold. The building, the area, and stage are all well arranged, and the general excellence of the company leaves little to be desired. The electric lighting and coloured lights are especially fine. The wonderful exhibition of the performing lions and the marvellous nerve of the trainer were things which those amused by the sensational could not fail to be pleased with. One lion among the beautiful specimens of Leos was so decidedly snarlish that I expected at any moment to see him spring on his keeper, and I could not help thinking what a wonderful thing "will power" and *sangfroid* is.

\* \* \* \* \*

A LITTLE mental reasoning carries one away from the animal world to human beings, and examples soon come to one's mind of men who are successes in life because of their will power and determination, and others, far more clever either mentally or mechanically, are failures because they never know their own worth or know how to assert themselves at the proper time. This applies as particularly to the photographic and optical lantern business as to other departments of trade; and many a man deserving of a fortune is content to rub on with a paltry or moderate income because he has not had determination or *nous* enough to get the value for his labour or brainwork at the proper time.

\* \* \* \* \*

MANY things that occur to me lead me to these conclusions, but it is difficult, without treading on dangerous ground, to give examples or particularise; so I must leave it to my readers to weave round

the instrument or apparatus they possess, or are interested in, the legend, history, or probabilities as to its origin and development. "Many grand schemes from little causes spring" may be allowed as a paraphrase of the well-known quotation. Those that come to my mind first are the daylight changing sensitive film, and the conception of rapidly moving figures in an optical lantern. The result of the first means millions of pounds, in which the public who have capital invested reap a good return, and the users of them have a vast amount of pleasure without any toil or technical difficulty.

\* \* \* \* \*

WHAT about the pioneer? One would like to know how much the man who first thought of backing a sensitive celluloid or paper film with a light-tight paper got out of the conception, or what return those who spent hundreds of pounds to make pictures move at more than eleven per second, after taking photographs at a greater speed than that, were able to place to their credit before the man came along with an "improvement" that enabled a syndicate or company to make it commercial.

\* \* \* \* \*

THIS word "commercial" means in trading what tact does in diplomacy and professional work. The veriest dunce, if he has tact, can pose for a time as the most learned, but, of course, in the end the lion's skin is blown aside, and the asinine form is revealed in broad daylight.

\* \* \* \* \*

As long as I can remember, those who desire to educate or improve their fellow-men have written sage advice and done their level best to expose imposture; but, notwithstanding this, a large proportion of the fraternity are still open to be gulled, hence the fine time that those who are particularly "slim" in business have. Look at some articles in shop windows, without specifying what trade or kind of establishment, that offer second-hand goods for sale, and many of them ask, when wear and tear are taken into consideration, the price a new article could be bought for. In some instances I have seen things I do know about, say, optical instruments, priced as second-hand higher than the original retail price. To purchasers of second-hand articles I say, Be sure you have what is reasonably suitable for your requirements, and that it is in such a condition that you will not have to spend much money in putting it in good working order.

\* \* \* \* \*

THINKING of the optical lantern, I was trying to apportion the honour or praise due to the various improvements of this much-used apparatus, and, remembering the oil and limelight lanterns as I knew them over thirty years ago, I called up in my mind's eye how the matter has progressively developed. First, the plano-convex achromatic lenses in combination of pairs replaced the old meniscus single lenses in combination, to be followed later by what the Americans largely adopted, the form of lens known as the photographic or Petzval lens. This, first of all, was of small diameter and comparatively short focus, but later British exhibitors followed the example of our American cousins and used large-diameter and long-focus

lenses. The general change in the form of front lenses came in with the adoption of the sciopticon form of lantern, so that two or three-wick mineral oil lamps could be used, and then the change was confirmed by the introduction of Dallmeyer's lantern lenses and condensers. The various mechanical details of the lantern and the metamorphoses, so to speak, of oxyhydrogen jets I shall have to refer to another time.

\* \* \* \*

A CONTEMPORARY reports the capture of a luminous crab by a dredge of the Zoological Society of Calcutta in the Indian Ocean, about a mile off the coast, and forty-five fathoms deep. It is nearly two feet in diameter, and its longest claws are about a yard in length. It has projecting eyes like those of a lobster, and is very voracious. It was put into a tank of sea water, and in two hours devoured some fifty other crustaceans and fishes. When darkness came it proved phosphorescent, emitting peculiar white rays and illuminating the whole tank. The crab was sent to the aquarium at Calcutta.

\* \* \* \*

THE latest fad in Paris is the substitution of cinematograph pictures for menu cards, says *Morris's Trade Journal*. Each course is preceded by a moving picture thrown on a screen.

\* \* \* \*

THE Exposition of "Life in the Royal Navy" concludes its stay at the Polytechnic, London, on July 7 next. The crowded audiences that have visited it each day for the past nine months, and the keen interest and enthusiasm that has been shown during the presentation of this series of animated pictures, warrant one in strongly advising those who have not as yet been able to witness it to take advantage of the remaining two days of its stay at the Polytechnic. I understand that Messrs. West intend to open again in London, during the forthcoming winter, with some new scenes of naval life of still greater interest, and that they are arranging to send this Exhibition to Australia and our other colonies.

G. R. BAKER.

#### THE PENETRATION CO-EFFICIENT OF DRY PLATES FOR LIGHT.

It is a well-known fact that the rays of light do not entirely lose their actinic properties when passing through a film of gelatino-bromide of silver; that, moreover, a part of the rays goes through unchanged, and by reflection from the back of the glass makes itself unpleasantly obvious in the form of halation. In what proportion, however, the light is absorbed by the ordinary films of dry plates, has, to our knowledge, not yet been determined,\* and, in order to ascertain this, experiments were instituted to find out through how many films actually a ray could still be detected. Glass plates were, for this experiment, on account of their thickness, obviously excluded. The gelatino-bromide films of the Anilinfabrik, Berlin, which from their good qualities were specially suitable, were used, and six films were placed one over the other and exposed under a sensitometer of from one to sixteen layers of tissue paper, for 120 M.K.S. (candle meter seconds). The sensitometer had such thickness that a very sensitive commercial plate with an exposure of 120 M.K.S. just allowed the number 16 to be read on development.

The films were exposed so that the first received a full exposure, and the second received the unused light which passed through the first, and so on. All the films were developed simultaneously in a dish with rodinal 1:30 for four minutes. The following numbers were legible.

Film No. 1.	Sensitometer No 15.
" " 2.	" " 11.
" " 3.	" " 8.
" " 4.	" " 4.
" " 5.	" " 7. Distinct, but not legible
" " 6.	" " 0. [after fixing.]

The lower films showed a faint general fog, in consequence of

\* The author seems to be unaware of the paper on this subject by Captain Abney (*Camera Club Journal*, November 1899).—EDS.

the light diffused by the films in the packet. The sharpness of numbers becomes as a matter of course, less sharp with each succeeding plate.

In order to express numerically in M.K.S. the light which was absorbed by each plate, a large number of films was exposed at the distance of one metre from the candle, and for various times of exposure, which were measured with a metronome, and then reckoned out in seconds. After development, which was accurately carried out as before, the plates were picked out which corresponded to the plates carrying the numbers 2 to 4. For example, to obtain the number 11 as the last as in film No. 2, an exposure of 33.3 seconds had to be given. The following table shows the exposure numbers found and the value reckoned according to rule:—

Film.	Light found.	Light reckoned.
No. 1 . . . .	120 M.K.S.	. . . . 120 M.K.S.
" 2 . . . .	33.3 "	. . . . 33.3 "
" 3 . . . .	9.4 "	. . . . 9.25 "
" 4 . . . .	2.6 "	. . . . 2.57 "
" 5 . . . .	— "	. . . . 0.71 } below the inertia
" 6 . . . .	— "	. . . . 0.2 } of the plate.

The numbers form now a geometrical series. Each film absorbs  $\frac{13}{18}$  of the incident light, and transmits  $\frac{5}{18}$ . The absorption-coefficient of the films tested is thus  $\frac{13}{18}$  (0.722) and the transparency or penetration-coefficient  $\frac{5}{18}$  (0.278). If the first film has transmitted  $\frac{5}{18}$  of 120 M.K.S. = 33.3 M.K.S., the second will transmit  $\frac{5}{18} \cdot \frac{5}{18} \cdot 120 = \left(\frac{5}{18}\right)^2 \cdot 120 = 9.25$  M.K.S., and it will be seen that the calculated value corresponds very well with the observed result.

If thus the first film transmit  $\frac{1}{a}$  of the total quantity of light, the second transmits  $\frac{1}{a^2}$ , and the third  $\frac{1}{a^3}$ , and the  $n$ th  $\frac{1}{a^n}$ . These coefficients were found with the films of Smith, Austin Edwards, and Kodak.\* From this it follows that most commercial gelatino-bromide plates have approximately the same properties.

The point is now to deduce the penetration coefficient from the recognised conditions with dry plates. These conditions are, according to the experiences of several years, approximately the same with all large dry-plate factories. There is to be taken into consideration here, principally, the thickness of the film, which, with machine coating is 0.035 mm., and the ratio of the weight of silver bromide to the gelatine, which is usually 1:1.5. For the absorption, however, the ratio of the weights does not apply, but the ratio of volume. This is given by dividing the absolute weight by specific gravity. If we assume, now, the specific gravity of silver bromide = 6, and that of gelatine = 1.3, we find in the emulsion the volume of silver bromide to 7 volumes of gelatine. Therefore a surface of 8 sq. mm. is covered with 1 sq. mm. of silver bromide and 7 sq. mm. of gelatine.

The silver bromide grain of a good emulsion has a mean size of 0.0035 mm.; there can thus, in a film of 0.035 mm., ten grains lie one over the other. If we consider that the complete gelatino-bromide of silver film is divided into ten films of 0.0035 mm. each, each film will contain one grain of silver bromide and seven equal-sized grains of gelatine. The outer film will absorb about  $\frac{1}{10}$  of the light incident on a surface of eight grains and transmit  $\frac{7}{10}$ . The second film again transmits  $\frac{7}{10}$  of  $\frac{7}{10}$  or  $\left(\frac{7}{10}\right)^2$ , and the tenth  $\left(\frac{7}{10}\right)^{10}$ . If this value is reckoned out, it will be found to be 0.26, and this agrees very well with value  $\frac{5}{18} = 0.27$ , found as above described. And the calculation corresponds to the actual ratio. The penetration coefficient of a gelatino-bromide of silver film appears to be dependent on the thickness of the film, on the size of the grain, and the volume ratio of silver bromide to gelatine.

If  $v$  = the volume of the silver bromide,  $v^1$  = the volume of the

\* According to Abney, *loc. cit.*, the light transmitted by the first film that acts on the second is 22 per cent., and that on the third film only 3 per cent., that on the fourth only 1 per cent., and that on the one-fifth only 0.5 per cent., and no useful light penetrates through the fifth film.—EDS.

gelatine,  $d$  = the thickness of the film, and  $k$  = the size of the silver bromide grain, the penetration coefficient is

$$\left(\frac{v^1}{v+v^1}\right)^{\frac{d}{k}}$$

From the experiments first described one can also reduce an estimated value of the inertia of a dry plate, that is to say, the time which one must at the most expose a plate to light without the formation of any light impression which will be visible after development and fixing.

It was proved that the light penetrating through the fourth film was so weak that the number 1 of the sensitometer was scarcely visible, and completely disappeared in the fixing bath; the light therefore which had penetrated through the fourth film must be looked upon as the inertia. If the penetration coefficient was estimated at  $\frac{5}{18}$ , there penetrated through the fourth film  $\left(\frac{5}{18}\right)^4 \cdot 120$  M.K.S., and, if  $\left(\frac{5}{18}\right)^4$  is reckoned out it is approximately  $\frac{1}{120}$ , and therefore through the fourth film penetrated  $\frac{1}{120} \cdot 120 = 1$  M.K.S.

As the sensitometer was made of a sheet of glass, and this laid on a sheet of glass in the printing frame, the light had to penetrate through two sheets of glass and one thickness of tissue paper of No. 1 of the sensitometer before it reached the film. It is thus possible to expose a very sensitive plate under two sheets of glass and one thickness of tissue paper to a naked candle at a distance of one metre for one second without any noticeable fog being produced. At a distance of two metres the plate can be exposed for four seconds, and at five metres for twenty-five seconds without any harm. With quick manipulation and a light source sufficiently removed, it is thus very well possible to change dry plates with a naked candle flame, as has already been pointed out by Captain Houdaille (*Bull. Soc. Franc.*, 1894, p. 536) and Captain Abney (*Practical Photographer*, 1895, p. 250).

J. GAEDICKE.

#### THE MACKENZIE-DAVIDSON STEREOSCOPIC FLUOROSCOPE AND MERCURY BREAK.

MANY attempts have been made during the past two or three years to obviate the difficulty which perhaps more than any other has prevented the full use of X rays in medical work. This is the fact that on the fluorescent screen and in the X-ray photograph the image is flat, and, in the absence of the third dimension, it is impossible accurately to locate a foreign body or an injury to a bone.

Stereoscopic photography and "localisers" of various forms are frequently employed with more or less success, but both of these take a considerable amount of time and experience to use, and in practice are only employed in a few special cases by some operators. It is evident that, if the object could be seen with the fluorescent screen in stereoscopic relief, so that one could tell at a glance that a foreign body was, say, one inch from the surface, the gain would be enormous, as a surgeon, seeing the object in its actual position and its true anatomical relations, could afterwards operate with absolute certainty. Mr. Mackenzie-Davidson has fully accomplished this in his stereoscopic fluoroscope, which is so arranged that it can be used with an ordinary coil and batteries, and so can be added to any X-ray outfit.

So accurate and so easy to utilise is the stereoscopic image produced by this apparatus that, if a bullet be hidden in a loaf of bread, the operator can, while observing the image, insert a probe into the loaf, and make contact with the bullet at once, or can insert forceps and extract the bullet.

The facility with which this can be done, the bullet being found always at the first trial, is due to the fact that the probe is also seen in stereoscopic relief at the same time as the bullet and loaf.

The instruments consist of a rotating slotted disc and a double mercury make and break, these being driven synchronously by an electric motor.

Two X-ray tubes are used, the double break illuminating them alternately.

The makers of the instrument are Messrs. Newton & Co., 3, Fleetstreet, London, E.C.

Dr. Mackenzie-Davidson's new mercury break is constructed to work with any coil and any voltage, but is specially efficient with high voltages.

It is so arranged that it will work a coil with 12-volt or 100-volt current, and yet will admit of full saturation of the primary in each case. The effect in X-ray work is very marked. Using 100-volt current with this break on the ordinary 10-inch Apps-Newton coil, an adult's knee takes about ten to fifteen seconds to photograph, and other portions of the body in proportion, so that, by its use with high voltages, the time of exposure is greatly reduced.

Again, when used with the fluorescent screen, the make and break are so rapid that there is no flickering whatever visible, and the brilliancy of the screen is greatly increased.

The nature of the spark produced is similar to that of the Wehnelt break, with this important difference, that it is absolutely under control and can be increased or diminished at will. It also entirely does away with the irregularity of the Wehnelt break caused by the unequal size of the bubbles, as the time of make and break with this instrument is absolutely regular at all speeds. It can be used with any coil, and is a most desirable addition to any X-ray outfit, for the following reasons:—

Time of exposure for X-ray photograph is greatly reduced.

The brilliancy of the image on the fluorescent screen is greatly increased.

Flickering of the image on the fluorescent screen is entirely done away with.

Direct currents of high voltage from the main can be used.

It forms, indeed, the most efficient make and break yet designed, while the simplicity of construction is such that there is nothing to get out of order, and the cost of production is comparatively low.

The makers of this instrument are also Messrs. Newton & Co., 3, Fleetstreet, London, E.C.

#### THE MAKING OF AN ANIMATED PHOTOGRAPH.

MESSRS. HEPWORTH & Co., of Walton-on-Thames, are issuing a little book treating of the making of animated photographs. It is well printed and produced; the illustrations are good half-tone blocks from good original photographs, and the letterpress is interesting and clearly compiled.

One or two extracts may be of interest to our readers:—

The cheerful amateur, with his hand camera, who is used to developing quarter-plate negatives, and thinks himself endowed with almost superhuman genius—not to say foolhardiness—if he develop as many as four in one dish, will ask how can it be possible to develop a strip of film  $1\frac{1}{4}$  inches broad and 50 feet long, without producing, as the result, a hopelessly blotchy and mottled film? Visions of big tanks filled with developer and other chemicals, with these big masses of film tangling and writhing like so much seaweed, will rise before his mind's eye, and he will be further mystified when he learns that, at the factory with which this booklet is concerned, they are in the habit of handling film of forty times this length, or 2000 feet, in one piece. But that is not all, for when the perfect negative is produced there is much to be done before a print is ready for use in the projection cinematograph. In the first place, a positive print from the 50 feet negative is required, and a moment's reflection will show that every picture must absolutely coincide with the perforations upon the edges of the film, exactly the same as in the negative, if the projected scenes are to register with one another with that exactitude which is necessary to give the illusion of continuity. These perforations are the means by which the mechanical arrangement jerks the film through the machinery step by step with absolute exactness, and a single hair's breadth of deviation from accurate registration between one picture and the next would mean a jump upon the screen of a foot or more. Then, of course, the positive print, which is made from the negative by the action of light, must in its turn pass through all these processes of development, fixation, washing, and drying, before it can be rolled up and banded to the exhibitor.

*The Negative.*—A cinematograph camera is simply an ordinary photographic camera on a very small scale, with a mechanical contrivance added, whose duty it is to draw the film in a series of jerks past the lenses. Every time the film comes to rest behind the lens a shutter uncovers it for a moment and covers it up again. In that moment one picture is taken, and the mechanism moves the film on to the next position; then the lens is uncovered again, and another impression made, and so on, the operation being repeated twenty times in every second until the film is finished. Messrs. Hepworth & Co., at their factory at Walton-on-Thames, have several of these cameras always in readiness, charged

with film, for any photograph which is to be taken, and their operators through the summer are continually coming and going, bringing into headquarters the exposed negatives which they have procured on their travels. Then, too, there is an excellently fitted and thoroughly complete stage, erected in the open air, where small dramas are enacted for the benefit of an audience of one—a cinematograph camera—but of this we shall have more to say later. For the present, let us suppose that an operator has just returned with a valuable film representing some subject of great interest to the public, who will expect to see it upon the screen at their favourite music-hall on the same evening. The film is taken immediately to the dark room in order that the latent image upon its surface may be developed into a finished negative. In the early days of animated photography the methods of handling such a film were very crude and unpractical, although, indeed, such methods, somewhat amplified, are still in use among the more conservative of the early workers. In the dark room, according to the old *régime*, the film would be wound upon a large drum, which was successively revolved in several troughs containing the different chemicals. Or, by a similar but still less satisfactory plan, the film would be stretched upon pins projecting from each of the four arms of a frame in the form of a cross, and the whole submerged successively in the different chemicals. It will at once be seen that the difficulties of producing an equally developed negative by these means are very great, to say nothing of the obvious disadvantages of being restricted to some definite length of film; for cinematograph pictures nowadays are very often taken upon a pellicle, hundreds of feet in length, and, by the crude methods suggested, such films would have to be cut up into shorter lengths, which would then be treated separately. But in the factory under consideration all these crude implements have been swept away, and their places taken by specially designed machinery, which is open to none of these objections.

*The Developing Machine.*—The spool of film, which has just been brought in by the operator, is placed upon a spindle at one end of this machine, and by purely mechanical contrivance the film is gradually drawn first through the developing solution, which is contained in a long trough running throughout the length of the room. As the exposed film passes slowly along this trough, it can be examined by the operator in charge, and the process checked the moment it is completed. The whole length of the film goes under his observation, and any portion which requires different treatment can have it without detriment to the remainder. Then the film passes through running water, removing all traces of chemicals, and is once more drawn—still by the same machinery—through another trough containing the fixing solution. After that a lengthy washing awaits it, before the machine urges it in turn through each of the other chemicals which remain to complete its evolution. Finally, it is received upon another large spool, and the completed film is taken into another department to be dried.

*The Drying Rooms* are well-ventilated rooms, varnished on walls and ceiling to minimise the risk of dust, and sufficiently and thoroughly warmed by gas-stoves. Near the ceiling run a number of parallel horizontal wires, on which are strung hundreds of wire hooks, and from these hooks the film depends in long festoons, reaching almost to the floor. After a simple preliminary blotting process, whereby the surface moisture is removed, the film is hung in these festoons and dried, and each room is capable of accommodating between 2000 to 3000 feet of film. The rooms are fitted with several electrically driven fans, and, owing to the carefully considered system of heating and ventilation, and the constantly moving atmosphere, negatives can be dried in a very short space of time, and in the case of our imaginary picture, where speed is so essential, all possible precautions would be taken to hasten the drying process.

The production of really popular cinematograph pictures is daily becoming a matter of greater and greater difficulty, for, whereas in the early days of the art people were well content to be shown photographs of railway trains, steamboats, and street scenes, and the easily got pictures of that kind, they are nowadays far more particular, and will not accept anything which is not of a distinctly novel or startling nature. To supply this ever-increasing demand, Messrs. Hepworth & Co. send their operators further and further afield in search of novelty, and those who remain at home are continually preparing and executing miniature dramas for the amusement and entertainment of their patrons. Upon a well-furnished stage in the open air these dramas are enacted, after careful and elaborate rehearsal, amid all the requisite surroundings of scenery and accessories which the subject demands. In fact, quite an important branch of the business is continually occupied in the painting of scenery, the construction of "properties," and the manufacture of dresses and costumes for these short comedies. The camera

forgets nothing and notices everything, and the scenery and all accessories must be just as carefully prepared for a play which has a run of one performance only, and that lasts but a single minute, as if a three hours' entertainment were contemplated in the hope of a run as long as that of *Charley's Aunt*. There is a little staff of actors within easy call, who rehearse again and again until they are proficient in their respective parts for each of their playlets, and the spectacles to be seen on this miniature theatre are by no means confined to the simple comedy or farce. Various strange and startling effects can be produced by photographic and mechanical manipulation, and the most startling transformations and appearances may be brought about by comparatively simple means—effects as weird and unaccountable as any of those attributed to the wonder-workers of old.

Another increasingly important branch of the business is the production of animated photographs exclusively for advertisement purposes, and here again the *al-fresco* stage is called into requisition. The motto, "Animated photographs are the best advertisement," is already an accepted truth by the few who have put the matter to the test, and it will not be long before its truth is far more universally recognised. When it is remembered that hundreds of pounds are sometimes paid for a single picture to be turned into a poster advertising "somebody's soap," and the immense popularity which such a picture has obtained, it will readily be seen that, could that poster be suddenly brought to life, and endowed with animation and movement, the value as an advertisement would be increased very many times. The stage is, of course, principally used for the production of interior views, and, as the premises of this firm are surrounded by very varied and beautiful country, it is almost always possible to find some situation which offers natural scenery suitable for most requirements where exterior views are necessary. Needless to say, a woodland scene, if carefully selected, is very much better for photographic purposes than any painted representation of the same view could possibly be, and an open field or hill-side scene can be far better rendered by going direct to nature than by calling in the aid of the scene-painter's brush.

#### THE ECLIPSE OF THE SUN.

MR. MAUNDER, in the current number of *Knowledge*, describes an observation of the Total Solar Eclipse, 28 May, 1900, which yielded unexpected results. He says: "Mr. Evershed conceived a bold plan, which proved successful in all but one vital point, for which indeed Mr. Evershed cannot in any way be held responsible. Forsaking the central line with its many seconds of totality, he took his station near the edge of the shadow, where, as he hoped, his total phase would be reduced to some 20 or 25 seconds. His object was twofold: to get a rolling or grazing contact of the limbs of the sun and moon whereby the 'flash' would be given out all along the osculating surface, and to get the 'flash' not near the sun's equatorial regions, as do the observers on the central line, but at the sun's pole. Thereby it may be judged whether the constituents of the sun's surroundings vary with their solar latitude. In addition he used two large prisms in conjunction with a large reflector. Mr. Evershed found himself, when the shadow passed, about one hundred yards outside it, and not, as he had hoped, two miles within. Though actually outside the total phase, he got some photographs of the 'flash' of most exceptional beauty, but probably not one-fourth of the result which he would have got had he had more accurate values for the position of the shadow track. In another way his experience is of very great value, though not by any means in the manner he intended or desired. The farmers and sightseers in his near neighbourhood had a vehement discussion as to whether the eclipse was total or not. They divided themselves into two parties, those who saw the sun completely disappear, and those who described the corona as creeping round to the moon up to a point where there was a small remnant of sunlight. It got as far as this point but no further, and straightway began to creep back again and vanish. These latter also spoke of the sharp dividing line of light and shadow which sped across the Mediterranean to their left hand. The division was, or appeared to them to be, bordered by a bright line. Investigation proved that both the parties were in the right, for they had been separated by some five hundred yards, the line of total phase passing between the inner party and Mr. Evershed's tent. This unique observation affords a most accurate datum to correct the computation of solar eclipses in the future. It is a pity, however, that such an observation should have been at the expense of Mr. Evershed's special researches."

## SOURCES AND PROPERTIES OF BECQUEREL RAYS.

[Reprinted from *Nature*.]

In the following article a general account is given of a few of the more striking phenomena connected with Becquerel rays, including some of the recent developments of the subject at the hands of Becquerel, M. and Mde. Curie, and others.

Among a large number of papers which have lately been published, dealing with properties of these rays, two are worthy of especial notice, giving a comprehensive view of the phenomena. For those who propose to study the subject more fully, no better guide can be found than Professor Elster's report in Eder's *Jahrbuch für Photographie und Reproduktionstechnik* for 1900. The foot-note references to original papers form a complete bibliography of the literature of the subject existing at the time when the article appeared, and it is surprising that Professor Elster should have succeeded in summarising so large an amount of matter in eleven very small pages. Dr. B. Walter's article in the *Fortschritte auf dem Gebiete der Röntgenstrahlen* is somewhat less condensed and more popular; the chief phenomena, especially the photographic and fluorescent properties, are dealt with at greater length, and the article is illustrated by a plate of radiographs showing the difference between the actions of Becquerel and Röntgen rays. Already Walter's paper, and, to a less degree, Elster's report, have become out of date on the subject of magnetic deviation, and for this and other later developments no better guide could be found than the well-condensed summaries obtained in the current monthly parts of *Science Abstracts*.

The discovery of these rays in 1896 was a natural sequence of the discovery of the Röntgen rays, and was led up to, on the one hand, by the attempts of M. Henry to intensify the action of Röntgen rays by the use of phosphorescent substances; and, on the other hand, by the theory, once abandoned, that the Röntgen rays were themselves the result of phosphorescence of the vacuum tube. Becquerel and other physicists made numerous experiments to test whether phosphorescent substances emitted rays capable of acting on a photographic plate that was enveloped in opaque paper, and it was found that rays which produce actinic action were emitted by the phosphorescent salts of uranium, not only when these salts had been exposed to the action of sunlight or of Röntgen rays, but, even after they had been kept in the dark for months, the "radio-activity" showing no perceptible falling off.

## POLONIUM AND RADIUM.

The next step was the discovery by Mde. Curie, that Bohemian pitchblende—a black, shiny ore of uranium—possessed a higher degree of radio-activity than uranium itself, and this result naturally suggested the view that the ore contained, besides uranium, some other substance to whose presence the increased action was due. By separating the pitchblende into its constituents, M. and Mde. Curie were led to discover the existence of two sources of radio-activity, one associated with the compounds of bismuth, and the other with those of barium occurring in the ore. Seeing that barium and bismuth obtained from other sources do not emit Becquerel rays, these radiations were attributed to the existence of two new substances, that associated with bismuth being named polonium, a name derived from the Polish nationality of Mde. Curie, while the other substance associated with barium chloride was called radium. The separation of these two substances has led to the production of rays of sufficient intensity to excite fluorescent screens, discharge electrified conductors, and, indeed, to reproduce, with differences, most of the properties of Röntgen rays. A third radio-active substance, produced from the residues of pitchblende, is recorded by Debierne, who names it actinium. It is precipitated by the principal agents for titanium, and it emits rays which reproduce the same phenomena as the rays emitted by radium and polonium, and are 100,000 times the intensity of ordinary uranium rays. Certain thorium compounds are also radio-active, a property first established in these by G. C. Schmidt and Mde. Curie, and subsequently investigated by R. B. Owens and Rutherford.

Since this article was in the printer's hands a paper by Sir W. Crookes on the radio-activity of uranium, read before the Royal Society on May 10, has been received. The author records an entire absence of radio-active effects in all the barium minerals in his cabinet from which uranium was absent, while pitchblende and other minerals containing uranium and thorium excited a photographic plate. Arrangements were made for working up half a ton of pitchblende, and the radio-activity of the uranium salts was definitely traced to the presence of a foreign body, which Sir W. Crookes has christened for the time  $U_{rX}$  (i.e., the unknown quantity in uranium), following a fashion initiated by Röntgen, and which has previously led to the introduction into our vocabulary of such terms as "X<sub>d</sub> air" (Italian "aria Xata" or *ixata*).

We would suggest the name "Crookesium" as a substitute. Whether uranium-X is, or is not, identical with radium seems not fully decided but it appears to be distinct from polonium. It is now proposed to try to separate the radio-active component of thorium.

## THE DARK LIGHT.

Le Bon, who claims to have anticipated the Becquerel rays in his "*lumière noire*," has expressed the opinion that the properties attributed to radium and polonium do not prove the existence of new elements, and may be accounted for by supposing the radio-active substances to be mere allotropic modifications of bismuth and barium. On this view there is no more fundamental difference between the properties of radio-active and ordinary barium than between phosphorescent and ordinary sulphuret of lime. Giesel, of Brunswick, also has adopted the terms "radio-active barium" and "radio-active bismuth" in preference to "radium" and "polonium." In support of the opposite view, Demarçay has proved that radium possesses a characteristic spectrum, and M. and Mde. Curie find that the atomic weight of radio-active barium chloride is greater than that of ordinary chloride, amounting, in one specimen, to as much as 145 as against 137.

The pitchblende used in the preparation of these substances is obtained from Joachimsthal, in Bohemia. Under the direction of Giesel, working in co-operation with Professors Elster and Geitel, the firm of E. de Haën, of Liest, near Hanover, have undertaken the preparation, in small quantities, of radio-active barium emitting rays that are unequalled in intensity, and have also placed on the market cheaper by products which also emit rays of sufficient intensity to visibly excite a fluorescent screen. The solid radio-active compounds of barium increase in activity from the time of solidification, but do not reach their maximum for more than a month. The barium preparations are all luminescent, the chloride and bromide, especially so when dry. According to Giesel, the bismuth or polonium preparations lose their radio-activity in a few weeks, and this property is also cited by Elster.

## BECQUEREL RAYS.

The radio-activity of barium bromide is found by Elster not to be destroyed by continuous heating for twenty-four hours *in vacuo*. After cooling, the strength is much reduced, but is restored after the lapse of a few days to nearly the original intensity.

Becquerel rays resemble Röntgen rays in their power of "ionising" air, a property they possess to such a degree as to discharge all conductors within a considerable distance of the radio-active substance. Their action on electric sparks has been studied by Elster and Geitel. A spark gap one cm. wide, consisting of a positive knob and a negative disc, was exposed to the radiations from a barium preparation. The sparks or brushes were converted into a violet glow discharge, but the former discharge was re-established on interposing a plate of lead. With discs made of semi-conducting card the radium affected the discharge at a distance of over one metre. According to Elster, heating a small trace of a radio-active substance in air in a Bunsen flame increases the electric dispersion of the air of the room.

Becquerel finds many bodies acquire the temporary power of discharging conductors under the influence of the rays, thus affording proof that these rays involve a continuous emission of energy. The bodies do not, however, act on a photographic plate, and their activity is lost on heating. This property is not assumed by the double sulphate of uranium and potassium.

There appears at present no prospect of utilising Becquerel rays as a substitute for Röntgen rays in surgery. The difference of behaviour of the two kinds of rays is well shown by two radiographs of the human hand accompanying Dr. Walter's paper. In the one taken with Röntgen rays the outlines of the bones are remarkably clear and sharp; in the other, taken with the rays emitted by Giesel's most powerfully radio-active preparations, a dark, ill-defined shadow of the outline of the hand is seen, but not a trace of the bones is visible. This latter radiograph, which was taken with the relatively short exposure of an hour, shows clearly the shadows of a needle and of a coin that were placed under the middle of the hand, proving that a certain proportion of the rays had actually passed through the hand, but without differentiating the bones from the rest. Experiments undertaken by Walter to account for the hazy outline of the Becquerel radiographs point to the conclusion that the Becquerel rays, when passing through substances of small atomic weight, experience a far greater diffuse scattering than Röntgen rays. Further, the secondary radiations emitted by both light and heavy substances under the influence of the Becquerel rays differ far less from the incident rays in intensity and penetrability than in the case of the secondary rays investigated by Sagnac in connexion with Röntgen rays.

A further difference lies in the far greater absorption of Becquerel rays by specifically light substances, such as those forming the flesh of the human hand. With the use of a platino-cyanide of barium screen, Walter observed the same absence of all traces of bones as with photographic methods, although the shadow of the hand was clearly seen on the screen.

#### COMPOSITE NATURE OF BECQUEREL RAYS.

The composite nature of Becquerel rays is suggested by experiments on phosphorescence and selective absorption, as well as on magnetic deviation. Mde. Curie has found that Becquerel rays are more easily absorbed when they have already penetrated an absorbing layer than when they have not. One aluminium disc absorbed a certain proportion of the rays; a second aluminium disc absorbed an even greater proportion of the remainder. According to the note on Mme. Curie's paper in *Science Abstracts*, "this is due to the fact that the less penetrative rays are absorbed in the first absorptive layers," but such a view would more naturally lead one to expect that the proportion of absorbed rays would be less at the second screen than the first, instead of greater; the phenomena can, however, be accounted for by the hypothesis that the first screen transforms the rays into secondary rays of lower penetrating power. The existence of such secondary rays has been supported by Villard, Meyer, and Schweideler, Dorn, and others. Becquerel has, however, shown that, in the case of polonium rays from the Curies' preparations, no secondary rays are emitted by aluminium. The phenomenon of selective absorption has been studied by Becquerel, who exposed various substances to the action of radio-active barium chloride, including hexagonal blende, platino-cyanide of barium, diamond, and double sulphate of uranium and potassium. The phosphorescence varied in different cases. When different screens were interposed, namely, aluminium, mica, black paper, glass, ebonite, and copper, the absorptions of the radiations which excite phosphorescence in different substances by the same screen were found to be unequal. R. B. Owens has shown that thorium radiations resemble those associated with the derivatives of uranium ore, but possess greater variety. There are indications that they are not confined to so few distinct types, if, indeed, the number of types is limited. Becquerel shows that the absorption of radium rays by screens is variable according to the distance of the screens from the source, and that the intensity of the radiation decreases with the distance more rapidly than it would do according to the law of the inverse square; both of these are results of absorption by the air. The view advanced by Le Bon two years ago, that Becquerel rays could not be polarised, has been confirmed by Rutherford.

#### MAGNETIC DEVIATIONS OF BECQUEREL RAYS.

The magnetic deviation of Becquerel rays has absorbed a large amount of attention during the last few months, and conclusions from recent experiments have in several instances been in contradiction with the inferences from earlier investigations. Thus a survey of the literature of the subject shows that, amongst others, the following views have been advanced: (1) that Becquerel rays are not deviated; (2) that they are deviated in air, but not *in vacuo*; (3) that the deflection gives rise to phenomena which are more marked with polonium than with radium; (4) that both radium and polonium rays are deviated *in vacuo*; (5) that radium rays show marked deviation, but polonium rays show no deviation whatever. The first negative result was obtained by Elster and Geitel; Giesel proved the magnetic deflection of the rays in air, and attributed the previously observed absence of deflections to the experiments having been performed *in vacuo*. Elster, by repeating the experiments with a different arrangement of apparatus, using the same radio-active bismuth and barium as in Giesel's experiments, has discovered the cause of his previous failure, and has established the magnetic deflection of the rays *in vacuo*. Giesel used a strongly radio-active bismuth preparation, and got more marked effects than with his barium compound; Elster, using a similar bismuth preparation and a relatively feeble one of barium, was led to infer that the barium radiations were the most deflected. In these experiments the rays are received on a photographic plate or fluorescent screen. P. Curie, on the other hand, has described an apparatus for comparing the magnetic deviation by means of the electro-dispersion produced by the rays. When not deviated, the rays pass out normally between two lead blocks, and traverse the space between the plates of a condenser, causing a current to flow; when deflected, the rays are absorbed by the lead blocks, and the current ceases.

Both Curie and Becquerel find that the magnetic deflection varies with different substances. According to Becquerel's paper of December 26, polonium showed no deflection, while radium showed a strong deflection,

The absence of deflection in polonium rays has been observed by Mde. Curie, who states that they travel in a straight line. In comparing these results with the different conclusions obtained by Elster, reference must be made to Dorn's hypothesis, according to which it is suggested that the primary rays are not deflected, but are transformed into deviable secondary rays. But, in a recent paper, Becquerel finds that the Curies' polonium rays are neither deflected by a magnetic field of 10,000 C.G.S. units, nor are they transformed into deviable secondary rays. He has also made experiments to test whether the curvature of radium rays is affected by interposing a screen, as would occur if the transmitted rays were secondary rays moving with lower velocity. No such effect has been as yet observed. The most probable inference at present is that there are two kinds of rays, one deviable and the other not. The Curies find both forms coexist in radium rays; and, from Giesel's experiments, the deviable rays certainly exist in some preparations of polonium, but were, doubtless, not present to an appreciable extent in the samples experimented on by the Curies and Becquerel. According to Curie, the rays from radio-active barium carbonate are deflected to a very different extent. Those rays which have the greatest penetrative power are the most easily deflected, and those rays which are not deflected only penetrate air to a distance of 6 or 7 mm. Becquerel finds that magnetically deviable rays are absorbed by different screens up to a certain inferior limit of distance, while they penetrate a screen that is placed sufficiently near the source.

When the magnetic field is uniform, and the direction of the rays is perpendicular to the lines of force, they describe circles and return to the starting point; when the rays start in a direction oblique to the lines of force, the paths are helices. These results have been recently verified by Becquerel, and from them it is possible to form a general prediction of the corresponding effects produced in a non-uniform field, such as that produced by a horseshoe magnet, which effects we now proceed to describe.

In Giesel's experiments the sensitive plate was laid on the poles of the magnet, film downwards, the polonium being placed below and in contact with the film. Between the black patch produced above the substance and the dark zone produced by the deflected rays, a number of dark traces were observed, resembling wavy hair, or like the ramifications in Lichtenberg's figures. Becquerel has shown that, when the radio-active barium is placed on one pole of an electro-magnet and a fluorescent screen on the other, the effect of exciting the magnet is to concentrate and contract the luminous area, a result unaltered by reversing the poles. When the rays pass across the lines of force, they, after proceeding upwards, are bent round, and impinge on the plate along a curve, which extends from one pole to the other, bending out of the way of the radiant substance in the centre. When a piece of radium preparation is placed on a plate in a uniform field near a plane normal to the lines of force, the result is an intense impression limited by a spiral, whose sense is that of the current which produces the field. This spiral is the trace, deformed by the field, of the line of intersection of the vertical plate and the plate on which the radium rests.

#### DEVIATION.

In the *Journal de Physique* for April, Becquerel shows that different radio-active compounds of barium emit rays that are equally deviated, and he establishes the fact that the deviation conforms to laws similar to those which apply to cathodic rays. The phenomenon of dispersion is established, and, by interposing strips of paper, aluminium, and platinum against the gelatine plate, on which the deflected rays are received, a kind of absorption spectrum is obtained, showing that the most deviable rays are the most readily absorbed under the conditions of the experiment. By calculating an inferior limit to  $H\rho$  (the product of the magnetic force and the radius of curvature of the path) for the rays transmitted by various screens, the absorption by different substances is compared, and the results are of the same order of magnitude as for the cathodic rays. These and other facts suggest that part of the radiation is of similar nature to the cathodic rays, where small, negatively charged masses are transported with great velocity, and the Curies' experiments prove the existence of such charges, which, however, are exceedingly feeble. According to this view, the magnetic deviation is given by the formula,  $vm/e = H\rho$ , and, in an electrostatic field of intensity,  $F$ , the rays ought to undergo a deviation,  $\theta = Fl \div (v^2m/e)$ ,  $l$  being the length of the path. It appeared, at first, that the electrostatic force required to make any such deviation visible would exceed the limit for which disruptive discharge would take place in air, and could only be obtained *in vacuo*. In a foot-note, however, Becquerel tells us that he has since observed the electric deviation in air with a field of about  $10^{12}$  C.G.S. units, and has

found for certain rays which pass through black paper the values  $m/e=10^7$  and  $v=1.6 \times 10^{10}$ .

#### CHEMICAL EFFECT OF BECQUEREL RAYS.

The chemical effects of Becquerel rays have been examined by M. and Mde. Curie and Becquerel. They may be briefly summarised here: The rays from active salts of barium transform oxygen into ozone, a process involving a continuous expenditure of energy. Potassium iodide is coloured blue. Glass in contact with the salts is coloured violet, ultimately becoming nearly black, and the colour penetrates the glass. This phenomenon is analogous to the colouration of fluor spar by cathodic rays. Platinocyanide of barium screens gradually turn yellow, then brown, and finally lose their fluorescence, which, however, is restored by exposure to sunlight. Fluorine continues to phosphoresce for twenty-four hours after being excited, and calcined fluor spar which has lost its phosphorescence regains its luminosity in the presence of radium. Chemical activity is confined to those radio-active preparations which are luminous, but is not always proportional to the luminosity.

According to the Curies' experiments, powerfully radio-active compounds of radium and polonium, when they act on inactive substances, are able to communicate radio-activity to them. This induced radio-activity increases with the time of exposure up to a certain limit. If the inducing substance is 5000 to 50,000 times the activity of uranium, the induced activity may amount to fifty times that of uranium. It is reduced to one-tenth of its amount in an hour after removal, but it may persist for many days, finally disappearing. The emanation of radio-active particles from thorium compounds, investigated by Rutherford, is remarkable. This emanation ionises the gas in its neighbourhood, and it will pass through thin layers of metal, through thicknesses of paper, or through a plug of cotton-wool. It is also unaffected by bubbling through hot or cold water, weak or strong sulphuric acid. The emanation retains its radio-active power for some minutes, gradually losing it. The positive ion produced in the gas by the emanation was found to possess the power of inducing radio-activity in all substances on which it fell, this power of giving radiation lasting several days. Whether the emanation be a vapour of thorium is doubtful.

The question as to the amount of energy emitted by the Becquerel rays has already been referred to in *Nature*, and need not therefore occupy our space further now. The problem of discovering the seat of this energy would seem of late to have taken another form. At first it was supposed that a difficulty would exist in reconciling the continuous emission of these rays with the principle of conservation of energy; now, however, that the amount of the emitted energy has been estimated, the difficulty is seen to lie in the experimental observation of changes of such inappreciable magnitude as would suffice to generate this energy.

Before 1896 physicists were just beginning to grasp Maxwell's theories, and to realise more clearly the simplification introduced into notions electric and optical by the conception of the ether. The discovery of rays capable of discharging electrified bodies in air has not only shown the fallacy of our preconceived dogmatic notions as to the division of substances into conductors and dielectrics, but has taught us that the properties of the ether are not so simple as we had anticipated. We can only wonder whether Maxwell would have been able to develop his electro-magnetic and electro-optic theories had the complications arising from Becquerel and other rays been before him, and the want now makes itself felt of a second Maxwell, who shall co-ordinate the newly accumulated mass of experimental facts into the form of a connected mathematical theory.

G. H. BRYAN.

#### GAS CYLINDERS AND THEIR MANIPULATION.

STRANGE as it may appear to those who are regularly manipulating compressed gas in cylinders, and who never experience the slightest fear in handling them, there exists on the other hand a large number of nervous people who look upon cylinders as bomb shells, and never feel comfortable in close proximity to them, and this nervous feeling is not infrequently found among amateur lanternists to such an extent as to cause them to become more or less shaky when manipulating a lantern show, even although they have quite satisfied themselves that there is no actual ground for such nervousness.

When it is borne in mind that every cylinder has to pass through a series of the most exacting tests before it is permitted to be used by the public, or even charged to a limited extent with gas, it must be evident that there is no ground for anxiety when manipulating highly compressed gases.

All cylinders that are charged and employed at a pressure of 1800 lbs. are firstly tested to 4000 lbs. per square inch, and, to make certain that

this straining in testing in no way weakens the cylinder for future use, special apparatus has been devised, whereby the elasticity of the metal employed in the manufacture of the cylinder is ascertained. This apparatus was designed some ten years ago, and since then has never failed to indicate the correct expansion and contraction of the metal in a properly constructed cylinder.

In manipulating the gas from a fully charged cylinder, confidence in the actual safety of the operation is of the first importance, and, if any one cannot approach the work without a feeling of nervousness, he should refrain from having anything to do with limelight projection.

For many years there was a distinct prejudice against the use of compressed gas in lantern projection, a prejudice that was fostered not so much by dread of accidents as from the liability of the cylinders to leak, and also by reasons of faulty valve spindles in those of earlier construction. All this (with professional lanternists, at least) has passed away, and this method of utilising gas has become a necessity with modern projection apparatus, and although it would, perhaps, be going too far to say that leaky cylinders do not now exist, still it is really wonderful what little inconvenience the public now experience from this source, especially when it is borne in mind what a number of hands a cylinder has to go through even in the course of a year, many of whom have but little experience in the turning on and off of the valves. That the utmost care is bestowed by the different oxygen companies, when charging previously used cylinders, is from this fact alone apparent, for no employé in any company would ever dream of sending out a cylinder whose valve was faulty, there being a simple but extremely certain test applied to every fully charged cylinder, to see that all valves are absolutely tight before such leave the works. It may, no doubt, happen that a careless assistant in some optician's warehouse may, by over-racking a valve spindle, injure the same in its sealing; but this is just where some experience is needed on the part of those permitted to manipulate a cylinder, and shows the necessity for the utmost vigilance and forethought on the part of those who are to operate with such cylinders, a golden rule being "never to depart without fully testing every part of a lantern outfit, and if any doubt take double cylinders."

It seems strange that what is really such a simple operation, as turning on the valve for the emission of gas from a cylinder, should puzzle so many people. Yet it is a striking fact, that many amateur lanternists, who would no doubt feel offended were any one to question them on this point, invariably do, in this simple operation, the very opposite of what they ought to do.

Some say they become nervous and lose their heads; at any rate, the experience of the oxygen companies goes far to show that the number of those who make mistakes in this direction are more numerous than many would suppose, and a few years ago this fact was apparent by the number of broken spindles that were produced by endeavouring to open a cylinder by turning the spindle in the wrong direction. This led to the various companies supplying a most ingenious key, with which it is practically impossible to turn a spindle in the wrong direction, or over-strain the same in shutting off the gas again; but, in the earlier make of cylinders, the spindles were made of softer metal than what is now employed, and this has to a certain extent improved matters in this direction.

Most people know, when using a screw-driver, that, when it is desired to send home a screw, the former must be turned to the right, and, when taking the same out again, the turning must be made to the left. Now, although the opening and closing of a spindle in a gas cylinder has to be done in exactly the same manner—that is, unscrew to the left when opening, and screw to the right when shutting off—somehow or other people will do the very reverse, and if the spindle is any way weak, or made of unduly soft metal, it is almost sure to result in the fracturing of the tool, and, unless an operator possessed of a large amount of experience be at hand with a suitable spanner, to unscrew the containing nut of the valve, there will be a poor chance of the intended show coming off with that cylinder, for a broken spindle is a very nasty thing to have staring one in the face, just on the eve of a lantern exhibition. If this awkward event should befall any one, the large spanner must be employed, with the utmost caution, and, if the gas does not come with a slight turning of the nut, it must not be proceeded with to any great extent, for fear of its being blown off, with disastrous results.

As a rule, however, the gas will respond to a slight turning with the large spanner; but this should only be attempted with caution and as a last resort.

In opening the valves of fully charged cylinders, only a slight turning of the valve spindle is necessary, or desirable, and, whenever a regulator

or fine-adjustment tap is being attached to a cylinder, the gas should always be turned on previously for half a second or so, so that a good rush of gas will effectually blow out any slight particles of grit or other matter which might otherwise interfere with the exact sealing of the regulator in the cylinder. It is surprising what a little matter in the wrong place will do when screwing up a regulator. To effect an absolutely tight union between the two nozzles, soft metal washers have been invented, but somehow or other these have never come into general use with professionals, at least so far as the West of Scotland is concerned. The idea, however, is a good one, and these soft lead washers are useful for preventing any leakage of gas between the cylinder and regulator.

The gauging of the contents of a cylinder is, of course, easily performed with a reliable gauge, and a little practice will soon teach any one to arrive at a correct estimation of the contents of a full, or partially full, cylinder. There is a very simple method—which is, perhaps, not so well known as it might be among lanternists—for at once reading the contents of a cylinder by means of a gauge.

In estimating the pressure as shown by the gauge, let the gas be very slowly and slightly turned on, and wait a little until the full back pressure of the cylinder has been admitted to it. On no account should the full pressure be at once screwed on. When the recording finger indicates the full pressure, note the number of atmospheres it indicates, and divide it by the constant factor of the cylinder. This factor, in the case of a forty-foot cylinder = 3; in the case of a twenty-foot cylinder = 6; in the case of a ten-foot cylinder = 12; and these factors are derived by dividing the capacity of cylinder with the number of atmospheres it will contain when full. All cylinders when fully charged contain 120 atmospheres, and therefore in the case of, say, a forty-foot cylinder, which indicates by pressure gauge, say, sixty atmospheres, when this is divided by three it shows it to contain just twenty feet, or, in other words, is half full; and the same with all other sizes of cylinders when divided by their own factors.

A reliable pressure gauge is a great convenience, and is absolutely necessary where much lantern work has to be undertaken. By, however, weighing the empty cylinder and noting carefully the tare of it, and again weighing the cylinder when fully or partially full, the contents of an oxygen cylinder can be estimated with a fair amount of certainty, because it is well known that one ounce of oxygen equals 0.7 of a cubic foot very nearly, and from this it is easy to calculate how much gas has been used from a full cylinder. In dealing with private cylinders this knowledge is useful, and I believe it was Mr. C. H. Cathcart who first drew attention to this method of ascertaining the contents of an oxygen cylinder. But for all practical work a gauge is necessary.

In turning off the gas at the close of an exhibition (or at any other time, for that matter), when a considerable amount of time is to elapse before the cylinder is likely to be used again, care must be exercised to see that the valves are quite tight; this is best done by placing a little water in the neck of the cylinder—if there is any escape of gas, it will be at once apparent. It should, however, be borne in mind that no undue pressure should be applied to valve spindles, and the large spanner should be used to tighten up the glands, if the same require it.

The question is often asked how much gas should have been used for some particular exhibition, and this is just one of those things that puzzle not a few. The chances of escape of gas by reason of faulty connexions and apparatus is so great that even experienced operators cannot, at times, account for the results they obtain, and sometimes the gases vary in quality to such an extent as to make the consumption difficult to understand. The question of economy in the using of compressed gas is one that has exercised a good many operators; a careless operator will run through a lot of gas without ever reaching a really good light on the screen; while, on the other hand, an experienced man will, by careful adjustment of apparatus and attention to fittings, get a better light with far less consumpt; and on the score of economy, where a cylinder has to do duty more than once, perhaps, a forty-foot cylinder will be found best, and there are those who maintain that a steadier pressure is got from a large cylinder than from those of smaller size.

It is, of course, well known that all hydrogen-regulator and fine-adjustment taps, so far as their union threads are concerned, are left-handed screws, but this does not mean that a hydrogen valve spindle has to be turned in the opposite direction to that of an oxygen cylinder when opening and shutting off the gas. The writer knows, however, that several instances are on record where the spindles on hydrogen cylinders have been fractured by operators turning them in the wrong direction, under the belief that the spindles were left-handed screws on hydrogen cylinders.

These mistakes, of course, only arise from ignorance.

T. N. ARMSTRONG.

## IMPROVEMENTS IN OPTICAL PROJECTION APPARATUS.

[Szczepanik's Patent No. 17,514 of 1899.]

THE patentee says that it is known that each portion of the opening in the diaphragm of an objective is sufficient to project an image. Hence, in order to project simultaneously two, three, or even more images, the pencil of rays passing through the diaphragm is divided into two, three, or more portions by means of mirrors. Consequently each portion forms an image which can be reflected by means of mirrors upon any desired surfaces.

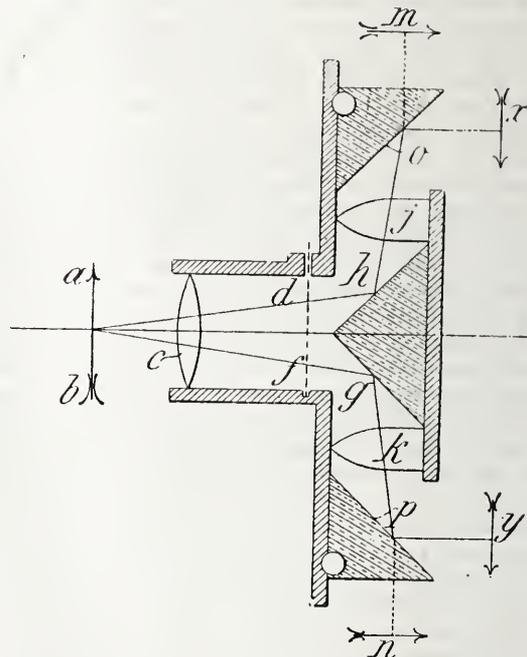

$a b$  is the object, which, in the case represented, is to be projected in duplicate.  $c$  is a lens or system of lenses.  $d, f$  is the diaphragm opening.  $g, h$  are two plane mirrors, the edges of which divide the pencil of rays passing through the diaphragm into two parts.  $j, k$  represent two lenses or systems of lenses.

It is obvious that the two lenses,  $j$  and  $k$ , yield exactly similar and sharp images, which appear on the surfaces,  $m$  and  $n$ . If, however, one wishes to direct the said images upon one and the same surface, two mirrors,  $o$  and  $p$ , must be used in addition, which are parallel to the mirrors,  $g$  and  $h$ . By this means two images,  $x$  and  $y$ , are reflected upon one surface.

For different sizes the lenses,  $j$  and  $k$ , must be moved away by equal amounts from the axis, which can be done in a known way by means of toothed wheels and racks, or of worms and worm wheels. If transparencies (*i.e.* translucent positives) are secured in the places of the images,  $x$  and  $y$ , and illuminated by means of condensers, one obtains from the two transparencies a common sharp image.

In a similar way, an apparatus for three images can be constructed.

By means of such an instrument it is possible to produce naturally

coloured images. This is done in the following manner: Three colour filters, for blue, yellow, and red respectively, are inserted; one before each projected image, and either in front of the surface on which the images are projected, or just behind the diaphragm orifice,  $d f$ . If, from the negatives obtained, one produces three transparencies, all the three images resulting from these three negatives, when placed in the position of the negatives from which they will have been produced, will, if three colour plates be used, be differently coloured, and will jointly yield, as is known, an image in natural colours. Since only a portion of the diaphragm is used, the luminous intensity of each individual image is small. In spite of this it is possible to project very luminous images by using a special source of light for each transparency. In this way one has at disposal three sources of light instead of one.

Since the exposures for different colours are different, the pencil of rays proceeding through the diaphragm opening must be divided by the mirrors in such a manner that the effects of the exposures for all the openings are equal in the same time for all three colours.

To take the photograph for each colour separately, the corresponding colour filter may be inserted in front of the objective, and the two other images that are not to be photographed be prevented from appearing by suitable diaphragms.

The apparatus hereinbefore described can also be used to produce two or more similar images simultaneously, also to produce simultaneously several images with different stoppings-off, and, further, for making use of one image for focussing on the focussing screen, and the other for photographing.

### LANTERN NOTES AND NEWS.

THE first illumination of the Electric Palace and Fountain at Paris took place recently. An immense crowd had gathered to witness the sight, and at nine o'clock the circulation became difficult in this part of the Exposition. The public were not disappointed, for not only was the front of the Electrical Palace lighted up with a succession of colours, but also the fountain of the Château d'Eau was illuminated for the first time. The appearance of the fountains when viewed during the day is pleasing; the jets of water in the various basins are projected to a considerable height, and a number of sprays are sent into the basins from different sculptural groups around the border. At night, when the light is sent up from below into the jets, a strikingly brilliant effect is obtained, and the cascades appear blue, green, purple, or golden, as the different coloured lights are used in succession; the fountain is thus visible from all parts of the grounds. The rich carvings and reliefs of the great central arch reflect the light of different colours, and are thus seen under a new aspect.

\* \* \* \* \*

THE London County Council's new by-laws issued a few months since deal with window-cleaning, painting, and flash or search lights. A fine not exceeding 5*l.* is imposed upon any person who, to the obstruction, annoyance, or danger of residents or passengers, orders or permits any one to stand on the sill of any window for the purpose of cleaning or painting, at a height of more than six feet from the level of the ground, without support sufficient to prevent the person from falling, and a fine not exceeding 20*s.* for the person who stands on the sill under the circumstances. The second part prohibits the exhibition of any flash light so as to be visible from any street and to cause danger to the traffic. The expression "flash light" means and includes any light used for the purpose of illuminating, &c., any word, letter, model, sign, device, or representation in the nature of an advertisement, &c., which alters suddenly either in intensity, colour, or direction. Search lights are prohibited under the same conditions as flash lights, the term "search light" meaning and including any light exceeding 400 candle power, whether in one lamp or lantern or in a series of lamps or lanterns used together and projected as one concentrated light, which alters either in intensity, colour, or direction.

\* \* \* \* \*

A SOUTH AFRICAN correspondent writes: "We here have one great drawback, we are unable to get gas in bottles, so have to resort to the gas-bag and saturator. Now, as you are aware, the

pressure on a bag is limited (mine is an eight-foot bag), and frequently I have two hundredweight pressure on same; it is not safe to do more. The intensity of the light is limited by the pressure, and not so much by the quantity of gas consumed. What is wanted is some small handy machine which will enable a lanternist to pump the oxygen from a bag into a bottle; this, I fancy, is possible, but would take some time to accomplish. Otherwise, I do not see how we can get a brighter light than about 400 candle power out here. A Manchester injector jet has been sent to me from England with an outfit, and of course as such is perfectly useless. I have, however, altered it, and am able to use it, but the light is far from good."

\* \* \* \* \*

A GLASGOW correspondent informs us that there are one or two new things coming out for next season's lantern production. One is a new regulator, and another a most ingenious lantern key, in fact quite a *multum in parvo*. There is a chance of a Compressing Company starting at Cape Town. At the present moment all compressed gas is sent from this country, and there ought to be a good field out there when things get settled down. Our correspondent adds: "I know one manager of an oxygen works who is seriously contemplating starting a company in South Africa. I have heard of a startling hitherto unsuspected source of danger in the use of saturators. They ought to be put down by Government."

### LIMELIGHT MATTERS.

#### THE QUALITY AND CONSUMPTION OF GAS.

"SOMEHOW or other, I did not get the light to-night I should have had." How often is a remark of this description heard at the close of a limelight exhibition, even the best operators being frequently at a loss to account for the poor light they have obtained; and then, very probably, in their eagerness to bundle up the apparatus, in order to catch the last train, no more is thought about the matter for the time being, but the following morning, on proceeding to gauge their cylinders, they are surprised at the amount of gas they have run through on the previous night, and are more puzzled than ever to account for the poor quality of the light and excessive consumption of gas. This is, doubtless, the experience of many operators in limelight work, and, when they endeavour to reason out in their minds the why and the wherefore for such a condition of things, it is just about ten to one they blame a leaky tube or badly fitting joint somewhere, or the regulators were faulty, or the cylinder valve was not tight, seldom placing the finger on the actual cause of the short-coming.

Most limelight operators, after a little practical experience with their apparatus, and especially by reason of their studying the aperture of the jet they employ, will be able to form a fairly correct estimate of the amount of gas they are likely to require in fulfilling a particular engagement on hand, and then, by making a fair allowance of margin over and above the estimated consumption, they enter upon their engagement without any misgivings on the score of running short of gas. Yet, even with all their forethought, how often is an exhibition saved by the narrowest shave?—for here again the question of excessive consumption of one or other or both of the gases crops up, and they are quite at a loss to under-

stand how such a condition of things could have happened, when, with the same jets, regulators, &c., they have been able to yield a better light for a much longer period with far less gas.

In limelight working (especially since the introduction of compressed gas in cylinders) the "mixed gas jet" has become deservedly popular with professional and amateur lanternists alike, for any misgivings on the score of safety which may have been felt in the days of gas bags do not exist in working from cylinders; but were many of these lanternists, who invariably use the mixed jet in preference to the blow-through form, asked in what proportion the gases are burned in such jets, quite a variety of opinions would be expressed.

In the early days of the lime light it is well known that the gases were mixed and stored in their combining proportions in *one bag*, these proportions being two-thirds of pure hydrogen and one-third of pure oxygen; but, with the gases in this state of combination, only very small apertures in the jet could be employed.

The extremely dangerous nature of the gas in this condition soon led to the gases being stored in different receptacles, and no sooner was this done than a much greater degree of safety and comfort in working was assured, especially when both gas bags were placed under double-pressure boards, and acted upon by one and the same set of weights.

With the introduction, however, of the double gas-bag method of working, further important changes took place; not only was greater safety secured, but a very important alteration took place in the quality of the hydrogen gas employed, and it is to this alteration, no doubt, that much misconception exists in regard to the different proportions of hydrogen and oxygen gas consumed at the present time.

It has been said that originally the gases were combined and turned from the one bag in the proportions of two-thirds pure hydrogen to one-third pure oxygen; but, to utilise the gas in this extremely explosive condition, only very small apertures in the nipples of the jet could be employed with safety, and it may surprise many operators of the present day, and who have had even no experience of gas bags, to learn that bores larger than one-eightieth of an inch could not be used to burn the gases when in their combining proportions in one bag.

Such extremely small apertures will appear strange to present-day operators, who now seldom use a jet with a bore smaller than the twentieth to the twenty-fifth of an inch, and frequently as large as the fifteenth of an inch; and, although it would be, perhaps, going too far to say that with such extremely small apertures a light was obtained equal to what an operator can produce with modern apparatus at the present time, still very fair results were yielded *with an extremely small consumption of gas*.

With the introduction of the double gas-bag method of working, "pure hydrogen" was seldom employed unless in out-of-the-way places and in laboratories, simply by reason of the much greater ease in filling a gas bag with carburetted hydrogen from the main supply pipe of any dwelling house. Pure hydrogen, therefore, was much more seldom in use, the carburetted form of this gas taking its place.

Lanternists, however, seem to have given but little consideration to the difference that exists between the combining proportions of carburetted hydrogen and oxygen as compared with that of pure hydrogen for lime-light purposes, and we see this exemplified in a marked manner by several practical limelight operators actually writing articles and handbooks, in which the combining proportions of pure hydrogen and carburetted hydrogen with oxygen are given as the same with both forms of gases. This has, doubtless, led to much misconception on the part of those lanternists who have an idea that it does not matter whether house gas or pure hydrogen be used, the consumpt of gas will be nearly the same in both cases. To understand exactly the wide difference that exists between the combining proportions of the three gases, a student would do well to study a good treatise bearing on the subject of gases. It may, however, here be remarked that with pure hydrogen the combining proportions are two parts of hydrogen and one part of oxygen, whilst with the carburetted form of hydrogen the proportions are two parts of oxygen to one part of hydrogen, but with the carburetted form of hydrogen greater impurities are present.

To many these combining proportions do not appear to dovetail with their actual experience in the use of these gases by means of the mixed jet, and this brings up the question of purity or quality of the gases burned.

It has been said that originally the gases were burned in their combining proportions by means of extremely small orifices in the jets. With modern jets, however, it is actually impossible to burn either pure hydrogen or carburetted hydrogen in the proper combining proportions with oxygen without explosion, although, doubtless, were extremely

small orifices used, it could be done as well now as in former times. But with the introduction of the double gas-bag method came also wider bores in the jets, and it was soon seen that the gases, when adjusted for the best light, were not burned in their combining proportions at all, and hence the different opinions expressed by different writers, who are found stating sometimes that the gases are burned in equal volumes, whilst others assert that much will depend upon the bore of the jet, for with large bores more hydrogen will be required than oxygen.

Practical lanternists generally consider that slightly more hydrogen than oxygen is consumed when working with fairly large or medium bores to their jets, and as a rule allow for such in estimating the quantity they will require, and in this they are quite correct, for with modern jets the gases are not burned in their combining proportions when properly regulated for the best light. The well-known "snap out" explosions may be cited as an object-lesson in this matter.

If a lanternist desires to satisfy himself on this point, he can easily do so by using any mixed jet, and when he turns on a supply of hydrogen and lights the same, the moment he admits the oxygen, so as both gases are in their combining proportions in the chamber of his jet, that moment the "snap out" explosion takes place. So long, however, as he so regulates both gases so that such a combination does not occur, so long will he keep a good and steady light.

With this knowledge, therefore, how does it happen that there is so much uncertainty in the quality of the light often procurable, as well as such a wide difference in the quantity of gas consumed? The answer undoubtedly lies in the word "Quality."

An operator may have carefully examined all his apparatus and quite satisfied himself that everything is as it should be, and still he will not be able to yield as good results as he would like, for the simple reason that he has no control over the quality of the gas he is burning. Take, for instance, the gases as supplied to the public at the present day by our large compressing companies! No one for a single minute would insinuate that any of these respectable firms would knowingly send out cylinders of gas of inferior quality, and yet the fact remains that poor gas does find its way into a lanternist's hand. How, then, can this state of matters be accounted for? Very simply indeed! Any of our gas-compressing companies are at times liable to have the valves of their pumps slightly wrong without their being aware of it, and the result of this is that atmospheric air is pumped into the cylinder along with the other gas that is being charged. It takes a little time for any of the men engaged in pumping to find out that their valves are not right, but before they are put right again the mischief is done and cylinders are charged, in the firm belief that pure gas only is contained in them, that may in reality have as much as twenty per cent. of atmospheric air.

It is when such faulty samples of gas reach the lanternist's hand that he is in a quandary with regard to his inability to get a satisfactory light, as well as to account for the unusual quantity of gas run through. No doubt our compressing companies do their best to prevent occurrences of this description, but machinery will give out by reason of wear and tear, and in the early days of the cylinder method of working, no doubt, this had much to do with old gas-bag workers asserting that the gas was better when made by themselves in a retort in the usual way.

It would therefore appear that lanternists are very much in the hands of the manufacturer in this matter, and that the only royal road is to take plenty of gas and trust to the quality being pure.

T. N. ARMSTRONG.

## STEREOSCOPE ADJUSTMENTS.

[From the *Photo-Review*.]

THE total reflection stereoscope of M. Drouin is constructed with a double reflection prism by means of which the apparatus is confined to the smallest bulk possible, while at the same time it is universal in its movements. By its aid one can examine not only correctly mounted stereoscopic prints, but even reversed views, and this whatever the size of the picture.

Whilst with an ordinary telescope the observer has only to place his eyes before the apparatus to instantly see the view, the total-reflection instrument demands some little trouble in the way of a species of focusing before each picture is perfectly seen. As those who may have occasion to use the instrument may find its construction and adjustment the following notes and diagrams are given with the object of making this clear.

Fig. 1 shows the stereoscope placed normally before the eyes for the

examination of a print. The prism, *p*, deviates in the ray of light reaching the right eye, *o*, in such a way that the right-hand image is perceived as if it were superposed on the left-hand image, which is viewed directly by the left eye, *o*<sup>1</sup>. It will be at once understood that, unless the prism, *p*, is in exactly the right position, this coincidence will not result. It is necessary to adjust it with each view examined, an operation which is done instinctively and without effort after a little

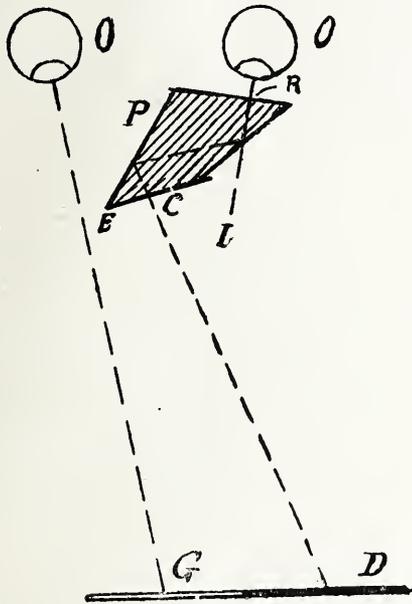

FIG. 1.

time. The quickest way to train the eye to thus instinctively make the necessary adjustment is to study the effect of each departure from the normal. This we do in the following diagrams.

Let us take the case of a properly mounted stereogram, indicated in the figure by two crosses, each in a square, one of X shape, and the other a St. Andrew's cross (fig. 2).

The first point to note is that the circular aperture, *r*, should be as close to the right eye as possible, and that the rectangular opening, *c*, should face the print, *D*. The angle, *e*, of the prism (fig. 1) should be

FIG. 2.

directed towards the left-hand image. When commencing to use the instrument, a simple subject is chosen, such as a portrait against a plain background. Most probably the two images will be rather smaller than usual, that is to say, there will be a small space between them. They should be mounted on a black card about sixteen inches long, considerably longer, in fact, than the two prints.

It will also greatly assist the manipulations which are described below if the prints are of different colours, one black and the other, say, blue.

The special stereogram having been thus made, it is held before the

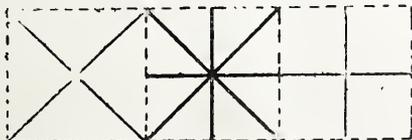

FIG. 3.

eyes at a distance of about fourteen inches, being supported in the left hand. The stereoscope is then taken in the right hand, placed in front of the right eye, and the left eye closed. We shall then see (with the right eye) the print through the stereoscope. We then place the latter so that the right image is in the middle of the field, and open the left eye.

What happens? Either in the two views, coinciding by chance, we perceive the effect of relief, or (most usually) we shall see two confused images impinging more or less on each other.

Let us here say, in parenthesis, that, when the right eye observes the right image in the stereoscope, it sees not this right image only, but part or all of the adjacent left image. Similarly, when viewing the left image directly, the observer sees also the right image. Hence, when by a con-

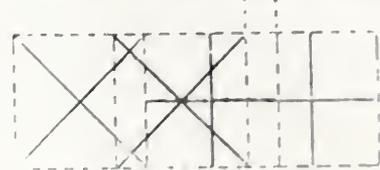

FIG. 4.

venient device these two images are superposed, the appearance of the conventional stereogram selected above is that shown in fig. 3.

Similarly, when the images are not exactly superposed, but are separated more or less from one another, we see four images, or parts of images, amongst which it is necessary to learn to distinguish the two useful images. These are shown in heavy lines in fig. 3.

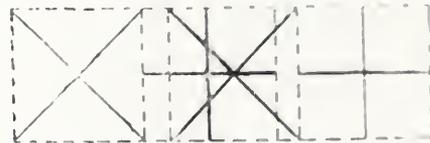

FIG. 5.

Going back now to the conditions referred to above, viz., to the moment when we had opened the left eye, we give the prism a slight rotatory movement on either side of its imaginary axis, *o* *L* (fig. 1). When this is done, one of the prints (the one observed through the prism) will be displaced in the direction of its height. The right image of this stereogram

FIG. 6.

is one of the useful images; the left image is the other. In order to get these two images super-placed, it is necessary to remember only that—

- (1). By removing the stereogram further from the eyes these images are separated from one another.
- (2). By placing the stereogram nearer, this distance is diminished.

FIG. 7.

- (3). By turning the stereoscope round *o* *L* in a clockwise direction, the right image is raised.

By turning counter clockwise, the right image is lowered.

Thus, when the image appears as in fig. 4, the prints are too near the eyes, and must be removed till *a* coincides with *b*.

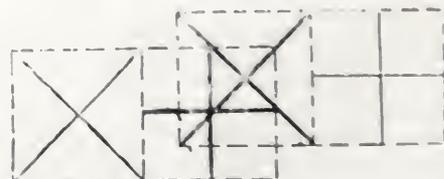

FIG. 8.

If, on the other hand, the effect observed is as in fig. 5, the prints must be brought closer.

The appearance shown in fig. 6 denotes that the prism should be turned in the direction of the hands of a watch.

On the contrary, fig. 8 is a diagram showing the state of things remedied by turning the prism in a counter clockwise direction.

These separated examples are sufficient to show what must be done in certain cases. Thus fig. 8 requires (1) that the prints be brought nearer, and (2) that a slight clockwise movement be given to the prism.

When the observer has grown used to this simple diagram, he will find no difficulty in making the necessary adjustments for any prints whatever. He may begin with, say, such a subject as a monument.

### PANORAMIC PHOTOGRAPHS.

SOMEHOW or other during recent years, there would appear to be a distinct falling off in the production of sets of negatives specially taken for the purpose of yielding panoramic pictures, the reason for this very probably being found in the existing rage for snap-shot views taken by means of small cameras held in the hand; for there is little doubt that with the advent of hand-camera work there came a distinct falling off in the demand for cameras of larger size, which were so much in evidence during the early days of the bromide dry plate.

Ten years ago hand-camera work may be said to have commenced. At that time the dry plate had enlisted a very large number of workers, nearly all of whom were in possession of a whole or half-plate size of camera, and panoramic pictures were among the regular productions of workers at that time. At the present day, however, very few are found making this class of pictures, and it seems a pity that such should be the case, for in many ways panoramic views by means of photography are not only useful in recording scenes, such as public functions, but at the same time are highly interesting in landscape work, where some of our grandest views are incapable of being included on a plate even by the widest-angle lens we possess.

To the professional worker panoramic work (or what may be termed as such in a limited degree) is frequently of considerable value, especially in these days of half-tone process blocks, where so much has to be done in book illustrations and for advertising purposes.

The preparation of negatives specially intended for being printed in panoramic forms calls for no special apparatus in their production beyond a good size of camera and a really sensible rigid tripod. It would, perhaps, be going too far, when criticising tripods, to say that a really perfect tripod ought to have no joints in its construction, and that the head ought to be as large as the base of the camera it is so intended to sustain; but, on the other hand, there is no doubt nine-tenths of the flimsy, rickety things sold at the present day as the most recent advances in "portability" are quite unfit for serious photographic purposes, and dealers really ought to prevent them finding their way into the hands of beginners.

In landscape working especially how often do we hear such expressions as, "Oh, if I could only just take all that view in! wouldn't it be splendid?" and so, probably from ignorance of the fact that, with a good photographic outfit and the requisite knowledge of how to use it on such scenes, many delightful views are never photographed.

Take, for instance, the whole-plate size of camera with a fairly good narrow-angle lens, a very wide range of views may be dealt with by taking three negatives from the same standpoint. It is well known that the chief factor in panoramic photography is the exercise of care that the camera is held absolutely horizontal on the tripod head when being slung round for the purpose of taking the different views. The tripod must be very carefully set up, and adjusted by means of a circular spirit level, and, when so adjusted, the utmost care should be bestowed in seeing that it is not altered in any way when the camera is placed in position. The spirit level is then applied to the baseboard of the camera when extended, and the picture that is to form the first negative is focussed on the ground glass; the camera is then swung gently round on the tripod head so as to include the portion of view where it was cut off in the previous view; the spirit level is then applied again, and finally the camera is swung to the opposite side of the first view, and the same care bestowed in seeing that at each three points the tripod is causing the camera to stand absolutely level. This is the first action a novice should take when attempting this work. To enable a proper registration of the three pictures when the negatives are printed, it is a good practice to draw two upright lines on the ground glass of the camera about half an inch from each end on the focussing screen, and, when selecting the first view to be taken, some prominent object or distinguishing mark is brought so as to occupy a position on one of these lines; this will enable the worker to know how far to swing the camera round in each direction when taking the other views on left and right of

the one first selected, and also provide for a reasonable margin when the prints are trimmed, as well as permit of their being most accurately joined on the mounting board or cloth.

It need hardly be stated that, when so much depends on good definition in the pictures at their extreme ends, the services of a really good covering lens are required. In landscape work the objective can generally be well stopped down with advantage in this respect; there are, however, other subjects in panoramic work where there is a limit to the angular aperture that can be employed.

A suitable subject being selected, the camera is first arranged to take the centre view, and the plate exposed, the other views being treated to the same exposure, and the three negatives developed to as nearly as possible the same densities.

It will not be long before any one who undertakes this work will begin to recognise that the printing of negatives taken for panoramic views is not the least important part of the operation, for it stands to reason that much of the beauty of these pictures lies in their colour being uniform throughout, and it is just here where a beginner needs a little guidance from those who have a practical experience in printing these subjects, so as to yield the three or more prints all of the same depth in printing and colour in toning. This is, however, not really a difficult matter, and should not deter any one from attempting this class of work.

In the case of a beginner, say, possessed of a good half-plate outfit, and the negatives being taken after the manner described, the printing is performed with an ordinary half-plate printing frame as follows:—

A strip of sensitised paper is cut from a sheet, so as to be sufficient to cover the three negatives; this means providing a strip of sensitised paper cut from the longer portion of a large sheet 19½ inches (say 20 inches) long by 4¾ inches broad.

This strip must be so folded (not cut into three pieces, as is generally done in ordinary printing) that each negative is printed in its proper position on the paper, *i.e.*, the centre negative being in the middle and the others to the left and right, as seen in the view. The paper, being so folded, will, if the printing is carefully done, suffer in no way, while each negative is being printed; but, if any anxiety does exist, a sheet of ordinary paper may be interposed between the folds, but in practice I never really resort to this expediency. After the first negative is printed to its proper depth, the print is removed and the next one placed in the frame, the proper unprinted portion of the sensitised paper is then placed in contact and the printing proceeded with. At this stage it may be well to describe, for the benefit of those who have never attempted equal printing in this manner, how the paper is folded at this stage. Say the first negative to be printed is the right-hand view, when the middle negative is next placed in the frame, the unprinted portion of the paper that is to receive left view is folded over and falls in between the already-printed portion. In this position, when the printing frame is opened for the inspection of the print, a printer can see in a moment not only the depth of the middle print, and how far it is printed, but can compare the same with the first portion, and detect in a moment when both negatives are printed to exactly the same depth. The left-hand negative is then treated in precisely the same manner, and, on removing the three prints from the printing frame, it will be found that each, so far as depth in printing is concerned, is identical with its neighbour.

In toning it is desirable to manipulate the three prints without severing them, but this is not always possible with amateur workers, who only possess small dishes and a limited supply of toning mixture. In any case the prints should be toned exactly alike, and, if due care has been bestowed in producing the negatives and the printing been carried to the same depth, there is no great difficulty in toning.

The trimming and mounting require to be carefully performed also. When the prints come to be trimmed, they will each be found to contain some portion of the same view at their extreme ends. Some particular object must be selected where the prints are to form a junction, and each print cut so that it will exactly correspond with the other at this particular part of the view. One or two trials will, however, enable any one to do this in a neat manner, and there will be no trouble from unequal shrinkage of the printing paper if the three prints are produced on the one strip in the same direction as instructed. When nicely trimmed, they are mounted in the usual manner on boards or cloth; if the latter, the same should be equally stretched on a deal plank or table by means of tacks, so that, when the photographs are dry, they lie nice and flat.

To the professional panoramic work is of much greater importance than many might imagine. It is not only in landscape work he has to operate, there are numerous other subjects, such as large works taken from a high elevation required for advertising purposes. Reviews and race meetings for book and newspaper illustrations, and many other

imilar subjects, not the least of which being large excursion parties, children's treats, Sunday-school gatherings disporting themselves in a field, &c. It is wonderful what good results can be obtained by carefully selecting a suitable standpoint from which the camera can sweep the entire view, results that cannot be approached by taking views here, there, and everywhere, at different standpoints.

Where shutter work has to be resorted to, the covering power of the lens must be carefully seen to, so that no falling off in the definition of the picture at the extreme ends of the plate is noticeable; this means using long-focus lenses on smaller-sized plates in many instances.

There is a wide range in which panoramic photographs may be made to do duty, and it is surprising we do not see professionals, as well as amateurs, practising such more largely than they do.

A. T. NEWTON.

### ON RADIO-ACTIVE BARIUM.

[Reprinted from the *Chemical News*.]

AFTER the uranium rays of Becquerel had been discovered, and G. C. Schmidt had shown that the thorium compounds emit similar rays, Marie found in uranium ore (pitchblende) a radio-active substance whose radiation was about 400 times that of uranium. They predicted in this substance a hitherto unknown element, coinciding in its chemical reactions with bismuth, and which they called "polonium." They did not succeed in separating polonium from bismuth.

These same experimentalists, in conjunction with M. G. Bémont, isolated in the same year a more highly active substance from the pitchblende, in which they likewise predicted a hitherto unknown element that they called "radium." Radium possesses the chemical properties of barium, and is inseparable from the latter as is polonium from bismuth. Demarçay examined the spectrum of radio-active barium, and found next to the intense barium lines a new line, which apparently belongs to radium. Mde. Sklodowska Curie determined the atomic weight of active barium, and found it eight units higher than that of inactive barium.

The existence of radium in radio-active barium compounds is established through the radio-activity, the spectrum, and the higher atomic weight.

F. Giesel likewise produced radio-active barium from pitchblende. He proceeded by a method quite different from that of Curie. Out of 1000 kilogrammes of raw material he obtained 15 grammes of the preparation of radio-active barium. He also found some polonium combined with lead.

Finally, it may be remarked that Debierne had also isolated from pitchblende a very active substance, whose properties resemble those of titanium.

Many other experimentalists have worked at radio-active bodies; but their experiments were conducted almost exclusively with reference to the rays emitted by these bodies.

We thus know of radio-active bodies which have five different origins: the compounds of uranium, thorium, polonium, radium, and Debierne's substance resembling titanium. Uranium and thorium have been long known as chemically well-defined simple bodies; on the other hand, the three last-named are so far only hypothetical elements. Of these three hypothetical elements radium is the best known, as there are most accounts about it. The objective evidence of these accounts scarcely convinces one that radium is an existing element. For the existence of this element, two circumstances come principally into consideration from a chemical point of view, viz., the higher atomic weight of radio-active barium, and the spectrum of the same. Mde. Curie found the atomic weight of radio-active barium eight units higher than that of the inactive, from which she concluded that radium must exist. But when we consider that radium, which so entirely resembles barium, must be divalent, and as high an atomic weight as uranium, and, further, base our reckonings on the atomic weight of radio-active barium (145.8) found by Mde. Curie, it appears that the preparation from which the atomic weight was determined must have contained about 2 per cent. radium chloride: that is a considerable quantity, and it cannot be assumed that such a quantity of a foreign element would not betray itself during the various chemical transformations.

Also, if a close chemical similarity between radium and barium is assumed, in consequence of which the two elements could not be distinguished and separated from each other by means of the usual analytical methods, it is yet difficult to accept radium as an existing element. Demarçay has examined the spectrum of radio-active barium

and found in it only one line which was visible along with the intense barium lines, and which did not belong to barium. The spectra of calcium, strontium, and barium are of the same type; they consist of sharp lines and shaded bands; even the grouping of the lines and bands is alike. It was to be expected that radium, which is almost identically the same as barium, would show a similar spectrum.

Also, one must take into regard the fact that these new hypothetical elements are always found combined with other well-known chemical elements. M. and Mde. Curie found polonium combined with bismuth; Giesel with lead. Radium is combined with barium; Debierne's element with titanium. All these radio-active bodies have the same source, uranium pitchblende, from which they were separated by different analytical methods.

It can scarcely be maintained that chemical elements exist which are in no way distinguishable from other well-known ones, except in radio-activity; and it can scarcely be supposed that these elements, which can be transformed into various compounds, would in no single case give evidence of their presence in the chemical reactions but through their radio-activity.

Such considerations led me to examine experimentally the question as to whether the radio-active bodies contained new elements. After all the radio-active bodies known hitherto, which are said to contain a new element, were separated from the uranium pitchblende by analytical methods, I chose the synthetic method for the decision of the proposed question. For it is obviously clear that the question of radium being a chemical element must be answered in the negative as soon as it is found possible to transform ordinary inactive barium into the radio-active variety. At the same time this might be the synthetic production of radium.

My experiments carried out in this direction gave a positive result. It appeared that one can transform ordinary barium into a radio-active form which apparently possesses all the properties of radio-active barium observed by different experimentalists.

For the production of radio-active barium sulphate, the following should initially be noted:—Uranyl nitrate is melted together with 2 or 3 per cent. barium nitrate, the nitric acid driven off as far as possible by sustained heating, and the remaining oxides fused in the electric arc. The fused mass is dissolved in nitric acid, and the solution evaporated, by which means a large portion of the baryta separates as nitrate. The hot solution is decanted from the crystals, diluted with three or four times its volume of water, and the radio-active barium sulphate precipitated with sulphuric acid. Only a small amount of sulphate is obtained in comparison with the quantity of barium nitrate used. I obtained, from 20 grammes barium nitrate, only 3 to 5 grammes sulphate, which is undoubtedly still largely mixed with ordinary barium sulphate.

The most favourable conditions for the production of radio-active barium are not yet determined. But the fact, that a radio-active barium sulphate can be obtained as above described, seemed to me to be sufficiently important to publish in a preliminary notice.

I have so far prepared three compounds—radio active barium sulphate, and from this the chloride and carbonate.

Radio-active barium sulphate is precipitated as a fine white substance, adhering rather readily to glass when the acid solution is treated with sulphuric acid or a sulphate. The precipitate, when well washed with hot water, dried, and heated, is white with a tinge of yellow, perhaps due to a trace of uranium. The substance was put into a little glass vessel, the bottom of which showed a faint gleam of light, and the glass placed on a sensitive photographic plate, wrapped in black paper. After two hours the plate was developed, and a strong black mark appeared, corresponding to the transverse section of the glass. Hence the preparation was radio-active, and its activity increased after some days.

Radium rays are said to penetrate their metal sheets; my preparation of active barium sulphate emitted rays possessing the same property. One half of a copper coin was ground down to about one-third the thickness of the other half. The coin was laid between the vessel containing the barium sulphate and the sensitive plate, wrapped in black paper, and left there for three hours. After development, the plate was found to have remained white on the spot corresponding to the thicker copper layer, and had become grey beneath the thinner copper layer, of which there was an image surrounded with an intense black margin, indicating the action of the rays received direct on the plate beyond the copper coin.

Radium rays illuminate a barium platino-cyanide screen; the rays of my substance exhibit the same property, though in less degree. The air becomes an electrical conductor by means of radium rays, and the same

is the case with my prepared active barium sulphate. The carbonate and chloride prepared from the active sulphate were also active.

This is, so far, the limit of my researches. They do not nearly suffice to decide the question as to whether radium is an existing chemical element, or not; but those facts render doubtful the existence of radium. The question can only be settled by a searching examination, and I have in hand the preparation of the necessary material in sufficient quantity to be able to undertake this examination.

BÉLA V. LENGYEL.

*Chemical Laboratory of the University, Buda-pest II.*

### SIR WILLIAM ABNEY ON COLOUR PHOTOGRAPHY.

*Nature*, in a recent issue, summarises Sir William Abney's latest experiments in colour photography.

In his last communication to the Royal Society, he describes a method of estimating the luminosity of coloured surfaces that is especially applicable when the source of light is a large surface, such as the sky. In "Colour Photography," Part III., it was shown that only one ray of the spectrum, a greenish-yellow, progressed in luminosity at the same rate as white light. If, for example, red, greenish-yellow, blue and white lights are made of equal luminosity, and the illuminating beams are simultaneously and equally reduced in intensity, the luminosity of the red will diminish the most rapidly, that of the blue the least rapidly, the other two remaining equal. Moreover, the colour disappears more quickly than the luminosity (except in the case of pure red), tending towards greyness, so that colours of feeble luminosity are more easy to match than bright colours. The new method of colour photometry is based upon these facts. By means of concentric rotating discs, which are, when necessary, slit radially and interlaced, the proportion of black and white that matches first a green and then a yellow disc is determined. The comparisons are facilitated by observing the rotating discs through a "black transparent medium," such as an unstained developed photographic film, which may be so dense that the colour practically disappears, giving place to a dull grey. The value of a red disc is ascertained by interlacing it with the green and blue discs to produce a grey, which is then matched with the black and white. Thus, having three standard colours of known values, the luminosity of any other colour can be ascertained by substituting a disc of it for one of the standard colours to produce a grey, and matching the grey as before. The results given by this method agree closely with those obtained by the method previously described by the author. Sir William Abney has in this way determined the luminosities of various coloured surfaces, and calculated the amount of black necessary for each, so that they shall be reduced to equal luminosity. He has then prepared a disc divided into several annuluses, each partly coloured and partly black, so that when rotated the whole appears of equal luminosity when illuminated by the light for which it is calculated. By the selection of suitable colours, such a disc is a very convenient and effective test for any defect in either the colour sensitiveness of a photographic plate, or in the coloured screen used to compensate its inherent deficiencies in this matter; for the rotating disc, which is equally luminous throughout, will give, when the negative is developed, an image of equal density throughout, if the sensitive plate and colour screen are properly adjusted to each other.

### ON THE MOUNTING OF LANTERN SLIDES.

[Paper read before the Photographic Society of Philadelphia.]

Our English cousins, who generally do things the hardest possible way, and generally have a good reason for doing it, have adopted the square  $3\frac{1}{2} \times 3\frac{1}{2}$  in. size for slides. The saving in weight of one hundred of these, as compared with one hundred American standard slides, is considerable, but after admitting this there is little to be said in their favour. As some of us have learned to our sorrow, there is but one right way to place a slide in the lantern so that the image may appear in its proper position on the screen. Now, with an English slide, which is square, it is possible to place it upside down, or on either of its sides, or right side up, and then turning it about, so that the left side of the picture appears on the right, to repeat the four operations again, making eight possible ways of inserting the slide in the carrier, and but one right way. With the  $3\frac{1}{2} \times 4$  in., or American slide, there are but four possible ways of inserting

in the carrier, three of which are wrong and one right. There are thus seven possible wrong ways of placing an English slide in the carrier there are but three in the American slide. It will be seen from this example how easy it is to run American slides through the lantern with a fair probability of getting them right as compared with English slides but, in addition to this, the greater margin on the lantern slides, and more ample labels, makes it easier to make them in some certain way which may be easily distinguished by the operator in a dimly lighted room.

At first sight it would seem a very simple matter to label a slide to easy identification and insertion in the lantern; but, from the number of different schemes which make their appearance in going over a miscellaneous lot of pictures, one is almost led to believe it is a most difficult problem.

The American Lantern Slide Interchange, soon after its inauguration formulated a set of rules governing the mounting and labelling of slides submitted by its members, which I regret to say have been violated time and time again by some, while by others they have been observed principally by their non-observance.

Supposing that the slides for an exhibition have been arranged in order, about the only mishap which may occur is that the picture appear on the screen upside down. The little thumb label, which some considerate persons place on the lower left-hand corner of each slide when it is viewed in its proper position, is of great value, and no one who has not had experience with these little white circles has any idea of the comfort and relief they are when they are placed on the right—that is, the lower left-hand—corner of the slide. But, if blindly followed, the thumb label is pretty sure to lead into trouble, because there are several schemes of applying it to the slide. The English are the most fertile in these, and, not being satisfied with one label, often insist on placing two, three, or even four on the cover glass. These are worse than nothing at all, as they are most misleading.

One of the neatest methods of applying the thumb label is on the mat placed between the slide and cover glass. The side of the mat which comes next to the condenser is left white, and on it may be written the title of the slide, the author's name, or any other data, while a black dot on the paper cover shows very distinctly, even in a dark room, the proper position of the slide in the lantern. This method, if universally adopted, would furnish a satisfactory solution of the problem of slide marking.

Respecting the title label, which is usually pasted on one end, but little need be said; so long as it is firmly attached to the slide and legibly written upon, its duty is fulfilled. Some people paste this label on the front, when the slide is viewed in its proper position, and some on the back; doubtless many paste it on the first side they pick up. This label is mostly pasted on the left-hand end of the back, opposite where you would endorse your name if the slide were a cheque. The English slides, which usually are made on much thicker glass than common in this country, often have the names written in very small letters on the edge. The advantage of this is that the title may be read while the slide rests on end in the box, but the space is so small that at best but a few words can be written. The title label on quite a number of slides is placed on the front, opposite the thumb label. This is irrational, as the name can then be read without turning the slide over and the position corresponds with the title when written on the white mat.

W. S. VAUX, JUNR.

### ON CUTTING AND MOUNTING STEREOGRAPHS.

[Reprinted from the *Australian Photographic Journal*.]

THE proper principles as to cutting the stereo halves do not seem to be thoroughly understood by some workers. The object of the stereoscope is to imitate artificially the ordinary vision, but there are certain limitations in the artificial stereoscopic vision which do not exist in the natural.

The eye is a very wide-angled lens, and the image thrown on the retina is very small compared with that of the photographic lens, so we are not conscious of any limit or boundary to the picture we see when we look out upon a landscape. It is vignettted, as it were, into imperceptibility. We may, by the action of the brain, widen or diminish the angle of perceptible view, as we concentrate our attention upon different objects in the landscape, but in no case are we conscious of any boundary to the field of vision.

But it is very different with the photographic lens. The angle of perfect definition is very much less, and, for the stereoscopic view

vey the same idea of scale and proportion as that seen by the eyes, the pictures must be very much larger than those thrown on the retina, and, as the two pictures have to be mounted side by side, with centres not more than three inches apart, it follows that only a narrow angle of view can be obtained, and the boundary of the stereoscopic picture will be unpleasantly conspicuous to the consciousness.

Our object is to minimise the disagreeable effect caused by this limit to the stereoscopic view. Now, there is a case in which there is an artificial boundary to the view seen by the eyes, and, if we study the conditions existing in such case, and try to reproduce them as closely as possible in the stereograph, we shall find that we have solved the difficulty in the way the most satisfactory to the artistic sense.

If we seat ourselves in a room and look out of the window, we see, beyond, a landscape limited by the frame of the casement. We are conscious of the limitation, but the window frame, with the adjacent walls probably in dark shadow, does not distract our attention from the landscape, and does not annoy us, unless, perhaps, some object is passing out of view; in which case we move nearer to the window, for it is obvious that the angle of view will vary with our distance from the window; and, if we want to see more to the right, we will move to the left.

Studying the details of what we see outside the window, we discover, by shutting each eye alternately, that the right eye sees more of the left side of the view than the left eye does, and *vice versa*.

The amount eclipsed by the window frame from the one eye of what the other eye sees varies, we find, according to our distance from the window. If we are close to the window, a wide strip is cut off; but, if we are at the opposite end of a long room, the pictures seen by the two eyes respectively are nearly co-extensive.

It follows from this that, to give our stereograph the effect of looking at a view through a window, we must so cut the two halves of the print that the right-hand half shall show a little more of the left side of the subject than the left-hand half does, and *vice versa*; but *how much* is an important question, to be decided only by the requirements of each individual subject.

As the stereoscopic effect is caused by the superposition or blending of two similar but not identical pictures, the portion of each half which is not contained in the other half will not appear stereoscopically, but will have a ghostlike effect. It is important, therefore, that this imperfect strip on each side of the true stereoscopic picture should be as narrow as the subject will permit. As I have already said, the further we are away from the window the narrower will be these strips; if, then, we cut our pictures so as to show the imaginary window against the distance of the landscape, there will be no perceptible overlapping; and this is done by cutting the sides of the two halves very nearly through the same point in each, that point being in the distance of the view.

But now another consideration comes in. If we are sitting at a distance from the window, we shall see intervening objects in the room; and in the case of our stereograph, if we place the window in the distance, we shall have the foreground and middle distance inside our imaginary room. This, of course, in most instances will be an improper effect; if we are looking at a view through a window, the whole of the view is outside the window, objects seen inside do not properly belong to the view; they generally obstruct or disfigure it, though in some instances they assist it by throwing back the distance.

Now let us return to our window and study the effect of objects situated within the room. Fixing the attention on the window, and observing an object between us and the aperture, we shall find that, looking with the right eye only, it shifts towards the left side of the window; looking with the left eye only, it shifts towards the right side of the window. If the object is near to the eyes, the shifting is very great, and, if it is nearer to one side of the aperture, it will perhaps shift entirely out of the view of one eye; and if, with the attention still fixed on the window or landscape beyond, we look with both eyes, we shall see, not one, but two ghostlike images of the interior object, semi-transparent against the distance.

From this study we shall find that the right eye sees more of the right side of an interior object against the aperture of the window than the left eye does—just the converse of the case of exterior objects.

It follows that, to make our stereoscopic view appear as being outside a window, instead of cutting the two halves with reference to the distance, we must cut them with reference to the nearest object that we wish to have outside the imaginary aperture.

But now come in the difficulties. If we bring the window very close to the eyes, the overlapping strip of the distance will be very wide, and, consequently, the true stereoscopic portion will be comparatively narrow. The halves themselves will also be narrow, because the shifting already

referred to makes the measurement between the two images of a near object much less than in the case of a distant object.

It is best therefore to compromise and to cut the print so as to show very near objects as being nearer than the window. If they come to one side of the picture, they will appear as overlapping the aperture, but this cannot be helped.

It is advisable, however, whenever it is possible, to avoid having any very near objects in the view at all, especially coming in on one side of it. When it is impracticable to keep such objects out, the evil can be minimised by bringing the lenses as close together as they will go, if you have an adjustable front, and also by cutting the one half narrower than the other; that is, if the near object comes into the view from the right-hand side, you take a little more off the outer edge of the right-hand half.

JUDGE DOCKER.

### INCANDESCENT GAS LIGHT.

THE *Photographische Chronik* warns its readers against tables of the comparative chemical action of various kinds of light, when an incandescent mantle is used for a standard light. "Lux," a Dutch contemporary, has given the following information concerning the solutions used for the preparation of gas mantles, and it will be seen that the light varies considerably according to the salts used.

FOR WHITE LIGHT.	
Zirconium oxide .....	40 per cent.
Lanthanum oxide .....	40 ..
Thorium oxide .....	20 ..
FOR ORANGE LIGHT.	
Lanthanum oxide .....	40 per cent.
Thorium oxide .....	30 ..
Zirconium oxide .....	27 ..
Didymium oxide .....	3 ..
FOR YELLOW LIGHT.	
Lanthanum oxide .....	40 per cent.
Thorium oxide .....	28 ..
Zirconium oxide .....	30 ..
Cerium oxide .....	2 ..
FOR GREEN LIGHT.	
Thorium oxide .....	50 per cent.
Lanthanum oxide .....	20 ..
Erbium oxide .....	30 ..

The mantles are afterwards stiffened with a solution of water glass. Concerning the intensity of the light which may be obtained with gas mantles, if we take 60 candles as the equivalent of a mantle, 1020 candle power may be had from 17 mantles, which, with suitable reflectors, may be increased tenfold, say 10,000 candles in round numbers. By diffusing the light with paraffin paper screens a loss of 20 per cent. results, but if we place two rows of 6 mantles each on one side of the sitter, and a row of 5 mantles on the shadow side, there still remains sufficient light to obtain full exposure in a few seconds.

### AN IMPROVEMENT IN RADIOGRAPHY.

[Reprinted from the *Scientific American*.]

In a paper lately presented to the Académie des Sciences, Dr. T. H. Guilloz describes a series of experiments which he has recently made which show the remarkable diffusion of the X rays by the surrounding objects, and the importance of this action in radiographic work. It is, in fact, difficult to obtain a good radiograph of the thicker portions of the body which will have a good contrast, and the plates thus obtained generally show more or less fog in the development. This cannot be explained by a pure and simple absorption of the rays; it has been supposed by some that the action was due to the diffusion of the rays by the air, but this is, in fact, so small as to be entirely negligible in a practical work, and could not produce the effect observed. After a number of experiments Dr. Guilloz seems to have established the fact that this action is due to the diffusion of the rays by the surrounding objects, such as the supports, containing apparatus, walls of the room and tissues of the subject, and in some cases by the body of the operator.

The following experiment shows how strongly worked is this secondary action or diffusion of the rays. The vacuum tube emitting the rays is placed above a large plate of lead about 1 m. square and 2 mm. thick. The plate has a rectangular opening in the centre, 4 by 10 cm., which allows the rays to pass. In order to have a region which is entirely

shielded from the action of the rays passing through the opening, a steel plate, 15 mm. thick, is placed over the lead plate, having one side in line with the side of the opening. The region below the steel plate is thus entirely protected from the action of the rays which proceed directly from the source, this being verified by using a fluorescent screen of platino-cyanide of barium, and it was found that it was impossible to obtain a silhouette of the hand or other object when placed against it. If now an attendant covers with his hand the opening through which the rays pass, or if the hand is placed in the path of the rays near the opening, the silhouette of the hand appears on the fluorescent screen. In fact, it is only necessary to place an object in the path of the rays, at any point where it may be viewed from the screen, to cause an illumination of the latter. It seems, therefore, that in taking a radiograph of a thick part of the body secondary or reflected rays are produced, not only at the surface of the body, but throughout its whole thickness, and the experimenter shows several radiographic plates which he has obtained by an exposure of two minutes under the action of the rays diffused by the body.

The negatives were obtained by placing a photographic plate in the position previously occupied by the fluorescent screen; the plate was wrapped with black paper, and one-half of it covered with tinfoil. An exposure of two minutes was made, placing before the uncovered half of the plate a pocket-book, the fingers, &c., this being done after all objects were carefully removed from the path of the rays. The tinfoil was then transferred to the other half of the plate and a second exposure made, while an attendant covered the opening with his hand. Upon development, the plate showed on the first half a scarcely perceptible image, this being, no doubt, due to a slight diffusion from surrounding objects; the other half, on the contrary, showed a vigorous impression, caused by the rays diffused from the hand. The experimenter lays stress on the fact that in taking a radiograph the operator should consider all the surrounding objects as capable of diffusing the rays, which strike the plate and produce a fog, especially with long exposure. In the case of those parts of the body which have but little thickness, this action may not be very perceptible, but for the trunk of the body, for instance, where a long exposure is necessary, these secondary rays play an important part, and the surrounding objects may give off rays which have the same order of intensity as those which have passed through the body. The best method of avoiding this action is probably to surround the subject by a lead plate which follows the contours of the part in question. A metal diaphragm may be used to advantage in front of the tube.

TESTING COAL BY THE RÖNTGEN RAYS.

EXPERIMENTS already recorded (says *Kuhlow's Review*) having led to the conclusion that the permeability of coal towards the Röntgen rays affords no reliable indication of the ash content of the sample, in that the accompanying slate is relatively transparent under their influence, whereas the presence of a comparatively small quantity of oxides of the heavy metals is sufficient to offer considerable hindrance to the passage of the rays, the author subjected the matter to further investigation, with the following results:—

A selection of the purest of a number of lumps of coal having been made, by examination with the Röntgen apparatus, the samples were reduced to powder and passed through a fine sieve (22 by 22 meshes per square centimetre), the ash content being determined, by direct calcination, as 1.66 per cent.

Next, the following six kinds of pit stone were powdered and sifted in the same way, their percentage of residue and iron content being also determined:—

	Residue. Per cent.	Iron. Per cent.
(1) Grey slate .....	93.14	0.79
(2) Black band .....	43.26	25.25
(3) Black band .....	65.50	39.03
(4) Black band .....	56.36	35.38
(5) Ferruginous slate...	43.84	19.00
(6) Ferruginous slate...	44.29	13.45

Mixtures were then compounded of the coal and stone samples, so that the percentage of ash was in each case alike, viz., 10 per cent.; and these, being placed in small paper boxes 17 mm. deep, were laid on the photographic plate and exposed to the Röntgen rays for three minutes, the distance between the plate and the source of the light being 25 cm. Notwithstanding their uniformity of total ash content, the samples exhibited very pronounced differences in regard to their permeability, the hindrance to the passage of the rays being in direct proportion to the amount of iron present; the one sample containing the smallest

quantity (0.07 per cent.) of iron was almost perfectly transparent, whilst that at the other extreme of the series (5.4 per cent. of iron) gave a fairly dense black print, the others ranging *seriatim* between these limits.

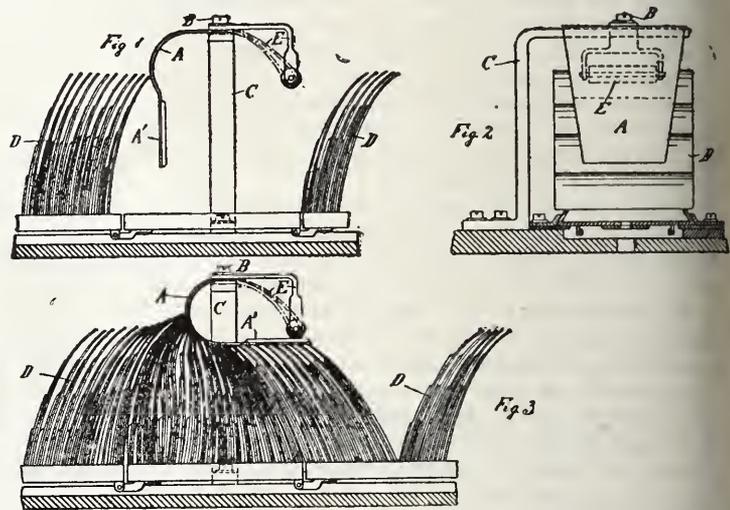

As for practical use the total percentage of ash is the sole point in question, the author therefore concludes that, however interesting it may be from a scientific standpoint, the Röntgen-ray test for ash determinations is quite valueless.

IMPROVEMENTS IN OR APPLICABLE TO APPARATUS FOR EXHIBITING "LIVING PICTURES."

[Malke's Patent No. 16,326 of 1899.]

THE patentee points out that in apparatus of the class in question it is usual to employ a block or bar to act as a brake upon the pictures passing under it for the purpose of holding back, or bending rearwardly, each picture until the proper moment for its release, but the brakes hitherto used act in a manner not making sufficient allowance for variations in the resiliency of the several pictures, or in their length; the brake hereinafter described, however, readily adapts itself to such variations, its construction is as follows:—

The brake consists of a flexible elastic strip A, which at A<sup>1</sup> is thickened

or strengthened so as to make it heavy and strong enough to flex the pictures passing under or by it. It is by a screw B, attached to a standard or upright C, placed in suitable position close to the path of the pictures. When the apparatus is in operation the pictures, D, successively pass the brake and are bent by it as will appear more particularly from fig. 2 of the drawings, the strip A also being bent. On the support C a stop E is provided, this stop E limits the extent to which the brake can be bent. The end of the stop may conveniently be fitted with a roller as shown in the drawings, to diminish friction. Between the pictures D springs of parchment may be interposed to give more force to their movement at the moment when they escape from under the brake.

MENTAL PERSPECTIVE.

THE following extract from a contribution to *Knowledge* for August, by Mr. Parr, will afford food for reflection to those interested in the apparent variability in magnitude of celestial bodies. He says, "That this enlargement of the sun or moon when seen on the horizon is purely illusory is acknowledged by all, so that it is evident some kind of mental deception is here at work which tends to falsify our estimates of distance, and, consequently, of magnitude. It has been suggested, for instance, that, when looking at the moon near the horizon, we are unconsciously aided in our estimate of its distance by reference to intervening landmarks, such as trees, hills, or houses, the distance of which we already know, whereas, when looking upward at the moon in the zenith, there is nothing whatever to guide us. Now it has been observed that the distance of objects is almost invariably under-estimated when we are deprived of our usual landmarks, as, for instance, at sea, and it is suggested that by analogy the distance of objects in the zenith, or at high altitudes, is similarly under-estimated. Thus, the moon, subtending, as it does, the same angle to us, whether on the horizon or in the zenith, appears to us larger in the former and smaller in the latter position, for, as pointed out by Mr. John Turner, 'of two bodies of equal angular magnitude, that which appears to us to be nearer we think the smaller.'"

## LANTERN MEMS.

THE lantern season has come round again, or rather is within measurable distance, for the evenings are now drawing in, and the summer games will shortly be replaced by winter ones. In looking und to find what novelties, either in connexion with the optical or mechanical parts of the lantern there may be to make known, one has almost to sum them up in the one word *nil*, and I hardly remember, in all my experience, when there was so little to engage the attention of the lantern industry as there is at the present time. Many explanations have been offered for the "slump" in lantern matters, but my own idea is that, in the course of one of those cycles that so curiously occur in all matters of business and daily life, we have come to a part approaching "inertia," but presently the industry will move with its accustomed force.

\* \* \* \* \*

WHAT is wanted is a "boom," something like the introduction of the triple lantern twenty-five or thirty years ago, an apparatus that required some technical skill and high-class workmanship to build up, sound common sense, patience, and practice to master details and operate properly, that cost sufficient money to prevent it being in the hand of every one, and so was valuable for exhibition purposes. Now it is only a matter of spending a small sum on a lantern, for very fair ones can be purchased at the present time from about 1*l.* upwards, and a child can work them. If a thing becomes too cheap, it is not then fashionable, and something else is taken up. It was the same with the table microscope. While it was considered *the* thing to have a fine binocular microscope, there was an immense scope for modification of designs, improvement in details, and the invention of apparatus; but, when the British professors followed the lead of the German biologists and introduced the German instruments of simple construction, and concentrated their efforts on bacteriology, then away went the microscope as a popular instrument. There are thousands of people at the present time that have no knowledge of how beautiful simple objects are under a properly constructed binocular microscope, and I should like to see the day return when popular *soirées* are given, and not merely a dozen microscopes on the table showing, except to the initiated, a most uninteresting series of rod-like and other forms of bacilli, but an array of microscopes numbering a hundred or more.

\* \* \* \* \*

THOSE who see for the first time gold sand, the wing case of a diamond beetle, the brilliant eyes of the jumping spider, young

oysters, and other "show" objects of this class, are simply charmed, and it only wants the lead to be taken by an influential circle of ladies and gentlemen for the binocular microscope to again become *de rigueur*. I have somewhat enlarged on the subject of the microscope to emphasise my remarks on the popularity of the lantern, for if the owner cannot say to his friend, "I have such-and-such an improvement in my instrument," and "I had this apparatus for producing a dark ground (or other) illumination effect made to *my own idea*, and I have had this modification and that addition to this part fitted," he does not get the pleasure for his outlay or feel the necessary pride in his belongings.

\* \* \* \* \*

THE day of simplicity is passing—at least, I hope so—in the interest of the lantern industry, and also for the popularity of the instrument as a scientific and entertaining adjunct. By this I do not mean that I should like in any way to curtail the use of simple lanterns for class purposes and showing photographs on club lantern nights, but what I should like to see is the introduction of something that will set the brains to work of the users as well as the makers of the apparatus, then friendly rivalry and some of the spare pocket money will do the rest. Are we to wait until colour photography is perfected for this day to come?

\* \* \* \* \*

ELECTRIC light lanterns will be more and more inquired after as electrical power is more distributed, and, judging by the way the roads are up in the suburbs of London and other large cities, and the concessions to companies for producing and supplying the current, it should not be very long before electricity is available at most large houses and all halls and places of entertainment. One or two new pattern lanterns are announced for use with the electric arc light lamp. They do not vary much from the lantern as used for the lime light except that they are higher so as to allow for the carbons, and are more roomy so as to have more ventilation. They are either of Russian iron, or, for comfort in working, mahogany bodies, asbestos-lined, with a Russian iron inside lining, with plenty of ventilation. The great thing is to protect the woodwork in front, if any is there at all, so that the direct heat rays from the arc may not affect it. In the Society of Arts' new lantern the support for the condenser and front carrying objective is made of metal and quite independent of the body of the lantern, the woodwork of which simply serves the purpose of keeping the parts cool that are likely to be touched by the hands. A recent report of the working of Davenport's arc lamp at one of the provincial colleges, sent unsolicited after two seasons' use, is very flattering to the designer of the lamp and gratifying to the makers. No doubt there are other good lamps out, but, from what I have seen of the "Davenport" for lantern and general optical projection, it leaves little to be desired.

\* \* \* \* \*

THOSE exhibitors who have returned from the Paris Exhibition are not very enthusiastic over its success, and one gentleman, well known in the scientific world and a popular lecturer with the

lantern, speaks very strongly of the way he was treated, the inconveniences he had to put up with, and the disregard shown for arrangements made, or the carrying out of a definite programme previously agreed to. One and all speak of the artistic beauty of the Exhibition, and the set of slides just published by Messrs. York & Son, which I have seen, shows this, also a view of the Seine frontage I saw recently taken by the Kodak Panoram, which gives a capital idea of the place, and illustrates the value of a panoramic camera for scenes with extended fronts. What an ingenious little camera the Panoram is! I was charmed with its simplicity and practical design. There is a big future for this. What a pity the Digue at Ostend faces north instead of south. It would be an ideal picture if it only had a midday light on it. However, Brighton, Eastbourne, Hastings, and Folkestone will not make bad pictures. I am just off to Holland. I do not know what success I shall have in snap-shotting, but am going to use the quarter-plate new folding Pocket Kodak, and hope to get something good. G. R. BAKER.

### INVISIBLE RAYS.

THE last five years have, perhaps, elicited the greatest interest outside, if not also inside, scientific circles in the nature and action of invisible rays of one kind or another. They may be either of the nature of electrical or light rays, *e.g.*, waves in the ether, or composed of travelling material particles emitted from certain bodies. The phenomena exhibited by them, however, have been so unexpected and striking that, unlike the majority of scientific researches, they have aroused interest in the public mind and kept it glowing.

There is no doubt that this recognition is at least partly due to the great practical applications to which some of these discoveries have led.

The work begun by Crookes, Lenard, and others, and followed up by Röntgen, resulting in the "capture" of the rays bearing Röntgen's name, has been extended, and is now being applied so extensively throughout the world as to surpass the utmost expectations of those investigators. No hospital or medical man now considers a difficult diagnosis complete unless the patient has been subjected to a searching X-ray examination. Adequate X-ray equipments have been sent out to the front in recent campaigns, much to the comfort of both surgeon and patient. Many instances might also be cited of the rays being applied in commercial practice.

The brilliant work of Hertz upon ether vibrations of longer wavelengths, those giving rise to electrical radiation phenomena, has been the solid foundation upon which have been built systems of "wireless" telegraphy. These systems, in the practical hands of Marconi and others, are effecting a radical change in some of our present methods of transmitting messages and signals.

More recent work has brought to our knowledge the existence of other rays, some closely allied to the above, others of apparently a different order. As all these rays, at the dates of discovery, seemed to have distinctive properties, each was given a name; but it is very probable that further investigation will reduce the list, twins or triplets coalescing to form one definite kind of radiation. For instance, those known as Lenard, Röntgen, cathode, and canal rays have many points in common, and there is no doubt that both Lenard and cathode rays originate Röntgen rays, but upon the identity of the two latter present experiments are conflicting. Investigations tend to prove that cathode rays consist of electrified particles, which are much smaller than a molecule and which travel with a velocity little less than that of light. Röntgen rays, on the other hand, will not convey an electric charge, nor are they, like cathode rays, capable of being deflected by a magnet. If they are flights of material particles, they may be looked upon as discharged cathode rays, when the absence of magnetic deflection would be explained. Other experiments seem to show, however, that the observed absorption of Röntgen rays is not sufficient to be consistent with this material theory, but that the rays must be of the nature of irregular ether waves.

The second order of rays referred to is apparently of much less energy than those just considered, and the experimental phenomena observed with them are less striking. They are, nevertheless, of the utmost interest, for, although recent researches upon them are sometimes confusing and contradictory, the results obtained are vastly extending the knowledge of the physicist in the atomic world. Becquerel's discovery that uranium and its compounds emit radiations that are capable, among other things, of acting upon a photographic film, of discharging electrified bodies, and of being reflected and refracted, has been extended by

various workers to other bodies which possess similar properties in different degrees. Thorium emits rays similar to uranium rays, except that they are not polarised by a tourmaline plate. Pitchblende (oxide of uranium) was found to be more active than uranium itself, and this fact led M. Curie to the discovery of the new metal polonium, which is about 400 times as active as uranium. Pitchblende, indeed, seems to be a veritable mine for these radio-active bodies, for since the discovery of polonium two other active elements, termed radium and actinium, have been separated from it: The first of these, discovered by M. and Mde. Curie, proves to have 900 times the radiant activity of uranium and is self-luminous. The chloride of radium produces a photographic negative in half a minute where uranium or thorium would take hours: Through aluminium it can render a film of barium platino-cyanide (of which X-ray screens are made) permanently luminous, sufficiently to make it visible in the dark, and without any apparent supply of energy. Uranium and thorium do not produce this latter effect, probably because their action is too feeble. Actinium, the latest addition to the family, and bearing a close chemical analogy to titanium, has been found by M. Debierne in the residues of pitchblende. Its radio-activity is a hundred thousand times that of uranium, but, although its activity is so much more powerful, actinium is not, like radium, self-luminous.

In May last Sir William Crookes embodied, in a paper to the Royal Society, some very astonishing results upon the source of these rays. In fact, by a brilliant series of experiments, patiently made, he has shown that absolutely pure uranium and its compounds are entirely inactive, and that the so-called radio-activity of these is due not to an inherent property of uranium, but to the presence of a foreign body, which can exist apart from uranium. To this body he has given, provisionally, the name of UrX—the unknown substance in uranium. We are confronted therefore with another supposed new body with very great radio-activity. Whether UrX is also the substance giving rise to the activity of radium, polonium, &c., further experiments will, perhaps, show. It certainly seems possible.

As to the causes or nature of the radiation constantly emitted by these substances, it cannot be said that anything definite is yet known. The results hitherto obtained point to the conclusion that, as regards their effect on gases, the types of this radiation are similar to Röntgen rays and to the secondary rays, discovered by Sagnac and others, that are emitted by metals when Röntgen rays fall upon them. It is as if all space were constantly traversed by Röntgen rays of very high penetrative power, only revealed by their being transformed into secondary radiations upon impinging on elements of very high atomic weights, such as uranium, thorium, &c. Crookes calls in the aid of Maxwell's "sorting demon" in suggesting a cause for these effects. He furnishes these radio-active metals with the "demon's" power, so that they are able to separate the rapidly moving from the slow-moving molecules of air, appropriating some of the energy of the former. The energy thus gained would seem to be employed partly in dissociating some of the gaseous molecules and partly in maintaining a radiation across the ether. The necessary smallness and small amplitude of these waves would make them similar in many respects to Röntgen radiation. The air around the active substance would be cooled, but more air would constantly take its place. Under ordinary circumstances the cooling is not detected, and the energy of the radiation appears to be created out of nothing.

The most feasible explanation at present seems to be the one put forward by what is known as the ionisation theory, which supposes that the rays, in passing through any gas, produce positively and negatively charged particles in that gas, and that the number of these charged particles, or *ions*, produced per second depends upon the intensity of the radiation and the pressure. Argued in this way, the conclusion is supported that Röntgen rays and Becquerel rays are similar. Upon first consideration of this theory it would appear that the body emitting these rays would suffer a loss in weight, but M. Curie has shown that the charges carried off are so feeble, and the mass of matter so small, that probably some millions of years would be required to remove one milligramme in the case of the most intense radiation that has yet been discovered.

Whether these emission phenomena will be satisfactorily explained upon the ionisation theory or not, the physicist in so considering them is certainly deriving much help in the realm of atoms and sub-atoms. We are not now investigating the attributes of the molecule as chemistry considers it, but are breaking it up, separating it, and arriving more or less closely at what is known as the ultimate physical atom—in fact, the original "protyle"—about which so much has been said for many centuries, but so little known. Physicists, the last few years, have come to the aid of chemists, and, by very patient work, have endeavoured to break up the

combinations, to simplify the complexities into which it is believed the ultimate and universal atom enters to form what are generally known as elements and compounds. To grapple with the phenomena exhibited by the invisible rays we are now considering, the existence of such sub-atomic conditions is demanded. Will the "protyle"—let it be the hydrogen one or a still more fundamental one—be raised from its submerged position and fixed upon a true scientific pedestal?

We now come to consider another set of phenomena, also due to invisible rays, but rays of apparently a different nature to those above. These phenomena are, perhaps, all the more interesting to the general reader, as they can easily be shown by any one at any time. Several workers have noticed the effect upon a photographic plate of various substances when in contact with or when placed in close proximity to the film. These active substances are capable of producing a latent image upon the film, which can be developed up in the ordinary manner in the developing bath. There is not much doubt but that, prior to the researches of the two principal experimenters upon this subject, viz., M. Colson and Dr. W. J. Russell, thousands of photographers had at times unconsciously performed the same experiments. Frequently has a photographer been puzzled over inexplicable fogging and markings upon his film, although he has been certain no light has had access to it. Sharply defined scratches, lines of print, and other markings have at times been brought out by developers when an "unexposed" plate has been immersed in them, the cause of the mischief having been traced sometimes to pieces of newspaper, &c., in which the plate has been wrapped.

The most active substances in producing this effect are some of the metals, such as magnesium, cadmium, zinc, and aluminium, also copal varnish, printing ink, and the essential oils. It was at first thought that the action was due to phosphorescence, or that these metals were to be considered as active bodies, emitting rays with similar properties to those from uranium, &c., for it was remarkable that such slightly volatile bodies should give off sufficient vapour to act thus upon a photographic plate. Later experiments show, however, that a vapour is given off from them, and that this vapour is the cause of the action. The rays are, therefore, of a different nature to those from the radio-active bodies described above. Since printing inks are so active, it was easy to show that boiled oil and turpentine are the active constituents, these bodies exhibiting separately the same activity as the inks and varnishes. These bodies belong to what are known as the terpenes, and it is an experimental fact that all the terpenes are active.

For experimental purposes, these bodies can be used either as liquids in small dishes or by saturating Bristol board or other neutral and porous bodies. Not all volatile organic bodies are active; vegetable oils are, but mineral oils, as far as they have been tried, are not. A striking fact with regard to the emission from these active bodies is that it gives an accurate picture of the surface from which it has come. A hard copal surface on glass will give a picture showing every brush mark, unevenness, and scratch on the surface, and if the action takes place through a thin sheet of gelatine, or even as many as six sheets, still the picture of the scratches is distinct. That the action is due to some kind of vapour given off from these organic bodies many experiments will show. Saturate a circular piece of Bristol board with drying oil, and at a little distance above it place a smaller circle of mica, which is perfectly opaque to the action, and again above this another piece of mica with a circular hole smaller than the circular mica plate, finally a photographic plate over all. By this arrangement no direct action can take place between the drying oil and the sensitive plate, but a vapour could work its way between the mica plates, and thus reach the photographic plate. This it will do, for, after an exposure of about three days, upon developing the plate a dark ring will be formed, shading off toward the centre. Again, the active power of these bodies can be transferred to a neutral substance. If vapour be the immediate cause of the darkening of the film, then it would be possible, if a piece of Bristol board were suspended above the drying oil, for instance, for the inactive board to take up that vapour, and to become photographically active. This has been found to take place. If the temperature in these experiments is raised, the activity is increased, and the times of exposure may be considerably diminished.

The emanations possess a selective action, for whereas gelatine, celluloid, collodion, &c., are transparent, glass, selenite, and mica, even in very thin layers, are quite opaque to the action. It is certainly remarkable that a vapour should readily pass through these transparent media, and not by mere absorption, but in such a way as to produce a picture of the surface from which it came.

Experimenting in a manner similar to the above, but substituting a piece of polished zinc, or of any of the metals enumerated above, for the

saturated Bristol board, the same effects are produced on a sensitive film; the time of exposure is, however, longer. Since the effects observed with the organic bodies and with these metals are so very similar, we are forced to conclude that the latter also give off a vapour which acts upon the plate. Zinc which has long been exposed to the air is inactive. An exposure out of doors for only three or four days diminishes very considerably its activity, but covered up indoors after three weeks it will still give a tolerably dark picture. If it has a bright but perfectly smooth surface, it is active, but not strongly so; rub the zinc with coarse sand or emery paper, and it is then obtained in its state of greatest activity. The same applies to all the active metals. If, when in this condition, any of them be placed in contact with a sensitive film, a beautifully sharp picture of the scratched surface is obtained. The great increase of the fresh metallic surface produced by the rubbing may account for the increase of activity which the scratching produces. If the zinc plate be raised only slightly above the photographic plate, a sharp picture of the scratches is still obtained, and of course, as the distance is increased, so is the indistinctness of the picture, until at last it fades into a general cloudiness. In this form the zinc plate can easily be made to act through a distance of an inch or more. The vapour from it can permeate the same media as the organic vapour, and the remarkably clear pictures which can be produced through several sheets of thin gelatine prove that the action is not one of mere absorption.

Another experiment, illustrating the way in which these metals can act, is to take a piece of ordinary perforated zinc, polish one side and lay this polished side against a plate of plain glass in a printing frame, then place the photographic plate against the dull side of the zinc and leave it in the dark for three or four days. Upon developing the plate, a reversed picture is obtained; the holes in the zinc will be represented by dark spaces, and the zinc itself by light ones. If the holes in the zinc are large, they are represented by shaded circles, so that these pictures are produced by the vapour emitted by the polished zinc, and which has crept into the open spaces, thus gaining access to the film.

Pure mercury is an inactive element, but it is made excessively active by even the faintest trace of zinc in it. Not more than  $\frac{1}{10}$  per cent. of zinc is required to effect the change. Magnesium and lead give the same result. This action has indeed been suggested as a readily recognised test for the purity of mercury in connexion with any purifying process.

The question now arises, What is the source of this action and how are the effects produced? Experimental evidence point very strongly to hydrogen peroxide being the active agent, although it can only be proved indirectly. Dr. Russell has shown that all the results produced upon the photographic plate, both by metals and organic bodies, can be produced by hydrogen peroxide. If some pure water is poured into a small circular dish and a photographic plate placed on top, nothing can be developed up even after a lengthy exposure of eighteen to twenty hours. If a trace of hydrogen peroxide is added to the water, a dark patch can be developed up after a short exposure. If the liquid contains only one part of the peroxide to a million of water, and the plate exposed to it for eighteen hours, a faint picture is produced. Plaster of Paris, wetted with a peroxide solution and allowed to set, continues active for a long time. If a large amount of the peroxide is allowed to act upon the plate, a reversed negative is obtained, the dark patch giving place to a light one. This result is similar to that obtained with dipentene—one of the most active of the terpenes—a dark picture being developed up after a short exposure, but, if the exposure is increased, the reversal takes place.

Just the same substances are opaque or transparent to the action of the hydrogen peroxide as are to the action exerted by the metals and the organic substances. Moreover, the metals arranged in their order of activity, magnesium, cadmium, zinc, nickel, aluminium, lead, cobalt, bismuth, tin, are just those that might be expected to decompose water, and, in the presence of oxygen, cause the formation of hydrogen peroxide and to induce it in this order of intensity. It may be mentioned here that the above list was arranged in this order from experiment, and at a time when there was no idea that hydrogen peroxide had anything to do with the reaction. Furthermore, in the case of the active organic bodies, it is a property of all the terpenes to give rise to hydrogen peroxide when oxidising. The mineral oils, on the contrary, are quite inactive, and it would seem therefore that all the organic bodies capable of giving rise to the formation of hydrogen peroxide when they oxidise in moist air. Recently, Mr. J. H. Vincent has brought forward further indirect evidence upon this point. He has shown that some of these bodies become active when treated with small quantities of ozone.

If the hydrogen peroxide is the active source for these phenomena,

how does it pass through the various "transparent" bodies? It cannot be said that a satisfactory explanation is yet forthcoming. The peroxide cannot pass through say—gelatine—by the ordinary methods of diffusion, and it would seem that the sharp picture of a scraped zinc surface that is obtained, upon development, after placing the zinc in direct contact with a film, should either be no longer visible, or become only a blurred result if such a sheet of gelatine is placed between them. This is, however, not the case, the scratches are still sharp. Dr. Russell suggests the action must take place by a process of dissolving, or by a feeble combination with the constituents of the gelatine, and thus reappearing on the other side. It cannot be assumed, however, that, in so travelling through, the molecule of the peroxide would preserve a straight course. If such a transmission does take place, the water which the gelatine contains is probably the body which enables the peroxide to pass through; for it can be shown that water aids the transmission of the action through other inactive bodies. For instance, if Bristol board in its ordinary condition is placed on a polished piece of zinc, the action from the latter passes through it slowly; but, if the board is damp, the transmission is much more rapid.

From what has now been said regarding this action, a photographer will very probably be able to trace to their source many irritating and hitherto unexplained developments. He will also be more alert as to what he uses as a covering for his plates. For instance, brass is an active body, a brass consisting of fifty per cent. zinc producing a fairly dark picture. Aluminium being also active, plates contained in aluminium backs are liable to become spoilt if allowed to remain there long. Wood also gives its own picture. The results observed, therefore, although simple in themselves, are of interest and importance, especially to photographers. It may be argued that the length of exposure required to obtain these impressions is so long, comparatively, that the effects will be quite negligible in ordinary work; but it must be remembered that plates and films are stored sometimes for weeks or months under coverings of various substances, and that brass and aluminium play an important part in cameras and slide backs.

In conclusion, it may be pointed out that glow-worms and ordinary bacterial cultures are capable of affecting a photographic plate, the action, in all probability, being also due to some kind of vapour emitted from them. Results are obtained even at a distance of an inch, whereas, if the bacteria are in contact with the film, definite pictures of the bacterial growths are produced. Self-luminous bacteria exert a much more powerful action than non-luminous ones.

JAMES QUICK.

#### PLEASING EFFECTS IN SINGLE-LANTERN PROJECTION.

THERE is no question about the fact that single-lantern projection has become deservedly popular since the production of lantern slides is a matter of such easy accomplishment by means of photography.

In previous years hand-painted slides were made to do duty in even what at that early period were deemed high-class entertainments, but, with the application of photography to this industry, a new era was introduced, and lantern projection jumped at once into prominence in many respects by reason of the truthfulness of the views displayed and the ease with which such were produced.

The optical lantern thus became closely associated with photography—an intimacy that has, and always will be, maintained, so long as lantern slides are produced by its aid.

The moment lantern slides were so effectively produced by means of photography saw a distinct change intervene on the part of photographers generally, in regard to the introduction of colour in the views specially prepared for the lantern; and this change was certainly fostered by the great majority of amateur photographers throughout the length and breadth of the land, who, very probably by reason of their inability to colour the slides they so easily produced by means of the now universal gelatine plate, were naturally seen bestowing more appreciation of black-and-white productions, to the utter neglect of really high-class coloured photographs, so seldom seen exhibited nowadays among our photographic associations.

On the other hand, there are, no doubt, many experienced lanternists and lecturers who have come to learn that, from among the public generally, there are a great number who have a strong appreciation for a little colour on the screen. Audiences are not always composed of high-art devotees, but are more frequently found showing their marked appreciation when a good coloured view is introduced among a series of plain photographic slides.

Apart from this desire for a few coloured pictures in a lecture set or entertainment, there is another matter bearing strongly on this question, which in these days of black-and-white projection is too liable to be overlooked, and that is the discomfort experienced by many in sitting out during the projection of a large number of black-and-white pictures, extending, it may be, over a period of one and a half hours.

With some people this discomfort takes the shape of a painful headache, with a nasty tightness across the forehead and pain in the eyeballs, and becomes more intensified the nearer a sitter approaches the screen. Hence how often do we hear expressions at the close of an entertainment such as the following: "I would have enjoyed it better if I had not got such a beastly headache."

Fortunately, the public seldom know the true cause of this discomfort, but a wise lecturer, or one who knows his business well, takes care to provide against such discomforts by introducing here and there, throughout his lecture, a few coloured pictures or otherwise tinted effects, for well he knows how beneficial they are with the public generally, notwithstanding that, now and again, a few individuals of the so-called "artistic set" never can see any beauty or utility in the introduction of such colour on the screen.

The writer can well remember discussing this matter with a prominent amateur photographer in the west of Scotland, who maintained that this feeling of discomfort was all bunkum, and did not, in point of fact, exist at all, where the ventilation of a hall or lecture-room was what it should be; and that, so far as his knowledge went, there never was a set of commercial lantern slides produced by a really first-class maker that could be said to be so black-and-white as to cause discomfort to any one in an audience.

This was throwing down the gauntlet with a vengeance! And so the writer took the earliest opportunity of showing him by ocular demonstration that others knew their business better than he could teach them. So, mentioning the names of three first-class makers of lantern slides, he selected the name of one who stands in the very front rank as a slide-maker, and I had not long to wait for my innings.

The lecture I requested him to attend was one on "The Holy Land," the lecturer being a gentleman who had travelled over Palestine and was intimately acquainted with the country, so that, on the score of the lecture being made interesting, nothing better could be desired. And so the evening came round, when we attended together. All went well, just as I expected, until the lecture was about three parts through. I then whispered, "Any headache, old man?" "Yes! I'm blowed, but I have a beastly pain across my forehead," he replied. "And I should never have believed it," he added.

No doubt some sets of slides are more liable to yield discomfort than others, but the remedy for this state of matters is well known, and consists in introducing at short intervals well-selected colour slides, or otherwise where commercial sets of slides have to be made use of, by resorting to the equally simple but effective alternative of using tinting glasses or screens. It does not follow that these tinting glasses should be employed with every slide. Such a procedure would yield a monotonous effect; but, on the other hand, a judicious use of a few carefully selected screens on slides that are specially noticeable for their strong contrasts never fails to impart a highly pleasing effect as well as to yield a fair amount of rest to the eyes of the spectators.

In providing for these adjuncts to a single-lantern outfit, little or no alteration is usually required in its structural parts, and, although provision is sometimes made for what is termed tinting effects in the best class of lanterns, strange to say, such provision is made in the worst possible manner, viz., by introducing tinting glasses between the objective and the screen. As to what is the proper place to interpose these tinters there is, fortunately, no doubt, for any one can easily understand that the only really sensible part to introduce them in is somewhere between the light and the slide. The reason for this is obvious, viz., such a position in no way interferes with the definition on the screen, which must be maintained at all other sacrifices. In the early form of high-class lanterns doors were provided behind the condensers in the body of the lamp. By this means tinting glasses were run through the aperture so as to intercept the light at a point between the lime and the back lens of the condenser, and this was a very suitable arrangement indeed. With many lamps such facilities, however, do not exist; but even with such lantern bodies the lantern front can generally be made to yield a passage between the condensers and the carrier sufficient to permit of a sheet of glass being introduced between the light and the slide. In private sets of lantern slides another expedient can be resorted to, viz., employing suitably tinted cover glasses according to the nature of the picture; but, of course, where a lanternist has to manipu-

late all sorts of slides at a moment's notice, he has no alternative but to use a lantern in which provision is made for such tinting glasses.

In nearly all lantern fronts it will be found that a fair margin of space is allowed for varying thicknesses of carriers, and, by blocking the collars forward by means of little wooden wedges, a space of a quarter of an inch or so is easily provided behind the carrier and the plate carrying the front of the condenser. This space is quite sufficient for the purpose, and is the ideally perfect position in which to employ tinting glasses.

It stands to reason that, if really good effects are aimed at, there must be provided a variety of tinters. This does not necessarily mean a large number, for, in reality, there is a limit to the number that can be utilised in a lantern. Three, or at most four, will be found ample for any series of lecture sets, and the tints or colours of these glasses are not difficult to obtain.

Having given some thought as to what are the best colours to provide, very likely an operator will find that for architectural subjects he will get the most pleasing effects with a pale French grey tint, and, in cases where portraits are shown, a nice light pink will be very suitable, whilst in well-defined landscapes and heavy outside subjects a greenish-yellow will prove excellent for the purpose.

These tinting glasses must be absolutely free from flaws, otherwise such defects will be painfully evident on the screen, and the colour of the glass must not be too decided. A very useful size (and it is one I employ regularly in single-lantern work in conjunction with a Beard's carrier, which gives an almost dissolving effect) is  $9 \times 3\frac{1}{2}$  inches. The carrier is blocked forward by means of a strip of wood that runs the whole way across the front of the lamp. This strip of wood serves a double purpose, not only does it provide a space of about a quarter of an inch for the glasses to run through, but it provides a platform for the tinters to run and rest on behind the slides. Any one who grasps the idea of introducing tinting glasses to his lantern will, with a little thought, soon find out the best means of doing so, according to the form of the particular lamp he employs. Front tinted attachments, *i.e.*, flaps, working on the front of an objective, are certainly useful where sky and foreground effects only are desired, but the same results can be achieved quite as well by means of the hand and suitably coloured glasses held to the top and bottom of the lens just where the rays are emitted; but to introduce such glasses in front of the objective only tends to spoil definition.

In rendering pleasing effects with a single lantern, it is surprising how much may be done with a really good carrier. This is not the place to suggest the employment of any one carrier in preference to another, but I am often asked how such-and-such an effect can be obtained, and my answer is generally, By means of the carrier. The old-fashioned backwards and forwards movement of carriers for single lanterns did good service in its day, but it is now quite out of date in high-class lantern projection, and it looks also as if the lantern fronts of early days are to be entirely swept away and open stages take their place, for there is little doubt much can be done with open stages that cannot be accomplished by closed-in tubes for the objectives. The open stage works much cooler also, and permits of the light and its adjustment being more easily manipulated.

T. N. ARMSTRONG.

#### THE MACDONOUGH PROCESS OF COLOUR PHOTOGRAPHY.

At the recent Milwaukee Convention of the Photographers' Association of America, Mr. Mark Forrest discoursed on the subject of the MacDonough Process of Colour Photography. He pointed out that light is the sensation produced by a luminous ray upon the retina of the eye, and the stimulation of the retina gives rise to the sensation of colour. This sensation of colour is due to the fact that the luminous rays have different rates of vibration, that is to say, that the rays travel in waves. The red waves are the longest, about thirty millionths of an inch. The violet rays at the other end of the spectrum are the shortest, about fifteen millionths of an inch; and every other colour, or possible variation of colour, lies between these two extremes.

Now, these vibrations or waves of light impress the brain with a sense of colour by their independent action upon what are called the nerve-fibrils, and these nerve-fibrils are variously affected according to the length of the light waves that reach them. They are practically divisible into three sections—one section is most sensitive to the longest rays and reflects to the brain a sensation of red, another section is most sensitive to rays of medium length and reflects to the brain a sensation of green, another section is most sensitive to the shortest rays and reflects to the brain a sensation of blue. When these nerve-fibrils are wholly unaffected—as when, for instance, one is wholly in a darkened room—the brain is

impressed with a sensation of blackness, which is the utter absence of colour. When the nerve-fibrils are equally affected, the resultant impression is that of white, which is the presence of all the colours. When the nerve-fibrils are unevenly affected, the resultant impression is that of a compound colour.

Observe that we have been referring to red, green, and blue as being the three primary colours, for the old theory that the primaries were red, yellow, and blue has been scientifically demonstrated to be incorrect. Yellow has been proved to be a compound of red and green. From red, green, and blue all other colours can be formed, and only by a combination of red, green, and blue can pure white be obtained.

It was along the lines of this theory that MacDonough worked, but one of the greatest difficulties he had to contend with was a means of properly decomposing a ray of light before it struck the sensitised surface of the plate. He first tried to stipple a screen by spattering it. He attained the result of properly decomposing the light, but found the method was impracticable because the irregularity of the marking made duplicates impossible, and he could not, of course, make a separate taking screen, by hand, for every picture.

At last he struck upon the plan of ruling the screen with equidistant lines of the three colours, and that is the form which is now used. It is difficult, however, to convey a clear impression of the fineness of the lines, which are ruled from 300 to 600 to the inch, so that the colour of the lines is only discernible through a powerful microscope.

Now let us suppose that you have your camera ready and want to take a picture by this process. There's no secret about it, nor is there the slightest difficulty of manipulation at any stage of the process. A ruled screen, called the taking screen, is inserted in front of the plate, perfect contact with which is ensured by moving a little lever at the side. On the front of the lens you place a chromatic balance shutter, whose object is to regulate the blue in the atmosphere, dependent upon the conditions of sunshine or shade, blue being the most actively actinic colour, and the one that is always most difficult to control. The shutter is made of three layers of coloured mica. By shifting the movable sections the operator can increase or lessen, at will, the proportion of blue in the light that enters the camera.

Now, when the light enters the lens, the taking screen splits up the ray into its component parts, just as a prism does, though in a different manner, and absorbs or transmits just so much of each of the three primary colours as is necessary to exactly duplicate the colour of the object. Suppose, for instance, you are photographing a piece of yellow cloth; now, yellow, as I have stated, is a compound of red and green. Accordingly, the red and green lines each transmit just so much of each as is necessary to make that particular tone of yellow; if it is an orange yellow, the red transmits more than the green; if it is a greenish-yellow, the green transmits more than the red. And so with every other colour or possible variation of colour.

When the plate receives the image of the object, it also receives an impression of the colour-value lines from the taking screen. From the negative a positive is made. Then a viewing screen, ruled in exactly the same fashion as the taking screen, except that the blue lines are a little lighter, is adjusted so that the lines exactly agree, and the whole picture immediately flashes into colour.

Now we come to the pictures; but, in viewing them, we must bear three things in mind:—

First, that, from first to last, the colouring is obtained by purely scientific means. No man's hand has doctored any of them with a paint brush, but the colour is purely dependent upon the decomposition of light.

Secondly, that these slides will illustrate merely a few of the many ways in which the process can be turned to commercial account. Some of the slides will be of interest for their beauty mainly, but there is hardly any form of business in which colour plays a part in which this process cannot be turned to better account for advertising and similar purposes than any other form of colour-reproduction that has hitherto been known.

And the third point is its value as a means of graphic education. In pathology, geology, astronomy, chemistry, botany, architecture, in fact, in almost every conceivable department of human knowledge, the use of such pictures as we are about to show you can be demonstrated to be of enormous value.

Mr. Forrest then described the pictures as thrown upon the screen, and, when the portrait of Mr. Tripp was produced, said: "And now, before going further, I want to say a few words about some of the little group of men whose faith and zeal encouraged MacDonough in his work, and have sustained the burden of that work since he died. This is a por-

trait of Mr. Dwight K. Tripp, the President of the International Colour-Photo Company. The value of his aid and service in connexion with this wonderful work it is hardly possible to over-estimate. To his fine faith in the feasibility of MacDonough's ideas and plans, and to his persistent encouragement and able care of the financial end of the enterprise, the success of his method is very largely due. Under every stress of discouraging circumstances, his confidence in the ultimate success remained unshaken, and it is largely due to him that the MacDonough process has now obtained recognition as an artistic method of registering the colour beauties of nature that is pregnant with the most wonderful possibilities."

#### PHOTOGRAPHY AND THE JAPANESE.

THE Camera Club *Journal* for September (to which we refer elsewhere in this week's *JOURNAL*) contains the report of a lantern lecture on Japan in April last by Mr. J. W. Groves, F.L.S., who, it is stated, exhibited a most comprehensive collection of lantern slides, some of which were from his own negatives, but the majority were commercial slides purchased in Japan and coloured with exquisite delicacy by native artists. He also showed some collotype prints, made by "Ongatoo," in Tokio, from photographs taken by himself in Kashmir, and both the slides and the collotypes were typical of the high degree of excellence to which the Japanese workers had attained in these as in other arts. The photographs illustrated in a very thorough manner the appearance of the country, the dress, customs, industries, and amusements of the people, and many details of every-day life.

The Chairman of the meeting, Mr. Arthur Diósy, in the course of some interesting observations, told his hearers he had had a very wide experience of photographic slides of Japan, having seen many hundreds of them, but he had never seen a collection which represented Japan and the Japanese more completely and truly than those which had been exhibited by Mr. Groves. They represented Japan in a twofold sense, first, because the subjects chosen and the skill with which the work had been done—both by Mr. Groves and by the native photographers, by whom some of the negatives had been taken—were the right subjects and the right skill for making true pictures of the country; and, secondly, because, when one compared the gruesome things that were usually produced in Europe as coloured lantern slides with the beautiful pictures which had been shown upon the screen, one was enabled to form an idea of the degree of true art which was the innate possession of every Japanese, for the Japanese were born artists. The excellent coloured slides which had been exhibited could be bought in Japan for about sixpence each, and the man who received fourpence each for colouring them was a truer artist than many men whose pictures were hung on the line at the Academy. The Japanese had an innate hatred of the ugly and an innate appreciation of the beautiful. Frequently, when he had been travelling in Japan, his bearers had stopped, not for the purpose of shifting the pole from one shoulder to the other, but to get a good long view of a beautiful spot, just as in this country they would stop for a good long pull of liquid refreshment. A whole library might be written on the "tags" furnished by Mr. Groves' slides. The photographs of Japanese women that had been shown were typical of the lower class, the lower middle class, and the geisha class, and not of the upper class, because it was exceedingly difficult to obtain a portrait of a Japanese lady under circumstances that would warrant its reproduction as a slide. The upper classes in Japan had a peculiar and very highly refined type of countenance of their own; the geishas, although generally of low origin, from their long training and education, to a certain extent acquired the look of the upper classes, but they never exactly resembled them. The geishas did not in every case take to a bad class of life, and they were no more obliged to do so than is an European actress. The life of a geisha offered abundant opportunities and temptations, just as did life on the stage in this country, but he would be very sorry to say that life behind the footlights was inseparable from immorality; in fact, his own connexion with the stage had made him know better. He knew several highly respectable married geisha ladies in Kioto, who derived a large income from their profession because they were clever, very well educated, and excellent conversationalists. The geisha was supposed to be able to sing and recite well, and to play well on the *samisen*, and to interest the man to whom she was talking. The secret of a geisha's success was the same as the secret of the success of a flirt in this country—she must be able to make the man to whom she is talking believe that he is the only man in the world. As to Japanese women as a whole—geisha, or dancing girl, or singing girl, or tradesman's wife, or lady—no photograph that could ever

be taken could do them justice even in the faintest degree, for their charm lay in essentials that could not be reproduced by photography. It lay in the wonderful lustre of their eyes, in the beautiful gloss of their jet-black hair, in the satin smoothness and softness of their skin, in the exquisite grace of their hands, fingers, and wrists, and particularly in their admirable grace of movement when seated, and in their beautiful silvery voice.

#### THE BAROMETER OF POPULARITY.

A REPRESENTATIVE of the *Daily Chronicle* has been making inquiries into the supply-and-demand aspect of photographing celebrities, and among those he addressed himself to were Messrs. R. Stanley & Co., wholesale distributors of photographs in this and other countries.

A member of the firm, he writes, not only gave him the benefit of his general experience, but even showed him some of the orders he had recently received from shops.

"Do you find that Generals are 'going off' in public favour?" I asked.

"Yes, very much so; the retail trade seems satisfied with the stock it already has in hand."

"Who provided the most lucrative subject in this particular line?"

"Baden-Powell, unquestionably first; Roberts second; and perhaps Kitchener third. But Kitchener was run very close by Generals Symons and White. You see, they were to the front in the early stages of the war, when the demand for photographs was at its height; moreover, they are both very good-looking men. General French is another of our handsome Generals who sold well."

"Good looks, I suppose, counted with lady purchasers?"

"To some extent; but I fancy that patriotism—that is to say, admiration of success—counted more."

"Apart from the war, what has been your best line of subject?"

"That is difficult to say, because the demand is so uncertain; I do not believe there is any trade in which this characteristic of uncertainty is so marked. Apart from popular actresses, we never know how we stand from week to week. Royalties, of course, are more steadily in demand than any other class. Public events give rise to a temporary boom. For instance, we could not supply orders for the late King of Italy fast enough. My trade is particularly typical of the uncertainty of the demand. Now, look at this order, which I received yesterday from shopkeeper in the States—from Boston. He orders:—One King of Servia, one Earl of Clarendon, two Duchess of Marlborough, two Empress Frederick, two King Humbert, one Blowitz, three Kruger, and three Lady Randolph Churchill. Of course, this is the outcome of special orders of certain customers, but they are characteristic. Last week I had quite a run on members of the Rothschild family, for no apparent reason. This week I have had a mysterious order for a set of photographs of the summer and winter residences of all the crowned heads of Europe. This is probably for a magazine article. Among authors, we have a steady demand for Blackmore and George Meredith, but neither of these can be supplied in the ordinary course of business."

"And how about the stage?"

"By far the largest demand at present in this department is for Edna May and La Cavallera, and it appears that ladies quite as much as men purchase these and other photos of pretty women."

For further information as regards stage subjects he called on Mr. Alfred Ellis, of Baker-street.

"The demand for photographs of stage celebrities has fallen off very much in recent years," his representative told me. "Of course the war and the consequent demand for Generals accounts for the present condition of this branch of our trade. But, in any case, we are not likely to see a revival of the days when Mrs. Langtry's portraits had such a phenomenal sale."

"What have you done most of in recent years?"

"I cannot for the moment say for certain; but, unquestionably, we had for a time to meet a very large demand for Miss Dorothea Baird as Trilby. This was the result of a 'boom,' and consequently was only of temporary duration."

In a recently published article in an American magazine the writer, a well-known American journalist, stated that, when visiting the quarters of the British officers held as prisoners in Pretoria, he found the portrait of a certain London actress hanging over most of the cots. The statement probably came as a surprise to English readers, and, judging from inquiries incidentally made, London photograph dealers cannot account for such a large supply of this particular subject in a very limited area. Moreover, captured officers were not usually accompanied by personal baggage. It happens that the lady was very popular at one time in New York, and that the article was written mainly for the American public.

PHOTOGRAPHY AT THE GREENWICH OBSERVATORY.

annual report of the Astronomer Royal was issued recently. From the report we see that during the year ending May 10, 1900, 503 plates have been taken with astrographic equatorials on 118 nights. Of these, 136 have been rejected for the following reasons: 27 because the exposure was interfered with by cloud, or because the images were too faint to show the stars of the ninth magnitude with a twenty-second exposure; 21 owing to faults in guiding or exposure; 14 on account of wrong focusing; 17 owing to imperfect printing of the *réseau*; 42 on account of defects in the photographic plates; and 14 from miscellaneous defects. From this it will be seen that something over twenty-five per cent. of the negatives were failures from one cause or other, not a very large percentage after all, seeing that nearly ten per cent. were due to faulty plates.

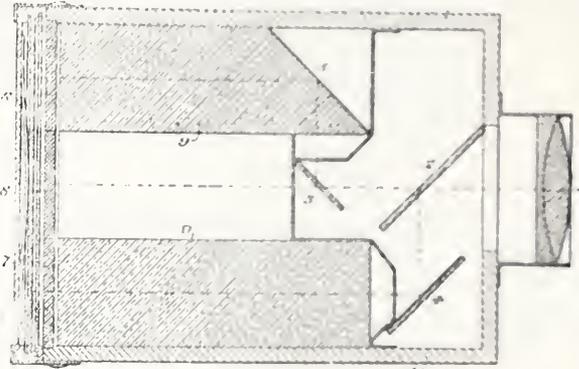

The report also shows the progress made with the photo-mapping of the heavens. For the Chart the number of photographs taken with ten-minute exposures were 243, and the number of successful plates 166 and the number of fields successfully photographed was 155. The total number of successful fields reported up to May 10, 1899 was 1027, but of that number previously considered successful 106 have since been rejected, so that the total number of successful fields secured to May 10 of this year is 1076, leaving 73 more to be taken.

Last year it was found that many of the negatives previously taken had deteriorated, and had to be replaced, and this is now being done. Reference has already been made in the columns of the JOURNAL to the alleged fading of the finest and more delicate details in gelatine negatives, and in the case of the negatives at the Observatory it is presumed that the deterioration has been caused by the damp in the building in which they were stored. One would almost have surmised that with negatives of such value as these they would not have been exposed to any such risk as that, because most of us know the effect of damp on gelatine negatives. It now seems that greater precautions are being taken to keep them dry in a place where they will not be exposed to the extremes of temperature they formerly experienced. If, as has been stated, the most delicate objects in these gelatine star negatives are liable to fade in the course of a few years, would it not be well, as a precaution, to at once reproduce them by a permanent process—collodion, for example, that has stood the test for fifty years, or nearly so? We see from the report just issued that it is intended to prepare a full description of the Observatory, illustrated by photographs. This will be an interesting volume when it is issued, but it is not yet commenced.

inclined opaque reflector 4, and the rays reflected from the plate 3 being directed on to an inclined opaque reflector 5, so that all three series of rays will be directed rearwardly through suitable lens constructions 6 and will form images side by side upon a single plate contained in a plate holder 7 at the rear end of the box, the rays, before reaching the plate, passing through suitable colour screens 8.

The reflected rays which form the side images of the series also pass through rectangular blocks 9 of glass interposed in the path of the rays between the lens structure 6 and the plate, whereby the focal point of these side rays is extended to such an extent that the images formed upon the sensitive plate will all be equal and properly focussed. For instance if the axial rays to the outer images are two inches longer from

Fig. 2

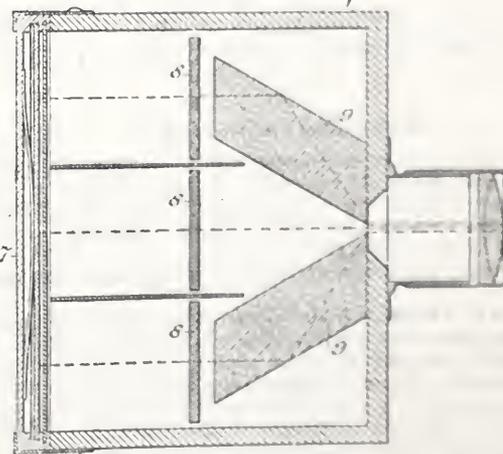

the view point than the axial ray to the central image, it is necessary to extend the focal point of the outer rays to the extent of two inches, and this may be accomplished by introducing in the path of each longer ray six inches of transparent substance having a refractive index of 1.5, which is approximately the refractive index of crown glass.

If a heavy silicate flint glass, having a refractive index of 1.96 is used, a length of slightly more than four inches will be sufficient, or in place of a solid block of refractive medium a glass tank of proper size and shape filled with a suitable liquid may be employed, as shown for instance at 9<sup>a</sup> in fig. 4.

In the construction shown in fig. 2 a single lens is employed at the front of the camera instead of the series of lenses within the camera, as

Fig. 3

shown in fig. 1, and one of the refracting blocks 9 has a prismatic front end which may be silvered so that it serves the purpose of a side reflector 5.

The construction shown in fig. 3 illustrates the application of the present invention to a camera having points of view practically coincident, though in reality very slightly separated. Both refracting blocks in this case are prismatic and serve also as reflectors for directing rearward the rays for forming the outer images.

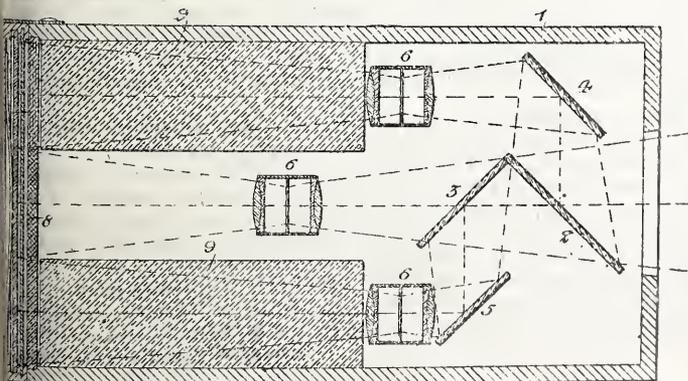

Mr. Ives adds, "It will be evident that in carrying out my invention two or more blocks of glass cemented together may be used in place of a single block, for instance in fig. 5 I have shown four blocks 9<sup>b</sup> used in this way, or the blocks may be separated from each other as shown for

THE IMPROVEMENTS IN PHOTOCROMOSCOPIC APPARATUS.

[Patent No. 12,181 of 1900.]

The object of the invention is to provide, in photochromoscopic apparatus, a simple means for equalising the size of the three images produced from a single view point and disposed side by side in the same plane, or for the optical super-position, at a single view point, of three such images. In the present invention the cone of rays to each outer image is

Fig. 1

etched out and the focal point extended by introducing in the path of the rays a body of glass or other refracting medium, which, in technical language, "retards" the light ray.

In fig. 1 the casing or box of the camera is represented at 1, while 2, 3 and 4 are transparent inclined reflectors arranged in the path of the rays, the rays reflected from the plate 2 being directed on to an

instance at 9°, in fig. 6, or one or more rectangular blocks may be combined with a prism, or the said prism may be combined with one or more tanks or cells filled with liquid, for instance in fig. 7 I have shown a

Fig. 4.

Fig. 5.

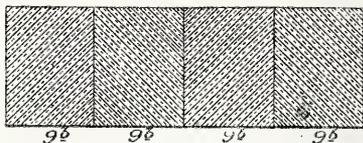

Fig. 6.

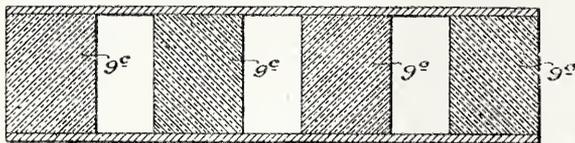

Fig. 7.

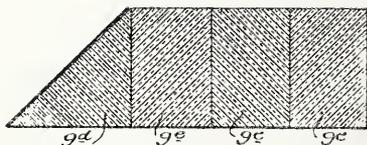

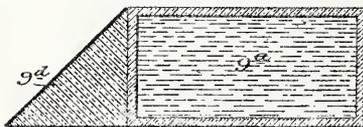

Fig. 8.

a prism 9<sup>d</sup> combined with three rectangular blocks 9<sup>e</sup>, and in fig. 8 I have shown the said prism 9<sup>d</sup> combined with a rectangular vessel 9<sup>a</sup> filled with liquid."

### MONOCHROMATIC LIGHT.

The importance of a monochromatic light in photographic research is becoming more appreciated by investigators in photometrics and sensitometry. Hence a digest of a recent exhaustive paper by MM. Charles Fabry and A. Pérot, in the *Journal de Physique, Théorique et Appliqué*, will be studied by those interested.

The authors take the various methods of producing a monochromatic light in turn:—

1. *Filtration of a Beam of White Light.*—The employment of the very best absorbents gives very rough results. A spectrum may also be projected through a slit, and this is a method which, though the results depend theoretically only on the dimensions of the slit and the defining powers of the apparatus, yet possesses the defect that the brightness of the source thus obtained is feeble as the approach to perfection is greater. Even with solar light it is not easy to obtain a sufficiently intense beam, and in any case the apparatus is rather complicated, including a powerful dispersive apparatus and demanding extremely rigid construction throughout, if the wave-length of the luminous source thus produced is to remain constant throughout a given time. Further, except in the case of solar light, there are no points to which the wave-lengths can be referred.

2. *Light Emitted by a Gas.*—Luminous gases usually emit a light, the spectrum of which is made up of a certain number of brilliant lines. This light is therefore made up of several truly monochromatic lights superimposed, which latter can be separated more or less easily according as the radiations are less or more close together in the spectrum. In cases where they are fairly widely separated, absorbents can be used. In general, however, it is necessary to employ dispersive systems, which need not possess a great refinement, except when closely adjacent beams are

concerned. Certain special methods are then used, such as those based on the double refractive power of quartz, as pointed out by M. Mascart, which answers very well for the separation of the two D rays, which are separated with difficulty in other ways.

A gas may be rendered luminous in several ways. In any case, the temperature of the vapour must be raised, but the method of directly heating the enclosing vessel is never used, for it would give altogether too feeble sources of light. Other methods are introduction of the vapour into a flame, and illumination by an electric discharge of one form or another. The light emitted by a gas varies so greatly, according to the method of illumination, that no accurate results are possible (in the case of observing the spectrum of a metal, for instance) unless the exact circumstances are stated.

*Flames* are extremely unreliable as sources of monochromatic light. The light is not constant, and is generally feeble.

*Gases or Vapours Electrically Illuminated.*—This method is not new, for it is that used in the Geissler tubes. MM. Michelson & Mosley have, however, recognised the remarkable property of the light emitted by these tubes, which, when containing metallic vapours, emit a relatively small number of very fine radiations.

A single tube can produce very different spectra, according to the conditions of electrical excitation. These differences are, no doubt, connected with the differences in temperature of the illuminated gas. The temperature should be much higher in the cases of rapid discharges than in those lasting a relatively short time. In this way the insertion of a condenser at an explosive distance reduces the fineness of the rays, whilst the excitation of the tube by alternate, or even by continuous, current gives radiations of remarkable fineness. When discharge occurs without disruption, only low-temperature rays are produced. With condenser and an explosive distance, the spectrum approaches that given by an induction spark in the air. It seems reasonable to suppose that the temperature is then much higher, the expenditure of energy having taken place in a much shorter time.

As the addition of a condenser gives rise to a certain number of new rays, the question arises as to the influence of the mode of excitation on the rays which are normally present. The points to be examined are as follows: What is the influence of the method of excitation of the tube on the wave-length, the fineness of the rays, the composition of those which apparently consist of several constituents, and in particular on the relative brightness of the components.

(1) *Bobbin with Condenser attached to the Secondary.*—The necessity of complete continuity in the discharge in order to obtain fine rays and definite wave-lengths led us to try other methods than this, in which this condition cannot be readily satisfied.

(2) *Alternate Current.*—The best results are obtained by alternating current of sufficiently high intensity. The light is very constant, the tubes last long, and there is no chance of trouble from a badly acting interruptor. The necessary current amounts to only some thousandths of amperes, but it must have a tension of about a thousand volts.

(3) *Continuous Current.*—The best result, from the point of view of fineness of rays and freedom from secondary components, is that given by the light obtained by connecting the two electrodes of the tube to a source of continuous current presenting a difference of potential of at least from seven to eight hundred volts. We use a battery of 500 small accumulators of 4 ampère-hour capacity, which can keep up the discharge for a very long time, since the current required is only three to four milli-amperes.

The illumination of the tube often calls for a difference of potential greater than that required for the excitation. We therefore permanently place in the circuit the induction apparatus known as the "piercer" of Breguet, in such a way that the electro-motive force produced adds to that of the battery. In order to regulate the current, we insert as well a resistance of a vessel of water in which dip two copper wires, the lengths of the immersed portions of which can be regulated. The light obtained is perfectly constant, easily adjusted, and the rays are extremely fine.

(4) *Electric spark*, for reasons which need not be given here in full, is not a very practical means of obtaining monochromatism.

(5) *Electric arc*, produced between a bath of mercury (positive electrode) and a pencil of carbon (negative electrode), is capable of giving very good results. Ultra-violet rays must be cut off with a solution of sulphate of quinine. Greatly superior results are obtained by producing the arc *in vacuo*. In order to obtain monochromatic light, when it is used under these special conditions, a solution of eosine is used to remove the green and violet; chloride of didymium removes the yellow chromate of potash, violet; and sulphate of quinine, the ultra-violet.

CHARLES FABRY AND A. PÉROT.

The excavations that have been in progress for some months past upon the site of the ancient forum at Rome have resulted in quite a curious discovery. Under a large square flagstone there were found three weights of 20, 30, and 100 Roman pounds, dating from at least two centuries before our era. These weights, which are of irregular elliptical form, are of dark green marble, and provided with a bronze handle in order to facilitate their manipulation.

## LANTERN MEMS.

I HAVE seen the *Royal Photographic Society's* Exhibition, and must congratulate the Council on the excellence of it. For some years past many visitors to the Annual Show have felt that, no matter how excellent some of the exhibits were, photography was not adequately represented. In the New Gallery all this is changed, and not only are examples of pictorial, technical, artistic, and scientific photography well displayed, but in addition there are specimens of some of the finest enlargements and high-class portraiture it has been my privilege to see. These, together with a really good show of photographic apparatus, deserve the name of Royal.

\* \* \* \* \*

ON the *Soirée* night one can only manage to take in the pictures at intervals, for there are so many friends to say a few words to, but what a contrast in the surroundings to the old days, what with ample room for everything, the delightful strains of music discoursed by an excellent band (the Royal Artillery, I think) the Gallery, the Exhibition room with lantern and screen. The smaller hall with the fine examples of enlargements, including the Kodak War pictures, and many well-known photographers' portrait work, also the central hall with the trade bays having typical and excellent collections of apparatus, and last the fountain "and the gold fish," as a well-known and popular Secretary sayeth.

\* \* \* \* \*

LANTERNS there were, but these I could not inquire into, as time did not permit, but I hope to find some novelties and improvements when I visit the Exhibition next time. The electric light being on, it has been made available for use in the Society's optical lantern, and also for lighting up the stereoscopic slides in the revolving stereoscopes and the specimens of photography in colour. There are some good stereograms, but I must say that I think the old French glass stereoscopic slides with the regular focus lenses were more pleasing than those taken with the shorter-focus or wide-angle lenses. There may be something in the fact of the higher-power oculars showing up the grain of the film, but, any how, that was the first impression made upon me.

\* \* \* \* \*

If amateurs and those only slightly interested in photography do not flock to the New Gallery and become enthusiastic, I shall be surprised, but they will want an expert as guide, philosopher, and friend at their elbow if they are going to make a selection of a

camera, for the patterns are multifarious, and each has distinctive merits. A man that has had a year or two's experience will be in a better position, for he will know the shortcomings of his old camera and his average requirements, and so be able to narrow down the choice. The question of glass plates, flat films, or daylight-changing roll films will not be so easily disposed of; however, the exponents of each system and gentlemen in charge of the camera exhibits will, no doubt, clear the horizon, and, if the questioner cannot make up his mind, they will, no doubt, do so for him.

\* \* \* \* \*

AMATEURS with limited time, and who do not mind paying for the development and printing being done by others, will continue to patronise the daylight roll-holder, for it has so many attractions, by reason of its simplicity and convenience, and, when the results are successful, gives great pleasure, for it becomes more fascinating on each occasion it is used, while those that have time will find agreeable occupation in developing. The advocates of flat films will grow in number as the excellent cameras for using them continue to circulate.

\* \* \* \* \*

My experience with the quarter-plate folding pocket Kodak in Holland was, on the whole, satisfactory. I like its convenient size and the method of focussing, but, for autumn holidays, and especially places where the principal buildings face north, it is necessary to be equipped with a walking-stick stand. The lens gives good results, but, for my own use, I shall have fitted a different form of finder, and I would advise a little spirit level to be fitted, it being a most useful accessory, and, in many cases, indispensable. Probably, as time goes on, a faster film will be produced for autumn use and places where brilliant sunshine cannot be counted on, for I suppose many Kodakers find their pictures are often under-exposed.

\* \* \* \* \*

THE natives at the Island of Marken, which one visits from Amsterdam by a trip in a steam yacht, are very curiously dressed folks, and the children would be agreeably interesting if they had not become spoilt by their system of begging, or rather extorting, one might almost say, money from users of cameras. If a charge was made for the right to photograph on the island, it would be far better than the youngsters clambering round one for money the moment an exposure has been made. It was most curious to see them turn their backs on the parties having cameras, and those in boats, on a signal from others on shore, ducking down to hide themselves. This, however, was all altered the moment the pieces of silver were being put into the youngsters' hands; but, what was most sad was the quarrelling among themselves, and the striking of one another's faces if one girl had more than another, and it was impossible to have in one's pocket enough small silver to serve them all alike, and they would have nothing to do with division of the fee.

\* \* \* \* \*

THE place is no doubt a show island, and, apart from the men, who are away fishing, I think the inhabitants realise that it pays

best to keep to their old costumes of embroidered or fancy waistcoats than to alter to more modern dress. Their spiritual or other advisers should look to it that so charming a place does not become the means by which the rising generation is degraded.

\* \* \* \* \*

THOSE lanternists who have not already got a copy of the "Primus" Lanternist's Pocket-book should lose no time in securing one, for it is conveniently arranged, and the particulars given most useful to an operator, while the lists of requisites for a show are a capital aid to memory, and prevent, if checked before starting for an entertainment, some important item being overlooked. The particulars respecting the electric light will also be of interest to those that contemplate availing themselves of the electric current for the optical lantern.

G. R. BAKER.

### LIVING LAMPS.

[Reprinted from the *Scientific American*.]

SOME years ago Dr. Raphael Dubois, of Paris, presented the writer with a photograph of the bust of Claude Bernard, which possesses an unusual interest, having been taken by the light of a phosphorescent insect—an elater—by M. E. Becqueral. The experiments and their details which led up to this were very interesting, but in this connexion it is sufficient to say that the picture was produced after an exposure of an hour to the rays of light of this small insect. Later M. Becqueral succeeded in taking a successful picture in twenty minutes, and another in two minutes, all of which is suggestive of the possibilities of the light produced by animals.

An excellent illustration of the splendour of the light of some of these insects is given by Professor Jaeger, the German naturalist, who says, "I feel particularly indebted to these little insects because during my excursions in St. Domingo they were frequently the means of saving my life. Often has dark night surrounded me in the midst of a dense forest on the mountain, where the little animals were my only guide." The light-giver referred to is *Pyrophorus noctilucus*, which is provided with three different lights; on each side of the thorax is an oval yellowish spot which emits a brilliant yellowish-white light, throwing the rays upward and outward, while between the metathorax and the first abdominal segment there is a lower light more brilliant than either; and, owing to their disposition, the light flashes almost continuously as the insect whirls along. The light appears to be controlled by the will of the animal, as, when the insect is feeding or eating, it is not seen, but becomes especially brilliant when the animal flies.

I have frequently experimented with these attractive little creatures in the South. The light when held very close to the large print of a book displayed the letters so that they could be read; the time of night was also told by holding the insect close to the face of a watch. The colour of the light was green. Dubois states that the eggs of a specimen kept by him gave out a bluish light. This naturalist found that the eggs retained their luminosity for a week, the light reviving when the eggs were placed in water. He produced luminous water by grinding the luminous organs to a powder and dissolving it in water, which at once assumed the appearance of molten metal.

The intensity of light is by no means in proportion to the size of the animal.

One of the most remarkable and brilliant light-givers I have ever observed was a marine worm, almost invisible to the naked eye; so small, in fact, that it would not be noticed by the casual observer. I have seen the surface of dark corners of a southern Californian bay dotted with seeming candle-lights, the effulgence of this minute creature. At first it was noticed on the bottom, forming a luminous spot as large as a fifty-cent piece; this rapidly increased until a light as large and as circular as a dinner plate appeared. So large and brilliant a light could seemingly be produced only by a large animal, but suddenly the light began to diminish, then rise from the bottom, coming up in a zigzag course, trailing blue, green, yellow, and

white flashes behind it until it reached the surface, where it rested, forming a phosphorescent light the size of a pea, but so bright that it could be distinguished thirty or more feet away. On certain warm nights I have seen the surface dotted with them. When disturbed, the spot swam off with a wriggling motion, emitting as it went the various-hued lights which seem to be thrown off as a luminous fluid. Yet this brilliant light-giver was a minute, almost invisible, worm.

The combined light of noctilucae is often so brilliant that by constant irritation a light is produced by which large print can be read. A French naturalist on the African coast improvised a lamp of these living lights by taking a tube fifteen millimetres in diameter and placing in it noctilucae, so that they formed a band at the surface twenty millimetres in thickness, when it was found that the light was sufficient to read large type by at a distance of two feet. To effect this, the animals were agitated with a stick; but, if a large number are placed in a glass of milk, they convert the glass into a white light, the intensity of which lasts several moments.

Another interesting example of a brilliant light I observed in a very small animal in the San Gabriel Valley. In walking just after nightfall, I noticed by the path an intense white light, which was found to be a minute myriapod, about a tenth of an inch in length, so small that I had difficulty in picking it up, though the light gleamed brightly. When it was finally secured, it was seen that the light was upon the head, while another, half as bright, was seen upon the tail. The head light was extremely beautiful, reminding one of a blazing match, and was continuous.

A number of myriapods are phosphorescent. *Geophilus electricus* of Europe is a light-giver, and often makes a magnificent display when suddenly uncovered, M. Audoin describing the soil as sprinkled with gold where he disturbed them. One of the most remarkable displays from these insects was observed by Mr. B. E. Brodhurst, who says that the light was so brilliant that he first observed it twenty paces away. It resembled an electric light in its brilliancy, and was produced by two centipedes and the luminous train they left behind. "The light illumined the entire body of the animal, and seemed to increase its diameter three times. It flashed along both sides of the creature in sections, there being about six from head to tail between which the light played. The light behaved precisely like the electric light, moving, as it were, perpetually in two streams, one each side, and yet lighting up the whole body. The trail extended from one and one-half feet from each centipede over the grass and gravel walk, and it had the appearance of illuminating mucus."

It is possible to read by the light of the humble earth worm. One of the most brilliant displays of animal phosphorescence I have observed came from such a source. Its discovery was accidental. In passing through an orange grove one rainy night in Southern California, I kicked aside a large clump of earth, when, to all intents and purposes, a mass of white molten metal went flying in every direction, affording an unusual display. The cause of the light was a single, possibly two, earth worms, not over two inches in length. The luminous matter was exuding from them and had permeated the surrounding soil, rendering it phosphorescent. The light-emitting mucus came off upon my hands, and the light lasted several seconds, gradually fading away.

Possibly the most remarkable light ever used for purposes of reading is the beautiful *Pyrosoma*, a columnar, jellylike creature, one of the free-swimming Tunicates. They are usually from one to two feet in length and three or four inches across, open at one end. The column is an aggregation of animals, each of which takes in water and expels it by an orifice in the interior, and this volume of water rushing from the open end propels the animal along. Its luminosity is wonderful, its name—fire body—well chosen. To illustrate its intensity, a Portuguese sea captain secured six of the animals, which he placed in glass jars, which were suspended from the ceiling of his cabin. By their own light he wrote a description of their beauties. Bennett, the English naturalist, placed a deep-sea shark, of the genus *Isistius*, in a jar in his cabin, and could easily have read by its light, describing the appearance of the fish as truly ghastly.

## LANTERN NIGHTS AT THE R.P.S. EXHIBITION.

DURING the Course of the Exhibition at the New Gallery, Regent Street, there will be displays by means of the optical lantern, every Monday, Thursday, and Saturday evening. As below:—

- Sat., Oct. 6. "Viterbo, Spolito, Perugia, and Assisi," by J. COOPER ASHTON.
- Mon., " 8. "Round about the Matterhorn and Aletsch Glacier," by HENRY SPEYER.
- Thur., " 11. Illustrated Lecture on Colour Photography, by E. SANGER SHEPHERD.
- Sat., " 13. "Gleanings," by EDWIN DOCKREE.
- Mon., " 15. Sundries, chiefly pastoral, by Colonel J. GALE.
- Thur., " 25. "Venice, its Churches and Palaces," by J. J. VEZEY. Illustrated by slides principally by Commander C. E. GLADSTONE, R.N.
- Sat., " 20. "Through County Donegal with a Camera," by HARRY SELBY.
- Mon., " 23. "Illustrated Lecture on Colour Photography," by E. SANGER SHEPHERD.
- Thur., " 25. "The islands and Highlands of Scotland," by JOHN A. HODGES.
- Sat., " 27. "Wonders of the Paris Exhibition," by S. J. BECKETT.
- Mon., " 29. "On the Peninsular Coast with a Hand Camera," by R. CHILD BAYLEY.
- Thur., Nov. 1. "Some Swiss Pictures," by JOHN GUNSTON.
- Sat., " 3. "Illustrated Lecture on Colour Photography," by E. SANGER SHEPHERD.

The ordinary lantern displays will be preceded by an Exhibition on the screen of examples of the various processes of Colour Photography.

## LIMELIGHT MATTERS.

## CONSUMPTION AND WASTE OF GAS.

It is a well-recognised fact in limelight working that, when an increase of light is desired, more heat must be generated by the blowpipe or jet to get it, and this increase of heat, in turn, can only be obtained by consuming more gas. It therefore follows that a really brilliant light cannot be produced without burning a sufficiency of gas to generate the necessary heat to obtain it. In carrying this simple principle into practice in such a manner as will enable the best possible amount of light being obtained without waste or unnecessary consumption of gas, very much will depend upon the condition of the apparatus that is being used and the care of the operator manipulating same.

The remark is still frequently made by old limelight operators, that more gas is used at the present day in working from cylinders than used to be the case when working off bags, and, no doubt, this is perfectly true. In the old days of gas-bags, an operator knew to almost a certainty the amount of gas he had under his control, and could always tell pretty well as he went along how his supply was holding out, and, if necessary, manipulate his taps to economise gas in the event of his running short.

With gas-bags, also, nothing like the same amount of pressure was used upon the tubes or jet fittings as we see regularly employed from cylinders at the present day, for, with gas-bags and the forms of jet commonly used years ago, a water pressure of about twelve to fourteen inches was sufficient pressure for the jets then in use; roughly speaking, this amount of water-tube pressure means something like a pressure of one half-pound per square inch. Compare with this the very great increase in pressure which it is now found necessary to employ with modern jets and regulators (a pressure which in some instances actually runs as high as fifteen pounds per square inch), with one particular form of jet to get the best results out of it, down to what may be called the minimum pressure of regulators set at two pounds per square inch for ordinary jets, and it will be seen in a moment that if, as was the case in the days of gas-bags, so much care was bestowed in seeing that everything was drum-tight in connexion with the bags and tubes, and that no gas escaped elsewhere than through the nipple of the jet, how much more so is such care necessary when using modern apparatus from cylinders.

No doubt, to a certain extent, the introduction of cylinders has tended to foster among operators an amount of indifference to what may be termed "slight escapes of gas," that would never have been tolerated with gas-bags. This very often arises, no doubt, from the fact that, with the knowledge a full cylinder of gas is being pulled upon, a mere slight escape somewhere or other is a matter of no great importance. These slight escapes, however, are of importance in many instances, and not only mean a serious waste of gas, but also pollute the atmosphere of a lecture hall, and in the case of hydrogen or coal gas are dangerous should any light come in contact with such leakage. Indifference to such matters means a slovenly worker, and, as a general rule, such workers never succeed in getting high-class results.

The various sources to which an escape of gas can be traced in limelight working are more numerous than many might imagine, and, speaking generally, each and all of these sources are under the entire control of a careful operator.

Considering the wear and tear to which gas cylinders are subjected, and that their valves are at the mercy of Tom, Dick, and Harry, here, there, and everywhere over the country, it speaks volumes for the care bestowed by our leading compressing companies that they are sent out in the perfect condition in which the public receive them, for such a thing as a leaky cylinder coming direct from the hands of a compressing company is now almost unheard of. To those not acquainted with the method of procedure employed by the pumpers it may be briefly stated that, whenever a cylinder is fully charged with gas, the valve is closed, the cylinder raised on end, and the cup or nozzle of the cylinder is then filled with water; if the valve is not tight, the water at once shows the escape of gas, and such cylinders are at once blown off and set aside for repair. Further, it is only fair to state, on the part of most of our leading firms of opticians who cater largely for the public in limelight working, that this method is also followed by them. Perhaps there is no greater disappointment to be met with in anything than that which follows a breakdown in a limelight entertainment through the failure of a gas supply. Accidents, of course, will happen, and empty cylinders have been known to have been sent in the belief that such were fully charged with gas; but so impressed have several of our leading firms in the West of Scotland become with the importance attaching to this matter, that they guard against the possibility of disappointment, and break down by appointing special gas men in connexion with their business, whose sole duty is to gauge and test every cylinder before it leaves their premises, and such men are personally responsible for the tightness of the valves and the contents of the cylinders being what is stated in the accompanying certificate.

Speaking generally, it may be taken for granted that all serious wastes of gas occur after the cylinders reach the hands of the users. Although so much care must be admitted as due to our various compressing companies in regard to the tightness of the valves, there is, however, another matter which is more liable to escape their notice, and which at times is responsible for a serious waste of gas, as well as giving a large amount of annoyance to those using the cylinders. In transit especially, when the cylinders are known to be empty, sometimes a nozzle of a cylinder comes in for very rough usage; and occasions do arise where new and slightly worn threads to regulators or fine adjustment taps, make it a matter of no little difficulty to so attach such regulators or taps to the nozzle of the cylinder without a serious escape of gas.

This is just one of the points that goes far to prove the advantage of any one possessing their own cylinders and attachments of every kind. Of course, in the broad run of limelight work such is impracticable; but it goes far to show how much care is necessary in seeing to everything beforehand. A careful operator will take nothing for granted before he sets out on any important commission, and will test everything, even to the screwing on of his taps, or regulators, on the cylinders he is going to use. This, however, is a fruitful source of waste of gas. A gas-tight connexion between cylinders and regulators, or taps, ought to be always provided for, and, as an aid to this end, soft metal-washers have been introduced, which are not nearly so much in use as they deserve to be.

It has been pointed out that, with the increased pressure necessary with modern apparatus, the strain upon rubber tubes and taps is at times very great, and if there is any crack or weak part in a rubber tube it will soon make its presence felt. Somewhat in recent years a flexible metal tube has been in use for high-pressure work. There is no doubt as to this sample of tubing standing an enormous pressure; but the old and time-worn rubber tube takes a lot of killing, and will be employed yet for years to come. There is no doubt, however, such, if not carefully used, is very liable to waste gas. A careless operator will blow off his tubes over and over again without for a moment giving a thought to

the amount of gas he is wasting. With gas-bags this was looked upon as a serious matter, but it is passed over lightly when working from cylinders.

Another fruitful source of waste of gas is often met with in faulty jets. As is the case with most mixing jets, after being used for a time, the leather washer on the top of the mixing chamber becomes worn out by reason of the great heat the leather has been subjected to, and any unscrewing of the cap of the mixing chamber is very liable to cause a badly fitting joint. When the jet is subjected to a high pressure when next being used, an unsuspected escape of gas is very liable to occur at this part.

Passing from wastes that may be termed attributable to faulty connexions and apparatus, we next have to consider the matter from the standpoint where such waste is clearly attributable to carelessness or want of knowledge on the part of an operator. A thoughtless operator will soon make his presence felt by noise of some kind or other. This may take the shape of hammering on his connexions with the cylinders in such a manner as would lead one to expect he was driving home a rivet in the hull of an Atlantic liner. Then, again, there follows a succession of hisses from the nozzles of his cylinders, in which he takes a delight, as it were, to let every one know, "I'm all here, and have plenty of gas to spare," never thinking that people have nerves, or of the amount of gas he is wasting every time he is opening the valves of his cylinders.

In what may be termed the consumption of gas, pure and simple, it is surprising the difference that will take place, using the same apparatus, by two different operators. In the one case, where a man knows his business thoroughly, a really brilliant light will be obtained, with no fuss or noise and with a really moderate consumption of gas. On the other hand, an inexperienced operator will frighten all nervous people in his vicinity by a series of hisses and snap-out explosions, never really obtaining a brilliant, steady light, and will run through double the amount of gas that is necessary.

It is well known that one of the most important items in connexion with the getting of a good light lies in the knowledge of being able to adjust the lime at its proper distance from the orifice of the jet, and it seems strange that so much that is misleading should be written, from time to time, on this subject by would-be experts in limelight matters.

To judge from much that has appeared in the public prints regarding this important point, many might imagine that in every case the distance from the lime to the jet was almost a fixed factor, averaging about one-sixteenth of an inch distance with every jet that is being employed. The fact, however, is, this distance is governed by two factors, viz., the aperture and pressure employed on a jet, and the pitch of the nipple.

With every jet there is a distance from the orifice where the mixed gases may be said to form their hottest focus. This hottest point generally lies just inside the blue or oxidating part of the current of the gases, and with large orifices, where a good pressure is being used, the farther from the orifice will this heat focus be situated.

Again, with some jets in which the angle or the set of the nipple is inclined to less than about forty-five degrees, the best results will be found when the lime is brought more closely up to the orifice, for with such jets the gas impinges over the face of the lime and yields a broader patch of incandescence than when a jet is set to an angle of about forty-five degrees. The fact is, every jet should be tried and tested for the heat focus, according to the aperture and pressure applied from the regulator when working at its best; and, if economy in gas is aimed at, as this pressure is cut off by the taps, so must the lime be brought nearer to the orifice.

A good deal has been written from time to time about the black spot; this signifies that the lime is too close to the orifice of the jet for the amount of gas that is passing. This black spot is an unerring guide, and should never be allowed to continue, for it means a chilling of the lime by reason of faulty adjustment.

The great aim on the part of an operator should be to obtain the greatest possible amount of heat concentrated on one part of the lime without waste of gas, and this is only obtained by so adjusting the lime to the jet as will provide for its being just on the confines of the blue or oxidating part of the current.

There is far more in being able to manipulate a powerful limelight jet than many imagine; with the gases properly adjusted by the taps and the lime set at its correct distance from the orifice of the jet there will also be less trouble from heating the shell of the lantern, and also less liability to fracture a condenser than is the case where the gases are improperly regulated and an excess of hydrogen is being wasted to no purpose.

T. N. ARMSTRONG.

## BORDIGHERA.

[Notes of a Lantern Lecture delivered at the New Gallery, Regent-street, Monday, October 1, 1900.]

THE short time at my disposal must necessitate brevity; in fact, only a running commentary as the pictures pass the screen.

Bordighera is about a couple of miles east of Ventimiglia, the frontier between France and Italy. To any one wishing a quiet, healthy winter residence I can heartily recommend Bordighera. Sheltered from the north by high mountains, towards the east it is somewhat flat, consequently there is more sunshine by an hour or more than is obtainable at Nice or Monte Carlo. Fast trains run daily to Monte Carlo in less than no time, as French time is kept at Monte Carlo and Italian time at Bordighera.

Her Majesty the Queen intended spending her usual spring holiday at Bordighera, but from political reasons the Continental trip was abandoned. The Empress Frederick stayed at the Hôtel Angst all the previous winter, and report says that she was so pleased with all the arrangements that she induced the Queen to entertain a residence there.

Bordighera is fast becoming Anglicised. Some noted Englishmen have villas there. Lord Strathmore has a lovely château. Dr. George McDonald has a fine large villa also. He has spent about twenty winters there. This speaks well for the climate. In a short time the English will want to be enfranchised.

Hotels are good and numerous. Charges moderate; good pension terms can be had from seven francs a day. The English community are well looked after spiritually and spirituously. There is an English church about to be enlarged, Dutch Protestant church, and, of course, a Catholic cathedral and other churches.

A very agreeable Vice-Consul in the person of Mr. Ed. Berry, banker and agent for Cook, has a large general store, where good Scotch can be had. A well-appointed reading-room is attached to the bank, where most of the English daily and illustrated periodicals are free for the use of visitors. Carriage drives are plentiful, and the charges moderate. There are many pretty little rock villages well worth visiting. William Scott has written and illustrated a work on *The Rock Villages of the Riviera* (A. & C. Black). To one making a flying visit, consult Baedeker and Black.

Clarence Bicknell, the great botanist, has published two works on the flora, besides building and furnishing a free library and museum in a lovely situation amidst tropical vegetation. The library contains over 6000 volumes in five languages.

Many of the pictures which will be shown to-night will appear in the *Traveller*.

A. L. HENDERSON.

## THE PHOTO-MICROGRAPHIC ROOM AND APPARATUS IN THE ANATOMICAL LABORATORY OF THE JOHN HOPKINS UNIVERSITY.\*

THE scope of photo-micrography can conveniently be divided into photo-micrography (1) with high powers, (2) with medium powers, and (3) with low powers.

1. Photo-micrography with high amplification (600 to 1200 diameters) is employed chiefly for the study of micro organisms and fine histological structures.

2. Photo-micrography with medium amplification (150 to 400 diameters) is applied to tissue work, where it is desirable to differentiate structural elements in pathology as well as in normal histological material, micro-urinary deposits, and the study of vital movements (amoeboid) of certain cells by serial exposures.

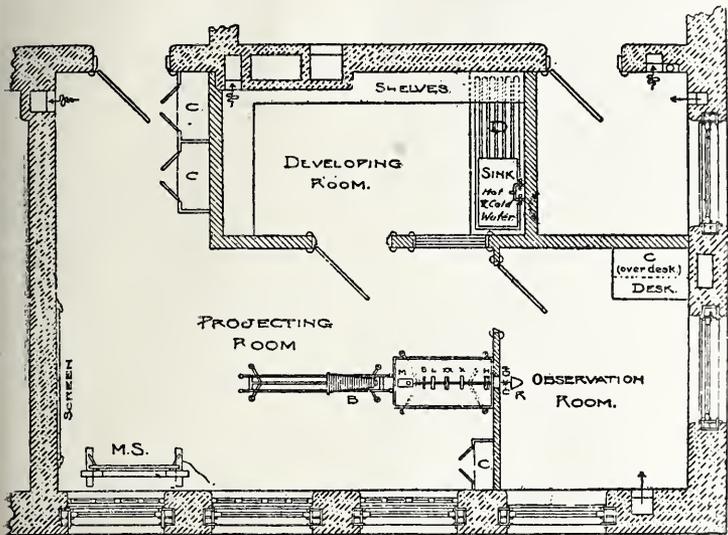

3. Photo-micrography with low powers (1-100 diameters) is applied in the study of various tissues with reference to their anatomical relations, and for injected specimens of whole organs.

It was with the above uses of photo-micrography in mind that the rooms and apparatus, described in this paper, were constructed and purchased. As seen in the plan, there are three rooms. The main room (Projecting room), is made perfectly dark by being painted dull, or flat black, and having the windows protected against the admission of light by three sets of blinds, Venetian blinds on the outside, an adjustable black cloth blind on the inside, and, over these, sliding panelled wooden blinds. It contains the tables carrying the condensers, microscope, camera, and the projecting apparatus consisting of a perfectly smooth plaster of Paris screen on the wall directly behind the camera and a small movable screen.

\* A. G. Hoen, M.D., in the John Hopkins Hospital Bulletin, Nos. 62, 63, May June, 1896.

The second room contains all necessary chemicals and water supply, for developing plates, and conducting such other manipulations as appertain to photography. It is lighted by incandescent lamps, one of which, for photographic purposes, is hooded with black velvet over a frame of asbestos, and covered on the lower side by three thicknesses of deep ruby glass.

The smallest room (Observatory room) is well lighted, and contains 4000 candle-power electric arc, the light from which is projected by a

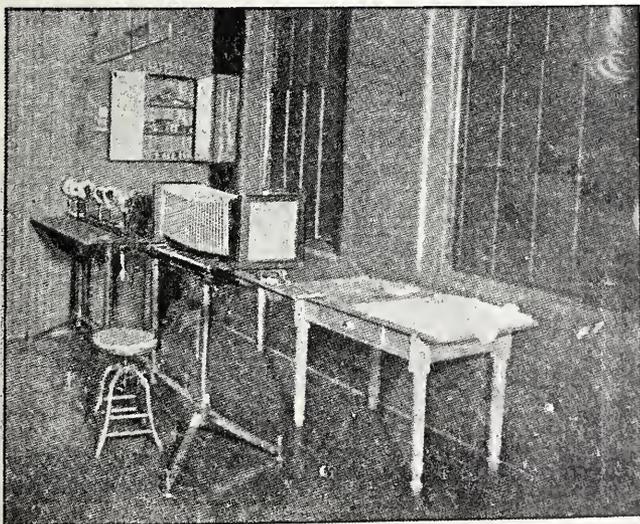

PLAN OF PHOTOGRAPHING ROOM

paraboloid reflector through an aperture in the partition into the apparatus in the large room. The arc lamp is mounted on a mechanical stage attached to the partition, which admits of vertical and lateral movements, so that it may be adjusted easily to the optical axis of the photo-micrographic apparatus. The carbon-holders are balanced by means of a

South-west corner of projecting room.

chain over a pulley in the lamp mechanism, the result of which arrangement with alternating current is that the combustion of the carbons is compensated by the descent of the upper and the ascent of the lower carbon in exactly the same ratio, and the arc is thus fixed practically at one point, remaining there from the time the current is turned on until the carbons are consumed. To overcome the considerable vibration of the carbon points, an adjustable guard is attached to the side of the lamp, to steady the upright rod of the lower carbon point.

The photo-micrographic apparatus consists of a special microscopic

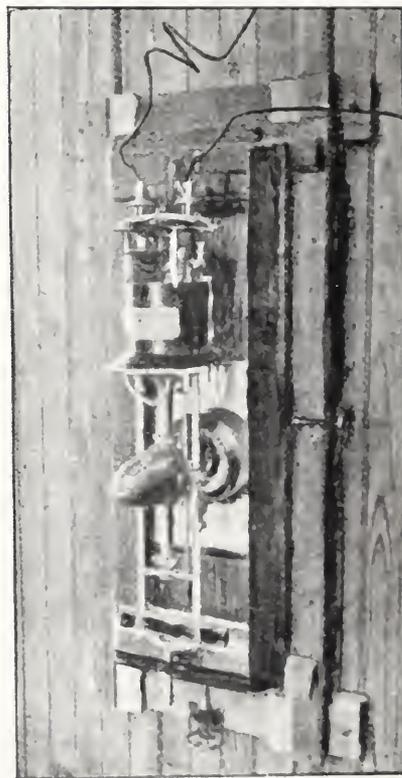

stand with 2, 2.5, 4, 8, 16, 35, and 70 mm. lenses, and Nos. 2 and 4 projection oculars. In addition to these are the following photographic lenses, which can be used for photographing with low powers, as well as for ordinary lantern projection:—

Anastigmat 1:	6.3,	focus	43 millimetres.
"	1: 7.2,	"	96 "
"	1: 7.2,	"	148 "
"	1: 12.5,	"	260 "
"	1: 18.0,	"	632 "

Besides these lenses, there is a complete projection table with its appendages, as well as the large camera. For delicate work there is a spectral illuminating apparatus after Hartnack. The anastigmat lenses are all interchangeable, and the large ones are fitted with a prism to photograph at right angles to the object, as is often necessary in photographing objects under fluids. An achromatic Abbé condenser is used, which, being supplied with two iris diaphragms, permits the use of entire aperture of the condenser, or only a fractional portion thereof.

As a means of bringing the two tables to an exact level, that the optical axis may be perfect, set screws are put into each of the iron pedestals of the table, these screws, resting in small metallic discs, which are simply laid on the floor in their proper position.

Two methods of illumination for high and medium powers are prac-

Helios electric lamp.

ticable. The first may be illustrated from fig. 1. The rays from the arc light (\*) are received upon the plano-convex lens x, which is so placed that the arc is in its principal focus, thus rendering all rays passing through it parallel. In their further course through the bi-convex lens, xx, the rays are brought to a focus, which is made to coincide, by adjusting this lens on the sliding bar, with the principal focus of the lower lens of the Abbé condenser in the microscope (m). The lower lens of the Abbé condenser renders the rays parallel, while its second lens converges them and bring them to a focus in the plane of the object, giving there a small but very bright image of the source of illumination.

The second method consists in the use of a plano-convex lens of much shorter focus than the above. It is mounted in a metal frame, which is fastened to the wall, and, by means of set screws, permits of perpendicular and lateral movement. The collar is also movable in the optical axis, so that adjustment for accurately focussing the lamp is accomplished by means of the set screw, which is moved back and forth until a bright beam of light, not greater in diameter than the lens itself, is projected on the screen.

The light filter used is the bichromate of potash and sulphate of copper solution, as recommended by Neuhaus. It is made as follows:—

Sulphate of copper .....	175 grammes.
Bichromate of potash .....	17 „
Sulphuric acid .....	2 c. c.
Water .....	from 500–1000 c. c.

More concentrated solution is applicable to specimens stained very slightly with the various blues (hæmatoxylin and aniline, &c.), or with the reds, particularly safranin preparations. The position of the light filter is of little moment, provided that the rays of light which pass through it are the only ones which reach the Abbé condenser.

The plates used with greatest success are those made by the Cramer Dry Plate Company, of St. Louis, Mo. They are orthochromatic in the widest sense, are very uniform, and the instantaneous and extra-rapid plates made by this Company are sensitive to an exquisite degree. The development of the plates is accomplished as advised by, and after the formula of, the manufacturers, by a combination of hydroquinone and eikonogen.

C. W. J.

### PHOTOGRAPHY AND ASTRONOMY.

[The following abstract from Dr. A. A. Common's address to the Department of Astronomy of the British Association deals with the aspects of Astronomy that are of more immediate interest to photographers.]

THE progress of the new astronomy is so closely bound up with that of photography that I shall briefly call to mind some of the many achievements in which photography has aided the astronomer.

Daguerre's invention, in 1839, was almost immediately tried with the sun and moon, J. W. Draper and the two Bonds in America, Warren de la Rue in this country, and Foucault and Fizeau in France, being among the pioneers of celestial photography; but no real progress seems to have been made until after the introduction of the collodion process. Sir John Herschel in 1847 suggested the daily self-registration of the sun spots to supersede drawings; and in 1857 the De la Rue photo-heliograph was installed at Kew. From 1858–72 a daily record was maintained by the Kew photo-heliograph, when the work was discontinued. Since 1873 the Kew series has been continued at Greenwich, and is supplemented by pictures from Dehra Dûn in India and from Mauritius. The standard size of the sun's disc on these photographs has now been for many years eight inches, though for some time a 12-inch series was kept up.

The first recorded endeavour to employ photography for eclipse work dates back to 1851, when Berowsky obtained a Daguerreotype of the solar prominences during the total eclipse. From that date nearly every total eclipse of the sun has been studied by the aid of photography.

In 1860 the first regularly planned attack on the problem by means of photography was made, when De la Rue and Secchi successfully photographed the prominences and traces of the corona, but it was not until 1869 that Professor Stephen Alexander obtained the first good photograph of the corona.

In recent years, from 1893 until the total eclipse which occurred last May, photography has been employed to secure large-scale pictures of the corona. These were inaugurated in 1893 by Professor Schaeberle, who secured a 4-inch picture of the eclipsed sun in Chili. These have been exceeded by Professor Langley, who obtained a 15-inch picture of the corona in North Carolina during the eclipse of May 1900.

Photography also supplied the key to the question of the prominences and corona being solar appendages, for pictures of the eclipse sun taken in Spain in 1860 terminated this dispute with regard to the prominences, and finally to the corona in 1871.

In 1875, in addition to photographing the corona, attempts were made to photograph its spectrum, and at every eclipse since then the sensitised plate has been used to record both the spectrum of the chromosphere and the corona. The spectrum of the lower layers of the chromosphere were first successfully photographed during the total eclipse of 1896 in Nova Zembla by Mr. Shackleton, though seen by Young as early as 1870, and a new value was given to the wave-length of the coronal line (wrongly mapped by Young in 1869) from photographs taken by Mr. Fowler during the eclipse of 1898 (India).

Lunar photography has occupied the attention of various physicists from time to time, and, when Daguerre's process was first enunciated, Arago proposed that the lunar surface should be studied by means of the photographically produced images. In 1840 Dr. Draper succeeded in impressing a Daguerreotype plate with a lunar image by the aid of a 5-inch refractor. The earliest lunar photographs, however, shown in England were due to Professor Bond, of the United States. These he exhibited at the Great Exhibition in 1851. Dancer, the optician, of

Manchester, was, perhaps, the first Englishman who secured lunar images, but they were of small size.

Another skilful observer was Crookes, who obtained images of 2 inches diameter, with an 8-inch refractor of the Liverpool Observatory. In 1852 De la Rue began experimenting in lunar photography. He employed a reflector of some 10 feet focal length and about 13 inches diameter. A very complete account of his methods is given in a paper read before the British Association. Mr. Rutherford at a later date, having tried an 11½-inch refractor and also a 13-inch reflector, finally constructed a photographic refracting telescope, and produced some of the finest pictures of the moon that were ever taken until recent years. Also Henry Draper's picture of the moon taken September 3, 1863, remained unsurpassed for a quarter of a century.

Admirable photographs of the lunar surface have been published in recent years by the Lick Observatory and others. I, myself, devoted considerable attention to this subject at one time; but only those surpassing anything before attempted have been published in 1896–99 by MM. Loëwy and Puiseux, taken with the Equatorial Condé of the Paris Observatory.

Star prints were first secured at Harvard College, under the direction of W. C. Bond, in 1850; and his son, G. P. Bond, made in 1857 a most promising start with double-star measurements on sensitive plates, his subject being the well-known pair in the tail of the Great Bear. The competence of the photographic method to meet the stringent requirements of exact astronomy was still more decisively shown in 1866 by Dr. Gould's determination from his plates of nearly fifty stars in the Pleiades. Their comparison with Bessel's places for the same objects proved that the lapse of a score of years had made no difference in the configuration of that immemorial cluster; and Professor Jacoby's recent measures of Rutherford's photographs taken in 1872 and 1874 enforce the same conclusion.

The above facts are so forcible that no wonder that at the Astro-photographic Congress held in Paris in 1887 it was decided to make a photographic survey of the heavens, and now eighteen photographic telescopes of 13 inches aperture are in operation in various parts of the world, for the purpose of preparing the international astrographic chart, and it was hoped that the catalogue plates would be completed by 1900.

Photography has been applied so assiduously to the discovery of minor planets that something like 450 are now known, the most noteworthy, perhaps, as regards utility being the discovery of Eros (433) in 1898 by Herr Witt at the Observatory Urania, near Berlin.

With regard to the application of photography to recording the form of various nebulae, it is interesting to quote a passage from Dick's *Practical Astronomer*, published in 1845, as opposed to Herschel's opinion that the photography of a nebula would never be possible.

"It might, perhaps, be considered as beyond the bounds of probability to expect that even the distant nebulae might thus be fixed, and a delineation of their objects produced, which shall be capable of being magnified by microscopes. But we ought to consider that the art is only in its infancy, and that plates of a more delicate nature than those hitherto used may yet be prepared, and that other properties of light may yet be discovered, which shall facilitate such designs. For we ought now to set no boundaries to the discoveries of science, and to the practical applications of scientific discovery, which genius and art may accomplish."

It was not, however, until 1880 that Draper first photographed the Orion Nebula, and later by three years I succeeded in doing the same thing with an exposure of only thirty-seven minutes. In December 1885 the brothers Henry by the aid of photography found that the Pleiades were involved in a nebula, part of which, however, had been seen by myself (*Monthly Notices*, vol. xl. p. 376), with my 3-foot reflector in February 1880, and later, February 1886; it was also partly discerned at Pulkowa with the 30-inch refractor then newly erected.

Still more nebulosity was shown by Dr. Roberts's photographs (*ibid.*, vol. xlvii. p. 24), taken with his 20-inch reflector in October and December 1886, when the whole western side of the group was shown to be involved in a vast nebula, whilst a later photograph taken by MM. Henry early in 1888 showed that practically the whole of the group was a shoal of nebulous matter.

In 1881 Draper and Janssen recorded the comet of that year by photography.

Huggins (*Proc. Roy. Soc.*, vol. xxxii. No. 213) succeeded in photographing a part of the spectrum of the same object (Tebbutt's Comet, 1881, II.) on June 24, and the Fraunhofer lines were amongst the photographic impressions, thus demonstrating that at least a part of the continuous spectrum is due to reflected sunlight. He also secured a similar result from Comet Wells (*Brit. Assoc. Report*, 1882, p. 442).

The advantage of large primary images in photography is now fully

recognised. For all other kinds of astronomical photography a fixed telescope is admirably adapted; and so, with all spectroscopic investigations, a little consideration will show that the conditions under which these investigations can be pursued are almost ideal. As to the actual form such a construction would take, we can easily imagine it. The large mirror mounted as a celostat in the centre; circular tracts round this centre, on which a fan-shaped house can be travelled round to any azimuth, containing all the necessary apparatus for utilising the light from the large plane mirror, so as to be easily moved round to the required position in azimuth for observation. In place of a fan-shaped house movable round the plane mirror, a permanent house might encircle the greater portion round the mirror, and in this house the telescope or whatever optical combination is used might be arranged on an open framework, supported on similar rails, so as to run round to any azimuth required. The simplicity of the arrangement and the enormous saving in cost would allow in any well-equipped observatory the use of a special instrument for special work. The French telescope has a mirror about 6 feet in diameter and a lens of about 4 feet. This is a great step in advance over the Yerkes telescope, and it may be some time before the glass for a lens greater than 50 inches diameter will be made, as the difficulty in making optical glass is undoubtedly very great. But with the plane mirror there will be no such difficulty, as 6 feet has already been made; and so with a concave mirror there would be little difficulty in beginning with 6 feet or 7 feet. The way in which the mirror would be used, always hanging in a band, is the most favourable condition for good work, and the absence of motion during an observation, except, of course, that of the plane mirror (which could be given by floating the polar axis and suitable mechanical arrangements, a motion of almost perfect regularity.)

One extremely important thing in using silver or glass mirrors is the matter of resilvering from time to time. Up to quite recently the silvering of my 5-foot mirror was a long, uncertain, and expensive process. Now we have a method of silvering mirrors that is certain, quick, and cheap. This takes away the one great disability from the silver or glass reflecting telescope, as the surface of silver can now be renewed with greater ease and in less time than the lenses of a large refracting telescope could be taken out and cleaned. It may be that we shall revert to speculum metal for our mirrors, or use some other deposited metal on glass; but, even as it is, we have the silvered glass reflector, which at once allows an enormous advance in power. To do justice to any large telescope it should be erected in a position, as regards climate, where the conditions are as favourable as possible.

The invention of the telescope is to me the most beautiful ever made. Familiarity both in making and in using has only increased my admiration. With the exception of the microphone of the late Professor Hughes, which enabled one to hear otherwise inaudible sounds, sight is the only sense that we have been able to enormously increase in range. The telescope enables one to see distant objects as if they were at, say,  $\frac{1}{1000}$  part of their distance, while the microscope renders visible objects so small as to be almost incredible. In order to appreciate better what optical aid does for the sense of sight, we can imagine the size of an eye, and therefore of a man, capable of seeing in a natural way what the ordinary eye sees by the aid of a large telescope, and, on the other hand, the size of a man and his eye that could see plainly small objects as we see them under a powerful microscope. The man in the first case would be several miles in height, and in the latter he would not exceed a very small fraction of an inch in height.

Photography also comes in as a further aid to the telescope, as it may possibly be to the microscope, for a certain amount of light is necessary to produce sensation in the eye. If this light is insufficient, nothing is seen; but, owing to the accumulative effect of light on the photographic plate, photographs can be taken of objects otherwise invisible, as I pointed out years ago, for in photographs I took in 1883 stars were shown on the photographic plates that I could not see in the telescope. All photographs, when closely examined, are made up of a certain number of little dots, as it were, in the nature of stippling, and it is a very interesting point to consider the relation of the size and separation of these dots that form the image, and the rods and cones of the reckoner which determines the power of the eye.

Many years ago I tried to determine this question. I first took a photograph of the moon with a telescope of very short focus (as near as I could get it to the focus of the eye itself, which is about half an inch). The resulting photograph measured one two-hundredth of an inch in diameter, and when examined again with a microscope showed a fair amount of detail; in fact, very much as we see the moon with the naked eye. Making a picture of the moon by hand on such a scale that each

separate dot of which was made to correspond with each separate sensitive point of the retina employed when viewing the moon without optical aid, I found, on looking at this picture at the proper distance, that it looked exactly like a real moon. In this case the distance of the dots was constant, making them larger or smaller, forming the light or shade of the picture.

I did not complete these experiments, but, as far as I went, I thought that there was good reason to believe that we could in this way increase the defining power of the eye. It is a subject well worthy of further consideration.

Dr. A. A. COMMON, F.R.S.

#### ALPHA LANTERN PLATES.

[Reprinted from *Photographic Scraps*.]

THE production of lantern slides and transparencies is one of the most interesting branches of photography, especially in the dark winter evenings, when the pursuit of our art is almost limited to those processes which can be executed by artificial light.

The manipulation of the Alpha lantern plates is simple in the extreme. A short exposure, in contact with a negative, to gas or other similar light, followed by plain development and plain toning, give us a variety of tones which are applicable to almost any subject or effect desired, such as blue for a moonlight or snow effect, or a brown tone which conveys the predominating colour of a rich autumnal scene. So good is the colour, so pure the lights, so delicate the detail, and so fine the grain of these plates, that the image appears to be but a stain in the glass itself.

Lantern plates of larger size can be used as transparencies for window decoration, and very light transparencies, but which must be full of detail, make nice pictures of the opaline class if backed up with plain white or tinted paper.

Charming decorative window transparencies can be made from half-plate negatives on whole-plate Alpha lantern plates, the picture being in a tone suited to the subject, with a border of another tone in a contrasting colour. For instance, the centre picture may be a moonlight effect in blue, with a border of orange, showing a space of ground glass between.

This is obtained by printing a picture about half-plate size on a whole-plate, a mask being used to produce a broad transparent border round the picture. On another whole-plate a border with a transparent centre is then made by using a disc larger than the picture on the first plate, exposing to light, and developing as though it were a picture. The two plates, toned to suitable colours, placed film to film, backed up with a sheet of the finest ground glass, and put in one of the many varieties of transparency hangers, will give a most effective and unique picture. It is, of course, obvious that these transparencies can be made in any size, according to the negatives at one's disposal, and the centre may be vignettted instead of masked, with equally good effect.

To work Alpha plates successfully, it is necessary to adhere closely to the instructions accompanying them.

It is essential to have a practically uniform light for exposing, and exposures should be made at the same distance. An average exposure would be about two minutes at six inches from the light of a No. 5 Bray's burner. By constantly exposing under these uniform conditions, a knowledge of the exposures necessary for negatives of varying density is soon obtained.

The choice of a developer is limited, very few being suitable for Alpha. The formula issued with the plates is undoubtedly the best in which the reducer is a simple hydroquinone one and the accelerator a weak solution of caustic soda. A well-restrained ferrous-oxalate developer, weak in sulphate of iron, is also admirable. Ordinary developers will not do, as most give a greenish colour, which is undesirable, except for certain effects, and with them there is a risk of more or less veil in the lights.

The development should be done in plenty of light. One thickness of the palest canary medium is quite safe; in fact, these plates can be developed without a yellow light in an ordinary room at a considerable distance from an ordinary gas light (not incandescent) if the direct light be shaded from the plates, and care be taken not to expose them unduly to this light until they are fixed.

The most suitable colour to develop to is a rich red. A greenish colour is an indication of under-exposure, and yellow of over-exposure, although these may be suitable for certain subjects.

After development, the plate is quickly rinsed in water and transferred to a weak hypo bath; for, if left in the washing water, the development is liable to continue, and make the picture too deep. After fixing, the plates may be washed and placed to dry where they will be free from dust, and, if necessary, may be toned at any time afterwards, or they can be toned immediately after fixing in the following Alpha toning bath:—

Water .....	10 ounces.
Hypo .....	2½ "
Ammonium sulphocyanide.....	¼ ounce.
Gold chloride .....	4 grains.

These should be dissolved in the order given, and made up at least one day before using. This bath can be used over and over again if strengthened from time to time, when the toning becomes too slow, with the following solution:—

Water .....	5 ounces.
Hypo .....	2½ "
Ammonium sulphocyanide.....	¼ ounce.
Gold chloride .....	8 grains.

This also should be made up some time before using. A toning bath which has been used repeatedly gives finer tones, and will keep indefinitely if not contaminated by foreign chemicals.

The fixed plate will be yellow in colour, and will dry red, but, in the toning bath, it will pass through the various warm tones to purple and purple-black, and, after very prolonged toning, to blue; but this latter tone is more readily obtained by washing the fixed plate thoroughly, and toning in the following bath:—

Water .....	5 ounces.
Ammonium sulphocyanide .....	20 grains.
Gold chloride .....	2 "

The images of these plates dry considerably deeper and all tones colder than they appear while wet, especially in the warmer range. For the colder tones it is necessary to develop the pictures a little more deeply than when warmer tones are desired.

A. J. A.

### THE NEW FOLDING FRENAS.

Manufactured and sold by R. & J. Beck, 68, Cornhill, E.C.

The new Folding Frena Cameras, Nos. 7 & 8, which Messrs. Beck have recently introduced, are on the same model as the No. 6 Frena, which was also placed upon the market this year; but, whereas that camera is fitted with a fixed-focus lens, the new models are fitted with focussing arrangements and other adjustments. Either Frena films or glass plates can be used with these cameras, but the No. 8 Folding Frena is so arranged that its special adjustments need not be used unless preferred.

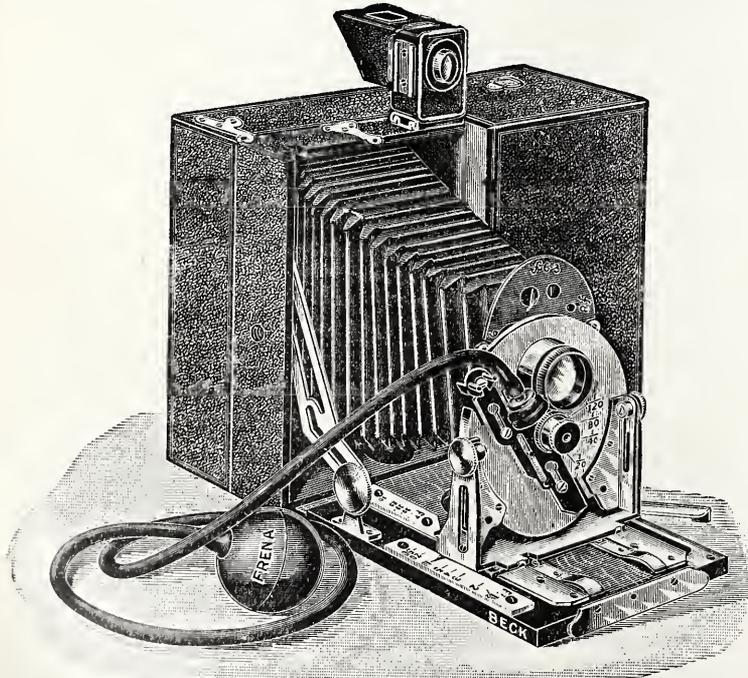

FIG. 1.—The No. 7 & 8 Folding Frena (open).

The Film-holder contains a sliding box, holding any number of Frena films from one to forty under spring pressure, the front one always being in the focus of the lens. To change the film, this sliding box is partially withdrawn while the camera is held with its lens end pointing downwards. By turning the handle the foremost film is automatically dropped into the receiving chamber, where the exposed films are deposited in a pack one by one, in the order in which they have been taken. By means of a new arrangement of the film-holder, the Folding Frena is constructed so that the lens, shutter, and camera can be detached from the magazine and film-changing portion. With the addition of a ground-glass attachment and double plate-holder, it can be used as an ordinary plate camera.

For focussing the camera a lever adjustment is provided and a scale of feet for setting the lens, which is especially adjusted in each camera so that entire reliance may be placed on its accuracy. Besides this an arrangement has been attached, so that the camera may be focussed by

the direct method, even while the film holder is attached to the camera. If the slide of the film-changing portion be drawn out as shown in fig. 4, a focussing glass, B, which is supplied with each camera, may be inserted in a spring trap-door, A. This focussing glass has a ground glass at one end, which, when inserted, is in the exact position that the film usually occupies, and by looking through the magnifying lens at the other end the centre of the picture may be focussed direct.

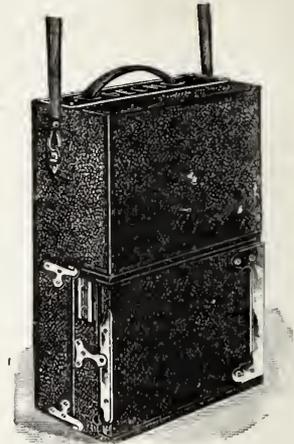

FIG. 2.—The No. 8 Folding Frena (closed).

A swing back is provided. The side links which support the tail-board are so made that the tailboard snaps under ordinary circumstances into the horizontal position, but for use of the swing back it may be clamped by means of two milled heads at any angle required. Fig. 3 shows the camera with swing back and rising front in use. The finder, which is shown in figs. 1, 3, and 4, is a brilliant finder made on the principle of the Cornex finder, which, whilst giving a brilliant picture, shows at the same time a perfectly stationary image. It packs away into the

FIG. 3.—No. 7 & 8 Folding Frena, showing Camera as used for Glass Plates. Swing Back and Rising Front are shown in use

camera when not in use, but, when attached to it, can be used for either horizontal or vertical pictures by merely revolving the back portion without shifting its position on the camera. The No. 8 Folding Frena carries one of the new Beck-Steinheil orthostigmat lenses, with an aperture of  $f-6.3$ , at which the margins of the plate are as sharp as the centre, and the rising front can be used to its full extent, namely, one inch. The front half of the lens may be removed, and the back half

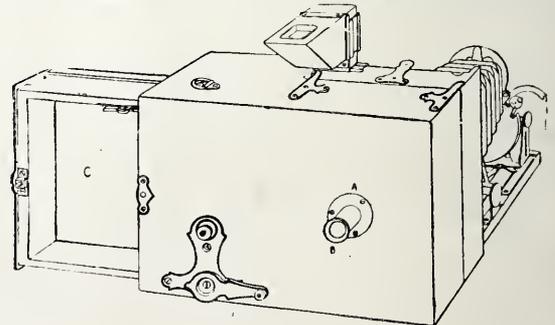

FIG. 4.

used alone as a lens of double the focus and one quarter the speed. For use with this back lens only, the tailboard of the camera can be pulled out, thus making a double extension.

The No. 7 Folding Frena is in every way similar to the No. 8, except that it is provided with a Beck autograph rapid rectilinear lens with an aperture of  $f-8$ , in place of the Beck-Steinheil orthostigmat. This lens, when the rising front is not used, covers the plate well.

## LANTERN MEMS.

It is curious how men that can sketch belittle photography. Recently one of these said to me, when talking of photography and hand cameras, "I have seen hundreds of photographs, but few pictures," and many times it had been his experience to see enthusiastic and other amateurs snapping away at something that was anything but artistic in composition, when close at hand there was really a picture to take. It seems to me from this conversation that a number of artists with pen and pencil do not avail themselves of the annual photographic exhibitions to become acquainted with what our best workers can do in the way of photographic picture-making. I think a walk round the New Gallery at the present season would be a revelation to them.

\* \* \* \* \*

THEN again with lantern slides, I have seen some lovely photographs projected on the screen, real art with a big A, and on one occasion had with me a friend who became quite enthusiastic over the beauty of the scenes depicted. There is no doubt the lantern is a splendid aid to art instruction, and the friendly criticisms of members on lantern nights at provincial and other photographic societies has had a most beneficial effect on the composition and technique of lantern slides, and from my experience with buyers of transparencies I can safely say that considerable advance has taken place during the past ten years in the judgment and discrimination of lanternists, for a photograph that is not artistic has very little chance of sale unless it portrays something that is necessary to complete a lecture or affords a useful contrast to a gem in composition and lighting.

\* \* \* \* \*

ONE of your correspondents recently wrote respecting the absence of figures in the slides representing the Paris Exhibition, but after all, unless as extras, they can hardly be included in a commercial set without it is very much extended; and then it is not commercial, for a set that goes beyond sixty slides is difficult to dispose of or even hire. No doubt there are many most interesting studies of characters at places like the World's Fair in Paris, but the difficulty of getting them is greater than can be imagined by those who have not tried to obtain them without giving offence to the subject.

\* \* \* \* \*

If we can go up to the subjects raise our hat and say, "Will you accept two guineas?" no doubt the subjects would be delighted and pose conveniently to our hearts' content and throw in a "smile" into

the bargain, but without some little solatium the photographer will have but a poor chance. One of the slides in the French set of the Paris Exhibition is labelled "Arabs at the P. E.," or something of the sort, but it would be certainly more correct to have added "back view," for the three men show only the backs of their heads and bodies. Then, again, let photographers try to take a near view of characteristic market women and men on the Continent, and see, if they get off in safety with their cameras, what expletives follow them from the individual snapped.

\* \* \* \* \*

ONE or two men I know have a happy knack of getting good records of characters; but, then, they have amiability and good nature written large on their faces, and a graceful smile and request is rewarded by a sitting after the promise (always kept) of a copy for the subject. Amateurs generally are learning the wisdom of the saw, "if you value your friends' friendship, do not take your friend's photograph;" that is better left to the professional photographer in the studio. Many early efforts of budding amateurs have provoked laughter, but more have brought tears or an early destruction of the print. Thus it is that scenes are more sought after than figures.

\* \* \* \* \*

I HEARD a good joke about an enthusiastic marine photographer this season at Margate. He was anxious to get some snap-shot of sea nymphs while bathing, and selected a quartette of charming girls in stockinette swimming costumes, who were diving from a boat. They were full of the innocent fun, and after they had been surreptitiously snapped by the Kodaker they plotted among themselves for the downfall of the intruder. So with pretty smiles they invited him to the boat, and they being irresistible he went, but soon found to his cost that it was not so agreeable as he expected, for they rocked the boat until it capsized, and the whole party tumbled into the water. The nymphs were in their element, but poor Mr. Photographer, who was fully clothed, was in a sorry plight, and the ladies had the satisfaction of thinking that his negative was spoilt.

\* \* \* \* \*

So many lanternists still feel shy of the electric light, and cannot realise that in the arc form it is the most suitable illuminant for the optical lantern, and the simplest and safest of all to use. Everybody who has the electric current available can get the most beautiful and successful results, with the minimum of trouble, and any quantity of light from 500 candle-power to 5000 can be obtained by utilising little or much of the current, and those who have private installations of only 50 or 60 volts can get excellent results. I recently saw a report from abroad of good work done on a 50-volt circuit, and excellent results obtained on a 60-volt one.

\* \* \* \* \*

THE electric light companies are now supplying for the sake of more economical distribution the currents at 220 volts; but, as this in working only requires a greater resistance of wire, it is just as satisfactory, if not more so, than the 100-volt current, and, although the initial cost is a little greater, the expense of working is practically nil, for the

carbons are very cheap, and also good, it may be remarked now, while the current used in a two hours exhibition would be covered by the amount of sixpence for the electricity used. Those societies and private houses that can get the current laid on should lose no time in doing so, if they wish to know what a luxury the working of an optical lantern is with the electric arc light as the luminant.

G. R. BAKER.

THE LONDON COUNTY COUNCIL'S NEW REGULATIONS  
RESPECTING THE USE OF CINEMATOGRAPH LAN-  
TERNS, &c., IN PREMISES LICENSED BY THE COUNCIL.

[Approved by the Council, October 16, 1900.]

1. No cinematograph, or other similar apparatus involving the use of a lengthy combustible film, shall be exhibited on premises licensed by the Council, until the Council has been satisfied that all reasonable precautions have been taken against accident and danger to the public.

2. Notice of any intended exhibition shall be given to the clerk of the Council by the licensee of the premises in which such exhibition is to be given, and the licensee shall be held entirely responsible for the proper and safe use of the apparatus. Such notice shall be given at least three days before the first day of exhibition. Opportunity shall also be afforded to the Council's inspector of inspecting the apparatus before the public exhibition takes place, in order to allow time for any necessary alterations to be carried out and approved by the Council. No gangway or exit must be in any way affected.

3. The cinematograph shall stand in a suitable fireproof room or closed sheet iron box of sufficient dimensions to allow the operators to work freely and fitting closely to the floor, which shall be covered with fire-resisting material within such room or box. The door or doors shall open outwards and be self-closing, and, of the three windows which are necessary in the front face of the enclosure, the centre one shall not exceed eight inches square, and the windows on each side shall not exceed six inches square; a flap screen, to cover all these three holes, shall be fitted and actuated both from the inside and from the outside of the enclosure; the space separating the audience and seats from the iron enclosure shall not be less than two feet in width at the sides and in the front of the enclosure, and the space at the back in which the door is situated shall not be less than six feet from the enclosure. The audience shall be completely excluded from the above space around the enclosure by a suitable barrier. No unnecessary combustible material shall be within the enclosure, and, as far as possible, all necessary combustible material shall be rendered fireproof, or shall be enclosed in fireproof receptacles. The part of the film immediately opposite the lens shall be provided with an apparatus which prevents the film, if kindled, from burning towards either of the spools.

4. The body of the lantern shall be constructed of wood or other non-conducting material, and shall be coated inside with asbestos; it shall also have an inner lining of sheet iron, and an air space shall be left between the iron and the asbestos lining. In the bottom of the lantern shall stand an iron tray, which shall be surrounded by a vertical edge at least one inch in depth. The lantern shall be provided with a metal shutter, which shall fall freely between the source of light and the condenser. This shutter shall be immediately dropped in the event of any accident to the apparatus or stoppage of the film, and shall only be raised when the film is in motion for the purpose of projection.

5. Where possible the electric arc light shall be adopted as an illuminant, the usual rules for securing safety in an electric installation being observed. Ether and other inflammable liquids shall not be employed under any circumstances for producing light. If limelight be used in the lantern, the general regulations for its safety, which are issued by the Council, shall be complied with, and any additional precautions which the Council may deem necessary for securing safety shall also be adopted. The use of acetylene gas will not be permitted.

6. The space in which the cinematograph stands shall, where possible, be illuminated by electric glow lamps; but a miner's safety

lamp may be substituted, if necessary. No naked gas or oil flames, or matches, shall be allowed in the space. The lighting of the hydrogen flame in the lantern shall be accomplished by means of an electric lighter.

7. The films, when not actually passing through the lantern, shall be kept enclosed in metal cases. The film which is passing through the lantern shall be [rewound, either automatically or by hand, upon another bobbin as fast as it emerges from the lantern front.

8. Not less than two, nor more than three, operators shall be engaged within the lantern space, and no other persons shall be within the lantern enclosure during the exhibition. The whole duty of one of the operators shall consist in taking charge of the film after it has passed through the lantern.

9. The licensee shall be held responsible for the employment of competent, experienced and trustworthy operators, and shall be prepared at any time to supply to the Council satisfactory credentials in this respect.

10. Smoking within the lantern space shall be absolutely forbidden at all times.

11. The Council reserves to itself the right of modifying any of the above regulations and of requiring the adoption of any further precautions, in addition to those specified above, as circumstances may require.

ALBUMEN LANTERN SLIDES.

THE lantern season is now with us, and the negatives taken during the past summer furnish ample employment for the winter evenings for making lantern slides therefrom. The method usually practised by amateurs is gelatine dry plates, either with contact or camera exposure. Many of the commercial slides, however, are still made by the wet-collodion process, and some by the albumen process, and there is no question that the latter is, far and away, better for the purpose than the former. But it is more troublesome to work, and consequently the slides cannot be produced so cheaply by the one process as the other. Amateurs vie with each other in the perfection of their slides, but their efforts are confined almost, if not entirely, to the employment of commercial gelatine plates, for few now make a feature of the collodio-bromide method. At the present time the gelatine lantern plates now on the market yield slides of great excellence, and it is only by actual comparison side by side that the superiority of albumen is noticeable. But, then, it is noticeable.

At one of the Society meetings the manufacturer of one of the best lantern plates on the market remarked that his object had been to imitate the perfection of albumen as closely as possible; a remark that seemed to admit the superiority of that process for the purpose of lantern-slide making. We have just said that the albumen is a troublesome process to work; so it is, but it is by no means a difficult one, and, up to the sensitising, all the work can be done in broad daylight. The light in the dark room, when that is needed, be only an orange light, and plenty of it may be admitted, so that it is a comfortable process in working. Albumen plates are slow—not more rapid than the slow gelatine lantern ones, hence their manipulation is very convenient. But for the trouble of the preparation of the plates, we believe that this beautiful process would be largely employed by amateurs whose aim is the production of slides with the acme of perfection. Most have seen the very beautiful albumen stereoscopic slides made by Ferrier in the fifties, and they have not been surpassed if equalled by any modern productions, and that is why we again bring this process to the notice of our readers. The formula for its working is given in the ALMANAC for the current year.

LIMELIGHT MATTERS.—LANTERN ACCESSORIES.

NOTWITHSTANDING that the great bulk of optical lanterns now offered to the public may be said to contain all the requirements necessary for projecting lantern slides within certain limits in a fairly satisfactory manner, there is no doubt that, once an operator enters into lantern work in a really ardent manner, he will not be long in finding out that here and there in even high-class instruments improvements can be

effected by carrying out some slight alteration, or by the addition of some simple little matter to the construction of the shell or other portions of the apparatus. Ask any of our leading lanternists their opinion on this matter, and not one in ten will reply otherwise than that their lantern outfit has been altered from time to time, until it is quite a different thing from its original form, and that innumerable little accessories have had to be added from time to time ere the same could be made to yield the satisfaction which they eventually derive when working in varying situations, some of which are at times very exacting.

One of the first matters that strikes an ardent lanternist, once he has entered into the spirit of limelight projection, is that of ventilation, and the best means of keeping his lantern from overheating. For many years, strange as it may seem, manufacturers in this country, at least, never seemed to grasp the importance of so making the bodies of their optical lanterns that the great heat always generated should have the best means of escaping from the shell. Wooden bodies lined with thin metal, having a ridiculously small air space between, were almost universally employed, and, in fact, are in many instances at the present time still made, the wooden exterior to a great extent preventing much of the heated air from escaping, and actually, as it were, bottling up the heat inside the lantern. The idea of these wooden bodies was, no doubt, to confer more or less comfort in the working of the lamp, for the great heat generated was sufficient to yield an eye-opener, in the event of the hand coming in contact with the unlined portion of a shell. Improvements in ventilation were for a long time little thought of, the main object being to make a lamp light-tight, or as nearly so as possible.

Shells were in former years (*i.e.*, before Russian iron came into general use) made with a larger air capacity, but from about the time of the introduction of the Sciopticon form of lantern the size of the shells was gradually reduced, until a few years ago the same in some instances were far too small for really practical use. To a certain extent a reaction has again, within the past few years, set in; but speaking generally the size of the shells, as found on the market at the present day, is still too small, and with such limited air capacity it is extremely difficult to employ powerful jets without overheating, and the consequent liability to fracture the condensers.

Take, for instance, the case of a metal body having an inner plain and an outer perforated lining. A very common form of such lamp will be found to be in size, so far as the interior of the shell is concerned, about 7 inches long by 5 inches in breadth, and 9½ inches high; and when such shells are made to do duty with a limelight jet, without some alteration in the way of providing extra air passages, for improved ventilation, it is almost certain that trouble will arise, in the shape of overheating and cracking a condenser. As a rule, the main influx of cold air is provided for at the rear of the shell—about the worst possible part of the lamp, for it tends to drive the heat up against the rear of the condenser. In using lanterns of this description, one of the first things an ardent lanternist will set about doing will very probably be the cutting out of apertures in the bottom of the shell, especially underneath the part occupied by the mixing chamber of the jet. This will at once effect a marked improvement, for it will provide for a steady flow of cold air being admitted just at the point where it is most required, so as to assist in carrying off in an upward direction the heat in and around the lime pin, and will at the same time tend to keep the condenser cool.

The cutting out of these apertures in the bottom of a lamp need not affect the light emission, which in many instances is far too much thought of.

No lanternist cares to work with a lantern which is so leaky as to cause unpleasantness to anyone sitting in close proximity to the same; but a little light from such air passages need annoy no one.

To obtain the full benefit of this simple means of improving the ventilation of a lantern a further accessory ought to be provided, in the shape of a couple of stools or blocks, upon which the base of the lantern ought to rest. These stools are conveniently made of blocks of wood, and will serve the double purpose of not only assisting a free passage of air right underneath the bottom of the lantern, but will act as a tilting board as well. In making these little stools, they ought to be of different sizes, and should be provided with little holes, to admit of the studs in the bottom of the lantern resting on them. This will be found to help wonderfully in keeping the lantern rigid. A very useful size to make these stools is as follows:—When the distance between the front and the back stool is, say, 12 inches, the front stool should be 2 inches in height and the rear one 1 inch high. By keeping to these proportions a lanternist can calculate to a nicety the amount

of tilt he will have on his lamp, the one in twelve, as in this case, yielding 1 foot in every 12 feet of distance, and such accessories as these ought to be found in every lanternist's kit; they do away with the need of tilting boards in a great measure, and permit of a nice free passage of air underneath the lantern, just where it is most needed.

Of the innumerable little articles that may be termed accessories to a lantern outfit, perhaps none are more useful than a few little wedges of wood. How often in lantern projection do we see novices failing to register properly their pictures on the screen? To a large extent this is caused by the carrier shifting in the lantern front. Such is easily prevented by seeing before beginning that the carrier is firmly wedged up, so that it is practically immovable in the front. A little wooden wedge will also at times be found useful to fix a lime tray securely when the guides are working too loosely. By fixing one on each side of the tray, after the jet has been finally centred, the same is held securely, and there need be no fear of the centre of light altering during the manipulation of the lantern, or the strip caused by the rubber tubing on the rear of the jet. As a rule, lime trays are better for having a little play in their guides; but this does not imply that they should be so slack, after the jet has been centred, as to make the same liable to get them out of register. A few wedges as accessories will be found very useful.

Such simple little things as nails and rings ought to be found in every lantern outfit. Yet how often do we hear an operator shouting for a few nails or something to tighten up his screen with. When this is an evidence it does not betoken ardent lanternism. A well organised outfit should embrace everything that can be reasonably required, without troubling strangers in the least degree. When this is provided, it confers an amount of comfort in lantern work that can only be appreciated by those who know by experience how rapidly and easily everything can be rigged up for a lantern display when they possess everything they require themselves.

In ardent lanternism, perhaps nothing tends to show an operator's ingenuity more than the manner in which he has provided for the packing of his outfit. And here again, like in many other things connected with lantern work, hardly two workers will be found to be alike. The packing of a lantern, and its accessories, is a science in itself, and often displays an amount of cleverness that is really genius. It is wonderful what can be done by altering the form of a lantern, and substituting some simple little contrivance instead.

Take, for instance, an ordinary single lantern outfit of the Sciopticon form, convertible for limelight working when desired. One of the most serviceable lantern outfits the writer ever witnessed was composed of one of these cheap, but excellent forms of lantern; but it was so altered as to be practically quite a different article when made to suit the taste of its owner. First of all, the telescopic front that usually runs in grooves to carry the objective was entirely removed, and dispensed with, and in lieu of the same a strong board of mahogany, 10½ inches long by 4½ inches wide by ¾ inch thick, was substituted for the same. This mahogany board was bevelled at the sides so that it ran in the guides of the front of the lantern body. At the front end of the mahogany board two holes were bored out, that permitted of two small bolts and nuts being used to hold an upright, which carried the objective, just like the front of a camera. By means of this simple contrivance, which could be taken to pieces and stowed away, a very bulky portion of a lantern was at once dispensed with, and the entire space between the slide stage and the front of the lantern was at anyone's disposal for the purpose of packing accessories, &c.

The manner in which these alterations permitted the packing being performed was truly astonishing. Inside the lantern there was stowed the mahogany board, the patent carrier that was always used, the rubber tubing; then on the top the condenser, wrapped in chamois leather; then the lime tray, containing cylinder key and innumerable other little accessories, such as wedges, &c.; the lantern top, and front stool of the lantern; not a single inch of space being wasted. This left the front space, which was nearly as large as that of the inside of the lantern, for other adjuncts, and all this was provided for by using a mahogany board instead of the usual telescopic front of the lantern. The whole packing into a box 16 inches long, 10 inches high, and 6 inches deep.

On the other hand, it must be admitted some lanternists are never satisfied unless they carry about with them quite a number of accessories that are of no practical use. These not only take up room, but are liable to get loose in packing, and do damage to other portions of an outfit.

In packing a lantern outfit, especially when time is limited—as is too often the case at the close of an entertainment—the temptation is very great to throw things, as it were, into their places, and then assuredly will come the truth of the old saying, “The more hurry the less speed.” One fruitful source of mess to a lantern outfit is that of trying by false economy to make limes do duty more than once. Nearly all the dirt and discomfort to the packing of a lantern outfit will be found to arise from the limes not being properly removed from the rest of the outfit. This is a point that clean operators are very particular about. Used limes should always be thrown out, and not a particle of their dust left to contaminate the rest of the outfit.

To enumerate all the odds and ends which come under the category of lantern accessories would indeed be difficult. There is, however, one item which ought to be carefully looked after, and that is provision for protecting the lenses and jets during transit. The former ought to be securely packed in leather jackets, or boxes which are now made especially for the condensers; and these probably are best carried in a separate handbag by the operator or lecturer himself. A few clean dusters for wiping the slides, and last, but not least, a clean towel for the operator's own face and hands, will be found a comfort on many occasions.

T. N. ARMSTRONG.

#### LANTERN NOTES AND NEWS.

“France and the Principality of Monaco” is the title of a new set of lantern slides which Messrs. G. W. Wilson & Co., Ltd., of Aberdeen, are just issuing. The set includes views of Paris, and incorporates former sets on France. It numbers 481 slides.

\* \* \* \* \*

Last week a conference of the Society for the Protection of Birds, at 3, Hanover-square, was followed by an “At Home” at the residence of its vice-president, Lady Theodora Guest, 26, George-street. Lantern lectures have long been an important factor in the furtherance of the cause; but now a new set of slides are to be added to the already fine collection, in order to illustrate approved “bird” songs, so as to constitute an entire programme for an evening's entertainment. The experiment was inaugurated effectively through the kindness of Madame Antoinette Stirling, who sang “The Quail” and “The Sparrow's Ditty.”

\* \* \* \* \*

At the last meeting of the West Surrey Photographic Society there was a demonstration by Mr. Sheed of lantern slide making, on Thomas's plates. The demonstration showed the great possible range of tones obtainable by the maker's formula, and Mr. Sheed found himself, he said, able to rely upon getting the particular tones he wanted with much more certainty than on many other brands of plate he had tried. He showed the possibility of getting from black to warm brown tones, and to nearly red ones, by altering the developer, as directed, and as experience suggested, and said his preference for the Thomas plate was the result of many trials, with the resulting ups and downs to be expected, assigning the ups to Thomas's plates principally. Matters of business also came before the Council, which does not meet again till January.

\* \* \* \* \*

On Monday night, at the Royal Photographic Society's Exhibition, at the New Gallery, Mr. Samuel J. Beckett showed upon the lantern screen a series of typical portions of the C.I.V. procession, numbering some seventeen pictures. Mr. Beckett informs us that the slides referred to were all taken and finished between 3 and 8.30 p.m., at which time they arrived at the Gallery. The negatives and also the slides were both dried off by heat, after treatment with formalin. They were accorded a very hearty reception indeed.

\* \* \* \* \*

It is the opinion of the “New Zealand Photographer,” and we quote it in virtue that some interest may attach to it, as the utterance of a distant onlooker, that the kinematograph, as a popular amusement, is about “played out.” At first (proceeds our contemporary) the novelty was an irresistible attraction, but the average sightseer soon tires of paying for the exhibition of scenes similar to those which he can see any day for nothing. There are some sights and scenes which will always attract and interest an audience—perhaps a prize-fight has proved the biggest draw of any—and this does not say much in favour of the intellectual qualifications of the average patrons of the show. A real Maori war dance, if it could be revived, would be a sure thing. The Haka or Poi dance would be very good subjects; but the Fijian

Meki would make one of the most animated scenes if it could be well represented. So the “kine on the battle-field” has not proved the success which was expected of it. You, see, the stirring events always happened at such unexpected times. There was no reliable programme for the man with the machine to follow, and he always happened to be “in” just a minute too late. Why, the best pictures of all were specially enacted before the camera. Some folks would call them “put-up jobs,” but once, the papers tell us, a camera really did go off and hit somebody. That was a realistic episode for which the models did not bargain. The next sensation promised is a film representing the decapitation of a hundred Chinamen. Those little things show the horrors of only a few executions will be as nothing to this. Just think of the thrill of emotion to be aroused, and the elevating tendencies of the exhibition, when you can see the Lord High Executioner cut off a hundred heads in turn.

#### PHOTOGRAPHY AND THE PRESS.

##### I.

So much money is now spent upon photographs for reproduction in the illustrated newspapers and magazines that some practical advice to those photographers who would be glad to pick up some of the shekels which editors are flinging around will probably be welcomed by most of those who depend upon the camera for a livelihood. As far as the daily journals are concerned, such as the “Mail” and similarly roughly and rapidly printed sheets, reliance is necessarily placed on line drawings. These are, however, usually based upon photographs, which are submitted by photographers from all parts of the kingdom and most parts of the world.

The methods followed differ. Occasionally a photographic print is outlined with waterproof ink, the silver (or iron) image being subsequently removed, leaving a line drawing ready for the zincographer to turn into a block. But in most cases the photograph is simply copied with pen and ink by one of a staff of specially trained black-and-white draftsmen retained for the purpose. Some establishments have arrangements whereby an enlarged positive image is projected upon a screen, from which the artist makes his drawing. By this procedure a quarter-plate negative will indicate a surprising number of facts upon which draftsmen can work.

##### RAPIDLY OBTAINED RESULTS.

As regards the general body of photographers, most interest will be centred in the methods used to quickly obtain negatives and prints which shall, in as short a time as possible, be ready for dispatch to the editor of an illustrated newspaper.

The writer, who has had many years' experience with editors of illustrated journals, specially urges upon all concerned to adopt every possible expedient for ensuring early delivery of a print. Although, as a rule, all prints are given out to the block-maker not less than two days before date of publication of a weekly newspaper, the majority of the illustrations are put in hand a good deal earlier; and although some editors will often take an important or an unusually striking print of a passing event even after the forty-eight hours' limit, they are somewhat shy of throwing out a block already finished, or an order for a print which comes to hand at the last moment. Hence half an hour may make all the difference between securing a fee from an editor and being too late. Thus a photograph taken during the afternoon in the provinces may just miss the evening mail to London should the photographer not be up to every possible dodge for working against time.

There are two procedures which, under ordinary circumstances taking a long while, may be very much shortened.

1. Making and drying the negative.
2. Making and drying the print.

As regards the first point most photographers are, or should be, aware that the development of a negative need not, under favourable conditions, take more than about four minutes in the reducer, the fixing, or clearing, may need five. The washing need not take more than one minute. Immersion in two baths of spirits of wine will permit of the film being dried in five or six minutes; that is to say, a glass negative, quite dry, can be obtained inside twenty minutes.

In our days, however, an increasingly large proportion of photographers, more particularly those who are more or less connected with the press, employ rollable and other celluloid films for obtaining the negatives. They may not be dried by means of immersion in alcohol, as it would attack the celluloid support. It is true that some makes of rollable film, such as the Cristoid film, which contains no celluloid, may be treated with alcoholic solutions, but at present nearly every one uses celluloid. As regards these films, they may be formalined, blotted, and the drying then accelerated by employing gentle warmth; but, if this be done, there is always some considerable danger of the film, sooner or later, peeling off from its support. A better course is to take them direct from the washing tank, let them be careful, blotted and backed up by a sheet of glass, and placed in an enlarging lantern of low actinic energy; with a fairly clean, quick, negative, and enlarging not more than two or three diameters, the time necessary for exposure is not

sufficient for the heat of the illuminant to injure the gelatine surface. This expedient not only saves time, but what is often of very considerable value, enables one to slightly enlarge the original. Thus a quarter-plate, which in nine out of ten cases is the size which will be used, may with the slightest possible loss of definition be turned into a half, or even whole-plate print.

Of course, those who are working with larger sizes, say half-plate and over, would not find the above expedient of so much service; but the celluloid film is rarely used for sizes exceeding 5 by 4.

MAKING AND DRYING THE PRINT.

For a very long time makers of process blocks impressed upon editors that, in order to get good results, a "silver" print was a sine-qua-non. By "silver," albumenised, gelatino-chloride, or collodio-chloride, paper toned with gold is meant. It is needless to say that this restriction meant the loss of a large amount of time. It is not easy to say why this exclusiveness should have been so long maintained—probably because with the above print-out papers there is usually present a good deal of detail combined with a considerable proportion of half-tone. In a "bromide" paper, although similar qualities may be present, it is quite possible—and, indeed, frequent—that shadows and high lights may both be deficient in details which the block is able to reproduce, although, in some cases, they may be just sufficiently visible to suggest a good deal to the eye of one looking at the photographic print.

But of late the exigencies of press work have compelled even the most conservative of process-makers to accept without a murmur, and handle without a mistake, pretty nearly every form of print which may be sent to him.

Anyhow, for rapid work, many of the leading illustrated papers are obliged to depend upon various makes of bromide paper, which, being printed in a few seconds, may be finished off in a few minutes.

That there may be as much detail, and as little scattering of light as possible, a paper having a glazed surface is generally used. Of these there are several varieties on the market.

WHITE NIKKO.

Take the one made by Kodak Limited known as Nikko. This is usually sent out with a pale, almost invisible, pink tinge, but for process work a white paper is preferable, in which form Nikko is procurable, although it is not stocked by most dealers, but requires to be specially ordered.

Nothing need be said as to the exposure or development of the above, except that the print should aim at possessing plenty of half-tone with bright lights and strong shadows. It is also a gain if the image is brown, or black inclining to brown. To which end many expedients are possible which will suggest themselves to the practised photographer—and none other is likely to undertake this business. Personally, ortol has been found a very satisfactory reducer to use. It is true that sometimes the resulting print is not very charming in its colour, being neither good black nor good brown, but, for all that, it yields a very satisfactory process block.

The formula advised is the following: Using twenty per cent. solutions of soda carbonate and soda sulphite, and a ten per cent. solution of ortol, mixed with half its weight of metabisulphite of potassium, and a ten per cent. solution of potassium bromide in reserve.

Take of each of the first two solutions, 2 ounces; of ortol solution, 5 drachms; make up to 12 ounces with water, and, if necessary, add quantity sufficient of potassium bromide, say 5 to 15 drops.

Fix in acid bath, rinse, and place in a solution of formalin. Blot off, and the print may be right away dried before any convenient source of radiant heat, say a fire or otherwise.

HECTOR MACLEAN.

A COMPLEMENTARY STEREOSCOPE.

DURING the process of viewing a landscape with both eyes, voluntary axial and involuntary focal changes take place as the attention is turned to and from various objects composing the landscape.

The general impression of solidity is the result accruing from two distinct impressions—one received on the retina of the right eye, and another received on the retina of the left eye, the nature of these dissimilar retinal pictures being determined first by the direction of the eyes' axes, and secondly by the refracting humours.

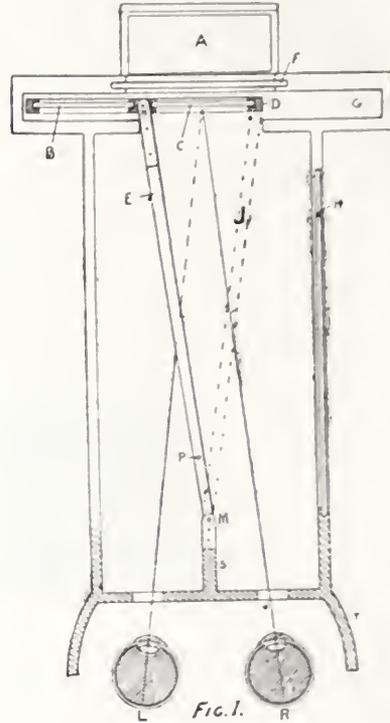

Although the sensation of relief is produced by a combination of the two retinal impressions, such impressions are not simultaneously conveyed to the brain. They are regarded separately—or, rather, at different moments, for exhaustive experiments have shown that the two retinae cannot be equally stimulated by rays emanating from the same source and at the same moment of time. In other words, we might say binocular vision is effected by the alternate exhaustion of the nerve fibres, creating temporal blindness to certain colours or degrees of light.

That the retina of either eye may become fatigued has been often demonstrated. The theory of accidental, or what is perhaps better known as complementary colours—the alternate appearance of positive and negative images—and the temporary blindness that follows when the eyes have been exposed to excessive light, all substantiate the accepted

view that the activity of the retina is limited to a definite period, and that it is only able to recover sensitiveness after a time of rest.

On this assumption the complementary stereoscope has been constructed, and it has been so designed that either coloured transparencies or plain black and white pictures may be used.

The apparatus, a sectional plan of which is shown in fig. 1, consists

of a box form stereoscope, without lenses. A ground glass window is fitted at F and R. The holder, D, in which the complementary pictures are to be placed, is attached by the pivot, X, to the partition, E, which partition is capable of turning on the hinge at M.

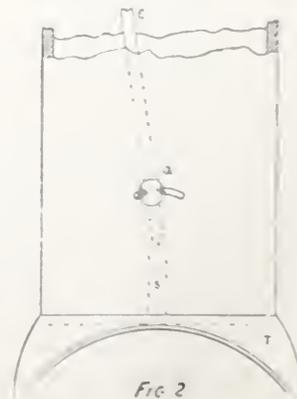

A reflector is formed by the mirror, A, hinged to the end of the apparatus, and set at an angle of 45 degrees. The movement of the swinging partition, E, is controlled by a knob, Q, shown in fig. 2, its play being limited by the slot. The dotted lines in fig. 2 indicate the position of the partition as it is turned towards the left-hand side of the apparatus.

It should be observed that the pair of pictures to be employed must not only be positives and negatives or printed in complementary colours, but also they must be stereoscopically taken.

The method of using the instrument will perhaps be best explained by referring to fig. 3, a negative and positive stereoscopic pair of pictures.

The eyes of the observer being placed at L and R (fig. 1), the left eye positive, B, is placed in the holder, D, at N, and the right eye picture, which is a negative, like C (fig. 3), is placed in the holder at C (fig. 1).

The partition, E, being moved to the left side of the instrument, as shown in the diagram, the stereoscope is held so that a strong light

may fall upon the mirror, A, reflecting the light to the window, F, by which it is diffused over the negative, C. The retina of the right eye, R, is thereby strongly stimulated with rays of light sifted through a

negative. At the same time the left eye is prevented from seeing anything by being shut off to the dark chamber made by the partition, *e*.

When the right eye has been looking at the negative for about thirty seconds, the partition, *e*, is suddenly shifted from the left to the right by means of the knob. The positive, *b*, is now presented to the left eye, but it is seen not as might have been expected, a plain picture, but it possesses stereoscopic relief.

This surprising effect is due to the fact that the right eye, after being stimulated with rays emanating from the negative, *c*, becomes temporarily blind to such rays, and is sensible only to rays of a complementary character. Thus whilst the left eye sees a left-hand positive, the right eye sees also a positive image, dissimilar to its companion view. Moreover, both being observed at the same point, they naturally coalesce. Thus, by the combination of a real and an accidental image, the observer becomes conscious of a stereoscopic relief, similar to that produced in an ordinary stereoscope.

Although the effect obtained in such a constructed instrument may only be retained for a short time, the mode of securing the effect is at least novel, and therefore worthy of note.

Although it is, perhaps, somewhat apart from our present subject, it is particularly interesting to note that when the dissimilar pictures, *b* and *c* (fig. 3), are examined in an ordinary stereoscope, the background

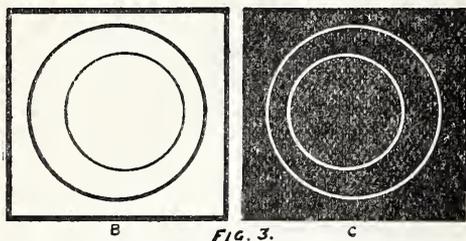

FIG. 3.

of the combined image presents a semi-transparent appearance, and looks very much like a piece of ground glass. It is difficult to say with any degree of certainty at what stage of the observation such a sensation is produced, and the manner in which the mind appreciates this intermediate tone must also remain a mystery.

We note, however, this semi-transparent impression cannot be retained by the observer for any considerable period; after a few moments' observation either white circles upon a black ground will be seen or the reverse. Such an alternate appearance of positive and negative images is due to the successive fatigue of the retina in each eye. If, for instance, still using the ordinary stereoscope, we close the left eye, the retina of the right eye will be stimulated with rays emanating from the picture, *c*. On suddenly opening the left eye again (which has been resting from light altogether, and thereby increasing its sensibility), we shall see, not, as might be expected, the semi-transparent image, but black circles upon a white ground. The same holds good, but in a reverse order, if we rest the right eye in the first instance, and afterwards use both.

The foregoing experiment is most successfully carried out by having both negative and positive images equally illuminated with reflected light, and the semi-transparent image is best seen if, after adjusting the focus, both eyes are closed for a few moments previous to the binocular observation.

THEODORE BROWN.

### ROYALTY AND THE CINEMATOGRAPH.

LAST week the Earl and Countess of Clanwilliam entertained a company of about four hundred at Abergeldie Castle, a cinematograph exhibition, given by Messrs. Walker & Co., Aberdeen, being followed by supper served in a spacious marquee erected in the grounds of the Castle. Her Majesty, who had warmly interested herself in the entertainment, had graciously indicated her desire that as many of the servants as could possibly be relieved from duty at Balmoral should accept the invitation of Lord and Lady Clanwilliam. Many of the materials for the lavish decoration of the marquee and of the hall in which the cinematograph display was given had been sent from Balmoral, and the servants of Lord Clanwilliam received the assistance of Mr. John Reid, the Queen's upholsterer, and his assistant, Mr. W. Macdougall; Mr. Troup, the head gardener at Balmoral, and Mr. Anderson, clerk of works at Balmoral. To Mr. Reid belonged the artistic arrangement of the draperies by which the coach-house—selected as the scene of the cinematograph exhibition—was transformed, for the nonce, into a spacious drawing-room. A feature of the decorations that attracted much admiration was due to the ingenuity of Mr. Anderson. Under the word "Welcome," in large letters, this gentleman had daintily traced out in vari-coloured leaves the monogram of Lord Clanwilliam, and the effect of the simple device was exceedingly pleasing. For the

decoration of the marquee pot plants, sent from Balmoral, were ranged along the tables, and many flowers were tastefully displayed by Mr. Troup and assistants.

Princess Henry of Battenberg, accompanied by her children, and Princess Victoria of Schleswig-Holstein were included among the guests of Lord and Lady Clanwilliam, but Princess Henry found it necessary to return to Balmoral immediately on the conclusion of the cinematograph exhibition. Prince and Princess Dolgorouki and party came from Braemar Castle; Sir Allan and Lady Mackenzie and party from Brackley; Admiral Sir Edmund Commerrell and party, including Colonel Caldwell, from Abergeldie Mains; Lord Glenesk and party from Glenmuick; Lady Biddulph and party from Birkhall; and Mr. Forbes, Queen's Commissioner, and Mrs. Forbes, from Craig-Gowan. The Royal and other distinguished guests occupied seats at the far end of the hall, from which, as the flooring had a considerable slope, they secured a perfectly unobstructed view of the cinematograms. The series of stirring war pictures, accompanied by a few explanatory words from Mr. William Walker, aroused much enthusiasm, and these were followed by local pictures, which appealed with peculiar force to the gathering at Abergeldie—such, for instance, as the presentation of colours to the 1st Battalion Gordon Highlanders by the Prince of Wales at Brackley, and the view of the Braemar Gathering at Balmoral Castle.

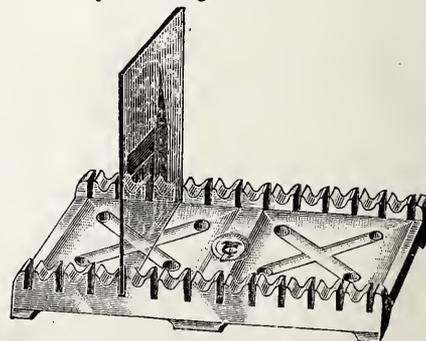

The Duke and Duchess of Fife also entertained their tenantry and retainers to a supper and cinematograph entertainment at Mar Lodge last week. The supper was served in the spacious mess-rooms at the stables, after which the company adjourned to the beautiful ball-room, where the cinematograph entertainment was held. The entertainment was graced by the presence of the Prince of Wales, the Duke and Duchess of Fife, Sir Allan and Lady Mackenzie, Miss Forbes, and Captain Fortescue. Over seventy of the tenantry present were in full Highland costume of Duff tartan. The men lined the pathway from the mansion to the ball-room, each bearing a lighted torch, which gave a grand effect in the inky darkness which prevailed. The distinguished party come down the path to the ball-room preceded by five pipers. Messrs. Walker & Co., Aberdeen, supplied the cinematograph entertainment, which was of the usual high-class order, as testified by the numerous rounds of applause. The performance, which finished shortly after ten o'clock, was highly appreciated by all those present, especially by the older members, many of whom had never seen an entertainment of the kind before.

In a letter to us, Messrs. Walker, whom we congratulate on the evident success of their endeavours to popularise high-class cinematograph entertainments amongst the "fine flower" of the North, remark of the first-mentioned display:—"We cannot remember any audience taking a more lively interest in the various items as they flashed along the screen than did the six hundred, which was calculated was the number present. The pictures we have marked are our own taking. Every item was followed by the keenest interest in the war, where we took them from Southampton to Pretoria."

### A PORCELAIN DRAINER.

Manufactured by Taylor, Tunnicliff & Co., Eastwood, Hanley, Staffordshire.

THIS neat and beautifully made porcelain drainer, will be found of the greatest service on the dark room bench or in the sink. It holds a dozen plates, as the illustration shows, and in case of need it may be utilised as a washer by standing it in a suitable vessel under a tap.

Two sizes are made, the one holding negatives up to half-plate, the other up to  $8\frac{1}{2} \times 6\frac{1}{2}$ , at prices of 9d. and 1s. respectively. We have used one of these drainers with the greatest satisfaction. The plates are securely held, and the drainer is so constructed that it has a firm base. It is obviously as useful for lantern slides as for negatives.

## EARLY HISTORY OF THE INCANDESCENT GAS MANTLE.

[Abstract of Cantor Lecture delivered before the Society of Arts.]

GREAT as has been the advance in incandescent lighting in England during the past eight years, we are still much behind Continental practice, and whereas in many towns in Germany from 80 to 90 per cent. of the gas burners are of the incandescent type, in London the percentage would hardly reach 20. This is largely due to the ability with which the English Welsbach Company have hedged around their great monopoly, and have kept up the price of burners and mantles; so that, although in Germany you can buy an incandescent burner and mantle for a mark, it costs the English consumer 4s., and the fact that a union jet nipple can be obtained for a penny compensates with a very large class of consumers for the fact that they obtain only one-tenth the amount of light from their gas that the larger outlay would render possible.

All burners owe their light-giving powers to incandescence, and the gas flame which emits light because of the glowing particles of carbon within the envelope of the flame has just as good a claim to the use of the term "incandescence" as the mantles which the term always now conjures up in our minds, the principle of which consists of consuming the coal gas in an atmospheric burner with a non-luminous flame, so as to obtain the maximum amount of heat. They merely replace the carbon particles by finely divided rods or threads of non-combustible oxides, with a greater power of emitting light when heated to a given temperature than the original carbon particles possessed.

Producing light by heating refractory bodies to incandescence is entirely an outcome of the nineteenth century, and dates from 1826, when Drummond first showed that a piece of dense lime could be raised to intense incandescence by the heat of the oxy-hydrogen blowpipe flame, the lime at later dates being replaced by buttons or discs of magnesia and also by zirconia. When using a comparatively large mass of material, as was done in these earlier experiments, the temperature needed to secure incandescence was above that which could be obtained by the use of air as the supporter of combustion, and it was a considerable step forward when it was realised that, by attenuating the body to be heated, and choosing a highly refractory material of low conductivity, an ordinary flame could be made to give the temperature which with the larger mass had required the use of such costly appliances as the oxy-hydrogen blowpipe.

Even before the middle of the nineteenth century the general principles upon which the incandescent mantle of to-day is based were known, for we find that Talbot, in an article on "The Nature of Light," published in the *Philosophical Magazine*, in 1835 (iii. 114), stated that "Paper soaked in a solution of chloride of calcium, and burnt in the flame of a spirit lamp, leaves a white network of ashes, which, when held in the feeblest alcohol flame, emits a brilliant light."

This experiment contains the germ of incandescent gas lighting, and embodies the principles adopted at the present day, namely, the saturation of a natural combustible fibre with the salt of a metal, burning off the organic matter, and leaving a skeleton of the oxide of the salt of the metal used, in so finely divided a condition that, when subjected to the heat of any non-luminous flame, it becomes incandescent.

Four years afterwards Cruickshank took out a patent for a cage or mantle of fine platinum threads woven together, and of such a shape and size as to thoroughly envelop the outer portion of the flame which causes its incandescence. Cruickshank, however, noticed that the luminosity of the wire was not so great as that emitted by heating the oxides of certain metals, and attempted to increase the light emissivity by coating the platinum wire with a paste of such oxides, but without much success, as it was found impossible to make the paste adhere to the surface of the wires for any length of time.

In 1848 Gillard first put the manufacture of water gas on a comparatively successful footing by introducing the principle of raising carbonaceous material to incandescence in a cupola furnace by an air blast and then injecting steam to form the water gas until the temperature fell, when the steam was cut off and the fuel again "blown" up to the necessary temperature to make water gas once more, a process which is the basis of all modern water-gas practice.

Water gas, consisting of nearly equal volumes of hydrogen and carbon monoxide, burns with a non-luminous flame, and, desiring to utilise it for lighting purposes, Gillard devised a cap or mantle of fine platinum wire, which was suspended in the flame and heated to incandescence. For some months this method of lighting was in use at Passey and Narbonne, but the trouble which has wrecked all attempts to utilise mantles of platinum soon showed itself, and the light emitted by the metal filaments rapidly grew less and less under the influence of the burning carbon monoxide, and finally the mantles

became so brittle that they fell to pieces. In 1849 Frankenstein introduced a lamp in which the flame from oil or spirit was caused to heat to incandescence a netted fabric, which was coated with a thin paste of magnesia and lime mixed with gum arabic. Owing, however, to the materials being merely pasted upon the fabric and not soaked into it, these mantles were very fragile and had no durability. Indeed, it is an impossibility to make a mantle exactly according to the instructions given by Frankenstein, who, as was afterwards explained by Werner, really mixed with his ingredients a little common salt, whereby some of the oxides were converted into soluble chlorides. These soaked into the fabric and so rendered the manufacture of the mantle possible.

So far the work done had been to establish the form of the mantle, and the principle of obtaining the material in a sufficiently fine state of division to become highly incandescent at the temperatures given by an ordinary flame, whilst Talbot had clearly indicated the way in which this might be done.

The only non-luminous flames available up to this period were those of the spirit-lamp and water-gas, but, at this epoch, Bunsen, the greatest of Heidelberg's great men, was planning and fitting those laboratories which have since then given so rich a harvest to the scientific world; and, while considering the methods of heating which should be adopted on the working benches, his attention was called by one of his assistants—now Sir Henry Roscoe—to the then novel contrivance of a non-luminous gas burner. Seeing at once the enormous convenience of such a source of heat, Bunsen brought his marvellous manipulative skill to bear upon the subject, and in a few weeks gave the world the "Bunsen burner," a burner which has done more for the gas industry than almost any discovery or invention connected with it, which has made coal-gas available for fuel purposes, and has enabled it, in conjunction with the incandescent mantle, to hold its own against the threatened rivalry of the electric light.

The next step of importance in the history of the incandescent mantle was the replacement of lime and magnesia, which up to this time had alone figured as constituents of the attempted mantles, by oxides of a more refractory character, having the property of emitting a more intense light at the available temperatures.

In 1852, Bergemann noticed that oxide of thorium when heated to incandescence emitted a beautiful light, while in 1863 Bahr, when heating nitrate of erbium upon a platinum wire, observed that it swelled up and left a residue of oxide, which emitted a brilliant greenish light. He communicated this result to Bunsen, and they made a joint investigation of the subject, the results of which were published in Liebig's *Annalen* for 1864, where they pointed out that the oxides of the yttrium group of metals, when heated to incandescence, emit a beautiful light of great intensity.

In 1878 Edison patented the idea of coating platinum wires with oxides of such metals as zirconium and cerium, the materials being applied as soluble salts, acetates, oxalates, or nitrates, which were then burnt off, giving a more coherent structure than was obtained by Cruickshank; the coated wires were afterwards heated by the passage of an electric current.

PROFESSOR VIVIAN B. LEWES.

## PRINTING SKIES IN ENLARGEMENTS.

Few negatives are produced in landscape work without the aid of special apparatus, such as a Parker sky shade, that behave well under enlarging. In some cases the skies are too thin, in others so dense as to permit of little or no light passing to the sensitive printing material, and as a result it follows that a blocking out or shielding operation has generally to be resorted to, when such negatives are being subjected to enlargement.

To many amateurs the operation of enlarging their small negatives affords much pleasure, especially when it can be performed with the aid of artificial light; but, judging from the class of work generally produced by novices by such means, it would appear that the printing in of suitable sky effects was an operation somewhat beyond the powers of the great majority of such workers, some failing to tackle the operation of blocking out the sky in the original negative, so as to yield a white surface for the printing of the sky negative; others, again, fail to comprehend the *modus operandi* of printing in cloud or sky effects from different negatives; whilst a further class of workers, possessed of more knowledge and courage, strive after strong effects, and in nine cases out of ten succeed in printing in a sky much too decided, or, as a painter would say, lay the paint on too thick.

The operation of enlarging direct from small-sized negatives may be divided into two distinct classes—viz. those performed with the aid of some enlarging apparatus and artificial light, and secondly when it is executed with the aid of daylight. As to the merits of the two

systems, there is not any doubt in the minds of practical workers as to which is the better means to employ, for in all cases where enlargements have to be produced the one chief factor to be studied is the proper lighting of the negative that is being enlarged, and there is no question about the fact that it is best performed by means of daylight, and some simple attachment to the window of an ordinary room, whereby it can be turned into what results practically as a large camera for the time being, or, as some term it, a dark room.

This lighting of the negative is of paramount importance, and cannot be neglected where high-class results are required. Fortunately, however, only the simplest means are required to make any suitable room, with, say, one window, specially adapted for enlarging purposes. No doubt amateur workers have a strong leaning to overtake this work by means of artificial light, simply by reason of the fact that it enables them to derive much gratification during their leisure time at nights; but daylight is to be preferred without doubt where circumstances permit of its employment.

Whichever method, however, be selected, the operations necessary to print in sky or cloud effects are practically the same in both cases, and consist, first of all, in so preparing the original negative, either by an elaborate amount of careful blocking out, as is often necessary in the case of some views where important details extend beyond the sky line, or by so shielding such parts during exposure of the foreground of the negative as will yield a proper surface for the sky negative. There is such a wide range of subjects in outdoor work that it is impossible to lay down any hard and fast line of instructions which would be applicable to all cases, beyond that of adopting some means whereby the sky portion of the sensitive material must be protected from reduction by means of any light other than that which passes through the negative it is intended to print on such portions.

This (so far as reserving the part required for the sky is concerned) is obtained by means of shielding or blocking out the sky in the original negative, and, of course, a similar treatment is required when dealing with the selected sky negative, for it must be specially prepared to suit the form of the picture projected on the screen, when the original negative has been carefully placed in situ and focussed.

In all operations of this kind it may be taken as a *sine qua non* that both the sky negative and the original negative that is being enlarged must be of the same size. This is necessary by reason of both having not only to fit into the same receptacle behind the lens, but, further, it enables anyone to nicely adjust the form of the sky portion to the shape or contour of the image projected from the original negative.

A simple example will make this clear to anyone undertaking this work for the first time. Take, for instance, an easy case, in which the background verging into the sky line is represented, as is often seen, by a range of mountains having well-defined outlines clear and sharply cut against the sky. To prepare the sky negative for such a subject, let the original negative be placed upon a retouching desk, and by means of a sheet of tissue, or other transparent paper, by means of a lead pencil draw a tracing of the outline of the hills. This is to act as template in producing an opaque mask to cover up the portions of the sky negative that would, if left unprotected, impress its image on the foreground and all over the picture. Having provided this white paper mask, it is laid over a piece of black or other opaque paper, and the latter is cut to exactly the same outline and dimensions in every way as the original negative. It is then carefully attached to the lower portion of the sky negative, and if it has been properly done, when the two negatives are superimposed it will be found that the sky negative exactly coincides with the outline of the mountains. This done, a worker is in a position to proceed to the exposure of both negatives. It is well, however, to impress upon novices in this work that a little care in making preliminary provisions against failure is never labour thrown away, for it must be borne in mind that we are dealing with an operation which in the case of failure, where very large sizes are concerned, means considerable loss in material.

In printing from two negatives it stands to reason that in the system adopted for enlarging there must not only be facilities for readily removing one negative, so as to substitute another in the exact position, but also, as will be necessary where to do this daylight is admitted into the room, there must be provision made to protect the sensitive material from any light that might enter when the negatives are being changed.

Many workers who limit their enlargements to what may be termed small sizes utilise their largest camera and dark slides; but the best system is undoubtedly that which places no limit to the extent of magnification, and at the same time permits an operator to have access

to his sensitive paper, and to be able to see what he is doing all the time.

The latter is a great power in the hands of a practical worker, for he can thereby shield off here and there any portion of either negative that he fancies requires special treatment. When the sensitive paper is contained in an enclosed slide, it is impossible to effect much, if, indeed, anything at all, in this respect.

The question may be asked how, then, can a sheet of paper on an easel be protected from light when changing a negative and daylight is admitted into the room? The answer is: Easily enough, by pinning over its surface a large cover, either of paper or other material. With the writer, who frequently makes enlargements up to six feet in length, such large sizes are regularly shielded when a certain negative is changed.

Success in such operations all lies in the word "preparations." If everything is carefully thought out beforehand, enlarging is by no means difficult; but the moment it is entered upon in a happy-go-lucky manner, that moment failure crops up of a certainty.

Some consideration must be bestowed upon the selection of the negative that is to do duty for producing the sky effect, and in very important cases it is well, after it has been prepared and masked off, as previously described, to pull off a print from both negatives by means of an ordinary printing frame their natural size. By this means it is easy to form an opinion as to the suitability of the sky negative, but an expert enlarger does not take long to get a sky negative to suit his purpose if he has not one beside him that has been photographed from Nature, he very soon will make one by means of a sheet of glass the same size as the negative and a slight modicum of oil-colour smeared upon the glass; and these artificial shields, or sky negatives (or call them what you like), produce most charming results and work softer than actual negatives taken direct from clouds in the sky.

In small sizes (say, up to 12 by inches), a clever worker can often, when the extent of the sky is not great, work in by hand charming effects of atmosphere and clouds by means of a suitable powder pigment, and thereby do away with double printing altogether. To many this may appear an extremely difficult matter to accomplish, but, in point of fact, it is extremely easy when the right materials are employed and are gone about with confidence. At first it is just ten to one a novice will overdo the work—that is, he will make the sky too heavy.

"The great secret of success lies in only rubbing in a soupçon of pigment, and softening off even that."

This can be effectively performed with a very soft piece of wash-leather, and the writer knows of nothing better than a little powdered starch, just discoloured with a trace of black crayon. Only the smallest trace of the latter should be incorporated with the starch, which must be very finely powdered, and applied quite dry, of course. And not only is this an efficient means of dealing with small-sized skies on bromide paper surfaces, but it is also a handy means of softening down a sky that has been printed in from another negative, and which requires some doctoring.

In using the powdered pigment, a novice must be careful to place upon his leather only the merest trace. With such he will be able to get plenty of effect and work the same nicely into any form or shape.

In printing in skies, where blocking out has been performed, and any prominent object, such as a church spire or monument, extends over the sky line, the same need not be specially shielded, for unless the sky negative be much overprinted, the same will not be visible on such dark portions of a picture.

A little thought and close application will soon enable anyone to make their own sky negatives, and to print the same with unerring precision into any form of picture.

## Correspondence.

THE AURORA LANTERN SLIDE CLUB.

To the EDITORS.

GENTLEMEN,—Would you kindly allow me, through your columns, to state that there are a few vacancies in the list of members of the Aurora Lantern Slide Club, of which I have been recently appointed Hon. Secretary.

I should be glad to hear from any lady or gentleman willing to join. The subscription is 3s. 6d. a year (October to October). Prizes are awarded by the votes of members to the two best sets of slides in each quarterly circulation.—I am, yours, &c.,

(Rev.) T. PERKINS.

Turnworth, Blandford.

## LANTERN MEMS.

To obtain a good instantaneous photograph in London during the afternoon of a November day requires not only a good apparatus but technical knowledge and special selection of position. To secure a good cinematograph record of a procession under such circumstances is a professional triumph. I am led to these conclusions after seeing on the screen the results of the animated photographs taken during the triumphant march of the City Imperial Volunteers through London, and contrasting them with results of hand camera snapshots in the Strand. Making allowance for the superior position chosen for the cinematograph camera, and a slightly earlier period of the day, the results must be acknowledged as wonderfully good.

\* \* \* \* \*

I PURPOSELY went to one of the Music Halls in order to see what the animated photographs were like, after my own hand camera films had been developed (with an absence of detail), and when I saw the results I had a good think. Why should my films be nearly clear celluloid? was it the fault of the particular lens, shutter, or rapidity of film, or was it the confined position of a narrow street with high houses shutting out the light? After comparing notes I put down the failure chiefly to unsuitable position, and after that to a too rapid shutter for such work; for a professional photographer I know was similarly situated to myself in another part of the Strand, by getting no results, while a member of his firm with a similar apparatus got some effective pictures of the crowd in Hyde Park and the procession near the Marble Arch.

\* \* \* \* \*

THOSE who had stand cameras and capped and uncapped, or who had very slow shutters, were most satisfied with their results, and one gentleman who had left his instantaneous shutter behind improvised a drop shutter, which enabled him to get some pleasing photographic records, which, in all probability, would not have fallen to his lot if his apparatus had been complete with the usual shutter. For late autumn and winter work large-aperture lenses, slow shutters, and rapid films or plates are necessities.

\* \* \* \* \*

THE hold the cinematograph pictures have on the general public is not to be wondered at, for the effects on the senses are almost magical. The scenes are so vivid, that the imagination has to be taxed to the slightest extent to conjure up the original surroundings, and to fill in the enthusiastic shouts of welcome and bravos which could only be

reproduced by a phonograph or something of the sort, and so, under the circumstances, have to be allowed for mentally. In cases of marching men the swing of the bodies and the manly bearing as they step out to the accompaniment of the band (supplied by the orchestra) is summed up in the one word real. Some day not far distant we shall, no doubt, have a combined instrument that not only reproduces movements previously photographed, but also gives out at the same time the sounds that accompanied the action.

\* \* \* \* \*

In a small way the records of native dancing and singing are being attempted by gentlemen connected with the Ethnological and Anthropological Societies, and by-and-by a cinematograph camera and phonograph will be synchronised so that the combinations work in perfect harmony, and motion and sound once recorded can be reproduced *ad infinitum*. These results can only be obtained at considerable outlay of time and money, and if an Edison does not come along, or the Mutoscope and Biograph Company do not succeed, the Royal Society should devote funds and form a committee with power to have constructed such an instrument. This would be invaluable in years to come if it was arranged that a national library of "records" be preserved for future generations.

\* \* \* \* \*

APROPOS of my remarks in last month's Memos on 'never take your friend's photograph if you value your friend's friendship,' a friend of mine whom I have known for thirty years, and who is a celebrated professional photographer, sends me the following: "I am in a position to confirm your remarks, for a friend of mine furnished a house at the sea side and invited me to join him and bring my camera. I did so and took various groups. On my return I sent prints which were technically good. In acknowledging the receipt of them he said, 'I received the photos, and after a good laugh we put them on the fire.'" How many cases occur where the prints meet with an early destruction, or are put away never to be got out again, without the same brusque statement of the fact being sent to the good-natured photographer, who had at considerable trouble to himself, and often at serious expense in time and money, desired to please his friends, and make a little return perhaps for some services rendered? The percentage of cases where portraits please the individual are small even when taken professionally, with all the advantages of studio for lighting and retouching of the negative before printing. So it is not to be wondered at that amateurs seldom succeed in giving pleasure by photographically reproducing a friend's face.

\* \* \* \* \*

MEN and women are all more or less conceited, and when they look in a mirror and see their reflections they are not as critical as the lens of the camera is, which brings out their peculiarities in the matter of wrinkles, spots, blemishes, abnormally large ears and nostrils, or drooping eyelids, and thus show what is missed when *looking* at the face of the individual, for the animation and expression in motion

draw the attention away from any structural defect of physiognomy. Beautiful women and handsome men, when photographed, have looked quite ordinary beings, and at times almost repulsive in features.

\* \* \* \* \*

ART, more art, is the cry, and the photographer who can best bring out the points of the face that will look nicest when printed is the same that will get most patronage. "Is that So-and-So? I should not have known her." It may be taken either way, as too good-looking or not good enough, according to the sincerity of the friendship.

G. R. BAKER.

## LIMELIGHT MATTERS.

### DISSOLVING IN SINGLE LANTERNS.

THE attempts to produce a pleasing dissolving effect by means of a single lantern only have, from the very earliest stage in limelight practice, been many, and numerous ingenious carriers have from time to time been designed to enable this popular method of projection being successfully performed.

The acme of perfection in dissolving one view or picture so that the same gradually vanishes from sight, and whereby another view is caused to take its place on the screen, has always been produced, as is well known, by the aid of two or more lanterns actuated by a simple method of mechanism, whereby the light from one of the lanterns is cut off at the same moment that the light is being turned on in the other, which is to reveal the new or coming picture on the screen, and there is little doubt that this ingenious, but, at the same time for years, mysterious method of showing pictures on the screen, was chiefly instrumental in bringing the optical lantern in great favour with the public, many of whom were not a little puzzled to understand how many of the striking effects were produced in what were termed dissolving views.

Triple lanterns, and more recently biunials, which, in the early years of limelight projections, were almost universally employed, were costly articles, and required experienced operators to manipulate satisfactorily; in fact, not only had the closest attention to be paid to the fittings of the lamp in all its parts, but much depended upon what is termed personal equation on the part of an operator, for it was almost essential to the success of an entertainment that the party manipulating the lantern should not only be conversant with the minutest detail of the same, but must at the same time have considerable practice with the various transparencies that were to be projected before the best results could be attained. In the early stages of limelight work, especially where high-class dissolving effects were to be produced, the preparation of the slides was a matter of the greatest import. This meant spending much time and attention in so packing the frames which, at that time, were used to carry the views, that these frames, when inserted in the lantern, would register in exactly the same position on the screen as the duplicate view from the other lamp was doing, for it was only by the finest adjustment that many of the striking effects could be superimposed on the vanishing view, and when these sets of particular views, specially prepared for dissolving effects, had been brought into a perfect condition for registration on the screen, there still remained the equally important factor of personal equation on the part of an operator in knowing exactly how to manipulate them.

The popularity of dissolving lanterns received a check when photographic positives were introduced. The ease with which actual photographic transparencies could be produced, as well as the great saving in expense over the hand-painted slides of early days, soon told against the employment of double and triple-deckers, and in their place single lanterns were made to do duty, until at the present day, with the cinematograph on one hand, and every Mission Hall and Society being furnished with their own lantern on the other, the truly good and royal triple, with its matchless dissolving effects, has become almost a thing unknown to the rising generation. In many respects this is to be regretted, for in the hands of competent operators a really high-class dissolving view entertainment is most enjoyable, and appeals to every class in a community both old and young, and there are those still to be found who doubtless, judging from the delight they experienced in their younger days, are bold enough to assert that such high-class entertainments as were given years ago were superior to much of the rubbish shown at the present day by means of the cinematograph. At all events, the desire for dissolving

views, or the merging of one view into another, on the screen is still shown in the attempts to produce such effects with single lanterns only.

It has been stated that what is termed personal equation played a most important part where double lanterns were employed, and it is not difficult to conceive, if such were necessary where perfect mechanism was employed, that this would be of equal import when dealing with apparatus less suitably adapted for the purpose that the dissolving taps specially designed for cutting off the gas from the lanterns.

To enumerate a tithe of the various carriers that have from time to time been designed to enable dissolving effects being produced with single lanterns only would be a difficult task. Speaking generally, such carriers have, with only one or two exceptions, never been universally adopted, doubtless by reason of the fact that their manipulation entails an amount of care and attention that is seldom forthcoming in any but the most ardent lanternists, or those who make a special point of studying the particular form of carrier they employ and the requirements necessary to work the same to its best advantage. That several extremely good forms of such accessories to single lantern projection are in daily use is well known, but the manner in which some of these carriers are manipulated by expert operators who have made a special study of their employment is perhaps not so widely known as it might be.

In one particular instance quite recently the writer of these lines was waited upon at the close of a limelight lecture, and was asked by an ardent lanternist if he would have any objections to give the information as to how the pictures had been projected on the screen during the evening, adding also, as a request, to be shown the particular form of carrier employed. On the latter being produced, much surprise was displayed by the stranger, who immediately ejaculated, "Oh, that is So-and-So's form of carrier; I used it once, but did not like it, and I never saw the same results produced with it as were seen to-night." Now, in this little episode we find the whole secret of success in the use of special forms of carriers.

Taken by themselves, such carriers go only a certain length in producing pleasing effects in single lantern projection, but, used in conjunction with other adjuncts, they yield vastly improved results, and this was just where the secret lay in the case mentioned. It was not the carrier in itself, but the manner in which it was employed in conjunction with the jet and lens that yielded the results so much admired. First of all, the entire set of slides was specially prepared in so far as the binding of the same were concerned, and, what was of equal importance, none of these transparencies were marked. The entire series were only bound at top and bottom. The reason for this will be seen later on. In lieu of masking each slide with the well-known paper mask, a metal mask was employed, which was a fixture in the rear of the carrier. By this means every slide shown was seen projected with one and the same shape of mask, a method first employed and recommended, if the writer mistakes not, by that clever lanternist, Mr. Chadwick, of Manchester. Not the least advantage accruing to this form of working lies in the certainty of always throwing each view on exactly the same spot on the screen, for this cannot fail where the lamp and carrier are rigidly fixed, the former on a rigid support, and the latter tightly wedged into its place in front of the condenser.

The form of carrier employed was that in which the coming slide is rapidly slid by means of a plunger in front of the view on the screen, and then, by redrawing the plunger, the previous slide is withdrawn, and at the same moment the same movement sets the front slide backwards into the exact plane the vanishing slide occupied in front of the condenser. The speed with which these changes can be performed is very great indeed when such is desired, but the best effects are probably produced by a slower manipulation of the plunger, and so working the rack and pinion of the objective as just throws the vanishing slide slightly out of focus at the moment the coming slide is being rapidly run across the face of the other, and when an operator becomes expert in the use of this form of carrier, and knows how to utilise the cut-off attachment of his single jet, so that he just lowers slightly his light at the same moment as he redraws the plunger of his carrier, perhaps the nearest possible approach to a dissolving effect in single lantern projection is the result.

A good form of mixing jet ought to possess a cut-off attachment. In the one employed on the occasion referred to the movement first cuts off the oxygen entirely, or partially, according to the distance the lever is moved. When the oxygen is entirely cut off the hydrogen is left still burning as a good by-pass admits of being done when dis-

solvers are employed in double lantern work, and then by again moving the lever of the cut-off movement the full volume of light is immediately passed through the slide.

Only a very little practice is required to enable an ardent lanternist to become quite an expert in working a single lantern as to yield pleasing effects in dissolving one view into another when such form of apparatus is used.

The slides having no opaque binding or edges such as would be the case were they bound up with paper masks in the ordinary form, permits of the front slide being rapidly placed in front of the other without being visible, for the coming slide is so far in front as to be out of focus, and where, just at the moment of changing, a slight turn of the screw of the objective throws the lens out of focus, the effect, especially when the cut-off movement of the tap on the jet is cleverly manipulated, is very good indeed, and often experienced lanternists in a hall are puzzled to learn how the thing is done.

Personal equation, no doubt, plays an important part in this method of working also, but it is only by carefully thinking out for oneself that much in connection with such lantern projection can be effected.

T. N. ARMSTRONG.

## BELGIUM—A RETROSPECT.

### I.

THE late Queen Mary is credited with having said that when she was dead the word Calais would be found written on her heart. I have never read whether any means were taken to verify her statement, probably not, and perhaps it was quite as well, for I cannot help thinking that if it should have been proved that our sincerest affections were always recorded on that important organ, and post-mortemisation (registered) became the custom, the results might occasionally be very startling, and perhaps make a very serious difference in the amount of regret or respect paid to the memory of those who had gone over to the great majority by those who had yet to shuffle off their mortal coil.

But, allowing for a moment the possibility of our affection being thus recorded, I have little doubt that in my own case (when examination time came) there would be a little snug corner inscribed Belgium.

The reason for this is not far to seek, and "thereby hangs a tale." When quite a youth I made the acquaintance of a gentleman who for many years had been going backwards and forwards to Antwerp and Brussels; and from him I heard of Flushing and the quaint dresses of the Zeelanders, of the winding Scheldt, of Antwerp's beautiful cathedral spire, which appeared now on the right, now on the left, as you neared the city; of the rows of old houses, restaurants and warehouses on the Quay, with its "nubby" little paving stones and fine trees; of the wonderful silvery-toned bells in the tall lace-like tower; of the beautiful interior of St. Jacques, of the Calvary and carved oak at St. Paul's; of the magnificent pulpit of St. Andrew's, of the winding streets with the little saints at the corners, and the little oil lamps swinging before them in the sunshine; of the marvellous processions through the principal thoroughfares on the 15th of August; of Brussels and its Guild houses, its old Town Hall; its Cathedral of St. Gudule, with its old stained glass and its elaborately carved pulpit, its gorgeous grand altar of white marble, its rows of graceful pillars decorated with sculptural saints ten feet high, and then the stories of its patron saint, St. Gudule. How that, on one occasion when she was at prayers, the devil blew out her candle—but it was instantly relighted by a superior power. How the good saint died in December, 712, and when she was buried in the following month the trees in the neighbourhood threw out their leaves and blossoms as her funeral procession passed, and some even followed her to the church doors, and planted themselves round the porch.

These glowing descriptions and interesting legends naturally created a great desire on my part to visit Belgium. The opportunity came in 1863, and on a fine Sunday morning in July I left the pool in the "Baron Osy" on my first Continental trip. About ten the next morning we passed Flushing, and entered the Scheldt, which at this point is about three miles wide. The entire country is flat, and nothing of interest occurred until the steamer neared the village of Lillo. Then a boat was pulled out from the shore, and in it was an officer evidently of some importance. The gangway ladder was lowered, and with much ceremony the illustrious stranger reached the deck. While I was wondering who this gaily-clad individual could be, he took off his white gloves, drew from his coat pocket a flag about the size of a pocket handkerchief, and tied it to one of the side ropes.

This important operation performed, he lighted a cigar and surveyed the ship with the satisfied air of a man who has bought one side of a street and is negotiating for the other. He nodded familiarly to the little Flemish pilot who took charge of our steamer at Flushing, and when he had finished his cigar he began to examine our luggage. Lo and behold, he was only the Douanier, and, considering the authority and uniform with which his Government had clothed him, he was a very courteous and obliging officer.

On went our boat up the serpentine Scheldt, and about one o'clock we neared the City. On past what used to be called the Big Dock, then the Little Dock, the Canal, the Steen Prison, and in a few minutes we were safely moored in front of the Old Hotel Danemarck.

How much all this has changed since then. The pilot still comes on board at Flushing, but the Customs officials do not make their appearance until the ship is berthed. Long before this, however, the great new North Docks—covering nearly 300 acres—will have been passed. These are now connected by a network of railways running down to the quays, where Atlantic liners and similar vessels may be found in large numbers; and, in place of the old houses and tree-shaded roadway, will be seen more than two miles of riverside galvanised iron sheds, intersected by railway trucks, hydraulic cranes, and every convenience for the rapidly increasing business of this important maritime city.

Any one anxious to see the great difference 35 years has made in Antwerp should first consult an immense oil painting by R. Mols to be found in the Museum, and then take the ferry-boat across the river to the Fete de Flandre (50 centimes return). He will then not only more easily realise the alteration, but can, if he has a camera, get some capital pictures at the little old village of St. Anne.

But if there is so much change on the river-side of Antwerp, what has there been in the city? The Place Verte is still the best known of its open spaces. The trees have, of course, grown considerably. The flower market is still held here, but the large bouquets (made on a sort of frame, and measuring perhaps two feet in diameter), which it used to be the regular thing to buy to take home, are things of the past—there is no demand for them. In the old days the steamers landed from the Quay Van Dyck, about five minutes walk from the flower market. Now, ninety-five per cent. of the tourists travel via Harwich, the boats go every week-day, and the Quay du Sud is nearly two miles from the flower market; besides, in the old days, passengers from Brussels drove through the city from the old station past the Place Verte. Now, the Brussels train brings its passengers to the side of the steamer. Many of the old buildings have been improved out of the Square. The statue of Peter Paul Rubens still occupies its centre, with the privilege of being snapshotted 20 times a day thrown in. There is still a band performance here two evenings a week, and the place is still illuminated with coloured lamps on special occasions; but, in place of the few instrumentalists and few lamps of years ago, I this year heard a band of 40 performers, and saw the Square illuminated by about 5000 Chinese lanterns.

The Marche aux Boulets is still the same, and the top of it is as narrow as ever. Then comes the well-known Place de Meir, at the top of which is a narrow neck leading into the Avenue de Keyser. This narrow part has often been a puzzle to many (it will not be so much longer, as it is being cleared away, and fine new buildings are being erected on either side of the widened area); but, in 1863, and for several years afterwards, the city terminated at this narrow neck. Here were the old fortifications and a drawbridge and moat; and the space on either side of what is now the Avenue de Keyser, and the boulevards, with their fine statues and beautiful trees, was practically fields. The fortifications are now nearly eight miles in length, and the removal of the ramparts to their present position has allowed the town to expand to six times its original size. It has been said that the fortifications look far more formidable than they really are. They are well worth seeing, but it sometimes saves trouble on such excursions if the camera is left at home.

Of course, the great glory of Antwerp is its cathedral. The restoration of its exterior has been going on, more or less, ever since I first saw it. Little shops at that time were built in all round it; these are being gradually cleared away. The north and south porches were in a very dilapidated condition, but during the last few years they have been practically rebuilt. The interior (with the exception of the enlargement of the organ gallery and the rebuilding of the organ) remains much the same as in 1863. It is considered the largest and most beautiful Gothic Church in the Netherlands. It is nearly

400 feet long, and I remember well, on the occasion of my first visit, being much impressed by its beautiful nave and side chapels. How many times I have seen it since I should not like to say, nor under how many different conditions. In its ordinary every-day aspect, with the pictures covered up, and its few straggling worshippers, from the good Catholic who goes faithfully through his rosary, to the poor woman who, with her heavily-laden basket of eggs, fish, or fruit, merely calls in on her way to market just to say a prayer or two, and, taking up her basket, walks away with a lightened step. With its parties of tourists, who, Baedeker in hand, walk about the place and talk as loudly as if they were in Trafalgar-square. Again, during its "close time," when the pictures are uncovered on payment of a franc each person, and the building becomes a part of a secular show. On a Good Friday, when it is profusely decorated with violet and white drapery and flags; when its large cross, swinging from the mighty roof, is covered with crape. On an Easter Sunday morning, with the sun shining through its coloured windows, its beautiful pictures surrounded by eager pilgrims to this Rubens' shrine; its banners, candles, and gorgeous dresses, and its spacious nave and side chapels filled with worshippers listening to the glorious strains of Haydn's Imperial or Mozart's (so-called) Number 12.

But possibly the most moving spectacle I ever witnessed within its walls was on August 9 this year, when a solemn service was held for the repose of the soul of the late King of Italy. Long banners and streamers of black cloth, relieved by silver stars hung loosely from the roof, or were looped up to the pillars by large rosettes. Pyramids of candles were on the high altar, a large black screen divided into four by a white cross, each section being ornamented by what used to be known as a pirate's flag, covering Rubens' beautiful "Ascension." The elaborately-carved stalls, decorated with black cloth, the lighted lamps covered with crape, the entire space between the nave and the altar occupied by burgomasters, diplomats, consuls, and the highest officials of the city and surrounding districts in all the most gorgeous uniforms and robes appertaining to their position; the full band, soloists, and chorus in the organ gallery rendering Mozart's "Requiem"; every available space almost packed with people assembled in memory of a good King who had been foully murdered; and in the midst of all this a mighty catafalque, with its purple, crimson, and gold drapery, rising some forty feet from the floor, and its base surrounded by about 200 large lighted candles. It was a scene of great solemnity and grandeur, and would have been more impressive still if we could only have forgotten that the coffin which crowned the pile, and which had been so solemnly blessed and incensed, was only an empty box.

I was just thinking how impossible it would be for photography to give anything like a faint idea of the scene, when my musings were interrupted by a young lady tourist, who pushed in front of me, stood on a chair, raised a hand camera, and snapshotted it. I have often wondered since whether the satisfied smile with which she changed the plate was present when she developed it.

When I first went to Belgium I was not on photography bent, the reason probably being that at that time practical photography and I were strangers; but I have made many and many a journey since accompanied by the camera. No, in 1863 I knew very little about it; and, judging by the results obtainable there at that time (more especially outdoor work), the Belgians were in the same condition. The swing back (which, notwithstanding its threatened extinction a few years since, is still, by many, considered an advantage) was at that time unknown, as the inebriated appearance of the tall buildings in confined situations testified. But I was naturally anxious to obtain pictures of some sort, and the only things available worth having were lithographs. Some of these were good of their kind, but the majority were very incorrect. Why this should have been I do not know. For instance, take the cathedral front of Antwerp, the width and height of this were well known, yet when, in later years, I compared the lithograph with a camera picture the proportions were woefully "out."

My first photographic experience was in 1866, when, flushed by the full fever of amateur photography (there was such a thing even then), I took across the Channel a complete wet-plate outfit with the idea of immortalising some of my friends. I am afraid that in all cases I did not quite succeed. Some pictures were satisfactory to the sitters; some were not—a state of things by no means unusual even at the present time. As to the immortalisation, well, I was looking recently at some prints from the negatives made on that journey, and, although

on the poor maligned albumenised paper, most of them are as good as ever.

It was not until the advent of gelatine, and I had then been looking upon photography from the bread and butter side for some time, that I began to take views in Belgium; and then, as opportunity offered, I did all the best-known parts of it—Antwerp, Brussels, Bruges, Ghent, Malines, Liege, Chaumontaine, Namur, Dinant, and dozens of other more or less well-known places. On some of my trips I was fortunate in having excellent companions. In 1883 I had one who was much interested in photography, and has since employed it very largely in hospital work. It was with this gentleman's assistance I obtained—without permission from the authorities—a negative of the colossal white marble bust of Rubens, which had recently been placed in the vestibule of the Old Museum (now the Academie). The officer in charge of the doorway was on one of the seats outside enjoying a cigar. There was no attendant in the vestibule, and the temptation was not to be resisted. My friend kept an eye on the gentleman smoking under the trees, and by the time he had finished his cigar I had packed up and was leaving my camera case in charge of the porter at the top of the stairs.

The year following (1884) there came to me in Antwerp a friend who was at that time engaged on one of the journals. I well remember going down to the Harwich boat to meet him, and, being afraid he had missed it, as all the passengers seemed to have come ashore. At last, however, I saw the top of a "stove-pipe" hat above the gunwale; my fears vanished, and in another minute my friend, whose entire luggage was contained in a large open-mouthed black bag, which I have often seen since, appeared at the gangway.

I have recalled the incidents of that journey many times since, more particularly when visiting the Musée Plantin. Many people pass through Antwerp, and know nothing of this museum, and yet it is most interesting. It presents a very fine example of the way in which some of the old Flemings lived and carried on their businesses under the same roof. Here Christopher Plantin set up his printing office in 1555, and for nearly 250 years it was carried on here by his descendants. The place remained practically closed for about 75 years, but fortunately its old furniture, tapestry, and paintings remain undisturbed, so that in 1875, when the Corporation of Antwerp purchased the house and contents, it obtained a unique reminiscence of the old city.

F. A. BRIDGE.

#### LECTURING WITHOUT AN OPERATOR AT THE LANTERN.

THE accompanying diagrams will serve to illustrate a system of lecturing without the assistance of an operator at the lantern. It is a well-known fact that with the usual limelight apparatus such assistance is absolutely indispensable; indeed, if he would do his work in every respect satisfactorily to the lecturer, the limelight operator is fully occupied in turning the lime, regulating the gas, adjusting the focus of the objective, and with the insertion of the slides at the desired moment. All these operations, however, are dispensed with by adopting the system which we propose here to describe. In the first place, the usual limelight is substituted with a 210 volt 50 candle-power focus incandescent electric lamp, simply connected to the main installation of the hall in which the lecture is being given. The advantage of using such a lamp is that an even light is secured which requires no attention whatever after it has once been switched on. For instance, in our first illustration, fig. 1B, is supposed to be one of the lamps of the hall, or, rather the shade of one of the lamps, for in reality the lamp has been removed and replaced with a male connection at the end of the flexible wire, F, at the other end of which is connected the 50 candle-power lamp in the lantern at P. We next come to the matter of inserting the slides, but, before dealing with the particular way in which these slides are prepared, we should say that the staging is somewhat altered from the usual arrangement. In short, between the two lenses forming the condenser, K and L (fig. 2), a mirror, M, is placed. This mirror is hinged at the bottom as shown, and is provided with a side wing, X, by which it is retained at any desired angle. The light emanating from the lamp is thus reflected from a horizontal to a perpendicular direction, and the position of the slide to be projected upon the screen is also changed from the vertical to the horizontal position. The object of this change in the position of the slide is to increase the distance between the lamp and the film, which really bears the image to be projected. The objective

lens is screwed into the top of the compartment in which the parts just described are contained. The objective is furnished with a mirror, c—needless to say, this mirror consists of plate glass silvered on the front surface, so that the reflected images are perfectly sharp. The novelty of the whole system lies in the construction of the mechanism by which the slides are brought successively into place for the purpose of exhibition. The illustrations the lecturer desires to show are printed by contact on a continuous roll of film similar to that used in the camera, but, of course, prepared according to the requirements of contact printing. The diagrams or photographs required for the lecture having been prepared, the two ends are joined together. We will now describe the mechanism as shown in fig. 3, which is a view of the apparatus with the front removed. There are four rollers, q q q q, acting as a guide to keep the film in the proper

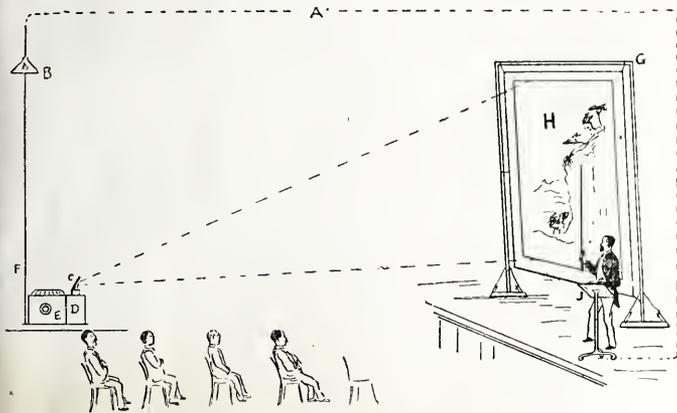

FIG. 1.

position over the horizontal condenser lens, L, and another similar roller at w. The roller, v, attached to the spring, v, is caused to press lightly against the film as the latter passes up between it and the side of the box. It should be mentioned here that the side of the box, and also all the rollers, are covered with velvet. At t there is a roller attached to a spring, s, which causes it to press against a larger roller, r, and it is to this latter roller that the motive power is attached. On the opposite side, or rather at the opposite end of this roller, a spring is attached in such a manner as to cause it to revolve when freed from a catch. Thus, one half revolution of the roller, r, causes the film to pass on exactly the length of one slide, from left to right, and as it passes between the two rollers, r and t, it is at the same time kept taut by being pressed by the roller, v, against the side of the box. The work generally done by an operator at the

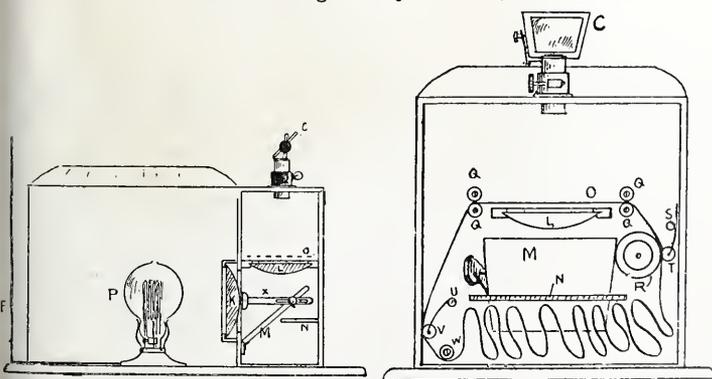

FIG. 2.

FIG. 3.

lantern is thus accomplished by the lecturer himself in the following manner:—Having wound the spring of the roller, r, and set the electrical catch, which is connected by wires to the lecturer's reading desk, J (fig. 1), and, having switched on the 50 candle-power lamp, the lecturer is ready to commence his novel performance. The first image on the film may consist of a title or a tinted curtain, which will appear to be drawn aside when operations begin. The change of pictures is effected at the desired moment by the lecturer pressing a button at his reading-desk when the circuit is completed, a current sent through the wires releasing the catch of the roller, r, and allowing it to turn half round, drawing with it the continuous film just far enough to bring the succeeding picture over the horizontal lens at L. The pic-

tures upon the screen are thus passed in panoramic order before the audience, without any confusion, and exactly at the right moment. It is obvious that by such a system it is quite impossible for the slides to get out of order, whilst, dispensing with an operator, the lecturer is saving much expense, especially if he be a traveller. It should have been mentioned that the rollers of the apparatus turn on spindles attached to the front side of the framework, so that the opposite side of the framework may be removed without interfering with the mechanism of the film-carrier, also that the object of the mirror, c, is to reflect the light rising from the condenser, L, in a horizontal direction towards the screen.

THEODORE BROWN.

NOTES ON LANTERN SLIDE MAKING.

At the Richmond Camera Club, on October 29, Mr. E. G. Richardson gave a demonstration on "Lantern Slides by Reduction." The apparatus required was practically two cameras, one of size sufficient to hold the largest negative from which a reduction was to be made; the other, a quarter-plate camera to hold the lens and lantern plate. The two cameras are fixed on a baseboard provided with means for focussing the negative the required size on the ground glass of the quarter-plate camera, which should be provided with a mask of the size of the desired image on the lantern plate. This done, a lantern plate is put in the dark slide of the quarter-plate camera, to which pieces of cardboard are adjusted so as to keep the plate in the middle of the opening. Some burning magnesium ribbon is then waved over the surface of the negative, in front of which a piece of ground glass is placed in order to distribute the light evenly, and the lantern plate is developed in the usual way. In order to ensure success, one or two points require attention: 1st, the ground glass must not be too near the negative, the distance being from three-quarters to one inch at least; and, 2nd, care must be taken to wave the burning ribbon well over the margins of the negative to ensure their being properly illuminated. Mr. Richardson made two slides on rapid Paget lantern plates from quarter-plate negatives. The quantity of wire used in each case was five inches, and the stop of the lens (a 5½ inch Wray rectangular) f-16. One of the slides would have been better if f 22 had been used, as the negative was thin.—A vote of thanks to Mr. Richardson terminated the proceedings.

At the meeting on November 5, Mr. Henry Little discoursed on "A Tour in Italy, Algeria," &c., illustrated by a number of very fine slides by himself. In order to complete his collection, he also showed some slides bought in Italy, and illustrating scenes which he had been unable to photograph himself. Ladies were invited to be present, and a large number availed themselves of the invitation. Mr Little was accorded a hearty vote of thanks at the conclusion of his lecture.

On November 12, Mr. Emery gave a most instructive paper on "Hints on Hand-camera Work." At the close a general wish that the paper should be printed for circulation among the members was expressed, and a cordial vote of thanks to Mr. Emery was passed with applause.

On November 19 a lecture by the Rev. F. C. Lambert on "Exposure and Development" was read. Mr. Lambert went very fully into the subject, and his remarks were illustrated by lantern slides designed to show the different results of over and under-exposure and over and under-development.

On November 26 Mr. J. D. Gibson gave a demonstration on making lantern slides by contact. He pointed out that any one wishing to pursue this class of work should see that his negatives were so taken as to enclose the desired view within the limits of a lantern plate. He proposed to use Alpha plates, with which a good range of colours could easily be obtained, and which were sufficiently slow to admit of the various operations being conducted in a room lit in the ordinary way. Mr. Gibson passed round some slides on Alpha plates which fully bore out his statements, and showed the result to be obtained by toning the developed image in the combined fixing and toning bath recommended by the Ilford Company, who make the plates. He then exposed two plates, giving each a different exposure, so as to demonstrate the different results obtainable by development alone, and two very successful slides were produced. He also made a slide from a negative provided by one of the members, and, although of a very different character from his own negative, a good slide was produced. He then demonstrated the ease with which an over-dense slide or over-

dense portions of it could be reduced by means of the ferricyanide reducer, and he finished his demonstration by masking a slide with binding strips and binding it very expeditiously. Mr. Gibson was heartily thanked for his interesting demonstration.

#### LANTERN LECTURE ON CORSICA.

At the weekly meeting of the Kingston and District Photographic Society on Monday, November 26, Dr. Munyard, one of the Vice-Presidents, delivered an interesting lecture on "Corsica" before a very large attendance. The doctor having been briefly introduced by the President (Rev. G. I. Swinnerton), commenced his lecture, which consisted mainly of running comments on some 150 slides of photographs taken by him last winter during his holiday in the picturesque French island. The slides were of great technical excellence and artistic merit, and were of such a diversified description that, although the lecture lasted over two hours, the interest of the audience was always maintained. Though not of large area—being some 150 miles at its greatest length—Corsica, with its wild and romantic scenery, offers opportunities for the most charming landscapes, and Dr. Munyard had used his camera to good effect in choice tit-bits, as well as in the scenes of awe-inspiring grandeur. Intermixed with these scenic pictures were typical portraits of the quaintly and plainly-clad peasantry; and views of some of the more imposing buildings of the island. The statuary of Napoleon I. called to mind that the greatest of all Frenchmen was first a Corsican and secondly a Frenchman, having been born at Ajaccio, a town of which the lecturer had much to say and many views to show. Another historical matter touched on was the occupation of the island by the British a century ago, after Paoli had vainly struggled for its independence. The island was the reputed home of the brigand, to whom the rugged nature of the country would afford shelter. Some of the hills appeared at first sight to have been shaped by human hands for military purposes, this somewhat curious formation being common. Corsica was known in that part of Europe as the Emerald Isle, and though it contrasted in scenery to the island nearer home known by that name, it was not unlike it in racial characteristics. The two centres of population, Ajaccio and Basia, might be described respectively as a pleasure resort and a commercial town. The houses in these places, as also in the villages, reached as high as eight storeys, and it was totally impossible for a stranger to gain any idea of the population, for in some instances one building would house between one and two hundred people. The lecturer showed many specimens of plant life, which was very profuse, and he stated that some plants which grew in England merely 18 inches high attained three and four times that height in Corsica. Dr. Munyard also described various trips he took into the interior of the island, displaying views taken by the way, a number of them being snapped whilst the train was in motion. A feature of the slides was a quantity of panoramic views, which gave excellent ideas of various places.

#### ANIMATED PHOTOGRAPHS: A PROTEST.

This, we are told, is the age of process, writes a correspondent of "The Outlook." Civilisation, urged onwards by science, is fast galloping to perfection, to the millennium of the poets. Electricity, the latest good fairy, enlightens the way and smooths the path, and the dawn of the twentieth century gives promise of yet more bewildering progress. Among other of the glorious inventions of the closing century that have been rendered possible by electricity is the animated photograph, sometimes termed the biograph or the cinematograph—barbarous word.

In the early days of this unquestionably clever invention we were regaled with the "suggestive" style of picture, unanimously popular with the crowd, and therefore highly profitable to the proprietors. Decency was in perilous danger of losing itself, and the discreet curtain was drawn on the photograph sufficiently late to allow the imagination to wander excitedly over the chasm-edge of pruriency. This variety of the animated photograph still lingers in the penny peep-shows which have sprung up like mushrooms over all the country. But in the most ambitious shows of the music-halls and variety theatres, it gave place to what may be termed the "brutal" class. We had, and still have, a life-like representation of the prize-fight, without the

blood and sawdust and foul language, it is true, but one can almost hear the thud of the sledge-hammer fists, the gasps of the fighters and the groans of the vanquished.

A few months back the country was shocked by the descriptions of the bull-fights which had become popular in Northern France. In England we had a "Cinematograph Bull-fight!" O nation of hypocrites! At a certain theatre in the heart of intellectual London I saw a most complete and vivid series of photographs of a Spanish bull-fight, which could have been hardly less revolting than the actual affair. Of the perceptive faculties excited by attendance at a bull-fight, the chief, the visual sense, is gratified in almost as complete a manner by the animated photograph, and but a small amount of imagination is necessary to enable one to fancy himself present at the real thing. I shall never forget the sickening charge of an old blinded horse by the infuriated bull. Its dying shriek will live in my imagination, as it rolled over with the blood pouring from its side, half staggered to its feet and dropped dead. Yet these pictures were vigorously applauded and apparently pleased the taste of the enlightened British public.

The latest stage is the "sacrilegious" picture. In a certain part of the Continent the peasants amuse themselves and attract sensation-seeking tourists by mumming the life and death of Christ. We have our own affairs to attend to and amend, and if we object to their peculiar ideas of play-acting and religion we can stop away. But the animated photograph has brought the thing into this country, and on the pier at a sea-coast town, a week or two back, one could see every Sunday evening the "Passion Play of Ober-Ammergau" faithfully represented in the biograph. Here in the centre of Christendom, in the diocese of Canterbury, the crowd is mildly amused by the dying agony of a stage Christ on the cross, and rushes off the pier for the "last drink" after gaping admiration at the naturalness of "the Last Supper."

Such is the record of the animated photograph; indecency, brutality, sacrilege—steps in the ladder of progress, ironic sign-posts on the march of civilisation. "Realism" is the cant word of the day. The great British public likes its pleasures hot and strong and real. But this pandering to the gross and brutal appetite of the crowd—is it not going too far? Is it not time to put the foot down, or are we content ourselves with the "laissez-faire" policy, so dear to the heart of the governing powers of England, and stand idly by to wait till it hang itself with the long rope?

#### CAPT. LASCELLES DAVIDSON'S IMPROVEMENTS IN CINEMATOGRAPHS FOR TAKING AND PROJECTING PHOTOGRAPHS IN COLOURS.

[Patent No. 23,863 of 1899.]

SUCCESSIVE exposures are taken behind different coloured screens, three in number according to the usual method, so that in the complete series of negatives every third exposure is taken behind the same colour screen. To view the resulting pictures, positives are made which may be dyed to the correct colours complementary to the colour screens, or it may be exposed behind colour screens similar to those employed in taking the photographs, these colour screens moving successively into position giving the effect of a moving coloured picture.

The colour screens or light filters consist of three stained glasses or sheets of celluloid or other transparent material coloured in the required manner. These screens may revolve at the back of the lens or just in front of the sensitive film or if three diaphragms are employed of different sizes they may be fixed in the said diaphragms which revolve or slide at each exposure. In any case the screens are made to revolve or slide either at the back or front or between the combinations of the lens, so that when the apparatus is put into motion to photograph an object the screens successively of red, blue-violet and green or yellow colours revolve or slide into position in time with the change of film and release of the exposing shutter. To give different exposures to the sensitive film according to the colour employed the colour screen may move in a variable manner as hereinafter described or the diaphragms of the three different apertures may be caused to drop into position after or before each exposure to limit the action of light in any required proportion.

By the arrangement employed, the film, colour screens and the different sized stops (if employed) as well as the shutter work automatically and in exact time with each other.

The accompanying drawings show a method of applying the invention in connection with a revolving shutter apparatus such as is at present employed, the colour screens rotating immediately behind the shutter.

"Fig. 1 is an elevation of part of the interior of a cinematograph apparatus showing my colour screen fitted to the revolving shutter at present employed ;

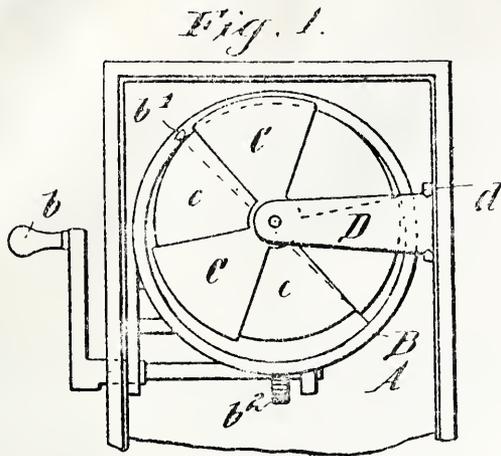

Fig. 2 is a similar view with the shutters and screens removed to show the gearing ;

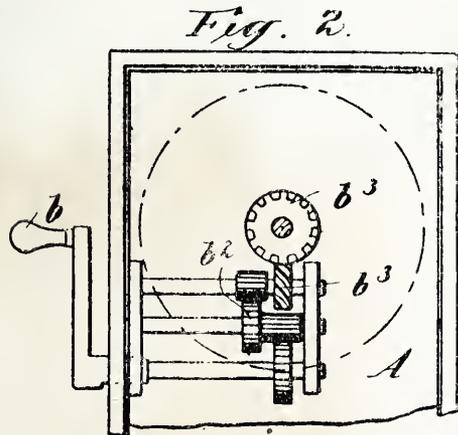

Fig. 3 is an elevation with the case in section at right angles to figs. 1 and 2 ; and

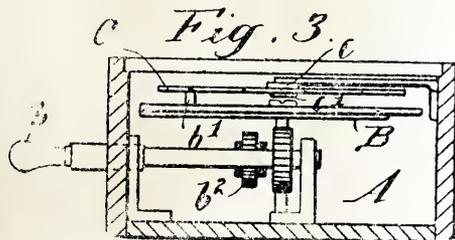

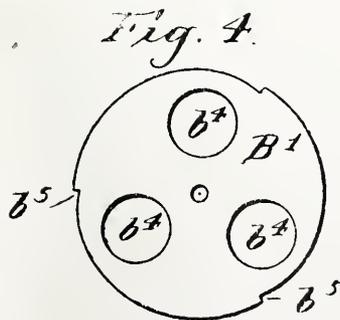

Fig. 4 shows the different form of screen more especially suitable for reproducing the photographs. As the other parts of the apparatus are of any well-known construction, I have shown only those parts which are necessary to an understanding of my invention.

A is the case of the apparatus which is placed in front of the

camera or reproducing apparatus, and this case carries behind the lens aperture the revolving shutter B which is turned at high speed by suitable mechanism. In the apparatus shown the handle b serves to revolve the shutter, through the toothed gearing b2 and the worm wheels b3 one of which is upon the spindle of the revolving shutter. These parts form no feature of my invention, and the shutter B may be rotated in any convenient manner.

In front of the revolving shutter is placed in three colour screen C having the coloured transparent plates c of the three colours required fitted between the arms forming the body of the screen. As already mentioned the body of the screen may be formed of vulcanite or other light, opaque material.

This screen is carried by the detachable bracket D the end of which is bent down and fixed by means of the plate d to the side of the case A. The bracket is fixed so that the pivot of the screen is eccentric to the revolving shutter and to adjust the tightness of the screen preventing it turning too freely the small nut c4 is employed which can tighten the screen to any required extent.

On the revolving shutter B I fix a pin b1 which projects from its surface to a suitable height and is adapted to engage the corners of the three arms forming my screen and to carry the screen round with the shutter the required distance for each revolution. As the screen is eccentric to the shutter the pin engages at each revolution with one arm, turns the screen over about one-third of a circle before it disengages and at the next revolution operates on the succeeding arm. Once in each revolution a fresh colour is thus brought behind the exposing aperture the next exposure being through the succeeding colour and so on each colour repeating at every third exposure.

By placing the pin b1 on the exposing shutter in a certain position the revolving colour screens can be moved out of exposing position to bring the opaque part behind the lens aperture after a certain short interval of time which could be made to vary according to the colours by making the parts of the three colour screen of different proportions. Or three pins such as b1 may be employed at different heights to engage successively the arms of the three colour screen, the position of the pins determining the exposure intervals of the respective colours. Instead of these methods being employed equal exposures may be given and the blue and green screens may be made to equal the red screen in actinic intensity by adding an extra screen of yellow or smoked glass, or any other means of equalising the colours may be employed.

The screen B1 shown in fig. 4 acts in exactly the same manner as that described, but I prefer it for use in reproducing photographs. It consists simply of a disc of vulcanite or like material having the apertures b1 filled in with coloured transparent material of different shades to the colours employed in the photographic screen. The edge of the disc is notched at b3 and the pin on the revolving shutter engages in these notches, turning the screen as already described."

### THE NEW PRESIDENT OF THE ROYAL SOCIETY.

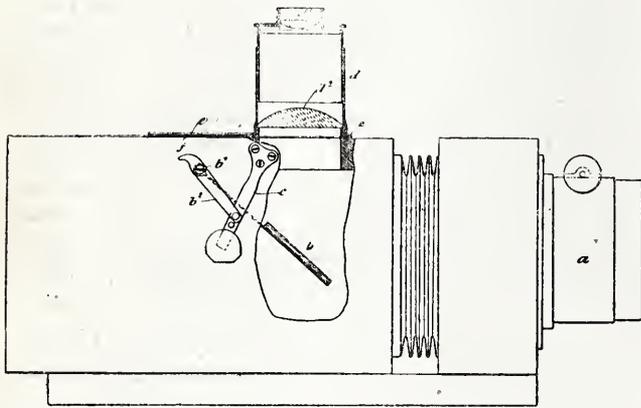

SIR William Huggins may be regarded as the father of astrophysics in this country, writes a daily contemporary. The year 1859 was epoch-making for science. Within twelve months Darwin announced the law of Natural Selection, and Kirchhoff invented the spectroscope. Three years earlier Dr. Huggins had erected a house at Tulse Hill, with an observatory attached. Kirchhoff showed that several terrestrial elements were to be found in the sun; Huggins determined to direct the spectroscope to the stars to discover, if possible, whether they also were formed of the same materials. The task seemed almost hopeless, for the light of a first magnitude star is forty thousand million times less than sunlight. Nevertheless, he and Dr. Miller, of King's College, set to work, devised new instruments and methods, and ere long proved that in the star Aldebaran were to be found sodium, magnesium, hydrogen, calcium, iron, bismuth, antimony, mercury—similar constituents to those that go to make the earth. In other words, the universe was one in materials. In 1865 Huggins examined the bright comet of that year spectroscopically and found it to be radiant with the luminous vapour of carbon. Nothing was ever done in that chamber of marvels, the theatre of the Royal Institution, more wonderful than when Dr. Odling illuminated it with gas brought to this world by a celestial meteorite. Dr. Huggins's discovery went to confirm Dr. Odling's theory that carbon, at least, was one of the constituents of comets. The most remarkable of his achievements was to make the spectroscope the measure of a star's motion towards or away from the earth. This was accomplished by observing how much the lines of the spectrum were shifted according as the star receded or came nearer. By this means the proper motions of stellar objects can be measured with considerable accuracy, and at some distant date astronomers may be able to form a plan of the visible heavens, as they can now of the solar system. As in Lord Lister's case, a supreme moment came in Sir William Huggins's career. It was on August 29, 1864, when he first tried the spectroscope on a

nebula—the one in the constellation Draco. He has himself described the feeling of suspense mingled with awe with which he put his eye to the spectroscope as if peering into a secret place of creation. "I looked into it. The spectrum was not what I expected. There was a single bright line only. But the riddle of the nebula was solved. The answer which the light gave was this: 'Not an aggregation of stars, but luminous gas.'" In other words, the astronomer at Tulse Hill, out of the murky atmosphere of London, had been the first of mortals to see and know that he had seen a sun in the making. The idea has been developed by Secchi, Vogel, and others; stars can be classified as young, mature, old, and declining; and there is scarcely more doubt about celestial than of terrestrial evolution. The metropolis is honoured by the rare fact that both the outgoing and succeeding President are Londoners. Sir W. Huggins is 76 years of age, and since his marriage, in 1875, has been ably assisted in his researches by Lady Huggins.

AN IMPROVED EYEPIECE FOR FOCUSING.

[Dallmeyer and Aldis's Patent, No. 12,759 of 1900.]

An eyepiece carrying its own screen is employed for focussing. For

this purpose the front face of the front lens of the eyepiece is "ground" or "greyed," so forming the screen.

The eyepiece is removable preferably fitting into guides on the top of the camera, the image being reflected into it by an inclined mirror inside the camera.

The drawing is a side elevation partly in section of a camera constructed according to this invention.

*a* is the lens, *b* the mirror carried by the shaft *b*<sup>1</sup> to which is fixed the handle *b*<sup>2</sup> on the outside of the camera. *c* is a spring for retaining the handle *b*<sup>2</sup> and mirror *b* in position. *d* is the eyepiece consisting of two plano-convex lenses *d*<sup>1</sup> *d*<sup>2</sup> the plane surface of the lower lens *d*<sup>2</sup> being ground or greyed. The eyepiece *d* slides in guides *e* in which also works a slide *f* to cover the opening when the eyepiece is removed.

The lens *d*<sup>2</sup> is capable of being adjusted in a vertical direction with relation to the mirror *b* and *d*<sup>1</sup> is capable of being adjusted with relation to the greyed surface of *d*<sup>2</sup>.

IMPROVEMENTS IN DEVELOPING DISHES.

[Levi's Patent No. 17,852 of 1899.]

"THE developing dish is provided with a special cover of adiactinic material, either transparent or otherwise (to non-actinic light), as thin metal, opaque celluloid, ruby glass, or any another appropriate material. A peculiarity of the cover is that two or three of its edges are "turned over" into the form of inwardly directed grooves, while the third or fourth edge of the flat rectangular cover is left uncurled. In the direction of the plane edge, the cover is made somewhat broader than corresponds with the superficies of the developing dish it is intended to protect, and as the curled or retroverted edges of the cover correspond with the shape of the projecting lips of the developing dish, it is evident that after immersing the sensitive plate in the developing, toning, fixing or other bath, this protection cover may be slided on, and thus sufficiently securely fixed, and when necessary removed again with the utmost facility. Celluloid, and other developing, toning, fixing and the like dishes are now commonly made with such expanded lips as are appropriate to the use of my invention, but, alternatively the dish may be specially made with an inner groove in the uppermost portion of either two or three sides, whilst the fourth or third

a... fourth side is made somewhat shallower to admit of the introduction of my sliding cover, which under these circumstances would simply consist of a rectangular flat plate, the edges not being turned over. Figs. 1 and 2 are sections at right angles to one another of a de-

Fig. 1.

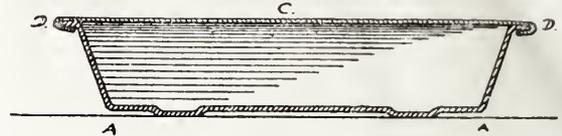

Fig. 2.

veloping dish with the cover applied. In both drawings *C* is the sliding cover, shown in transverse sections, *D D*, in fig. 1, and in longitudinal section at *E E* (fig. 2), *A A* (fig. 1) being a transverse, and *B B* (fig. 2) a longitudinal section of the developing dish. The lateral edges or lips of the developing dish, embraced by the downwardly inward portions of the cover will be seen at *D D* (fig. 1), while the straight of flat ends of the cover, permitting it to be slidden on to the edges of this developing dish from either end thereof, will be seen at *E E* (fig. 2). The direction *E E* is, of course, that in which this protection cover is to be slidden into its position on the dish, shown."

"IMPROVEMENTS" IN PROJECTING PICTURES IN NATURAL COLOURS.

[Krayn's Patent No. 10,000 of 1900.]

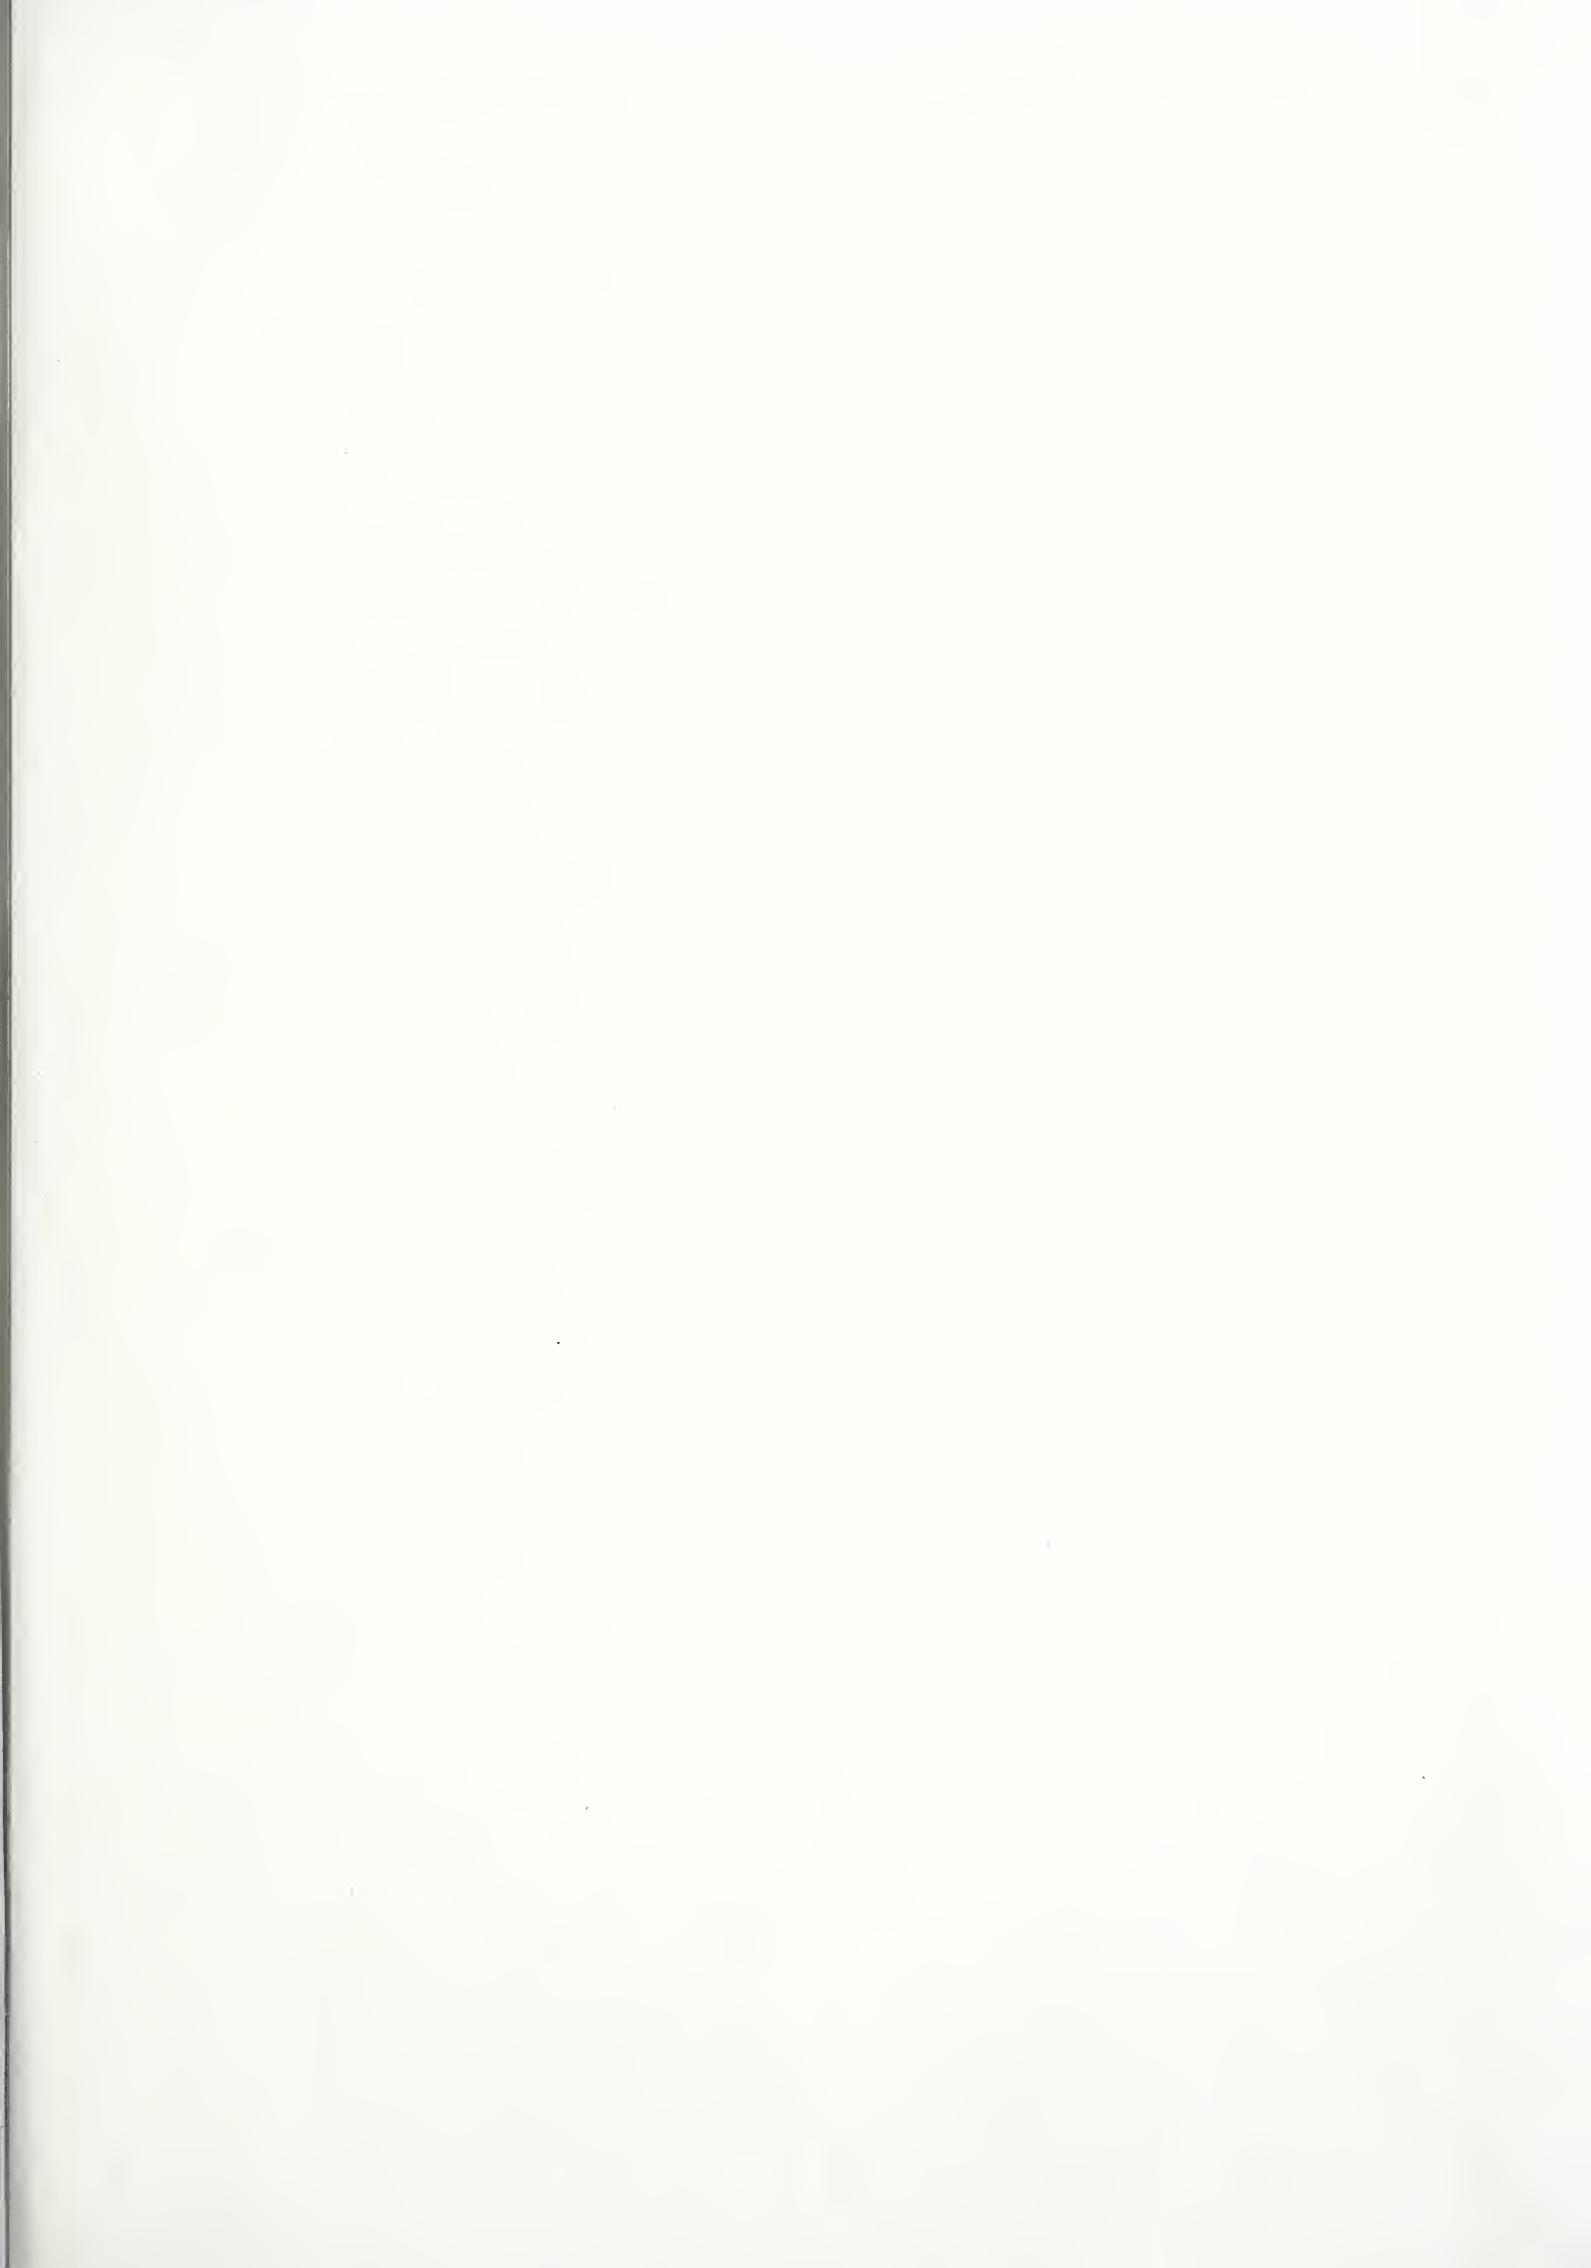

THREE exactly similar photographs are taken through red, green, and blue screens respectively. A diapositive of each of the pictures is then produced, and these three diapositives, with their respective coloured screens, are caused to pass successively in front of an illuminated opening, each picture being momentarily arrested in front of the opening, as in a cinematograph. This may be accomplished by mounting the diapositives upon a disc or wheel which has intermittent angular motion imparted to it by means of gearing similar to that employed with a Geneva stop. The disc may carry three diapositives only, or it may carry six or nine or other multiple. Instead of being mounted upon a wheel the diapositives may be carried by a ribbon which may be similarly intermittently moved. The rapid successive presentation of the three pictures with their coloured screens causes them to appear to be projected or viewed in their natural colours, according to the same law as governs the action of the cinematograph and similar apparatus.

SOFT TRANSPARENCIES FROM HARD NEGATIVES.

[Received too late for the ALMANAC.]

HAVING failed to make lantern slides from several negatives, with strong contrasts, full of detail, but very dense from over-development, the following plan, although entailing a little trouble, was found efficacious. In case of failure, the original negatives are still available, being untouched in any way, not, as in the case of reduction perhaps, irreparably ruined. Place the negative and an ordinary plate film to film in a printing frame, making sure both are hard against one side and end of the frame. Expose as usual in making a transparency, but only carry development far enough to yield a thin transparency. Fix and wash; when dry place the transparency in contact with the negative, that is film to film, and they will be found to coincide, and be in perfect register. When in that position, bind them on one side or end with a lantern-binding strip, although this is not absolutely necessary. Now make the lantern slide or transparency if the negatives is to be reproduced in the camera. Expose first for the dense parts, with the negative and transparency together, cap the lens, remove and fold down the transparency from the negative, and then expose for the thin parts. As an example an exposure of one minute was given for the high lights and two seconds for the shadows.
