Sir F. Bramwell's letter to the *Times*, last March, was followed by other objections and suggestions. Most of the letters were written by people whose knowledge of the subject was evidently most limited. One objection—it is an old one, but it was pressed home—is that the whole metric system collapses because it has since been discovered that the measurement of the quadrant was inaccurate, and consequently the metre is not the 10,000,000th part of the meridian after all. Perhaps it is, more probably it is not. It does not matter in the least. The length of the metre is established once for all, whatever the length of the meridian may be. Look at the standard chosen for the British weights—an old brass weight, which had been in the office of the Clerk of the House of Commons for 70 years. What a standard! If you clean it, it loses weight; if you do not, it gains weight, especially in such an atmosphere as that of London. I think I hear some one say, "Oh, but there are now a platinum pound and a platinum yard, and those are the standards." Very well, and we on our side have a platinum kilogramme and a platinum metre, with an exact copy in every capital in Europe. Those are our standards, quadrant or no quadrant.

Sir F. Bramwell, in his letter to the *Times* last year, contended that the kilogramme is inconvenient, as being too large a unit. He said that one frequently sees, in Paris and elsewhere, the price of certain articles marked up as so much per half kilogramme. This is perfectly true, and the remark applies chiefly to chocolate and confectionery. Tobacco here is bought by the half pound or less, never more. By parity of reasoning, the pound is too large as a unit. In fact, it is impossible to contrive a weight which shall be equally suitable for all purposes. The kilogramme may be, probably is, too large *quâ* confectionery, but it is certainly too small *quâ* coals, and many other articles.

In the same letter Sir Frederick objects to the use of decimals for any purpose whatever, he greatly prefers vulgar fractions. Though he does not say so, I presume he also objects to logarithms. He says he has frequently noticed that when buying tickets at a railway station the French ticket clerk will figure the sum out on paper, while the Englishman calls out the amount at once. That may be so in some isolated cases, but it is essential to know what calculation each clerk has to deal with; the one may be very obvious, the other much more complex. On many of the French railways the tickets are sold by women well advanced in life, and elderly ladies are not usually lightning calculators. My own experience is quite otherwise. For many years past I have been accustomed to make my calculations in this way: if the problem is presented in British measures, I get a clerk to convert them into the metric equivalents; and then, and only then, do I take the matter in hand myself. If great accuracy is not required, I use a slide rule, which I cannot do with British measures, except in a few isolated cases. Otherwise I figure it out. I get the result re-converted, and I find I save both time and figures, notwithstanding the two conversions.

Another instance of the extreme convenience of a decimal or centesimal notation is this: if we get a lot of facts and figures which we wish to compare, the first thing we do is to convert them into percentages. Until this is done it is impossible to understand them. When the metric system is used, the percentages come out automatically.

Sir Frederick, in his campaign against decimals, says that people are constantly misplacing the decimal point, and thus bring out absurd

results. If the result is absurd, a man goes over his calculation again; but it is not my experience that the decimal point is liable to be misplaced, the rule on the subject being so simple and plain. I am a bad hand at adding up a column of figures. I hardly ever bring out the same result twice running, but I do not think I ever misplaced the decimal point in my life.

The great objection urged by Sir Frederick and others who wrote to the *Times*, is the want of divisibility of the number ten. It can be divided by two and by five. Twelve, on the other hand, can be divided by two, three, four, and six. This may be to some extent an objection to the metric system, but it certainly is not an argument in favour of the British weights and measures, which do not run on twelve or on any common factor. To begin with: ten pounds go to a gallon, and ten chains to a furlong; three feet to a yard, five and a half yards to a perch, and so on. Lastly, 437½ grains go to an ounce, and 277·274 cubic inches to a gallon. Sir Frederick avows a preference for duodecimals, and wonders why they are practically never used. The reason is, that if we had six fingers on each hand we should no doubt have had a duodecimal arithmetic, but, having only ten fingers, we count in decimals.

The most astonishing proposal was made by a correspondent of the *Times* in a letter which appeared soon after that of Sir F. Bramwell. He suggested that we should all go to school again, forget decimals and learn duodecimals; we should then start a new system of weights and measures copied from the metric system, but based on the number 12 instead of 10. All this because three and four will not divide ten.

In point of fact, the non-divisibility of the number ten by certain integers is a theoretical objection to the metric system so long as it works entirely in ten, but in practice it does not. A kilogramme is divided into 1000 grammes, and this is divided by two, four, five, eight, and ten. It is not divisible by three and six, for these numbers are in the nature of things as antagonistic to a decimal notation as five and ten are to a duodecimal one. The number seven does not fit into either. What is called the decimal system is, in fact, a milliary one, and, looked at in this light, it is quite as divisible as a duodecimal system. The metre, again, is divided into 100 centimetres, divisible by two, four, five, and ten, but it is also divided into 1000 mm., in which case the number eight must be added to the list of divisors. Nothing is perfect at first. It shakes down after a little experience is gained. Originally, the metric system was much more a question of decimals than it is now. Every time the standard, *i.e.*, the metre, was divided by ten, it received a name derived from the Latin. Every time it was multiplied by ten it received a name derived from the Greek. The same holds good of the gramme, which is the standard of weight. Most of this has disappeared, and is to be found only in books of equivalent weights. No one speaks of decagrammes or of hectogrammes, and but very rarely of centigrammes or decigrammes. From the milligramme we go straight to the gramme as the next unit, smaller weights being expressed as 200 milligrammes or 300 milligrammes as the case may be. In the same way there is no unit between the gramme and the kilogramme, so that there are only three recognised units of weight, the factor being 1000.

In the same way the litre, the standard of fluid measure, is divided into 1000 cubic centimetres or fluid grammes. We have indeed got the hectolitre or 100 litres, because that is a very convenient measure, but here it stops, and any large quantity is expressed in hectolitres, just as in Britain the flow of the Thames, for instance, is expressed in gallons, for which purpose I may remark that the gallon unit is too small. Again, the metre is divided into 1000 mm. Those of you who have seen German or French engineering drawings will find the dimensions invariably expressed in millimetres, and beyond a metre in metres. To put in a complication of decimetres, centimetres, and millimetres would be to approach the British practice of, say, two feet seven inches and a bare  $\frac{3}{8}$ . Occasionally the centimetre is used, *e.g.*, by dressmakers, but even they know nothing of decimetres. If we handle a polarising saccharimeter, we choose a tube of 100, 200, 300, or 400 mm. I contend that in the metric system, viewed as a milliary system, this objection of divisibility practically disappears. Viewed from another point of view, it disappears altogether. If the metre is looked upon as a measure of 1000 mm., we start from the smallest practical unit. No division is necessary. It may be necessary to multiply, but you can multiply by any figure you like if you cannot divide.

Would there be any practical difficulty about introducing the metric system into Great Britain? I think not. There are some curious relations between the metric weights and measures and those at present in use in this country, and here we come back again to a series of perfectly undesigned coincidences.

The metre is ten per cent. more than the yard, the kilogramme is equal to 10 per cent. more than 2 lb. Fifty kilogrammes are equal to one cwt. within 1½ per cent. One thousand kilogrammes are equal to one ton, also within 1½ per cent. The litre is equal to a quart less 10 per cent. The hectolitre is equal to 20 gallons, plus 10 per cent., or 22 gallons. The hectare or French acre is 2½ English acres. One hundred mm. are equal to four inches; the kilometre is two-thirds of an English mile, or, say, two miles equal three kilometres; so that these coincidences, none of them quite exact but very nearly approximate, would serve as a guide until people were accustomed to the new measures. As a matter of fact, metric measures are already in use officially. The kilowatt, which is the Board

of Trade unit for electrical measurement, is founded on the centimetre, gramme, second or centigrammes system, and has nothing whatever to do with the Imperial legal measures.

The limit of weight of the Parcel Post is 11 lbs. Why is the number 11 chosen? Certainly not on account of its easy divisibility, for nothing will divide it; but 11 lbs. happen to be five kilogrammes, and, what is more, it is intended to be 5 kilogrammes.

The limit of weight for the minimum of foreign postage is really 15 grammes, and we have adopted one-half of an ounce as a rough approximation; so that we have already made a start, though only a small one.

I have not alluded to the subject of a decimal coinage, because it is a very much less important thing. The kilogramme is a kilogramme wherever you take it, and a metre is a metre, and a litre is a litre in all parts of the world; not so with money. This is complicated by the rate of exchange, which is constantly varying. Take, for example, the Latin Monetary Convention. Italy and Spain decided to adopt the French monetary system. The Italian lira and the Spanish peseta were made equal to the French franc, and the coins contain the same amount of metal, so that one would expect that the rate of exchange between these countries would never vary.

About two years ago I was in all three countries. In France I got 25 francs for my sovereign; in Italy, 27 lire; and, in Spain, 37 pesetas. In Greece there is a gold coinage equal to 20 francs, but you never see a gold coin in Athens; they are all in Paris, where they pass current as 20 francs. In America the Mexican dollar, which contains rather more silver than the American dollar, is worth only half as much as the American dollar. The United States stamp has doubled the value of the metal. Even the exchange between the two strongest financial centres, London and Paris, is constantly varying.

An international system of weights and measures is a perfectly practicable thing, while an international monetary system is a Utopian dream.

## EXPOSURE AND DEVELOPMENT.

### I.

[Paper read before the Chiswick Camera Club.]

THE operations of exposure and development are so intimately associated with, and dependent on, the nature of some of the materials employed, that a part of the time at our disposal may be profitably devoted to a brief consideration of a few of their characteristics. It may, I think, be conceded that the plates we propose to use should have our first attention.

In a general way, these may be placed in two classes, *viz.*, those incorrect for rendering colours, and those specially sensitised to give a more perfect representation of various colours in monochrome. It will be found that the former, varying from slow to extremely rapid, will require for each grade a somewhat different treatment throughout, depending principally on the quality of rapidity possessed by the sensitive coating. Orthochromatic plates, on the other hand, are made with a somewhat less varied range of rapidity; yet those which are sensitised for the correct rendering of a considerable portion of the spectrum are so sensitive and require such careful manipulation that they may be considered as having no value whatever in the hands of the beginner.

Adverting now to the uncorrected or ordinary plates, it is well known that, in the hands of the photographer accustomed to slow plates, the tendency of an extremely rapid plate is to give a somewhat thin negative, having a small range of gradation compared with a slow one, under what might be considered correct exposure and normal development in both cases. This is said to be in a great measure due to the thinness of the coating of emulsion, which reaches a state of great fluidity in the process of preparation to give extreme sensitiveness, and with which it is consequently difficult to give the plate a thick coating. Conversely, the slow plate, which tends rather to greater contrast under suitable conditions, will generally be found to have a much thicker film than the rapid one.

To those who elect to work with very rapid plates a number of difficulties present themselves, due principally to their rapidity or extreme sensitiveness. The difficulty of obtaining vigour or contrast has already been alluded to; another is that much greater care must be exercised in all operations, from the time of opening the packet of plates up to the fixing of the negative, in order to avoid fogging from unsafe light. With some brands of rapid plates there is also a liability to chemical fog, or veil, under certain conditions of development, and, finally, there is what is known as less latitude in exposure with the rapid than with the slow plate. This latter quality, however, appears to be somewhat misunderstood, and is often taken to mean that a rapid plate, having received a moderate over or under-exposure, is less amenable to treatment during development than a slow plate that has received an equally incorrect exposure. If any experiments have been made proving this to be a fact, they were not accessible for the purposes of this lecture. Abney, however, states (*Photography*, November 24, 1899) that "latitude of exposure is more wanting in it than with a slow plate. It will not bear five or six times the correct exposure, for it is apt to begin to show reversal, and then the high lights become feeble and bad." So far as general experience in the use of rapid plates goes, the difficulty seems rather to

have been in measuring accurately the very short exposures sometimes given.

Let me explain by an example: Suppose that you have to make an exposure with a rapid plate, and that by some means you have discovered that half a second would be correct; also that you intend exposing a slow plate on the same subject, and for which two seconds would be correct time. Now, assuming the limit of error on the part of the operator to be a quarter of a second, it is obvious that in the case of the rapid plate, the possible error would amount to fifty per cent. over or under. In the case of the slow plate, however, the same error of a quarter of a second would only amount to twelve and a half per cent. of the intended exposure.

With regard to gradation, Capt. Abney says (*Photography*, vol. viii., p. 637) that "rapid plates have, as a rule, a longer and more correct scale of gradation than slow plates," a statement that, of course, assumes the possession of sufficient skill to manipulate the plates to the greatest advantage.

The foregoing has probably indicated that the choice of the beginner should fall upon plates of low, or medium speed, and that these should be used exclusively until all their capabilities are known. One of the most serious mistakes made by beginners is that of changing from one make of plate to another, with the vain hope of finding a plate capable of compensating for the operator's unskilful or careless manipulation. Undoubtedly a very large percentage of the failures made, not only by beginners but by fairly skilled photographers, may be traced to the constant search for that eternal will-o'-the-wisp, the perfect plate. It may be taken as an axiom, that the perfection of any brand of plate is measured by the photographer's familiarity with its good and bad qualities; the more thoroughly these are known, the more perfect will the plate appear and the less will be the desire to make a change. Probably every brand of dry plate obtainable has certain peculiarities and limitations, which must be carefully studied and mastered if the best results are desired. It will be wise also to undertake only those subjects which are within the reasonable capacity of the plate.

At this point may be profitably urged upon the beginner the necessity for the utmost care, and cleanliness, in all photographic operations; also for guarding against stray actinic light in the dark room as well as in the camera and plate-holders.

Many beginners are in doubt as to the best method of illuminating the dark room when developing plates, and are apt to think that it is best to use daylight wherever possible. If this course is adopted, it will be found practically impossible to produce negatives of uniform quality, owing to the great variation in the strength of the light at different times of the day and year and the consequent variations in the appearance of the negative during development.

A much better plan is to perform all developing operations, even in daytime, by the aid of a good artificial light, such as a gas-burner or a fairly large lamp that may be depended on to give a uniform flame for some hours without attention.

The quantity of light permissible in the dark room is also a source of much concern to the beginner. A plentiful supply of light, so conducive to comfort and good work, is not inconsistent with good work, the danger lies in the quality of the light. This should be tested by direct experiment before risking the development of negatives by its aid, whether it be daylight or artificial.

A simple test may be made as follows: put a plate in a dark slide, or plate-holder, in perfect darkness. Then light up the room as intended to be used for developing, and place the plate-holder in the same position that the developing dish would occupy. Draw the slide so as to expose one quarter of the plate for, say, five minutes, then open half way and expose a further five minutes, and finally give a third exposure of five minutes with the slide three-fourths open, leaving the remaining fourth part of the plate unexposed.

Having placed everything in readiness, turn out the light and develop the plate in darkness for five or six minutes, rinse in water, and place in a fixing bath before lighting up again.

The result will clearly indicate whether the light is safe; it need not be condemned if the veiling of the exposed plate is very faint, as, in ordinary working, the dish should always be kept covered during development, except during brief intervals when examining the negative.

When filling dark slides or plate-holders, the plates should be dusted by passing a suitable brush or pad slowly over the whole of the film. Your attention is directed to the word *slowly*, because it has been found, from experiment and experience, that a rapid brushing of the film is liable to set up what are supposed to be electrical conditions, with the result that particles of floating matter are immediately attracted, and firmly attach themselves thereto. The natural consequence is a plentiful crop of pinholes, and hair marks, on the negative.

It will be found a useful precaution, to pass the dusting brush along the edges of the plate, to remove all particles of glass adhering to them as a result of cutting operations, and which are only waiting to become accidentally dislodged to take their apparently natural place on the sensitive surface of the plates.

It is always advisable to fill the dark slides as short a time as convenient before using the plate.

There are at least two good reasons for this, the first is, that gelatine

plates will eagerly absorb moisture from the atmosphere, and that a comparatively brief contact will be sufficient to render them slower, or less sensitive, over the portions affected.

The second is, that, in spite of all precautions, the substances used in the manufacture of dark slides appear to be able, in course of time, to exert a more or less harmful influence on the sensitive coating of the plate. For the same reasons, any unused plate should, at the earliest opportunity, be transferred back to the makers' boxes if not wanted again for a week or two.

With these introductory remarks, we will proceed to consider the first of the operations properly pertaining to this lecture, viz., "Exposure."

In the first place, we shall try to fully understand what it is that we wish to accomplish when we expose a plate. If we want to include in our picture the full range of light and shade presented to us in the majority of subjects which we may consider suitable for the camera, we are confronted with the fact that the materials at our disposal, both for negative and printing purposes, are quite incapable of reproducing them.

Only those scenes, or subjects, in which the range of light and shade come within the scale of gradation obtainable in the photographic negative, can be considered susceptible of what is known as correct exposure.

To the vast number of subjects which range beyond the limits of our plates has been applied the time-honoured and little understood rule, "Expose for the shadows and let the high lights take care of themselves."

A too rigid adherence to this maxim, must inevitably lead us to frequently make exposures in which the highest lights in our subject will be very much over-exposed, and require the utmost care during the development of the plate to secure even an approximately correct rendering.

On the other hand, except for occasional pictorial purposes, it is not desirable to strive for exact exposure in the high lights, and leave a large portion of our negative entirely devoid of detail. Regarded in this light, the maxim above quoted is, doubtless, of value.

Our advice, then, would be to first practice upon subjects having a moderate range of light and shade, leaving the more difficult ones, in which over-exposure in the high lights becomes inevitable, until a thorough familiarity with both plate and developer has been acquired.

The scope for the beginner's skill having thus been somewhat narrowed, we may endeavour to explain the ways and means for obtaining correct exposures. There are quite a number of factors entering into the problem; but, as many of these concern only special cases, we shall deal with only three of the principal ones, viz., the speed or sensitiveness of the plate, the relative aperture of the lens, and the actinic value of the light illuminating the object to be photographed.

Of these the two former are subject to our own choice; that is to say, we can choose a rapid or a slow plate, and we can stop down the lens as desired.

The third factor may be determined either by measurement, by the use of tables of light values, or by the exercise of the personal judgment of the photographer. Obviously the latter method has no value to the beginner, who is without that prolonged experience which might give him an excuse for trusting to his own judgment. We shall probably be not far wrong if we say that blind guesswork in the matter of exposure can never conduce to reliable or satisfactory results any more than would the hap-hazard compounding of the solutions used for development. Exposures founded on experience, which may be dignified by the term *modified guesswork*, are still made by a very large number of undeniably capable photographers. Many of these depend almost entirely on the appearance of the image on the focussing screen as a guide to exposure.

Yet many of these old and successful photographers who scorn the help of tables or actinometers admit that they are useful to beginners since it took them many years to acquire the judgment on which they depend.

At the time when many of us began photography, the handy meters or light-measuring instruments now available did not exist, and in their absence those who desired to have some guide in making their exposures were glad to avail themselves of the late W. K. Burton's tables, showing the relative exposures necessary for various subjects at different times of the day and year. Later on, these tables became embodied in, or formed the basis of, exposure calculators by Mr. Dibdin and others. The Dibdin instrument is made of cardboard, and sold for the modest sum of sixpence. In these calculators, however, there is still a very important factor left to the decision of the operator, viz., whether the light at the moment is to be considered dull, gloomy, or bright, a decision which may at times baffle even a fairly trained judgment. There also remained a certain amount of calculation to be made when using a rapidity of plate other than that for which the instruments were made.

G. F. BLACKMORE.

#### A CHAT ON BALANCES.

At the meeting of the London and Provincial Photographic Association on March 29; Mr. A. Mackie passed round about thirty platinum prints from his series of British Museum subjects. In reply to several

questions, he stated that the negatives were on ordinary plates, unbacked, and pyro-ammonia developed. The exposure in every case was a matter of minutes, the shortest three minutes and the longest forty or more. Mr. A. Haddon gave what he styled a chat on

BALANCES.

The subject was suggested to him by the words of one of the members at a meeting not very long ago when speaking about the developer required in a certain colour process, namely, one grain of pyrogallol per ounce of water. The question was asked, How can this quantity be weighed? Hearing this, he was at once led to the conclusion that the balances used by photographers were, as a rule, incapable of weighing to a grain or less with any degree of accuracy, and he therefore thought that a chat on the principles upon which balances depend might be considered of some interest.

The mathematical balance, he said, might be taken as a beam of some rigid material having no weight, supported at its centre, and furnished with a means of attaching to its ends two pans at an equal distance from the fulcrum. In attempting to embody these principles and to produce the device in brass or other metal, certain difficulties arise. Firstly, our beam, however produced, is not absolutely rigid; secondly, it is not weightless; and, thirdly, the difficulties of supporting the beam and attaching the pans to the ends of the beam are very considerable. As a rule, the distances of the pans from the fulcrum are not strictly equal, as they should be. The weight of the substance of the beam creates a difficulty in that, if it is not supported truly at the centre of gravity, either above or below, the sensitiveness of the balance is affected. If the centre of gravity is above, then the beam will be in unstable equilibrium, for, as soon as it is displaced, the centre of gravity goes to one side, and the beam topples over. If the centre of gravity is below the point of suspension, then, as soon as the equilibrium is destroyed, the whole mass of the beam is carried to the opposite side, and a large weight is required in one of the pans to restore the equilibrium. The sensitiveness of a balance depends, therefore, a great deal upon the centre of gravity with respect to the point of suspension. The foregoing facts were clearly explained by diagrams upon the blackboard.

Another serious difficulty to be overcome is that due to flexure of the substance employed for the beam itself. This is overcome in part by the form given to the beam and by a system of struts, which also was figured on the board. By these means, whether a small load is placed in the pan or a tolerably heavy one, the sensitiveness of the balance is not affected by complications arising from flexure. As a rule, beams so constructed are provided with a screw movement, by which the centre of gravity can be adjusted with respect to the point of suspension.

In order to reduce friction at the points of suspension, both of the beam itself and the pans at its two ends, to a minimum, in the balance constructed nowadays and for some years past a knife edge is given to the beam at these points, which rest upon a truly plane surface. The wear and abrasion of the knife edges and plane surfaces is reduced to the lowest possible amount by employing agate for these parts, but great accuracy is required in the grinding of the bearings. Another factor which determines the value of the balance is the relationship of the three knife edges. They must be exactly in the same straight line, and the centre of gravity as near to that as it is possible to make it. Then the question of a pointer or indicator comes in. With an accurate balance one would not determine the weight of a thing by trying to find the point of equilibrium, but by displacing the balance from its normal or zero point, and reading an equal number of oscillations on the divided scale by means of a pointer.

By observing these several points a tolerably accurate balance should be produced. Laboratory balances, in principle, conform to them, and very good instruments are made by Messrs. Oertling, of London. Balances, better in some respects than these, are made elsewhere, with a shorter beam and perhaps more sensitiveness, and some have an additional movement whereby the relative positions of fulcrum and pan supports may be adjusted. As a rule, however, in well-made balances the error does not exceed 5 in 100,000, and when that is the case it is immaterial which pan is used for the weight and which for the substance to be weighed.

Delicate balances, such as those under discussion, are always kept under cover in a glass case, to obviate draughts, which, however slight, would upset equilibrium and render it impossible to weigh with exactitude. Ordinary balances such as photographers are in the habit of using have very little sensitiveness. Mr. Haddon had an example, bought some twenty years ago, which would only just show the slightest movement with a one grain weight. In the same category was the majority of the balances used by photographers. One grain was not a large amount, but photographers should all have it in their power to weigh one grain with exactitude. As previously mentioned, with some balances it is a matter of importance that the weights are always placed in a certain pan owing to inaccuracies in construction. With a weight known to be accurate, however, used with a balance the beam of which is known or suspected to be out, a very close approximation to the accurate weight of a substance can be made. The substance to be weighed is placed first in one pan (called A) and its weight determined in B. Weight and substance are

then changed about and the weight again determined. The true weight would be equal to the square root of the product of the two weights. A less exact determination would be the mean between the two figures.

The weights themselves, however, are not what they might or should be. Mr. Haddon had measured some of the weights supplied with balances, and ascertained that a weight of ostensibly two drachms measured 120.83 grains—more than three-quarters of a grain out. The percentage was small, he admitted. The same proportion of error was found with a one-drachm weight, which was ascertained to be 60.42 grains. Below are given the true values of other weights tested by Mr. Haddon:—

Weight as marked.	Actual weight.
40 grains ... ..	40 $\frac{1}{3}$ grains.
30 " ... ..	30 $\frac{1}{10}$ " "
20 " ... ..	20 $\frac{1}{10}$ " "
10 " ... ..	10 $\frac{1}{10}$ " "
6 " ... ..	6 $\frac{1}{10}$ " "
3 " ... ..	3 $\frac{1}{2}$ " "
2 " ... ..	1 $\frac{1}{2}$ grain.
1 grain ... ..	1 $\frac{1}{5}$ " "

Perusal of this table shows that, where (as in the smallest weights) greatest accuracy is wanted, a greater percentage of error is found. Of course, if our balance and weights cost only 2s. 6d. or 3s. 6d., the want of accuracy is not to be wondered at; but, at the same time, increase of price generally affected the quality of the balance, and the weights remained very much as given above. Photographers should look round, therefore, and see that they get decent balances and decent weights.

The question of weighing one grain of pyro is not a very serious one, it is true. If our weights and balances are not strictly accurate, we can, as somebody suggested, dissolve ten grains in ten ounces of water, using an ounce, which would then contain a grain, and throwing away the nine ounces. But this practice with such a dye as is recommended for the Lippmann process—quinoline red, costing one shilling per grain—would be out of the question. It would pay to purchase, under these circumstances, a more expensive balance, provided that the extra labour necessary to make it a perfect instrument had been expended on it.

Four or five years ago Mr. Haddon saw a toy which involved a principle which he had embodied in a better form in the construction of a most sensitive balance at little or no cost. One could weigh with accuracy one-fortieth of a grain, and anybody who could solder together a few pieces of wire was able to construct one of the same accuracy. Instead of two pans, one each side of the fulcrum, this balance had one only, being devised on the counterpoise principle. Briefly, it consisted of a standard, from which was suspended, on loops of silk fibre, a beam of very light construction, carrying at one end two mica pans one above the other. At the other end was an adjustable screw counterpoise. As erected on the table, it was counterpoised very nearly with a weight of ten grains in the lower pan. A long aluminium pointer working on the face of a divided scale is used for reading. A piece of aluminium wire, which was very nearly one grain (perhaps a few thousandths out), was then dropped into the upper pan, the pointer as the result being deflected to a considerable extent. Using now a weight of one-tenth of a grain, a movement of five divisions was noticeable on the index, so that one-fiftieth of a grain would be easily weighed, and a deflection of one degree would register this amount. Of course, to use such an apparatus at its best, there should be a cover over the balance.

In order to weigh two grains of anything with this balance, the ten grains weight would be replaced by eight grains, material being added to the upper pan until the equilibrium was restored. By having an adjustable counterpoise, weights of any magnitude within the strength of the apparatus can be measured. A hastily but very lightly constructed model on similar principles was also shown and found to register to one one-hundredth of a grain. The first would equal this feat under cover. The apparatus was examined with a deal of interest, and a vote of thanks was passed to Mr. Haddon for his remarks.

A HALF HOUR'S TALK ON PHOTOGRAPHY.

An attempt to condense within a half-hour's talk the whole science and practice of photography is one that would probably "stagger" the average "humanity" of the most skilled enthusiast. But Mr. F. O. Bynoe boldly essayed to accomplish the impossible the other evening at the Thornton Heath Polytechnic, and the satisfaction of his audience demonstrated that his happy methods of rapid explanation were eminently successful in transmitting a fund of information which was interesting and instructive both to the novice and the experienced worker. It must be admitted, however, that his talk extended somewhat beyond his time limit, for, when this was reached, his hearers demanded more, thus manifesting their appreciation of what they had already listened to.

Mr. Bynoe gave a rapid but most lucid sketch of the different varieties of lenses, and their special uses. The single lens, the R.R., the portrait, and the tele-photo, were all described and illustrated by specimens. Astigmatism and its difficulties were briefly referred to.

The "talker" then briefly alluded to the various processes at present in vogue for the production of pictures. The silver print, the gelatino-chloride, the platinotype, the bromide, the velox, the gravure, the carbon, and the gum-bichromate processes, were handled tersely but with sufficient reference to their chemical and manipulative details to convey an intelligent apprehension of them all. Each was exemplified by specimen prints, some fine carbons lent by the Autotype Company being much admired. The clear though necessarily sketchy demonstrations of the principles which formed the basis of each process convinced us that Mr. Bynoe knew what he was talking about, and that his knowledge was founded on actual and practical experience.

The defects of dark rooms were touched upon, and, by the help of a spectroscope, safety from the intrusion of the green or violet rays, which so rapidly fog our plates, was shown to be within reach of every operator.

Exposure was next dealt with, and the latitude afforded by reliable plates or films was demonstrated by negatives and prints of a subject which had been produced under the same conditions by exposures varying from one-fifth to one-eightieth of a second. It was remarked that each of these results, considered by itself, was fairly acceptable, although the correct exposures were clearly evident when the intermediate ones were carefully examined.

From this point Mr. Bynoe proceeded to remark upon portraiture as being the most tempting pitfall into which amateurs generally slipped. He spoke of the importance of effective lighting, and the avoidance of strong shadows thereby, showing that, by certain simple arrangements, pleasing as well as truthful portraits could be secured in the majority of cases.

A list of books relating to photography to be found in the local library was then given, and the speaker also made some suggestion as to other books, the study of which would be serviceable to all who desired to excel in that fascinating hobby. This brought the talk to a close, and it must be admitted that Mr. Bynoe managed to crowd into the short interval at his disposal an immense amount of instruction, which it is barely possible to glance at in the present brief report.

On the motion of Mr. G. Edwards, seconded by Mr. Rogers, a unanimous vote of thanks was awarded to Mr. Bynoe for his address.

#### ANNUAL DINNER OF THE PLATE-MAKERS' ASSOCIATION.

WE are informed that the Third Annual Dinner of the Plate and Paper-makers' Association will be held on Wednesday evening, May 2, at the Restaurant Frascati, Oxford-street, London, W. Hitherto none but members have attended this annual dinner, but on this occasion it is hoped that dealers and members of the trade will avail themselves of the opportunity of being present in order to show their approval of the objects of the Association. The dinner will be held in the week when many country dealers, &c., may be on a visit to London. Tickets for the dinner, price one guinea, including wine, may be obtained from the Secretary of the Association, W. J. Eales, London Chamber of Commerce, Botolph House, Eastcheap, E.C.

#### COUNTRY LIFE PHOTOGRAPHIC COMPETITIONS.

OUR admirable contemporary, *Country Life*, which is published at 20, Tavistock-street, Covent Garden, W.C., announces that, on account of the great success that attended its recent photographic competition and the interest it created amongst a large number of the readers of *Country Life*, many of whom sent photographs of high artistic merit, it has been decided, in order to further encourage the art, which is so eminently suited to lovers of country life, to begin another competition for photographs of spring subjects. The beautiful effects to be obtained in the garden at this season of the year are varied, and, although the following short list by no means covers the whole ground, it will suggest the class of subject that may be worthy of the attention of intending competitors:—

*Spring Flowers.*—Particularly the artistic effects obtained by growing narcissi, scillas, tulips, and other flowers in meadow grass, or beneath trees, by man and by nature.

*Spring Flowers on the Rock Garden.*—To show effects, not merely of many kinds, but of individual flowers in pretty aspects.

*Spring Flowers in the Border,* or massed upon the lawn or in beds.

*Spring Flowers in the Shrubbery.*

For the best set of not less than twelve photographs a prize of 5*l.* will be awarded.

The photographs should be silver prints—preferably on printing-out paper—not smaller than half-plate size, and should be carefully packed, and addressed to the Editor in a parcel bearing the words "Photographic Competition" on the outside. For the purpose of identification, each individual photograph must be clearly marked with the name and address of the competitor, but no responsibility for the safe keeping of

the competing photographs can be accepted, although every care will be taken to return safely any unsuccessful photographs if stamps for this purpose are enclosed.

It is understood that all reproduction rights of the successful photographs will pass to the proprietors of *Country Life*, and, if required, the negatives of these pictures will be given up to them. The proprietors also reserve to themselves the right to make use of any of the unsuccessful photographs upon payment of from 5*s.* to 10*s. 6d.* for each picture published, according to their idea of merit.

The competition will close on June 21, and the decision of the Editor, which will be final and without appeal, will be announced as early as possible after this date.

#### SOME PHOTOGRAPHIC ODDS AND ENDS.

ON March 27 Mr. C. S. Baynton read a paper before the members of the Birmingham Photographic Society, the subjects touched upon being the dark room, and dark-room lights, and the making of lantern slides.

The dark room, Mr. Baynton thought, was a greatly neglected part of the photographic equipment, and the apartment which was dignified by the name of dark room was not in many cases conducive to successful results.

The three essential requirements were: 1. Cleanliness; 2. Plenty of room in which to work; 3. Plenty of light of the proper kind. Cleanliness could be secured, to a great extent, by covering the floor with oilcloth, which materially lessened the number of dust particles floating about in the air.

Coming to the most important question of dark-room illumination, the lecturer said that a great number of photographers blamed the plate-makers for defective plates, when, in many cases, the fault lay in the use of an unsafe light. The effect of this was to cause lack of brilliance and often general fog all over the plate. The remedy was obvious; but, while the light should be safe, it need not be of that kind such as mostly led to the spilling of developer and the use of language usually reserved for the dark room. As a result of many trials, Mr. Baynton had come to the conclusion that a light filtered through yellow paper and orange fabric was quite safe, except, of course, for isochromatic plates. The new material known as glacier also gave very satisfactory results. A general principle might be laid down that, if one could see the illuminant through the filter, the light was unsafe, and should be rejected.

The second part of the paper dealt with the making of lantern slides. Mr. Baynton urged the importance of correct exposure, as any error could not be rectified in the subsequent development. To prevent the accumulation of a stock of cover glasses, it was advisable to make some trials by giving different exposures to portions of the same plate and comparing the developed result. Development should be continued till the prettiness has gone off the slide when looked at as it lies in the dish, and, in order to judge density, a yellow light was much to be preferred. Care should be taken always to maintain the solution at a uniform temperature, and a golden rule was always to use one brand of plates, to start with slow ones, and to stick to one developer.

Many workers are probably unaware that lantern plates are subject to halation as much as negatives, and all plates should therefore be backed to prevent this. Fixing should be carried out in an alkaline solution, as less colour would then be lost when warm tones were desired.

Finally, let not any one think that the slide was complete when fixed and dry. A finishing touch yet remained, which might make or mar the whole, to wit, the mounting of the slide. How often did we see slides which might otherwise be things of beauty and a joy for ever spoiled by inattention to this simple detail. The maxim, "Spare the knife and spoil the picture," applied equally to lantern slides as to pictures on paper.

#### THE NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.

IN view of some remarks recently made in our pages relative to the above Association, it may be of interest if we print the rules. They are as follows:—

1. That the Association be called The National Photographic Record Association.

2. That the aim of the Association shall be to obtain photographic records of all objects and scenes of interest in the British Isles, and to deposit them, with explanatory notes, in the British Museum, where they may be safely stored, and be accessible to the public under proper regulations.

3. That the constitution of the Association shall be as follows: Patron, Vice-Patrons, President, Vice-Presidents, and other officers and members.

a. Vice-Presidents, who shall be elected annually; the qualification shall be a subscription of one guinea per annum.

b. Members, who shall be representatives of photographic, scientific, archaeological, literary, artistic, or any other learned societies, not exceeding three for any one society, upon payment by the respective societies of an annual subscription of one guinea.

c. Members, whose qualification shall be (1) a contribution of photographs to the number of six approved prints for the year; or (2) a

subscription of not less than ten shillings per annum. Members may at any time compound for their future annual subscriptions by the payment of five guineas.

d. Members who shall be honorary, county, or district secretaries, whose appointment shall be made by the Council and confirmed at each annual meeting, and whose duty it shall be to collect photographs in their respective localities.

4. The business of the Association shall be transacted by a Council consisting of the President, Secretary, Treasurer, Curator, and twenty members, all of whom shall retire annually and be eligible for re-election. The Council shall be elected at the Annual Meeting, and all members of the Association shall be entitled to vote and shall be qualified for nomination.

5. All photographs sent in shall be submitted to the Council, with whom shall rest the power of approval.

6. The Curator shall keep an account of the collections of the Association, including particulars of photographs received from time to time, which he shall give a receipt on behalf of the Association to the respective donors. He shall also prepare a list of photographs received during the year, with the names of the donors, for the purpose of being printed and circulated.

7. The Annual Meeting shall be held in the month of February.

8. The Ordinary Meeting of the Council shall be held in February, April, June, October, and December.

9. Voting at all meetings shall be by show of hands, the Chairman for the time being having the right of a casting vote in the event of votes being equal.

10. At the Annual Meeting seven, and at the Ordinary Meetings of the Council three, shall form a quorum.

11. Subscriptions shall be due on January 1 in each year.

12. The Council shall have power to fill up any vacancy in their own day occurring in the interval between Annual Meetings, and to make by-laws; such by-laws to have the sanction of a General Meeting before coming into operation.

13. These rules shall only be altered at an Annual Meeting or at a special General Meeting called for the purpose. Notice of proposed alterations shall be given in writing to the Secretary one calendar month before the date of such meeting.

BY-LAWS.

1. Photographs must be printed in carbon, platinum, or other permanent process, and be deposited unmounted with the Curator, who shall have them uniformly mounted upon official mounts provided for the purpose.

2. For the sake of uniformity, whole-plate ( $8\frac{1}{2} \times 6\frac{1}{2}$ ) shall be regarded the standard size for photographs. Two or more prints of a smaller size may be placed on one mount. Photographic enlargements beyond whole-plate size are not recommended.

In all cases it is desirable in taking pictures that a relative scale of size should be indicated. Thus a man or child might appear in an archway, or near a boulder stone, or a measured rule might be introduced where more scientific accuracy is desirable, and for the purpose of recording the orientation of the building or subject photographed it is desirable that the point of the compass towards which the lens of the camera points when the photograph is taken should be notified.

THE CAMERA CLUB.

THE past month has seen no startling development in the world of photography, and therefore the Camera Club, in common with other photographic societies, has had a restful time; but, as it is customary to place upon the programme a lecture, or demonstration of some kind other than every Thursday evening, the energetic Honorary Secretary has performed his onerous duty by inviting discourses on varied subjects. Travels and wanderings in far-off lands, described by the travellers or wanderers themselves, are always interesting, especially if they be illustrated, as they generally are, by original lantern slides; indeed, the lantern slides are often the excuse for bringing the subject before a photographic club, if excuse be needed by an assemblage which is always glad to welcome in their midst any one who has an interesting story to unfold.

On one of these March evenings a highly respected member of the Club essayed to take the lecturer's place and thus perform a promise made some months previously. This was Mr. Webber, who on a former occasion, when in the course of a paper on soldering the lecturer produced a blowpipe, volunteered to melt a halfpenny in a few seconds against any one in the room. On that occasion he made good his boast, and the halfpenny was reduced to an amorphous condition. From that little experiment grew the notion that Mr. Webber, with his long experience as a practical goldsmith, an experience stretching over considerably more than half a century, might be persuaded to show to the Club on some future occasion some of the mysteries of his craft. Truly it was not a photographic subject with which Mr. Webber now, in confirmation of his promise, brought before the Club, but there was a saving clause in that it had to deal with the noble metals—argentine

et aurum—metals without the salts of which photography, as we know it to-day, would have been impossible.

It is true that photographers have little to do with the precious metals themselves, but Mr. Webber reminded them that they might sometimes get a closer acquaintance with pure yellow gold if they would only be more careful to save the remains of an exhausted toning bath, instead of letting it run down the sink. He, it is true, is only an amateur photographer using gold for toning in very modest quantities, and yet he was able to show a long ribbon of the shining metal which he had recovered from waste solutions. Still more interesting and useful was the information which he had gleaned from careful notes of the amount of gold chloride purchased compared with the metal recovered. He said that he proved that it was possible to get back in this way no less than seventy per cent. of the gold purchased for use in photography. This is a matter which should be noted by professional photographers in a small way of business, who too often totally neglect this source of economy, although in large establishments it is, of course, well looked after.

There were other little bits of information concerning the precious metals which Mr. Webber vouchsafed to his hearers which could not be readily gleaned from the usual sources. For example, although silver has become cheaper and cheaper until a half crown is hardly worth a shilling intrinsically, gold has, in spite of Klondike and in spite of the Rand mine, kept its price to a penny during the past seventy years. Why this should be so, no one seems to know. We learn further from Mr. Webber that the "pure gold" of commerce is not really pure, but is of a purity represented by 996 parts in 1000, whereas fine silver may be put at 999 in 1000. After a preamble embodying these and other facts Mr. Webber proceeded to weigh out 9 dwts. of gold, 2 dwts. of silver, and 1 dwt. of copper. He then melted the silver and copper together under the flame of a blowpipe, afterwards adding the gold, in this way making a small bar of malleable alloy. This was hammered into a die—a simple half-round channel cut in a block of steel—the two ends of the bar were brought together, joined with a bit of gold solder, and in this way a finger ring was formed, which was afterwards taken away by the lecturer to be finished in the lathe. But before this was done Mr. Webber begged on behalf of the Club that the ring would be accepted and worn by the Hon. Secretary, Mr. Godfrey. And so a very pleasant episode and an interesting evening closed. We understand that Mr. Webber has consented, at the request of the authorities, to repeat this demonstration of gold working at the Photographic Convention, which meets at Newcastle in the summer.

On the 29th ult. the subject which occupied the attention of the Club was of a very different character. Mr. Burchett, a member well known as a capable painter as well as a photographer, gave an interesting discourse concerning landscape composition and arrangement, and was able in the course of his remarks to refer to the various excellent studies from his easel which hung upon the walls of the club room. But he depended more upon the examples which he executed in charcoal on large sheets of paper in illustration of his words.

Mr. Burchett commenced his paper by stating that a mere transcript of nature was incapable of giving much pleasure to the beholder, especially when, as in photography, the charm of colour was absent. In making a picture certain conditions of construction were necessary so as to develop the chief beauty of the subject, and that beauty might show itself most in foreground, the middle distance, or the sky. In every case the other parts of the picture must be subservient to this principal part, where beauty most resided. With regard to the general arrangement of a picture, it might be grouped under three different kinds of composition, namely, the angular, the pyramidal, and the circular, and in order to show how these three could be worked out, and how, in many cases, they overlapped one another, Mr. Burchett proceeded to draw with black chalk many striking examples. Thus the angular method of composition was illustrated by a cliff scene with a dark rocky foreground, all on one side of the canvas, which the artist proceeded to "balance" by the interposition of cloud forms on the other side.

The next formal method of composition to be illustrated was the pyramidal, used much by the old masters in their paintings, if we except the very early ones. In this case Mr. Burchett rapidly drew a ship lying idly by a quay, with a fisherman's hut to lend interest to the scene, the whole composition being comprised in lines which formed a pyramid, the base of which was the bottom edge of the canvas. The circular type of composition gave opportunity for another seascape, in which the sweep of a broad bay was balanced by the circular form of the clouds overhead. It was shown that, although this matter of balance in a picture was most important, it could be abused. For example, Mr. Burchett drew rapidly a landscape having a ruined mill at one side, and showed how the picture could be spoiled by putting a similar erection on the side opposite. Such a combination would, of course, be far from impossible in Holland, but it is constantly found that Nature requires considerable alteration before the items which she offers so lavishly to the artist can be welded into a picture.

Mr. Burchett was then able to show that there were many pictures, full of charm without formal composition, which depended upon their decorative effect and upon what he called rhythm. As examples, he showed sketches illustrative of the rhythm in sky and sea, and the rhythm of a ploughed field, and of growing corn. He followed these examples by pictures woven out of the rhythm of lines and curves. The lecturer

concluded his remarks with an exhibition of lantern slides, which emphasised his previous words. Most of these were taken in the winter time, amid the northern heights of London, and the lecturer urged upon his hearers that they missed many chances of taking lovely landscapes by putting away their cameras as soon as the cold weather set in.

Mr. Burchett's lecture was followed by an interesting discussion, which was initiated by the Chairman, Mr. Porter, of Eton College, in a few well-chosen words. Mr. Humphery said that he was delighted to hear from an artist of Mr. Burchett's eminence that picture-making was possible without sticking to absurd rules. The most lovely thing in nature was a lovely woman, and yet no one could seriously contend that the female form was either angular, pyramidal, or circular. After this the discussion began to drift in the old groove, photography as opposed to art, and the well-known ideas were once more trotted out by various speakers. But all acknowledged that they were under a debt of gratitude to Mr. Burchett for an excellent and painstaking discourse.

#### WEST SURREY PHOTOGRAPHIC SOCIETY'S EXHIBITION.

THE West Surrey Photographic Society held its Twelfth Annual Exhibition of members' work at the rooms of the Society, the Railway Hotel, Battersea Rise, S.W., on the 28th, 29th, 30th, and 31st ult.

In reviewing the Exhibition of the West London Photographic Society a few weeks ago, we felt it our duty to call attention to the unfortunate propensity of the members to confine their studies to a very small number of the many classes of subjects which are available for treatment by photography, with the result that their Exhibition gave one the impression that the members instead of cultivating originality were content to copy one another. What we said of the West London Society Exhibition we might say almost word for word of the Exhibition at present under review. The West Surrey Exhibition was divided into four classes, and, counting the Seascope Class as one with the Landscape Class, the classification usually adopted, the combined class contained no less than three-quarters of the entire number of exhibits. This proportion would not be too great, perhaps, had a fair amount of diversity existed in the class of scenery or even in the style of treatment, but it really seemed as though the Exhibition consisted almost entirely of the work done at some half-dozen of the Society's outings and that it was the custom of the members on these occasions to place their cameras in a row, each endeavouring to get as nearly as possible the same picture as his neighbour. While we fully recognise the pleasure and the educational good that may be derived from such excursions and the benefit the Society may also derive from the promotion of good fellowship amongst its members, if the result of them is to be the reduction of all the work done to a monotonous equality of subject, character, and quality, each member had better make his excursions in search of the picturesque under conditions which will necessitate the exercise of his power of selection.

Naturally, in a Society Exhibition, any tendency on the part of the members to follow in a beaten track is more noticeable than at other times; but one of the principal objects in holding an exhibition is to demonstrate to those exhibiting wherein is scope for improvement in their work, and we trust the members will follow the indication which must have been as clear to themselves as it was to us.

We have mentioned that the branches of photography other than landscape, &c., were evidently in little favour, with the exception of a passable figure study, the Portraiture Class being extremely weak. The remaining class, which included all other subjects, had a few small architectural studies which were not without merit. One or two fruit and flower pieces were passable, and a number of specimens illustrating an application of photography to the designing of patterns were interesting. A series of "zoo" pictures contained several that were very good examples of animal photography.

The Exhibition was well arranged, but one or two of the exhibitors indulged in plush and other gaudy frames, which ought to have secured the rejection of their exhibits.

In spite of our strictures, we must say that, as a whole, the work was distinctly in advance of that shown last year. In most cases the photography was technically good. The work was generally small in size, and the few enlargements there were not as a rule particularly successful.

The Judges were Colonel Gale and Mr. J. Taylorson.

#### AWARDS.

- Class I.—Landscape: Messrs. W. G. Rowse and I. E. Meadowcroft.  
 Class II.—Seascope: Mr. S. Smith.  
 Class III.—Portraiture: Withheld.  
 Class IV.—Other Subjects: Mr. T. G. Tryhorn.

## Our Editorial Table.

#### THE "HOLBORN" DISH COVER.

Manufactured and sold by George Houghton & Son, 88 and 89, High Holborn, W.C. THE "Holborn" dish cover is designed to protect plates from the light during development, fixing, &c. It is made of xylonite, and fits any dish

of the same material. As may be seen from the illustration, the cover can be slid on and off with the greatest ease. Messrs. Houghton rightly point out that it is advisable to keep a plate protected during development

even from the ordinary non-actinic light of a dark room. When the plate is under-exposed and requires prolonged development, this is especially the case. This cover will make a dish sufficiently light-tight to allow even of actinic light being used in the dark room if necessary.

THE Photographers' "Peerless" Note Book, which Messrs. George Houghton & Son, of 88 and 89, High Holborn, are issuing, should be found in the waistcoat pocket of every amateur photographer. Many useful data relative to exposure are given, and there are numerous spaces for making records of exposures. A railway accident insurance policy and other features, constitute the Peerless Note Book a useful thing to carry about.

MESSRS. ELLIOTT & SON, of Barnet, have recently given publicity to their announcement that they have placed on the market the "Medium" plate, for field and studio use, to supersede the "Studio" plate, which by reason of its name, was but little used by amateurs. We have made camera tests of the sample of the Medium plate sent us, and found them highly sensitive, giving images of remarkable softness and freedom from granularity. For portrait work, in particular, the Medium plate seems to us to be particularly well adapted, and, no doubt, during the season just opening, it will be in great request for that purpose.

*How to Use Collodion Emulsion Successfully* is the title of a little book issued by Messrs. Penrose & Co., of Upper Baker-street, Lloyd-square, E.C. It is very freely illustrated, and the instructions and formulae are both terse and authoritative. The book appeals to process workers, who should find it of the highest service in making negatives for half-tone engraving.

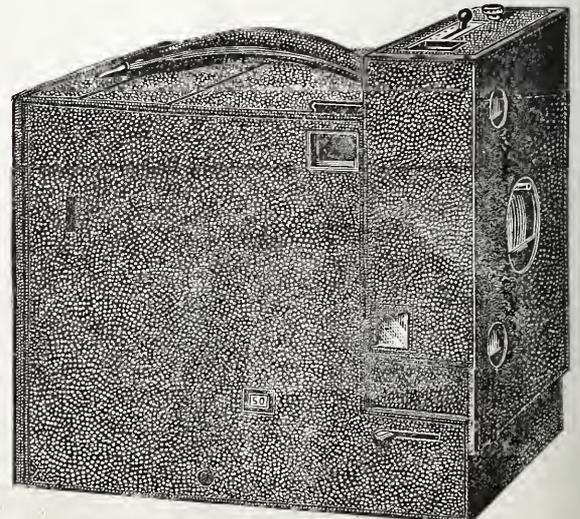

MESSRS. PERCY LUND & Co., of Bradford, have recently made some additions to their very useful series of Nature mounts. These are supplied in a variety of neutral tints, and, from actual use, we can readily say that these mounts make very effective and artistic supports for photographs. They are supplied in packets or sheets. Messrs. Lund say that there is scarcely a postal club in the kingdom where these mounts are not extensively employed.

Mr. JONATHAN FALLOWFIELD, of 146, Charing Cross-road, London, W.C. sends us his Lists of "Job Lines," which he is now offering for sale. No. 1 is devoted to apparatus; No. 2, to dry plates, films, papers, &c.; No. 3, to mounts of all kinds, for views or portraits; No. 4, to general photographic goods. We can recommend these lists to those of our readers who are on the look-out for bargains in photographic apparatus or material. They are all sent post free on application.

#### THE 5x4 "TELLA" HAND CAMERA.

Manufactured and sold by the Tella Camera Company, Limited, 110 Shaftesbury-avenue, London, W.

THE 5x4 size of plates or films, which at one time was very popular with amateur photographers, seems, after a period of comparative neglect

to be regaining much of its former share of notice, and the Tella Company, wisely taking advantage of this circumstance, are this season making a feature of supplying the Tella Hand Camera in two sizes

quarter-plate and 5×4. It is due to the introduction of the camera for taking the larger film that we have been enabled once more to put the Tella to practical trial in the field. Our most recent experience of this clever changing system, which removes an exposed film from the focal plane, places a new one in position, and indicates the number of exposures made, by the simple in-and-out movement of a sliding-frame in the base of the camera, is that it works with unerring certainty. In the way of film-changing methods we know nothing so simple and effective. But the entire camera is a marvel of concentrated ingenuity applied to the prime purpose of imposing the least possible trouble on the photographer. Simple lever movements control the focussing scale, the lens aperture, and the speed scale. You set the shutter by pulling out one little rod, and the release is effected by a touch of the finger on another. A lens of high quality, two exceedingly brilliant finders, and horizontal and vertical fronts, summarise the remaining features of the Tella camera, which is beautifully finished, and so compact that its dimensions are kept within the small space of 9×7×5 inches. It is two years since we first tried the Tella camera. After this comparatively long interval in hand-camera history, we remain of the opinion that the Tella changing system is one of the most notable achievements in mechanical ingenuity to be found in modern photography.

## Studio Gossip.

A FIRE, caused by the vapour of spirit coming in contact with flame burst out one morning last week at 146, Strand, W.C., in a building occupied, in the upper floors, by the Strand Engraving Company, and, on the ground floor, by W. Christmas, hosier. Two rooms, occupied as a studio, were gutted, and the rest of the building was damaged.

"HE STOOD ALONE."—In her recently published article on Lord Beaconsfield, Lady Dorothy Nevill tells the following story: "I possess several old-time photographs of Lord Beaconsfield, and about one of these I cannot help relating the following anecdote: The picture in question was given me by Mrs. Disraeli, and in doing so she somewhat indignantly said, 'Fancy, the photographer actually wanted Dizzy' (so she always called him) 'to be taken standing near a chair, but I soon settled that, for I said Dizzy had always stood alone, and he shall continue to stand alone.'"

THE WAR AND PHOTOGRAPHY.—According to "Dagonet" in the *Referree*, the war has had its effect on the sale of photographs. The heroic male has, for the time being, taken the wind out of the sales of the graceful female. Mr. Alfred Ellis, of Baker-street, states that, since the war fever set in, he has a far greater demand for officers than he has for actresses. At the present moment you can count in the shop windows ten Baden-Powells to one Mabel Love. After Baden-Powell, the popular photographs are, of course, Lord Roberts and Lord Kitchener, but "B.-P." heads the list of sales by a good margin.

MR. FISHER UNWIN is publishing a book which Mr. Oliver G. Pike has been writing on wild bird life. Mr. Pike is a photographer, and here he gives pictures of British birds and their nests amid nature's surroundings. Some of the photographs were hard to get, and the difficulties and disappointments of the task are recounted. Mr. Pike's observations on birds have, like his pictures, been gathered first hand. The larger part of his volume refers to the birds which frequent woods, fields, hedgerows, and streams—the great bird world. In other chapters, however, he writes of the birds that are peculiar to the Norfolk Broads.

PENALTIES OF GREATNESS.—The penalties of greatness are, indeed, numerous, and increasingly so. The *Sydney Evening News* recalls the fact that that when Admiral Dewey, after the Battle of Manila, met General Greene, of the United States Army, he invited him to his cabin, with the remark, "Come and see my family." The "family" consisted of hundreds of photographs of babies—fat babies, thin babies, pretty babies, ugly babies, good-humoured babies, bad-tempered babies, and every other possible variety. "This is my family," said Dewey, "they are all George Deweys, and their parents have sent me all their photos."

MR. J. G. MAINDS, of 7, Huntly-terrace, Shettleston, Glasgow, writes: "I often notice you are approached through Correspondence columns of THE BRITISH JOURNAL OF PHOTOGRAPHY for advice on studio building. This week you have 'ANXIOUS INQUIRER.' Some of these people are really anxious, and, as I have a large and varied experience of studio-building—indeed, it is a hobby of mine—and am at the same time a professional photographer of some standing, I think I could help some of them, by way of preparing plans and estimates, better, I find, than any architect I have yet employed for the purpose. I should be glad if you would put me in communication with any of your correspondents."

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, April 11, 1900, at eight o'clock. Members' Open Night.

The South London Photographic Society's Easter Excursions are to Salisbury, Romsey, Wilton, and Stonehenge, under the leadership of Mr. A. E. Allen, and to Wells, Glastonbury, and Cheddar. Friends of kindred societies are welcome.

ROYAL PHOTOGRAPHIC SOCIETY.—Ordinary Meeting, Tuesday, April 10, at 66, Russell-square, at eight p.m. "The Municipal Encouragement of Photography," by Thomas Bedding. The Exhibition of photographs by the National Photographic Record Association will close Saturday, April 21. Admission on presentation of card, ten to four.

MR. R. W. PAUL, of 44, Hatton-garden, kindly sends us two bromide prints from negatives received last week from a military friend at Paardeberg, one showing Cronje in his cart about to start for Capetown after his surrender, which scene is taken in Lord Roberts's camp at Paardeberg, and also a view of the Boer shell-proof pits in their camp, showing the camp exactly as it was left by Cronje's army on its surrender.

YORKSHIRE PHOTOGRAPHIC UNION.—The following gentlemen have been elected as the officers of the Union, 1900-1:—*President*: Mr. Percy Lund.—*Vice-Presidents*: Mr. Godfrey Bingley (Leeds), Dr. Hollingworth (Hull), and Mr. J. H. Rowntree (Scarborough).—*Treasurer*: Mr. Alexander Keighley, F.R.P.S.—*Hon. Secretary*: Mr. Ezra Clough. The Annual Excursion has been arranged to take place on Saturday, June 23, 1900, to Fountains Abbey and the immediate neighbourhood.

THE NEWCASTLE CONVENTION.—On Thursday, March 29, there was a meeting in London of the Council of the Photographic Convention of the United Kingdom. Mr. C. H. Bothamley occupied the chair, and there were present Messrs. F. A. Bridge (Hon. Secretary and Treasurer), S. B. Webber, J. L. Lyell, E. J. Humphrey, S. H. Fry, Thomas Bedding, A. Cowan, W. E. Dunmore, H. Snowden Ward, and E. J. Wall. Nearly the whole of the details for the meeting next July were discussed and settled.

ON the 22nd ult. the Brixton and Clapham Camera Club held a smoking concert, organized by the popular President of the Club, Mr. W. E. Dunmore. A capital evening's entertainment was provided by some accomplished vocal and instrumental performers, including Mr. H. Vivian Hyde, the Messrs. Fraser (banjo duettists), Mr. Walter Howard (son of the famous Moore & Burgess Minstrel of that name), Mr. Aubrey Wills, and many others. In the course of the evening a collection was made for the *Daily Telegraph* War Fund.

THE Plymouth Photographic Society has been fortunate in securing as Judges of its Sixth Annual Exhibition, to be opened on May 23 next, Dr. P. H. Emerson, F.R.P.S.; Dr. Aldridge, of Plympton, an amateur artist and photographer; and Mr. H. R. Babb, who, in addition to being the Head Master of Plymouth's oldest school of art, is a photographer. Entries close on May 9, and, with double fees, a week later. Silver and bronze medals and certificates of merit are offered for landscape, figures, architecture, and lantern slides in members' and open classes.

THE Royal Meteorological Society attained its jubilee on Tuesday, April 3 having been founded on April 3, 1850. The celebration of this fiftieth anniversary was commenced at a Commemoration Meeting held on Tuesday after-noon, when the President, Dr. C. Theodore Williams, delivered an address. A *conversazione* was held at the Royal Institute of Painters in Water Colours in the evening. In addition to the pictures in the Galleries, there was also an exhibition of meteorological instruments, models, and photographs, and lantern demonstrations were given by Colonel H. M. Saunders, Mr. T. C. Porter, and Mr. W. Marriott. On Wednesday, April 4 there was an excursion to the Royal Observatory, Greenwich, and a dinner at the Westminster Palace Hotel. As a memento of the jubilee of the Society, a bronze commemoration medal, bearing on the obverse a portrait of Luke Howard, F.R.S., has been struck.

THE Copyright case of *Hussey versus Harmsworth* was tried before Mr. Justice Ridley and a common jury last week. It was an action to recover penalties and damages for an alleged infringement of copyright in photographs. Mr. Rentoul, Q.C., and Mr. Watt appeared for the plaintiff, and Mr. Robson, Q.C., and Mr. Scrutton for the defendant. The plaintiff was Mr. Charles Hussey, a journalist and photographer, and the defendant, Mr. Richard L. Harmsworth, proprietor of *Golf Illustrated*. The case for the plaintiff was that, without his licence or permission, the defendant reproduced in his work, published in June 1899, copies of three photographs which he took at the Romford Golf Links. These photographs had previously appeared in two other publications with the plaintiff's permission. As soon as he saw the reproduction by defendant, the plaintiff registered his copyright in them under the Act of 1862, and he claimed penalties imposed by that Act for subsequent publications, besides damages and an injunction. The defence was that permission to reproduce the photographs was obtained from the publishers of the works in which they first appeared, but legal objections to the plaintiff's claim were also raised, involving the interpretation of certain clauses of the Act. Ultimately the parties agreed to judgment for the plaintiff for 20l. and costs on terms. The learned Judge said he thought that was a very reasonable arrangement.

AFFILIATION OF PHOTOGRAPHIC SOCIETIES.—A meeting of the Executive Committee was held on Tuesday, March 27, at 66, Russell-square, Mr. H. Snowden Ward in the chair. Steps for the acquisition of an illustrated lecture on "Gothic Architecture" were taken, and an announcement will be made in due course. Further business respecting the Conference of the Lancashire and Cheshire societies was transacted. A report was received from the Sub-committee on the possibility of getting together a lighter collection of pictures for circulation. This is not intended to supplant the existing collection, but it is expected to be useful for one-evening shows where it is not wished to incur the expenses of carriage of the larger collection. Replies from the authors of Affiliation lectures who are willing to read their papers for a consideration were received. Their names will be indicated in the *Photographic Red Book*, and the terms can be ascertained from the Secretary. Final arrangements for the revision of some of the above lectures were made, and the work will be effected during the summer months. The following lectures and slides are likely to be soon ready for circulation: "Scenes on the Pennsylvania Railroad," with notes; "Royal Meath and County Wicklow," 100 slides, with

notes by members of the South London Photographic Society; "Tinworth's Panels," seventy slides, and notes upon his life; "Colour Photography up to Date," by Mr. E. J. Wall; "Architectural Photography Pictorially Considered," by Mr. H. W. Bennett.

**THE NATIONAL PHYSICAL LABORATORY.**—Mr. R. T. Glazebrook, F.R.S., Director of the National Physical Laboratory, Old Deer-park, Richmond, Surrey, has issued a circular letter respecting this newly formed establishment. In the year 1898 a Treasury Committee, of which Lord Rayleigh was Chairman, recommended the establishment of a National Physical Laboratory for standardising and verifying instruments, for testing materials, and for the determination of physical constants, by the extension of Kew Observatory. At the request, and with the support of Her Majesty's Government, such a National Physical Laboratory has been established, and the Royal Society have appointed an Executive Committee to manage it, and, among other duties, to control the work which has in the past been carried out by the Kew Observatory Committee at the Kew Observatory. This work has been transferred by the Kew Committee to the Royal Society. The Executive Committee, of which the President of the Royal Society is Chairman, Lord Rayleigh Vice-Chairman, and the Permanent Secretary of the Board of Trade an official member, includes representatives of the Royal Society, the Kew Committee, the Institutes of Civil, Mechanical, and Electrical Engineers, the Iron and Steel Institute, the Society of Chemical Industry, and the Institute of Naval Architects. It is the intention of the Committee to continue and extend the work of testing scientific instruments hitherto carried on at the Kew Observatory, and they believe that this will be benefited in every way by the increased facilities for experimental investigation afforded by the resources of the Laboratory. The Committee are glad to add that Dr. Chree, together with all the present members of the Observatory staff, have consented to transfer their services to the National Physical Laboratory, so that the continuity of the work will be fully maintained. Certificates will bear the heading, "National Physical Laboratory, Richmond, Surrey," and will be signed by the Director. Instruments and other articles sent for testing should be addressed to the Director, National Physical Laboratory, Old Deer-park, Richmond, Surrey.

LAST week there was a Torchlight Carnival at Penge in aid of the *Daily Telegraph* War Fund. We learn from the *Beckenham and Penge Advertiser* that, conspicuous amongst the illuminated premises, the front of the Platinotype Works was bright with Chinese lanterns and electric fairy lamps, and that one of the most striking and picturesque ornaments in the procession was a perfect copy of the new Vickers quick-firing gun, manufactured entirely at the Platinotype Works, Penge, under the sole direction of Mr. J. Smith, the engineer of the Company. As regards size and bore this ornamental weapon is an exact copy of the 4.7 inch naval gun which played so prominent a part in the defence of Ladysmith, but in detail it is a reproduction of the latest and most successful quick-firing gun, manufactured by Messrs. Vickers, Sons, & Maxim, Limited, to the order of the United States Navy. The dimensions of a somewhat smaller gun, a three-inch model, were copied by permission of Messrs. Vickers, and every detail has been most faithfully reproduced by Mr. Smith and the employes at the Platinotype Works. The length of this cleverly made model is twenty-one feet. It is most substantially put together, as may be gathered from the fact that, although almost entirely composed of wood, it weighs just upon ten hundredweight. The interior is lined with metal, and the construction of the real weapon has so far been followed as to make it possible to fire the model. This has been accomplished by a very ingenious plan, devised by Mr. Smith himself. The only ammunition, if such it can be called, that is used is compressed air and hydrogen gas, but this gives a tremendous report, and on trial within the works several windows were shattered; and therefore it was not thought desirable to bring the gun into action while in procession. The pattern Vickers gun can be fired every five seconds, but Mr. Smith can do even better than this with his adaptation, though probably it would not be so effective in actual warfare. The gun is mounted on the new type of Naval conical mount, and the cradle and hydraulic buffers with which the recoil is regulated have all been very ingeniously copied in the manufacture of the model. In fact, at a very short distance, it would be impossible to pick out the model from the actual gun, and this similarity has been rendered all the more striking by the coat of paint in which it appeared. The free movement of the model has been carefully arranged for, and it can be run round, elevated, or depressed, and, in fact, behaves as a proper naval gun should. The shield only was omitted, and it was found impossible to include this as there was some danger of the top colliding with the bridges *en route*. The whole was placed on a car drawn by four horses, with mounted men in R. H. A. uniform, and a number of formidable-looking armour-piercing shells carried alongside to complete the effect. The gun crew, smartly attired in the regulation naval costume, stood to the "ready" on either side, and completed the effect, the reception with which they were greeted testifying to the great popularity of the tableau. We have been favoured with a photograph of the gun and its crew. The former looks astonishingly real and workmanlike, and the Jack Tars appear quite capable of casting aside mimicry and rendering a good account of themselves in actual warfare. We congratulate all concerned in the construction and exhibition of the Penge quick-firer, which, rumour says, will be "let off" on the night of Mafeking's relief.

## Commercial Intelligence.

MESSRS. J., J. J., & T. G. BLUNDELL, refiners and dealers in gold, silver, sweep, &c., of Wardour-street, W., have removed to No. 199 in that thoroughfare, and not 190 as stated in a previous paragraph.

**LONDON STEREOSCOPIC AND PHOTOGRAPHIC COMPANY.**—The report of the Directors for the year ended December 31 last recommends that a dividend at the rate of four per cent. per annum, less income-tax, be paid on April 6, and that 241L. be carried forward to the current war.

The Thornton-Pickard Manufacturing Company send us a new edition of their illustrated catalogue, printed in the Spanish language. They now issue four distinct catalogues—English, French, German, and Spanish—and will be very pleased to supply any of our readers who have friends in the different countries where these languages are spoken with a catalogue to send to them if they are interested in photography.

MR. HENRY F. PURSER, of 33, Hatton-garden, E.C., inform us, that under the name of the Busch Camera Company, he intends to supply the photographic trade with a series of hand and stand cameras, ready fitted with Busch lenses. This step has been taken as a result of the increased popularity of these lenses and a desire continually expressed in the photographic world to be able to buy ready-fitted cameras with the Busch lenses.

MESSRS. R. & J. BECK, Limited, of 68, Cornhill, London, E.C., are introducing a new Frena film, "The Tropical" (Austin-Edwards'), which are specially manufactured to resist tropical climates. The emulsion is rapid, being slightly faster than the Austin Edwards' Instantaneous. It is manufactured on a new formula to ensure the maximum power of resisting deleterious climatic influences. The films are packed in tinfoil and oiled paper; nevertheless, Messrs. Beck recommend as an extra precaution that films in damp and hot climates should always be kept, when not in use, in the tin boxes sealed with surgeon's plaster, which they supply for this purpose.

## Patent News.

THE following applications for Patents were made between March 19 and March 24, 1900:—

PROJECTION APPARATUS.—No. 5292. "Improvements in Projection Apparatus." Complete specification. J. J. FRAWLEY.

APPARATUS.—No. 5307. "Improvements in Photographic Apparatus." E. A. HARDY.

VIGNETTING FRAMES.—No. 5424. "Improvements in and relating to Vignetting Frames for Photography." R. BURGESS, JUN.

DARK-ROOM LANTERNS.—No. 5564. "Improvements in Dark-room Lanterns." Complete specification. A. C. JACKSON.

DARK SLIDES.—No. 5583. "Improvements relating to Dark Backs and Holders therefor for taking successively several Photographs on the same Plate." C. LAUX and H. KRANZ.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
9.....	Bradford Photo. Society .....	<i>Wensleydale</i> . George Thistlethwaite.
9... ..	Glasgow and West of Scotland .....	Annual Lecture Competition.
10.....	Birmingham Photo. Society .....	{ A Loan Collection of Lantern Slides from Various well-known Workers.
10.....	Hackney .....	{ Latest <i>Vexol</i> Printing. Donald C. Nightingale.
10... ..	Isle of Thanet .....	<i>Portraiture</i> . Harold Baker.
10.....	Leeds Photo. Society .....	{ <i>Chance Shots taken on a Business Journey</i> in Switzerland. J. H. Walker.
10.....	Royal Photographic Society .....	{ The Municipal Encouragement of Photo- graphy. Thomas Bedding.
11.....	Bootle .....	Prize Slides.
11.....	Croydon Camera Club .....	Conversational Meeting.
11.....	Photographic Club .....	Members' Open Night.
12.....	Leigh .....	{ <i>The Hand Camera; its Use and Advan- tages</i> Mr. Lythgoe.
12-18 .....	Liverpool Amateur .....	Excursion: Ludlow and District. Leader, Paul Lange.
12-17 .....	South London .....	Excursions: Salisbury, Romsey, Wilton, and Stonehenge. Leader, A. E. Allen. —Wells, Glastonbury, and Cheddar.
13.....	Croydon Camera Club .....	Excursion: Cuckfield and District. Leader, W. H. Rogers.
13.....	Whitby .....	Members' Work and Apparatus Night.

### ROYAL PHOTOGRAPHIC SOCIETY.

APRIL 3,—Lantern Evening,—Mr. J. J. Vezey in the chair.

The decision of the Council of the Society to inaugurate a series of lantern evenings, to be held monthly from November to April inclusive, has been amply justified by the success of the meetings which have taken place during the session, which terminated on Tuesday evening. The lecturers chosen have been recognised, both as authorities upon the subjects with which they have dealt, and as masters of the art of lantern-slide making; and the large audiences which have assembled on each occasion have thoroughly appreciated the excellent provision made for their entertainment, a considerable number of ladies having accepted the special invitation which is given to them to be present at the interesting and enjoyable gatherings. There has been no

monotony about these lantern evenings, for a pleasing variety of subjects has been illustrated, the list including *Medieval Towns of Germany*, by Mr. J. J. Vezey, with slides by Commander Gladstone; *Ely Cathedral*, by Mr. F. H. Evans; *Round about the Matterhorn*, by Mr. H. Speyer; *Shakespeare at Home*, by Mrs. Snowden Ward; *Beauty Spots of British Scenery*, by Mr. J. A. Hodges; and Mr. F. P. Cembrano's series of slides referred to below. Having regard to the entirely satisfactory result of the experiment, there can be no doubt that the Council will arrange for the monthly lantern evening to become a permanent feature of the winter session of the Society.

SLIDES NEW AND OLD.

Mr. F. P. CEMBRANO, who has, during the past few years, unfortunately almost entirely discontinued photographic work, exhibited a collection of slides, which he grouped together under the above title, and which, for technical and artistic excellence, would be difficult to beat. Beginning with some winter scenes in the neighbourhood of Richmond, which proved that it is not necessary for Londoners to go very far away in their search for good subjects for the camera, he next showed a number of Convention views, taken in Scotland, and these were followed by some fine studies of sheep and cattle, photographs of the Norfolk Broads, and many other very interesting and beautiful pictures. The final series were from negatives taken in Seville. The Cathedral, in size inferior only to St. Peter's at Rome, being 415 feet long, 293 feet wide, and 150 feet high to the roof of the nave, was illustrated by several interior and exterior views, one of the Giralda, a bell-tower of Moorish origin, the lower part of which was built in the twelfth century, being especially noticeable. The Casa de Pilatos, or house of Pilate, in which Pontius Pilate is said to have lived, was represented by two or three slides, but the most beautiful of all were those of the Alcazar, the chief relic of the Arab dominion in Seville, and a building which, in interest and beauty, is excelled only by the Alhambra and Granada. The photographs of the wonderful halls and courts of the Alcazar were received with repeated applause and much admiration. At the conclusion of the Exhibition, Mr. Cembrano showed a reproduction of one of the pellicles sent by pigeon post during the siege of Paris, containing several pages of news from the beleaguered city, and he presented the slide as an addition to the Society's collection.

COMING EVENTS.

At the Ordinary Meeting to be held on April 10, Mr. T. Bedding will read a paper on "The Municipal Encouragement of Photography." At the Technical Meeting on April 24, Mr. Bridges Lee, M.A., will deal with "The Latest Developments of Metro-photography." On Wednesday, April 25, Mr. F. H. Evans will open an Exhibition of his works, mainly architectural, which will remain open until May 25. There will be no meeting on April 17 (Easter Tuesday).

PHOTOGRAPHIC CLUB.

MARCH 28,—Mr. Hans Müller in the chair.

Messrs. J. J. GRIFFIN & SONS' representative gave a demonstration of the now well-known Velox printing papers, and in the course thereof answered a number of questions put to him by the meeting. It was, he said, impracticable to use Velox paper for direct enlarging on account of its slowness, but, for contact printing, he claimed for it a great superiority over bromide paper, both for its clear whites and pure grey-black deposit. There was no suspicion about its permanence. Prints made in 1897 showed now no signs of deterioration, and he saw no reason to expect any. Velox paper seems to have both species and varieties. That known as Carbon Velox is especially for contrast; Special Portrait Velox is most suitable for general purposes and soft effects. Brilliant results may be secured from thin, flat negatives on Carbon Velox, which, with an average negative, would tend to give chalkiness. It is called Carbon because of the deep black colour of the images obtained, and the name must not be confounded with the carbon printing process. Warm tones on Velox paper may be secured with kachin developer, and one or two prints were made. The speeds of Carbon and Portrait Velox were given roughly as four to nine respectively. It seemed to be not altogether certain that a number of warm-toned prints, which should be quite uniform in tone, could be obtained from one negative without developing them all at one time in one dish, and this, of course, is somewhat of a drawback. During a discussion regarding the relative claims of bromide paper *versus* Velox paper, the demonstrator championed the cause of the latter paper, and, although the meeting was not prepared to agree with all he said on this matter, it was conceded that the results upon Velox paper were very satisfactory and often beautiful. A quality peculiar to Velox is that one cannot develop beyond a stage decided by the exposure received. With a correct exposure no over-development can take place, but a sufficient exposure must always be given. In other words, there seems to be little latitude in exposure. It was also asserted that no variation of distance in exposing the paper to the gas or other light would alter the contrast of the result. There is thus no inducement to protract the exposure with that hope. An acid fixing bath with a hardening agent is recommended, because of the large quantity of alkali used in the developer. After such treatment, prints may be toned in hot hypo and alum at 104° without hurt. The paper is a loosely wove paper and floats. On this account it is said to wash more quickly than ordinary papers. Several prints, both warm and black in tone, were produced before the meeting during the evening.

**Croydon Camera Club.**—The Tenth Annual Dinner.—The attendance at the above, held on Wednesday, the 28th ult., at the King's Arms Hotel, Croydon, was larger than for some years past, and the proceedings were kept up with all the vivacity and *esprit* of former gatherings. The "artistic temperament" seems to lend itself to mirth and brightness, so that, when, at the outset, the Chairman (Mr. Hector Maclean, President of the Club) laid down the rule that all speeches must contain at least one laugh, and must not occupy over five minutes, those present seemed to have not the slightest difficulty in complying. Indeed, laughter was the order of the evening. Mr. Albert

Spearpoint, perhaps, was the chief conspirator in the killing of "black care," his singing of the serio-comic being superb in its energy. Mr. Feast also scored up a multitude of smiles for a dramatically rendered recitation, in which a bilious beadle parodies the "Dream of Eugene Aram." Another who made his mark was Mr. Baldwin, the Paget (sur)-prise plate-polisher. His "Wail of a Banner-bearer" proved, as the President remarked, anything but a "wale of tears." The high water-mark of interest culminated with the toast of "The Croydon Camera Club." In reply, Mr. MACLEAN lightly touched upon what the Club had done during the past few months, referred to the valuable services rendered by the Hon. Secretary (Mr. W. H. Rogers), and took the opportunity to state the financial result of the "Khaki" Lantern Show, from which it appeared that, after paying all expenses, the net profit amounted to as much as 82l. 15s. 9½d., an announcement which was received with prolonged cheering. An innovation in the list was the toast to "The Kindred Societies," speaking to which the PRESIDENT stated that both he and the Club knew how to welcome any similar society, whether old or new, near or far. He added that they had already sent out some photographic missionaries to convert the "Heathens," and would gladly continue to help the young Society, which had lately been formed, under the Presidency of Dr. Fowler, with whose name the toast was coupled. Dr. FOWLER, in well-chosen words, acknowledged the broad-mindedness of the Club, and spoke of the various members who had, in different ways, helped the young Society by giving demonstrations and otherwise.

**South London Photographic Society.**—This Society held their Annual Meeting on Monday last. The Hon. Secretary presented his report, showing the membership was still increasing, and had now reached a total of 201. The meetings had been well attended, and the long period excursions a thorough success. The Annual Exhibition, held in March last, had drawn a large number of competitors in the open classes. The Society had purchased a new 12x10 outfit and the long-desired book-case. Alterations to the rules were made, the most important being the permanent election of Vice-Presidents. The election of officers for the current year resulted as follows:—*President*: Mr. C. H. Oakden, F.R.P.S.—*Vice-Presidents*: Messrs. A. E. Allen, H. E. Farmer, J. T. French, S. W. Gardner, M. Howell, and W. F. Slater, F.R.P.S.—*Committee*: Messrs. G. Brown, E. R. Bull, C. Churchill, C. F. Dickinson, A. Fellows, W. Howell, E. Mathews, E. G. Ruckes, and G. J. T. Walford.—*Delegates to the Affiliation of Photographic Societies*: Messrs. C. H. Oakden, and F. Goddard.—*Curator*: Mr. W. C. Boyce.—*Hon. Lanternist*: Mr. H. F. Mawbey.—*Captain of Cyclist Members*: Mr. H. Esler, 4, Queen's-road, Peckham.—*Vice-Captain*: Mr. F. W. Grigg.—*Hon. Treasurer*: Mr. E. A. Whitby, 26, Philpot-lane.—*Hon. Secretary*: Mr. F. Goddard, Woodlands, Vanbrugh-hill, Blackheath.—*Assistant Secretary*: Mr. S. W. Whiteman.—*Excursion Secretary*: Mr. H. E. Beckett.

**Aintree Photographic Society.**—The Annual Meeting of this Society has just been held. The general and Exhibition balance-sheets being satisfactory, the following Executive for the coming year has been elected:—*Patrons*: The Right Hon. Lord Mayor of Liverpool and City Councillors Messrs. Farmer, McGuffie, and Kelly.—*Hon. President*: Mr. Isaac E. Bennett.—*President*: Mr. John Harris.—*Vice-Presidents*: Messrs. William Lockier and Charles Henry Adkins.—*Council*: Messrs. Rigby, Lloyd, Kidd, Smith, Bamford, Watson, Heron, Ackerley, Warburton, and Ansell.—*Lanternist*: Mr. Thomas Beer.—*Treasurer*: Mr. Thomas Binnie.—*Reporter*: Mr. Daniel J. Neill.—*Secretary*: Mr. Theo. Wood, of Highfield-road, Walton.—*Assistant Secretaries*: Dr. Nixon and Mr. Ralph Walker. A syllabus for the next twelve months is in course of preparation.

FORTHCOMING EXHIBITIONS.

1900.

- April 6, 7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.
- May 23-25 ..... Plymouth Photographic Society. Hon. Secretary, W. H. Harris, 5, Clarendon-place, The Hoe, Plymouth.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

THE METRIC SYSTEM.

To the EDITORS.

GENTLEMEN,—Mr. "Free Lance" shows, in his answer (page 206 of THE BRITISH JOURNAL OF PHOTOGRAPHY), that he has a bad temper. When he uses sarcasm towards others, it is high smartness and perfect truth, while, when others use it, it is a lack of veracity. Compare his letter with that of "J. F. T.," and you will find the first one as full of empty

words, playing on the word "livre," as the second letter ("J. F. T.'s") is full of sense and facts, and easily understood by any one. Every one here (except the legal documents) uses the word "livre" to mean half a kilo, or 500 grammes, and it has no other meaning when weight is meant; and when a party asks for a pound, or half, or quarter pound, why should he feel more obliged to ask otherwise, such as 500, or 250, or 125 grammes, than an Englishman who does not ask for 16, 8, or 4 ounces of anything. As to the reference of weight as to metric system, I may add the following: A cubic metre, if filled with distilled water, will weigh exactly 1000 kilos, and a cubit decimetre will then be 1 kilo, a cubic centimetre will be 1 gramme, hence one can see how the meter and the kilogramme are related one to the other.

Says "Free Lance," "The fact is, for all ordinary purposes of life, a decimal system of subdivision of weights and measures is a failure." Proofs of this will show themselves in time in England, and peacefully, notwithstanding "Free Lance's" powerful opposition. In the meantime, if France would succumb under "F. L.'s" adverse opinions, it can stand it. However, since the metric or decimal system is used in Germany, Austria, Belgium, Italy, Spain, &c., and if not yet in America, there is a good start at it with the dollar system of 100 cents, and the other measures will follow, even if in 1821 adverse opinions were expressed; but opinions change with time. As a continuance of this would prove of little interest to the public in general, I will answer no more on this subject.—I am, yours, &c.,

A. LÉVY.  
Asnières (Seine), April 1, 1900.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

©COPYRIGHT.—COPYRIGHT asks: "If having a copyright photograph, am I at liberty to send same to more than one illustrated journal for publication, and to receive payment for each?"—In reply: Yes.

S. B. R.—We should say it is simply a case of the shutter not being set to sufficient rapidity. In No. 2 the locomotive is broadside on, and that is a difficult subject to secure quite sharply unless you have extreme rapidity of shutter and plate. In No. 1, the fact that the carriages are less unsharp than the locomotive is due to the fact that they are situated at a greater distance from the camera.

J. U. H.—1. *The Studio and What to Do in it*, by Mr. H. P. Robinson, published by Sampson Low & Co., St. Dunstan's House, Fetter-lane, E.C., might assist you. 2. Messrs. Watson, of Holborn, sell the Guerry shutter, which admirably answers the purpose. We have no experience of the one named, nor of that mentioned in No. 3. 4. Not imperative, but in our experience desirable. 5. We have not seen the apparatus.

VALUE OF LENS.—TUFFY writes: "I have placed in my hands to sell a large portrait lens, for which the late owner paid, I believe, 34*l.* 10*s.* to Messrs. Ross. It is twenty-eight inches focus, and ought to be splendid for large heads. I am asked not to take less than 12*l.* for it, and think it should be saleable at that price. Will you please say what is your own idea of the price named?"—We should say the price was reasonable to any one who wanted such a lens. By the way, we do not find any lens, of that focus and price, quoted in the catalogues of Ross. Are you sure it was made by that firm?

THE REV. GERARD W. BANCKS, of Durham House, Green-street-green, Dartford, writes that he is interested in the photography of children, and asks us to tell him where he could get any help in this branch of the art. "Are there any books published, or any collections of reproductions of photographs of child studies? Who are the chief child photographers?"—In reply: We know of no book specially devoted to the subject. As photographers of children Messrs. Byrne, of Richmond; Messrs. Speight, of Regent-street; and R. Faulkner, of Baker-street have been very successful. A study of their productions might prove helpful to our correspondent.

NOISE OUTSIDE A STUDIO.—QUERY writes: "I occupy a second-story flat (with exception of one room between my reception and workroom) at a rental of 43*l.* This room, valued at a rental of 5*l.*, my landlord has let (together with one of the basement shops) as a tailor's work-room. Noisy talking, laughter, and singing repeatedly goes on, in addition to the din of sewing machines, &c., which, apart from making my premises seem low when customers come, is most irritating and annoying. As I pay the larger rent, can I legally raise objections?"—In reply: Better consult a solicitor on the subject. You might have a remedy if the noise, &c., interferes with your business.

BATTERY FOR ELECTROTYPING.—S. SELLS asks: "What is the best form of battery for depositing copper on photo bas-reliefs?"—The Smee form is the most convenient and cleanly to employ, and it is the one in most general use where a dynamo is not available. The Daniell is also a good form for electro deposition, but we ourselves much prefer the Smee with large-size plates.

THE ORTHOSCOPIC LENS.—T. HEWILL. You have been misinformed. The orthoscopic lens is not free from distortion, but the distortion is in the opposite direction to that given by a single lens, that is, the marginal lines are curved outwards—pincushion distortion. With a single lens they are curved inwards—barrel-shaped distortion. The orthoscopic is, however, a good lens for some purposes.

COPYRIGHT.—W. A. A. says: "I have a negative that was taken by an operator of mine about ten years ago at the customer's own house, which has now become valuable to me. It was not registered at the time, and I cannot register it now in the operator's name, as he died a month or two after he took it. Can I register it in my own name?"—No. The copyright in the picture was vested in the author, and, as he has been dead over seven years, it has lapsed.

CARBON PRINTS STICKING TO GLASS.—M. WARLEY says: "Can you kindly tell me the cause of these prints sticking so firmly to the glass? The plates were well rubbed over with French chalk, and the collodion was the usual enamel collodion, allowed to set well before it was put into the water, and all the ether and alcohol was well washed out of the film before the tissue was squeezed upon it. I have been pretty successful with the carbon process, single transfer, but have only just tried glass, and all the prints stick in this way."—From the appearance of the prints, we have no hesitation in saying that the glass was not thoroughly clean when the French chalk was applied. The plate must be absolutely clean, or there will always be the danger of the prints sticking.

CONVERTING METALLIC GOLD INTO CHLORIDE.—SCUMY TYPE asks for the best way to produce chloride of gold from the metal. He has a quantity of old metal, and would like to turn it into chloride. Also, what would be the easiest way to crystallise the same?—The gold contains an alloy which must be got rid of. Put the metal in a Florence flask and pour on it nitro-hydrochloric acid—one part nitric, and five parts hydrochloric, and three parts water. A gentle heat will facilitate the solution. When dissolved, dilute with water, filter, and then add a solution of pure sulphate of iron, which will precipitate the gold. Wash well, and redissolve in acid. Then crystallise in a Berlin evaporating dish over a sand bath, but not at too great a heat.

DIFFICULTIES IN COPYING, &c.—J. H. T. writes: "I have to copy some papers, many of them stained, and some yellow, others faint, and in pencil. 1. Would a screen be any value? 2. If so, what colour? 3. If a screen no use, how can I obtain greater contrast than exists in originals? They desire them black and white, especially a black. The plate I used was photo-mechanical, speed 14, by Wynne's calculator, I am accustomed to use his infallible meter for ordinary copying, and the invaluable lens Dallmeyer's stigmatic, stop *f*.32. Please, also say what is eau-de-javelle, ALMANAC, p. 947—have an idea it is calcium chloride."—1. and 2. A screen would be of no advantage. 3. Orthochromatic plates, sensitised for yellow, would help. Give a full exposure and develop, so as to get as much contrast as possible. A full amount of pyro and a liberal dose of bromide. Eau-de-javelle is hypo-chlorite of potash, see p. 1035 of the ALMANAC.

STUDIO-BUILDING.—COUNCIL says: "I notice in this week's JOURNAL that you answer one of your correspondents, *re* Studio-building, that the district surveyor might require structure to be of brickwork and glass." I was thinking of buying a portable studio, as per enclosed, and erecting it at back of premises. Would you kindly say if it could be objected to by district surveyor, as it is only wood and glass? I understand these portable buildings are tenants' fixtures. If you think it could not be objected to, would you also say if you think them practicable for professional work? They are made up to 24 ft. long, but I have never seen one, so don't know what they are like."—The by-laws relating to buildings vary in different towns, and we are not aware how they stand in yours. We should say that the structure you propose would be allowed if it were placed at some distance from the house, but you had better consult the town surveyor. The studio, if merely placed on the ground, and not in any way attached to it, would be a tenant's fixture. The studio, as shown in the cut, would do very well for professional work, though it would be better a little longer.

PREVENTING THE ADHESION OF PRINTS TO GLASS.—J. H. P. writes: "Can you oblige with the information to prevent prints from sticking to glasses during process of imitation enamelling? I have had great waste (see prints herewith). I may say I am convinced the printer has chalked the glasses properly, also used alum, although I fancy he guessed the measurement. Would that make a difference? The washing process is, I think, right—four hours in running water (always in circulation). It does not matter how long the prints are allowed to stay on glasses, sometimes they refuse to leave without sticking in various places, so it cannot be that they are not dry enough, and I know it is possible to give them too much drying if placed too near the fire. They come off all right in summer; it is during the winter months I have this bother. Would you recommend a stove-pipe arrangement for heating the room, and have temperature a certain degree? If so, please say what degree."—If the prints are alumed and the glasses thoroughly cleaned and French-chalked, the prints should not stick. If these conditions are fulfilled, we cannot conceive why they do. We rather surmise, from the letter, that some artificial heat has been used in the drying. If that is so, the sticking may readily be accounted for.

### EX CATHEDRĀ.

THE war in South Africa is understood to have had a depressing effect on the sale of all classes of books and other publications, except those dealing with the subject which occupies such a prominent place in most people's minds just now; but we are pleased to find that those disturbing influences have left THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC unaffected. It is our agreeable duty to notify our readers that the entire edition of the ALMANAC for 1900 has been quite exhausted within about three months of publication, and that our publishers are unable to supply further copies. We may, perhaps, be permitted to cite this interesting fact as an indication of the undiminished hold which the ALMANAC retains upon its large army of readers, amongst whom are to be found all classes interested in photography.

\* \* \*

THE April number of the Camera Club *Journal* contains the following remarks: "We notice, with much regret, two paragraphs in THE BRITISH JOURNAL OF PHOTOGRAPHY of March 16

last, in regard to our report of Mr. Henry Speyer's lecture on "Round About the Matterhorn," when the Chairman made some remarks with regard to the photographic Press. THE BRITISH JOURNAL OF PHOTOGRAPHY expresses surprise that the gentlemen responsible for the editorial control of the Camera Club *Journal* should have permitted that publication to be made the vehicle of such strictures. We can assure our readers that we are anxious to be on the most friendly terms with the photographic Press, and we have a very high opinion of THE BRITISH JOURNAL OF PHOTOGRAPHY and its able and genial Editor. Any idea of casting strictures was far from our thoughts. As we have said before, the proceedings of the Club are reported fully in our *Journal*, and it must be clearly understood that remarks made at our meetings, although reported in our pages, are not to be regarded as *ex cathedra* statements of the Camera Club, or even as in any way expressing the personal views of the members of the Editorial Committee. From what we know of the Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY, we feel sure that he will accept this statement in the same spirit in which it is made." We do so unreservedly, of course, and, in closing the incident, take the opportunity of assuring the Camera Club and its *Journal* of our unabated interest in the one and our high esteem for the other.

\* \* \*

LINENDRAPERS, it is well known to our lady friends, are in the habit of marking their wares as so much three farthings. "One eleven three" is well known to be practically two shillings, as the farthing change out of that amount means a packet of pins, which, of course, carries a good profit. Cutting stationers and others are now following on similar lines, but in this case usually a lead pencil or some other trifle is given. The latest idea that has come under our notice is photographs. A friend of ours recently made a purchase at a stationer's, and a farthing change was required. "Sorry I have not a farthing, but would you mind taking a packet of these photographs?" The packet was accepted from a pile on the counter, and it contained six collotype prints of fair quality, views of the Tower of London, done up in an envelope bearing the title and the name of a well-known London house, a limited company.

The prints were of about the half-plate size, on paper about  $8\frac{1}{2} \times 6\frac{1}{2}$  inches. It is very difficult to imagine how these pictures were produced to give as a farthing change, and, presumably, carry a profit at that—that is, if they were produced with such a view. Be that as it may, they were given in the usual way for the farthing change. In face of this, one may well ask, What is photography coming to?

\* \* \*

At a meeting at the Guildhall last week, the Chairman of the Gresham Committee of the Court of Common Council, in reply to a query, said that seven out of the twenty-seven panels in the Royal Exchange had already been filled with paintings by distinguished artists, and that four more are in course of preparation. These will also be by well-known artists—one by Mr. E. A. Abbey, R.A., one each by Mr. and Mrs. Ernest Normand, one by Mr. Brangwyn; the name of the fourth artist was not given. These pictures, like the others, are the presentations of various donors. At the same meeting it was decided that the forthcoming Loan Exhibition at the Art Gallery at the Guildhall should be open to the public on Sunday afternoons.

\* \* \*

It was also stated, at the same meeting of the Common Council, that six competitive designs for the new Law Courts at the Old Bailey had been received, and that the Corporation were being assisted in their selection by the President of the Royal Institute of British Architects. Those who desire to obtain photographs of the Newgate prison and its surroundings should now lose no time in securing them, as they will very shortly be pulled down. The buildings do not, it is true, make very artistic pictures, but, although not ancient, they have great historical interest, for some of the greatest criminals of modern times have been confined, tried, and executed within their precincts. A few years hence, when the buildings have vanished, photographs of them will be interesting, and still more so to future generations. There are but few photographs now of the old Temple Bar, but they are very interesting to those of the rising generation who take an interest in historic buildings, though it was only cleared away a comparatively few years ago. So it will be with Newgate and its surroundings in the next generation.

\* \* \*

WE have frequently referred to photography as a witness in Courts of Law, but we do not remember a case in which it was employed as it was some days ago at the West London Police Court. Four well-known firms, brewers, torpedo-boat builders, soap-makers, and dyers, were summoned for permitting smoke, causing a nuisance, to issue from their chimneys. The Clerk to the Chiswick Council, in supporting the summonses, produced photographs showing the position of the chimneys and the smoke issuing from them. These photographs evidently had great weight with the magistrate, for he is reported to have said, while looking at one, that the chimney had been "caught in the very act." In one of the cases the magistrate asked the manager of one of the works what he had to say to "those silent witnesses." In the end, three of the firms were fined, on the two summonses, each five pounds, with ten shillings costs, to include the expense of the photographs, the magistrate stating that they were necessary witnesses. In the fourth case it was contended that the chimney shown in the photograph, and emitting a quantity of black smoke, did

not belong to the firm summoned, and, on a technical objection as well, this summons was adjourned. We all know that it is within the scope of a skilful photographer, in a case of this sort, to emphasise the smoke issuing from chimneys by minimising the exposure of the negative; or, on the other hand, to ameliorate it by a full, or over, exposure. Still, in any case, photography will prove that smoke, more or less a nuisance, may be issuing from the chimney shaft—another application of commercial photography.

\* \* \*

THOSE of our readers, doubtless the majority, who are satisfied that January 1 next marks the beginning of a new century may be interested to learn, on the authority of a contemporary writer, that "the first people to live in the twentieth century will be the Friendly Islanders, for the date line, as it may be called, lies in the Pacific Ocean just to the east of their group. At that time, although it will be already Tuesday to them, all the rest of the world will be enjoying some phase of Monday the last day of the nineteenth century" (December 31, 1900). "At Melbourne the people will be going to bed, for it will be nearly ten o'clock; at Manila it will be two hours earlier in the evening; at Calcutta the English residents will be sitting at their Monday afternoon dinner, for it will be about six o'clock; and in London, 'Big Ben,' in the House of Commons will be striking the hour of noon. In Boston, New York, and Washington half the people will be eating breakfast on Monday morning, while Chicago will be barely conscious of the dawn. At the same moment San Francisco will be in the deepest sleep of what is popularly called Sunday night, though really the early dark hours of Monday morning, and half the Pacific will be wrapped in the darkness of the same morning hours which become earlier to the west, until at Midway or Brook Island it will be but a few minutes past midnight of Sunday night."

\* \* \*

THE Royal Meteorological Society celebrated its jubilee on day last week, when the new President, Mr. C. Theodor Williams, read the address of the late President, Mr. G. J. Symons, written shortly before his death, supplementing it by an address by himself. In it he mentioned the history of the Society, and the work it had accomplished, and made special reference to the large number of photographs of lightning the Society had accumulated. On more than one occasion we have commented upon the value that the daily forecasts of the weather, as issued from the Meteorological Office, would be to photographers, if they were reliable or even fairly more reliable than they usually are. We have before now said that if the weather forecasting for different districts were entrusted to boatmen, farmers, and the like, we should get more reliable forecasts than we now get from the Meteorological Office. Evidently the *Standard* is of a similar opinion to ours, for, in a leading article on the jubilee of the Royal Meteorological Society, it says that "many a shrewd country labourer or Alpine guide can forecast weather for local purposes even better than a Meteorological Office." This opinion entirely coincides with ours, and, it being the case, one may well ask why such aid is not invoked. It would not absorb much of the fifteen to twenty thousand pounds which the Meteorological Department annually receives. What the public—and more particularly, photographers, farmers, and others whose work is largely dependent upon the weather—want to know

s, not what, theoretically, we ought to have, but what we shall have, notwithstanding the sources from which the information is obtained.

\* \* \*

THE ancient house facing Chancery Lane, in Fleet-street, is to be saved to London, though only by the "skin of the teeth." When the adjourned report of the General Purposes Committee of the L.C.C. came before the meeting last week, which was that the freehold of the old house, No. 17, Fleet-street, that was alleged to have been the Palace of Henry VIII. and Cardinal Wolsey, though it was really built in the reign of James I., should be acquired, an amendment was proposed that the report be referred back. The mover of the amendment is evidently no great very admirer of ancient buildings, however fine or historical they may be, for in his speech he is reported to have characterised this as a "rabbit hutch," and said it would be a wicked and wanton waste of public money if it were spent in that way. When the amendment was put to the vote, there were fifty for it and fifty-one against it, a majority of one only. The opposition to the Committee's recommendation then proposed other amendments, which, we are pleased to say, were one after the other defeated. On the original motion being put to the vote, it was defeated on a show of hands, but, on a division being called, it was carried by sixty against fifty, or by a majority of ten. Thus this interesting old house, the only relic of old Fleet-street, so beautifully described by Sir Walter Scott, is to be saved, but by a near "squeak" only, from the vandalism of a large proportion of the London County Council.

#### THE NATIONAL PORTRAIT GALLERY FROM A PHOTOGRAPHIC STANDPOINT.

AT the back of Trafalgar-square, opposite St. Martin's Church, stands the comparatively little-known National Portrait Gallery, which possesses a valuable collection of oils, water colours, engravings, crayon sketches and miniatures of British notabilities, from which photographers should be able to obtain many useful hints. It is always interesting to compare the best portrait work of the artist of the brush with that of his brother of the camera, and to notice the merits and limitations of each. The principal advantages that Art (in the painter's sense of the word) seems to possess are its power of giving us colour and colour values, and its ability to idealise, to pick and choose, rejecting bad points and retaining good, to say nothing of its greater obedience to the creative power of the artist. Granting all this, however, there still remain some things in which photography is superior, as, for instance, in delicate beauty of detail and correctness of outline. The photographer is at his best when he takes to himself the lessons of the sister arts, and learns to make the mechanical subservient to the beautiful.

Let us take a few of the paintings in this Gallery and see what instruction they may have for us. One of the first to attract our attention is an excellent portrait of the Duke of Cumberland by Reynolds. The average photographer would probably exclaim against the heaviness of the shadow side of the face; but notice the greater dignity and power thereby given to a rather weak and sensual countenance, also how the lack of detail in the dress and the dark, gloomy background serve to concentrate the attention with irresistible force on the face itself. We shall observe here and elsewhere how painters

give the features just as they are; there is an absence of any equivalent to our retouching, any attempt to soften down the unpalatable or to mollify lines and furrows, but we must remember that their power of giving the natural flesh tints allows more latitude in this respect.

Nearly opposite, Allan Ramsay's *George III.* demands our notice. The robes and drapery strike us, from a photographic point of view, as being rather stiff and wooden; we may allow ourselves a little satisfaction in the thought that the camera would have rendered them more flowingly. But consider the truly regal expression the artist has given to what, if we may believe the historians, was not a very majestic face. We, alas! can only take things as we find them, with very little ability to seize our subject's best and happiest traits.

In the next room, Sir William Allan's *Walter Scott at Abbotsford* compels our ungrudging admiration. Here photography must own itself fairly beaten, for it could never have given us that fine dark interior, coupled with such exquisite lighting of the face and figure. That delicate *chiaroscuro* with subtly hinted romance of colour is at present unattainable by us, whatever the future may have in store.

Then this portrait of the young Dickens by Maclise. We must admit at once that a photographer might spend a lifetime on his sitter, and yet fail to catch such a characteristic and illuminated expression. The very soul seems to be looking out from that face. Yes, the painter can give us his sitter's history, the photographer but the tale of a passing moment. And yet that evanescent and momentary glimpse of the man may be also satisfying and conclusive if the photographer have but sufficient tact and *savoir-faire*.

It is not only the individuality of the sitter that seems to receive more justice from the painter, but the artist himself apparently has greater scope for the exercise of his own fancy. In example of this, notice the long row of Victorian celebrities by Frederick Watts. The *ego* of the artist seems to breathe in every one of them, a soul full of poetry and love of the beautiful. The noble portrait of Tennyson is evidently one of a poet by a poet. We seem to hear the very lilt of "Maud" and "The Princess," to catch the mystic sadness of "In Memoriam," and the chivalry and self-sacrifice of "Idylls of the King," as we stand before it.

Then let us look on the thin, ascetic face of the same artist's *Cardinal Manning*. Cannot we see there history, environment, minutest idiosyncrasies shown forth that he who runs may read? Notice the value of the accessories and surroundings—the scarlet hood and skull-cap, the lace-fringed cotta, the pectoral cross. Observe the effect of the dominant colour, the princely red, a hint to us that we may perhaps make our prints in suitable pigments to obtain a special result. This face fascinates; the piercing, sorrow-laden eyes, the sunken cheeks, the thin, tightly compressed mouth, the commanding majesty of the expression.

The head of *Thomas Carlyle*, another of Watts' successes, may teach us a few lessons. Where is the photographer who would have dared to present this rugged, untamed bear as the artist has done, with all his gruffness and ill-humour so palpably plain, his shock-headedness and general untidiness all shown forth in their naked truth? And yet it is a picture that will live, a record valuable to posterity.

One very noticeable point in all the portraits by this artist is their breadth of treatment, and what we shall call great diffusion of focus. They may serve as a reminder to us that

the wealth of detail, in which some of us glory, is not always a gain, and that suppression and restraint have certain rewards of their own. We have, however, many in our ranks, nowadays, who preach and practise this doctrine, and whose work in portraiture might well be placed beside those just mentioned, and yet not lose so alarmingly by contrast.

A picture which ought not to be passed over is one of *Sir Richard Burton*, by Leighton. The effectiveness of a dark background is here strikingly illustrated, also the fact that the most natural and unaffected pose is generally the most striking. See how even a crumpled collar contributes its quota to heightening the success of the whole.

In comparing the works of earlier artists on the opposite side of this room, it is impressed upon us that, like photography, British Art has greatly improved since its beginnings. The technique and force of the latter portraits are far superior. There is a certain daubiness and vulgarity visible in the former productions that is sometimes quite painful. In the adjoining corridor we shall not fail to notice the splendid life-size portrait of *Sir James Hope Grant*, by his brother. There are various photographic possibilities here suggested that will not be lost upon the observer. There are also several fine works by Sir Thomas Lawrence, and the Count D'Orsay's *Duke of Wellington*. In the next room to this is a magnificent three-quarter length of *Charles Darwin*, by the Hon. John Collier. The masterly lighting and rendering of this massive, furrowed, silver-bearded head is well worth attentive study.

A matter on which, from our standpoint, a little self-congratulation may perhaps be excusable, is that of frames. It is doubtful whether, whatever time-honoured custom may dictate, gilt frames are really the most suitable for oil paintings. Be this as it may, there is no question that photographers have a far greater range of choice, and a better chance of getting an harmonious setting for our pictures; and, although, on the whole, the frames here exhibited are in good taste, yet in a good many cases they are glaringly unsuitable, though, no doubt, the artists were not to blame. Yes, we certainly see these things better managed at the Royal and the Salon.

It is interesting to examine the colours employed in these pictures, as far as they can be ascertained, as to their permanency or otherwise; by this means useful data will sometimes be obtained. Our spotting tint, for instance, will often become quite different and objectionably apparent after a short time, a nuisance which might have been avoided if more lasting pigments had been employed; in carbon printing also the wisdom of a similar selection is evident.

Needless to say, only a tithe of the pictures in this instructive collection can be mentioned in the limits of a short article, but it should be said that there are a large number of portraits in crayon, water colour, &c., also an array of Early English works in the upper galleries.

It has occurred to some to wonder why cannot we photographers have a National Portrait Gallery of our own! The idea is worth ventilating. Permanently housed in a good central position, a representative collection of photographs of men and women of note, in the carbon or other lasting process, might become of great historical and technical value to coming students of our times, when the founders of it should have passed away. And, as it requires some self-denial to plan for the benefit of posterity only, let us consider how useful it would be as a kind of ever-present standard for us to judge and measure our work by.

**Ammonia in Intensification.**—The paper by Monsieur F. Lateur, which appears on another page, is of interest from the very direct bearing it has upon that much-used process of intensification, mercuric chloride followed by ammonia. Several conflicting statements have been made as to the composition of the black product left on treating the mercurially bleached silver image by ammonia. M. Lateur's experiments, although not made with a view to the solution of a photographic problem but of an analytico-chemical one, do certainly show that, even after treatment with a much stronger solution of ammonia than ever used by photographers as a "blackening" reagent (Lateur's solution contains nearly ten per cent. of real ammonia,  $\text{NH}_3$ , i.e., about thirty per cent. of liquor ammonia ('880), a considerable proportion of the silver chloride is left in association with the mercury. The proportion separated by the ammonia indicates that a compound of mercury and silver exists, as suggested by Mr. Chapman Jones in his paper, "On the Product of the Action of Mercuric Chloride upon Metallic Silver," which appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY, 1894, p. 183.

**A Laminated Photographic Image.**—M. A. Trillat has contributed a paper to the *Comptes Rendus de l'Académie des Sciences*, describing the means by which he has succeeded in converting the reduced silver of a negative into a laminated condition. The object of this transformation was to ascertain if phenomena of colour interference would result. In the first place it was necessary to dissolve the image without removing any silver from the film, and for this purpose solutions were unsuitable. However, by exposing the plate to the fumes of nitric acid, after cleaning, polishing, and hardening the film, the image was obliterated. The film became quite transparent, and the silver deposit appeared to be changed into a colloidal condition. It is necessary to well polish and harden the film, otherwise the result will be inverted and yield a positive instead of a negative, also the colours will be iridescent instead of localised. To produce the laminated image, the plate is placed in a suitable receptacle and subjected to a current of sulphuretted hydrogen. The image speedily reappears with bright metallic lustre, and in vivid tints, but the action must not be carried too far, otherwise the colours lose their strength and become diffused. A negative treated in this way gives a bright, polychromatic image when examined by reflected light, and, if looked at through the glass, the colours are often complementary. The colours are not amenable to change by treatment, but moisture causes transitive variations. Generally there is no relation between the colour of the image and the object, but it seems to vary according to the density of the deposit. It therefore seems possible that the colours may be localised according to the thickness of the film, which might be made to correspond with the colours of the object.

**An Automatic Actinometer.**—The *Photo Journal* gives a report of a paper read by M. P. Donse, at a meeting of the Rouen Photo Club, describing an actinometric balance. It is an adaptation of an instrument made by Bellain in 1834. A tube, with a bulb at each end bent downwards, forms the beam of the balance. One of the bulbs is filled with ether, and the tube exhausted and hermetically sealed. As the slightest variation of temperature between both ends of the tube will cause distillation, if one arm be covered with black varnish, a thermic actinometer is formed, which may be used in the same manner as a pair of scales. Adjust the tube at equilibrium upon a pivot, and affix a long pointer to the tube at the point of suspension. This may be provided with a scale for reading the deviations of the balance. When the instrument is brought into the light, a variation of temperature will be caused between both ends of the tube. The ether will pass gradually by distillation from one bulb to the other and deflect the pointer. By means of the scale the quantity of light action may be definitely ascertained. An electric attachment may be fitted to ring a bell, or close a shutter, as soon as a given exposure has been made, and the instrument may thus be adapted to carbon printing or many other purposes.

**Colour Screens.**—*The Photographische Chronik* devotes an article to the correction of the blue filter for three-colour work, which usually transmits the ultra-violet rays in addition. Although the lens and the glass of the colour screen cut off a portion of the ultra-violet rays, there is generally a residuum of sufficient importance, to affect the result and give undue prominence to the blue in the final print. An aqueous solution of aeskulin is recommended as the most suitable means of correcting the blue filter. If the latter consists of a solution of methyl violet and basic cupric ammonium carbonate, it will not only transmit the blue, but also the violet, and a large portion of the ultra-violet rays. If a small quantity of aeskulin be added, the light between G and H of the spectrum will be cut off. A plain solution of aeskulin in water, although it has only a slight yellow tinge, is of great value as a screen for orthochromatic plates when used for landscapes, and it prolongs the exposure by only one-third or one-half. The solution will not keep for a lengthened time, and acquires a deeper yellow colour, even if kept in a stoppered glass cell. It is therefore desirable to prepare it by substituting alcohol for one-third of the water, and adding a few drops of a solution of sulphite of soda. The solution will then keep from five to eight days. It is also preferable not to add the aeskulin solution to the blue filter, but to use it in a glass cell, placed in front of the latter. When expcsing for the other colours, the cell should be emptied and filled with water only.

**Tele-photography.**—A prize is offered for the best tele-photo lens of 60 to 100 cm. focus, suitable for balloon photography. The competition is open to opticians of all nationalities, and full particulars may be obtained by application to Lieut.-Colonel Renard, Director of the Central Military Aeronautic Station, Chalais-Meudon, Seine et Oise.

**Aluminium.**—*The Deutsche Photographen Zeitung* gives some interesting statistics concerning the price and production of aluminium. Fifty years ago the metal could only be obtained by a tedious process in the chemist's laboratory, but, thanks to the intense heat of the electrical furnace, its production has now become a large commercial industry. In 1855 the entire output of aluminium was only 1300 kilos, but in 1898 the production had risen to 4,000,000 kilos. Of this quantity the United States alone produced 2,500,000 kilos. In 1855 the price was 50*l.* per kilo, but in 1856 it fell to 15*l.* From 1856 to 1886 the price was 5*l.*, but in the latter year it fell to 3*l.* 10*s.* In 1890 it stood at 15*s.*; 1891, 12*s.*; 1892, 4*s.* 9*d.*; 1894, 4*s.*; 1895, 3*s.* 2*d.*; 1897, 2*s.* 7*d.*; 1898, 2*s.* 1*d.* At the present time aluminium may be bought at 2*s.* per kilo, and it seems probable that a further reduction in price will take place.

**The Temperature of the Sun.**—According to the *Wiener Freie Photographen Zeitung*, fresh calculations have recently been made as to the temperature of the sun. From time to time extraordinary statements have been made, and the prevalent idea twenty to thirty years ago was that the heat of the sun must be estimated at some millions of degrees. The more accurate measurements of recent years have placed the estimate at much lower figures, but these have varied between 2000° and 70,000° C. The diversity of opinion is attributable to the uncertainty of our knowledge of the absorption of heat by the atmosphere of the earth, and likewise as to the variation in radiation dependent upon the temperature of a hot body. Stefan's law of radiation has been found the most reliable, and Professor Lummer's experiments show that it is correct up to a temperature of 1500° C. Upon this assumption Professor Warburg, of the Physical Institute, Berlin, calculates that the temperature of the sun is 6249° C., and it follows that, if we wish to learn under what conditions various substances exist in the sun, we must first produce such a temperature by artificial means.

**Pyrogallol and Oxygen.**—*The Photographische Chronik* publishes a short note on the action of oxygen upon pyrogallol. If caustic potash or soda be mixed with a solution of pyrogallol, to

which a preservative has not been added, each atom of pyrogallol will absorb three atoms of oxygen. If ammonia be added, four atoms of oxygen will be absorbed, but the reaction, although rapid at first, will slow down considerably. The dark brown substance thus obtained will represent eighty-five per cent. of the original quantity of pyrogallol. It is soluble in water, and its formula is probably  $C_{20}H_{20}O_{16}$ . Dioxide of carbon is formed in the process, and unites with the excess of alkali. In the first stage of the oxidation a substance is formed resembling purpurogallin; it is red, crystallisable, and soluble in ether. Its composition is  $C_{20}H_{20}O_{11}$ . When the reaction is complete, the product represents about ten per cent. of the original quantity of pyrogallol. Its formula is  $C_{16}H_{16}O_{12}$ , and it is soluble in ether also. It is only possible to ascertain by exhaustive experiments which of these two products is formed in the film in the process of development with pyrogallol.

#### A CONVENIENT FORM OF DRY PYRO DEVELOPER FOR TRAVELLING, &c.

PROCURE four tins of equal and any desired size. One is for dry pyro, the second for powdered dried carbonate of soda, the third for dried sulphite of soda, and the fourth for a bottle of bromide of potash solution.

To prepare 100 cubic centimetres of developer according to the Ilford formula, dissolve in 100 c. c. of water 2 grammes of the dry soda, 2½ grammes of dry sulphite, ½ gramme of pyro for soft, up to 1 gramme for dense negatives, and add 1 c. c. (20 drops) of bromide of potash solution containing 11.4 grammes in 100 c. cm. This gives the Ilford concentration, except that, more exactly, one should add  $\frac{1}{11}$  to  $\frac{1}{17}$  gramme of pyro. If one further substitutes a ten per cent. solution of bromide, one has a formula exceedingly simple in the proportions of the ingredients. The formula is calculated on the assumption that crystallised soda and sulphite contain forty per cent. and fifty per cent. respectively of anhydrous sodium carbonate and sulphite. If the two latter be thoroughly dried and sifted through a fine sieve, the former will dissolve in less than a minute with constant stirring, the latter in ten seconds. The pyro dissolves instantly. If the salts are at all moist, they will form lumps which dissolve more slowly; this may be avoided by first mixing them on a piece of paper.

Anhydrous sodium carbonate can be prepared from soda crystals by drying them in the oven, and there is no danger of overheating them. The anhydrous sulphite may also be prepared by drying sulphite crystals, although the sulphite will thereby be more or less oxidised to sulphate. A slight oxidation does no harm. Sulphite oxidises continuously when not kept air-tight, whether in solution, or in the form of crystals or dried salt; of these the last is the most permanent. Commercial sulphite always contains sulphate of soda, according to Dr. Andresen, sometimes twenty-five per cent., and up to ten per cent. of the more harmful hyposulphite, which may be the cause of the observed difference in the energy of developing solutions made with different makes of pyrogallol. It is therefore well to buy the sulphite ready dried, and of a responsible dealer.

A tin 1½ inches in diameter by 3 inches in height will hold 15 grammes (half an ounce) of pyro, and somewhat more than a proportionate amount of the other substances, giving 3 quarts of normal developer. The solids can be measured out with more than sufficient accuracy, after a little preliminary practice in weighing a series of measured portions. For measuring one can use a horn or wooden salt or mustard spoon, or a glass or metal spatula. The sulphite and carbonate of soda may be mixed together, and measured out in a pistol cartridge to which a handle has been soldered. Hard rubber boxes make a neat substitute for tins, and a hard rubber bottle for the glass bottle and case. With the addition of a celluloid measuring "glass," three or four xylonite trays, and a package of acid fixing salt in cartridges, blocks, or tablets, one has a compact and non-breakable developing outfit. For printing, a tin of platinum paper, another of oxalate of potash, and a hard rubber bottle for hydrochloric acid are much more satisfactory than bromide paper if one can get sunlight.

E. Merck, manufacturing chemist, in Darmstadt, Germany, sells dried sulphite and carbonate of soda at 6*d.* to 7*d.* a pound, and hard rubber bottles, and has lately introduced a very convenient form of acid fixing salt in tablets of 2½ grammes each, at 1*s.* 4*d.* a pound.

This developer is less expensive than that in tablet form, and it

enables one to easily alter the proportions of the ingredients. Moreover, one avoids thereby the bother of crushing tablets to a powder, and the trial to one's patience in bringing the larger bits into solution.

W. S. DAVENPORT.

### A CINEMATOGRAPHIC FEAT.

A CYNIC once made the sapient remark that he did not care to undertake a certain work which he was told would be of benefit to posterity, on the ground that posterity had never done anything for *him*. This man was certainly not a maker of "animated photographs," as they are called, for such pictures will, we may assume, be of infinite value to the generations yet unborn. Every public event, and more especially those in which Royalty takes part, has its attendant cinematographers, who vie with one another in alertness, both in securing their pictures and bringing them before public criticism with as little delay as possible. The interesting ceremony in which our beloved Queen took part last week in Dublin was no exception to the rule, and every movement of every person who was there was faithfully recorded by the busy lens. There was much in this ceremonial which had about it a pleasant quaintness of mediæval flavour, and it was therefore more picturesque in character than most functions of the kind. The cinematographer had, for this reason, more scope for his work, and one of them who was present, and who was fortunate enough, by the courtesy of the Lord Mayor, to obtain the unique privilege of a reserved "pitch" on the Corporation stand, has had no reason to regret his journey to Dublin and back. This was Mr. Ceci Hepworth, who secured in his camera not only a fine film of the ceremony itself, but also obtained splendid pictures showing the whole of the procession, and studies of the enormous crowd, mad with loyalty, and full of expression and movement. This entire series of cinematograph pictures has a length of 325 feet—that is, nearly seven times the usual length of such films. It is noteworthy that, on the evening of the same day upon which the negatives were taken, they were travelling to London. Early on Thursday morning they were developed at the factory at Walton-on-Thames, and on the same evening, at eight o'clock, they were exhibited to a delighted and enthusiastic audience at the London Hippodrome. When we consider the great length of this film, comprising no fewer than 5200 pictures, and remember that the negative had to be developed, fixed, and dried, and that positives from it had to go through the same operations, we must consider this a very creditable photographic feat. Positive copies of this unique film were sent the same evening by post to Dublin and other chief cities, so that the loyal inhabitants of Britain were able to follow the movements of their Queen in the Emerald Isle very shortly after the chief ceremonial connected with her visit there had closed.

### EXPOSURE AND DEVELOPMENT.

#### II.

WE come now by natural sequence to consider the latest method of determining the actinic value of light, and the simple consequent operations required for the rapid solution of our problem of correct exposure, with some pretensions to scientific accuracy.

One of the earliest, if not actually the first, light-measuring instrument for the purpose of determining negative exposures was the Watkins meter, although long prior to its advent actinometers were in constant use for carbon printing, &c. This instrument, especially in its latest form, may be relied on for deciding at any time of the day, by means of a strip of sensitised paper, the comparative actinic value of the light. By using a series of scales engraved on the instrument, it is not difficult to determine with remarkable accuracy the correct exposure with a given plate and aperture of lens. A more detailed description of this instrument seems unnecessary, especially for beginners, as an equally ingenious instrument, known as Wynne's exposure meter, can now be obtained at about half the cost of the Watkins meter. The Wynne meter is so handy that it may be carried at all times without inconvenience, and will be found of such real service that its cost will soon be repaid by the saving in plates alone.

If you have now been led to make fairly accurate exposures of your plates, we may transfer our thoughts to the dark room, and consider the necessary arrangements for, and the operations connected with, the second section of our lecture.

It is taken for granted that every beginner makes use of an exposure note-book, not necessarily one of the orthodox ones with columns ruled therein for noting lens, stop, plate, time of day, &c., but at least one in which is noted such information as will assist in the intelligent development of the plate. For instance, the nature of the subject, conditions of light, whether strong contrasts exist, and whether over or under-

exposure is known or suspected, will be found of value for reference in the dark room when about to develop the plates.

The dark room itself might with advantage be considered in some detail; but, bearing in mind the extremely varied accommodation, or *want of it*, that most amateurs have to be content with, the task seems hopeless. A few words of advice on the subject generally may, however, be of service. The dark room, whether temporary or permanent, should be reduced to something like order, so that the materials and apparatus needful for the operation of development may be made conveniently accessible. That measures, dishes, &c., should be scrupulously clean goes without saying.

For the beginner the question of the best developer is a comparatively simple one. Our choice should naturally be the formula advised by the maker of the plates, to the exclusion of all others. A thorough acquaintance with it will pave the way for possibly useful changes later on. In the mean time, the earnest student of photography, and especially that part dealing with the development of the latent image, will find that, by varying the proportions of the ingredients composing his adopted developer, remarkable variety and certainty of results are possible. This point can hardly be too strongly emphasised; the acquirement of the greatest skill and accuracy in making exposures may be utterly nullified by errors in development, which are almost inevitable when many developers are tried and not one of them thoroughly mastered in all its possible variations.

The beginner will do well to commence, from the first, by purchasing the necessary chemicals and making up his own solutions. This will give him a definite knowledge of what they contain; for instance, he will know—and, if he is wise, he will write upon the labels of the respective bottles—how many grains of pyro his solution contains per ounce, how many grains of soda per ounce of fluid, and how many minims of bromide solution contain one grain of the restrainer. Similarly, of course, if other chemicals are used.

In order that we may take full advantage of the knowledge we have already gained in exposing our plates, it is essential that the photographer should know, at least in a general way, the function that each of the ingredients composing his developer has to perform. Let us assume that the old and well-tried pyrogallie acid has been selected as the reducing agent. Alone this chemical has practically no reducing power, but, in conjunction with an alkali, it serves to reduce the practically invisible salts of silver, after exposure to actinic light, to the metallic condition. Other things being unchanged, the greater the proportion of pyro the greater will be the power of reduction or density-giving capacity of the developer, if its action be permitted for a sufficient length of time. Beyond a certain proportion, however, say of five or six grains per ounce of fluid, no useful effect will be observed, but, on the contrary, the surplus is liable to be detrimental by becoming oxidised and staining the film.

This latter defect may, however, be obviated somewhat by the use of a large quantity of a preservative chemical; but the remedy is in turn apt to produce undesirable results, such as rendering the developer perceptibly slower in the case of sulphite of soda, and in causing frilling, or a partial separation of the film from the glass, in the case of acid preservatives.

The action of the alkali may be taken (without entering into the exact chemical changes which occur), to lead to the more or less *rapid* production of the visible image, that is to say, that development may be carried on very slowly by the use of very small quantities of alkali, or it may be hastened by larger quantities.

The addition of a moderate quantity of a third ingredient, bromide of potassium, is often necessary for the purpose of retarding the appearance of the image, until it is possible to determine whether the plate has had a fairly accurate exposure, and with some makes of plates to prevent a general veiling, or fogging, of the negative.

To resume, briefly, we find the functions of the ingredients of our developer to be:—

- Pyro = reducing power or density giving.
- Alkali = rapidity of action or detail giving.
- Bromide = controlling action.
- Water = diluent, tending to softness.

Let us now consider how best to utilise these varied powers in the production of a good negative. An analysis of a large number of formulæ shows the average quantity of pyro, carbonate of soda, bromide of potassium, and sulphite of soda, to be 3 grains, 24 grains, one-third of a grain, and 24 grains respectively per ounce of developer.

In making use of the formulæ given by the plate-makers, it should be borne in mind that they are probably intended for use in the portrait studio, by professional photographers, to whom the time spent in development is a very important consideration. They therefore contain a larger amount of alkali than is necessary for amateurs to use when dealing with landscape or other subjects by tentative methods. Probably two-thirds the amount just given would prove more satisfactory in the beginner's hands, so that the quantity per ounce of developer would be 16 grains instead of 24. The figures thus modified may, for our present purpose, be called the normal quantities.

We will now proceed to develop a rapid plate, which, we will assume has received a correct exposure. It has been already stated that the rapid plate has rather a tendency to give softness on a thin negative; we

Therefore decide that our developer may contain the normal quantity of pyro or density-giving agent. With the alkali we must be more cautious, and at the beginning put in only one-fourth, or less, of the normal quantity. To still further keep the plate under control we add, say, half the normal quantity of bromide and begin development.

At this point we may advise that the quantity of solution used should be rather on the liberal side, so that it may not approach exhaustion before the image is completely developed.

The solution should also be applied in such a way as to cover the plate quickly, since any delay in covering parts of the film may be expected to lead to very annoying markings on the negative.

A very good plan for ensuring the greatest possible freedom from air bubbles and pinholes is to have a flat camel's-hair brush standing handy in a jug or glass of water. With this brush the developer, immediately on application, is gently brushed backwards and forwards a few times over the whole surface of the plate. This has been found a most effective substitute for dusting the plate prior to pouring on the developer.

As development proceeds under the action of the above-mentioned solution, we shall find that the image shows first in outline, and follows with a fair proportion of detail. If further progress seems to be in the direction of too great density, additions of alkali may be made up to, or slightly in excess of, the normal quantity. If these various stages have been carefully watched and conducted, a thoroughly satisfactory negative should be the result.

We may now consider how our procedure should be varied in dealing with a slow plate assumed to be correctly exposed. Bearing in mind the fact that the slow plate tends rather to vigour or harshness under the influence of the average developer, we shall, in this case, be careful to start development with not more than half a grain of pyro per ounce of solution, the other constituents remaining normal.

The first appearance of the image should be somewhat similar to that of the rapid plate, followed by an inclination to full detail with hardly sufficient density. We may now add another half grain of pyro, and shall probably be able to complete our negative without further modification, unless we require a very vigorous one.

In cases where the exposure is unknown or uncertain, it is better to adopt what is known as tentative development. This practically means that over-exposure is assumed to be possible, and the plate treated accordingly. We therefore mix our developer with the normal amount of pyro, say double the usual bromide, and not more than one-tenth the normal alkali.

If the exposure turns out to be fairly correct, the latter may be increased from time to time as needed, and, in the case of rapid plates, it will be the only modification required. With slow plates, however, it may also be necessary to dilute the developer in order to avoid over-density in the high lights.

We now approach the most difficult and unsatisfactory part of our subject, that is to say, the procedure to be adopted in cases of over and under-exposure.

To deal fully with this alone would occupy more than a single evening, with the probable result that our ideas on the subject would be obscured by the mass of evidence in favour of, and opposed to, various methods of treatment.

We had better, therefore, get some idea of the earliest symptoms of over and under-exposure during development in cases where their existence is not already known, and then refer briefly to simple general methods of treatment, leaving the more profound study of the subject, including the use of special developers or combinations of the newer reducing agents until we become expert in the use of our chosen developer.

In cases of great over-exposure we may expect to find the entire exposed surface of the plate begin to darken, with practically no outline or contrasting parts. With less over-exposure the image may show a fair and promising outline for a second or two, succeeded by a general darkening as before.

We must therefore watch the earlier stages of development with the utmost care, until the gradual appearance of the high lights, one after another, informs us that no serious error in exposure has been made.

Should over-exposure be revealed, the developer should be poured off at once, and the plate flooded with two or three changes of water, or, preferably, washed under the tap, and then soaked for four or five minutes in a solution of about 10 grains of bromide of potassium per ounce of water. To this solution may then be added, from time to time, a small quantity of developer containing the normal quantity of pyro, but not more than a quarter the normal amount of alkali. Development will proceed slowly, and a patience must be exercised, even to the extent of thirty or forty minutes, if the best possible result is desired.

On this point Mr. Alfred Watkins says: "In any exposure, over or under, the contrast between any two tones that have a difference of deposit increases with length of development up to a certain limit, although with some plates (prone to fog) that limit is reached before maximum density in the high lights is attained. To obtain this maximum contrast with an over-exposed negative, the negative is very dense, and takes long to print. Most photographers stop the development of over-exposures long before maximum contrast is attained."

This statement indicates that we should carry the slow development

of over-exposed plates much beyond printing density, and rely on uniform reduction afterwards to give us a printable negative.

Before leaving the subject of over-exposure it may be well to point out that an over-exposed plate that has been partly developed with a normal developer will rarely produce so good a negative as if it had been treated for over-exposure from the beginning. This fact alone is a sufficient reason for taking the notes of exposure before referred to, and without which the beginner will find himself seriously and unnecessarily handicapped.

Under-exposure, so far as it is amenable to treatment, is a much simpler matter, inasmuch as the image has no tendency to appear with the almost incredible rapidity shown by some brands of plates when over-exposed. Our precautions and arrangements for treatment may therefore proceed in a more leisurely manner.

The first evidence of this defect will be the appearance of all the brighter parts of the subject in patches, which continue to gather density before there is any sign of the finer detail. Continued development with the same solution would merely accentuate the early indications, and ultimately lead to what is known as a soot-and-whitewash negative.

Our first operation will be to dilute the developer with an equal or greater quantity of water, and to add a little alkali. Increase of density should now be almost arrested, and further detail appear in the half-tone if the operator will patiently allow the modified developer time to act. Should there still remain a considerable area without detail, a further small addition of alkali may be made. At this point, however, the negative must be carefully watched, as veiling or general fog may be expected so soon as the solution contains the maximum amount of alkali that the plate will permit. Not the slightest advantage is to be expected by allowing the negative to remain in the developer when once veiling begins; on the contrary, a passable negative may be entirely ruined thereby.

Although rarely taken into full consideration, except as a matter of personal comfort, the temperature of the dark room, as affecting the developing solutions therein at the time of use, plays an important part in the production of a negative, and it may exercise a harmful influence if ignored, or it may be made to act beneficially if its effect be rightly understood. It appears that the temperature of development affects the result in two ways: first, the latent image itself is supposed to vary with variations in temperature; and, second, the chemical reactions of development are accelerated or retarded by a rise or fall in temperature. For practical purposes we may look upon the effects of heat as equivalent to increase of exposure, and therefore use warm developer for under-exposed plates and cold developer with over-exposure.

Thus, in cold weather, we may get an appearance of under-exposure, and the opposite in warm weather.

It must be remembered, however, that there is a danger of softening and melting the film if the temperature is raised much above 70°.

Although the succeeding treatment of the negative does not properly form part of the present lecture, a few words thereon may not be amiss.

It is well known that the film of the negative, when removed from the developing solution, retains in the gelatine an appreciable quantity of the chemicals employed, so that the negative should be well washed without delay, or further action will take place. When washed, the negative may remain in water without injury, if it is desired to develop a number of plates, before proceeding to fix them.

This latter operation is a most important one, and every negative should be allowed to remain in the hypo bath at least ten minutes after the last trace of unreduced silver has disappeared from the back. Neglect of this precaution may be expected to lead to a yellowing and fading of the image in the course of a few months.

Washing after fixing should be thorough; and with the final rinse, prior to drying, the film should be gently rubbed all over with a pledget of wet cotton-wool, or brushed with a soft flat brush, under water. This will remove any small particles of dirt that may have settled on the film during the previous operations.

Such a simple operation as drying the negative would appear to offer no possible opening for further trouble. It is, however, a fact, that one of the most annoying defects, known as drying marks, may be brought about by a want of care or a knowledge of how to avoid them. Marks may be expected if heads of moisture are allowed to form on the film, instead of draining away uniformly over the whole surface. The remedy is, either to remove the drops with the corner of a piece of blotting-paper, or to gently wipe the whole surface of the film with a pad made of an old linen handkerchief, before putting the plate in a rack or standing it up to dry.

Another constant source of markings is an appreciable change of temperature when the film is partly dry, or a change from a quiet to a distinctly draughty situation, or *vice versa*.

Finally, a negative that is worth keeping is worth varnishing; the neglect of this precaution has caused the ruin of many a negative by silver or other stains.

It will have been observed that this lecture contains no formulæ and no suggestions for variations in the compounding of Nos. 1, 2, and 3 solutions; for these the photographer is referred to one of the numerous text-books, or to the directions given by the plate-maker.

The object has been to direct attention to the intelligent and

systematic use of the materials and apparatus at our disposal, and to the earnest study of cause and effect, leading up, through exposure and development, to the confident and pleasurable practice of the art of photography.

G. F. BLACKMORE.

PHOTOGRAPHICALLY RECORDING OSCILLATING RAYS OF LIGHT.

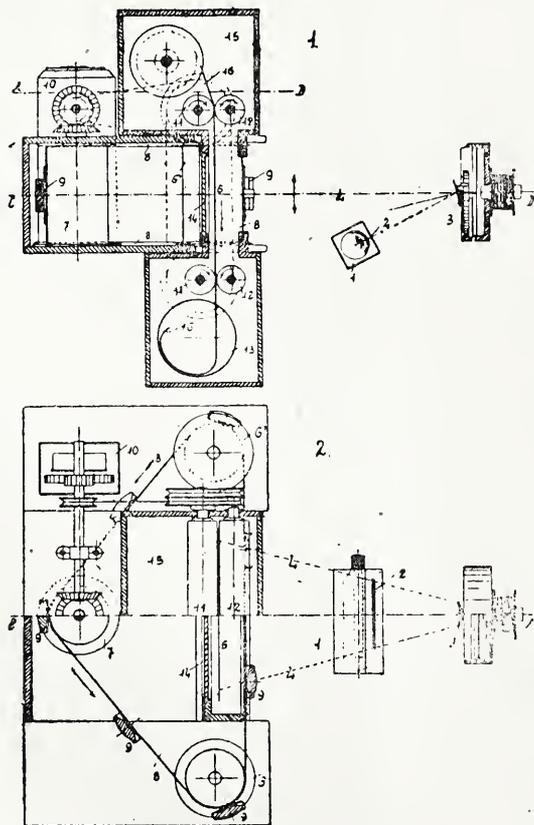

[Patent No. 22,613 of 1899.]

THE invention of Messrs. Anton Pollak, Gyula Egger, and Dr. Frederick Silberstein.

1 is a source of light of any suitable kind from which a group of light rays falls through a narrow elongated slit, 2, on to a concave mirror, 3. This concave mirror is connected with the movable body, the oscillations of which are to be recorded, in such a way that this mirror by reason of this connection executes oscillating movements on an axis which is parallel to the slit, 2, before mentioned. In the case shown in the drawing the mirror is connected with the diaphragm of a telephone, for instance, or a telegraphic receiver.

The oscillating movements of the concave mirror impart oscillating movements to the reflected light rays, 4, also, so that at the point, 5, an actual oscillating picture of the slit, 2, results, which is recorded by the devices hereinafter described.

An endless band, 8, is carried over rollers, 6, 6<sup>1</sup>, and 7. This band, 8, is provided with openings at equal distances apart, in front of which

openings a cylindrical lens, 9, is fastened on the band in such a way that the geometrical axes of these cylindrical lenses, 9, stand at right angles to the direction of the movement.

The roller, 7, receives a rotary motion from a driving mechanism, such for instance as a clockwork, 10, so that the band, 8, is moved forward in the direction indicated by the arrow. The cylindrical lens for the time being between the two rollers, 6 and 6<sup>1</sup>, allows separate parts of the group, 4, of reflected rays to pass through the lens as it moves from the roller, 6, to the roller, 6<sup>1</sup>. The focal distance of the cylindrical lens, 9, is so calculated that the part of the light rays, 4, which is absorbed by the lens, is also concentrated at 5 into an intense point of light. An endless sensitive strip of paper is slowly moved forward by means of rollers, 11 and 12, in the direction indicated by the arrow in such a way that the said intense point of light falls on the sensitive strip.

Of course, care must be taken that the sensitive paper is entirely excluded from all foreign light in a box, 15, which perfectly excludes light, and it is collected after the exposure in a receiver, 13, from which the light is also excluded.

A red observation glass, 14, may be arranged in the box, 15, behind the paper strip in order that the oscillations of the point of light during the exposure may be inspected.

The distance of the separate lenses, 9, on the endless band, 8, is exactly as great, or somewhat smaller, than the width of the sensitive strip, 16.

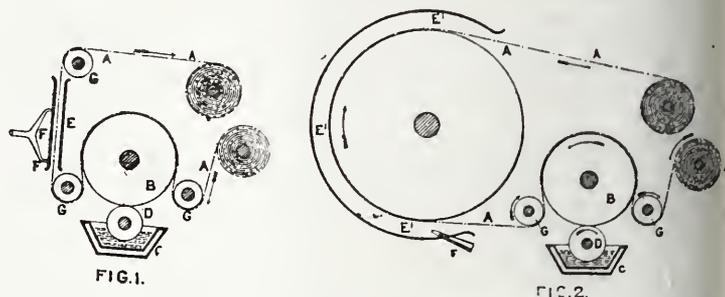

The working of the whole apparatus is as follows:—

For the purpose of recording the oscillating ray of light, 4, the driving mechanism, which moves forward the endless band, 8, and the strip, 16, in the direction indicated, is started. The optical arrangements herein before described produces on the sensitive paper a sharp point of light which, in consequence of the oscillations of the mirror, 3, oscillates in a vertical direction, but, in consequence of the movement of the cylindrical lenses, 9, executes a continuous horizontal movement. As soon as one lens, 9, has passed in front of the sensitive strip, 16, or somewhat before that time, the following lens comes into action and conveys the oscillating point of light again transversely over the paper strip, 16. As, however, in the mean time, the sensitive strip, 16, has also moved a given distance in a direction at right angles to the direction of movement of the endless band, 8, the following oscillation curve will encounter the sensitive strip at a distance from the previous curve of oscillation corresponding to the difference in the movement executed. The developing and fixing of the exposed sensitive strip takes place in the ordinary manner.

COATING SENSITIVE FILMS, PAPERS, &c.

[Patent No. 5793 of 1899.]

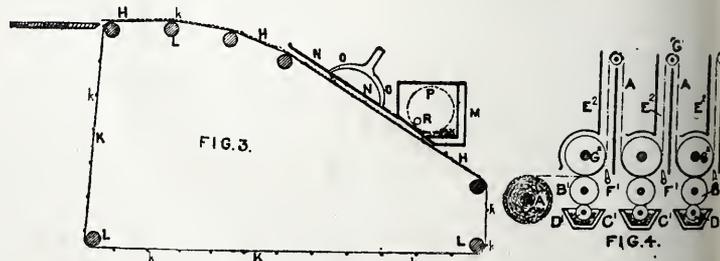

THE invention of Mr. J. E. Thornton. For coating a sensitive emulsion upon a support of thin, flexible material, A, such as paper, celluloid, or other web material, a machine is constructed with a roller, B, to apply the emulsion to the film, A, a jacketed or heated trough, C, a doctor roller, D, rotating in the trough to convey the emulsion to the coating roller, B, and enclosed chamber, E, through which the web support when coated, passes air ducts, F, through which heated air is forced and caused to impinge upon the travelling web support, A, and guide rollers

g, placed to conduct the material over the coating roller and through the drying chamber, E.

A straight drying chamber, E, as shown in fig. 1, or a curved or cylindrical drying chamber, E<sup>1</sup>, as shown in fig. 2, may be employed.

For the coating of a stiff or rigid support, H, such as plates of glass, celluloid, mica, or the like, the machine is constructed with a travelling carrying band, K, passing over guide rollers, L, and provided with a number of transverse ribs, k, by which the plates, H, are held in position thereon. Above or in close proximity to the travelling carrier band, K, is placed the trough or box, M, for containing the emulsion, and over the travelling carrier band, K, is formed the drying chamber, N, with the

air ducts, O through which the heated air is forced upon the coated plates as they are carried through.

In the emulsion box or trough, M, is placed a revolving silver gauze cylinder, P, which rotates in the emulsion, and inside the gauze cylinder is placed a flat air tube or nozzle, R, the width of the plates, through which a blast of air is forced. In the side of the trough or box, M, opposite the air tube, a slit is formed, through which the emulsion adhering to the silver gauze of the cylinder, P, is blown in a fine spray on to the plates, H, carried by the travelling carrier band, K.

An exceedingly fine layer or coating of the emulsion is deposited on the support, A or H, and dried as such pass through the machine, and

the process is repeated and again until the finished coating of the sensitive emulsion is the desired thickness. It will be necessary in this manner to apply about from ten to twenty coats to obtain a thickness equal to that usually applied at the one operation.

The paper or flexible film support may be reeled as shown after each coat, and passed repeatedly through the apparatus or a number of coating rollers, and drying chambers or cylinders may be arranged in one machine (see fig. 4), so that the support may be fully coated with the requisite number of fine coats at one operation.

In fig. 4 the apparatus is made up of any number of sections, comprising a coating roller, B<sup>1</sup>, trough, C<sup>1</sup>, ductor roller, D<sup>1</sup>, to apply the emulsion to the coating-roller drying chamber, E<sup>2</sup>, into which the heated blast of air is injected by the nozzle on the perforated pipe, F<sup>1</sup>, and guide rollers, G<sup>1</sup> and G<sup>2</sup>, the roller, G<sup>2</sup>, may be heated if desired. Likewise a number of spraying apparatus may be used for plates.

### THE ACTION OF AMMONIA ON A MIXTURE OF MERCURIC AND SILVER CHLORIDES.

[From *Comptes Rendus*.]

In order to detect the existence of silver in presence of a mercurous salt, different treatises on chemical analysis direct the treatment of the mixed chlorides of mercury and silver with ammonia. The mercurous chloride is thus converted into amido-mercurous chloride, Hg<sub>2</sub>ClNH<sub>2</sub>, and the silver chloride passes into solution. This simple process succeeds when this latter body is present in notable quantity in the mixture, but otherwise it is unsatisfactory, the mercurous compound retaining the whole of the silver chloride. It therefore struck me that some few experiments on this phenomenon would not be without interest. The following experiments were made.

Equal weights of a precipitate, containing the mixture of the chlorides in a known proportion, were successively digested three times with aqueous ammonia of specific gravity .960. Each digestion lasted ten minutes, during which time the mixture was frequently agitated. The residual silver chloride was determined in the precipitate remaining after each digestion.

The quantities of chlorides employed in each series of experiments was obtained by mixing solutions of the salts of such strength as to give exactly .0478 grammes of mercurous chloride and .0483 grammes of silver chloride per cubic centimetre.

In each experiment the total weight of the chlorides was about one gramme, and the volume of ammonia used for each digestion about 30 c. c.

The following table gives the results obtained:—

Total weight of chlorides.	Silver chloride introduced.	Silver after 1 digestion.	Chloride, 2 digestions.	Left, 3 digestions.
.959	.290	.224	.213	.204
.958	.193	.187	.185	.180
.957	.096	.093	.089	.093
.956	.048	.044	.044	.040

Inspection of these figures reveals the fact that (1) an appreciable quantity of silver chloride is always left, even after three digestions. (2) With the exception of the first experiment, almost the whole of the silver chloride remains in the final residue, each digestion removing only insignificant quantities. These latter, in fact, were only recognised with difficulty in the filtrate, owing to the presence of the ammonium salt produced by the neutralisation of the alkali.

In order to satisfy myself that a weaker solution of ammonia has not a superior solvent action on silver chloride, I repeated the experiments given in the third column above, but with a solution of ammonia half the strength. The results were:—

.204	.180	.093
	compared with	
.204	.180	.093

previously obtained. Dilution, therefore, has no influence on the result.

The ratio of the residual silver chloride, after three digestions, to the total weight of the mixed chloride is  $\frac{.213}{.959} = 213 \text{ i.e. } = \frac{1}{4}$ , a ratio which corresponds pretty closely with the figure .233 obtained by Chapman Jones on the examination of the action of aqueous ammonia on the compound, Hg<sub>2</sub>Cl<sub>2</sub>AgCl, the residual compound being, according to this author, Hg<sub>2</sub>AgNHCl.

A better analytical method is to treat the residue left by ammonia with warm concentrated nitric acid, mixed with enough hydrochloric acid to convert the amido-chloride of mercury into mercuric chloride. In the presence of silver a white residue is left, which does not blacken in ammonia, but entirely dissolves.

F. LETEUR.

### THE PHOTOGRAPHY OF CLOUDS.

M. ANTONIADI, in the April number of *Knowledge*, gives some hints, accompanied by excellent illustrations, on the photography of clouds. "It

has been found that the number of days yielding interesting forms of clouds is but a limited one. Long weeks succeed each other without one recording a single typical cloud. Occasionally, however, we may observe the richest forms undergoing rapid and singularly beautiful transitions. . . . The first point to be attended to in cloud photography is to have the camera and plates always ready, so as to be in a position to immediately photograph any evanescent atmospherical phenomenon. Trivial as the statement appears, it is of paramount importance. In fact, without this precaution, the negatives of rainbows, solar halos, lunar coronæ, &c., would probably never have been secured at Juvisy. As a rule, the duration of fine cloud effects, or of the optical phenomena of the atmosphere, are of very short duration, and the loss of time involved in fetching plates or engaging in other preparatory work at the last moment is often a source of disappointment; for instance, to see a bright rainbow fade off and vanish when 'everything is ready' produces a tantalising effect too galling to be endured more than once when economy of time will serve as a preventive medicine. . . . The proper time to give to the exposure is the beginner's stumbling-block. In fact, the question is of a very complex character, inasmuch as it depends on a large number of factors, such as the angle of the object-glass, the diameter of the stop, the sensibility of the plates, the saturation of the screen, the luminosity of the clouds, the sun's altitude, &c. Laying down a rule for the exposure is an impossibility under such circumstances."

### A FEW WORDS ON FILMS.

A good deal has already been written on the question of films *versus* plates (and *vice versa*) for negative purposes, and it is quite evident that the last word has not been said on the subject yet. For lantern-slide purposes, there are many who prefer glass to film for making the original negative, owing to the grain of the latter. Film has certain disadvantages, but there is little doubt that for negative-making it is coming more and more into use. The question might be put, If film was the same price as glass, would the latter be discarded for all purposes where it is now used, except perhaps for studio work? Some authorities have gone so far as to state that it would, but it is, perhaps, too much to claim.

There is no getting away from the fact that the specific gravity of film and glass differs greatly; but, at the same time, it is equally true that users of film have to pay fairly heavily for the convenience, as a comparison of the prices of film and glass will show.

But many will consider that the convenience of greater portability which film offers is for many purposes—out-door work generally—worth paying for. The Tella Company pithily puts it in this way: "Fifty films weigh 6 ounces; fifty plates would weigh 5 pounds." Comment is unnecessary. In the first place there is no magazine camera on the market which takes fifty glass plates, and, if there were, it would be a cumbersome affair, and, when on the photographic expedition, the worker, after carrying his weighty instrument until his arm refused to carry it further, would feel disposed to pitch the whole concern into the nearest ditch. It might be said that such a number of plates is never required, or very rarely; but, assuming this to be true, a hand camera designed to take a much less number of (glass) plates becomes inconvenient to carry if the distance traversed is at all considerable.

There are many (including the writer) who have found a Frena—as a hand camera—almost all that could be desired. When fully charged with forty films, the weight is not appreciably inconvenient when carried for long distances, and the operation of exposing and changing is merely a matter of moments.

An enormous quantity of spool film is used nowadays; and, now that the Kodak Company is issuing films for half a dozen or less exposures, the sale is not likely to be diminished. Many of us have been initiated into the mysteries of photography through the agency of a Kodak, and many users of these popular cameras have, doubtless, suggested to the Company the desirability of introducing a spool for six exposures, as it certainly was decidedly inconvenient, when it was desired to develop the first portion of the film before the whole had been exposed, to cut off the required portion. The writer attempted the operation of cutting off and fixing up again once, and he did not feel disposed to repeat the experiment. Now such an operation has been made unnecessary.

As the photographic papers inform us, inventors are still busy in the direction of film-manufacture, and much is expected, or, at least, much is claimed, for some of the new makes that are being put on the market—the Secco, the Sandell, the Thornton, &c. Some of these new brands, like certain medicines, are expected to do wonders; we shall see.

Whether the cards separating each of the Frena films are at all harmful to the keeping qualities of the film, the writer is not in a position to say; but this much can be said, they form a useful and effective preservative in case of accidental opening of the box containing them to white light. In this event, the edges of the films only will have suffered, *i.e.*, assuming that the pack has not been much disturbed whilst so exposed.

It would be interesting, I think, if some writer who is accustomed to use film for interiors, &c., where there would be possible effects of halation, would give his experiences. It is generally considered that film

greatly minimises the effect of halation, and one does not hear much of backed film.

The writer of these discursive notes is aware that he has said nothing but what is well known; but those to whom these remarks are obvious will, perhaps, kindly remember that there are always new workers to whom a brief consideration of the utility of films may not be without interest.

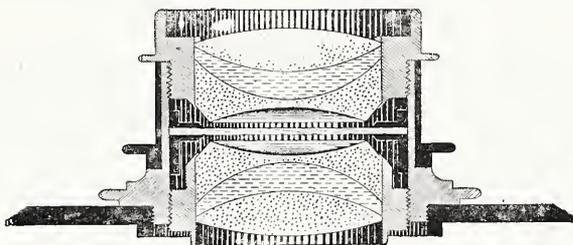

J. A. RED.

### THE NEW STEINHEIL LENSES.

Messrs. R. & J. Beck, of 68-69 Cornhill, E.C., who have commenced the manufacture in England of the Steinheil orthostigmat lens, have kindly furnished us with the following interesting notes on the subject:—

The introduction of the now famous Jena glasses rendered it possible to produce two kinds of lenses which should consist of two positive equal or similar parts, each of which is in itself chromatically, spherically, and astigmatically corrected; consequently the finished lens contains these three corrections, whereas formerly lenses of two positive equal or similar parts could only be corrected chromatically and spherically, as, in attempting to effect the astigmatic correction, an unsymmetrical construction resulted. Astigmatic corrections can only be made in the case of symmetrical cemented lenses on a divisional surface of two mediums which present the concave side to the more highly refractive medium, whilst the spherical correction can only be made on a

The Beck-Steinheil Orthostigmat.

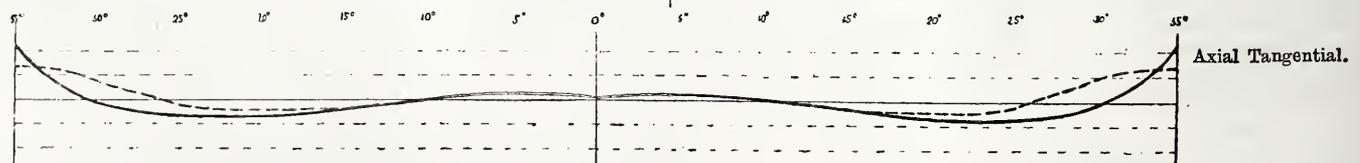

divisional surface which presents the concave side to the not so highly refractive medium.

Having this principle as a basis, lenses can be constructed out of symmetrical or similar halves which on the first divisional surface of the separated halves have the astigmatism corrected, and on the second surface the spherical aberrations. This is the principle on which the Beck-Steinheil orthostigmats are constructed, and necessitates the characteristic that a positive lens is enclosed by a double convex and a double concave one, both of which have a higher refractive power than the enclosed lens.

By examining the accompanying illustration the construction of the orthostigmat can be fully appreciated.

The lens possesses the full working aperture of  $f.6.3$  in the smaller sizes to  $f.6.8$  in the larger, and considerably more than covers to the very corners of the plates listed; in fact, although the No. 3 orthostigmat is listed as covering only a quarter-plate at full aperture, yet it might fairly be listed as covering a  $5 \times 4$  or even a half-plate at the aperture  $f.6.3$ , so perfect are the corrections.

The formula of the orthostigmats in common with most of the best modern anastigmats is such that microscopic errors in the workmanship

of the twelve surfaces most seriously injure the quality of the finished lens. Messrs. R. & J. Beck have therefore introduced into their factory at Kentish Town a new method of manufacture, and testing to ensure that the exquisite definition obtainable with this formula of lens should not in any way be diminished by errors in manufacture.

Each surface is polished and figured on the principle adopted for the manufacture of large astronomical telescope object-glasses. The tests employed are such that an error in a surface which does not exceed a fraction of a wave-length of light may be detected immediately; this accuracy entails of necessity the employment of the most skilled labour, and consequently an increase of price over lenses manufactured in the old way, compensated, however, by an immense increase in optical quality. These new anastigmatic lenses, at present manufactured by Messrs. R. & J. Beck, Limited, have foci varying from  $3\frac{1}{2}$  to  $23\frac{1}{2}$  in., and covering plates from  $3\frac{1}{2} \times 3\frac{1}{2}$  to  $28 \times 24$  in. They are applicable to all kinds of rapid instantaneous work requiring the maximum definition with as large an aperture as possible, or for process work where speed, angle, and covering power are required.

The curve which is here illustrated is taken, so Messrs. Beck inform

us, from a finished orthostigmat by actual measurement (at full aperture) and represent the amount of curvature of the field for both radial and tangential rays respectively. In order to make the curve visible, the errors have been exaggerated in a vertical direction, the horizontal dotted lines representing a distance of 1 mm. out of focus on either side of the central plane. When it is remembered that the photograph of a point would be represented by a circle not larger than  $\frac{3}{100}$  of an inch in diameter, in the case of a lens having 1 mm. variation in the curvature of the field and in the curve illustrated, it will be observed that, until we get to about an angle of  $64^\circ$ , the Beck-Steinheil orthostigmat will give almost microscopic definition over the whole range of its plate at the full aperture, and also allows of the use of the rising front even with the aperture of  $f.6.3$  to the extent of at least an inch in the small to 2 or 4" in the larger.

### THE AFFILIATION OF PHOTOGRAPHIC SOCIETIES.—LANCASHIRE AND CHESHIRE CENTRE.

A MEETING of delegates from affiliated and non-affiliated societies in the Lancashire and Cheshire district was held in the rooms of the Liverpool Amateur Photographic Association on Monday, April 2, Mr. John P. Welch (President of the L.A.P.A.) in the chair.

The minutes of the previous meeting of the centre were read and confirmed, after which Mr. F. W. Parrott (Manchester A.P.S.) stated the reason why the work of the centre as previously established had not progressed.

Mr. H. Snowden Ward (London) explained the circumstances attending the calling of the present meeting, which was arranged at the request of a couple of affiliated societies in the district.

Mr. S. E. Collinson (Preston Scientific Society, Photographic Section) asked that the advantages of the Affiliation might be stated for the benefit of delegates from non-affiliated societies. So far as he could see, the principal prospect of advantage was the lectures. He had had no experience of the lectures supplied by the affiliated societies, but had borrowed travelling lectures from other sources, and found that his Society considered them practically useless. He asked if the lectures were guaranteed by the Royal Photographic Society.

Mr. Snowden Ward explained the principal advantages of the Affiliation in detail, but pointed out that it was not in any sense a business arrangement, but simply an organization whereby certain affiliated societies subscribe a small sum per year, and appoint their own delegates to employ the funds so raised in any way they pleased for the advantage of the societies.

Mr. D. E. Benson (Southport P.S.) said that, from long personal experience as Secretary, he could speak highly of the value of the Affiliation lectures. He was doubtful how a local centre would work, since, although the smaller societies would be very anxious co-operate, very little co-operation was in their power. Hence the benefits would be very one-sided, the one or two large societies in the district giving all and getting little or no return.

Mr. Fred A. Schierwater emphasised what the Chairman had said about the anxiety of the L.A.P.A. to assist the neighbouring societies in every way possible, but he feared that there were very few of the lectures and demonstrations given at the Liverpool meetings which could well be transferred to neighbouring societies. The Affiliation lectures were specially prepared as travelling lectures, whereas most of the Liverpool Society's arrangements were for extempore lectures or for demonstrations which required the presence of their originator.

Mr. Paul Lange (Liverpool A.P.A.) again emphasised the anxiety of Liverpool to assist as far as possible, but feared that a suggestion which had been made that the Liverpool Society should practically undertake the control of the local centre was one which could not be carried out, as all the working members were more than busy with their own matters, and, further, as a matter of general convenience, it seemed desirable that the smaller societies should volunteer to manage the work. If they did so, he felt sure that they would never appeal in vain to the Liverpool or Manchester Societies for assistance. He asked that Mr. Wade should express the opinions of the Manchester Society, as, in spite of the fact, through a misunderstanding, Mr. Parrott had been unable to take up the work of the centre, he felt quite sure that Manchester was the best place for a nucleus.

Mr. J. W. Wade (Manchester A.P.S.) asked that the representative who had come from London would say exactly what was expected from a society like the Manchester or Liverpool Societies in reference to the smaller affiliated societies, and particularly whether lecturers before the larger societies were felt to be under any moral compulsion to offer their papers to the smaller societies. He feared, if this were so, there would be

much difficulty in inducing good men to lecture. A scheme of federation had been formed a few years ago by Mr. Coulthurst and other Manchester men, but it had failed of materialisation because of the difficulty of providing for the large and the small societies to work on the same lines.

Mr. F. W. Parrott (Manchester A.P.S.) said that he attended the last meeting as the representative of a small Society (Altrincham), now he represented a large one, and, though it might seem inconsistent, he must admit that the problem looked very different from the two different points of view. The large societies had practically all to give and little to gain from any increased work in a local centre. As a matter of fact there was a good deal of exchange between the larger societies (Liverpool, Manchester, Leeds, &c.), and their experience showed the enormous value of such co-operation. He felt sure, therefore, that similar interchange between the smaller societies would be equally, or perhaps even more, advantageous. A practical difficulty which had for long prevented his Society from joining the Affiliation was the Affiliation rule whereby a member of an affiliated society had practically an unlimited right of using the rooms, lectures, and other conveniences of any affiliated society. In cases where there was a large society with considerable funds and a fairly high subscription, surrounded by closely neighbouring societies with small funds and small subscription, this rule was felt to be a disadvantage.

Mr. Snowden Ward briefly replied to the last two speakers that there was no "expectation" that, because a gentleman prepared a lecture for a large society, he would necessarily undertake to repeat it for the smaller ones in the district, and that the rule to which Mr. Parrott referred had never been interpreted by the executive as giving visiting members such rights as Mr. Parrott feared, but that it was considered a matter of honour that the members of the affiliated societies should only make use of other societies' courtesy in any way as would not possibly be felt as an abuse. The Liverpool Society had, he believed, found the question arise, and had satisfactorily dealt with it.

Mr. Welch suggested that possibly the larger societies could help the smaller ones when engaging lecturers from a distance, for, if the larger society paid the lecturer's fee and travelling expenses, it was possible that he would arrange to repeat his lecture on the next night for a neighbouring society for a reduced fee and practically no travelling expenses.

Mr. Collinson feared that, even in a group of the smaller societies, his own (Preston) Society could scarcely offer much real help, as its members were bashful, and it was difficult to induce them even to address their fellow-members.

Mr. Benson feared that Southport was in the same position, and that they had the further difficulty that they could hardly invite a gentleman from a distance, since their meetings were very small. They had found the Affiliation lectures answer all practical purposes.

Mr. Schierwater referred to the question raised by Mr. Parrott, who said that the Liverpool society, while most anxious to extend all possible courtesy to all *bonâ-fide* visitors, had found it necessary to distinctly state that the clause allowing reciprocal advantages as a right must only apply to societies beyond a twenty-mile radius. He moved, as a definite recommendation to the executive, that the rule allowing the privilege of attending meetings, using dark rooms, &c., of other affiliated societies be removed.

Mr. Parrott seconded this, and it was carried.

Mr. Lange appealed to the delegates present to supply a volunteer secretary for local centre, and, after considerable further discussion, in which many detail points in the working of the Affiliation were raised, Mr. Benson proposed that a meeting of the secretaries of the affiliated societies be called once a year, at the beginning of the session.

Mr. George Birtwhistle (Sefton Park) strongly supported this, as also did several other members. Finally, Mr. Welch suggested the resolution: "That the secretaries of affiliated and non-affiliated societies in the Lancashire and Cheshire district be summoned by the Secretary of the Affiliation to meet during the first week in September, the object of the meeting being to arrange for mutual assistance in drawing up the season's programme." This was carried unanimously.

On the proposal of Mr. Collinson, seconded by Mr. H. Snowden Ward, the thanks of the meeting were tendered to Mr. Welch for his services in the chair, and to the L.A.P.A. for the use of the room.

### THE BIRKENHEAD EXHIBITION.

The following is the list of the Judges' awards:—  
Class I. (Landscape).—Silver gilt (No. 39), W. T. Greatbach; silver (No. 15), Edward Atkinson; bronze (No. 23), C. F. Inston.

Class II. (Seascape and Marine).—Silver (No. 122), C. F. Inston; bronze (No. 115), T. E. C. Wilson.

Class III. (Portraiture and Genre).—Silver gilt (No. 154), Robert Ayton; silver (No. 145), R. S. Webster; bronze (No. 175), C. M. Wane.

Class IV. (Architecture).—Silver (No. 200), W. T. Greatbach; bronze (No. 196), J. C. Warburg.

Class V. (Photo-mechanical).—No award.

Class VI. (Photo-micrography).—Silver (Nos. 231, 232), A. E. Goodman.

Class VII. (Stereoscopic Work and Transparencies).—Silver (No. 238), John H. Spencer; silver (No. 241), L. S. Wilks.

Class VIII. (Hand-camera Work).—Silver gilt (No. 262), C. F. Inston; silver (No. 254), W. E. Inston; bronze (No. 250), T. E. Corney Wilson.

Class IX. (Lantern Slides, sets of 6).—(a) Silver gilt (No. 312), Ernest Marriage; (b) silver (No. 320), John Gunston; bronze (No. 325), Wm. Harvey; bronze (No. 343), Eustace Young.

Special.—Gold medal for best picture (No. 39), W. T. Greatbach; gold medal for best set of lantern slides (No. 320), John Gunston; *Amateur Photographer* medal (No. 39), W. T. Greatbach; *Photography* medal (No. 60), James Patrick.

Donors of medals:—Gold Champion Medal—Sir Elliot Lees, Bart., M.P.; C. J. Procter, Esq. Silver and bronze (one of each)—W. H. Lever, Esq.; T. L. Dodds, Esq., J.P.; H. B. Smith, Esq.

The Exhibition, which was a large and representative one, was kept open for two extra days, on account of its very great success. We congratulate Mr. Inston and the executive of the Birkenhead Association on having organized the Exhibition, the photographs thereat constituting about as good a collection of modern work as it would be possible to get together.

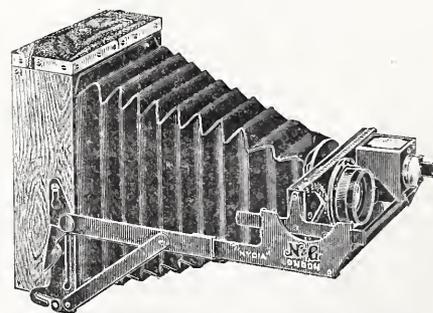

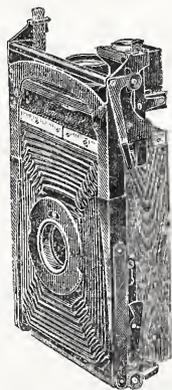

## Our Editorial Table.

### THE NYDIA POCKET CAMERA.

Manufactured and sold by Newman & Guardia, Limited, 90-92, Shaftesbury-avenue, London, W.C.

THE latest introduction of the well-known house of Newman & Guardia, Limited, makes a direct appeal to that large class of photographers with whom compactness and portability of apparatus are *desiderata*. The "Nydia" camera, when closed up, measures no more than  $7\frac{1}{4} \times 4\frac{1}{2} \times 1\frac{3}{4}$  inches, and when loaded weighs under one and three-quarter pounds. Thus it may be comfortably carried in most coat or jacket pockets. From a careful examination of the instrument we have been enabled to ascertain that it is quickly "got ready for action," and just as quickly folded up; that the setting and release of the shutter are accomplished by simple mechanical movements, and that the popular "N. & G." changing system has been so improved, that the entire plate is now lifted into the bag, and thus the more easily placed *in situ*. We append a detailed description of the Nydia, which, with the accompanying illustrations will enable the reader to acquaint himself with the minutest details of this cleverly devised and exceedingly well-made little instrument:—

The body is the changing-box itself. A set of light but very strong

metal struts connects this with the front, and holds all parts rigidly set out when in use. The bellows is attached to the box, and by a simple device (a slight rotary movement) it can be instantly fixed to or detached from the back of the shutter, making an absolutely light-tight joint.

The whole operation of setting and re-folding the camera takes only four or five seconds.

The "Nydia" is stocked fitted with four different makes of lenses, viz.:—French rapid rectilinear, *f*-8; Wray rapid rectilinear, *f*-8; Ross new symmetric anastigmat, *f*-8; Zeiss Satz anastigmat, *f*-6.3. These lenses are supplied in extra light and small cells, and the Zeiss anastigmat has been specially computed by the Jena Works for the "Nydia." All have the normal focus for quarter-plate— $5\frac{1}{2}$  inches. The "Nydia" mount is fitted with a frictionless Iris-diaphragm, and the scale is engraved up to *f*-45.

The shutter measures only  $4 \times 1\frac{1}{2} \times \frac{5}{16}$  inches, and is made entirely of metal and dust-proof. The blades work between the lens combinations, by a vertical slit. The action is smooth, there being no vibration with any exposure. The pneumatic cylinder is entirely enclosed, and the scale is graduated for automatic exposures of  $\frac{1}{2}$ ,  $\frac{1}{4}$ ,  $\frac{1}{8}$ ,  $\frac{1}{15}$ ,  $\frac{1}{30}$ ,  $\frac{1}{60}$ , and  $\frac{1}{100}$ th second—all tested. Time exposures can also be made.

The finder is of the real image type, and very light; it gives a picture

$\frac{1}{4} \times \frac{1}{2}$  inch. It can be quickly changed from the vertical to the horizontal position by merely sliding it in and out of its spring holder. The camera has the full range of focus from two yards to infinity. A lever and scale enable the worker to alter or fix the focus in an instant. The friction of the guide-plates is adjustable.

The magazine of the "Nydia" is similar to the "N. & G." changing-boxes. The boxes are made in two forms: No. 1, for twelve cut films only; No. 2, for eight plates or eight films. Any kind of  $4\frac{1}{4} \times 3\frac{1}{4}$  films or plates may be used; the latter, however, must be coated on thin glass.

The boxes are all interchangeable, and easily fixed to and detached from the camera, so that, by using several boxes, the number of exposures a photographer can make without resorting to a dark room is practically unlimited.

A vertical swing of ample latitude is provided by the metal framework.

## Studio Gossip.

THE biograph now being exhibited at the Westminster Aquarium shows the fight between Sharkey and Jeffries at the Coney Island Athletic Club last year. The films are the largest and longest yet seen in England. They are  $7\frac{1}{4}$  miles long, and contain 216,000 separate photographs. The cost of production was 1250*l.*, and 4 cameras, 400 arc lights of 800,000 candle power, and 12 skilled operators were in requisition. The light concentrated over the 24-foot ring was sufficient to light a city of 50,000 inhabitants.

MIRRORS of glass were, in all probability, first made at Venice in 1300, and that enterprising republic enjoyed a monopoly of the manufacture for about a century and a half. The Venetians guarded the secrets of the manufacture with the utmost jealousy. By their statutes any glass-maker carrying his art into a foreign state was ordered to return, on pain of the imprisonment of his nearest relatives, and if he disobeyed emissaries were delegated to slay him. From the twelfth to the end of the fifteenth century, pocket mirrors, or small hand mirrors suspended from the girdle, were indispensable adjuncts to ladies' toilets. The cases in which they were enclosed were generally of ivory, carved with representations of some real or imaginary scene. Sometimes, however, these were of gold, silver, enamel, ebony, and other costly materials, lavishly decorated with the highest efforts of art, workmanship, and jewellery.

## News and Notes.

THE NEWCASTLE CONVENTION.—From the list of those present at the Council meeting on the 29th ult. the name of Mr. H. M. Hastings was accidentally omitted.

MR. FREDERIC VILLIERS, the war artist, will, on Thursday, April 19, give a lecture at St. James's Hall, in which he will recount his experiences during the South African War. During the course of his lecture he will show a large number of slides taken from hitherto unpublished photographs.

ROYAL PHOTOGRAPHIC SOCIETY.—The Exhibition of pictures by the National Record Association will close on Saturday, April 21, until which date it is open, to those interested, from 10 a.m. to 4 p.m. On Wednesday, April 25, Mr. F. H. Evans will inaugurate an exhibition of his photographs (mainly architectural) at 66, Russell-square, at 8 p.m., with an address. Tickets may be had on application to the Secretary.

DURING a recent visit to Christmas Island, 200 miles south of Java, C. W. Andrews, of the British Museum, was able to verify by photographs the story that the palm crab (*Birgus latro*) climbs trees, which is done not only to secure the fruit, but also to feed on juices from cuts in the tree tops. Some of the smaller land crabs do great service in renewing the soil by continual burrowing, doing work performed elsewhere by earthworms.

THE Easter Excursion of the Borough Polytechnic Photographic Society, this year, is to Chichester Cathedral, under the leadership of Mr. F. W. Gregg, who has prepared, for the information of members and friends joining the party, some useful notes, with plan, giving the most suitable times, formulated by practical experience, for photographing the various aisles and principal objects within the Cathedral. A portion of the party will make a week-end stay, and "do" the surrounding places of interest, whilst the remainder will travel by early train on Easter Monday for the day only. Headquarters will be made at the Bedford Temperance Hotel. A cordial welcome is extended to members and friends of other societies, and full particulars can be obtained from the leader, Mr. F. W. Gregg, 37, Angell-road, Brixton, S.W., or from the Hon. Secretary, Mr. P. C. Cornford, 103, Borough-road, S.E.

HYDROGEN AS A SOLID.—A year ago Professor Dewar astonished and delighted the scientific world by liquefying hydrogen. Now he has gone a step further, and has produced hydrogen as a solid. In a series of beautiful and unique experiments, made before an interested audience at the Royal Institution last week, he showed how this gas could be solidified by surrounding a tube containing it with liquid air to prevent the ingress of heat, and then, by applying a powerful air pump to the liquid hydrogen, transformed it into a white opaque solid. Discussing the question of the utility of solid hydrogen in scientific research, Professor Dewar said the mere fact of its transformation from a gas was interesting simply because it was an elementary body of the lowest atomic weight and its molecules had the greatest rapidity of motion of any known body. One of its uses was in the solidification of oxygen, and it could also be used in the separation of mixed gases.]

CELLULOSE TETRACETATE.—A note in *Pharm. Centralh.* states that this ester is prepared by heating a mixture of molecular proportions of cellulose with magnesium or zinc acetate and two molecular weights of acetyl chloride and eventually with acetic anhydride. Nitro-benzole (as a solvent) is gradually added to the acetylising mixture, the greater part being added at the last when the temperature is highest; the reaction is represented by the following equation:—

$$C_6H_{10}O_5 + Mg(C_2H_3O_2)_2 + 2CH_3COCl = C_6H_6O_5(C_2H_3O_2)_4 + MgCl_2 + 2H_2O.$$

Cellulose tetracetate is insoluble in alcohol, ether, and acetone, but soluble in chloroform, in glacial acetic acid, and in nitro-benzole. It separates from the latter as a transparent jelly; it is not acted on by alkalis nor by strong acids. It differs from nitro-cellulose in not being explosive, and may be used as an insulator for electrical purposes.

THE causes of the deflection of a projectile as it leaves the gun is the interesting and important study which Professors Cranz and Koch have begun. The experiments thus far have been made with an ordinary rifle, and the method has consisted in throwing a beam of light from a bright spot on the barrel upon a rapidly moving sensitive film, the vibrations of a tuning fork being photographed at the same time for comparison. The position of the reflecting spot and the size of the powder charges are systematically varied. The gun reaches its greatest vibration after the ball has left it, but motion before is distinctly recorded, and is especially marked with reduced charges. The true theory is yet to be worked out. Release of the barrel from the weight of the projectile, waves of heat causing unequal expansion and the thrust of the gas ring against the rifling, are among the suggested causes of the vibration, but the real explanation will, doubtless, be found in a combination of several forces.

AT the recent annual meeting of the Association of Chambers of Commerce the following resolutions referring to the metric system were carried unanimously: (1) That steps be taken by this Association to again urge Her Majesty's Government (a) to introduce into, and endeavour to carry through Parliament, as speedily as possible, a Bill providing that the use of the metric system of weights and measures shall be compulsory in this country within a period of not more than two years from the passing of the Bill; and (b) to adopt the system with as little delay as possible in all specifications for Government contracts. (2) That in the opinion of this Association it is necessary, in order to promote knowledge of the metric system of weights and measures, and money among the people, that the Education Department should require Her Majesty's Inspectors to hold a real and effective examination of scholars in this system in the public elementary schools, and that a deputation of this Association do wait upon the Vice-President of the Committee of the Council on Education, and call his attention to the necessity of such examinations by Her Majesty's Inspectors.

ROYAL INSTITUTION.—The following are the lecture arrangements at the Royal Institution after Easter: Dr. Hugh Robert Mill, three lectures on Studies in British Geography; Dr. Alexander Hill, two lectures on Brain Tissue considered as the Apparatus of Thought; Mr. R. Warwick Bond, two lectures on (1) Ruskin, Man and Prophet, (2) Ruskin, the Servant of Art; Professor Dewar, four lectures on A Century of Chemistry in the Royal Institution; the Rev. Canon Ainger, three lectures on Chaucer; Professor Stanley Lane-Poole, two lectures on Egypt in the Middle Ages; Dr. Alfred Hillier, two lectures on South Africa, Past and Future; Sir Frederick Bridge, three lectures on the Growth of Chamber Music from Allegri's Symphonia (1580-1552) to Haydn's First Quartet (with musical illustrations). The Friday evening meetings will be resumed on April 27, when a discourse will be given by the Right Hon. Lord Kelvin on Nineteenth-century Clouds over the Dynamical Theory of Heat and Light. Succeeding discourses will probably be given by Professor T. E. Thorpe, Mr. Sidney Lee, Professor J. A. Ewing, Mr. Francis Fox, Sir Henry Roscoe, and other gentlemen.

THE "Autographed Photograph" Young Lady writes to our contemporary, *The Stage*: "I wrote to M<sup>de</sup>. Sarah Bernhardt when she was at the Adelphi last June, asking if she would favour me with her signature to an enclosed photograph of herself. As I had no reply, I wrote again, asking if she would allow some one to put it in the post, as it was already done up; and I have written twice to Paris, but can get no answer. I think she might have let me have the photograph back. My crime certainly did not merit so severe a punishment. I have wondered so many times if she ever saw my letter; and you so often mention the subject of autographs that I thought I would venture to ask if you could tell me whether M<sup>de</sup>. is obdurate on the subject. I sent the same request to M. Coquelin, and he was so exceedingly kind as to send me the signature. I am glad to see that some of the musical profession are following Mr. Barrett's example. But I wrote to an eminent singer in January, asking him if he would favour me with his signature, and enclosing a small donation for the benefit of the funds he might prefer. He has neither answered my letter nor acknowledged the order! I have written four times, enclosing a stamped, addressed envelope each time, but he will not deign to reply. It is not the value of the order I care about—he is quite welcome to that; but I think he might have had the courtesy to send back one of the envelopes just to say he received it. I have been much interested in the account of Miss Hosmer's adventures in pursuit of Sir Henry Irving's and Miss Terry's autographs. I can sympathise with her! I am so fortunate as to possess both their signed photographs. I shall never forget Sir Henry's kindness in sending his; there are not many people like him, for he always does everything in just the right way. No wonder he is loved as he is."

## Commercial Intelligence.

THE PHOTOGRAPHER AND THE THEATRE COMPANY.—At the last sitting of the Grantham County Court, before his Honour Judge W. Wightman Wood, Mr. H. J. Bliss, photographer, London-road, Grantham, sued the Grantham

theatre Company to recover the sum of 5*l.* 17*s.* 6*d.*, the value of oxygen gas, c., supplied. The defendants paid 4*l.* 1*s.* 4*d.* into court. Mr. J. B. Barlow appeared for the plaintiff, and Mr. T. Norton defended. In opening, Mr. Barlow said the gas was supplied for the purpose of producing limelight at the theatre, and the contract between plaintiff and the defendant Company's secretary (Mr. J. H. Sneesby) was that it should be supplied at catalogue price. Mr. Bliss said he had supplied the Theatre Company with oxygen since 1894 at catalogue price. He had an interview with Mr. Sneesby in November last, when he arranged to supply the Company at Brin's catalogue price, prompt payment to be made on the fifteenth of each month. He had applied all the gas charged for, and that was at the price quoted in Brin's catalogue. Miss Edith Thompson, in the employ of the plaintiff, gave corroborative evidence as to the agreement for the supply of gas. The defence as that prior to November last the defendants had been getting their gas direct from Brin, and, when Mr. Bliss sought their custom, he was told that they had no objection if he could supply gas at the same price as they had been paying. Mr. Sneesby showed complainant what price the Company had been paying, and complainant agreed to supply it at that price. When the account was sent in it was found to be excessive, and Mr. Sneesby complained to that effect. Mr. J. W. Bolton, Chairman of Directors of the Grantham Theatre Company, said he saw plaintiff at the end of October or the beginning of November last, and complainant asked to supply the Company with gas. Witness asked if he could supply it at the same price as they had been paying, and his reply was that he could. Mr. J. H. Sneesby, Secretary and Manager to the defendant Company, said the arrangement between him and complainant was that complainant should supply the gas at the price the company had been paying when they dealt direct with Brin. Other evidence having been heard, his Honour found for the plaintiff for the amount claimed, *ss.* 4*s.* 2*d.*

LONDON STEREOSCOPIC AND PHOTOGRAPHIC COMPANY, LTD.—The Fifteenth Ordinary General Meeting of the shareholders of the above-named Company was held on Thursday at 106 and 108, Regent-street, W. Mr. William Clarke, who presided, said: "It is rather curious that about this time last year Mr. Kennard (the Chairman of the Company) was kind enough to make an explanation with regard to my then absence in Egypt, and I have to make a similar explanation on his behalf to-day. He unfortunately, owing to the illness of his wife, has been compelled to take a voyage, and has not yet returned. I think I have very little to say concerning the affairs of the Company, but I regard the position as very satisfactory. There was less business done last year in the bicycle branch than had been done previously; but, of course, we knew that that was only a flash in the pan for the time being; but we are still carrying on the business, and find it more or less remunerative. What is more material is the progress of our photography work. As we all know, owing to the war, from the month of October last year to the end of the twelve months pretty well every one who had a 5*l.* note to spare very generously and properly put it into one of the excellent funds in aid of the families of those who have gone to the war, and I need hardly tell you that in this kind of business, if the spare 5*l.* note goes in that direction, there is so much less to be spent on what I may term the luxury of photography. Coal and food are necessities of life; but you can hardly say that of photography; and, although every trade must feel the effects of the war, I think it affects us more materially than, perhaps, any other industry. Although we did less amount of business last year in bicycles, it was by no means inconsiderable. It is rather remarkable, but exceedingly satisfactory, to observe that our net profits for the year are practically the same as in the year before. In other words, our purely photography business was very much better, and our four per cent. which we have earned during the past year was almost solely from photography. I think that is a very satisfactory state of affairs. What this year will bring forth I do not pretend to prophesy. Amongst the large number of officers at the front are many who are our customers, and no doubt we shall feel the effect of their absence. However, we shall do all that we can, and we cannot do more. Up to the present moment our business has been well maintained, and I see no reason to think that it will be otherwise. There is a certain amount of monotony at the meetings of this Company; but it is not altogether, perhaps, unsatisfactory. For three or four years we paid only two and a half per cent., but this is the fifth year that we have paid four per cent. Perhaps that is not a very large dividend; but I would remind you that we have a good deal of 'top hamper' in regard to the amount of our capital, and I think that, if we keep up our four per cent. in these times in a business of this character, it is not at all unsatisfactory. I now beg to move the adoption of the report and accounts as presented." Mr. Albert Slee Hicks seconded the motion, which was unanimously agreed to. The Chairman proposed the re-election of Mr. Hicks to his seat on the Board, and the motion was seconded by Mr. Thomson, and unanimously carried. Mr. Hicks thanked the shareholders for their renewed confidence, and said he had no doubt as to the successful future of the Company. On the motion of Mr. Lemaire, seconded by Mr. Stanbury, the retiring auditors (Messrs. W. B. Peat & Co.) were re-appointed. Mr. Cuthbertson moved a vote of thanks to the Directors, and said he thought they were to be congratulated on the results of their efforts for the past year. He believed their personal and practical interest in this Company was very great, and that they spared no pains to put it in a foremost position in London. He was especially gratified to see the efforts they were making in reference to fine-art studies, as he thought that was a move in the right direction. Mr. Douthwaite seconded the motion, which was unanimously passed. The Chairman acknowledged the compliment, and said the Board would do their best to keep up with the times, and meet the competition of the day. They had a large number of things brought to their notice in the shape of novelties and patents, and if they went into all of them they would soon be in bankruptcy. But they tried to select only those things that were of marketable value, and he thought they had been fairly successful in that respect. A great feature of their present work was the photography in relief, which was of a highly artistic character, and was becoming very popular. He concluded by moving a vote of thanks to the General Manager (Mr. Mitchell) and the staff, by whom, he said, the Company was really well served. They

had not only a skilled staff of men, but men who had the interests of the Company deeply at heart. This was not an easy business to carry on, and, under the circumstances, he thought their staff did remarkably well. Mr. Hicks seconded the motion, which was unanimously passed. Mr. J. Lillie Mitchell thanked the shareholders on behalf of himself and the staff generally. He remarked that even the smallest orders involved a large amount of detailed work, and had to be followed through every department. They had recently made a new departure in photography by calling in the assistance of an able artist, who took in hand the photographs, utilised certain parts, and produced an artistic picture in black and white, which was copied and offered to the public. The relief work was also an important branch, and, he thought, a very striking novelty. The Company had, with the patentee, secured the sole right for the next three years of publishing the portraits of celebrities by this process. The Company's pictorial post cards maintained their popularity in spite of all competitions, and he certainly thought they were the best value for one shilling that anybody could have. They were just issuing to the public a souvenir war sheet, comprising portraits of military men who figured most conspicuously in the present war, including one of General Roberts, which was recognised as the best in the market. They were to be sold at one shilling each, but it was the intention of the Company to send copies to the different convalescent hospitals where our wounded soldiers were being looked after, as it was considered it would be gratifying to them to see likenesses of their leaders. At the suggestion of a shareholder, who pointed out that this Company possessed the privilege of a Royal Warrant, it was unanimously resolved to send a message of congratulation to H.R.H. the Prince of Wales on his providential escape from assassination at Brussels. A vote of thanks to Mr. Clarke for his conduct in the chair terminated the proceedings.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
16.....	Bootle .....	{ Excursion: Ince Woods. Leader, Mr. Wright.
16.....	Borough Polytechnic .....	{ Excursion: Chichester Cathedral. Leader, F. W. Gregg.
16.....	Stafford Photo. Society.....	Prize Slides.
17.....	Gospel Oak .....	{ Illustrated Lecture: <i>How a Lens is Made.</i> Lent by C. P. Goerz.
17.....	Hackney .....	{ The New "Pressed" Gas Light for Portraiture. Messrs. Adamson Bros.
17.....	Isle of Thanet .....	{ Demonstration: Film Photography. Secco Film Company.
17.....	Redhill and District .....	{ Lakes, Mountains, and Glaciers of Switzerland. Jas. A. Carter, B.A.
18.....	Croydon Camera Club .....	{ Plates and Papers for Pictorial Effects. A. Horsley Hinton.
18.....	Southsea .....	{ The Photographing of Flowers. H. T. Malby, F.R.P.S.
18.....	Tunbridge Wells .....	{ Demonstration of Secco Films by the Makers.
18.....	Woodford .....	Exposure. Alfred Watkins.
19.....	Darwen .....	Members' Lantern Slides.
19.....	London and Provincial .....	Projection. Thomas E. Freshwater.
19.....	Oldham .....	Exhibition of Members' Transparencies.
20.....	Croydon Microscopical .....	{ Demonstration of the Manipulation of Secco Films.
20.....	West London.....	{ Beginners' Meeting: Subjects and their Treatment. J. Brown.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 5.—Mr. H. C. Rapson in the chair.

Mr. W. THOMAS laid before the meeting a matter which had been brought to his attention by Mr. W. H. Atkinson, of Batley, Yorks. Some three years ago a greenhouse was put up in the neighbourhood, and the builder asserted that the glass used was quite new. Eighteen months after its erection Mr. Atkinson noticed that one of the panes of glass bore a faint likeness of a man's head and shoulders, and looking again, after another four months had elapsed, found that the image was much more pronounced. With a desire to get to the bottom of the affair, he had the glass removed, and this Mr. Thomas now submitted. The image was undoubtedly formed by a lens, and the suggestion was that the glass was a spoiled plate from a photographer's studio. It appeared also that the portrait had been recognised as that of a man living in the neighbourhood, although no steps appear to have been taken to confirm this, and so to trace the photographer. The image was fairly strong, and resembled that on a collodion plate.

Mr. R. CHILD BAXLEY, who had had part of the negatives through his hands, said he had submitted it to various tests. Dilute nitric acid failed to affect it, as did a violent scrubbing with Hudson's soap, and again mixed sulphuric and nitric acids. Not to miss a possible means of affecting the image, cerium sulphate—the new reducer—was tried, but to no purpose. Ultimately it was found that sulphuric and nitric acids put upon the plate, and gradually warmed over the gas, had the desired effect, and the deposit, whatever it might be, was removed.

Mr. S. H. FRY related the details of an incident of a similar nature which came within his own experience. Some years ago a man complained that certain plates had been exposed before coming into his possession in the ordinary way by purchase. He sent along a couple of the plates that he had exposed and developed with the rest of those in the box. Examination of the negatives revealed the fact that there were two images; one was that produced by the photographer, and the other was a portrait of a girl employed in the plate factory. It appeared that the girl served as the model for the testing of the plates, and that these test negatives had been only partially cleaned, re-coated, and issued.

Mr. A. MACKIE stated that in the old days, when glass plates were repeatedly used, it was not an uncommon thing to find such secondary images as this passed round, due to imperfect cleaning.

It was found that one side of the plate in question freely took pencil impressions, and scraping with a knife brought something away. But, as Mr. Welford said, although one could easily accept the explanation so far advanced, it was difficult to account for the development (so to speak) of the image while the glass was exposed upon the greenhouse.

#### PHOTOGRAPHIC CLUB.

APRIL 4.—Mr. F. A. Bridge in the chair.

Mr. W. THOMAS, F.R.P.S., gave a chat on

#### LANDSCAPE PHOTOGRAPHY,

which was listened to with considerable interest, the capabilities of the lecturer in this branch of photography being well known. With reference to the lenses to be used, Mr. THOMAS remarked upon the deeply rooted impression with most people that a good lens of the rapid rectilinear type was a necessity. In his own work, which covered a very wide range, he was shown, however, that this was not necessarily the case. He had secured effects which, in his own opinion, were some of the best he had done, employing cheap spectacle lenses, varying in price, according to his requirements, from pence to three and four shillings. He passed round a set of Busch lenses of this character, with the capabilities of which he was entirely satisfied, the definition being all that he could desire. Mr. THOMAS strongly emphasised the value of long-focus lenses, and showed a picture of Scarborough Headland to illustrate his points. Touching briefly on the much-discussed question of "tinkering" the developer, he then passed on to describe his practice of making rough notes of any effect which might strike him in any of his wanderings, urging the cultivation of a similar habit by others as a considerable aid to picture-making by photography. These notes, for the greater part, consisted of rough sketches in crayon, pencil, or oils, and, when at some future time he might be striving after some particular effect, consultation of these notes proved a great help in carrying out an idea. With practice, anybody, he believed, could acquire sufficient skill to make very useful memoranda of the kind referred to. The lecturer then showed his method of "dodging" or improving a negative, which experience might have demonstrated as in want of a little faking. A piece of tracing paper is laid down on and affixed to the back of the negative. Upon this, with black lead, the "working up" is applied until a satisfactory result is arrived at, frequent "rough pulls" meanwhile being taken to show how matters were proceeding. Several negatives were passed round, some of them particularly fine cloud studies. In this connexion he said that he always used a yellow screen and an isochromatic plate for cloud work, and, in concluding a most interesting and instructive chat, gave expression to the following additional information: In aiming at the production of pictorial work by photography, one must first qualify, he said, as a "good photographer," then as a "skilled photographer," and then, and not till then, attempt to employ that indescribable "something more" which is necessary to the production of a "picture."

A short discussion ensued, in which the Chairman made a few remarks as to truthful photography, drawing comparisons between the kind of work advocated by Mr. Thomas and that known as "bread-and-butter" photography. A hearty vote of thanks to Mr. Thomas for his lecture was given with acclamation.

**Hackney Photographic Society.**—April 3, Mr. F. C. Gosling presiding.—Among other items was an interesting discussion on the action of rosin and hydroquinone as developers, alone and combined. The CHAIRMAN showed a very portable home-made view-finder, which was made to fold up for the pocket, and could be used either as a direct vision-finder or with a reflected image. Several members also described home-made contrivances for hastening the removal of hypo from prints and negatives. Finally Messrs. WEBB and PRINGLE gave an exhibition of lantern slides, illustrating a cycling tour in Normandy.

**Edinburgh Photographic Society.**—At the last meeting, Mr. James Hay presiding, Mr. J. EDINGTON AITKEN read a paper on Paper-making, with special reference to its photographic uses, stating that the British paper-makers had not been able to supply the demand for photographic paper, so that the photographer had been compelled to go to the Continent. The lecture was illustrated by twenty lantern slides, and there was a demonstration of paper-making, a sheet of paper from wood pulp being produced in the room.—Mr. JOHN WARRACK, jun., then read his essay which won the silver medal at the recent Exhibition. The paper dealt with still-life photography, showing that in this line of art the photographer was cut off from illegitimate aids, and nothing but a feeling for composition and a genuine artistic taste could carry him through the ordeal. Richness of effect was not gained by complexity of subject or by the gorgeousness of component parts, but rather by the perfection of harmony that transfigured a few simple elements into loveliness. And if a study of still life brought the photographer to realise this, and apply to his other work the knowledge that it was not what he saw, but how he saw, that mattered, he would find that in engaging in it he had not only gained an inexhaustible resource, but had harboured an angel unawares, and that henceforth his labour had become a delight, and his day's work a romance. Both lecturers were cordially thanked for their papers.

#### FORTHCOMING EXHIBITION.

1900.

May 23-25 ..... Plymouth Photographic Society. Hon. Secretary, W. H. Harris, 5, Clarendon-place, The Hoe, Plymouth.

Those who desire to send photographs to the above Exhibition should write for prospectuses to the Hon. Secretary, whose address is given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Patent News.

THE following applications for Patents were made between March 26 and March 31, 1900:—

- STEREOSCOPIC CAMERA.—No. 5606. "An Improved Form of Hand Camera, Convertible from a Stereoscopic to a Single Pattern by Moving an Outside Lever." W. TYLAR.
- DESIGNING MACHINE.—No. 5618. "A Photographic Designing Machine." Complete specification. R. H. BASKETT.
- PRINTING FRAME.—No. 5702. "The 'Register' Photographic Printing Frame." G. HYDES and W. BOTTOM.
- SHUTTERS, &C.—No. 5737. "Improvements in Appliances for Adjusting and Working the Shutters and Diaphragms of Photographic Cameras." A. WATKINS.
- PHOTO-CHROMO-STEREOSCOPES.—No. 5799. "Improvements in Photo-chromostereoscopes applicable also to Cameras." T. K. BARNARD and F. GOWENLOCK.
- PRINT-TRIMMER.—No. 5804. "An Improved Contrivance or Device for Cutting or Trimming Circular or similar Photographic Prints or the like." H. WYKES.
- FINDERS.—No. 5934. "Improvements in and relating to Photographic Finders." W. W. BEASLEY.
- COLOURING PHOTOGRAPHS.—No. 5939. "Improvements in Colouring Photographic Portraits." F. W. HAYWARD.
- STEREOSCOPIC VIEW.—No. 5984. "An Improved Stereoscopic View." W. H. GRANT.
- LENS MOUNTS.—No. 6029. "An Improvement in Lens Mounts for Photographic Cameras." Complete specification. W. TAYLOR.
- SHUTTERS.—No. 6058. "Photographic Shutter Working without Jerks, and Adjustable for Different Speeds for either Instantaneous or Time Exposures." Communicated by N. Hansen. Complete specification. W. J. MUNDEN.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE NEW COPYRIGHT BILL.

To the EDITORS.

GENTLEMEN,—In the copy of the new Copyright Bill in your JOURNAL of March 30, I see that, "when a photograph is made of any person for a valuable consideration, the owner of the copyright shall not, during the life of the person photographed, be entitled to sell or exhibit, without his consent, copies of his photograph; but, save as aforesaid, the owner of the copyright in a photograph may deal with his right of copyright without the consent of the owner of the photograph, or of any copy thereof."

It seems to me that under this clause the photographer may, after the death of a person, sell copies of the photograph of a private person or a lady, and even transfer the right to do this by mere delivery of a negative (possibly by mistake), and that such a right is hardly contemplated by those who have draughted the Bill and should be opposed.

It must be evident that, even if a negative were stolen, the family of the subject of a photograph would be unable to prevent the holder of the negative from using it as he chose, to their great annoyance, for it would be practically impossible to prove that copyright had not passed by delivery; in this case therefore there would be no protection even in the good feeling which animates the large body of the profession. I trust that this may be modified, or gentlemen will become cautious how they allow the ladies of their families to sit for their photographs.—I am, yours, &c., J. F. T.

#### AN ADDRESS WANTED.

To the EDITORS.

GENTLEMEN,—Through the medium of your valuable paper I was enabled to ascertain the address of a sculptor, competent at carving busts from photographs, I now desire a like advantage for the name of a clever hand at cutting cameos also from photographs, thanking you or your informant in advance.—I am, yours, &c., W. D.

[We shall be happy to receive such an address from those of our readers in possession of it.—EDS.]

#### STEREOSCOPIC PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—I have read with much enjoyment your article on Stereo Photography in the ALMANAC, especially that part detailing your "little

experiment." This I have succeeded in, and can now get a full stereoscopic effect with even unmounted prints. I find, however, that the effort affects my eyes at the time, and my object in writing is to ask you whether, if frequently practised, the effort might not injure the eyesight.

I may say that by getting people to focus their eyes on some object a few feet away, and then to insert in the line of vision the twin photos, viewing them *without altering the focus of their eyes*, several have obtained the proper stereo effect; but all complain that it affects their eyes.

I am immensely pleased to have acquired this, but should like to be assured on the question of eyesight.

I send you a couple of views of the Falls here (Umgeni River, 300 feet, sheer drop), taken from across the valley. Being only on a visit, I am unable to mount them.

If you have time to reply, will you kindly address me at Box 106, Lorenzo Marques, Delagoa Bay. I need hardly say that any remarks *re* photos sent will be much appreciated. Trusting I am not troubling you unduly,—I am, yours, &c.,  
H. W. WEEDON.

*Howick Falls Hotel, Howick, Natal, March 15, 1900.*

[We do not think that our correspondent's eyes are likely to suffer injury by using them in the manner referred to. It is several years since we acquired this command over the power of accommodation, and we have traced no ill effects to it. We have known photographers to exercise this form of optical control for over thirty years, and they have not complained of having harmed their sight. The radii of curvature of the crystalline lens are altered by the influence of the ciliary muscles, which agency also parallelises or converges the optic axes. This is all that may be assumed to take place in looking at binocular views without a stereoscope, and it is difficult to see that any harmful effects can ensue, *provided that the photographer is endowed with normal vision and binocular prints are not mounted at wider centres than 2 $\frac{7}{8}$  in.* A separation of over 3 inches certainly strains most eyes, and *might* cause divergent strabismus. The prints sent are capital.—EDS.]

#### DUPLICATING DIFFRACTION GRATINGS.

*To the EDITORS.*

GENTLEMEN,—As to the question of novelty in making screens on a thin transparent substance from a ruled grating, as shown by Mr. Thorp, of Manchester, and referred to by Professor Wood, I would like to state a few facts as to the originality of this method of making Diffraction Gratings.

At the beginning of this century, Sir Wm. Herschel experimented with throwing powdered hair into the air before a concave mirror, on which a beam of light was incident, the reflected light received upon a screen gave a perfect spectrum, the particles of scattered hair taking the place of the grating shown by Professor Wood. Sir David Brewster followed up this experiment, and showed an analogous phenomenon in mother-of-pearl, which substance, you know, is obtained from the pearl oyster; and, if a piece with nearly parallel surfaces is taken, and ground down on a stone until the image of a candle, reflected upon its surfaces, is of a dull reddish-white colour, on placing the eye near the plate, we shall see the reflected image of the candle on each side of the centre image, but showing a perfect spectrum, and the angle at which we hold the mother-of-pearl will determine the number of these spectra, exactly as shown by Professor Wood. If the mother-of-pearl is ground extremely thin, and placed in the path of a beam of light, we get the same result exactly as shown with the grating. In making this experiment, Sir David Brewster had occasion to fit a piece of mother-of-pearl to a goniometer with a cement of resin and beeswax, and, upon removing it, he was surprised to see the whole surface of the wax shining with the prismatic colours of the mother-of-pearl. He at first thought that a small film of the substance had been left upon the wax, but soon found this to be a mistake, and it became manifest that the mother-of-pearl had really impressed upon the cement its own power of producing the coloured spectrum. Black wax is the best to use, but transfers can be made on balsam of tolu, isinglass or gum arabic, and to clean surfaces of lead or tin by hand pressure, or the blow of a hammer, and it was calculated that the veins to produce these colours were so small that 3700 of them were contained in an inch.—I am, yours, &c.,

*April 7, 1900.*

W. P. DANDO.

#### ORTOL IN INDIA.

*To the EDITORS.*

GENTLEMEN,—With reference to the letter on the above subject, on page 143 of your number of the 2nd instant, I suppose that "Tippoo" is trying to be comic in his account of how he failed to make up ortol into a proper solution; but it does not appear to have occurred to him that it was probably his own fault.

Ortol is used regularly by several photographers in my neighbourhood, and they all speak of it in the highest terms. I only write these few lines to prevent others being put off a really good thing by the condemnation of one who has, apparently, made a muddle of his one trial at making up the developer *in one solution*.—I am, yours, &c.,

SULTAN.

#### THE METRIC SYSTEM.

*To the EDITORS.*

GENTLEMEN,—It is not our business to offer an opinion as to the advantages or disadvantages of the metric system for "the ordinary purposes of life;" the fact that a large proportion of the intelligent public demand it is enough for us to consider. We have, therefore, decided that, in future, all formulæ for our Barnet plates and papers will be given in the metric system as well as the English weights.

For the convenience of our customers we are issuing a little pamphlet giving all our formulæ in this form, together with other useful information, a copy of which we shall be pleased to send, as soon as it is ready, to any one sending us their address.—We are, yours, &c.,

*Barnet, Herts, April 7, 1900.*

ELLIOTT & SON.

#### DECEASE OF THE LEWISHAM CAMERA CLUB.

*To the EDITORS.*

GENTLEMEN,—I regret having to request you to announce that this Club has been dissolved, a resolution to that effect having been carried, *nem. con.*, at the Annual General Meeting held on the 3rd inst.—I am, yours, &c.,

THOS. P. ROGERS, *late Assistant Secretary.*

*44 Manor-road, Brockley, S.E., April 9, 1900.*

#### STRIPPING ENAMELLED PRINTS FROM GLASS.

*To the EDITORS.*

GENTLEMEN,—I have noticed lately a lot of your correspondents complaining of the difficulty of stripping enamelled prints from glass. This difficulty can be entirely done away with by applying a little waxing solution on a tuft of cotton-wool and polishing well afterwards. The prints will then be found to strip quite easily. The waxing solution can be made by dissolving white wax in benzole, or can be bought from almost any dealer.—I am, yours, &c.,

RUPERT GOODCHILD.

*Laurel Bank, Alexandra-road, Manchester, April 19, 1900.*

#### REFLECTIONS.

*To the EDITORS.*

GENTLEMEN,—In your JOURNAL of the 30th ult. I notice a paragraph, by our dear old friend, Mr. York, with reference to the demolition of that block of buildings at the south end of Tottenham Court-road, which removed, "at one fell swoop," the studio where, more than twenty years ago, the now historical "Brittlebank meetings" were held.

Ah, me! I have been sad ever since I read that paragraph; and even now feel sentimental, and, like Silas Wegg, inclined to "droop into poetry." Twenty-one years ago (echoes of melody whose voice is fled)—yes, here (I mean *there*) in 1879, "in the prime of summertime" (evenings not "calm or cool," by the bye), a party of gentlemen—members of the old South London—met in that studio, "far removed from the busy haunts of men," and redolent with the odours of fried fish from the restaurant below (the studio, not the gentlemen) to discuss the possibilities of gelatine. "Where is that party now?" scattered! very considerably scattered.

And can it be that the National Record Association, among the hundreds of photographs it has already accumulated, has no picture of these premises? But no matter—a friend has kindly sent one to me, and, knowing your reverence, Mr. Editor, for all that has contributed to photographic journalism, I have taken the liberty of forwarding it to you, that in the quiet evenings ("when the lights are low") you may ruminate on the importance of these early meetings.

Yes, who can tell the influence of those meetings on the future of gelatine? If those gentlemen had never met in that far-distant time to nurse the new baby, how different things might be now. But for these meetings the baby of twenty-one years ago might not be the giant he is at present. The cinematograph might be still unknown, our thoroughfares might never have been traversed by thousands who only "press the button," and leave others to "do the rest." The professional might still be working in an atmosphere of collodion and cyanide; we might still be struggling on with only two photographic journals; photographic societies might not be flourishing (more or less) in every parish; there might even be no National Record Association.

But why continue these sad reflections? Go to! The County Council has spoken; a once-hallowed spot has departed, and, "like the baseless fabric of a vision," left "not a wrack behind."—I am, yours, &c.,

REQUIESCAT IN PACE.

[Our friend is good enough to send us a print from a negative of the celebrated Tottenham Court-road corner, and that print is at once added to our collection. The photographic studio is shown in the top part of the picture, and we see by the theatrical bills on the walls that the photograph was taken in the eighties, *Claudian* and *Called Back* being some of the dramatic fare then current. We never had the opportunity of attending a "Brittlebank meeting," but we have the pleasure of knowing most of those who did. Perhaps no more enthusiastic or better-informed band of workers ever gathered together for purposes of mutual help and study in practical photography.—EDS.]

## VIGNETTED NEGATIVES.

To the EDITORS.

GENTLEMEN,—Referring to the above article in THE BRITISH JOURNAL OF PHOTOGRAPHY, I enclose you a print from a negative vignetted in the camera eight years ago, and recently adopted for the medallion—a style that is much admired in my studio—the rounding-out of the oval with stereoscopic effect has met with great admiration. If you see anything in the photograph worth your notice, I shall be glad to know it.—I am, yours, &c.,

G. HIGGINSON.

The Polygon Studio, Bowdon, Cheshire, April 9, 1900.

P.S.—You may remember my name in connexion with the carbon process when I was in Southport over twenty years ago.

[We are very much obliged to our old correspondent and supporter for the print. As a specimen of camera vignetting, it is admirable, while, as an example of portraiture, it has great delicacy of rendering, and is altogether excellent.—EDS.]

## EXPOSURE AND DEVELOPMENT.

To the EDITORS.

GENTLEMEN,—With reference to a recent lecture of mine now appearing in THE BRITISH JOURNAL OF PHOTOGRAPHY under the above title, may I anticipate any criticisms of its elementary character by pointing out that it is one of a series of six "Lectures to Beginners," prepared by the members of the West London Photographic Society, and delivered during the current session for the benefit of their less experienced fellow-members? The officers of this Society attach great importance to lending a helping hand to beginners, and have endeavoured to give effect to their views in this series of lectures and demonstrations.

The above lecture was repeated by invitation at a meeting of the Chiswick Camera Club.—I am, yours, &c.,

G. F. BLACKMORE.

34, Wendell-road, London, W., April 9, 1900.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street, Strand, London; W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED :—

G. V. Simmons, 53, Bridge-street, Portadown.—Photograph entitled "Hurry back, ladde."

G. B. Bradshaw, High Bank Studio, Altrincham.—Photograph of Amateur Naval Brigade in Patriotic War Fund procession, Altrincham.

PHOS (St. Paul).—1. We are sorry that such information is not available. 2. Woodbury's book on gelatino-chloride, published by Hazell, Watson, & Viney, 1, Creed-lane, London, might assist you.

CHOICE OF LENS.—P. BIDGOOD says: "I want a lens, and I am undecided as to which to have, a  $f$ -5.6 or a R.R.  $f$ -8, price being a consideration. Will you, please, tell me if there is really very much difference in their rapidity?"—Yes. The latter will require just double the exposure of the former when both are worked with their full aperture. When both, however, are stopped down to the same ratio, the one will be as quick as the other.

FLASH LIGHT.—A. WILMOT writes: "Will you please say if the enclosed formula is a good one for a flash light. It is said to give a most actinic light, and be of very short duration?"—The formula will give an excellent light, but we should advise our correspondent to have nothing to do with it, as it is a very explosive and dangerous mixture. All these highly explosive compounds are liable to "play tricks" at times, and when they do it is generally when least expected.

GOLD PRECIPITATING.—LANCS writes: "Can you tell me the cause of this? I dissolved a tube of Johnson's chloride of gold in two ounces of water as usual. As soon as it dissolved the solution turned a purplish-brown tint, and next day there was a brown deposit at the bottom and on the sides of the bottle. The bath made with it will not tone at all?"—The cause is either that the water was impure or the solution was made in a dirty vessel, and the gold has been precipitated.

FORMULA WANTED.—AMERICAN writes: "Messrs. — have recently placed on the market a paper that is worked in a similar fashion to blue print paper, with the exception that it is afterwards passed through an extremely weak hypo bath. As Mr. — lists this in his catalogue, I suppose it to be a well-known paper, and I would be greatly obliged if you could give me the formula by which it is made."—In reply: If our correspondent will send for Patent No. 8771 of 1884, to the British Patent Office, London, he will probably obtain the information required. The specification will cost eightpence, postage extra.

COPYRIGHT.—LA LA writes: "I photographed a football team for a publisher (he paid me 10s. for cabinet size) for publication. He placed it among several others in book form, and put 'Copyright' on the front cover of book. He now writes to say that, if any publisher wants copies from us for publication, we must refer them to him, as it is copyright. I want to know, is it copyright, as we were never told anything about it before? We have given no consent for copyright."—In reply: The publisher is within his rights. According to the Act, you received "valuable consideration," i.e., payment, and therefore the copyright does not rest with you.

WORKING UP ENLARGEMENTS.—FORWARD writes: "Will you please inform me what is the colour used for working up platinotypes and bromide enlargements? Sepia, when it is used, I find not the exact shade. I have been told lampblack answers. If this is correct, will you inform me what it is soluble in?"—The ordinary water colours are employed, but, of course, they have to be blended to match the tint of the picture. Ivory black, modified with indigo, is very good for platinotypes. "Sepia" photographs are seldom the colour of the true sepia, and the water-colour sepia generally requires modification to match the tint of the picture.

BLACK TONES; SPOTS ON PRINTS.—AMATEUR writes: "Will you please inform me the way to get a black tone, also the cause of white spots on print enclosed? I find the fault is in the negative, as it appears to be full of brown specks."—If a black tone is required, we should advise the platinotype or the carbon processes. Dark purple-blacks may be obtained on albumen paper if a strong negative be employed; but in all silver processes, if dark tones are desired, a vigorous negative is essential. Gelatine papers are not well suited for black tones. The spots in the negative are evidently due to its being printed from with damp paper, which has stained the negative or spotted it.

FOGGED PLATES.—R. M. writes: "I shall esteem it a great favour if you will kindly give me the benefit of your advice regarding the accompanying negatives. Do you consider No. 1 too intense, and is it over-exposed? I gave it one-fiftieth of a second with  $f$ -11, and I think No. 2 was the same. Both are fogged at the sides, No. 2 more than No. 1; both were of the same batch, and put at the same time in the plate box about a fortnight before exposure. Can you account for this?"—In reply: No. 1 presents the appearance of having been slightly under-exposed and over-developed. The plates were probably fogged before development, and the latter has intensified it. No. 1 would give a very hard print.

FORMULÆ WANTED.—W. C. Napier writes: "1. Would you do me the favour of informing me, in accordance to what formulæ the standard hydroquinone developers put up in packets dry. 2. Also I have seen 'Combined Toning and Fixing' put up in small packets dry. Could you give me the formula of a combined bath for P.O.P. which may be stored dry in packets?"—1. We are unable to give the information desired, as the Company who put the materials on the market do not publish the formulæ by which they are compounded. 2. Here, again, we are unable to reply, inasmuch as chloride of gold is a deliquescent salt. However, any of the formulæ that contain alum, lead, &c., will tone without the gold, and the ingredients can, of course, be put up as a powder.

FIXING TANKS, &c.—C. P. writes: "I use quarter, half, and whole-plates, and in fixing the quarter and half-plates in a flat 10x8 dish it is all right, as one is always fixed by the time I developed one; but, when it comes to developing and fixing several whole-plates at one time, it becomes vexatious, for I am obliged to wait until one is fixed before developing another, and I don't care to pay so much for a porcelain or rubber fixing box, as they cost about three dollars here, but I would like a cheaper yet as good a substitute. I see several washing boxes, but they are made of zinc, and hypo soda is injurious on that metal; could you suggest a cheap and serviceable one?"—In reply: Messrs. Taylor, Tunnickliff, & Co., of Hanley, Staffordshire, manufacture grooved, "granitine," plate-washers, which might answer our correspondent's requirements. They are obtainable from all dealers here.

RETICULATED COLLODION.—G. J. JOHNSON writes: "I am engaged on some fine scale work by micro-photography, using both wet and dry-collodion plates. Unfortunately a troublesome reticulation appears sometimes on the wet collodion, and always on a well-known maker's dry-collodion plate. My object is to secure the finest grain of deposit and the thinnest film. So far I have not succeeded beyond photographing distinctly 5000 lines to the inch. Can you help with any suggestions to avoid the reticulation and to secure fine deposit?"—The only suggestion we can make is to try another brand of collodion for the wet process. If the dry plates show reticulation, it is clearly due to the collodion used, and there is no remedy, as it exists in the film itself. The finest deposit obtainable is by the albumen process. In this process the image partakes more of the character of a stain than an actual deposit of silver.

STUDIO-BUILDING.—"STUDIO" writes: "I am about to erect a studio in my garden, as per illustration, which I trust is made clear to you, but am in doubt about the wall at the farther end of the garden. I should like, if possible, to place the studio at the far end, that is to say, up close to wall, as it will be more convenient. Will you kindly say if you think the wall will interfere with the lighting in studio, or if same will be best placed in the centre of garden. My studio is thirty feet long, with the centre ten feet of roof and both sides glazed, as per rough sketch following. I want to make use of the north light, so shall be extremely obliged if you will enlighten me on the above query before I place studio in position."—The wall at the end will in no way interfere with the light in the studio, indeed it will be an advantage rather than otherwise, by stopping off the afternoon sun. You can place the studio close up to the wall if you choose.

### EX CATHEDRA.

WE have the authority of the *Scientific American* for the announcement that Mr. George Eastman has presented the princely sum of \$200,000 to the Rochester (N.Y.) Mechanics Institute without conditions. The money is to be expended in enlarging the present building. A year ago Mr. Eastman distributed several thousand dollars among *employés*, according to their terms of service. Our contemporary adds that "thus the people of his own city are benefited by his generosity, while the public at large derive benefit from the use of his inventions and appliances. He has been most successful as an organizer and leader of large corporations."

\* \* \*

At the Society of Arts, on Monday evenings May 7, 14, and 21, Professor Vivian B. Lewes will deliver a series of Cantor Lectures on the "Incandescent Gas Mantle and its Use." As the subject is of interest to many photographers, we append the heads of the three sections under which Professor Lewes classifies it:—Lecture I. (May 7).—"The History of In-

candescent Gas Lighting."—The discoveries that led to the mantles of to-day; the oxides suitable for mantle-making, and their preparation; the services of thoria and ceria, and the methods adopted for their extraction. Lecture II. (May 14).—"The Manufacture of the Incandescent Mantle, and the Influence of the Process employed on the Life of the Mantle."—Manufacture by impregnation of vegetable fibres, and by moulding the oxides into thread; the recent advances in mantle-manufacture; the theory of the incandescent mantle, and the causes which lead to luminosity. Lecture III. (May 21).—"The Gas Burners employed in Incandescent Lighting."—The theory of the Bunsen burner; the adaptation of the Bunsen burner to the incandescent mantle; modern burners and their aims; the effect of the chimney; chimneyless burners; high-pressure burners; the influence of the quality of the gas on the conditions of burning; the use of water gas in incandescent mantle burners.

\* \* \*

IN the JOURNAL of February 16 we referred to the Order in Council providing that acetylene, when in admixture with atmospheric air or oxygen, should be deemed to be an explosive within the meaning of the Explosives Act, 1875. It is now stated that the operative clause in the Order is as follows: "Her Majesty is pleased, by and with the advice of Her Privy Council, to order and prescribe that acetylene in admixture with air or oxygen, declared to be an explosive by this Order, shall be prohibited from being manufactured, imported, kept, conveyed, or sold. Provided that nothing in this Order shall apply to acetylene in admixture with air when such admixture takes place only in a burner or contrivance in which the mixture is intended to be burnt. Provided also that nothing in this Order shall be held to apply to an admixture of acetylene and air which may unavoidably occur in the first use or recharging of an apparatus properly designed and constructed with a view to the production of pure acetylene."

\* \* \*

THE shelves of the Patent Office must be well laden with specifications of patents for modes of soldering aluminium, yet

still it remains a most difficult feat, as the work might almost be called. We hear of still another patent, and, of course, it is said to be good, in fact to answer extremely well. We believe the method hitherto considered the best is still jealously regarded as a trade secret. Apart from secret processes, the great point in soldering this most difficult metal is absolute cleanliness. The parts to be soldered must be scraped or filed till perfectly clean, and then thinly "tinned" by heating or rubbing with a stick of solder. The surfaces are next brought together and the soldering iron drawn along the joint, using a small quantity of extra solder.

\* \* \*

WE do not now hear much of annatto, which once was widely recommended for plate-backing, caramel having met with greatest favour of late, and being, indeed, an excellent agent by reason of its solubility, avoiding any difficulty in sullyng the gelatine surface. It has been suggested to us lately that the well-known *dragon's blood* might be used with advantage, but we cannot see that its use would be free from the drawbacks of other powders, for, though it is soluble in alcohol and ether, it is insoluble with water. It would, no doubt, be less costly than coloured collodion, and more readily removed, but the collodion idea has been well exploded some time since. We note an ingenious method of obtaining a pure caramel by first heating pure sugar to 180°–190° C. in the usual manner, and getting rid of the unchanged sugar by adding yeast, and thus causing fermentation; but, for photographic purposes, a little unchanged sugar is of no injury.

\* \* \*

THE question of the absorption of Röntgen rays by various metallic solutions has been investigated by Messrs. Gladstone and Hibbert. They find that, using the same acid in combination with various metals, the opacity increases as the atomic weight of the metal increases. Bromides and iodides are very opaque, and of other salts the nitrates, chlorides, and sulphates obstruct the rays with increasing strength according to the order we place them in. The opacity is not a simple function of the thickness of the layer, but varies logarithmically with the thickness.

\* \* \*

FOR ordinary purposes, a well-made litmus paper—and there are wide divergencies of excellence and of sensitiveness in the various litmus papers sold—answers for most photographic requirements, the testing of the silver floating bath for albumenised paper being nowadays the main occasion when anything of the sort is needed, though it is still of importance where wet collodion is employed, as usually in process block-making, &c.; but, when we come to test the purity of our chemicals, a good indicator is an almost necessary adjunct. The most recent candidate for public favour is a new agent termed luteol, whose merits are extolled in an article in the *Moniteur Scientifique*, as quoted in the current number of the *Chemical News*. Our readers may not deem it necessary to know much of its chemical constitution; still, we may quote the writer, who states that luteol is "nothing else but" oxy-chlordiphenyl-chinoxaline. It is easily soluble in alkalies, alkaline carbonates, or ammonia, and gives then a pronounced yellow. The moment enough acid is added to neutralise the alkali, the luteol is precipitated and the colouration disappears, a faint white cloudiness taking its place. This indicator appears to be of marvellous delicacy, a distinct yellow being

visible when either litmus or phenolphthalein cease to indicate; and, what is of importance, the change of colour brought about by the change from acid to alkali, or the reverse, is very quick.

\* \* \*

MR. C. G. ABBOTT, who has charge of the Astro-physical Observatory of the Smithsonian Institution, has been comparing the light from the Welsbach and other incandescent mantles with the indications given by the orlometer, so as to form an estimate of their relative efficiencies. He found the illuminating powers to differ considerably, and even the Welsbach burners were, compared with the actual energy produced, very wasteful. The greater part of the energy obtained lay on the infra-red region, where, of course, it was useless for light-giving purposes. Excluding, however, this portion of the spectrum, the Welsbach proved superior to any of the others, and more particularly in the red, orange, and yellow regions. In contrasting Welsbach burners with other sources of illumination, for a fair comparison to be made, a mantle that has been in use for some little time should be employed, for we need scarcely draw attention—at any rate to habitual employers of this light—to the fact that the illumination given by a mantle, say a month old, is a fraction only of that given off from one recently put on the burner. Whether this loss of power be due to the dissipation of one of the mantle constituents or to the deposit of iron carbonyl upon the meshes does not need to be decided, the fact of the loss of power is too true.

#### THE FORTHCOMING ECLIPSE OF THE SUN.

As some of the most important facts regarding the constitution of the sun are only observable on the rare occasions of its eclipse, such an event naturally holds a place of high importance in the investigations of the various astronomical associations of the world, and the impending eclipse is attracting exceptional interest on account of the central line of totality passing through regions within easy distance of our own shores notably in Spain and in Portugal. A wise preliminary precaution has been suggested, in view of past experience thirty years ago, that is, to make all possible arrangements beforehand with regard to customs duties and customs officers, who, of course, are known all over the world for their courtesy and consideration! We call special attention to this matter from a knowledge of the large number of individual observers who are going over on the present occasion.

The observatory of Madrid naturally offers special facilities for the work of observation, and the Spanish Government will offer every facility to foreign astronomers who may come for the purpose of observation on the 28th prox. It is probable however, that few will avail themselves of this opportunity, as Madrid is not well suited for the purpose, Naval Moral, on the Caceres line, and 200 kilometres from the capital, being far better, the period of totality extending there for two minutes.

Many observers are going to North Portugal, and will probably choose Oporto as their post of debarkation, and proceed from there to Ovar, which is close to the coast, and only twenty-two miles distant from the former town. Many reasons will deter them from choosing Lisbon, which, besides, possesses little interest to the traveller. There are no seaport towns on the west coast of Spain where the eclipse can be observed; if a coast station be desired, a Mediterranean one would have to be

ected. Eclipse observations owe the greater part of their value in recent times to the aid which photography renders, and we anticipate a large number of practical astronomers will be on the spot. They may be expected after the serious work is over to secure what views they can of popular interest, and within thirty or forty miles of Oporto lie Bætalha and Alcobaça, where may be seen what are reputed to be the most beautiful specimens of pure Gothic architecture to be found in Europe. There will, it must be remembered, be no hotel accommodation at Ovar, but easy tram and railway communication with Oporto exist. It has been stated that the fare from Marseilles to Oporto and back will only be 18*l.*, but to get to that port in France from London would need, first-class, perhaps another 15*l.*, while the fare by the Royal Mail Company's boats to Oporto and back from Southampton is only 10*l.* 17*s.* 6*d.*

It will, perhaps, be interesting to those unfamiliar with the subject to know what the professional observers will actually do when they get to work on the eclipse day. For some days beforehand their instruments will be erected, and a series of full-dress rehearsals made daily of the various operations to be carried out at the critical moments. Taking the work done by the eclipse expedition at Vizsburg, as recently described at length in *Nature* by Sir Norman Lockyer, the following brief synopsis may serve this purpose. Numbers of assistants were detailed to various duties in addition to those performing the actual photographic operations. These consisted of photographs taken with a six-inch prismatic camera, with two prisms; with a nine-inch ditto, with one prism; with an integrating spectroscope and its camera; with a six-inch equatorial and a graining spectroscope (17,296 lines to the inch); and with the coronagraph. Finally, the now ubiquitous kinematograph was at work, besides a number of hand and stand cameras in charge of Mr. Turner, assisted by five volunteer observers. In addition to this, the Marquis of Graham brought with him two kinematographs—one for recording the whole phenomena of the eclipse, and another for photographing the moon's shadow as it swept across the earth's surface.

One point that renders the forthcoming eclipse of such special interest is the fact, that not until June 29, 1927, will there be an eclipse of such easy access as the present one, and in that year the east coast of Ireland and the north of England will be favoured with the sight of a total eclipse. There will, it is true, be one in 1905, visible in the neighbourhood of the Pyrenees and Sicily. We shall not be entirely without a sight of the eclipse, partial only, in our own country, for in the south-west counties the obscuration will extend to three-quarters of the entire disc, and in the Orkneys to one-half.

We may conclude our epitome of the points of interest in regard to the eclipse of May, 1900, by pointing out that at the British Astronomical Association meeting of the 28th ult., a paper by the Rev. S. W. Johnson was read, on "Suggestions for the Observation of the Partial Phase (such as seen in England) of the coming Eclipse." Among these suggestions were to search for irregularities in the dark limb of the moon, especially if any of the black disc of the moon could be seen outside the sun. At the same meeting Mr. Maunder suggested that in this country it would be very desirable to photograph the corona at the time of the greatest obscuration. To do this well it would, of course, be desirable to have a telescopic finder (with sunshade, of course), but that need not be a difficulty. It could easily be attached to a camera, and if

the latter were supplied with a tele-photographic lens, used at its utmost power, there is no doubt that at the time of greatest obscuration views of the sun and corona might be obtained quite large enough to be both of interest and observational value.

#### THE NEWCASTLE CONVENTION.

THE arrangements for the meeting of the Convention at Newcastle-on-Tyne in the week July 9 to July 14 next are in such a forward state of preparation that it is expected the *Handbook* will be sent out to members early in May. In style and get-up the book will be more attractive than hitherto, and it will have several illustrations.

The Trade Exhibition—always a useful feature at Conventions—may be expected to be large and interesting at Newcastle. Already many important firms have booked space, and it is anticipated that the whole of the accommodation available for this purpose will be taken. Its geographical position constitutes Newcastle-on-Tyne a most important centre for photographic business, and there is little doubt that a great many visitors to the Convention would appreciate the opportunity of inspecting the latest novelties on the market.

The evening meetings promise to be unusually attractive. We have been informed that Dr. P. H. Emerson, the renowned author of *Naturalistic Photography*, will read a paper. It is expected that Mr. C. H. Bothamley (a past President of the Convention) will communicate the results of some experiments in connexion with development. Sir J. Benjamin Stone, M.P., President of the National Photographic Record Association, will address the Convention on "Record Work by Photography," a subject in which he takes such deep interest. Probably Mr. J. Bridges Lee, M.A., will deal with the important matter of metro-photography. These arrangements are not yet complete, but it is anticipated that one of the attractions of the evening meetings will be a series of photographs illustrative of the part which the camera has played in the war in South Africa.

It is only three weeks since we outlined the programme of receptions and excursions which have been arranged by our Newcastle brethren. We need not again refer to it, except to say that visitors to the Convention will be singularly fortunate in the opportunities that have been provided for them of doing photographic work amidst the historically grand surroundings which Hexham, Alnwick, and Durham, as well as Newcastle itself, are celebrated for. So far the Newcastle Executive has worked remarkably well in the matter. The London Executive, with Mr. F. A. Bridge, as energetic and thorough-going as ever, at its head, is loyally co-operating to make the meeting numerically and otherwise successful, and the entire programme, when it is issued, will, no doubt, show that the Fifteenth Convention holds out every inducement to old and new members to be present and take part in the proceedings.

#### THIRTY YEARS OF AMATEUR PHOTOGRAPHY.

[Paper read before the Dundee and East of Scotland Photographic Association.]

I AM not sure that I could furnish any good reason for having chosen this subject, further than that I feel somehow impelled towards it. I heartily agree with Thoreau, when he says, "I have yet to hear the first syllable of valuable, or even earnest, advice from my seniors. Here is life, an experiment to a great extent untried by me, but what does it avail me that they have tried it?"

I give no advice to the young. Photographic life is untried by them, what avails it that I have tried it? It is thankless work giving advice, and this is as it ought to be; for, when the best is said, are we not all fools to begin with, and is experience not the best teacher for us?

For over thirty years I have wandered in the pleasant highways and byways of amateur photography, and, while I make no attempt to instruct the young, I would like well to compare notes with my contemporaries, to take the bearings, and see whether the devious paths all lead to the same goal.

This is to be no mere recital of early processes and plans of doing things, no more is it to be an attempt at a humorous description of the many makeshifts that had to do duty for a proper equipment. I mean to aim at a higher mark.

First, then, I ask myself have I found what I sought when I took photography up? Do I still consider that the mistress I have so assiduously wooed for so long is worth the winning? To this question I unhesitatingly answer, Yes! I answer yes, although, to my certain

knowledge, I have never in all those thirty years, produced one *perfect* picture. It would seem that this is little encouragement to those only as yet setting out, but it is not really so. In photography, as in most of sports, the life of the thing is in the chase, and success, or capture of the quarry, means an end and ringing down of the curtain. When I think of the toilsome days, and the sleepless nights, which my hobby has cost me (not to mention the pounds, shillings, and pence at all), and then cast my eye over the handful of passable pictures I have done, my mind is apt to misgive me, and suspicions enter my head that I might have been more profitably employed. This is a sordid and unworthy view of the matter, and I soon rise superior to it. Although the possibilities in photography were only half what they are, it would well repay one for the spending of his leisure time upon it, and, although the results in the shape of tangible entities were even non-existent, the amateur photographer would still be no worse off than the chess-player, who, like the fishers of old, toils all day and catches nothing. Judged by results, would any one say that the bush or tail of a miserable fox is an adequate return for thousands spent on a hunting stable?

I allow that the results in photography are miserable enough, even the best, but they are there, there is *something* for your trouble, and you can at least assert that you have been guilty of no cruelty to obtain them, you have selfishly sacrificed no creature's life for mere sport to yourself.

My thirty years, if they have brought me many of the happiest days of my life, have also brought me some sharp disappointments. Wonderful as the results of photography are, I have yet to see the photograph which entirely fulfils my ideal.

It may be the absence of colour, it may be the incorrect rendering of the tone values of nature, it may be the human eye which sees a something which never can be *mechanically* reproduced. I do not know, but, even on the low plane of a mere copying machine, a camera comes far behind the human hand guided by the human heart and the human head.

I am not foolish enough to maintain that a photographic reproduction of a simple subject, such as an engraving or a plaster cast is not true to nature, but the havoc which the camera and plate play between them with the subtler effects of nature are deplorable. The very minimum of information which an artist tries to convey informs you as to the kind of day he represents. The artist in black and white even can do this, and, if moderately skilful, manages to infuse a something which suggests morning, noon, twilight, or night.

Exclude blazing sunshine and snow, and who can tell from a photographic picture what was the kind of day which gave the impression.

A trifling under-exposure converts a sunny effect into the gloom and darkness suggestive of a thunder-storm, while a dungeon photographed suggests, where the light falls, beams of pure sunlight.

You meet me, of course, with the remark that these are instances of failure from incorrect exposure. To that I reply, Granted; but if such widely divergent effects are got inadvertently, and even by experts, man's short life here is insufficient to give him the cunning to infallibly seize the subtle sweet and mysterious effects he sees in nature. How many touches go to produce the effect upon an artist's canvas, and every one, without doubt, an experiment? Were it not so, why touch and touch again? It is a case of trial and error with him a thousand times repeated, for, even should he alter nothing, he builds up on the assumption that the effect is not yet correct.

Contrast this with the one *single* experiment, the exposure, in a photograph, and can you wonder that we so seldom succeed?

But you may say, There are innumerable fine photographs; how do you account for this? I account for this, or rather I reply that, fine as they are, they are, nevertheless, as dirt to the glorious effects in nature which called them into being. Let those who doubt this ask themselves, Have they made an entirely successful rendering of a snowscape? Have they reproduced the little points of pure white, the delicate half-tones, and luminous shadows?

Or, again, have they photographed the breaking wave on the seashore, successfully rendering the tone values of the crest, the green shadow, and the blue of the sky reflected in the backwash?

"Now fades the glimmering landscape on the sight,  
And all the air a solemn stillness holds."

Let the sceptic sally forth with his camera and try to seize this "glimmering landscape fading on his sight." No, no! for some reason it is beyond him if he knows enough to see it.

This, then, was the first of the serious disappointments in my photographic experience; it was, I must add, the most unexpected. Likeness to nature, "the heritage of the youngest photographer," I have as

yet found to be unattainable either by me or any other one working with a camera.

My second serious disappointment came when I discovered how futile it was to attempt to make pictures either by selection of subjects or creation of them. Selection, so far as it goes, does something for you; it should never be neglected; but, oh, how seldom does it make a real picture for you! Suppose you were to succeed, by selection of view, in eliminating objectionable features (a thing you will rarely manage); does not yet follow that a fine picture is left. People say, "Oh, nature is always beautiful!" But nature is not always notable, far less at her best, conditions necessary to render it worth while reproducing her. When I say that by selection, you may eliminate objectionable features, I do not only mean chimneys, walls, commonplace houses, or detail of that kind, but I also include objectionable composition.

In this connexion let me state that the really grand photographic pictures which have come under my notice have shown little evidence of intention on the part of the artist to arrange or select. I do not mean that the pictures were in any sense accidents; I merely suggest that the real pictorial value lay in nature's arrangement, and that the part played by the artist was rather that of a discoverer. If I were inclined to give advice at all, it would assuredly be to content yourselves by playing the *rôle*, and to lay this thoroughly to heart, that success in photography lies almost entirely in the *discovery* of pictures, and that very, very little is left to the photographer in the making of them.

This applies with as much force in portraiture as in landscape, and it is an easy matter to pick out figures that have been posed from those who have posed themselves. Professional portraitists have made merry over the ridiculous poses assumed by those who desire to pose themselves. I am not so sure but it would be the better plan, however; and to allow an awkward fellow to pose himself would, one would imagine give more of the character of the man. If I cannot have art and truth together, give me truth by preference. I know a particularly sedate lady, who happens to possess a very fine profile. She is straight in the back, and altogether a difficult subject to throw into graceful lines. This lady has been photographed again and again, and the usual way of getting over the difficulties of her case is to turn and twist her about, and compel her, for art's sake, to assume positions which she never, consciously or unconsciously, adopted in her life. The consequence of this treatment is that, in her portraits, she has the appearance of a giddy young thing, a painfully palpable absurdity to any one who knows her.

Of course, the sensible man says, "Oh, I would never dream of adopting such a pose in such a case." Well, if he would not do this or something approaching it, he is one in a thousand, and deserves to be encouraged. In portraiture, as in landscape, *evident* arrangement must be conspicuous by its absence. And what can be said of those frightful atrocities where the whole subject is made up and arranged? A moderately good-looking girl is discovered; she is clothed in a muslin rag of some kind, with a waist band and shoulder straps; she stands leaning upon a canvas fountain, a jug in one hand, a bunch of paper roses in the other; she turns her eyes devoutly upwards (why, goodness only knows) and the picture is complete. The lighting is the lighting of a studio, and she is no more a "drawer of water" than I am. Indeed, if you look closer, you will probably discover that it is not a water vessel at all, but is to carry home the water in, but a terra-cotta reproduction of some ancient Egyptian urn more suitable for the custody of the ashes of her fathers. This, by your leave, is an "art study." Sham is writ large on the face of it. She is an English girl, and not a foreigner. The lighting is of the studio, not of the street; the fountain is paper, so are the roses the expression put on for the moment. Who can work up any enthusiasm over this sort of thing when, by looking closely, you can see that she uses "Thingumy's" patent hair-fasteners? Of a verity this the familiarity which breeds contempt. I must know a deal less about my heroine to think much of them.

Double printing has much to answer for, and it is my opinion that it is beyond the power of man to make a connected and accurate whole from parts. It is not enough to see that the lighting is falling in one direction. The precise amount of light falling upon each and every part must also be correct, and, manifestly, this cannot be correct if you first photograph the landscape without the figures, and then the figures without the landscape, for you do this of set purpose to alter the relations of the one to the other. These have been my chief disappointments, and, although not many as to number, serious as to kind. Whether you work with pencil, brush, chisel, or other tool, the very first requisite is, surely, that your slave be obedient, for, if there be a will in the machine you use, who knows what share you have had in the joint production?

In photography, conscious, deliberate art cannot be hid. The lens is searching a tool that it lays every trick of the trade bare and painfully exposes the sham. I visit an old man in a garret, who makes a scanty living by constructing bird-cages. The walls of his little place are cracked with age and broken up by a great number of nails, nags, and that not. The contents of his room are littered about in sweet but natural confusion. His little broken-down fireplace is heaped with unremoved ashes. He sits upon a low stool opposite a diminutive window, his long grey hair falling down in ragged, unkempt tresses over his job. He works in his shirt-sleeves, sleeves that are a perfect dream in tone from long absence from the washing tub. The whole combination is a picture, and many a time I have wished to turn my camera upon it, though this is impossible from the cramped conditions and size of the garret. I have discovered this picture. To alter or arrange in any way would spoil it. Take it as it is, and truth is stamped upon every detail; nothing is out of place, nothing is wanting. The more searching the definition of your lens, the more evident the reality. Think how impossible a thing it would be to set such a piece to bear the searching scrutiny of the lens. In the first place, these effects of light and shade are impossible in the studio. These old walls cannot be produced by other means than time and the smoke of half a lifetime. The man has been produced only after years of stooping over his bird-cages, and his grey hair falls into a natural position by the action of gravity working for a long time upon it. He handles his half-made cage in a way no mere actor could be taught to do, and the expression is of one who is laboring earnestly.

A lay figure may do well enough for the painter, who composes his picture chiefly from recollections of natural conditions stored up from previous experiences, but the photographer may have seen many cracked and wrinkled old men suitable for his subject now, but he cannot work them into his photographic picture as the painter does. In place of falling back upon previous experience for the cracked wall and wrinkled face, he must, if he would make a picture of them, have them there before him; and, this being a difficulty, he unfortunately makes up something which he fatuously believes cannot be distinguished from them. I vote for truth and reality in photography as the highest art, say, as the only possible art. If you earnestly desire to elevate the art, cease arranging, and inventing, and elevating your own taste. Keep your eyes open. Whenever you come upon a little bit of nature that appeals to your artistic sense, take it. Ask no one to stand as a figure in the picture; they will show up extraneous, or worse. Bind yourselves by no rules, but let your feelings guide you. It will be no long time before experience will have taught you what you may attempt, and what not. You may be told a hundred times and forget after all, unless you try and fail. As a set-off against my disappointments, I have lived to see the advent of snap-shot photography. The bulk of snap-shots are inimitable, but now and again, when circumstances are propitious, or in other words, when the picture is really there to take, see what glorious results. The war correspondents in South Africa have given us one or two gems. Looking at them, even in the cheap reproduction by process block, one has sometimes a doubt whether, after all, they are not copies from some fine old works of art. I am not referring, of course, to the vivid elaborations from photographs which one sees in every journal, but to the genuinely untouched snap-shot.

And now, as a wind up, let me say a word or two on small matters. Thirty years of experience have littered up my den with cameras of all kinds and sizes. It has filled my shelves with countless books on the subject; it has crowded every available corner with tripods, rolling presses, burnishers, and I know not what all besides; it has left me with chemicals enough to stock a laboratory; and all this to no purpose now. I have learned wisdom, and I have paid the price. My working plant now is simple enough. I have a light stereo camera, with four double dark slides. I have a light alpenstock tripod. I have a dish or two. I have a small vial of dilute ammonia and bromide, and a jar of hypo. I have a couple of stereo printing frames, a few pieces of sensitised albumenised paper, and a small stock of mounts. I think, with horror, of the terrible loads I used to shoulder; with horror of the vast accumulations of prints, apparatus, and material I had to find room for. Never again shall they hang round my neck, like the old man of the sea. They were my willing slaves and companions in many a long summer-day's outing, and I have a kindly feeling towards them; but it is all over between us, or all that. They will not be parted with; they will have house room; carefully tied up and put snugly away.

As I began with a quotation from Thoreau, so I end with him, and side with him when he says, "When I see a poor labouring man, staggering along with all his possessions in one bundle on his shoulders, I

do not pity him for having so little, but commiserate him for being burdened with so much."

I look back to the days of my youth and innocence with longing, when my kit was so simple that a soap-box easily contained it all. I was free then, with a freedom which bade me a long good-bye as my photographic flocks and herds (so to speak) increased a thousand fold.

J. K. TULLOCH, M.B.

#### PHOTOGRAPHIC CRITICISM.

IN *Camera Notes* for April, M. Robert Demachy, the eminent French photographer, submits the following ideas on the subject of photographic criticism: "Ten years ago criticism on photographic exhibits was an easy thing indeed. Any sort of photographer could write four columns of mixed praise and blame; and, after having digested this, the reader knew exactly what to think of Mr. So-and-So's work, for the scientific critic had told him on what paper the negatives had been printed, how deep, and in what colour. A short paragraph on the marvellous definition, the crisp high lights and well-detailed shadows, and a line or two describing the subject, completed a criticism that left nothing to be desired. The next exhibit would perhaps be considered disgraceful, over-exposed, unequally toned, slovenly focussed, &c. This time not a word on the subject itself, but—'what were the Judges thinking of when they admitted a photograph taken with a lens that did not cover more than two-thirds of the plate?' and so on. At that time exhibitors did learn something from the critics. They knew when their work was bad, and they knew why. So they hurried to Dallmeyer's to buy marvellous lenses; they worked out abstruse calculations with pencil and actinometer; invested in new measuring glasses and patent scales, and finally turned out the perfect negative, yielding a perfect print. And they were happy and contented, because their work was good; they knew for a certainty that it was good, and that no photographer worthy of the name could say it was bad, or imagine anything better.

"Things are changed nowadays. We can never be really satisfied with our work, for there is no limit to its improvement; and our critics, who are not satisfied either, do not seem to know why and wherefore, if I may judge from most of the articles it has been my lot to come across.

"Photography, or, to speak more correctly, a certain number of photographers, have taken up a new line. Their goal is different from that of their predecessors; their standards of excellence are borrowed from those of other crafts, and yet their Judges remain the same. If a surgeon used his scalpel to carve a statuette from a piece of oak, would the Royal College sit as a jury and ponderously examine his work from a medical point of view? This is, however, the sort of thing we have to submit to most of the time. It is worse, indeed, for us poor photographers (pictorial photographers, we call ourselves, for life is precious, and we keep clear of the word 'artist'), who stand under cross fires, abused by our community and slated by illustrious painters, who seem to write more often than they paint. We have lost Mr. Gleeson White, whose straightforward criticisms, founded on clear and sound reasoning, gave precious lessons without causing offence. His place has not yet been filled, and now nearly all critical articles on photographic exhibitions teach photographers nothing, and leave them either indifferent or confused in their minds.

"For criticism does not consist in telling a man that his model is bandy-legged, or that his landscape would look better if it was hung upside down. Of course this is very witty, but it has nothing to do with criticism, for a critic ought to speak like a sort of doctor, who diagnoses the disease and points out the remedy. To be able to do this he must have studied both, and made a careful examination of the patient himself.

"Do our photographic critics proceed in this way? I have seen some of them at work, rushing through the exhibition rooms notebook in hand, and their eyes fixed downwards on the point of a rapidly scoring pencil, in tow of some panting organizer; indeed, I have played the part of the tug-boat myself, and viewed the proceedings from a closer position. But let it be understood that I have met a few exceptions to the rule—rare ones, it must be owned. These men worked several hours a day, for three or four days, on a hundred and fifty pictures each. They knew these pictures so well that they could have drawn a scheme from memory of every one, and they hated the very titles of them for weeks afterward. But their criticism had weight. It might be disputed, but at any rate it was founded on patient study, and it gave sound reasons for its verdict. Criticism of this order is never offensive and unkind. It does not aim at being satirical or funny. The little pin scratches, and the little jokes of

the genuine critic, even if they are perpetrated in a moment of irritation, do not stand the polishing process, or they vanish later on under the stroke of the red pencil. This sort of criticism makes photographers look at their work with other eyes; I have often met men who laughed at such or such a suggestion offered in a serious and polite style in the course of one of these articles, but, through a mysterious coincidence, it happened that this very suggestion was accurately carried out in their next production, which looked all the better for it.

"Our critics, nearly all of them, have adopted a very useful exordium, which will conveniently fill up a column and a half, and will leave a deep impression on the easily convinced public. It is generally headed 'Photographs that are Not Photographs,' and the curses of Daguerre are called down upon men who 'imitate' wash drawings, charcoal drawings, or aqua fortis. But nothing has ever prevented artists in monochrome from using our dirty black, purple violet, or sickly brown tones for their pictures. It seems to me that if they choose lampblack, India ink or sepia, it is merely because these colours give a very superior artistic effect, and for no other reason. And yet we should be ordered to keep to our old silver tones and effects, just to please Daguerre—whose metallic-surfaced prints, by the way, had no earthly resemblance to the gelatino-chloride outrages of to-day.

"After this exordium comes the question of brushmarks in bichromated gum prints, treated in such a way that we believe the critics are under the ridiculous impression that brushes are really not needed in developing gum bichromate, but that they are purposely dabbled all over the print just before framing, to try and get the effect of oil painting.

"Further on we come across the names of Rembrandt and Van Dyck, Velasquez, and Rubens, and other demi-gods, and the learned critic takes some pains to impress us with the patent fact that our photographs are far from equalling the work of these celebrated painters. But if we are suspected of having studied their composition and their treatment of light and shade, a thing that every painter does, we are accused of imitation and lack of personality.

"Finally, we are severely warned that a photograph ought to be a photograph and nothing else. Now, this sounds very fine, and at first sight appears to be very clear. But what is a photograph? How shall I know a photograph from something that is not a photograph? A simple-minded man would answer: 'A photograph is an image produced by means of a lens or a pinhole, and fixed on some medium or other by means of a chemical reaction caused by light.' But this answer does not explain matters satisfactorily, for pictorial photographs are produced in this very way, and yet they are often accused of not being photographs. Is a photograph to be recognised by its aspect only? Then, which is the photographic aspect? A print on albumen is quite different from a Daguerreotype, and has nothing in common with a platinum print; carbon does not look like gelatino-bromide, and chloride paper has a different aspect from tin-type. Which style are we to adopt if we want to glory in the name of photographers?

"Perhaps the critics mean that a photograph is undoubtedly a photograph when it is printed on a distinctly inartistic medium, highly glazed, and when it represents a subject utterly devoid of composition, offensive in tone and false in values. This might be the true reading of the enigma, but then we must admit that the critics encourage us to produce detestable work, and this is impossible, of course.

"All this is very confusing, and yet it could be made so clear. Why do not critics admit that a photograph can be of any sort of colour, printed on any sort of paper, developed by any sort of means, sharp or fuzzy, light or dark, provided it is taken with a camera and printed from a negative? Then let them divide photographs in two classes, the technical and the pictorial, and judge the work of a man according to the end which he pursues, not according to fixed rules and standards that have been invented in other times and for other purposes. If the critics come across a print of a new and disconcerting aspect, instead of saying 'this is not a photograph,' let them understand that it is only a photograph different from other photographs, just as salted paper was considered very different from Daguerreotype in the old times. And, lastly, let them give us good reasons for their praise or for their blame, reasons that may encourage us on the road we have chosen, or teach us what we are to avoid in the future."

#### THE NATIONAL PHOTOGRAPHIC EXHIBITION.

ABOUT sixty firms of photographic manufacturers, &c., will be represented at the Second National Photographic Exhibition, which will be held at the Portman Rooms, Baker-street, London, W., from Friday next, April 27, to Saturday, May 5. It may therefore be anticipated that a

large and varied display of photographic apparatus, material, and "appliances"—a truly comprehensive word, according to Mr. Justice Kekewich—will be on view, and that the visitor, be he professional, amateur, or trader, will see everything that is new and noteworthy in the way of manufactured productions designed for use in the taking of photographs. The Exhibition is fixed at a time of year when the interest of the public and consequently that of the trade, in photography is at its keenest, and the Portman Rooms are so accessible from all parts of the metropolis that a large attendance may assuredly be counted on. During the fortnight there will be many daily attractions in the shape of lectures on X-ray photography, colour photography, cinematography, liquid air, tele-photography, and other subjects, by Messrs. T. C. Hepworth and Cecil M. Hepworth, and the Imperial Band will also frequently perform. Thus the Exhibition promises to be a pleasant place for the photographer to visit. We wish it every success.

#### FURTHER HINTS ON P.O.P. MANIPULATION.

THE writer's article entitled "P.O.P. Manipulation," which appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY on January 5, 1900, having elicited several inquiries upon points which he did not at first think it necessary to touch, perhaps the following supplementary remarks may be useful to those who have had no previous experience of P.O.P.

P.O.P. is what is technically known as an emulsion paper; i.e., an emulsion of the sensitive silver salts is prepared in a colloid, which is then spread upon the paper. The colloid used for P.O.P. is gelatine in a more or less hard or insoluble state, whence the emulsion is known as gelatino-chloride, and, by reason of the fact that water and heat combined dissolve gelatine, P.O.P. prints cannot be dried off with blotting-paper or by the action of heat, neither can they be hot-burnished; the prints also require a little more careful handling than albumen while in the wet state, as they are rather tender, especially in hot weather, and, if they are washed in a rotating washer, a very great force of water should not be employed.

P.O.P. is supplied by the manufacturers in the usual sheets, and various standard sizes, besides which they will always cut odd sizes in quantities; but photographers who do a very varied trade do not find it convenient to buy all their sizes ready cut, as it sometimes means keeping a very large stock of paper; so they buy the sheets and cut them as they require. When this is done, the fingers should not be in a hot and moist state while handling the paper, or finger-marks and lines will be left upon the finished print. These will generally tone redder than the other parts of the picture. If the hands perspire freely, common white cotton gloves should be worn during the operation, when the paper may be handled with impunity. Still, if ordinary care is used while handling, no more trouble should be experienced in cutting P.O.P. than in cutting albumen. P.O.P. may be exposed for a short while to subdued daylight while cutting, but, if left for any considerable period, discolouration may take place, as the paper prints rather quickly. Ordinary gaslight, incandescent electric light, or candle light, have no effect upon it, but the light of incandescent gas, acetylene gas, or the electric arc, will discolour it, although usually it requires a considerable exposure unless the lights are very strong.

When a tube, box, or packet of P.O.P. is first opened, if the edges are discoloured, even if only slightly so, it may be taken for granted that the paper has been manufactured some considerable time.

If P.O.P. prints are not squeegeed down, a good way to dry them is to thread some common wooden paper-clips (which can be obtained commercially at about 6d. per dozen) upon a string, hang the string across the room like a clothes line, placing in a draught if possible, clip each print by the corner, and leave until dry. The only disadvantage about this way is that the corner by which each print is clipped must be cut off, as the wet film sticks to the clip. Perhaps an even better way is to have a small wooden rod suspended across the room, and pin the prints to this by the corner, leaving them to hang, thus only a pinhole is left, and this may be so close to the edge that it is removed in the final trimming. The writer has tried hanging a string across the room, and simply laying the prints over this, film outwards, in the same manner that clothes are sometimes hung, but he finds that there is usually a mark left across the print where it has hung over the string, and which often shows up when mounted.

It is very important that P.O.P. should be kept in a dry place until it is required to be used, as it keeps very much better in a dry state. If the place where it is kept is damp, it should be placed in a box at the bottom of which is some common chloride of calcium. This greedily absorbs moisture, and, when it gets damp, it may be dried by the action of heat, and used indefinitely. The length of time that P.O.P. will keep is largely determined by the way in which it is stored. The best way of storing it is undoubtedly to keep it in a flat state under some pressure, and covered with clean brown paper to exclude light and air as much as possible, for access of the latter quickly discolours it. Where sheets

ave to be stored, it is rather awkward to keep them in a flat state, so they should be tightly rolled and kept in the tubes supplied by the manufacturers, and covered with the damp-proof paper as also supplied by them. It is not advisable to keep P.O.P. for any great length of time if it can possibly be avoided, but sometimes, through circumstances over which photographers have no control, such as living in remote districts or fluctuations of business, it is necessary to keep it for some little time, and then a little care will keep it in good and workable condition for a few months, where neglect will spoil it in as many days. P.O.P. should not be left lying about exposed to the air, as this quickly discolours it even in a dark room, and particles of dust, more particularly if they are of a metallic nature, settle upon it and leave black spots upon the paper. These are often very small, and usually appear as if ink, or some other black substance, had been splashed upon it; and, although this difficulty may be overcome to some extent in the shadows, in the high lights they are very troublesome.

There is very little difference in most of the commercial P.O.P.'s, although some photographers can work best with one brand, while another photographer cannot get on with it at all to his satisfaction; still, a good photographer should get good results with any good make. Most P.O.P.'s have some little peculiarity which one photographer seems to manage better than others do, and this probably accounts for the fact that one photographer swears by one particular brand, and declares that it is the best, while another is equally convinced that some other makes the best, and the one used by the former photographer is no good, when, as a matter of fact, the only difference is in their methods of working, which are more adapted to the particular brands they affect.

In trying various P.O.P.'s, it will be found that some kinds are very much thicker than others, this sometimes occurring with different batches from the same maker. Many photographers are under the impression that this is due to one film being thicker than the other, and in their opinion better; but such is not the case, and it would be almost impossible to make such a marked difference with the film alone, and would never happen with the same manufacturer, as the machinery by which P.O.P. is coated practically ensures that it cannot vary in thickness, for with this machinery it is very difficult to lay an abnormally thick coating of emulsion upon the paper. The difference is caused by the variation in the thickness of the baryta substratum with which the raw paper is coated previously to receiving the emulsion, and it makes no difference to the print itself whether the paper is thick or thin. The thick paper has the advantage that it is perhaps not quite so liable to tear when wet as the thin paper is; but one great disadvantage is that, when thick paper is mounted, it projects very much above the mount, and looks rather unsightly, besides which, in quantities, there is a difference in packing as well as the cost of carriage, for baryta is a very heavy substance.

C. T. SUTTON.

## PHOTOGRAPHERS AND THE ILLUSTRATED PRESS.

### THE ILLUSTRATED PRESS: A NOTE.

THE reading public ought to be fairly well supplied in the matter of illustrated weeklies soon. The *King* and the *Sphere* have come to swell the ranks. Long life to them will be the wish of most, although some may consider that the market is already crowded. Certainly the competition is keen; but the reading public is always increasing.

There is one feature concerning Messrs. Newnes' new weekly which will appeal to journalists as contributors, and that is, it is announced that payment will be made for contributions on *acceptance*. Few existing journals adopt this policy. The methods adopted by certain journals is certainly not a credit to journalism. There is one pretentious journal which manages to exist on something very much approaching misrepresentation, to put it mildly. An intimate friend did a considerable amount of work for it, and invariably had much difficulty in getting payments. Before breaking off his connexion with it, he sent a number of photographs to it, which were accepted for reproduction. A price was agreed upon, and the photographs duly appeared, but enlarged to about four times the original size. Months went on, and no payment was forthcoming. But this particular journal is still in existence, and some of the leading photographers allow their work to be reproduced in its pages. Doubtless they are paid promptly enough, and, as they probably belong to the Copyright Union, they would not charge a less reproduction fee than half a guinea. If a journal cannot deal honourably with its contributors, why should it exist at all?

That photographers can increase their incomes by allowing their work to be reproduced in the respectable illustrated journals is undeniable. A young professional of the writer's acquaintance made over 30*l.* in this way in one year simply in his spare time. There are many firms, of course, who make a speciality of presswork, and a fairly long list of individual photographers might be given who are practically journalists though photographers.

But one or two of the existing journals should be avoided, *i.e.*, if you desire something more remunerative than merely seeing your photographs published and your name in print.

### PHOTOGRAPHS *versus* DRAWINGS.

Photographs *versus* drawings is a matter just now receiving a considerable amount of attention at the hands of those connected with the illustrated Press, and it is a question probably not without interest or importance to many of the readers of this JOURNAL. The writer has more than once seen it asserted in prominent publications recently that the illustrators are viewing with alarm the increase in the number of reproductions from photographs which find a place in the illustrated journals. It needs no pointing out at this time of day that the photographer cannot be ignored by the illustrated Press. At the same time, no one, I think, would care to see the black-and-white man ousted altogether. Photographs generally probably can appreciate a good drawing as well as a good photograph. "Art and Actuality" is the motto of one of the prominent illustrated weeklies, and a judicious blend of photographs and drawings probably finds most favour with the purchasing public.

In a paper such as the *Daily Graphic*, where it would be commercially impossible to employ art paper, a line drawing is preferable to a smudgy photo block, although where there is no great detail, as in a portrait, a photo block can be satisfactorily reproduced.

In connexion with the general question, the following notes written by the contributor of the "Art Notes" in the *Pall Mall Gazette*, who is no mean authority, may not be without interest. He writes:—

"Somebody has estimated the increased sale of the higher class of illustrated journals since the beginning of the war at one hundred thousand copies, and there is no reason why the estimate should be extravagant. Not only are the bookstalls crowded with excellent illustrated matter, but there seems a ready welcome for every new comer. From the artist's point of view, the one depressing fact is the enormous preponderance of photographic blocks. The public want pictures, but are no longer to be taken in, apparently, by the imaginative 'war artist,' whose knowledge of battles was often confined to the weekly bout with his landlady or his washerwoman. Sometimes these stirring *tableaux* were done from sketches more or less authentic, but a vivid imagination and a handbook of the British Army were more abiding aids. Now, in the uncompromising craze of the day for reality, the photographer has gone to the front—into the fire zone, even—and the result, if not so imaginative, is vastly more interesting. Two of the latest new illustrated weekly papers differ essentially in their choice of the old and new methods of war illustration. I would like to say that the artists score off the photographer, but they do not. The public want the facts as near as may be, and are too deeply stirred to be put off with melodrama. The *Charge of the Lancers*, done (in St. John's Wood) with a fine artistic instinct, has no chance against the much more prosaic picture by the photographer, *The Black Watch Advancing in Open Order at Magersfontein*, or *The Men of the Suffolks Preparing their Christmas Dinner*. And why should any artist grudge the photographer his success? A 'news block' (to use its technical term), reproduced from a photograph, is the 'penny-a-line' illustration of journalism, and, however interesting, has nothing to do with art. The 'living picture' of the biograph and the dead one so common at the Academy are not more divided in purpose or execution. When unthinking people say, 'I prefer a photograph to an illustration,' they compare things that have no possible ground of comparison. We ought to welcome the photographer in the newspapers, for he teaches a number of lessons that the public is otherwise slow to learn, and we need not regard him as the supplanter of the artist. Truth to tell, illustrations of stories and incidents in which the artist is tied down in theme and treatment can rarely be dealt with seriously as works of art. Occasionally the artist rises superior to his limitations; sometimes the subject evolves the man, but, generally, we are all too ready to class as 'art' that which has no relation to it. Because a number of estimable young men who do not like office work have taken to pencils rather than to pens, we are asked to call them artists and to be generous. There is only one consolation. If the draughtsman is rarely an artist, the photographer never is an artist."

Some of the papers are not disguising the fact that they are relying mainly on their photographers, and a glance at the periodicals in question will readily confirm this.

Now let us hear what Mr. Clement Shorter, the editor of the new comer, the *Sphere* has to say, and no man is able to speak with greater authority on all matters appertaining to illustrated journalism. He says, "My ideal newspaper—at any rate, at sixpence a week—is assuredly not a journal entirely composed of photographs. . . . I am inclined to think that we are on the eve of a great reaction, and that the sixpenny illustrated newspaper composed almost entirely of photographs has but a very poor future. Photographs are cheap, the general effect cannot be other than monotonous, and it does not seem to me that, as compared with newspapers which employ good black-and-white artists, the public can be considered to get a very good sixpennyworth for their money. I do not mean to say that there is not plenty of room for photographic journals; it is merely my contention that they could be done much cheaper than at sixpence. . . . I wrote an article on 'Illustrated Journalism' in the *Contemporary Review*, I declared that the essential thing to recognise was the limitation of the photographer and the limitation of the artist. Your photographer can do many things better than the artist, he can give a sense of reality to many an incident that the most accomplished

artist will fail to do, but there are a hundred occasions on which the photographer utterly breaks down; at a royal wedding or a royal funeral he is entirely out of place; he may not enter Westminster Abbey, and, were he to do so, the results would not be very satisfactory." Mr. Shorter goes on to say that it is true that on the battle-field the photographer can do much, mentioning what arrangements he has made to be supplied with photographs from the front. I think it will be admitted that here we have two interesting opinions which fairly cover the whole ground.

It must, in justice to the photographer, be pointed out that not infrequently a very effective drawing is made by the black-and-white artist from a photograph. In some cases it is quite possible that, through one cause or another, it may be impossible to reproduce a photograph depicting an important incident of the war. Through insufficient exposure or other cause, it may not be possible to make a reproduceable block, but sufficient detail may be shown in the photograph to give the artist material for his picture. Surely an editor, who claims that in his journal only actual photographs are reproduced, would fail to take advantage of the black-and-white artist in this case. Actuality need not necessarily be sacrificed.

#### A COPYRIGHT NOTE.

If a contributor obtains from a photographer photographs for reproduction, an interesting point to be considered is, should the contributor in question pay the reproduction fees before the photographs have been reproduced? To illustrate this point I give an instance. Some months ago a contributor to one of the magazines obtained a number of photographs from a worker who has made a speciality of a certain subject. The photographs (and accompanying matter) were accepted for reproduction in the early autumn of last year. They have not, however, yet been published. The photographer in question, desiring his fees, writes to the contributor referred to for payment, and, there being several photographs, this is not an inconsiderable amount. He claims that it is nothing to do with him as to whether or when the photographs are published, or, indeed, whether the photographs are published at all, for we can, for the purpose of argument, assume the possibility of the journal in question failing before the photographs are published, which, in these days of competition in illustrated journalism, is not an impossible event. The contributor is willing enough to pay the ordinary price of the photographs, but does not feel disposed to pay the photographer his reproduction fees until the photographs have been actually reproduced, for the contributor does not benefit, at any rate only indirectly, by the publication of the photographs. If the photographs were not used by any chance, the question is, is the contributor still responsible for the payment of the reproduction fees? It seems rather unusual and unreasonable that the contributor should both find a possible market for the photographs and have to take all the risk. If the photographs are published and paid for, it is the photographer who will benefit to the greater extent.

J. A. REID.

#### EXPERIENCES OF A PHOTOGRAPHIC DEALER.

"He is a jolly nice fellow, but a poor musician!" This is a German saying, well understood in the Fatherland. This might be varied in the case of a great many amateur photographers—"He is an excellent musician, but a terribly poor photographer!" There is Mr. Harmonious, for instance, professor of music, an authority on organ-building, but his knowledge of photography is of the most primitive order, in spite of his having invested some years ago in a well-advertised quarter-plate camera. Music he has at his finger-tips, but the focus of a lens is still a hidden mystery to him.

When the musician called on the dealer the other day, he incidentally mentioned that he was writing an article on "The Construction of the Piano," illustrated by some drawings, and wanted to know whether the drawings were fit for photographic reproduction. On being shown the drawings, it was pointed out to him that the paper they were done on was too yellow to yield a good result by photography, and that finger-marks would be painfully evident in the negative. He then mentioned that he was the possessor of a camera, but never could get on very well with it; could not get the picture sharp, and the negative went black all over in the development. It was suggested he should fetch the camera, as it might be possible to find out what was the matter with it. It was accordingly submitted for inspection. The owner had no idea that the lens moved in the focussing jacket, and knew nothing about stops. He didn't know he might reverse the slide, and take vertical as well as horizontal pictures. So far he had only used the slide horizontally. This was probably the result of having purchased the apparatus at some store, where no attempt would be made to explain the various parts of the apparatus to him, the business idea being simply to price the article down at the lowest that the proprietor would permit, and take the cash. Whether the apparatus was in order, or understood by the purchaser, was farthest from the salesman's thought, the only idea in his mind is another "line," get the money and put the sale down on the sheet. The owner of the camera had, in fact, not mastered even the rudiments of photography. After the various movements of his instrument had been explained, he left, supplied with a dozen quarter-plates and twelve ounces of developer (hydroquinone), in two bottles, labelled No. 1 and No. 2.

The day following, our amateur turned up again, somewhat annoyed, and said: "Look here! the plates you sold me yesterday were no good at all. I exposed several, and developed them, but could not get anything out at all; and, to test the matter, I took the others out into the light and looked at them, and, from what I see, I don't think they are of the right colour." The dealer assured him the plates were all right, and, as he had been sold an unbroken box, he might depend upon it that they had not been tampered with. To convince him, the dealer invited him into the dark room, and showed him an unexposed plate, and then took him into daylight to compare this plate with those he had brought back, and so convinced him there was nothing wrong with the plates. The dealer inquired what exposure he had given, and was told about three seconds (this was in the middle of the summer). It was at first a puzzle why the professor had not succeeded with his plates; but, when he turned to the dealer and said, "Do you mix the two solutions for development?" the explanation was not far to seek. The dealer's reply, "Of course; didn't you do so?" brought the answer, "Oh, no, I only poured the solution from No. 1 bottle over it, and, when nothing came out, I put it into the fixing bath, thinking it might come out afterwards, but it didn't."

After explaining that the solutions have to be mixed in equal proportions before development, he invested in another box of plates, and went away a wiser and more determined man.

Next day the professor turned up again with two terribly fogged and out-of-focus negatives, and wanted an opinion of them, and whether they could be printed from. The defects were pointed out, and he was told they were no good at all, and, to illustrate this, a good negative was shown him. He saw he was hopelessly out, and the two negatives he had brought went promptly, where all bad negatives should go, into the dust-bin. However, he had with him two more exposed plates, and asked for them to be developed in his presence. This was agreed to, but they turned out worthy companions to those he had developed, being out of focus and badly fogged. After putting several questions to the professor, as to his dark-room, light, keeping the focussing cloth over the camera when drawing out the slide, &c., it was found that he did not possess such a thing as a focussing cloth. To demonstrate to him the use of a focussing cloth, we went into the garden, taking a stock camera, and, after posing the professor, with some shrubs as background, exposed a plate, which, when developed, yielded a good-quality negative. This the professor took, without waiting for it to be washed or dried. So much for the dealer's work, and this is the last that has been seen of him for any business purpose. It is supposed he has been more successful since, and so does not need the "advice" of a mere dealer in photo goods.

"Do you keep Snooks's combined toning and fixing bath?" is a customer's question at 9.45 p.m. (The dealer lives in a somewhat busy and late neighbourhood). "No, we do not," is the reply, "but perhaps you may get it at the pawnbroker's and photographic dealer's lower down." "Oh, no, they don't keep it, I have been there already." "Perhaps you may get it at the drug store," was the dealer's reply. "They were just shut up when I got there" was the reply. "Why not try the chemist a little higher up," the dealer ventured to suggest. "Do you think he is still open? You see, it is not for myself, but for a friend of mine. I generally get mine in town, at So-and-So's stores. Sorry to have troubled you." "Oh, don't mention it," the dealer replies. "Good night, sir."

"How much are those whole-plate porcelain developing dishes?" is another customer's query. On hearing the price he suggests he ought to get them a little cheaper if he took two of them. It is agreed to make a reduction of sixpence if he takes two. "Well, I shall not want them just now, I'll look in at the end of the week." Thus the dealer draws another blank.

Now and then our friends the photographic chemists are at fault, and their chemical knowledge is rather at sea as far as photography is concerned, for, being in want of some potassium ferridcyanide, the dealer in his turn called at one of the local chemists, who also sells photographic materials and chemicals, and asked for an ounce of potassium ferridcyanide. The assistant hunted high and low for about ten minutes, and, being unable to find any, told the dealer he did not think they kept it in stock, as it is so seldom used. When told that it was almost in daily use for reducing negatives, he replied: "Oh, we generally reduce our negatives with bichloride of mercury!" On being challenged on this point, he admitted that he had made a mistake, but imagine the position of the poor amateur who takes such advice. It is to be hoped that photographic chemists do not generally speak with such authority if they are in doubt. A bread pill is a safe prescription and a little liquorice compound harmless, but picture the face of an amateur photographer who tries to intensify his already too thin negative with potassium ferridcyanide, and sees it disappear altogether; or, on the other hand, to reduce the under-exposed and over-developed one with bichloride of mercury. That face will pale by degrees as his negative gets whiter and whiter, and then another will be added to the collection of spoilt negatives. The experiences of the dealers is, as a rule, willingly and cheerfully placed at the disposal of amateur and other photographers, and it is only fair when this is so that the services should be appreciated. In the old days a substantial fee was charged for instruction in photography, but with competition, and very severe competition too, came the announcement, "No charge for instruction" to purchasers of apparatus. This being so, it is only right and just that the matter should be reciprocal, and if a dealer gives the photographer in-

formation that is useful to him, and helps to turn failure into success, he should, if he does not see his way, or hesitates to pay, directly for the information, make it a matter of honour to buy what he wants in future of him, or as far as he possibly can, so that there may be a *quid pro quo*. The dealer, no matter how he may be interested in his business and love photography as an art, keeps his place open to endeavour to get a living—for the rates and taxes fall due whether customers or other photographers' negatives turn out faulty or not.

Hypo.

### INVISIBLE STARS.

In a recent lecture on this subject, Sir Robert Ball, the Astronomer Royal for Ireland, made the following eloquent remarks to his audience: Go out on a clear night and raise your eyes to the sky. There you see shining above you some bright and beautiful gems, and many hundreds of small stars. Next get an opera-glass to strengthen your view, and immediately the number of visible stars would increase tenfold. There they lie in profusion, from the brightest glories of the firmament down to the feeblest points, whose twinkle you can only just discern by glimpses. Make now a supreme effort to sound the depths of the universe to the utmost extent to which our faculties are capable. Call to your aid the experienced engineer and the skilful optician; bid them construct the mightiest instrument that their combined talents can fabricate, convey your telescope to the summit of a lofty mountain, under the purest and most translucent sky which this globe has to offer, and then on the clearest and darkest night place your eye to that magic tube. There are displayed a host of sparkling points, innumerable as the sands on the seashore, and so faint as to be only just discernible when our vision is strained to the uttermost. Are we to suppose that even under these circumstances we have seen all the stars of heaven? We have seen but the merest fraction of them. Out beyond, out far beyond that star dust, which is the last thing our mightiest telescope discloses, lie stars and systems of stars, which no human eye has ever seen or ever can see, even when every aid has been invoked to strengthen the senses with which nature has provided us. These are the invisible stars. There is a peculiar difficulty in photographing the stars, with which every practical photographer will sympathise. The sitter will not stay quiet. We cannot arrest the diurnal movement of the heavens; but what we can do is to cause the whole apparatus to move smoothly and regularly so as to follow the stars. No machinery could be relied upon to carry the plate forward with the precision which is necessary for a perfect picture. Its performance must be checked by the incessant attention of the observer who is seated at his post. By gently turning a handle to or fro he can so control the machinery that each star shall be kept at the same point of the plate for hours, until at last a perfect picture rewards his patience. My esteemed friend, Dr. Gill, her Majesty's Astronomer at the Cape, has sent me, for the purpose of this lecture, a superb plate which he has taken of the most famous star cluster in the heavens. In the centre lie a mass of stellar points so close together that you can hardly distinguish them separately, while all around are multitudes of the outlying stars belonging to the same system. A few minutes' consideration will, I think, show that never before has a more majestic spectacle been inscribed within the four corners of a photographic plate. A globe resembling our earth, complete with all its continents and all its oceans, would be an utterly imperceptible object if placed among the glittering points in that system. Those stars are suns of stupendous magnitude and gorgeous lustre. It is possible that, among so large an audience as I am now addressing, there may be some colour-blind people. The normal human eye will distinguish the seven colours of the rainbow, the red, orange, yellow, green, blue, indigo, violet. If, however, you had an ordinary photograph plate at the back of your eye instead of that marvellous retina, the red in the rainbow would be discerned but feebly, you would begin to see the green and the blue much better, the violet would seem brighter still. The most vivid hues would be in the inner part of the arch, which to the ordinary eye appears to be quite devoid of tint, but is, nevertheless, painted with many particular kinds of light to which the photographic plate is peculiarly sensitive. If we could imagine a photographic plate to express its candid opinion of the visual powers of the human race, it would say that every man, woman, and child among us was most miserably colour-blind; for the sun and every star pour forth a multitude of beams of light. Some of those beams belong to colours which we can see, others consist of the invisible light which can affect the photographic plate. Modern research is gradually making us in some degree acquainted with the marvellous complexity and interest of this thing which we call light. How wondrous is the subtlety of that mysterious ether which fills the firmament. At one time it can tremble with ripples no more than the ten-millionth part of an inch in length, and at another time it can roll with ethereal billows which measure a thousand miles from crest to crest. Our eyes show us a few vibrations in one particular region, photographic plates disclose a few other vibrations, while yet others are exhibited to us in the splendid experiments of Hertz. Had we eyes to which this Hertzian light was visible, we should be able to see through stone walls with the same faculty as we can now see through glass. It sometimes seems to me that our eyes are as inadequate

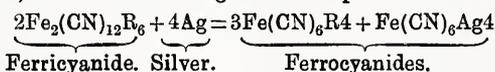

to interpret fully what the sun dispenses as would be the ears of a man who could only hear the beating of a drum when attempting to listen to an orchestral performance of a symphony. The solemn tones of the organ, the exquisite delicacy of the stringed instruments, would strike no responsive cord within him. Almost equally imperfect are our eyes for the interpretation of those marvellous radiations which the sun sheds abroad with such prodigality. His beams really contain a vast orchestra of vibrations, of which our eyes can only disclose to us a couple of octaves. At certain places within the mighty compass of the instrument we can devise a photographic plate or a Hertzian resonator to astonish us with a few additional octaves, but of the full volume of the harmony we are almost entirely ignorant. When we think that the other suns in space, to the number of uncalculated millions, are each of them simultaneously filling the ether with its particular orchestra of vibration, when we think of the marvellous way in which that medium transmits those delicate movements throughout the length and breadth of this universe, then, indeed, we begin to realise the sublimity of those words uttered in the beginning, "Let there be light."

### TONING WITH FERROCYANIDES.

[Translated from *Camera Obscura*.]

THE first use of ferrocyanides as toning agents was the process of uranium intensification published by Selle in 1866. In 1867 Eder and Toth, in *Photographische Correspondenz*, gave the theory of this process, which, as further described by Stieglitz in 1895, and afterwards by Valenta, is widely used at the present time in various commercial solutions. I recently undertook the study of this question from both the theoretical and practical sides, the results of my labours having been communicated to the French Photographic Society in January 1899.

I may first refer here to the use of ferrocyanides for toning purposes in general before I proceed to give practical details. If an image in metallic silver be immersed in a solution of a metallic ferricyanide, the result is the formation of a ferrocyanide of silver and of the metal originally combined with the hydro-ferricyanic acid. Thus, if R represent a mono-valent metal, the chemical change is thus expressed:—

If the working conditions are such that an insoluble ferrocyanide is formed, the silver of the original image will be finally converted into one of ferrocyanide. Most ferrocyanides being highly coloured bodies, and the colourless salts of this acid being readily converted into coloured substances, it is evident that this process places at our disposal a large number of colours.

The various metallic ferricyanides requisite for producing these colours are not commercial substances, and some of them, moreover, are extremely unstable bodies, so that it is necessary to make use of solutions which will generate the ferricyanide required at the moment we require it. This is done by mixing in certain proportions a solution of any alkaline ferricyanide (that of potassium is generally used) with a solution of the salt of the given metal, which must obviously be a salt which has, of itself, no action on the silver image. Ferric chloride and cupric chloride are, for this reason, to be avoided.

In instances where the metal forms several ferrocyanides of different colours (uranium is a case in point), every variation in the proportion of the two salts favours the formation of one or other of these ferrocyanides, and therefore produces a different colour of the image. It is an invariable rule, however, to avoid excess of alkaline ferricyanide in the toning bath, for the reason that excess of this salt favours the formation of ferrocyanide of potassium, a soluble salt which diffuses through the liquid precipitating some of the salt of the other metal. Hence a certain proportion of the coloured ferrocyanide is lost to the image, and goes to cause trouble in the bath. The conversion of the mixture of potassium ferricyanide and of the salt of the second metal into ferricyanide of this latter metal is never absolutely complete, however small the proportion of ferricyanide in the solution; there is always a certain proportion of uncombined alkaline ferricyanide, the prejudicial effect of which is magnified when the image under treatment is subjected to continual motion, because, under these conditions, the soluble salt which is produced will have a chance to diffuse into the liquid before being converted into insoluble form at the place at which it has been formed.

It is important to note, too, that the presence of any ferrocyanides in the solutions before use must be guarded against, as must also its formation by causes other than those already mentioned. As pure a solution as possible of potassium ferricyanide forms the basis of the several processes, and, as the various baths are more or less sensitive to photochemical decomposition, it behoves the operator to work in a fairly weak light. Care must also be taken to remove all substances other than metallic silver which can reduce ferricyanide. The treatment of the image in a solution of an oxidising agent is a plan to be commended, as a preliminary to toning, for the sake of obtaining pure tones and high lights.

It must be noted as well that most coloured ferrocyanides are extremely readily affected by the most dilute alkaline solutions, even of alkaline carbonates. Ordinary tap waters contain notable quantities of carbonate of lime, the action of which upon the insoluble ferrocyanide must be prevented. This means that washing must be done in acidulated water.

The tones obtained are the same so long as the proportions of the reacting salts are kept constant, whether the solution be used strong or weak. Weak solutions, it need hardly be said, offer the very practical advantage of controllability of action.

In the majority of cases the white and opaque ferrocyanide of silver which is formed only chokes up the image. In all cases where the process is used for toning (and not for intensification) purposes, it is advantageous to remove this ferrocyanide of silver by the action of some solvent which has no effect on the coloured deposit; sulphocyanide or thiosulphate is suitable for this purpose, according to circumstances. If, however, it is left in, there is the advantage that, if the colour is not suitable, the original image can be resuscitated by a series of very simple operations. The introduction into the toning bath of solvents of silver salts will be thus avoided in the case where such introduction is possible.

Instead of removing this ferrocyanide of silver, it can be utilised as the basis of fresh coloured products identical with, or different from, those already obtained. Thus, silver ferrocyanide in the presence of ferric or cupric chloride is at once converted into ferric or cupric ferrocyanide:—

This change can then be followed by an intensification or modification of the colour produced by the first toning. The toning can be effected simply by immersion in two successive baths, the first converting the silver into ferrocyanide, and consisting of an alkaline ferricyanide; the second converting this ferrocyanide into a coloured ferrocyanide. This transformation is possible only so far as the reaction, analogous to that foreseen by the previous equation is exothermic (*i.e.*, produces heat when it takes place). This will be the case whenever the chloride of the metal, the ferrocyanide of which is required, can be used. Toning in a single solution is, however, to be preferred to the use of two solutions, for the sake of the control it gives over the progress of the reaction, and the more vigorous image given when it is used.

*Preparatory Measures applicable to all the Toning Processes.*—These toning processes are applicable to any image obtained by development on a surface coated with sensitive silver salts, and some of them (uranium, molybdenum) actually intensify the prints; others (copper, iron) reduce them. The development of the print should therefore be stopped so as to produce an image of suitable density. The greatest care is necessary in fixing and washing. After thorough treatment in water, which is changed at frequent intervals, the prints should be placed for a few minutes in an oxidising bath, composed of a one per cent. solution of nitric acid or of persulphate of ammonia, followed by a further short washing.

The first solution to be prepared is that of ferricyanide of potassium (red prussiate). This solution is readily decomposable in the air, especially when exposed to light, and should therefore not be kept any longer than is necessary. The crystals should be washed with a little water prior to being weighed out.

## A.

Potassium ferricyanide.....	4½ grains or 10 grammes.
Glacial acetic acid.....	44 " " 100 "
Water .....	1 ounce " 1000 c. c.

This solution will be mixed, according to the directions below, with various other solutions. In all cases the dish in which toning is conducted should be kept still; the toning should be done in a feeble light, preferably by lamp light, and in the intervals between examining the print the dish should be covered with a card. The image, having reached the desired tone, is rinsed several times in acidulated water (acetic or nitric acid may be used for this), and is then washed for a few minutes (not more than four or five) in ordinary water. This brief washing in ordinary water will not, with most kinds of tap water, in any way reduce the image.

If the foregoing precautions be taken, toning will take place with great regularity, and gives great range of tones according as the process be arrested at an early or late stage in the operation. The prints show only the slightest tinge of colour in the highest lights, so slight, indeed, as to be quite unobjectionable in paper prints. This can, however, be completely removed by very short immersion of the print in a very weak solution of carbonate of soda, the action of which can be stopped by transference of the print to a weak acid bath, and afterwards to water. The permanence of the prints produced in this way is perfect. I have kept them for ten years in the windows of a chemical laboratory under the most unfavourable conditions, including damp, light, sulphuretted hydrogen, and acid vapours. Prints toned with uranium and iron have withstood these prejudicial agents, and have not shown the least sign of alteration.

*Uranium Toning.*—The theory of the process is briefly as follows: Two double ferrocyanides of uranium and potassium are known. The one, of a fiery red colour, has the formula—

It is somewhat soluble in pure water, but insoluble in water made acid with certain acids, notably acetic acid. It is formed when a few drops of a uranic salt are added to a strong solution of alkaline ferrocyanide. Under these circumstances, the most usual result is a limpid liquid of a bright red colour, which, when neutral, deposits the ferrocyanide formed, only very slowly. It is possible, however, that in such a medium as a gelatine film, which obstructs the movements of solutions to a great extent, this reaction would come within the range of practical use.

The other ferrocyanide is of a reddish-brown colour, and has the formula—

It is completely soluble in water, and is formed when a few drops of a dilute solution of ferrocyanide of potassium is added to a strong solution of uranic salt kept in excess. The precipitate quickly coagulates into an amorphous, almost opaque, mass. We thus see that the excess of uranic salt in the toning bath favours the production of brown tones, whilst the excess of ferrocyanide enables red tones to be obtained, but at the risk of diffusion upsetting one's calculations.

The commercial salts of uranium are the acetate and the nitrate. Although the latter can be used, it seems more reasonable to use the acetate, seeing that the solution is acidified with acetic acid. The equation already given and the formulæ just cited show that, for the formation of the brown ferrocyanide (2), the proportion of the two salts must be 8 molecules of potassium ferrocyanide ( $K_6Cl_2(CN)_{12}$ ) to 18 molecules of uranic acetate ( $UO_2 \cdot (C_2H_3O_2)_2 \cdot 2H_2O$ ), *i.e.*, 5264 parts of the first to 7668 parts of the second.

The red ferrocyanide is formed, on the other hand, by mixing 8 molecules of ferrocyanide and 15 molecules of uranic salt, *i.e.*, 5264 parts of the first with 6390 parts of the second. It is advisable to exaggerate these proportions in actual practice, increasing the proportion of uranic salt if the brown ferrocyanide is desired, and the relative weight of ferricyanide if the red ferrocyanide is wished for. After toning, the gelatine has become insoluble in water at a temperature of 60° C.

In practice I use the following solution (cold):—

## B.

Uranic acetate .....	4½ grains or 10 grammes.
Glacial acetic acid .....	44 " " 100 "
Water .....	1 ounce " 1000 c. c.

The solution of the acetate is so slow that it is necessary to prepare the solution some time before. The solution, however, keeps indefinitely. The toning bath is made by mixing A and B at the time of using as follows:—

Tone	Sol. A.	Sol. B.
Sepia brown .....	50 c. c. ....	100 c. c.
Reddish-brown .....	50 " .....	70 "
Fiery red .....	50 " .....	55 "

[The English reader may substitute minims or drachms for c. c. in the above formulæ.—TRANSLATOR.]

If the tone is too intense, it can be reduced by a longer washing in ordinary water (unacidulated); but a better plan is to immerse it after several rinses in a ten per cent. solution of sulphocyanide of ammonium, which will give great transparency to the image and will leave a better gradation. The same volume of solution can be used to tone several prints successively; but, as the liquid soon becomes turbid, it cannot be kept for use on another occasion.

*Iron toning.*—The theory of this process is somewhat as follows:—If a few drops of a solution of a ferric salt be added to a solution of potassium a blue liquid is produced, but no precipitate, *i.e.*, a soluble blue is formed which treatment with an alkali shows to be a double ferricyanide of potassium and iron (ferrous) and not a ferric ferrocyanide.

The only insoluble ferrocyanide which can be used in toning with iron salts is Prussian blue:—

This is obtained by adding a few drops of ferrocyanide of potassium solution to a solution of a ferric salt. This substance, which is absolutely insoluble in water, in cold solutions of acids, is instantly decomposed by ammonia, and by caustic alkalies, having a residue of reddish ferric hydrate,  $Fe_2(OH)_6$ .

Only one coloured product entering thus into the case, the tone obtained varies only very slightly with a very considerable variation in the proportion between the two constituents of the bath. The point to be avoided is a too large quantity of ferricyanide, which favours the formation of soluble blue. If, on the other hand, we wish to obtain a clear blue colour, we should keep down the proportion of ferric salt, an excess of which tends to greenish tints, though less so if the immersion of the print is not prolonged.

The choice of the ferric salt is an important point; those combined with a mineral acid act directly on the silver image, *e.g.*, ferric chloride, sulphate, and nitrate. Although I have successfully used ferric sulphate, the results with these salts are most capricious. The ferric salts of

organic acids are much more suitable, and from them we select ferric ammonium citrate on account of its good keeping properties. It has the formula—

The exact proportions corresponding to the formation of Prussian blue, without excess of either reagent, are one molecule of ferricyanide of potassium and one molecule of ferric citrate, or 658 of the first to 716 of the second. The presence of an acid in the solution is an advantage on the score of opposing the formation of insoluble basic salts.

In the practical use of the process I make the following solution in the cold:—

C.		
Ferric ammonium citrate ...	4½ grains or	10 grammes.
Glacial acetic acid .....	44 " "	100 " "
Water .....	1 ounce	or 1000 c. c.

This solution should be kept away from the light, preferably in bottles of non-actinic glass. It should be thrown away if it is found that, when mixed with A, a blue precipitate appears. The toning solution consists of:—

Tone.	Sol. A.	Sol. B.
Blue .....	50 c. c.	75 c. c.

This mixture is made and used in as feeble a light as possible; it is, in fact, the ordinary sensitising solution for ferro-prussiate papers. The image turns at first a bluish-green, passing afterwards slowly to a clear blue. Washing may, in this case, take place in ordinary tap water. The image can be cleared by placing the print for a few minutes in a bath of sodium thiosulphate, afterwards washing well in water. If only a slight blue fog is to be cleared off, immersion for a few seconds in an extremely weak solution of ammonia (about one per cent.) will answer. This brightens the blue, which takes on a violet tint; but in a very short time, especially if the ammonia solution is not sufficiently diluted, the image entirely disappears. This treatment must therefore be used with caution.

*Uranium-iron Toning.*—For the production of green tones, the use of uranium and iron salts in conjunction has been frequently recommended. A print toned by uranium to a red colour is immersed in a solution of a ferric salt, which, attacking the ferrocyanide of silver, produces a certain quantity of Prussian blue, the mixture of which in the film with the red uranium ferrocyanide gives rise to a green. This method is, however, very fitful. It often happens that, in consequence of the impermeability of the gelatine in the toned parts, the ferric salt only gains access to the silver ferrocyanide in the clear parts, producing therefore a very curious two-colour effect. It is very much better to form the two ferrocyanides at one and the same time. Thus:—

Tone.	Sol. A.	Sol. B.	Sol. C.
Green .....	50 c. c.	50 c. c.	50 c. c.

The practical precautions have been mentioned above when describing the production of red and blue tones. I may repeat that the solution must be kept at rest, and the operation performed in a feeble light. Washing takes place in acidulated water.

*Molybdenum Toning.*—The addition of a few drops of a solution of ferrocyanide of potassium to that of a salt of molybdenum gives a brown precipitate of the formula (according to Wyronboff):—

With excess of alkaline ferrocyanide a brown, limpid liquid is produced, which deposits, after some time, a different double ferrocyanide of brownish-red colour, but which, judging from its solubility, scarcely lends itself to the production of coloured images. It has the formula:—

We will select, as a source of our molybdenum, the commercial ammonium molybdate—

In this case the reaction can take place regularly only in the presence of a fair proportion of acid which will combine with the ammonia coming from the molybdate, and with the potassium from the ferricyanide.

It is easy to see that the necessary proportions of the several salts are 15 molecules of molybdate to 28 molecules of ferricyanide, with at least 216 molecules of acetic acid; this means 18,540, 18,424, and 12,960 parts by weight respectively of these substances. Much excess of potassium ferricyanide in the bath would bring about the loss of the image by diffusion. Without, however, going so far as this, the tone can be pushed towards the red, owing to the partial formation of red ferrocyanide of molybdenum. In practice we just prepare the following solution:—

D.		
Ammonium molybdate ...	6½ grains	... 10 grammes.
Glacial acetic acid .....	44 " "	... 100 " "
Water .....	1 ounce	... 1000 c. c.

The molybdate dissolves only very slowly. It should be finely powdered,

and the mixture heated at intervals until the dissolution of the salt is complete. To make the toning bath:—

Tone.	Sol. A.	Sol. D.
Sepia brown .....	50 c. c.	60 c. c.
Reddish-brown .....	50 " "	50 " "

After toning and washing, the print may, if it is thought desirable, be placed in a solution of thiosulphate in order to give it greater transparency. The prints obtained in this way are of an agreeable tone, and less sensitive to the action of tap water than those toned by uranium. Pure whites are easily obtained, and the process is very inexpensive. The bath can also be mixed with the bath for toning with iron (C), but the results obtained exhibit no special features.

*Copper Toning.*—When ferricyanide of potassium is added to an aqueous solution of a copper salt, a precipitate of cupric ferricyanide falls down. A solvent for this precipitate must therefore be found before a toning bath can be made. Ammonia, sometimes suggested, is of no use, because it dissolves also the cupric ferrocyanide formed in the reaction. I used last year with great success an acid solution of potassium oxalate. Quite recently W. B. Ferguson has recommended the use of a neutral solution of potassium citrate. Cupric ferricyanide,

is formed as a gelatinous purplish-red powder when one mixes sufficiently concentrated solutions of any copper salt and ferrocyanide of potassium. The best salts of copper are the acetate or the sulphate, which is a very common commercial product, and is easily prepared in solution. The necessary proportions are one molecule of ferricyanide to three molecules of copper salt, a slight excess of copper salt being used to slow down the action of the ferricyanide on the silver. This means 658 parts of ferricyanide to at least 747 of copper sulphate, a proportion (6:7) almost exactly the same as that advised by Mr. Ferguson. In practice, therefore, the following three solutions are prepared:—

No. 1.	Ten per cent. solution of neutral potassium citrate.
No. 2.	" " cupric sulphate (cryst.)
No. 3.	" " potassium ferricyanide.

Mix in the order given just before use.

Tone.	No. 1.	No. 2.	No. 3.
Purple .....	100 c. c.	7 c. c.	6 c. c.

No attempt should be made to clear the image after toning. To do so would mean the probable removal of the image itself. By adding a certain quantity of ferric ammonium citrate to the above solution beautiful violet tones are obtained.

*Restoring the Original Image.*—It is always easy to bring back the image to its original condition (whatever may have been the treatment of it) so long as the salts of silver formed in the course of the various reactions have not been removed. All that is necessary is to first remove the coloured ferrocyanide, and then reduce the residual silver salt to the metallic state. For the first operation a very weak solution of an alkaline carbonate answers for uranium, and a similarly dilute bath of caustic alkali for iron-toned prints. The ferrocyanide of silver thus left is converted into chloride by means of a weak solution of hydrochloric acid, washed, exposed to light, and developed with any developer. The density is exactly that of the original print.

L. P. CLERC.

## WEST'S PRINTING PROCESS.

[Patent No. 2373 of 1900.]

DR. WEST applies a compound which, when the print is immersed in a bath of water or other suitable material, will be dissolved, and with the bath form a solution for toning or fixing the print. With a paper sensitised in accordance with his patent elsewhere specified, which includes ammonium nitro-ferricyanide and ammonium ferric citrate, the coating on the back of the paper will consist of a concentrated aqueous solution of a salt of copper, which is allowed to dry.

“For this purpose I prefer the double citrate of copper and magnesium, but other cupric salts will give more or less satisfactory results when used in this manner. The purpose for which this coating of a copper salt is applied to the back of paper sensitised in accordance with my patent above specified is that, after such sensitised paper has been exposed to light, as in printing under a negative, and the same placed in a little water, the copper salt is dissolved off from the back of the paper, as well as are the salts from the sensitised side of the paper, and the two combined form a mordant or fixing solution, which effectually prevents the prints from becoming blue, as would be the case were such prints not subjected to a proper fixing agent. In my patent elsewhere referred to, and in the use of the common sensitised paper, it is necessary to place the fixing or toning chemicals in the bath preparatory to immersing the print; but, with sensitised paper having the fixing or toning solution applied to the back, the necessity of preparing a toning or fixing bath is avoided, the copper salt on the back of the paper being dissolved in the first washing water, which is added in small quantities, and not changed for a sufficient length of time, say, about ten minutes,

to enable the copper to act freely upon the print. After this bath nothing is required except a brief washing in clear water, as is usually done with prints fixed or toned in a separate bath. As before stated, different colour effects may be produced by changing the fixing or toning compound."

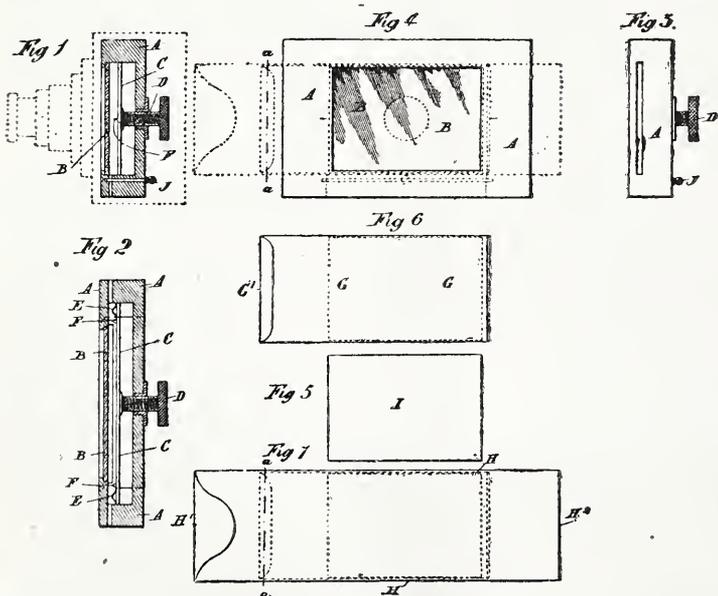

WRIGHT'S FILM AND PLATE-CHANGING APPLIANCES.

[Patent No. 4621 of 1899.]

THIS is a camera box with a movable internal leaf adjustable and affixable by a screw or other appliance from the back, the plate being so arranged that it can be drawn sufficiently backwards to allow of a film or sensitised plate with its holder to be inserted through a slit, and by a forward movement of the leaf be pressed closely towards a glass or opening in the face of the box. The inner leaf has a cutter or blade at each of the two ends which pierce, and by which a film or plate can be retained in position, and the holder after insertion can be severed ready for withdrawal through end slits of the box, the ends of the holder projecting for that purpose. There is also a slit at the bottom of the box to allow of the film or plate to fall into a bag beneath, the screw or nipping appliance being moved sufficiently for the film or plate to be released, and then for a slider to be drawn backward to allow the film or plate to drop. The holders are in the form of envelopes, and preferably two of these are provided for each film or plate, one envelope being enclosed within the other, and the film or plate so arranged as to be centralised in the box that the one end of each envelope projects ready to be drawn out and thereby leave the film or plate exposed for the image.

The inner leaf has rubber or felt pads which close up the slits.

The operation is as follows: The films in a flat condition with the envelopes are slipped into the box, the leaf is moved towards the glass, and in so doing the envelopes become pierced by the blades, the closed

ends of both envelopes on one side of the box are cut or torn off, the envelopes are withdrawn separately from opposite ends, the film is pressed to the glass, the image is then taken, the inner leaf is moved away from the glass, and the slider is withdrawn, the film or plate falling into the bag, and, on a complete backward movement of the slider, the box is ready for a fresh envelope, and film or plate for a repeat.

The following is the description:—

A, box or case, with glass, B, fixed in front opening; C, back-closer, operable by screw, D, from the back; E, E, pliable fillets for back-closer to press against the internal portion of box, A, to prevent entrance of light to the film or sensitised plate; F, F, knife or lancet blades, so fixed in box, A, that the points retain the plate or film in position, and also serve as piercers to pass through the two envelopes, G, H, when the back plate, C, is forced home by the screw, D.

The cutting edges of the knife or lancet blades look in both directions, and can sever either envelope, according to whether they are inserted from the right or from the left-hand side of the box, A.

It is preferable to insert the envelopes, with the film or sensitised plate within them, from the right-hand side, and with a portion of each end of the larger envelope exposed, one exposed end, say H<sup>1</sup>, of which has to be cut or torn off, and with it is also cut one end of the inner envelope, say at the line, a, a, leaving the opposite end, H<sup>2</sup>, exposed, to be drawn out from the side of the box, A, said envelope being severed, preferably centrally, along its length for its free exit when drawn out.

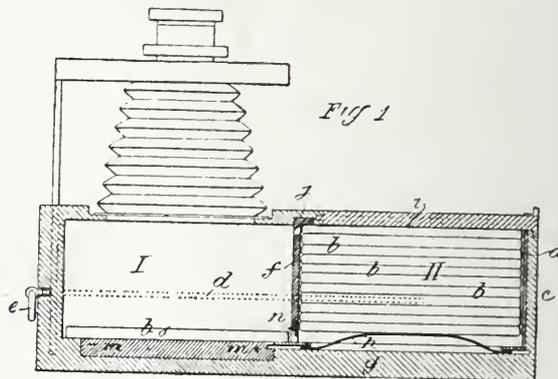

The cut end, G<sup>1</sup>, of the inner envelope, G, is now left exposed, and, as it is gripped and severed centrally lengthwise and drawn out, the film or

sensitised plate, I, is left within the box, A, and close to the glass front, on the further movement of the leaf, C, will be pressed to glass, B, for the picture or image to be taken in the ordinary way by the camera lens, all light being excluded in the manner already described.

DE GEOFROY'S MAGAZINE FOR HAND CAMERAS.

[Patent No. 6705 of 1899.]

THIS magazine consists of a drawer, a, in which are placed, in the ordinary way, metal frames, b b b, in which are held the sensitive plates. It can be moved into a space formed at the back of the dark chamber by a box, c, which is fixed or removable (in the latter case, it is provided with a screen or shutter). This box is of such dimensions that, besides the necessary space in I, in the optical axis of the objective, for lodging the plate to be exposed, there is sufficient space in II to receive the drawer, a. This drawer may be moved so as to be drawn either into the

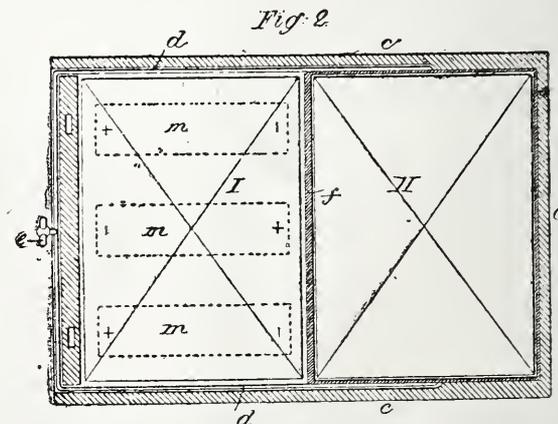

position, I, or the position, II. One or two rods, d d, which are fixed to the drawer, and which terminate in the ring, e, on the exterior of the box, c, permit of this operation being performed.

The side, f, of this drawer, which also forms one of the walls of the dark chamber proper, is of a height equal to the total thickness of all the plate frames, less, at each end, the portion necessary to allow the passages of the end or top and bottom plates.

Upon the bottom, g, of the box, e, are fixed in the part, II, of the magazine, one or more flat springs, h h, which press the piles of plates against the opposite wall, i.

These springs are placed according to the line of displacement of the drawer, so as not to prevent the movement of it.

At the upper part, i, of the box, B, are arranged one or more small

pieces, j, in the form of inclined planes, which project only sufficiently to seize one frame, b, and so placed as to permit of the frames coming along with the drawer, from the position, II, into the position, I (by reason of the flexion of the springs), but so as to hold the top frame by catching its edge when the drawer returns to the position, II.

The apparatus will then be in the position shown in fig 1, that is to say, the top frame, b, being held back by the stop, j, falls, when the drawer is pushed right back, and has come to the position, II, and the fallen frame takes up then the position, b, s, and is held there by the force of one or more permanent magnets, m, let into the floor, g, at the bottom of the chamber, I, and flush with the inside surface, the frames which hold the sensitive plates being made of suitable metal. When the frame has fallen to the bottom of the chamber, I, it is held there stationary by the magnet or magnets.

## Our Editorial Table.

A SECOND edition of Mills' *Photographer's Exposure Note Book* has been issued by Messrs. Dawbarn & Ward, Limited, of 6, Farringdon-avenue, E.C. In assisting the photographer to arrive at correct exposures, and in supplying him with means for making records of them, this little book, which is published at 1s., should be found of very great use.

### ROANOID.

MESSRS. LONSDALE BROTHERS, of Green-lanes, Harringay, N., write: "Noticing an inquiry for a material suitable for covering hand cameras, &c., we beg to send for your inspection a sample of our Roanoid, which we are selling for this purpose. It is thirty-five inches wide, price 4s. per yard, any length. You will see that it is almost indistinguishable from real hide. It will not scratch or rub up on the surface like leather, and is in consequence more durable, besides being waterproof." Judging by the sample sent, Roanoid appears to be an excellent substance for covering hand cameras.

### INSTRUCTION IN PHOTOGRAPHY. TENTH EDITION.

By Sir W. de W. ABNEY, K.C.B., D.C.L., F.R.S.

London: Sampson Low, Marston, & Co., St. Dunstan's House, Fetter-lane, E.C.

WE have in our possession the first public edition of Sir William Abney's book, an admitted classic in photographic literature. It was issued when the author was instructor in photography at the School of Military Engineering, Chatham, and it consists of 168 pages. The date on the titlepage is 1874, and the information it contains is entirely pre-gelatine in character. Since then each succeeding edition has grown with the growth of our knowledge of photography, but the book has never departed from its reputation of being a well-considered guide in practical photographic work, based upon that authoritative mastery of theory with which Sir William Abney's name is rightly associated.

The tenth edition of *Instruction in Photography* numbers some 500 odd pages, and the newest matter principally relates to half-tone work in monochrome and colour. Some of the subjects dealt with in the course of the volume are the action of the spectrum, the theory of development, phenomena in development, the dark room and its fittings, lenses and shutters, preparation of plates, gelatino-bromide paper and films, defects in gelatine negatives, wet-plate photography, collodion dry-plate processes, production of transparencies and enlargements, artificial lighting, theory of silver printing, preparation of sensitive papers, the platinotype printing process, mounting prints, the carbon process, photo-lithography and zincography, photo-reliefs and photo-engraving, &c.

Abney's *Instruction in Photography* is a work which has always appealed to those photographers who are not content with a mere superficial smattering of the subject, and of the new edition it is right to say what has often been said before of this valuable book, viz., that it should always be at hand for reference. The tide of publication of late years has been heavily laden with photographic books, but Abney's *Instruction* is in no danger of being swamped. Unquestionably it remains the ablest and most useful photographic text-book in our language.

## Studio Gossip.

A NEW YORK correspondent states that, while photographers were at work in the Orange Mountains, New Jersey, recently, taking a series of pictures which were to be reproduced on a kinetoscope as representing the battle of Spion Kop, one of the cannons was fired prematurely. Two of the most prominent actors in the sham fight were seriously injured. The incident will, doubtless, add unexpected realism to the scenes. Many pictures have been "faked" in this way, purporting to be reproductions of battles in Cuba, the Philippines, and South Africa.

THE Röntgen rays have been called in to throw their light on a point of law. During the hearing in the Chancery Division of an action by the Dunlop Pneumatic Tyre Company to restrain an alleged infringement of a patent, an expert stated he had examined a tire by the Röntgen rays in order to determine its position under air pressure. It was then suggested that Mr. Justice Buckley should have the advantage of a personal examination. Assent being given, the whole Röntgen apparatus was set to work on the Bench beside the Judge, who was able, by the aid of a screen, to see how the otherwise invisible wires concealed in the rubber tire lay against the rim. The demonstration occasioned much interest in court.

THE new material for paper-making, about which a good deal has been said of late, turns out to be the guaxima, which grows wild in great abundance in Brazil, particularly on low lands near the sea. Brazilians believe that this fibre would prove an excellent substitute for jute, which is all imported, and that it would prove the basis of an important industry. The threads are long

and very strong, and will resist the action of water, the fibre being used by fishermen for their nets, which last for years if soaked in a tincture of arceira bark. The process of elaboration of the guaxima fibre does not require long maceration in vessels, as is the case with jute, immersion for a few days in running water being sufficient to loosen the green outer bark with the hands, after which the rods are exposed to the sun in order to dry the woody part; this then contracts, and allows the fibres to be easily separated.

THE PARIS EXPOSITION.—The Paris correspondent of a contemporary says that outside Paris a few days ago over 2000 trucks filled with exhibits were lying exposed to wind and rain, and by the order of the Government not one was allowed to enter the grounds before the 18th inst. It is probable that, now that the official opening is over, the Exhibition will be closed for a few weeks in order to give the workmen breathing room. If the public is admitted indiscriminately, the show will never be finished. The question of illumination is hopeless. Up till last Friday night the cables had not been tested, and in some instances the connexion had not been established. If there is at night anything like the crowd at the opening of the 1889 show, which trampled under foot the glow-worm lamps in the gardens, the installation will have to be practically recommenced. One of the most amusing bangles is the question of statuary. The welcoming figure over the main entrance is *La Parisienne*. It is a modern creation, and infinitely more suggestive than the usual goddess of labour using her wings as umbrellas for a savage-looking workman with a pick axe, and a woman with a child at her breast, apparently keeping off flies with an olive branch. After it had been put up, the authorities noticed that the *Parisienne* was dressed in furs, and came to the conclusion that this was out of place for a purely summer show. Whether she has to be smashed up and removed is still an open question. As to the statues in general, they are asleep in their boxes, and for the very good reason that the pedestals have not yet been built; and a study of Venus in the simple costume of a pure mind, leaning against a tree, and Adam and Eve basking on a tulip patch, might reasonably be considered as inartistic.

## News and Notes.

PHOTOGRAPHIC CLUB.—April 25, at eight o'clock, Lantern Evening. Slides by Mr. E. A. Newell.

VISCOUNT MAITLAND, who is the adjutant of the 20th (Rough Riders) Battalion of the Imperial Yeomanry, left for the front on Saturday last.

THE Southport Photographic Society's Exhibition of members' work will be open from May 28 to May 31 inclusive. The Society's silver and bronze medals will be placed at the disposal of the Judges, to be given, if the work merits it, for the artistic and technical excellence of photographs.

EXHIBITION OF MODERN ILLUSTRATION.—The Science and Art Department have consented, at the request of the Council of the Society of Arts, to organize an Exhibition of Modern Illustrations, consisting of specimens of typographic work suitable for books, magazines, and newspaper illustrations.

WOODFORD PHOTOGRAPHIC SOCIETY.—Mr. E. J. Wall will give a technical lecture on Colour Photography before the members of the Woodford Photographic Society on Wednesday, the 25th inst. If any gentleman interested in the subject, or any members of neighbouring photographic societies, would like to attend, the Hon. Secretary, Mr. F. G. Emler, of the Florence Villas, Chelmsford-road, Woodford, would be glad to supply the necessary permission.

THE next meeting of the Physical Society will be held on April 27, at eight p.m., at the Solar Physics Observatory, South Kensington, when Sir Norman Lockyer, K.C.B., will give a short account of the physical problems now being investigated at the Observatory, and their astronomical applications. If the night is fine, the thirty-six inch reflector, and ten-inch and nine-inch reflectors, will be used for the observation or photography of celestial objects and their spectra. The large Apps-Spottiswoode coil and Rowland grating will also be shown in operation.

CARBIDE OF CALCIUM PROSECUTION.—At the Thames Police Court on Thursday, April 12, the Argo Steam Shipping Company, of 4, Cullum-street, E.C., were summoned for an offence against the Petroleum Acts. Mr. Bunting, who prosecuted on behalf of the Thames Conservancy, said the steamship *Reiter* brought a case of carbide of calcium up the Thames, above Thames Haven. Such a thing was prohibited, unless it was in a special vessel. The case in question was brought to the docks, and, after the defendant's attention had been called to the fault committed on the other side, they had the case reloaded and sent back to Bremen. Carbide of calcium was a dangerous substance, as, when brought into contact with damp, it gave off an explosive gas. Eventually the magistrate imposed a fine of 40s. and 2l. 2s. costs.

KINDNESS REWARDED.—Max Martin Ross, a native of Swindon, aged forty-five, was charged at the Birmingham Police Court with stealing a camera, two lenses, and three dark slides, value 5l., the property of Joseph Medlam, of 125, Livery-street, Birmingham. It appeared from the prosecutor's evidence that he took the prisoner into his house about Christmas time out of compassion, having known him twenty years previously. As he represented that he understood photography, witness gave him the use of a dark room, and a room as a studio. After staying with him for some time, the prisoner suddenly disappeared with the goods in question, which he pawned for 25s. The prisoner, who pleaded guilty, was sentenced to three months' imprisonment, the Chairman saying that he had shown a very peculiar kind of gratitude to a man who had been so kind to him.

## Commercial Intelligence.

THE AUSTIN-EDWARDS MONTHLY FILM-NEGATIVE COMPETITION.—The prize camera for the current month has been awarded to Mr. T. E. Colney Wilson, 16, Swiss-road, Fairfield, Liverpool, for his negative, *Evening Calm*.

MESSRS. TENNANT & WARD, of 289, Fourth-avenue, New York, inform us that the demand for copies of the *Photo-Miniature* has necessitated the re-printing of No. 3, dealing with "Hand-camera Work;" and No. 4, dealing with "Photography Outdoors."

The practice of photography is reported to be making headway among amateurs in the Bilbao district of Spain. Photographic goods were at first supplied by French houses, who were subsequently largely supplanted by the exertions of German agents, who offered cheaper articles. British houses are stated to confine themselves to sending catalogues of their goods; there also appears to be an impression abroad that British photographic materials would be more expensive than German, and that cameras and plates would be made to measure different from those in current use.

THE WARWICK COMPETITIONS.—The following is the list of awards of the Warwick Competition for the current month:—10l. prize, Alfred Bainbridge, 342, Leeds-road, Nelson, *Quiet Moments*; 5l. prize, W. B. Green, Grasmere, Gladstone-road, Watford, *All on a Gallows Tree*; 1l. prizes, R. H. Beavan, 74, Petteril-street, Carlisle, *A Portrait*; J. Brooks, 35, Liverpool-street, Brighton, *The Foot Bridge*; Albert Durn, The Studio, Wootton-under-Edge, *The First Copy-book*; Nichol Elliot, The Studio, Coldstream, N.B., *A Portrait of Lady*; G. H. Gill, 133, Trinity-road, Upper Tooting, S.W., *Our Cook*; C. R. Girardot, 11, Westland-road, Watford, *The Little Mill*; P. Goodchild, 2, Colonnade, Leamington, *The Gleaner*; W. G. Gould, 47, Kenwyn-road, Clapham, S.W., *My Father*; Lillie Green, Hunton Bridge Farm, King's Langley, *Threshing Wheat*; A. G. Lawson, 32, Ashley-road, Crouch Hill, N., *March Many Weathers*; W. H. Machin, 82, Bedford-street, Moss Side, Manchester, *Violin-maker's Workshop*; J. Peat Millar, Braehead, Beith, N.B., *Portrait of Little Boy*; V. T. Paul, Photographer, Lr. Morrab-road, Penzance, *Lilies*; E. W. Philpott, 96, York-road, New Cut, Bristol, *After Rain*; J. R. Reynolds, 15, St. Mary's-road, Sheffield, *Winter Weather*; S. von Schubert, Downside College, Bath, *In a quiet Somerset Wood*; J. W. Smith, 4, Britannia Buildings, Chesterfield, *An Electrical Dynamo*; W. T. Stokes, Ivydean, Grove Avenue, Moseley, *Berry Hall*; C. E. Thompson, Fordingbridge, *A Portrait of Dog*; J. Watson, 3, Grey-road, Walton, Liverpool, *A Letter from the Front*.

In the Peterborough County Court last week Samuel Finney claimed 10l. 16s. 3d. from the Eastmid Company, Limited, for wages due and expenses incurred on behalf of the defendants. The Company entered a counter claim for 17l. 11s. 2d. for damages for leaving without notice, using the studio, &c. Mr. F. W. Atter was for the plaintiff, and Mr. J. Batten for the defendant Company. Finney stated that he was engaged by the Eastmid Company, Limited, which consisted of Mr. Parr (Secretary), Mr. Marriott, jun., and Mr. Marriott, sen. (Directors) on June 19. A letter was received on June 14 offering the position at the Peterborough studio at a salary of 30s. per week, with certain commission. The terms were accepted, and there was to be a month's notice on each side. All went well until November 20, when claimant agreed, on certain conditions with the Company, to accept a salary of 25s. a week in future. The claimant wrote a letter stating the conditions, but not one was complied with, and therefore he claimed the whole of the 30s. On June 5 he left without giving any definite notice. As to the counter claim, Finney admitted having used the studio for lodging for some time. There was no objection made to this, neither was there any intimation that a charge would be made upon him. He provided his own bedding, and used the gas when required. Asked why he left the Company's employ, Finney stated that he had not received any salary for several weeks, although he had applied to the Company for his wages on many occasions. After a lengthy hearing, evidence having been given by Mr. Parr, the Judge reduced the plaintiff's claim, and allowed several items on the counter claim, which gave plaintiff 5l. 7s. 8d.

THORNTON-PICKARD, LIMITED, v. THORNTON.—The Thornton-Pickard Manufacturing Company, of Altrincham, write us: "It is a source of satisfaction to us that the Judge's verdict was in our favour as to the constructive portion of the agreement, and that he stated that in his view Mr. Thornton had broken the agreement in commencing to make films. After having established so much, it is very disappointing that the verdict should go against us on such a technical point as the over-wideness of the clause relating to "other photographic appliances." In our opinion, the Judge gave this Company credit for claiming more than we have ever wished to claim. We have never held the opinion that the agreement would prevent Mr. Thornton from commencing business as a chemist, and selling nitrate of silver, bromide of potassium, gelatine, distilled water, or the numerous other chemicals and articles which, when brought into certain combinations with each other, form photographic appliances. For instance, we hold that he would be perfectly justified in making or selling the articles mentioned above as such, but when an emulsion is made of gelatine, nitrate of silver, bromide of potassium, &c., and it is coated on to some substratum such as glass or celluloid, then we arrive at a photographic appliance, which we hold that Mr. Thornton is debarred from dealing in either directly or indirectly. We have not as yet had time to consult our solicitors as to the advisability of appealing to a higher court, but we have little doubt that they will recommend us to do so. We add one or two extracts from the official shorthand report of Mr. Justice Kekewich's judgment. Speaking of a film, his Lordship says: "I suppose it might be otherwise described, but it is a photographic appliance, and, being a photographic appliance, it comes within the words here, 'other photographic appliances,' and Mr. Thornton seems to me, according to the strict construction of this clause, to have clearly prohibited himself from directly or indirectly carrying on, or being engaged in, or concerned in, or interested in the business of a manu-

facturer of or dealer in films." Again, speaking of the constructive part of the agreement, he remarks: "So far I am entirely with the plaintiffs, and think there has been a distinct breach of the covenant. Then comes the more difficult question to my mind whether the covenant itself is void in law." As you know, the Judge ultimately decided that the covenant, or at any rate the clause relating to photographic appliances, was void in law.

## Patent News.

THE following applications for Patents were made between April 2 and April 7, 1900:—

SENSITISED PAPER.—No. 6074. "Improvements in Photographic Sensitised Paper and the like." J. E. THORNTON and C. F. S. ROTHWELL.

PROJECTION.—No. 6086. "Improvements in the Method of and Means for Taking and Projecting Photographs." T. THORP.

SHUTTERS.—No. 6088. "Automatic Timing Device for Photographic Shutters." J. E. THORNTON.

PANORAMIC CAMERAS.—No. 6235. "Improvements in Panoramic Cameras." Complete specification. M. T. STONE.

CAMERAS.—No. 6346. "Improvements in and connected with Cameras to enable Sketches or Tracings to be made." A. R. TINDALL.

KINEMATOGRAPHS.—No. 6351. "Improvements in and relating to Kinematographic Instruments." Communicated by L. Senfter and H. Terrot. W. G. HEYS.

SHUTTERS.—No. 6461. "Improvements in or relating to Photographic Shutters." Communicated by H. M. Reichenbach. A. J. BOULT.

RELIEF PHOTOGRAPHS.—No. 6531. "A Process for obtaining Objects in Relief by Means of Photography." J. ITIR and W. C. ELBOROUGH.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
23.....	Bradford Photo. Society .....	Negative-making, by the Members.
23.....	Glasgow and West of Scotland .....	{ Paper on <i>The Composition of a Picture</i> . — Exhibition of Prize Slides.
24.....	Aintree .....	<i>The Lowlands of Scotland</i> . D. J. Neill.
24.....	Birmingham Photo. Society .....	{ Demonstrations: <i>Development</i> . E. Underwood, C. F. Jarvis, and G. Whitehouse.
24.....	Bootle .....	{ Demonstration: <i>Wellington Films</i> . Harry Wade.
24.....	Hackney .....	{ <i>On Tramp with a Camera</i> . H. W. Dunkley.
24.....	Isle of Thanet .....	Demonstration. Mr. Forwalk.
24.....	Leeds Photo. Society .....	<i>The Lofoten Islands</i> . Howard Priestman.
24.....	Royal Photographic Society .....	{ <i>The Latest Developments of Metro-</i> <i>photography</i> . Bridges Lee, M.A.
25.....	Photographic Club .....	Lantern Evening: Slides by E. A. Newell.
25.....	Woodford .....	<i>Colour Photography</i> . E. J. Wall.
26.....	Leigh .....	<i>Enlarging</i> . Mr. Foxhall.
26.....	London and Provincial .....	Open Night.
26.....	Oldham .....	{ <i>Technical Control for Pictorial Results</i> . Reader, C. A. Hempstock.
26.....	South Norwood .....	{ Demonstration of the <i>Secco Films</i> . Practical Demonstration of the Various Methods of Reduction and Intensi- fication. Mr. Baldoek.
27.....	Croydon Microscopical .....	Prize Slides.
27.....	Whitby .....	{ Excursion: Edgware and Whitechurch. Leader, F. W. Bannister.
28.....	Borough Polytechnic .....	{ Excursion: Abrook Common. Leader, Hilton Grundy.
28.....	Brentford .....	{ Excursion: Rosset and District. Leader, W. A. Taylor.
28.....	Liverpool Amateur .....	

### ROYAL PHOTOGRAPHIC SOCIETY.

APRIL 10,—Ordinary Meeting,—Mr. T. R. Dallmeyer, F.R.A.S. (President), in the chair.

#### NEW MEMBERS AND FELLOWS.

Nine new members were elected, and five candidates for membership were nominated. The President announced that five members had been admitted as Fellows of the Society.

#### THE MUNICIPAL ENCOURAGEMENT OF PHOTOGRAPHY.

MR. THOMAS BEDDING read a paper with the above title, in which he called attention to what had already been done for photography by some of the English municipalities, and suggested another field of usefulness for the Society, besides those at present before it. To photographers, he said, there should be something more than indirectness of interest in the fact that in several of our large towns the art-loving instincts of the inhabitants had manifested themselves by the erection of galleries, which were used in many cases for the reception of permanent collections of paintings, sculpture, and so forth, by past and present masters, and in others for the holding of periodical exhibitions of such works. He submitted that the interest of photographers in the matter lay in the hope that the encouragement thus afforded to the older forms of graphic expression might in future comprehend the youngest of them, namely, photography; and the object of the paper was to show that many

local authorities had already taken sympathetic action upon the subject, and to suggest that the Royal Photographic Society should take advantage of its power and position to co-operate in movements of the kind whenever opportunities occur. The recognition of photography by some of the great municipalities as worthy of being brought as prominently to the notice of the public as paintings and other works of art must have a most important influence in what is generally termed "raising the status of photography," and was equivalent to an admission that, in its pictorial aspects, the work of the camera had earned the right to a distinct place amongst modern methods of graphic expression. Further, a well-arranged display of the best modern work in a provincial town would not only agreeably surprise the public who inspected it, but would also have an educational influence on professional men and others acutely concerned in lifting commercial photography off the plane of mediocrity on which most of it unfortunately stood. The paper proceeded to refer in detail to the winter courses of lectures on photography delivered from time to time at Liverpool and Manchester under the auspices of the Corporations, the inclusion of a photographic section in the spring exhibitions of paintings at the Walker Art Gallery at Liverpool, the exhibitions organized by the Leeds Photographic Society, with the assistance of the Corporation, and the municipal photographic exhibitions held at Bradford, Derby, and Huddersfield. The author of the paper thought that the evident willingness of the great municipalities to encourage photography might be stimulated to further efforts in the same praiseworthy direction if it were known that, in addition to the co-operation of the local societies, that of the Royal Photographic Society was also available. The loan of the Society's permanent collection, when requested, would be a step in the right direction, and the influence which the principal and most representative Society in the world could bring to bear on foreign as well as British exhibitors would, no doubt, materially add to the success and prestige of a purely local display. In the matter of facilities for studying photography in the laboratory and the Exhibition gallery, London was well provided for; but the paper concluded with the statement that, however great the municipal encouragement of photography might eventually become, it would be incomplete without the intervention of the most powerful municipality in the world, that of the City of London. The City had done a great deal for many forms of art and industry, and, if at some future time the Royal Photographic Society could be instrumental in persuading the historic Corporation to lend its powerful encouragement to photography, in the form of a comprehensive exhibition or otherwise, a useful step forward would have been taken.

Mr. C. R. ROWE mentioned the action which had been taken in the West of England and at Derby with regard to photographic matters, and suggested that Mr. Bedding's paper should be printed in pamphlet form and forwarded to the town clerks of some of the larger boroughs, in order that it might be brought under the notice of the Corporations.

Mr. J. A. SINCLAIR referred to the excellent work which had been done by the London County Council at the Bolt Court Technical School, which, he said, was frequented by large numbers of apprentices employed at newspaper offices and photo-mechanical works, and who took a very keen interest in the instruction that was given.

Mr. J. W. MARCHANT thought the present was an opportune time to bring the subject forward, so far as London was concerned, having regard to the fact that the new municipalities created by the recent London Government Act were to come into existence in November next.

#### COMING EVENTS

April 24, Technical Meeting, "The Latest Developments of Metro-photography," by Mr. J. Bridges Lee, M.A. On April 25, Mr. F. H. Evans will formally open the third of the series of House Exhibitions with some remarks upon the examples of his architectural and other works, which he has consented to exhibit in the Society's rooms.

**Hackney Photographic Society.**—April 10, Mr. A. Barker presiding.—A demonstration was given by Mr. D. C. NIGHTINGALE on the new developer kachin. It was claimed that this was equal to any other developer, and possessed, besides, advantages peculiar to itself. It was clean, very stable, easily controlled, and economical in use, it being possible to use the same solution repeatedly. It gave good warm tones in gaslight development papers, without addition of ammonium carbonate.

**North Middlesex Photographic Society.**—April 9.—Mr. J. H. GEAR gave a lecture on

#### NEGATIVE AND PICTURE-MAKING.

He dealt with exposure of the plate, and impressed the necessity of getting it correct to get good results. He gave a formula for a standard pyro-soda developer, and said that for slight under-exposure rodinal or para-amidophenol was good for reducing contrasts, while hydroquinone, if properly used, was good for over-exposure or increasing contrasts. Sodium nitrate was a very useful chemical in the dark room, and was more serviceable than potassium bromide for stopping development. Sharpness of definition, in his opinion, should always be obtained, any degree of softness desired could be obtained in after-manipulation. He then passed through the lantern slides from negatives without any after-treatment, and from the same when clouds and other additions had been made, pointing out the reason for doing so. He showed how the introduction of suitable figures improved and harmonised with an otherwise uninteresting landscape, and gave many other hints in picture-making.

**Aintree Photographic Society.**—An excellent paper was placed before this Society last week from the Royal Photographic Society, entitled,

#### PHOTOGRAPHIC DEFECTS AND THEIR REMEDIES,

by Mr. E. Dockree, illustrated by fifty lantern slides, the whole proving a good object lesson to beginners and veterans alike, such subjects as vibration, halation, fog, irregular development, injudicious use of apparatus, focussing, and distortion, with their cure, being fully demonstrated. Every Society would do well to procure this paper and slides for an evening, as it cannot help but be interesting to those who dabble in photography.

#### FORTHCOMING EXHIBITIONS.

1900.

May 23-25 ..... Plymouth Photographic Society. Hon. Secretary, W. H. Harris, 5, Clarendon-place, The Hoe, Plymouth.

July 9-14 ..... Photographic Convention of the United Kingdom (Newcastle-on-Tyne Meeting). Hon. Secretary and Treasurer, F. A. Bridge, East Lodge, Dalston-lane, London, N.E.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### MYSTERIOUS IMAGES.

To the EDITORS.

GENTLEMEN,—With reference to the phenomenon brought to the notice of the London and Provincial Association by Mr. Thomas, I would remind you that in the old days, when we had to do everything for ourselves, it was the practice to test the efficiency of the cleaning of our plates—especially when they had been used before—by breathing on them, when traces of imperfectly removed images showed on the surface; in this case it would seem probable that the plates had been imperfectly attended to, and that consequently vapour had settled unequally on the surface, and thus caused an unequal deposit of the fine dust always flying about; we all have experience of the way in which this deposit adheres to our windows, and in this case the result has been the production of the old image in a visible form.

My own practice was to leave plates for a whole night in a ten per cent. solution of nitric acid, and I never found any relics of the old picture after they had been well sluiced in abundant water, not even when mercury had been used to intensify.—I am yours, &c.,

April 12, 1900.

J. F. T.

#### OZOTYPE.

To the EDITORS.

GENTLEMEN,—Some time ago Mr. Manly told one of your correspondents that there would shortly be on the market an improved solution and tissue for the practice of Ozotype. I have seen nothing of this since, though I have looked out anxiously for it, and should be glad to learn if there is any prospect of an early redemption of the promise.

Whatever the advantages of carbon are to the professional photographer, it has the disadvantage to the amateur, who only wants very few prints from any one negative, that experiments are necessary to ascertain the proper exposure for the picture, and that they have to be repeated for each negative, and the results noted. Platinotype does not require this, as a very short experience enables one to print with fair certainty. Ozotype promises to put carbon printing in this respect on a par with platinotype. This would be a great boon to amateurs, for the black tones of platinotype do not quite meet the wants of all subjects. I very seldom lose a platinotype print when the weather is decent, but should, I fear, lose a good many in carbon as at present worked.—I am, yours, &c.,

J. F. T.

#### A CINEMATOGRAPHIC FEAT.

To the EDITORS.

GENTLEMEN,—Knowing your desire for accuracy in noting any photographic achievement, I beg to point out the fact that the feat you give publicity to has been beaten some time ago by the British Mutoscope and Biograph Company, Limited, and a record established which will be very difficult to break.

I will not trouble you by citing innumerable parallel cases with the above, as they are an every-day occurrence with the above Company, but, as an instance of marvellous dispatch and organization, the following, I think you will agree, makes the record:—At the Crystal Palace, in May last, at the opening of the Article Club by H.R.H. the Duke of Connaught, the arrival of the Duke and Duchess, just before one o'clock, was photographed on a film of considerable length, the negative developed, dried, and a positive printed, developed, dried, and prepared for exhibition, and shown upon the screen at the Crystal Palace (Biograph Pavilion), at three o'clock the same afternoon.

The developing, printing, &c., was all done in an improvised dark room, fitted up expressly for this picture, where the great facilities the Company have in their extraordinary dark rooms at Windmill-street were missing. I may also instance, as an equally great feat (showing

what perfect organization can do), the Grand National Race of last year, when the finish of the race at Liverpool, late in the afternoon, was brought to London and shown at the Palace Theatre the same evening, all the developing, printing, &c., being done at Windmill-street. Every week at the Palace Theatre events taking place in the afternoon are shown the same evening, and, during the last few months, war pictures have been shown with marvellous quickness after the event, that to give you any details would occupy too much of your valuable space. Hoping you will insert this, as your leaderette might create a false impression, except to those familiar with the Biograph at the Palace Theatre.—I am, yours, &c.,

W. P. DANDO.

18 & 19 Great Windmill-street, London, April 13, 1900.

### EXHIBITION OF THE SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES.

To the EDITORS.

GENTLEMEN,—In connexion with the Fifth Annual Congress of the South-eastern Union of Scientific Societies, to be held this year at Brighton on June 7, 8, and 9, a photographic Exhibition is being organized to illustrate the various applications of photography to scientific work. The Exhibition will not be limited to work done by members of the affiliated societies, but the Committee will welcome any offers of loans that would be likely to prove interesting and instructive. Should any of your readers desire to send exhibits, either in the way of prints or lantern slides, I should be glad if they would communicate with me not later than May 7.—I am, yours, &c.,

H. E. TURNER,

Hon. Photographic Secretary.

Lindfield Lodge, Folkestone, April 16, 1900.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

#### PHOTOGRAPHS REGISTERED:—

A. Wragg, 30, Burscough-street, Ormskirk, Lancashire.—*Photograph of Ormskirk Parish Church.*

E. Eccles, 15, Broad-street, Bury, Lancashire.—*Four photographs of Mr. James Byrom, Mayor of Bury. Photograph of the Bury Football Players.*

REFERENCE.—C. T.—If your late employer refuses to give you a reference, there is no law to compel him to do so. It would be useless for you to go to the County Court on the matter.

R. G. (Manchester).—The paper is not manufactured in England, but you may obtain it of the agents, Messrs. Otto König & Co., 27, Cross-street, Finsbury-pavement, E.C., or through a photographic dealer.

COLLOTYPE WORKER. We have some recollection of the attempt to float the Company, but none of the publication of any details of the process, which we were privately informed was some form of collotype.

STEREOSCOPIC RELIEF.—STEREO. The exaggerated relief in the slide is due to the lenses being much too far apart for a subject so very close to the camera. In this instance they should not have been separated more than two or two and a quarter inches.

SANDARAC SOLUTION.—W. CONWAY writes: "Is not gum sandarac soluble in methylated spirit? The book says it is, but the man from whom I got some (sample enclosed) says it is not. Any how, I cannot get it to dissolve."—The sample sent is not sandarac at all, but a common kind of gum arabic, which, of course, is not soluble in spirit.

BOOKS WANTED.—E. JONES writes: "Will you please tell me of a book on portraiture without a studio, and also a book on retouching, and where they may be obtained?"—*Home Portraiture*, by Richard Penlake, published by L. Upcott Gill, 170, Strand, W.C., price 2s. 6d.; *The Art of Retouching Negatives*, by Robert Johnson, published by Marion & Co., Soho-square, W., price, we believe, 2s.

BOOK WANTED.—H. GREAVES writes that, as a reader, he will feel obliged if we can favour him with any information as to how or where he might purchase any book publication on the working up of bromides in black and white, as also on retouching, that is to say, giving best instructions on same.—In reply: Johnson's *Art of Retouching, and How to Finish and Colour Photographs*, published by Marion & Co., Soho-square, W., should suit our correspondent.

ALTERATION OF FOCUS BY STOP.—T. ABRAHAMS says: "I have a rapid rectilinear lens (no name), and when I focus it with the full opening and get a sharp image, and then put in a smallish stop, it does not seem so sharp as it did at first. Why?"—The lens evidently has a considerable amount of spherical aberration. You will have to focus with the stop with which the negative is taken, or one a size larger, when the light is too feeble to see with small stops.

PRINTS ON SALE OR RETURN.—STATIONER writes: "An amateur here asked me to sell some of his views, saying he would send some on sale or return. I sold a few and returned the rest. He refuses to take them back, and wants me to pay for the lot, saying that, as I put them in the window, they had turned yellow and are no good to him. Can he recover?"—Certainly not, if they were supplied on sale or return. If the prints have turned yellow or faded, that is his fault—his careless work.

VEILED LANTERN SLIDES.—FOG complains that all the slides he develops with ferrous oxalate have a veil or deposit on the surface. As he prefers the colour given by this developer, he wants to know how to avoid the veil.—The water used clearly contains lime, and the deposit is oxalate of lime. The only way of avoiding it is to employ distilled water, or water free from lime. The deposit may, however, be easily removed. Simply flow over the plate a little very dilute hydrochloric acid, which will dissolve it at once, leaving the picture clear and bright.

PHOTOGRAPHIC SUPPLIES ON THE NORWAY STEAMERS.—INQUIRER writes: "I should be greatly obliged if you can inform me whether it is correct that during the visitor season to Norway the boats are fitted with a photographic store for the sale of photographic materials; and, if so, I should be glad if you can give me the name of the firm or firms who have the right of sale."—In reply: We believe that dry plates and other photographic materials are obtainable on the Norwegian steamers leaving Newcastle-on-Tyne. For the name of the firm having the right of sale, we must rely upon some reader who has made the trip.

WATER.—1. The hardness of the water is caused by the presence of lime. The well-known Clark's test consists of the addition to the water of a solution of soap in alcohol; the quantity of soap in the solution is known, and, according to the quantity of soap used in producing the desired results, so the degree of hardness of the water is determined. 2. Desirable, certainly. 3 and 4. Lime salts are deposited in prints, negatives, &c.; though, chemically, their presence may be disregarded. 5. Not by a mere attachment to a tap that we know of; your simplest plan will be to boil the water you use for developing, toning, fixing, &c. This will get you over your difficulties.

COPYRIGHT.—COPYRIGHT writes: "Will you kindly tell me (1) if I can now copyright an old view negative, which I recently lent to be copied on to an illuminated address, and which would give me power to stop the sale of collotype copies which are being offered. (2) Also if I can claim damages for copies already sold, as I know the number of copies that have been supplied to the dealer. I have been so badly treated in the matter, and don't wish to take any action unless I get further annoyance. So far as I can remember from your Correspondence columns, registration would be as effective now as if it had been done at first. (3) You might also tell me what issue of THE BRITISH JOURNAL OF PHOTOGRAPHY contains copy of the Copyright Act."—In reply: 1 and 2. Registration can, of course, be made now; but we doubt if any action you brought would have a retrospective effect in the recovery of penalties, &c.; but for infringements after the date of registration you could, of course, recover. 3. It is printed in our ALMANAC for 1900.

LENS FOR STUDIO.—EDWIN MATHEWS writes: "In the Answers to Correspondents column of your issue dated March 30, in reply to 'Cranion,' you say you do not know of a lens that will take 'full lengths' in a studio of 15 ft. length. I am working professionally in an ordinary bay-windowed room, and have only a space of 14 ft. 6 in. from background to lens, and in that space I manage both 'full lengths' and other styles (cabinet). The lens I am using, is a 6½ × 4½ Special Rapid portrait lens by Houghton & Sons, and the price (don't laugh) 2l. 15s. I enclose a few prints, all taken with this lens. You will admit, I think, they are not bad, considering the conditions. I shall be glad to give any information in my power to your correspondent."—There is a wide difference between working in a studio but 15 ft. long, and having a space of 14 ft. 6 in. between the background and lens. The camera, stand, and operator require another two or three feet. The full-lengths sent, with one exception, are children, the exception being a lady of short stature placed quite close to the background. In this, the bottom of the dress is quite out of focus. What is generally understood, with reference to lenses, for full-length portraits, is of adults of average height, say, five ft. eight or nine, and that is what opticians mean in their catalogues.

STUDIO-BUILDING.—C. F. A. writes: "1. I intend erecting another studio, and near the glass side there will be a stone wall, about 3 feet 6 inches high at one end, and 4 feet 6 inches at the other. How near could I come to that wall without interfering with the light of studio? The glass side of studio will be next the wall, with N.E. aspect. 2. What focal length are portrait lenses used for general purposes—say, for taking full-length *cartes-de-visite* to cabinet groups? Or, in other words, what would be the most suitable focal length for general professional work, excepting large groups? 3. Would a studio 20 × 8 feet be large enough for such work as that mentioned? 4. As a length of 25 to 30 feet is recommended for a studio lighted at both ends, would 15 to 20 feet be long enough for one intended to be wrought from one end only, and be efficient for professional work? 5. What would be the most suitable focal length of lens for a studio 20 × 8 feet?"—1. If you get 4 or 5 feet from the wall, there will not be much light obstructed. 2. The lens most generally used for full-length *carte-de-visite* portraits is about 8 inches equivalent focus, and for full-length cabinets about 11½ inches. Both these lenses require a distance of 18 feet between sitter and camera. 3. The studio would be too short for either of these lenses, therefore shorter-focus ones must be used. 4. The lighting has nothing to do with the length of the studio. 5. For full-length *cartes*, 6 inches, and for full-length cabinets, about 8½ or 9 inches.

### EX CATHEDRÁ.

We are happy to announce that the third Traill Taylor Memorial Lecture will be delivered in London next November by Mr. F. E. Ives. The subject of the lecture will be "The Optics of Trichromatic Photography," and the author will treat of it in its historical and practical aspects with illustrations and demonstrations. Mr. Ives promises to show some new devices of his own, which he is reserving for first exhibition on the occasion of his lecture. In all probability the lecture will be delivered at the House of the Royal Photographic Society in Russell-square, and may be relied upon to attract a large and interested audience. Mr. Ives has been engaged for over twenty years in studying the application of the colour-sensation and colour-vision theories to photography, and has probably added more to our knowledge of this fascinating subject than any other living experimentalist. In our ALMANAC for 1899 we briefly summarised his heliochromic work, the full record of which has occupied a large part of our space for many years past.

PHOTOGRAPHERS nowadays have little to do with dangerous chemicals. The case was different in the collodion days, when a good supply of ether was generally in stock, and cyanide of potassium was the general fixing agent. At present photographers have little use for collodion, except for enamelling, when a little ether is often required for thinning it. Many amateurs, however, are not aware of its dangerous properties, and that its vapour is highly inflammable at ordinary temperatures, and, when mixed with a certain proportion of air, highly explosive. Last week two serious accidents in London from volatile chemicals were chronicled. One was from an explosion of ether, when several men were knocked down and two so badly injured as to necessitate their removal to the hospital. The other was from the bursting of a carboy of bisulphide of carbon, when two shops were wrecked, though no one, except from broken glass, was injured. Although the newspaper reports attribute the explosions to the bursting of a bottle of ether in the one case and of a carboy of bisulphide of carbon in the other, there is little doubt the explosions that did the damage were due to a mixture of the vapours with atmospheric air. Those photographers who have to do with volatile chemicals, such as ether, benzole, bisulphide of carbon (one of the solvents of indiarubber), and the like that give off inflammable vapours, should, for safety, store them in a cool out-house during hot weather, as they may expand, burst the bottles, or blow out the stoppers, and let the highly inflammable and, under some circumstances, explosive vapour escape, when, if a light is brought near, a serious accident may happen.

\* \* \*

At a recent meeting of the Edinburgh Photographic Society a paper was read on paper-making, with special reference to its photographic uses. The author made reference to the fact that the British paper-manufacturers hitherto had not been able to supply a photographic paper, and that photographers had to go to the Continent for it. We have often commented on this fact, and expressed surprise that the whole of the photographic paper used throughout the world is made at two, or at most three, German manufactories, where the output must be enormous. The price they charge for it is considerably in

excess of the best English papers, therefore it is much to be wondered at that British makers do not enter the field with a suitable photographic paper; still more so, remembering that, in the old calotype days, it was only English-made papers that were found suitable for the negatives—Turner's, Hollingworth's, Whatman's, &c. It is evident that British makers let the photographic paper trade slip out of their hands, and, so far as we are aware, have made no serious attempt to get it back again, and that is not a little surprising. Although this country is dependent upon Germany for its photographic paper, large quantities of the best British papers go to Germany. A friend of ours, travelling in Germany last year, asked at two or three different stationers' shops for the best quality letter paper, and with each purchase the water-mark bore the names of our best manufacturers.

\* \* \*

THE Danish police, like their *confrères* here, evidently utilise photography, for we read, in a telegram from Copenhagen, that a report on the examination of the royal saloon car in which their Royal Highnesses the Prince and Princess of Wales travelled when the dastardly attempt was made upon the Prince's life had been sent to the police at Brussels. This report was accompanied by some five or six photographs of the interior of the carriage, as well as the bullet that had been found. In some countries on the Continent, we are told, photography is more largely employed by the police than it is here, and that the work is, as a rule, of a better quality technically. We are sorry that we cannot accord a high standard of excellence to the general run of the photographs produced by our Police department.

\* \* \*

MESSRS. DAWBARN & WARD, Limited, of 6, Farringdon-avenue, E.C., draw our attention to two lists they are issuing, which should find very widespread uses. The one is a list of books and periodicals supplied by the firm. The portion of this list which relates to photography occupies eight closely printed pages, and it includes all standard books on the subject that are in current request. Some such list as this was greatly needed; for, although it carries completeness to the point of including many rubbishy productions which the photographic world can easily do without, its handiness as a source of reference may be depended upon to constantly assert itself. The second of Messrs. Dawbarn's lists relates to the Index of Standard Photographs—"age cannot wither nor custom stale" our unalterable objection to that dreadful word *photogram*—which aims to be a guide to the hundreds and thousands of subjects in the collections of photographic publishers and professional photographers. We learn that this list has grown from an estimated 112 pages to over 300 pages, and the subscription has consequently been raised to fifteen shillings. Editors, publishers, and others should find that outlay a highly profitable investment, for a list of photographs like that given in the Index is of incalculable value.

\* \* \*

OLD BOND-STREET on Saturday morning last witnessed the speedy gathering of a typical London crowd full of vocal enthusiasm for one of the heroes of the hour, Sir George White, the defender of Ladysmith. It appears that Sir George, who was repairing to the handsome studio of Messrs. Langfier, Limited, of 23A, Old Bond-street, for the peaceful purpose of sitting for his portrait, was recognised by the

passers-by, who rapidly congregated in considerable numbers and cheered the gallant General to their hearts' content. We understand that Messrs. Langfier, whose skill and enterprise are undeniably great, took several excellent negatives of Sir George. It is to be hoped that it will not be long before his fellow-generals who are still fighting in South Africa will find themselves confronted with no more arduous task than that of facing the photographer's lens in the capital of the Empire they are serving.

\* \* \*

LAST week the Artistic Photographic Company, Limited, of 72, Oxford-street, London, W., published a two-column advertisement in the *Daily Telegraph* relating to a free gift for a limited period to every reader of that journal, simply as an advertisement. It ran as follows: "In order to further increase the popularity of our renowned permanent guinea enlargements, which we reproduce from any ordinary photograph for the exceedingly small sum of 5s. 6d., we have decided to present each purchaser, with their first order, for a limited period, a charming little miniature on porcelain, framed complete, in chaste English-made gilt frame. Instructions: Send us a photograph (*carte-de-visite* or cabinet) and we will reproduce from the same a beautiful photographic enlargement, guaranteed absolutely permanent, skilfully finished by hand, and handsomely mounted on plate-sunk India tint mount, measuring 18 x 14½ inches, resembling a rich steel-plate engraving, for which one guinea and upwards is usually charged, together with a miniature, as before stated, for the small sum of 5s. 6d. inclusive."

\* \* \*

THE advertisement elsewhere says that it is "almost incredible that for 5s. 6d. we [the Company] reproduce a large portrait, equal in every respect to those for which ordinary photographers charge from one to two guineas." It is not by any means the first time that we have called attention to advertisements of this kind, offering the public low-priced bromide enlargements for which it is said that photographers charge pounds or guineas where only shillings are asked by the enterprising firms who conduct profitable businesses by almost giving photographs away. The Artistic Photographic Company know perfectly well that five-and-sixpenny bromide enlargements are not sold for one or two guineas, and that consequently ordinary photographers do not make such charges for work obviously not worth it. We suggest that in future they omit such erroneous statements from their advertisements. It will not harm their business one bit, but it may save "ordinary photographers" from the possible charge of making exorbitant profits.

\* \* \*

A FRIEND who occupies a prominent position in the photographic world sends us a copy of a circular issued by Mr. Walter McIntosh, of 46, Ryevale-road, Balham, London, S.W. This refers in glowing terms to an instrument termed the *realistoscope*, obviously a stereoscope, and to the wonderful effects seen in the *realistographs*, commonly called stereoscopic slides, when viewed by that instrument. We must do Mr. McIntosh the justice of saying that his eulogies of stereoscopic photography are expressed in ornate and glowing language which excites our deepest envy; we can never hope to approach him in the power of investing binocular work with a wealth of verbal glory such as Mr. Swinburne himself might find it

difficult to equal. We have no recollection of having seen any of Mr. McIntosh's realstoscopic work, and are therefore surprised to find in his circular that we are quoted as terming "beautiful and fascinating. They" [some slides], we are made to say, "will bear examination and re-examination." Moreover, "The Editor of the *Photo-Almanac*" (reference presumably being made to ourselves and our *ALMANAC*) is also credited with this criticism: "An elegant, interesting, welcome addition to the drawing-room table. The effects must be seen to be adequately appreciated. 'A thing of beauty,' it will philosophically prove 'a joy for ever.'" Whenever we pass an opinion in these pages or in those of the *ALMANAC*, we have no objection to its reproduction, but we demur to having thrust upon us the paternity of sentiments that have an alien origin. Probably Mr. McIntosh's stereoscope and his binocular slides are all that he says they are; but, as we have not seen either one or the other, we must ask those of our readers into whose hands his circular may fall to note that we are not responsible for the favourable criticisms Mr. McIntosh assigns to us.

#### VIGNETTED NEGATIVES AND VIGNETTING.

In an article a few weeks ago we described a few methods of producing vignettted negatives so as to avoid the vignetting in printing. From communications since received we judge that the idea of making vignettted negatives was quite a novelty to many, while, as we explained, it is one of the oldest methods of producing this style of picture. Since the present system of making vignettes, namely, by vignetting each print in the printing frame, became almost universally adopted, very little improvement seems to have been attempted to improve the artistic appearance of the pictures. They are simply the figure shaded off into blank space, sometimes cleverly done, at others just the reverse. Often the negatives are taken with a plain light background placed behind the sitter, sometimes with one with a light landscape scene, or, indeed, with any other that may be in general use at the time. Some photographers, however, who produce the best vignettted portraits employ special backgrounds for them. These are light at the top and shaded off with cloud-like effect towards the bottom. Such backgrounds are a great aid to the printers, as they render the vignetting easier in the printing.

Amateurs generally employ vignetting glasses or the vignetting masks, with the conventional oval or pear-shaped openings, as sold by the dealers for the purpose. Professionals, however, usually employ masks, which they make themselves to suit the subject, cut out of cardboard, brown paper, zinc, &c., placed at some distance in front of the negative while printing; the farther the mask is from the negative the softer and more delicate, of course, is the vignetting. A very light background, as first mentioned, is an assistance to the printer, but it does not in most cases improve the effect of the portrait, it being usually almost of the same tint in the print as the lighter portions of the face and the dress; whereas a darker one would throw out the portrait better if it were softly and delicately shaded off, but that would naturally increase trouble and involve more skill on the part of the printers. However, vignettes as they are now made are unquestionably very popular with the general public, and in all probability will continue to be so for a long time to come. Although that is the case, is there any reason why they should not be improved upon? In the majority of cases there is ample scope for it.

It is a noteworthy fact that, while the uniform shading off of the background and figure in direct prints is almost universal, the case is different with worked-up vignettted enlargements. Here the artist usually introduces a little sketchy hatching, or cross hatching, in the background, and where the figure is shaded off somewhat after the style of the celebrated Richmond drawings. This when artistically done—which, by the way, is not always the case—greatly enhances the picture. That being so with enlargements, why should it not be so with direct prints?

Our older readers will remember the photo-crayon portraits of thirty or more years ago, and the favour they met with at the time, that is, in the hands of those who could produce them successfully. When skilfully done, these pictures could scarcely be distinguished from veritable crayon drawings, although, as a matter of fact, there was not a particle of hand work upon them; consequently they were very profitable to their producers. For the benefit of our younger readers, we will explain what they were, and how they were produced, as it will serve to illustrate our remarks on the effect that a little sketchy work has upon a vignettted photograph. An enlarged transparency by the wet-collodion process, vignettted in the camera, was made usually on a 15 × 12 plate. It was imperative that this transparency—and here was the difficulty—must be exceedingly thin, though full of detail in every part; indeed, it was but a phantom image when viewed by transmitted light. This transparency was simply backed up with a piece of white or tinted crayon on paper, upon which some sketchy hatched lines were lithographed. The hatching, of which there were different forms, was so located that it just came where the picture and background was vignettted off, and gave the finish. The effect, as we have just said, was scarcely distinguishable from a well executed crayon drawing, upon which a considerable amount of skill and time had been expended. The difficulty that many found in making these pictures was in getting full detail in the transparency while it was thin enough, and of suitable warm black colour by reflected light. These pictures were the invention of the late Mr. Napoleon Sarony.

The above named gentleman, about the same period, also introduced hatched vignettes, direct prints, after the style of the Richmond heads. We shall now describe how they were made, as the methods may serve as a hint to those who, at the present time, may desire to improve the present style of vignettes, making, of course, such modifications in the systems as may suit their practice. One of the methods was vignetting the negatives in the camera, and that, on the whole, is the more simple plan, inasmuch as no vignetting is required in the printing. A mask, with a suitable opening for the subject, is placed in the camera, well out of the focus of the lens, similar to that described for producing dark vignettes a few weeks back. After the portrait has been taken this mask is replaced by another—its counterpart—which protects only the previously exposed portions of the plate. A white screen, upon which there are some suitable sketchy, hatched lines, is then placed in front of the camera, and the lens focussed upon it, and a second exposure made. We now get the figure vignettted into the hatching, with a margin that is quite opaque.

Another method of getting a similar result, in the finished picture, is by double printing. In this case a vignette is made in the printing frame in the usual way. Then a negative, taken in the camera, of a hatched drawing on white paper, is placed on the print and exposed to light, though not

deeply printed. The opaque portions of this negative will protect the parts already printed, and the effect in the finished picture is very effective and artistic. It is scarcely necessary to mention that a series of negatives, with hatching to suit different subjects, is essential, as it also is when vignettted negatives are made in the camera, for it is obvious that what would suit one subject might not be suitable for another. What would suit a three-quarter figure would by no means suit for a head and bust.

At the time that Mr. Sarony introduced this style—about 1865—the *carte-de-visite*, on glossy albumen paper, with purple-brown tones, was all the rage, and these pictures, though novel, were not quite in keeping with the celebrated Richmond heads—the pictures were incongruous. The case would be different now with cabinets on platinum papers. We recently saw some platinotypes in this style that were very artistic and effective, and they were very unlike ordinary photographic vignettes. They very closely resembled small crayon drawings, as the paper was rather rough. Of course, a still rougher paper might be employed for larger portraits with good effect. We commend the idea to professional portraitists who may be on the look-out for a novelty for the season.

**A Long Eclipse.**—As additional to our remarks upon eclipses in our last, it will be of interest to note that the 1905 eclipse we referred to as occurring in a district within easy distance from this country is specially remarkable in one respect—the length of time the sun's disc will remain obscured. It is by no means probable that any one viewing that will again have the opportunity of photographing the phenomenon for so protracted a length of time. It is impossible, of course, to predict what science may do for human longevity, but it is fair to assume that it will not help a man to live to the age of over three hundred, that being under the time that will elapse before a totality of nearly three minutes and three-quarters—the duration of the 1905 eclipse—will occur. Time, an hour after midday, August 30, 1905; place, in central line, Burgos, Spain, is a date to make a note of.

**Minimum Limit of Star Magnitudes.**—Our readers are, of course, aware that the smaller the magnitude of a star the longer the exposure necessary, and it might be supposed that, granted suitable means for keeping the image always on one spot, there would be no limit to the magnitudes that could be photographed if exposures sufficiently protracted, extending say over several nights, were to be given. But in practice it is not so, there is a practical limitation existing, governed by "atmospheric glare." So far as this country is concerned—in dry countries at high elevations the limit might possibly be extended—Dr. Roberts, practice indicates, as far as can at present be predicated, that, when a plate has been exposed for a sufficient number of hours, for a star of the eighteenth magnitude to be impressed, the fog brought about by the photographic power of the atmosphere itself, or of the natural luminosity of the sky, is so great that any increase of exposure would produce "fog" sufficient to overpower any star image whose luminosity was in defect of that of an eighteenth-magnitude star.

**Becquerel Radiations.**—The study of the field so ably worked by M. and Mde. Curie is fertile in new discoveries. M. M. A. Debierne appears to have separated—in an impure state, certainly—another new substance with active radiation power. At present it has only been obtained in an impure state—in fact, a sort of impure thorium; but it is shown that the new metal is not either polonium or radium, the Curies' discoveries, though all of the trio are extracted from a similar source—the residues obtained after the treatment of pitchblende.

**The Eclipse at Sea.**—The Orient Line, in the interest of those who might like to see the eclipse from the deck of a steamer, have arranged to so navigate their Royal Mail steamer *Ormuz* as to

bring the vessel off the coast of Portugal, during the eclipse, upon the central line of totality. The course of the vessel is from London or Plymouth to Gibraltar or Marseilles, and the trip will occupy fifteen days. The *Ormuz* is to leave London on the 25th proximo.

**The Picture Season.**—Next week the Royal Academy will be opened. The Spring Art Exhibition at Vienna is now open, so is a loan Exhibition of paintings at West Ham, as well as the annual show, under the auspices of the Corporation of the City of London, at the Guildhall. Several other exhibitions of pictures will also be open shortly. The Exhibition at the Guildhall this year is confined to the work of British artists only, and only one picture by the same painter is shown. This gives students the opportunity of seeing and comparing within a small space the distinct styles of the different artists better than perhaps could be done in a larger exhibition, such as the Tate Gallery. There are in all 115 paintings by the same number of artists. Many of the works are loaned from the permanent collections of several other Corporations—Manchester, Birmingham, Liverpool, Leeds, Nottingham, Glasgow, and other towns. The National Art Galleries of Sydney, N.S.W., have also contributed from their treasures. This Exhibition will remain open, Sunday afternoons as well, for several months. Photographers will do well to visit the pictures, as they will probably never have the opportunity of seeing such a collection again in a single building.

IN connexion with the Vienna Art Exhibition we read that the small gold State medal has been awarded to three British artists. One of the chief arguments of the advocates of the abolition of medals at photographic exhibitions is that the Royal Academy gives none, yet British artists compete for them on the Continent—or, if they do not compete for them, we have never heard of an instance where they were refused because their acceptance would be *infra dig.* when awarded. In most of the annual exhibitions at Munich R.A.'s and A.R.A.'s come in for some of the medals, and we have little doubt they are highly appreciated by their recipients.

#### JOTTINGS.

THE copyright agitation may as well be relaxed for the present, a Lord Monkswell's new Bill, which was read a second time in the House of Lords last month, and referred to a Select Committee, was Governmentally declared, by the mouth of Lord Balfour of Burleigh to have no chance of passing into law this session. It has to be submitted to colonial opinion and criticism, and after that to make its way through the two Houses of Parliament at home—a long journey through a hostile country, to be sure; for the friends of photography cannot hope that an almost idyllic measure, which classifies the productions of the camera as artistic work, gives protection for life and thirty years afterwards, and abolishes compulsory registration, will escape the unpleasant attentions of the little knot of painters and publishers who are in league for the purpose of persuading Parliament that the photographer has no mission in life except to be the prey of unsympathetic competitors. But I have mistaken the temper of the Copyright Union if, next year, when the Bill is under consideration, past experience is not taken as a guide in preventing, as far as possible, the conversion of a measure by no means unfavourable to photography into such a scandalous attempt at spoliation as that which formed the subject of discussion at the Society of Arts a month or two ago.

MEANWHILE a new and closer danger threatens those photographers whose work is reproduced in the illustrated newspapers. From the evidence that has been placed before me I conclude that an offensive alliance exists amongst the conductors of those publications, and that their immediate aim is to force the minimum right of reproduction fee of half-a-guinea down to five shillings. Photographers are being asked by circular to agree to accept the smaller sum where a photograph is reproduced a second or third time, and to sign an agreement to that effect. I know of cases where such a request has met with emphatic refusal, and I have been asked to warn photographers not to walk into the trap that is so cunningly prepared for them. It is clearly a move on the part of the ill-

rated journalists to make the minimum fee five shillings, for, of course, the inducement held out to the photographer is that three reproductions at 5s. each are more remunerative than one at 10s. 6d., and its partial success, which is not improbable, will help to make photography for reproduction purposes less and less remunerative. For years past many newspapers have offered from 5s. to 10s. 6d., as reproduction fees; and so we get an idea of what they think the minimum and maximum payments should be. And this differs from the ideas of the Photographic Copyright Union.

LAST month I announced that Dr. P. H. Emerson would have a "one-man show" of his famous photographic work at the Royal Photographic Society's House in June next, and now I can add the further information that, on the opening night of his Exhibition, he will personally deliver an address on the subject of his photographs. These are being specially framed for the purpose, and, as I have often said in these pages, they will be a revelation to many of those who have only recently taken up photography. It must be eleven or twelve years—in the old days of the Camera Club in Bedford-street—since Dr. Emerson addressed a London audience. Himself one of the most virile and fascinating figures in the photographic world, the charm of his manner and style, not less than his perfect fundamental knowledge of pictorial photography, will undoubtedly assure him a great reception when he opens what I venture to say will be the most interesting of the series of one-man shows the Royal Photographic Society is now holding at Russell-square.

THE Third Annual Dinner of the Plate and Paper-makers' Association, which takes place on Wednesday next, is another reminder of the force of the saying that threatened institutions, like threatened men, live long. When the Association was first formed, its early decease was widely prophesied, and I am giving away no secret in saying that some of its present supporters were amongst those who boded, if they did not actually wish, disaster to the movement. There is no doubt that, in regulating discounts and attacking the evils of price-cutting, the Association has done good work, and, though in minor matters of policy it may be open to individual criticism or disapproval, its influence, on the whole, has made for the advantage of all branches of British photographic trade. By the way, the Association and the Copyright Union, to which I have already referred, parallelise at several points, for the latter body numbers among its objects the prevention of the cutting of prices in copyright fees, the protection of its members against unfair or illegal methods of doing business, and so on. It is only through the neglect and apathy of photographers that the Union, in its own wide sphere of action, is not so successful as the Association undoubtedly is in its broad field of activity.

THE revised rules for the guidance of Judges at Photographic Exhibitions are in my humble opinion deficient in one important respect: they give the Judges power to exclude from the exhibition room, while the adjudication is in progress, "all persons," which obviously includes exhibitors and others interested in the destination of the awards, but the rule is not made obligatory. It is only too frequently the case that judging has to be done under the very eyes and noses of a group of covetous competitors. I have been told that the most unblushing attempts are sometimes made to influence the awards by members of a society holding an exhibition. If the rules included a provision that no competitor should be present at the time of judging, a great deal of embarrassment and unpleasantness would be avoided. It is too much to expect, I suppose, that competitors could be prevented from hanging round exhibition entrances, and directing the attentions of Judges on their arrival to the precise position of their photographs, and it would be difficult, if not impossible, to stop letter-writing to Judges with the object of influencing awards. But this sort of thing is and has been done, and I for one am determined, the next time any of it comes under my direct observation, that the culprit shall be publicly exposed. The medal-hunter who recoils from no dirty trick to secure a paltry disc of metal is a despicable person who, in the language of Mr. Alderman Cute, should be "put down."

I AM much obliged to my friend, Mr. Edgar Scamell, who, on the 30th ult., was kind enough, in answer to my request for information about the exact status of the National Photographic Record Association, to send a copy of the rules, the annual report, and other details, showing that that body stands on a firm basis and is likely to have a continuity of administration. What I was anxious to elicit was whether the present excellent work which the Association has taken in hand was likely to be carried on if, at any future time, there should be a change of officials, and Mr. Scamell's letter assures me it is. That is all. I trust the Association will go on and prosper, and that future generations will thank it for accumulating a large collection of permanent photographs illustrating buildings, scenes, customs, and so forth, which Time is doing his best to improve out of existence. The Exhibition which has just closed at Russell-square attracted a great amount of attention, though some of the prints shown will probably give posterity a very poor opinion of the photographic abilities of some of the contributors. However, the Association's objects are excellent, and I hope to live to see what it has done, and is doing, more widely known and appreciated than it is at present.

SPRING has come at last, and outdoor photography is therefore now possible, under conditions of personal comfort and with natural surroundings that make landscape work peculiarly attractive. The young bright green foliage and the blossoms that cover the country look singularly beautiful on the ground glass, at any rate. I have often thought that the life of a travelling photographer, journeying by caravan from village to village, for six or seven months a year, must be a pleasant one. Quite recently I was assured by a gentleman who has taken up this branch of professional work for a living that it is not only pleasant, but profitable. He is on the move from April till October, staying a week or so in each place. The whole photographic equipment is drawn by road. I believe the retouching, printing, and mounting are done on the spot, and the enlarging put out. My friend smilingly said that perhaps this kind of photography is a little *infra dig.*; but, then, what it loses in dignity—if indeed, there is any loss in that direction—it gains in profit and pleasure. It is a mild kind of gipsying, and therein lies its element of attractiveness, I suppose. After all, a vast part of the world's business is done on the road. Actors, musicians, singers, and others of the kind, travel from place to place for a living, so why not photographers? And where does the loss of dignity come in?

GENERAL WATERHOUSE, in a letter to the Editor of *The Journal of the Photographic Society of India*, in which publication so many valuable writings of the distinguished experimentalist have appeared, touches a note which will find an echo in the minds of all earnest students of photography. "There are many scientific problems requiring attention, which busy people cannot give them," writes General Waterhouse. Perhaps there could be no more effective rejoinder to a statement recently made in my hearing, that there was very little left to discover in photography. The truth is that no matter in which direction one turns, photography, at the end of the century, presents many avenues of experimental research, into which scientific inquirers are only just penetrating. Most of the advances that have been made in colour work, in optics, in chemistry, during the last twenty-five years, a period of time covered by gelatine photography, still leave many "scientific problems requiring attention," as General Waterhouse expresses it. An utterance of this nature from such an authoritative source is deserving of every respect, for it will serve to remind practical workers, who are prone to think scientific investigation has said its last word on their behalf, that finality of knowledge in photography has not yet been reached. New discoveries may be slower in coming than in past times, but it is because, as General Waterhouse hints, individuals become busier with the march of the years. To day the man of science, above all others, finds himself improving upon Goethe, and, crying "Time, Time, give me more time." The most valuable ally of Science is Time.

## DO NEGATIVES FADE?

THE announcement made by Dr. Roberts, in his recently issued volume of *Astronomical Photography* that the images on gelatine negatives are liable to fade after a time is new to many. The Doctor mentions that a negative, in which, when first taken, he was able to count 403 stars, after the lapse of about nine years 131 of them—about one-third—had disappeared. This is a serious matter for the scientific world, seeing that the whole of the negatives now being taken under the international scheme of mapping the heavens are by the gelatino-bromide process. If the smaller stars are liable to fade out of the negative after the lapse of a few years, many will possibly have disappeared before the chart is completed, consequently much of its astronomical value will be curtailed. Gelatine prints are well known to be liable to fade, but negatives that have been *carefully* manipulated have hitherto been above suspicion. We have italicised the word "carefully" because we all know that negatives that have received but perfunctory treatment are likely to change with time; but that is scarcely probable to have been the case with Dr. Roberts's negatives, for it cannot be assumed that any point would be neglected in the production of such a valuable series for the object in view. This brings us to the question, Do gelatino-bromide negatives necessarily fade?

If they do, the matter is of importance to every photographer who has negatives that are valuable now and likely to continue to be so in the future. Of course, in the star negatives the images of those of the fainter orbs are very faint indeed, so also are the most delicate tones of a good portrait or landscape negative, and, if the fainter portions of the image are prone to fade away, after a few years the negative will necessarily become harder and less full of delicate tones. Therefore the matter is of serious import, and it should receive the attention of chemists, with the view of increasing the stability of the negatives produced by the present almost universal gelatine process. In our own practice we have not detected any change in negatives that were made more than twenty years ago, which were carefully fixed in new solutions of hypo and thoroughly washed, then coated with collodion, and afterwards varnished with a hard spirit varnish, although they have been frequently printed from and no particular care has been bestowed upon their storage.

## "ANTHONY'S OF NEW YORK."

PROMPTED by the recent removal of the well-known stock house, Messrs. E. & H. T. Anthony & Co., of New York, to larger premises in that city, Mr. Henry Dietrich contributes to *Anthony's Magazine* for April a brief sketch of the history of the firm, which may have some interest for those of our readers who have been brought into business relations with that respected house, and for the far larger number who know it only by reputation—a deservedly high and respected one in the trade. Says Mr. Dietrich:—

"It is now thirty-one years ago (February 10, 1869) that we moved to 591, Broadway, from 501, Broadway, and Mr. Edward Anthony considered it at that time a good move as to locality, space, and business generally. 'Up town' was the cry. Times have changed again, progressive impulse still holds sway, the upward tendency still obtains, and, obedient to its dictates, we once again have moved up town.

"Well do I remember the day when I made my first entry at 501, Broadway. It was in September 1860, in answer to an advertisement I called, but was seriously in doubt whether I should go upstairs or not, seeing nothing at the entrance but a small show-case containing a few pictures and some bottles of collodion and varnish. The firm's name at that time was E. Anthony. I finally ventured upstairs, and great was my astonishment when I reached the upper floor to find it stocked with all kinds of photographic paraphernalia, to me a great mystery. I was engaged, and suggested making a written contract. Mr. Anthony, however, said in his quiet way, 'There is no necessity for it; we consider our position permanent.' He kept his word well in this as in all other matters.

"Pictures on albumen paper were then in their infancy, almost unknown to the general public, and the favourite picture was the so-called Ambrotype, a direct positive on purple glass, with black asphaltum varnish backing, put up in a case with mat, glass, and preserver. The sizes of pictures varied greatly, and included  $\frac{1}{16}$ ,  $\frac{1}{8}$ ,  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ ,  $1$ , which last size corresponds with our present  $6\frac{1}{2} \times 8\frac{1}{2}$ , and occasionally a larger size, which latter were greatly admired and much talked about. It took at this time from three to six glass-cutters, cutting from morning until night, to fill orders and keep up the supply, while three or four young ladies were constantly occupied in fitting the cases. And those cases! I have studied languages, algebra, mathematics, and even buried my youthful

head in trigonometry, but the Ambrotype cases beat them all. They were classified by letters—X, XX, XXX, CVX, RRX, KN hook, KN two hooks, TM snap—and each letter made in a variety of sizes. I was in utter despair when I started, but finally succeeded in becoming thoroughly acquainted with them.

"The frame department, which in later years occupied a whole floor, was at this time just started. A small closet with glass door contained from one to two dozen  $6\frac{1}{2} \times 8\frac{1}{2}$  and  $8 \times 10$  oval glass frames, which constituted the entire stock. It was about this time that the first stereoscope (opera-glass style) made its appearance from Paris. Thus the winter passed, and with the spring of 1861 came the declaration of war. The first shot was fired at Fort Sumter, and New York was in fever heat. The big meeting on Union Square will never be forgotten by those who witnessed it, and few men on that day cared to be seen on the street without a Union badge. No desk, no counting-room, no work-bench was without a flag decoration, and when Mr. Edward Anthony came back to the store from down town at noon-time of that day his silk hat was pierced and decorated by two pretty good-sized United States flags.

"After three years' leave of absence from the store and service in the army I returned to my old quarters. What a change had taken place in that period. Ambrotypes on the decrease, slowly, but surely; prints on albumen paper on the increase, their reputation rising day by day. American manufacturers of albumen paper had already started. On one of the upper floors we manufactured our own albumen paper. *Cartes-de-visite* were at that time the principal style. Stereoscopic pictures and stereoscopes (Professor Towler had in the mean time invented the sliding stereoscope) commenced to be fashionable. A special clerk had to attend to the orders for stereoscopes, which were sold by the gross. The firm's name had now changed to E. & H. T. Anthony, Mr. Edward Anthony having taken his brother, Henry T., into the firm as a partner. Mr. Henry T. Anthony superintended the technical, and, to a large degree, the chemical, part of the business, and was always ready and willing to give advice to the numerous operators, printers, and retouchers from the different galleries, who came to look upon him as the best friend they had.

"Anthony's collodion and varnish had now gained a world-wide reputation, and orders for it by the barrel were frequently received. Albums (in the beginning with openings for *cartes-de-visite* only) had made a favourable entry into the market, and were manufactured in large quantities, and the firm had rented a whole floor in the old New Haven Railroad Building, corner of Franklin and White-streets, where fifty girls and many workmen were employed in their manufacture. Another factory for the manufacture of albumen paper was opened at 65, Broadway. The business had now steadily increased to such an extent that the members of the firm were obliged to look for another partner to relieve them somewhat of the almost too heavy burden of their work, and Mr. W. H. Badeau, a trusted *employé*, was taken into the firm. The firm's name was changed at this time to E. and H. T. Anthony & Company. After a lapse of several years Mr. Badeau severed his connexion with the house, and Mr. V. M. Wilcox, another *employé*, took his place. The number of *employés* had now almost doubled, and the business had increased to many times its original volume.

## PROCESS ENGRAVING.

[Abstract of paper read at the Society of Arts and reprinted from its *Journal*.]

My first experience in producing illustrations was in assisting my father in photographing drawings on wood. I remember working for some of the best and leading wood-engravers of that period. My father invented a process for this purpose, which was afterwards adopted by the late John Swain. I have a vivid recollection of a very simple process worked by my father, which he kept secret, it being too simple to patent. He took a photograph, *i.e.*, an albumenised silver print, and pasted the photo face downwards on to the plain boxwood. For pasting he used some special glue of his own; when dry, he merely rubbed the paper away with his finger by moistening it. The paper very easily coming away, the photograph was left on the wood. My father discovered this quite by accident: an old photograph having stuck on a wood block, he started rubbing the paper quite absent-mindedly, when he perceived that the albumenised film of the silver print remained on the wood.

The final step which brings us to the present time, though not by any means, I am sure, to the end of the chapter, is the superseding of the wood-engraver by the mechanical or process engraver.

Photo-engraving, which is in reality process, is older than photography, since Niépce in 1814 commenced experiments, and in 1824 (if not earlier) actually produced proofs from photo-etched plates. His process was just to purify bitumen and then to coat a silver or pewter plate with it, exposing to light under an engraving or in the camera. The bitumen, where it became insoluble under the action of light, resisted the solvent

action of oil of lavender which was afterwards applied, so that a resist was produced and the plate was afterwards etched. The only records of Niépce's early experiments are furnished by some correspondence between Niépce and Daguerre.

Eventually Niépce entered into partnership with Daguerre and endeavoured to form a company to work their new invention, but without success—capitalists looked upon it as much too risky a venture. Niépce's desire and object when the first glimpse of photography appeared was to find a substitute for engraving. Letters written by Isidore Niépce at that period tend to show that from Niépce we obtained the germ and idea of process engraving.

The first published results of the Daguerreotype process proved that the nitric acid attacked the silver forming the dark part of the image, whilst it had no action on the mercury in the light part. After a few minutes biting the plate was washed, inked up, and proof pulled, but the results were very imperfect, and the plates did not stand printing owing to the softness of the silver.

Fox Talbot's first process was patented in 1852. This process was called phototypy. Up to this time it may be said to have been the most important process of the day. It is curious to note that Talbot, when copying what we now term a half-tone subject, used what he called a photographic veil over the plate. This veil was composed of two folds of thin black gauze; the method was imperfect, but it only shows that, at this time, Talbot was endeavouring to make half-tone blocks by means of breaking up the tones by the aid of a gauze or screen. In fact, he actually suggested the use of those glass plates, ruled with fine lines or covered with opaque dots, which are the basis of half-tone work. But, in referring to this process, it must be borne in mind that it was really a species of photogravure, and was not a process for producing type blocks for printing in magazines or newspapers—his plates had to be printed in a copper-plate press—the plates he made were, however, the first of their kind and very excellent. Talbot may well claim to be the English inventor of photogravure.

Carl Klic, of Vienna, is said to have improved upon Talbot's methods considerably. The idea of a lined screen was followed by Berchtold, in France, and C. J. Burnett, in England, in 1857 or 1858. In 1861 Baron F. W. von Egloffstein experimented with ruled screens in Philadelphia, and, in 1865, E. and J. Bullock patented and worked for fifteen years a process in which the grain was produced by a line netting of cross lines.

#### AUTOMATIC ENGRAVING.

The earliest attempts in the direction of automatic engraving were based on the principle of biting away the metal with acids. The great difficulty encountered was to ensure that the action of the acids should be exercised only in the direction required. Nitric acid had a habit of etching away the delicate parts, and even at the present day it is not unusual for this to occur. Many experiments were made, but for a long time the results were failures. It was left to a Frenchman, M. Gillot, to perfect the etching of the line block. I have just received an interesting letter from M. Gillot, jun., who states:—

"My father, who was a lithographic artist, took over a small lithographic business whose speciality was printing small labels. The lithographic method not being quick enough, it struck him to bite or etch the stone deeper, to enable him to print typographically instead of lithographically. Whilst experimenting on this, the idea occurred to him to use metal; he therefore experimented, and successfully succeeded in etching on zinc. This took place about 1848, but the printers were very much against the new method. After six years' patient work he submitted his invention to the Society for the Encouragement of National Industries. He called his process "Gravure Panconographique," a name still in use at Messrs. Gillot's at the present day."

Gillot encountered, as is usual, an amount of professional opposition—the French engravers were averse to helping the new method by any encouragement, dreading that the new process would supersede their own art. Publishers also spoke disparagingly of it as "The Process," and, in consequence of the disrespect with which the term was then associated, M. Gillot adopted the title of Gillotage for his work. It was M. Phillipon, of the *Journal Amusant*, who came first to his assistance, and, foreseeing the value of the process, gave up all wood-engraving and used Gillot blocks instead. M. Gillot was greatly assisted by his wife, who was a good artist herself. M. Gillot died in 1872, after having invented and perfected one of the most important inventions of the century, and founding the first and most important process establishment in Paris.

The earliest public recognition of its value was at the Exhibition of 1855, when the distinction of Honourable Mention was conferred upon the process.

My father had for many years been experimenting with photography on zinc, but it was not until after many years of labour that he succeeded in perfecting his process sufficiently to practically work it, and then only by adopting the Gillot method of etching. It may be interesting to mention that the first etcher who came from Gillot, of Paris, to introduce the method into England, in 1876, is still working for me.

It is curious to note that, although forty years have passed since Gillot invented line zinc etching, the method has not much improved. His

method was perfect, and the results obtained then were equal to those of the present day. (I am referring to pen-and-ink or line work.)

It must not be forgotten that all the early plates were either drawn on zinc, or on transfer paper, or lithographic stones, and then transferred to zinc and etched. It was not till later that the method of photographing direct on to the zinc was adopted. It was my father who at that time was endeavouring to photograph direct on to zinc, and his process, by those who were capable of judging, was considered the finest ever introduced. Mr. Comyns Carr, in a lecture before this Society, referred to it specially and described it; but a certain amount of patience was required to get any decent results. In the early days I had to do all the practical work, to take the negative, print it, and prepare it ready for etching. The difficulty was in obtaining the result on zinc—the only methods then in use were either by albumen or bitumen, neither of them perfect if you desired to obtain delicate results. Another method, employed previously to this, was to prepare albumenised sensitised paper, to print the same and ink it up, and then to treat the print as a transfer by transferring it on to the zinc in the same manner as a lithograph. My father's process was in the form of a sensitised carbon paper, which was printed and then squeegeed without pressure on the zinc, thereby retaining all the fine lines, and not smashing them, as was the case with the earlier transfer method. After the carbon was developed, the plate had to be carefully etched and then rolled up. It was here that the difficulty arose. A certain knack was required to ink the plate, owing to the plate "tinting," i.e., the white parts inking up as well as the picture, and to such an extent that one could not remove the blemish without damaging the work. I found a solution (nut gall) which helped me greatly in getting rid of this tint; but, although I tried to teach a good many, I only came across one man who had the knack of doing it. This process was worked for some years, until, with the advent of improvements and the increased output of blocks, I dropped it.

When Klic was last in England (about the year 1883) I assisted him in experimenting in the reproduction of half-tone engraving. Meisenbach was just then coming to the front, and Klic had some scheme of making cross-line screens. His idea was to make these screens photographically by photographing a single lined negative both ways, and reflecting the light through the lined negative in such a manner as to secure a sort of halation, or softness, between the points that the lines cross. Dry plates were used at that time, and, instead of using daylight or electric light, a very strong bull's-eye lantern and a rapid dry plate were used. Although a lot of experiments were made, nothing came of them. I am afraid I had not much faith in the process, and was not really enthusiastic over it. My father and myself experimented on making different screens. We had one idea of making a sort of chess-board screen consisting of black and white squares, and for this purpose we got an artist to make the board, and for six months he worked on this wretched inartistic mechanical work, nearly blinding himself, as the board had to be reduced so very much, the results were too small to be practically useful.

At that time wire gauze was used, also lace and silk. Some fine results were obtainable through the wire gauze, but the scientific principle and method of breaking up the dots had not been discovered. It was Mr. Ives who first went thoroughly into the matter, and whose researches and experiments have proved of great value to the trade. There have been a good many processes which would have proved useful had they been workable commercially, but, when an inventor brings you a new process and shows you the result, he does not tell you how long he has been preparing the specimens, and how long it has taken him to perfect the one he shows you—all he knows is that theoretically it can be done in, say, two days, not telling you that it took him perhaps a month to obtain the result he is showing you. My father had an idea of making half-tone reproductions without the aid of screen or grain, and certainly he did succeed in getting examples on stone which were simply marvellous. Had the process been workable, it would have revolutionised lithography, for he obtained delicate half-tones from the stone. His method was briefly as follows: He prepared a carbon paper upon which the picture was exposed under a negative, the paper was transferred to the stone, not with pressure, but simply by squeegeeing it. After the print was soaked, the paper was taken off, the carbon was left on the stone and developed, we then had a beautiful photographic print on the stone. This was dried and then slightly etched with nitric acid, after which the carbon picture was washed off and the stone was treated in the ordinary way—that is, inked up—and the effect of the process was that all the half-tones were retained. Messrs. Maclure & Macdonald had one of these stones, and tried it on their machine, and had no difficulty in printing from it, as the more they printed the better the picture became, because, owing to the porous nature of the stone and the action of the carbon tissue, the picture had sunk right into it. But it was impossible to work this process; it was the most erratic process ever invented. The specimens I referred to took about twelve months to prepare—that is to say, about forty had to be made before we got a good one. But it was the first and only process ever invented that enabled a pure half-tone to be printed direct from the stone. The process was a secret one, and my father and I were the only ones ever to work it. There have been various processes, such as heliotype, phototype, collotype, &c., but all these were printed from gelatine films or moulds.

There was a very curious process at this period which I saw worked, and that was to get a reproduction either enlarged or reduced from existing pictures on stone or wood. You had a large piece of smooth indiarubber stretched in a frame, which you contracted or stretched, according to whether you wanted it reduced or enlarged, and some very good results were shown. The process was amusing, inasmuch as you could distort a picture to any extent you liked, and with portraits you could get the most comical effects. Those comical indiarubber faces that children play with, or one of these distorted mirrors, will give you some idea of its comicality.

Pretsch blocks were really the first half-tone grain blocks. Pretsch discovered that the bichromated gelatine film possessed the property of reticulating itself with minute vermicular markings, when it is wetted after the usual exposure to light. This is specially noted when the film has been rapidly dried, and when it contains a portion of chloride of calcium; the reticulation varies according to the heat at which it is dried, according to the exposure, and to the light and shadows of the picture. The one fault with this process is that the grain may become unduly prominent and so destroy all fine detail.

The Pretsch process was developed by Swan, who obtained the gelatine relief with carbon tissue, thus avoiding irregular swelling and granulation of the gelatine, and afterwards by Geymet, Roussillon, and Dawson among others. General Waterhouse in 1880 used fine sand sifted in the gelatine relief on a copper plate while it is still soft.

Messrs. Sprague's process must be mentioned as being based on the reticulated gelatine grain principle. They have used this process very successfully in connexion with supplements for various papers and insets, most of their reproductions being printed from stone, the type-high blocks not being so successful as those results from stone. They call their method the Ink Photo Process.

Although several attempts have been made to introduce grained half-toned blocks, the result has not been successful, because they lack depth and have not the softness of the ordinary half-tone block. The finest results, so far, have been done in France, by Goupil, but then they have had the advantage of exceptional printing.

Amongst other processes was one called the silver-line process. It is a very pretty process, and a Frenchman I knew in the eighties induced several publishers, to their loss, to work it. One well-known publisher in those days, who dabbled in process, always considered his downfall due to the money he had sunk in endeavouring to bring this process to a successful commercial issue. The silver-line process was to coat a zinc plate with bitumen, expose it under a positive, so that, after developing, the plate was etched slightly, and a metallic alloy capable of resisting the acid deposited on the lines. The process, owing to its pretty appearance, charmed a good many, but it also proved costly.

Another inventor tried to make use of glass as a substitute for zinc in the preparation of surface blocks by the etching method. Hydrofluoric acid instead of nitric acid was used. It was proposed to use it for large pictures for illustrated newspapers, and to some extent this was carried out in a paper published in Australia, but I cannot find any facts relating to this. I only mention it as a curious experiment. In endeavouring to give a brief report of process engraving I find the records on process are really very meagre. This is owing to the fact that an endeavour was made to keep most of the processes secret. Although a good many processes have since come into existence, the differences between many of them are very slight, many being merely variations on some small point.

Another process in use in the early days was the gelatine process. This consists in printing the picture on a sensitised film of gelatine; if this gelatine is soaked in water, the parts representing the whites swell, and the darks, really the picture, remain as they were, as the light has rendered them insensible to water; from this swelled gelatine mould a cast is made and electrotyped. The process is used only, I believe, by one firm, Messrs. Dawson. Some of the results obtained are very good, but I am afraid nowadays the process is looked upon as old-fashioned.

Messrs. Dawson also worked another process, by which some very excellent results have been made, and it has held the field for a considerable time for special classes of bookwork, but, of course, for rapid periodical work it was not suitable. They called this process typographic etching. This process differs from all others. It has less of a mechanical nature than the modern process, and it depends upon the skill of the draughtsman who works it. The design is drawn with an etching needle on a metal plate covered with wax; the metal is therefore bared at the lines, which are separated by ridges and spaces of wax. For outline work the process is admirable; elaborate drawings can also be made, and they are best made by the artist himself who is familiar with the etching needle, but artists are slow to adopt any little training which would have made them proficient in sketching on the prepared surface. In referring to this excellent process, one is reminded of the process called the Glyphographic process, invented by Edward Palmer about 1842. There is no special interest attached to Palmer's process beyond an earnest and unsuccessful attempt to supersede wood-engraving. The process never came into practical use. It ruined its inventor, who gave up a good business as an optician and found himself in the Bankruptcy Court, not an unusual proceeding for inventors who have tried to bring process

engraving to a successful issue. Your true inventor seems essentially drawn towards the Bankruptcy Court, and has hardly ever derived any benefits from his inventions; it has generally been some smart business man who has taken up an old idea, improved it, and gained the credit and kudos which really never belonged to him.

Amongst the processes which were a good deal advertised, but came to nothing, was the Sutton process. A syndicate was formed to run this process, and a demonstration, including a luncheon, took place for the benefit of the press, who, not having a practical knowledge of process work in general, gave glowing accounts of it. It was demonstrated that blocks could be made in less than half an hour, but what was obtained was only a gelatine dry plate cast from which an electro had to be made. The results were by no means good, and the syndicate, after working it for some time, disappeared quietly, in the usual manner of unpractical syndicates.

Mr. Woodbury also attempted to make type blocks from his reliefs. His process—Woodburytype—although in much demand at one time was only adapted for supplements and insets, as the prints were from intaglio gelatine moulds and not adapted for type work. Mr. Woodbury made his block by breaking up a transfer taken from his mould and transferring it on to zinc to be etched.

Mr. Ives, in 1878, patented a process. His plan was to take an inked Woodbury relief and to press it against a grained or embossed paper, the picture on the grained paper was then copied in the camera or transferred to zinc direct. In another improvement of his he took a cast in plaster from the Woodburytype; on the plaster cast he printed lines or stipples by means of an indiarubber stamp. By flowing the plaster over with collodion he was able to transfer the ink to the resetting film, and after slipping the film off he made a print from it on the plate.

Some thirty-four years ago the Graphotype process was in use for a short time and, although to a certain degree ingenious and original, it was not found sufficiently practical. Briefly the process was as follows:—The drawing was made in an ink consisting of glue and lampblack upon a block prepared by compressing precipitated chalk into a solid cake. When the drawing was completed, the whites between the lines were brushed out, the block was treated with silicate of potash to harden it, and electrotyped.

In commenting upon what we may call the chalk block period, my father, August Henschel, worked a similar process, with the difference that he used photography in connexion with it. His was a mechanical process—the drawing, which had to be in line, was photographed on to cardboard, which was coated with a thick solution of caseine, plaster, and other ingredients sensitised with bichromate; this was placed between a roller to take off any unevenness, and then exposed under the negative. It was then developed, and the parts unexposed were washed away, leaving the picture in relief—this was dried, an electrotype was taken, and the large white spaces were deepened by the aid of an engraver. Now, this process was a pure mechanical process, as it gave an absolute facsimile result of the artist's own drawing, which the other chalk process did not give, and some very good results were obtained, but at that period publishers were not so sympathetic in adopting any new process.

#### PAST AND PRESENT.

It is interesting to look back upon those early days and compare our present methods. I can well remember a time when, if a block was turned out in a week, it was thought something wonderful; afterwards, when I succeeded in turning out a block in twenty-four hours, it was specially noticed in the Press, and, when a double-page pencil drawing by Melton Prior for the *Illustrated London News* was reproduced in nine hours, the fact was regarded as marvellous. Nowadays half-tone blocks are wanted in two to four hours, and line blocks in two hours. It is nothing unusual to have to deliver a double-page block from a wash drawing in six hours, and in some cases we are expected to make the blocks in less than that. There is no doubt we are arriving at a time when it will be almost possible to supply blocks whilst you wait. From an artistic point of view this is to be deplored, but we live in an age of nervous rush, and one must go the pace or be left behind; it is the pace that kills the workman as well as his art, for certainly no one can put his best work into a block when only minutes are allowed for a difficult process requiring hours. I can call to mind in 1879 having some very difficult old engravings to reproduce; they were for a book on *Marie Antoinette*, by Lord Ronald Gower, and it took the best part of a year to do what now could be done in a week. It is not a question of getting it right there and then; oh, no, it was a case of doing it over and over again! You can imagine the monotony of redoing the same picture until it was perfect. A portrait of Cetywayo which I was doing then is so vividly impressed upon my memory that to this day I seem to see every line in it. I had to do that wretched portrait about fifty times before I could get it right. It is no wonder, then, that the Company which worked this process in its early days came to an untimely end. (The title of the Company, by the way, was The Direct Photo, Litho, and Metallo Gravo Printing Company, Limited.) Another thing to be considered was that in those days every one was prejudiced against process or zincography, as it was then called; wood-engravers were up in arms against it, printers said it could not be printed—(printers always do

ay that). I have found that printers are really the most conservative of conservatives, and will not touch anything new unless forced to do so. Zincos were then not so deeply etched, and required more delicate handling than woodcut, and when Meisenbach blocks came into existence the printers had, much against the grain, to change their method of printing. Soft backing and heavy blankets and rough paper would not do, and the early results of Meisenbach blocks were really heart-rending; but, luckily, the proprietors of the *Graphic*, the *Illustrated London News*, and *Lady's Pictorial* saw the value of this process, and assisted in improving the printing, and printing has steadily gone on improving.

Being on the subject of printing, I may just refer to the process blocks made for the *Daily Chronicle* some five years ago. It was due to Mr. J. Pennell's energy and enthusiasm that the *Daily Chronicle* went in so largely and extensively for line drawings, and all by the best artists of the day. The results were exceptionally good, and a good many wondered how it was that they printed so well, keeping all the delicate lines and quality. The fact was that they had adopted a method I suggested, namely, that of using original blocks for every one of their machines, and bending and fixing them on the cylinder. There was a little prejudice in adopting this method at first, but when it was tried the results were perfect and have never been equalled. Unfortunately, time not always permitting his for their occasional illustrations now, they stereotype them, and the result is nothing like so good.

One always hears that they hurry along things in America. Well, from my own experience, blocks have to be produced in much shorter time here than in America; for instance, as a record of quickness, I may mention that over thirty square feet of line blocks had to be, and were, delivered within nine hours, and on that same day my firm had to turn out in all seventy square feet of blocks in twenty-four hours, and, in spite of this rush, the blocks were all perfect. The blocks included those large page illustrations that appear in the *Daily Chronicle*. These page illustrations were, by the way, the largest zinc blocks that had ever appeared in any newspaper. To realise this quantity of work, you must consider how many wood-engravers would have been required, and how long it would have taken them to engrave seventy square feet of blocks.

Meisenbach must be credited as the inventor and pioneer of the half-tone process. He patented this process in 1882. The effect was that wash drawings, oil paintings, water-colour drawings, in fact, anything that could be photographed, could be reproduced direct without having recourse to redrawing it in pen and ink or engraving on wood. It is this process which has killed wood-engraving all over the world. The important feature of the process was the use of a finely ruled glass screen, which was interposed in the camera between the original and the negative, the effect being to break up all the gradations and half-tones into different sized blacks and cross lines. In the early days Meisenbach used single lines for these, and by shifting the same in the camera obtained these dots and cross lines.

Mr. Ives really improved upon the Meisenbach method, for, whereas Meisenbach used a single line screen, and withdrew the line screen during exposure, and replaced it instantly in a transverse position, producing thereby a cross-line effect, Ives obviated this turning operation by putting two of his machine-ruled screens together, face to face, and sealing them. The diamond-ruled screen of to-day is practically the same as Ives's early invention, although Max Levy improved upon it by producing it on his improved engraving machine.

Many other experimenters stumbled over similar experimental results, but it was not until Dr. Eder wrote his treatise on the "Formation of the Dot in Half-tone," and was followed by contributions from Count Turatti, E. Deville, Max Levy, Ives, and others, that the theory and principle of what Ives called the optical V were made generally public.

The enamel process, which was discovered by an American named Purbeck, greatly assisted in improving process work.

Amongst the processes for the purpose of converting photographs into half-tone blocks may be mentioned the Luxotype process of Brown, Barnes, and Bell, in which no screen was used, but the part to be copied was embossed by the aid of a wire gauze and plate by rolling or pressure, and this embossed print was strongly side-lighted. The results were not satisfactory—whether the process was ever worked commercially with success I don't know.

Another method of making a grained negative without a screen was suggested by Messrs. Krantz and Zeisler. An image of the subject was projected lantern fashion on a white screen, ruled with black lines, and the composite subject photographed. In using a gauze or ordinary line screen the tendency was to get a monotonous flatness, and the effect had to be obtained by what is called fine etching—a method by which the original artistic drawing was often etched away beyond recognition, for, since the detail of the original had to be put in, everything depended upon the artistic skill of the etcher. It was owing to this amount of fine etching required and the flat result obtained that process blocks in the early days got such a bad reputation from artists.

HAND ENGRAVING.

This is a point upon which a good many people differ, but there is no doubt that a good engraver may considerably improve a block. Unfortunately, however, publishers want their blocks done at so much a square inch, and will not pay for extra work. If only editors and

publishers would realise that it would pay to spend a little more money on their engravings. I do not say anything about weekly periodicals, because there it is a question of time; but it is gratifying to see that the *Graphic*, whenever possible, spend a certain time in hand engraving the blocks. Wood-engravers are now turning their attention to process work, and with their artistic skill ought to be able to improve and work up process blocks. To what extent this can be done one has only to scan the American periodicals. But, if a good wood-engraver has not had the proper training for engraving on a process block, then he had better leave it alone. To engrave a process block well requires proper training. The point to consider is whether the older wood engravers will take the trouble to learn it, or whether a new school of engravers on process blocks will arise.

The *Century Magazine* shows the finest examples of this class of work, and what I am glad to see is that they acknowledge the wood-engraver's name under each block.

It was about 1883—the advent of the Meisenbach process—that things got a little forwarder. Meisenbach fairly revolutionised process engraving. It was the advent of the American screen and the beautiful results obtained in America that caused a rush of process firms to be started in England. The firm to show the lead in using the Levy screens and producing the finest work at the time was Andre & Sleigh, and, certainly, for some years they held a good lead, but, with the screens and improvements from America becoming universally known, good work was done by several firms. Meisenbachs gave up their old screen and took up the Levy screen as well, so that after a time it became a survival of the fittest, and it is curious to note that, in spite of competition, the old firms such as Meisenbach, Swain, and Hentschel, all established since 1887, have held the lead for turning out good work.

Amongst firms who must be mentioned as doing fine work are the Swan Engraving Company, Ward & Co. (who both had the advantage of Mr. Ives's personal experience), the Art Reproduction Company, whose workmen first came from Angerer & Gœssli, the well-known Vienna firm. It may be interesting at this point to give you some idea of the progress of process, and the decline of wood engraving as shown in the London Directory:—

	1876	1879	1884	1887	1895	1900
Wood-engraving.....	—	130	162	158	131	80
Process.....	1	2	6	14	53	56

The first process firm in England was Leitch & Co., and the firm was started by the proprietors of Kelly directories; the business was eventually taken over by the late John Swain, the wood-engraver who foresaw the future of process. The second firm was Cattell & Co., which consisted of some of the original employes of Leitch & Co.

Out of the fourteen firms in existence in 1887 there are only five at the present moment existing, and out of the fifty-three firms who were doing business in 1895 twenty-two have gracefully retired. It is interesting to view the figures and notice the increase of process engraving since 1879 to 1900; but, although there was a great rush between 1887–1895 to enter and swell the ranks of process men, the last few years has shown a steady decline. Competition and cutting prices has been the ruin of those firms who rushed into business on insufficient capital and with little experience.

Wood-engraving has not been able to compete against the rapid strides process has made. Mechanical processes, which have been the outcome of photography, have educated the public eye to a more delicate, more minute style of work; the public taste has been influenced by photography; the simple outlines which were once accepted as satisfactory now no longer suffice, and it is, perhaps, unfortunate, from an artistic point of view, that the public have taken so much to photographs, to the detriment of the artist, for, although photography is excellent, it could be made so much more artistic in conjunction with an artist using his artistic feeling to embellish and improve the picture.

The precise style of illustration that may be fashionable at any time will be partly a matter of taste, partly dependent on the means at the command of the artist and the process in vogue. At the present day the artist has not to restrict himself to the extent he did in the early days as to how he should draw for process. My own feeling in the matter is that artists should be allowed to draw and use what material they like; it is the business of the engraver to invent a process which will reproduce the artistic effect of the artist. The rapid strides that process, and especially half-tone process, has made enables us to reproduce any drawing, no matter how drawn, whether in wash, pencil, or any other material. When process first came into use, every artist had to draw only in line or grain; no half-tint or tints were permissible, and he had to use black ink or brown ink and white paper. There is no doubt the restrictions placed upon artists by the photo-engraver seriously hampered the artist, and helped to render his drawing mechanical. Very few artists seem to grasp the idea of drawing with that crispness necessary for a line process block. How often have I been handed a drawing on yellow paper drawn in blue ink, and have been expected to obtain a satisfactory result; and how often the lines were drawn so faintly that it was necessary to force them up to make any block. What was the result? All the feeling was gone, and the process engraver was condemned as usual with, "What can you expect from a process block?"

But, after all that one may say against process—and a lot of hard things have been said about it, and especially by artists, who have forgotten that the very advent of process has been the means of creating more work—let us only consider for one moment whether so many illustrated periodicals, books, or newspapers could be published now had it not been for the aid process has given to the publishers in enabling them to place before the public what was an impossibility in the days of wood-engraving. Process is not perfect yet by any means, but its progress is by no means at an end, and one conspicuous advantage it has over wood-engraving is that the actual work of the artist is more faithfully reproduced than by the wood-engraver. You may retort, "Yes; but not so artistically, because your wood-engraver was an artist, and your process engraver is a machine." Suppose we grant this; but the process engraver, although a machine, endeavours to throw all the artistic skill possible into his work. If, owing to the rush of the present day, he cannot do this to every block, he should not be blamed for that, but the publisher, and especially the public, should be blamed, for all they seem to want is cheapness—cheapness and rapidity. If you offer a publisher better work, he often replies, "Oh, I know the work is much better, but the other is good enough for the public!"

The impetus process has given to illustrated journalism one can only realise after examining the illustrated periodicals for the last seventeen years; the progress has simply been marvellous, and the subject is so large and so interesting a one that it would take hours to enumerate or even give the briefest history of it. For instance, about 1883 there were only four sixpenny weekly papers, using about eighty blocks, nearly all wood-engravings; now there are about fourteen sixpenny papers using some 1000 process blocks every week.

PRINTING.

This is always a sore point; the process engraver always gets blamed for his block if the result is bad. "Oh, it's the block, the printing is all right." Although England has made rapid strides in its printing, it is still far behind America, and why this should be I cannot understand. Printers will not understand that a printing room should be kept as clean and as evenly heated as a studio—but what do we find? The machine room is generally somewhere in the basement, but that would not matter if the surroundings were kept as they should be, and an even temperature kept up; now, an even and warm temperature is one of the main secrets of good printing, and yet how little attention is given to it. The fact is the whole question of blocks, ink, printing, and paper, is not sufficiently studied together; one man orders the ink, one the paper, one sees to the printing, and another to the blocks, but there is rarely a capable practical person who will see that the co-operation is secured which is necessary toward getting the best result. It is a case of each one for his own department, instead of working together. England has good artists, can supply blocks superior to any abroad, and England should be in a position to compare favourably with America. Let the printers give their attention to this, and the day may come when America may learn something from England. Whatever credit the English illustrated press may claim for the progress it has made, I think process has had a good deal to do in furthering this success.

CARL HENTSCHEL.

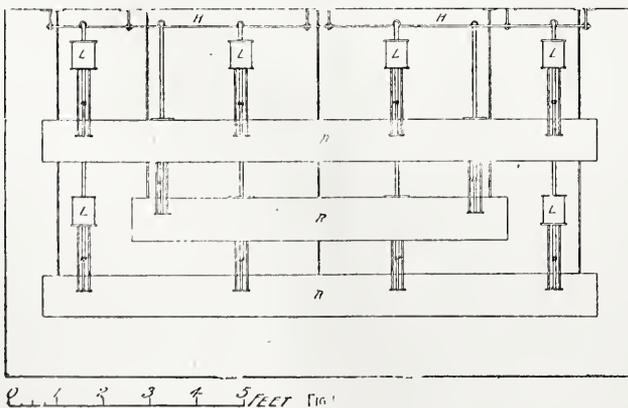

MORGAN'S ELECTRIC LIGHT APPARATUS.

[Patent No. 5514 of 1899.]

Fig. 1 is a front elevation, with the wooden or other framework removed, and showing the arrangement of the lamps of a ten-arc installation, with the movable reflectors and diffusers.

Fig. 2 is a section on end, showing the position or probable angle of lighting.

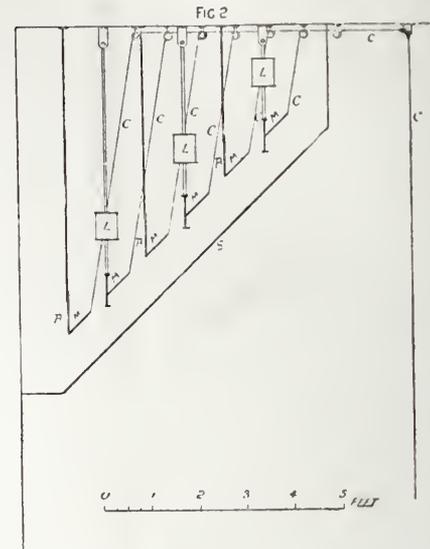

Fig. 3 is a plan, showing the arrangement and method of

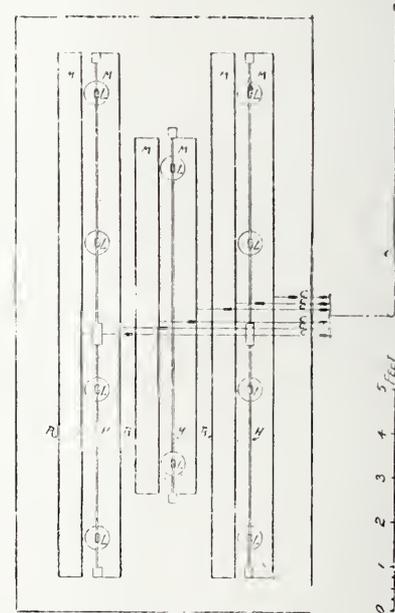

manipulating the cords for moving the reflectors and semi-transparent mediums.

Fig. 4 is an elevation, showing the wooden or other framework for holding in place the ground glass or other semi-transparent screen.

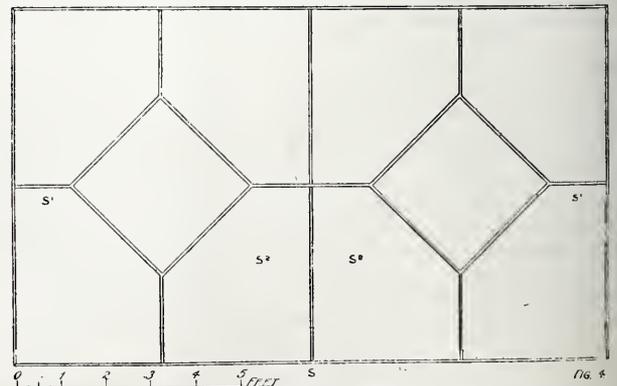

Fig. 1 is a rod or rods, from which the arc lamps [are suspended, L L are the arc lamps, which work in series or otherwise, R R are the movable reflectors, for assisting in diffusing the light from the arcs. L L (fig. 2) are the arc lamps, R R are the movable reflectors, M M are the

mediums of semi-transparent material for partially intercepting, breaking up, and diffusing the direct rays from the arc lamps. These latter are placed in such a position in front of the arcs that they may be used as interceptors and diffusers, or dropped by means of the cords, c

below the level of the arcs, when the operator is requiring a more concentrated light. s is a semi-transparent screen, placed at any desired angle, in front of the arrangement of arc lamps, reflectors, and diffusers, and assists in further breaking up, and distributing or diffusing,

the light coming from the arc lamps, as well as conceals from observation all the mechanical parts. H H (fig. 3) are the hangers for the arc lamps, L L are the arc lamps, R R are the reflectors, M M are the mediums

already referred to, and c shows the cords and arrangement of the same, whereby the mediums may be raised into, or lowered out of position as desired. Fig. 4 (s) is a screen, the framework of which may be made of wood, iron, or other material. It may be divided into any required number of spaces by astragals, s<sup>1</sup>, into which is fitted ground glass or other semi-transparent material. The screen, s, is placed in front of the arc lamps, reflectors, and diffusers as already described, s<sup>2</sup> s<sup>2</sup> are the movable panes for giving access to replace carbons, etc.

MORTON'S LANTERN SCREENS.

[Patent No. 9005 of 1899.]

The invention consists of having a sheet of cloth stretched tightly and securely held between two sheets of glass, mica, or other transparent material. If, however, it is desired, for economical or other reasons, the cloth may be fixed to a plate of glass and varnished.

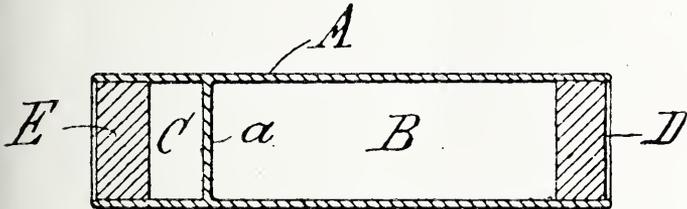

GRIFFIN'S SYSTEM OF PACKING PHOTOGRAPHIC CHEMICALS.

[Patent No. 12,337 of 1899.]

This relates to the method of storing or packing and dispensing measured quantities of chloride of gold in the shape of crystals or powder as a toning substance for photographic purposes, but is applicable also to other photographic chemicals used in minute quantities.

The quantity of gold chloride necessary for a toning bath is so small that the correct measurement by means of the ordinary appliances at the disposal of a retail dealer or photographer presents some difficulty.

In order to avoid this defect, Messrs. Griffin dilute a conveniently large quantity of the toning substance, preferably a multiple of that required for a toning bath, with a suitable quantity of chlorate of potash or other innocuous substance, the two ingredients being uniformly incorporated with each other, so that a given quantity of the mixture contains a known

and constant quantity of the toning substance, which mixture is then measured off and packed in doses suitable for a toning bath.

They also provide a special glass tube large enough to hold the quantity of photographic chemicals or mixtures necessary for a toning or a developing bath, the said tube being open at both ends and provided with a transverse partition between the same, or two tubes being joined and fixed together end to end, so as to form two compartments for the chemicals or powders which are to be used for a developing or toning bath, or other photographic bath, for instance, one compartment for chloride of gold and the other for alkali. Each compartment, after having been charged with the required quantity of chemical or mixture, is closed with a cork and hermetically sealed with wax or by other suitable means. In this manner the two chemicals are kept separate, and prevented from decomposition until required for use.

In the accompanying drawing A represents a glass tube embodying the invention. The tube has a glass partition, a, made integral with the tube, so as to divide it into two compartments, B and c, which are filled with the required chemicals or mixtures, and then closed with stoppers, D and E.

SCHMIEDER'S METHOD OF PRODUCING PHOTO-LITHOGRAPHIC PRINTING SURFACES.

[Patent No. 24,934 of 1899.]

The surface is first roughened or grained, preferably by means of very fine sand blast, in order to obtain a uniform fine grain; it is then carefully dusted and washed with a weak solution of nitric acid. The stone or plate is now warmed, and its surface coated with a weak solution of isinglass or other suitable gelatinous substance, which coating is allowed to dry in a temperature of about 100° F.

A solution consisting of

2000 weight units of	distilled water,
20	" " albumen, and
10	" " saccharic acid,

is thereupon applied to the coated surface by means of a fine brush, and allowed to dry.

Of two other solutions, one consisting of

1000 weight units of	distilled water,
50	" " chloride of zinc, and
2	" " chrysaniline,

the other consisting of

500 weight units of	distilled water,
15	" " bichromate of ammonium, and
7	" " bichromate of potassium,

equal quantities are mixed, and some of the mixture is poured over the prepared surface. The plate or stone is then placed in an upright position to allow the superfluous liquid to drain off.

When the film is thoroughly dry, the photographic negative is placed upon it and the exposure is made. With a good light of normal intensity, from ten to fifteen minutes will be required for completing the exposure.

The surface is then rolled with a specially prepared ink applied to a stiff roller. The said ink comprises the following ingredients: suitable proportions of lampblack, wax, Venetian turpentine, lithographic ink, and a few drops of oil of lavender are melted together, well mixed, and ground up with small quantities of finely powdered asphaltum, colophony, or resin, and pure beef fat.

The picture is thereupon developed by lightly passing over it a sponge saturated with water until the picture shows clearly, when the surface is carefully cleaned and covered with a coating of dissolved gum arabic for the purpose of protecting it from impurities and dust.

The gum arabic is subsequently washed off, and the ink is removed by the aid of turpentine, whereupon the surface is washed with dilute nitric acid in order to decompose the sensitive film. The surface is then, while being kept wet with a weak salt-water solution, rolled up with strong ink until the picture shows well, and any necessary retouching may now be performed in lithographic ink, or the like.

Finally the surface is subjected to the known acid treatment as usual with lithographic chalk drawings, and the stone or plate is then ready for the ordinary lithographic printing process.

It will be observed that the picture is now on the stone or metal surface itself, the sensitive film or coating having been destroyed by the decomposing process, as described, after having served to receive the impression of the photographic negative.

One stone or plate is sufficient for producing a perfect monotone in several depths of tone, gradually blending with each other, from negatives taken from nature, or from Indian ink, wash, or other drawings, etchings, and like originals, with all and every detail and gradation of light effects, while three, or at most four, stones or plates will be required for reproducing originals in colours.

THE NATIONAL PHOTOGRAPHIC EXHIBITION.

AMONGST the firms having stands at this Exhibition, which will be open from April 27 to May 5, are the following: Messrs. H. Purser, C. P. Goerz, Thornton-Pickard Manufacturing Company, Butcher & Son, Houghton & Son, Benetfink & Co., O. Sichel & Co., Wm. Tylar, J. J. Griffin & Sons, L. Gaumont & Co., Marion & Co., Moulton Brothers, J. F. Shew & Co., J. Mazars, Columbia Optical and Camera Company, Morgan & Kidd, Secco Films (Limited), The Tella Camera Company, Photochromoscope Syndicate, Wallis Brothers, The Warwick Trading Company, W. H. Assender & Co., Frederick Boehm, David Allan, Lancaster & Son, Harrington & Co., R. W. Thomas & Co., Seabrook Brothers, Prestwich Manufacturing Company, The Camera Construction Company, Thornton Film Company, Lambert Matthews, Bean & Ringwood, Illingworth & Co., Rogers & Webster.

Our Editorial Table.

MR. W. D. WELFORD, of 166, Romford-road, E., sends us a sample of his new "Professional" vignette. It is made throughout by photography, and consists of three films bound together. They are only bound at the edges, which allows of a slight separation of the films, thus adding to the softness of the result. As this vignette is being made entirely for professional photographers, Mr. Welford has decided only to supply it direct to the user. The prices are: 1/2-plate, 1s.; 1/3-plate, 1s. 6d.; whole-plate, 2s. 6d.; either oval or pear-shaped opening may be had.

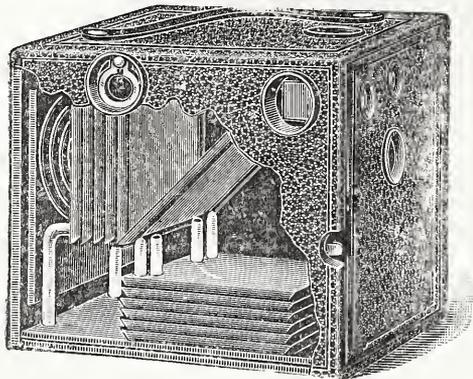

THE CYKO HAND CAMERAS.

Manufactured and sold by John J. Griffin & Sons, 20-26, Sardinia-street, Lincoln's Inn-fields, London, W.O.

IN a note we have received from them, Messrs. Griffin tell us that their idea in introducing these instruments is the following: There is still a very large public, viz., mechanics, clerks, and the lower middle class who

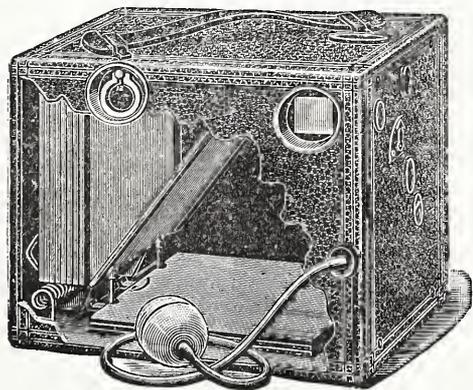

are practically untouched by photography. The Cyko cameras are introduced with a view of meeting the need of this public for a reliable and practical instrument, attractively finished, and capable of producing entirely satisfactory photographs at a price, within the reach of the class referred to.

These "forewords," if we may so term them, constrained us to look for a simple form of hand camera, easily worked, and sure and certain in its mechanical movements. In the expectation that we thus formed we were not disappointed. The Cyko is so simple that a child could successfully manipulate it after five minutes' instruction. The No. 4, which we tried, is covered with black leather, is light, portable, and

neat in appearance. It takes twelve sheaths, which easily fall into position, are securely held, and, when an exposure is made, a sheath is released and dropped by the simple action of turning a small nickel ring on the outside of the camera. We submitted this movement to repeated practical trial, and for a camera of the kind we could not expect a changing action to work with greater satisfaction and smoothness. The remaining features of the Cyko camera are thus described:—

The lens is an achromatic, combination meniscus. The shutter is very simple of construction. It is always set, requiring but a touch to make the exposure, automatically resetting itself without further effort. When one has made twelve exposures, one has only to open the camera at the

back and draw out the tray carrying the twelve plates, which are removed by merely lifting them off.

The bulb release prevents possible jarring of the camera, a register shows the number of exposed plates, the plate-holders are made of aluminium, the diaphragms permit three different openings, with a cut-off, which, when set, locks the shutter and prevents accidental exposures. Decidedly the Cyko should be popular among the class for whom it is intended; our trials of the instrument showed us that nothing could be simpler than the three easy movements of setting and releasing the shutter and changing the plate.

## Studio Gossip.

**PHOTOGRAPHIC ENTERTAINMENTS.**—We read that "book" and "flower" teas are giving place to the "photograph" entertainment. Each guest, instead of pinning on coat or dress decorations which represent the name of a book or flower, supplies a photograph of himself or herself taken when he or she was but a mere child. These photographs are spread out on a table, and the assembled guests endeavour to name the pictures. The hostess, of course, provides a prize for the person who identifies the largest number of photographs.

**A PHOTOGRAPHER SUED FOR WAGES.**—Albert Hemsall, photographic operator, of 23, Oliver-street, Nottingham, sued George Caldwell, photographer, of King-street, Nottingham, at the Nottingham Police Court, to recover the sum of *£17s. 6d.*, balance of wages due to him as a workman under contract for wages entered into by him with the defendant, his

employer. Mr. Clayton appeared for the plaintiff, and stated that the defendant was apparently in a good position, having a fairly large business in King-street, Nottingham, and lived in a large house at Lenton. The plaintiff stated that the defendant engaged him for seven weeks, as assistant operator, at a salary of *12s.* per week, and he had only paid him *2s. 6d.* The Bench made an order for the immediate payment of the amount in question.

**PHOTOGRAPHIC ATTRACTIONS AT THE PARIS EXPOSITION.**—The Optical Palace Section of the Paris Exposition comes in for unfavourable criticism at the hands of a correspondent, who says that, "on arriving at the Palais de l'Optique, one is ushered through the folds of a funeral-looking curtain into a pitch-dark room, a process which at first suggests initiation into the Eleusinian mysteries. Such a fate, however, does not await you. By dint of straining your eyes, you observe that a magic-lantern is being manoeuvred at the end of the room, and accordingly expect something interesting to ensue; but, when the white disc on the sheet becomes filled with horrible little black splotches, which an invisible lecturer explains to be the bacilli of tubercular plague, and, when the plague bacilli are followed by their *confrères* of typhoid fever, you do wisely to retreat in sadness. It is not necessary to visit the Paris Exhibition to gaze on disease germs. Whatever may be the future surprises which the Palais de l'Optique has in store for us, it cannot be said that its programme yet includes anything of a very original nature. There are some rather attractive projections of lunar landscapes, and others of submarine life; but, with these exceptions, the various side shows are somewhat insipid, and in one or two cases the reverse of decent. The much-talked-of telescope, which is said to bring the moon within the distance of a single metre, is the hit of the section, and, when this is at the disposal of visitors, the unfavourable impression created by the other exhibits may perhaps be counterbalanced."

**THE METHODS OF AMERICAN PROFESSIONALS.**—An American contemporary tells us that Sarony and Aime Dupont, of New York, were great portrait photographers because they understood the effect of distance. They knew how to pose subjects, so as to bring out the desirable elements and to conceal or repress those that are undesirable. Dupont once illustrated this to a class of amateurs in his Fifth-avenue studio. A stout and a skinny woman were placed side by side about fifteen feet from the camera, their right arms bared to the shoulder, the one looking like a match and the other like an Indian club by comparison. The first exposure was made to reproduce this contrast. In the second picture the women were placed face to face, or just enough so to bring the skinny arm nearest to the camera and the fat arm furthest from it. The difference in distance was the width of the women's bodies, say, about sixteen inches. The result was amazing to the amateurs, the skinny arm being enlarged and the fat one reduced, until both appeared to be perfectly proportioned. Sarony allowed a conceited fellow to pose himself. He threw out his chest, sprung his shoulders back until the blades touched, stiffened his neck, clinched his teeth, gave his eyes a cold stare, pinned his left arm to his body, and stuck his right thumb between the buttons of his Prince Albert coat, leaving the greater part of his rather small and well-shaped hand spread across his ample paunch. Unquestionably he presented an excellent figure to gaze upon in the original, but, when a single sample photograph was printed, his hand was as big as a ham. It was so much closer to the camera than his other features that it was enlarged out of all proportion. Sarony charged a big price for the negative, and refused to print any more pictures from it.

## News and Notes.

**THE South London Photographic Society** returned on Wednesday to their headquarters, after enjoying their Easter vacation, to hear Mr. E. A. Robins lecture on "Dekko." So ably did the lecturer manipulate the exposure and development that, together with the specimen prints exhibited, his audience were quite carried away with both paper and process.

**THE Thornton Film Company** have concluded arrangements with Mr. Walter D. Welford to demonstrate their new glassoline films before the photographic societies of London, the south of England, and as far north as Birmingham. Mr. Welford will be glad to hear from hon. secretaries desirous of arranging a date for this demonstration. His address is now Warwick Lodge, 163, Romford-road, London, E.

**SCHOLASTIC CINEMATOGRAPHY.**—The New York Public Schools will be represented at the Paris Exposition by an interesting exhibit. A number of moving pictures will be taken, showing the assembly and dismissal of pupils the school workshop in operation, the cooking class at work, kindergarten games, gymnasium scenes, and recess amusements. A hall has been set aside on the banks of the Seine to show the work.

In a lecture at University College, Sheffield, on the internal structure of metals, Professor T. O. Arnold said that the startling suggestion of Dr. Sorby that metals should be regarded as crystallised igneous rocks has now been proved to be true. Lantern slides were exhibited, showing the internal architecture of pure gold and copper, and also the effect that the introduction of small quantities of bismuth had upon these metals.

**THE Berlin Photographic Company** are publishing a set of photogravures of Burne-Jones's chief pictures. Following their Exhibition at the New Gallery, these were photographed at the "Grange," the residence, for so many years, of the famous artist. Only a limited edition of the work will be available, and each volume will bear the signature of Sir Philip Burne-Jones. He is to hand over all the royalties due to him to the Committee of the Burne-Jones Memorial Fund. Mr. Walter Crane has designed a cover for the album.

**THE NEWCASTLE CONVENTION.**—In our brief recapitulation last week of the attractive programme of papers and excursions for the Newcastle meeting of the Photographic Convention of the United Kingdom in July next, we omitted

April 27, 1900]

to mention that by the kind invitation of Mr. W. D. Cruddas, M.P. for Newcastle, the members will visit Haughton Castle, one of the thirteenth-century Border castles, which was formerly held by ancestors of Mr. A. C. Swinburne, the poet. The members will drive to Haughton from Hexham. †

MR. S. H. ASHLEY OAKES writes from the Liverpool School of Photography, 73a, Lime-street, Alwin Hall, Liverpool: "Many prominent amateurs and some professional photographers have urged me to place my thirty years' experience at their disposal, so I have just opened a school of photography at the above address. My terms will be moderate, and, as the success of the scheme depends entirely on the support I get, I should be glad of the co-operation of those (either ladies or gentlemen) who may desire my services in the art-science to which I have devoted the best years of my life."

THE West Surrey Photographic Society announces, in connexion with the six lectures on the art side of photography, entitled "The Technique of Picture-making," now in course of delivery by the President, Mr. J. T. Price, that a series of competitions has been arranged in connexion with the summer outings, by which the members hope to strengthen themselves in the out-of-door practice and use of photography, leaving the study of the technique of the negative to the winter sessions. The first lecture was on "The Diagonal Form of Composition in Pictures," and the first competition will be for a land or seascape. Combination printing will be allowed, the finished picture being alone the aim. The lessons to be learned are the sole objective of the series. The winning prints framed and a plate attached with particulars will remain in the Society's possession for one year and for the Exhibition, and will then be returned to the winner.

CHICHESTER CATHEDRAL presented a very photographic appearance at Easter, when some twenty members and friends of the Borough Polytechnic Photographic Society (including representatives from the South and West London societies) made their annual architectural excursion to that place. Every facility was readily afforded the party, both on Saturday and Monday, for photographing in any part of the Cathedral, and it goes without saying that some good work was accomplished. Several beginners, who had recently joined the Society had their first practical experience in interior photography under the friendly eye of the "older hand." Sociability and good fellowship prevailed throughout, and the inner man was admirably looked after by the genial proprietress of the Bedford Temperance Hotel, whose catering was highly praised by all. Mr. F. W. Gregg distinctly scored in his efforts to provide for the comfort of everybody.

THE FORTHCOMING ECLIPSE.—The Secretary of State for Foreign Affairs has received a despatch from Sir H. MacDonell, Her Majesty's Minister at Lisbon, containing information regarding the facilities which will be granted by the Portuguese Government to foreign astronomers visiting Portugal in May next for the purpose of viewing the total eclipse of the sun. Astronomers from abroad will be exempt from payment of the usual Customs duties on production at the Custom House, on arrival, of a certificate drawn up by the astronomical society to which they may belong. This certificate, however, should be legalised by the nearest Portuguese Consulate before starting. A Government notice has now been published in the Official Gazette, stating that the King has nominated a Royal Commission for the purpose of assisting in every way those who may come from abroad for scientific observations and for superintending astronomical arrangements generally.

THE Röntgen Society's Ordinary General Meeting will be held on Thursday, May 3, at 20, Hanover-square, at eight p.m. The following demonstrations will be given:—Professor F. R. Barrell, A new Method of Localisation, without plumb-lines or threads; Dr. Dellpratt Harris, On a form of Focus-tube designed to be Self-heating; Mr. Chisholm Williams, A new X-ray Film, Cristoid; Mr. Mackenzie Davidson will show, if possible, the Stereoscopic Fluoroscope. The following exhibits have been promised: Mr. Bowron, (a) A portable eight-inch spark coil, with improved break, (b) A semi-portable fifteen-inch spark coil, with improved break, (c) A milliampèrimeter, for measuring the secondary discharge of induction coils; Mr. J. H. Gardiner, Skiagrams of British reptiles, &c.; Mr. Isenthal, Jet mercury break, &c.; Dr. F. H. Low, A portable ten-inch coil, &c.; Messrs. Parsons and Eachus, A portable set, eight-inch; Mr. E. H. W. Shenton, Skiagrams—localiser couch; Mr. Wimshurst, Influence machine with vulcanite plates.

EXHIBITION OF MODERN ILLUSTRATION.—With reference to our recent paragraph on this subject, it is notified that the Board of Education have decided, at the suggestion of the Council of the Society of Arts, to hold during the autumn an Exhibition of Modern Illustration in the Victoria and Albert Museum, South Kensington. The Exhibition will consist of works in black-and-white intended for book, periodical, and newspaper illustrations, and will be confined solely to modern examples of typographical work executed since 1860. This limit covers the time during which photography has been available for reproductive purposes, and during which, consequently, the original drawings have been preserved and are available for exhibition. The Board will be assisted in the selection and arrangement of drawings by an influential Committee, with some additional members, which had already been organized by the Society of Arts. It is proposed that the Exhibition shall be opened about November 1, and remain open for four months. The drawings will have to be sent not later than October 1. Any further information will be furnished on application to the Secretary, Board of Education, South Kensington, S.W., to whom all communications on the subject should be addressed.

THE following is a list of the latest Warwick and Star film subjects, produced by the Warwick Trading Company, of 4 and 5, Warwick-court, W.C.: Return of the Heroes of Ladysmith; Arrival of H.M.S. *Powerful* Naval Brigade at Portsmouth, April 11, 1900; Portsmouth Preparing to Welcome the Heroes; Arrival of H.M.S. *Powerful* at Portsmouth; Sir George White's Return from Ladysmith; The Queen's Visit to Dublin.

THE KODAK COMPANY'S FREE LESSONS IN PHOTOGRAPHY.—Kodak (Limited) announce that they have arranged to give lessons as to choosing a camera, and as to methods of developing and printing. They believe this will prove attractive to ladies and gentlemen who may be thinking of taking up amateur photography, or who may wish to understand how photographs are produced. These lessons will be entirely free of charge, and will be given at the Oxford-street branch, 115, Oxford-street, W., where a reception-room has been specially arranged on the first floor, and an instructor will be in attendance. The arrangements will be as follows: 1. For those who only require one lesson, covering all the practical work in outline, instruction will be given from 11 to 12 and 1 to 2 o'clock each day. 2. Further, a connected series of five lessons, with illustrations and demonstrations in full detail, will be given every week, one lesson each day, commencing Monday and ending Friday. These lessons will be given from 3 to 4.30 p.m. daily, and will deal with all the practical processes. The subjects each day will be as follows: Monday, Introductory, Apparatus and its Use; Tuesday, Developing and Fixing, and Demonstrations of Different Methods of Developing Rollable Films; Wednesday, Printing and Toning Solio P.O.P.; Thursday, Printing Dekko and Bromide Paper; Friday, Enlarging and Lantern Slides.

THE metric system and its cost is the subject of a recent article in an American magazine, which points out that more than twenty years ago, in a report on the subject made to the Franklin Institute by Dr. Coleman Sellers and the late William P. Tatham, it was stated that, according to calculation, in a well-regulated machine-shop, thoroughly prepared for doing miscellaneous work, employing 250 workmen, the cost of a new outfit, adapted to new measures, would not be less than 30,000*l.*, or 120*l.* per man. If new weights and measures were to be adopted, so the report continued, all the scale beams in the country would have to be regraduated and readjusted, the thousands of tons of brass weights, the myriads of gallon, quart, and pint measures, and every measuring rule and rod of every description throughout the land, would have to be thrown aside, and others, which the common mind cannot estimate, substituted. The great mass of English technical literature would become almost useless, and would have to be translated from a language which we, and the nation we have most to do with, understand perfectly, into a new tongue which is strange to most of our people. As a question of cost, those who advocate this change consider it carefully. To the teacher, to the closet scholar, to the professional man, to those who never handled a rule or a measure, but use weights and measures only in calculation, it may seem merely a matter of legal enactment; but to the worker, the dealers in the market-places, to those who produce the wealth and prosperity of the land, the question is a most serious one. Altogether, the ultimate benefits of the change proposed would be of less value than the damages during the transition. Those who choose to do so can use the metric system, and no one can object to it; but for the Government to require its people to use that, and no other, would be an arbitrary measure, which they would be neither willing nor able to bear.

### ROYAL PHOTOGRAPHIC SOCIETY.

APRIL 24,—Technical Meeting,—Mr. T. Clapton in the chair.

#### A DEVELOPING MACHINE.

Mr. W. F. CRAWFORD exhibited the "Express" Developing Machine, an apparatus for developing twenty-four negatives at once. The exposed plates are held in radial grooves between two glass discs, revolving on a spindle in a developing trough, similar arrangements being provided for fixing and washing. The machine is also adapted for use with films, and for developing or toning prints, the films or prints being supported in celluloid carriers.

## Commercial Intelligence.

MESSRS. SPATZ, manufacturers of photographic lenses, of 19, Rue Thi-boumery, Paris, intimate that, since the establishment of the business, twelve years ago, more than 100,000 lenses have left their works.

PHOTOGRAPHIC SURVEYING.

Mr. BRIDGES LEE, M.A., read a paper on "The Latest Developments of Metro-photography," in the course of which he explained the method of surveying by means of his photo-theodolite, and illustrated the results obtained by it. Metro-photography has been defined by Mr. Bridges Lee as "that branch of technical applied science which is concerned with the determination of the forms and dimensions of objects from photographic pictures of those objects." By means of photographs taken from the roof of the Grand Hotel, in Northumberland-avenue, he showed how the exact position, dimensions, height, &c., of buildings or objects could be exactly determined and measured, the general idea of the instrument being to secure accurate and, as far as possible, automatic records on the faces of photographs of all, or nearly all, information which might be necessary for their correct interpretation for map-making purposes. The photo-theodolite is so designed and arranged that, whenever a photograph is taken (the apparatus having been first carefully levelled), there will be recorded on the negative accurate traces of the principal plane, the horizon plane of the instrument, the magnetic bearing of the principal plane, the principal point of the perspective, and a true scale of angular distances right and left of the principal plane. It has been extensively used in Canada and in North and South America, large tracts of country having been mapped by its aid, and it is in use to some extent in several Continental countries, particularly in Germany and Spain. A light-filter of chromium green glass is employed in taking the negatives, this having been found to give better results for distant views than the orange glass commonly used with surveying cameras.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 19.—Mr. Philip Everitt in the chair. Mr. A. HADDON reported the result of his experiments upon the piece of glass shown recently by Mr. Thomas. Briefly, a piece of glass, supposed to be new, used for glazing a greenhouse, was found to develop in the space of eighteen months a strong image—the portrait of a man. Mr. Haddon failed to obtain evidence of either silver or mercury. He had come to the conclusion that, accepting the conclusive evidence that the glass at one time had been a photographic negative, the developer or something else had at the outset induced an incipient decomposition of the glass, and that exposure for a long time in the greenhouse to moisture and carbonic acid had continued the disintegration of the glass to the extent shown, the action being greatest where there was most silver in the original deposit. The distinct grey tint of the image was the silver. The weathering action of glass was, as a rule, due in the same way to the chemical action of moisture and carbonic acid, and not physical action.

Mr. THOMAS E. FRESHWATER gave a short chat on a branch of projection, namely, that of colour, by various methods at the disposal of the lantern lecturer. His remarks did not pretend to deal with the scientific aspect of the matter, as to go into this would require more than the time at disposal. He regretted that in their present state the very beautiful results of Professor R. W. Wood's diffraction process of colour photography could not be shown upon the screen. He was able, however, to pass one of these round for examination, made by Professor Wood and left by him on his departure from this country. As yet the colours were somewhat crude, but the process was a step in the right direction. Mr. Freshwater then showed on the screen, by means of a narrow slit and several specimens of gratings, the diffraction phenomena produced by ruling plates with as many as 3000 lines to the inch. With the first grating—one with 3000 lines per inch—the third order of the spectrum was plainly seen. Other gratings, including Thorpe's moulded copies, were shown, and varying degrees of dispersion, according to the frequency of the lines per inch upon the gratings, were obtained, the effects being very fine. Newton's colour test, a disc composed of slips of glasses of the primary colours, was shown, rapid rotation in the lantern giving a close approximation to white light upon the screen, while, at rest, the component colours forming the disc would, of course, be separately seen. Various mechanical slides for the projection of animated designs well known at lantern exhibitions were also shown. Some results by Joly's colour process were next projected, and some examples of Lumiere's colour slides by the superposition of three stained photographic films. The function of the ruled screen in the Joly process was demonstrated by shifting, while the image was yet upon the screen, the ruled viewing screen the space of a single line at a time, when colour effects of an alarmingly false and exaggerated nature were produced. Referring to the development of the spectrum plate used in this process, Mr. Freshwater remarked that in his own work with them he found no reason for exceptional precautions about the dark-room light used. The negatives of some slides, made by himself and shown, were quite free from fog, but they were developed in the light he used for ordinary plates, direct light, of course, being excluded from the dish, in his case by means of a piece of ruby glass laid over it.

The CHAIRMAN said that with the same plates he made no further allowance for their greater colour sensitiveness than that involved in holding the dish above the source of light, so as to prevent direct light from reaching the plate.

Croydon Camera Club.—April 18.—The meeting was opened with a display of prints taken on the Club excursion to Cuckfield, sets being shown by Messrs. Maclean, Frost, Rogers, Kough, Bryan, and Wratten. The PRESIDENT (Mr. Hector Maclean, F.R.P.S.) then exhibited and explained a novel and ingenious miniature apparatus called "La Petite Cinematograph," which is specially suited to the amateur who desires to enjoy the delights and wonders of animated photography. The instrument in question, which measures but 8 x 4 x 3 inches, is substantially and carefully made, the outer case being of polished mahogany. Although its cost is but 5*l.* 10*s.*, it will, without fail, take, print, and project moving photographs, each film running for the standard time occupied by the larger machines, viz., about fifty seconds. With the limelight a capitably illuminated picture, six or more feet in

diameter, can be shown. The films supplied for use with the machine cost but 2*s.* 6*d.* each. La Petite Cinematograph may also be used as a snap-shot camera and as an enlarging camera. The lens works at *f*-4. Members expressed much approval of the simplicity and compactness of the machine, which is made by Mr. Hughes, of Brewster House, Kingsland. Mr. MACLEAN promised to bring up some results of exposure with the above.

FORTHCOMING EXHIBITIONS.

1900.  
 May 23-25 ..... Plymouth Photographic Society. Hon. Secretary, W. H. Harris, 5, Clarendon-place, The Hoe, Plymouth.  
 July 9-14 ..... Photographic Convention of the United Kingdom (Newcastle-on-Tyne Meeting). Hon. Secretary and Treasurer, F. A. Bridge, East Lodge, Dalston-lane, London, N.E.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

Patent News.

THE following applications for Patents were made between April 9 and April 14, 1900:—

- COLOUR PHOTOGRAPHS.—No. 6756. "Improvements in Colour Photographs." T. W. BARBER.  
 SHUTTERS.—No. 7009. "Improvements in Photographic Shutters." S. D. MCKELLEN.  
 CINEMATOGRAPHY.—No. 7035. "Improved Cinematoscopic, Cinematographic, Chrono-photographic, and Chromo-photographic Apparatus." H. L. HUET and A. DAUBRESSE.

Correspondence.

- \* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
 \* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

PHOTOGRAPHY IN CHINA.

To the EDITORS.

GENTLEMEN,—The enclosed price-list of the Chung King Photo Stores may be of interest. As a passer-by I have been struck with the fact that, except at Shanghai and Hong Kong, there are no places in all China where so good and complete a stock of material is held.

The Stores owe their existence to the energy and enterprise of Mr. Davidson, of the Friends Mission, who has not only taught himself the practice of the black art, but also the Chinese assistants who work the processes; and quite a number of local Chinese portrait photographers owe their occupation to his initiation.

The Chinese take very kindly to having their likenesses taken. They much prefer to be photographed full face, both sides well lighted, so that their faces look as round, or flat and waxy, as possible. Shadows, lines, wrinkles, &c., are very objectionable.

A fact in connexion with these Stores is rather noteworthy. Everything has to be taken from Shanghai 1000 miles up the Yangtse by steamer at a cost equal to the freight from home to Shanghai.

Then there is the long, difficult and dangerous voyage of some 500 miles up the rapids and gorges of the Upper Yangtse in native craft, a considerable proportion of which are wrecked. This journey takes nearly two months by the cargo junks at the most favourable time of the year.

Freight and loss by wreck are expensive items; nevertheless, portraiture is marvellously cheap, as may be seen by the list.—I am, yours, &c.,

J. GRANT BIRCH.

Chung-King, Ssü-ch'uaw, Western China, February 24, 1900.

[The circular which Mr. Birch is kind enough to enclose in his interesting letter is as follows:—EDS.]

CHUNG-KING PHOTO STORES.

PORTRAITS.

Price for First Copy.

	Unmounted.	Mounted.
Carte-de-visite .....	Taels .40	Taels .45
Cabinets .....	.60	.65
Whole-plate (8½ x 6½) .....	1.00	1.10
10 x 8 groups .....	2.00	2.25

	Price per Copy after First.	
	Unmounted.	Mounted.
Carte-de-visite .....	Taels ·10	Taels ·12
Cabinets .....	·15	·20
Whole-plate (8½ × 6½) .....	·25	·35
10 × 8 groups .....	·40	·60

	Price per Ten Copies.	
Carte-de-visite .....	1·00	1·25
Cabinets .....	1·50	2·00
Whole-plate (8½ × 6½) .....	2·50	3·25
10 × 8 groups .....	4·00	5·50

The above price for ten copies includes the first.

Second Sitting, if required, price extra.		
Carte-de-visite .....	·15	
Cabinets .....	·20	
Whole-plates .....	·40	
10 × 8 .....	·60	

VIEWS.		
Quarter-plates (4¼ × 3¼), each .....	·05	·07
Half-plates (6½ × 4½), ,, .....	·10	·15
Whole-plate (8½ × 6½), ,, .....	·18	·25
(10 × 8), ,, .....	·30	·50

N.B.—The above prices are in taels and cents. The tael at present is worth a little less than 3s. English.—J.G.B.

THE KEEPING QUALITIES OF DRY PLATES.

To the EDITORS.

GENTLEMEN,—We have noticed from time to time during the last few months notes in the photographic press as to the keeping qualities of dry plates. The following correspondence from Professor Carlton Lambert, of the Royal Naval College, Greenwich, may therefore be of interest to your readers. On March 6 last Professor Lambert writes:—

“It may interest you to know that I have just taken two excellent negatives on plates of your manufacture, which are fifteen or sixteen years old. I have the box and ten of the plates (half-plate) remaining.”

In reply to our application for particulars of batch number and some of the unexposed plates to test, we received the following letter:—

“I am now sending you the packet of plates referred to, minus two which I have used, and each of which gave me excellent negatives and prints, which are at your service, or will be if you care to have them. You will be able to verify the age of the plates. I speak from memory only when I say that I believe they are about fifteen years old.”

The batch number we found to be 2119, and, on referring to our manufacturing book, we found the batch was actually made in August 1889, thus nearly eleven years old.

Recently turning out some old stock, we came across some packets of plates about ten years old, and on exposing them obtained good negatives, therefore it would appear that the keeping qualities of dry plates have been very much belied.—We are, yours, &c.,

MARION & Co.

22 and 23 Soho-square, London, W.C., April 8, 1900.

OZOTYPE.

To the EDITORS.

GENTLEMEN,—I have noticed in your Correspondence column a letter signed “J. F. T.” with reference to “Ozotype.” If your correspondent will kindly wait about a month longer, he will be able to obtain all the materials required for the working of the process. The sensitising solution, and a specially prepared tissue called “pigment plaster,” will be put upon the market, and a handbook giving full instructions will be published. In view of the number of personal applications that are made to me for information and materials, I will take this opportunity to assure intending workers that every effort is being made to supply them commercially as soon as possible; but few people know the difficulties, delays, and attention to the smallest detail involved in placing an entirely new process upon the market.—I am, yours, &c.,

140, Haverstock-hill, N.W., April 21, 1900.

THOMAS MANLY.

LONDON VISITORS TO THE CONVENTION.

To the EDITORS.

GENTLEMEN,—Although it is still a far cry to the Convention, I should like a preliminary note inserted in your columns to the effect that I am undertaking the arrangements for a party to travel to Newcastle by one of the fine boats of the Tyne Steam Shipping Company, of which my father is Managing Director. The steamer sails on July 7 from the Free Trade Wharf (Stepney Station) at seven p.m., and, with anything like reasonable weather, will arrive at Newcastle at six p.m. on the Sunday, a voyage of twenty-three hours.

We shall have the evening on the Thames, and the best part of Sunday at sea, with many opportunities for hand-camera work. I am unable to obtain reduced fares, owing to the fact that at that time the boats are invariably full, but I shall be able to arrange for reserved berths and make the party comfortable generally. On Saturday night there will be a concert in the saloon.

The fare is 12s., and contract for meals 6s. 6d. for the voyage; return fare, 18s., the boat leaving Newcastle on Saturday, July 14.

I should be glad to hear early from those who would like to join the party for a pleasant voyage to the Convention.—I am, yours, &c.,  
166, Romford-road, E., April 20, 1900. WALTER D. WELFORD.

ACHROMATIC STOPS.

To the EDITORS.

GENTLEMEN,—I notice in last week's JOURNAL some cameras for sale, the lenses of which are fitted with achromatic stops. Can any of your readers explain the use of these and their advantages, if any?

Some time ago I remember instantaneous dark slides being advertised for sale, and it occurs to me that, if achromatic stops and instantaneous dark slides could only be used in conjunction, the result ought to “stagger humanity.”—I am, yours, &c.,  
DROF SHUTTER.

Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to “THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY,” 24 Wellington-street, Strand, London, W.C. Inattention to this ensures delay.†

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

- T. M. Barbour, 1, Brierley-street, Bury.—Two photographs of the Bury football team. Photograph of Mr. George Koss.
- A. & G. Taylor, 127, Sauchiehall-street, Glasgow.—Photograph of the Scottish International football team and officials, 1900.
- G. Morrison, Cumberland-square, Birr.—Photograph of Birr Castle, Parsonstown. Photograph of Nenagh Catholic Cathedral. Photograph of Lord Rosse's telescope.

ADDRESS.—The last address advertised was 64, Union-street, Stourbridge.

E. J. SMITH.—Theoretically, your requirements would be met by the use of the Cadett spectrum plate and the special filters provided for them.

STEVEN (Glasgow).—1. Schlippe's salt is sulphantimoniate of sodium. 2. The question concerning acetylene is too vague for us to answer; kindly repeat it explicitly.

REX.—Sorry we are unable to offer a suggestion; but we recommend you to write to or call upon the London agents, Messrs. A. E. Staley & Co., 35, Aldermanbury, London, E.C.

R. N. R.—A matter in which we regret we are unable to help you, as it is an old and strict rule of ours never to give comparative advice. If you can favour us with a call, we shall be glad to see you.

FORMULA WANTED.—DRY PLATE asks for a good formula for matt varnish. A good formula for matt varnish is that given on page 1087 of the ALMANAC, and we do not think it can well be improved upon.

THOMAS LEWIS.—We have no personal knowledge, but probably the necessary facilities could be had, or ascertained, at the establishments of the Eastman Kodak Company, Avenue de l'Opéra, 5; Place Vendôme, 4.

J. McLAINE (Portree).—The initials probably stand for the name of Messrs. George Mason & Co., of Buchanan-street, Glasgow. Such a lens would probably fetch a third of its value in the sale-room. We do not undertake to answer questions through the post.

STALE PLATES.—W. H. W. The fault is, that the plates are stale. Of course, there is always a risk of that in buying job bargains at a quarter of the regular price. The chemist evidently knew the plates were faulty, or he would not, of course, have sold them at so great a loss.

ADDRESS WANTED.—E. BOLAM writes: “Can you inform me the London address of Messrs. Griffiths & Griffiths, stereoscopic slide publishers?”—In reply: We do not know Messrs. Griffiths & Griffiths' address. Does our correspondent mean Messrs. Underwood & Underwood, off 26, Red Lion-square, W.C.?

FORMULA WANTED.—F. D. P. writes for a formula for making a collodion emulsion for ferrotype dry plates.—Personally we have had but little experience with emulsions for ferrotype pictures, and we know of no better formula than those given in the ALMANAC. We do know, however, that some workers have been successful with them, but whether they modified them to suit their requirements, or not we are unable to say.

- COPYING OLD PAINTING.**—W. NASH. If the painting is as yellow as you describe, and has no blue in it, use an isochromatic plate without a yellow screen. Under the circumstances, it would be of no advantage.
- AGREEMENT.—OPERATOR.** We have read through the agreement, which we have posted back to you, and it seems very fair and equitable. Bear in mind, however, that it is of no value until it is stamped. Get it stamped without delay; it will only cost you sixpence.
- WATER.**—Our answer to your questions, which we have not retained, was intended to convey the advice that you should use boiled water for all your operations, and so it reads to us. We used the tap water of your immediate neighbourhood for years, and found no ill effects to result on our negatives and prints, of which we made many hundreds.
- THE NEW POSITIVE PROCESS.**—DAN OSBORNE writes: "Can you let me know whether the new positive process is on the market yet, or likely to be?"—In reply: If our correspondent refers to the positive process of Messrs. Thornton & Rothwell, described in our pages a few weeks ago, he had better write to the Thornton Film Company, Altrincham, Cheshire.
- MARKINGS ON GLASS POSITIVES.**—R. WALTHER asks: "Can you please tell me the cause of the silver-like markings in the shadows of the two glass positives enclosed, they are by the wet-collodion process?"—The two pictures arrived smashed, through faulty packing. The stains are due to the pictures being taken on dirty plates; *i.e.*, very imperfectly cleaned.
- COPYRIGHT QUESTIONS.**—PIPER writes: "1. How can I get to know if a photograph is registered or copyright? 2. Can a photographer make a photograph of a group, copyright or registered, without the consent, in writing, of the members of that group?"—In reply: 1. By searching the register at Stationers' Hall, London, E.C. 2. Yes; if he was not paid for taking the photograph.
- STUDIO-GLAZING.—ROOF** writes to know the best kind of glazing for a studio roof, to ensure it being quite waterproof. We know of nothing better than good putty. It should be made with the best linseed oil, and a little white lead in it is an improvement. After the glass is cemented in, a couple of coats of paint should be applied. A great conducive to a water-tight roof is rigid sash bars that do not give with a strong wind and so crack the putty.
- BOOK WANTED.**—E. DICKSON writes: "I should be greatly obliged to you if you would inform me what you consider the best all-round book for a beginner, and where to be obtained?"—In reply: A very good book for a beginner is *Early Work in Practical Photography*, by Mr. Ethelbert Henry. It is published by Messrs. Dawbarn & Ward, of 6, Farringdon-avenue, E.C. If this does not meet your requirements, write again, and we will make a further suggestion.
- ADDRESS WANTED.**—MR. ROBERT STEWART, of 135, High-street, Elgin, writes: "In the JOURNAL of February 24, 1899, Mr. C. Brangwin Barnes has an article, 'The Restoration of Daguerreotypes,' and I wish to send him one to restore for me, if he takes these in hand. Will you please send me his address?"—In reply: For the moment we cannot place our hands on Mr. Brangwin Barnes's address. Will that gentleman please communicate with Mr. Stewart direct?
- BLACK TONES.**—J. WILMOUR says: "Herewith four prints, and, as you will see, they are of a very warm brown tone, and I can get nothing else tone as deep as I will. I want to get a deep purple-black like I see in some of the old albumen prints."—You will not be able to get them on gelatine paper, nor, we suspect, on albumen paper, from such weak negatives as the samples sent were evidently made from. Deep purple-black tones are only obtainable, even on albumen paper, from very vigorous negatives.
- STOPPAGE OF WAGES.**—C. J. E. writes: "Will you please say what is the rule with regard to Good Friday and Easter Monday? Our governor has stopped our wages for Good Friday, and is going to do the same for Easter Monday, as he says we were not at work, and should not be paid. There are four of us employed, and we are all served alike."—Such a proceeding is very unusual; indeed, we never heard of such a thing before in the photographic profession. We much doubt its legality, with weekly servants.
- INK ROLLER FOR COLLOTYPE.**—T. CROWLEY says: "I am going to try collotype, and a friend has given me a leather litho roller that has laid by, covered with ink, for ten or twelve years, and is very hard. Do you think this will do for the leather roller for collotype work?"—In its present condition, certainly not, and we doubt if it can be made available without a new leather cover. Before having it re-covered, you might take it to a lithographic printer and ask him if he can get it in good condition for you—though we doubt it.
- OPALESCENT COLLODION.**—C. FISHER says: "I had a bottle of enamel collodion which had got too thick to flow well, and I thinned it with methylated spirit. Now it does not flow a bit better, and the film, when dry, is like whitewash; what is the reason?"—The collodion should have been thinned with a mixture of ether and alcohol, then it would have been all right. Methylated spirit, by itself, should not have been employed. Add some ether to it, and if "methylated finish" was not used, though we suspect it was, all will probably go right.
- STUDIO-BUILDING.**—DAN OSBORNE writes: "I want to build a portable photographic studio, one that can be bolted together quickly, outside to be of zinc. I want gallery, developing room, and waiting room; or could you tell me where I could get one? I want all information it is possible to get, as I think of making it myself."—In reply: Messrs. E. C. Waiton & Co., of Newark, would probably supply you with a suitable studio. As a guide to construction, Mr. Bolas's book on the subject, published by Messrs. Marion & Co., Soho-square, should be found useful.

- STAINED NEGATIVES.**—HUGO WEITZELL. The stains are clearly due to imperfect fixation. Had the negatives been properly fixed in the first instance, they would not have become stained in the intensification. The remedy in the future is obvious, though the stains cannot be got rid of now.
- COPYRIGHT.—DOUBTFUL.** You seem to be somewhat confused about the Copyright Act. The Bill introduced in the Lords last year, and the one this, have not become law, therefore they in no way whatever affect the existing Act. The law remains the same as it has been since 1862. The introduction of new Bills does not affect existing laws until they are passed.
- RENOVATING BLINDS.**—D. MCFARLANE says: "Last spring I had new white blinds for the roof of the studio, now they are very dirty and stained with water from the roof. When I have had blinds washed before, they never have hung or run on the rollers well. Can you give me any hint as how to avoid that this time?"—We fear not. Linen or cotton blinds, after they have been washed, are rarely satisfactory, as they generally stretch unequally, and for that reason do not roll tightly on the rollers, and "bag" in the centre. Moreover, after a year's exposure under the roof of the studio, the fabric usually gets pretty rotten.
- MARKINGS ON PLATINOTYPE PRINTS.**—ARTHUR JONES writes: "Enclosed platinum print has streaky markings, which markings, I am sorry to say, appear in many of my prints, the cause of which I am at a loss to account for. Should be glad if you could assign a cause for such faultiness, and tell me how to remedy it. I use a fresh developer and dry pad, also the paper is free from damp."—The print sent has the appearance of being floated on the developer while there was a scum on the solution, such as will, sometimes, arise when it has been allowed to remain long in the dish. This is the only way we can account for the markings on this particular print.
- ASPECT FOR STUDIO.**—QUANDARY writes: "I intend to start business in this town, and have the option to two places, and cannot decide which to take. In either I shall have to build a studio. One is in the best street in the place and the best place for business; the other is in not so good a situation for business. In the first place referred to I can only get a south-east by east light; but in the other I shall get a direct north light. I shall be much obliged if you will give your opinion as to what I should do."—By all means decide upon the best business situation, even if the studio will not be quite so easy to work as one with a north light. Bear in mind, the quality of the work is more dependent upon the skill of the worker than aspect of the studio.
- DETERIORATION OF LENSES.**—H. H. asks: "Do lenses deteriorate by constant use? I used to take my *carte* pictures with a pair of No. 1 B lenses on a bi-lens camera. Now I use a cabinet lens for the purpose. Three or four years ago I took off one of the No. 1 B's and put it on a smaller camera, and have since used it for midgets. Now I have replaced it on the old camera, and have been taking some stereos with it, but in all cases the lens that has been in constant use does not give so bright a negative as the other—that half looks slightly fogged, while the other is brilliant and clear."—In all probability, with the lens that has been in constant use, the blacking on the mount has become somewhat worn off or bright. Reblack the insides of both the tubes, and we have little doubt but the lenses will again work in unison as well as they ever did.
- VALUE OF LENS.**—TAFY writes: "The lens I wrote about a fortnight ago was acquired by the present owner from the late Mr. Heavysides, of Durham, when he took over the business. Wishing to know the value of this and other lenses, he wrote Messrs. Ross, and was informed that Mr. Heavyside had paid 34*l.* 10*s.* for it. I think this was the price; but, any way, the facts are about as I state them. The lens would possibly be catalogued at 38*l.*, and ten per cent. discount allowed. Personally, I don't know the date of the purchase; it may have been thirty years ago or more."—Probably the lens is one of the old 38*l.* portrait lenses; if so, it is for 10 × 8 portraits, and of about eighteen inches focus, not twenty-eight inches, as stated in your previous letter. These large, old forms of lenses have not much value in the market at the present time.
- ERYTHROSINE IN BICHROMATE PROCESSES.**—CONSTANT SUB. writes: "In your JOURNAL of December 22 last, p. 806, there is a short note entitled, 'Erythrosine and Bichromate Films,' of which, to save you the trouble of reference, I subjoin a copy: 'The *Photographische Chronik* mentions that the sensitiveness of the bichromate processes may be considerably enhanced by the use of erythrosine. As an instance, it mentions that the exposure of an ordinary collotype plate was reduced to an hour and a half in bad winter light, whereas in the ordinary way it took two and a half days to print under the same conditions. Similar results have been observed with photo-litho papers and the fish-glue and albumen processes.' As I would like to try the effect of such addition, I should be glad to know in your Answers to Correspondents column: 1. Whether you have had any experience of its efficacy or otherwise in this direction, as this might save me the trouble of trying it? 2. Whether it is easily obtainable of good quality or I would have to get it from London; and, if the latter, from whom, and (if you know without the trouble of finding out) the price of small quantity for trial? 3. The quantity I would have to add to a solution of bichromate of potassium of, say, ten per cent. (or other, if better) strength? 4. Being a dye, would it stain the paper, or, thus combined with the bichromate, be washed out, as is the case with the latter alone, in, of course, the more or less unexposed parts?"—In reply: 1. We have not tried the addition. We quoted the note as it appeared in our Continental contemporary. 2. Erythrosine is readily obtainable from such houses as Hopkin & Williams, Cross-street, Hatton Garden. The price is about 1*s.* 6*d.* an ounce. 3. Not having tried the addition, we cannot offer an opinion. 4. Probably a tint, more or less, will remain in the film.

### EX CATHEDRÁ.

WE are asked by the Hon. Secretary of the Royal Photographic Society to announce that the Fellowship Admissions Committee will meet early in June to consider applications from members for the Fellowship. Candidates must send in their applications, on forms to be obtained from the Secretary, by May 31. For the information of intending candidates we append, once more, the regulations which have been drawn up by the Council to govern the admission of Fellows:—Admission is by the Council. Applicants must first become ordinary members of the Society. It is desirable that a candidate should furnish the names of one or more members of the Society to whom he is personally known. Every application shall be accompanied by a statement of the qualifications of the candidate in relation to one or more of the following heads: Important contributions to photographic knowledge, either in theory, practice, or invention; the production of notable work, either in pure photography or in the arts and sciences kindred thereto; work done in disseminating photographic knowledge; any public service tend-

ing to the advancement of photography. The heads specially dealing with students are as follows: The student must show, to the satisfaction of the Council, that he has received a suitable general education, and that he has a good knowledge of photography in general, or, at least, a fair knowledge of the general subject and a special knowledge or experience in one or more of its branches. As to general education, the Council suggest the following examinations:—the matriculation, preliminary or entrance examinations of the various universities and colleges, the Oxford and Cambridge local examinations, the higher examinations, the higher examinations of the College of Preceptors. In photography and allied subjects, the Council suggest the examinations of the City and Guilds Institute in photography, especially the Honours stage, the examinations in chemistry, physics, drawing, painting, and other allied subjects held by the Department of Science and Art and the various educational bodies.

THE measure of success which has so far attended the Yorkshire Photographic Union since its formation about fifteen months ago is set forth in the annual report just issued. From this document we learn that the main feature of the Union's work is its lecturing scheme. The lecturing staff of the Union for the past session numbered twenty-five names. These gentlemen promised to deliver, in the aggregate, eighty lectures to the federated societies. The subjects of the lectures cover practically all photographic topics, of an elementary as well as an advanced character. The list contains the names of the best photographic workers in the county. The number of lectures actually delivered by the Union staff during the past session is eighty-four, four more than the total number promised. The average number of lectures supplied to each society during the past session is five. The Union now numbers eighteen societies, representing, roughly, about 1500 members, and the Committee claim that it has justified its existence. "It has done for the photographic societies what no other organization has ever attempted to do; it has infused new life into some societies that were drifting into a moribund condition; it has brought the various societies in the county

more closely together, and the officials into personal contact with each other; and last, but not least, it has made the position of secretary of a small photographic society, at any rate, much less onerous." The modest and business-like programme of the Union appears, indeed, to have been well carried out, and the record of its first year's work is one upon which it is distinctly to be congratulated. We wish the Yorkshire Photographic Union a continuance of its initial success, and trust that the sphere of its usefulness to photography will enlarge with its age.

MESSRS. F. & R. SPEAIGHT, who for some time past have devoted themselves with great success to juvenile portraiture, announce an exhibition of photographs of "Children of Royal and Noble Birth" by Mr. Richard N. Speaight, at their studios, 178, Regent-street, London, W. The Exhibition will be open to the public from May 11 to August 4, and we gather from a list sent us that it will include sixteen portraits of Royal children, and considerably over 100 of young people of noble birth. The Exhibition should be very attractive, especially to ladies, a great number of whom will, no doubt, avail themselves of the opportunity afforded them by Messrs. Speaight of studying the productions of this interesting branch of photography. As a proof of their success in children's portraiture, Messrs. Speaight are able to announce that they are "child photographers to the Royal Family," an unofficial recognition, we take it, of the satisfaction which their work affords to their distinguished patrons.

\* \* \*

THE prospectus of the forthcoming Exhibition of the Royal Photographic Society at the New Gallery, Regent-street, was issued this week. In another part of the JOURNAL we reprint those parts of the document which specially deal with the five sections into which it is proposed to divide the Exhibition, viz.: 1, Pictorial Photography; 2, General Professional Work; 3, Photographic Apparatus and Material; 4, Photo-mechanical Processes; 5, Scientific and Technical Photography. Those of our readers who are interested in the Exhibition, and have not received a copy of the prospectus, may obtain it on application to the Secretary of the Society, 66, Russell-square, W. The increased space obtainable at the New Gallery, and the subdivision of the building into several large rooms, gives the Royal Photographic Society this year the opportunity of making some important experiments in regard to the scope of its Exhibition. For a considerable time past there have been complaints that professional work, photographic apparatus, and what is understood by the term "technical photography" have not been encouraged at the exhibitions held in the Pall Mall Gallery, and the prospectus before us is, we apprehend, symptomatic of an attempt to remove those disabilities, if such they be. In other words, the scope of next October's Exhibition has been widened to the utmost extent, and, if the evident expectations of the prospectus are realised, a thoroughly representative and comprehensive Exhibition should result. We shall have other observations to make on this subject later in the year.

\* \* \*

THE interesting Society of Arts' paper on process work by Mr. Carl Henschel, which we reprinted last week, gave some details of the extent to which engraved half-tones are used by many of the London newspapers; but it would appear from

some recently published remarks by Mr. S. H. Horgan, the head of the *New York Tribune's* art department, that London is pushed hard by New York for rapidity and enterprise in this class of work. Mr. Horgan tells us that on Thursday, January 21, 1897, there was published on the front page of the *Tribune* a portrait of the Hon. Thomas C. Platt, on the occasion of his election as United States Senator. This portrait was printed from a "half-tone" engraving, which up to that time was regarded as an impossible method for the daily newspaper. Still, the *Tribune* printed this half-tone picture on its rapid web-perfecting presses without any change in its machinery or in the quality of ink or paper used. From that date to this the illustrations in the *Tribune* have been the marvel of other newspaper proprietors, both in the United States and in Europe, and half-tone illustration is being tried with more or less success by newspapers everywhere. What possibilities the future holds for this latest improvement in newspaper engraving and illustrating may be predicted from the *Tribune's* recent triumphs in photographing famous dinner gatherings and reproducing the photographs perfectly by the fast-printing press a few hours later. In the way of rapidity, the last-mentioned instance of the New York journal's enterprise would not be easy to excel. Mr. Henschel's references to the practical extermination of wood-engraving by half-tone are virtually duplicated by another American writer, who remarks that photo-engraving has driven out of employment the ordinary engraver on wood. A few men of extraordinary artistic ability, like Cole and Johnson, are unaffected by this invention, but the art of ordinary engraving on wood is as dead as the old art of alchemy. By the new art of photo-engraving the design of an artist can be reproduced in high relief without the intervention of any engraver, and at about one-tenth of the old cost in time and money, but the work so done, while faithfully executed, is insipidly weak. To bring out its best points the old engraver on wood now finds some employment in retouching and developing the monotonous work. Notwithstanding all the great improvements by machinery the old truism holds as good now as it ever did, "The man is more than the machine." All through, matters in these respects are very much the same in New York as in London.

#### IODIDE OF MERCURY INTENSIFIERS.

WE are aware, of course, that to some photographic purists mercurial intensification of any sort is *anathema marcanatha*, but the fact remains, that mercurial salts are, and have been, since the advent of collodion photography, in constant employment for increasing the opacity of negatives that, without its aid, would not give presentable prints. It is not many years since we examined some mercurially intensified negatives, which we saw undergo the operation of intensification over forty years ago, yet they were in perfect condition. The process was the preliminary whitening by mercuric chloride, followed by a blackening with weak solution of ammoniac sulphide. For many years this, with the occasional substitution of ordinary ammonia solution in lieu of the sulphide, was in common use; indeed, the early workers in collodion, when requiring a negative, perhaps, more frequently used a "converted positive" than a directly developed negative. After a while a number of other variations were introduced, preference being given to one or the other in capricious fashion. In the early

ys of gelatino-bromide plates recourse was often had to intensification, mostly on the old lines, till Mr. B. J. Edwards produced a novelty in the shape of a one-solution intensifier, made by mixing mercuric chloride and potassic iodide solutions and adding "hyposulphite of soda;" a plan reduced to more exact method by Mr. Watmough Webster, who first precipitated, separated, and washed the mercuric iodide, and dissolved it in definite proportions.

Used with care, the Edwards' intensifier was a most valuable intensifying agent, and, as regards permanency, we have reason to believe excellent. We have seen negatives seven or eight years old intensified by this agent which were apparently unchanged; yet we are bound to say that we have seen a far larger number that had certainly undergone a change for the worse—the density of the image lost and a yellow stain over it. The negatives that had stood the test of time were such as had been subjected for a brief time to a second bath of pure hypo after being intensified.

This intensifier gave a beautifully clean result, and, when freshly made, brought about the increase of opacity with little or no apparent change in the colour of the image. One great advantage of a one-solution intensifier is the facility it affords for local treatment. Taking the plate after being slightly washed after fixing, we have found it a perfectly simple matter to add to the opacity of any particular region of the negative by simply applying the solution, with the finger, with a gentle rotary movement, flushing the solution away with a copious supply of water when the required effect was produced. It is as better to slightly overdo the density, so that an after-treatment with hypo would clear the negative and tend to the permanency of results. Negatives treated by this, or, indeed, by most mercuric intensifiers, can, if too dense, be easily reduced again by a hypo solution.

Within the last few months Messrs. Lumière and Seyewetz, whom photographers are already greatly indebted for their published investigations of many photographic problems, have produced a further most important modification of this intensifier. In lieu of dissolving the mercuric iodide (a brilliant scarlet powder used by painters under the name of scarlet vermilion) in hypo, they dissolve the dry iodide in sulphite of soda solution. When well washed for not too protracted a time, the negative so treated may be looked upon almost as permanent; but, to be on the safe side, the inventors recommend that, after well washing, the plate be put in some ordinary developing solution for a short time; it is then expected to be absolutely permanent. The formula is simple—consists merely in dissolving one per cent. of the red mercuric iodide in a ten per cent. aqueous solution of anhydrous sulphite of soda. Whenever and wherever this formula has been reproduced the anhydrous salt forms an integral part of the constituents; but, if pure sulphite of the ordinary crystalline kind (so long as it is in good condition and not effloresced) be employed, it will be equally efficacious. But it must be remembered that the anhydrous is, through the absence of water, about double the strength of the crystalline form.

We have tried the new iodide-in-sulphite intensifier, and have nothing but praise for it, and a careful study of Messrs. Lumière and Seyewetz's paper upon the cause of deterioration in negatives intensified with mercuric iodide warrants us in arriving at the conclusion that negatives intensified by this new process, with the precautions alluded to being taken, will prove to be absolutely permanent.

**Ghostly Images.**—A mysterious image on a piece of glass, used in glazing a greenhouse, has proved an interesting topic at two or three meetings of the London and Provincial Photographic Association. No satisfactory evidence was forthcoming as to how the image got there, beyond the undoubted fact that the glass was at one time a photographic negative, a portrait of a gentleman. In the days of the wet-collodion process, when the glass was frequently used over and over again, it was no infrequent occurrence for a previous image to make its appearance when the negative was developed. This image was, of course, always very faint, and sometimes, in the hands of charlatans, was passed off as a "spirit photograph." These secondary images were more frequent when patent plate was employed than when ordinary crown glass was used. This was easily accounted for by the fact that the latter had the natural surface of the glass, whereas the former had an artificial one, brought about by the grinding and polishing it had undergone. When this glass had been cleaned and polished, and then allowed to remain standing for a day or two, the old image could often be seen by simply breathing upon it; but, if the glass were treated with nitric acid, or it was cleaned with tripoli or rouge, which removed some of its surface, a previous image rarely made its appearance. With Daguerreotype plates, too, when used a second time, it was not an infrequent thing for a trace of the previous image to show faintly in the picture. With gelatine plates this is not at all likely to happen, for the glass is always used with its natural surface, and is rarely employed a second time. The glass upon which negatives have been taken and cleaned off is often employed for glazing greenhouses and garden frames, and much of it has been sold for that purpose, and we shall not be at all surprised if other mysterious images are discovered as time goes on.

**The Forthcoming Exhibition at Glasgow.**—The promoters of the International Exhibition to be held in Glasgow next year clearly mean it to be a great success, and, no doubt, it will be. There is already a guarantee fund of over half a million sterling. Last week, at the meeting of the Common Council of the City of London, a deputation from Glasgow, headed by the Lord Provost, attended, and solicited the co-operation and support of the City of London Corporation, not in the shape of money, but in loans from the City's collection of works of art, drawings, models and other objects of interest. It is almost needless to say that the request was readily accorded, and it was at once referred to the Library Committee to ascertain in what ways and in what directions the City of London might be represented at the Exhibition in loans of interesting and useful objects. In the interview the Lord Provost mentioned that at the last exhibition, held in Glasgow in 1833, the net profits amounted to 50,000*l.*, which was devoted to the purposes of the Art Gallery and to other useful and meritorious ends in the interests of their citizens. Glasgow, like many other municipalities, has very fine art collections, and it has lent some of its treasures to the present Exhibition at the Guildhall. Many of the municipal art galleries have a finer collection of pictures than that owned by the Corporation of London—the first city in the world; but efforts are now being made to increase it. Photography will be a feature in the forthcoming Glasgow Exhibition, and it is to be hoped, and expected, it will be well represented both from home and abroad, as it will be an international show.

**Was it a Wart on the Nose?**—An amusing paragraph has appeared in an evening contemporary. According to it, an enterprising clothing firm at Chicago was desirous of presenting their customers with souvenirs of Admiral Dewey, and ordered 5000 white medallion portraits of that celebrity. When they were delivered, it was noticed that each presentment of the hero of Manila showed a wart upon his nose. Then Mrs. Dewey and Admiral Schley were telegraphed to, and both averred that the nasal organ in question was wartless. The medallions were therefore returned, but the one who supplied them affirms that they were all right, and is threatening law proceedings to recover payment for them. Now, it is quite conceivable that, if the die-sinker worked from a photo-

graphic portrait, and most probably he did, and the one supplied to him had a spot on the nose, say, from a pinhole in the negative or a spot on that individual print, he might well have thought it "was part of the play," and therefore reproduced it, possibly with emphasis, and, as he may have thought, to enhance the likeness. What is more natural? Any how, it will be noticed that the tale comes from America, and we are not responsible for the facts.

**A Paris Innovation.**—It has been decided by the Paris Municipal Council to place tablets at the corners of the principal streets, inscribed with a brief statement of their origin and history. These will, no doubt, prove of interest to visitors to the French capital, and photographic ones should note. By this innovation they will be enabled, when photographing the street, to get its history and origin on the negative, that is, provided the corner of the street happens to be included in the view. It will be interesting to see how the history and origin of some of the streets will be dealt with—those, for example, that have had their names changed from time to time for political reasons. If the same system were followed in London, it would, no doubt, be interesting to country visitors, that is, if the street corners of the busy streets of our metropolis were more convenient places for persons to stop and read. One thing is certain, if the system were adopted, and that is, that it would afford plenty of food for discussion in the newspapers as to how many of the old streets, lanes, and courts in the City came by their names.

**Photography and the Koran.**—The authorities at the Paris Exhibition seem at the present time to be somewhat in a fix. In order to prevent fraud, it appears that the admission tickets of the exhibitors must bear photographs of their holders. There are, however, a large number of Mussulman exhibitors and their assistants, and it is quite against the tenets of the Koran that they should have any likeness of themselves made. For this reason a number of Algerians, Tunisians, and other Mohammedans positively refuse to have their photographs taken. The authorities, it is said, are very much perplexed as to the means to be taken to overcome these religious scruples. But it is very obvious that one party or other will have to give way. It is pretty well known that in Mohammedan countries professional portraiture is not a good business, that is, amongst followers of the Koran.

#### THE PHOTOGRAPHER'S YEAR.

##### MAY.

"Life looks like a dream  
On a bright May day."

So sang the member of a string band on the shady side of the street of a west country town more years ago than one now cares to count. The voice was probably not of the first water, more than the skill of the accompanists, but it was a bright May day, both of the yearly calendar, and the life calendar of at least one of the listeners. May ever since to him has been the dream month. Not the dream that comes after the late supper, this is the November one. But the day dream that steals gently over the soul, when with a free conscience and an unobstructed liver, their fortunate possessor, with straw hat tilted over his eyes, lies on the sloping bank watching the ripple of water and soft sway of tree-tops. Many others, doubtless, without the help of the singer and the band, unconsciously regard the month in much the same fashion. The touch of ethereal sweetness in the air, the freshness of tree and hedgerow in their new dress, the grace and colour of flowers, and the song of birds compel the feeling and give rise to the highest pleasure. With the average grey of things earthly as normal standards to compare with, we are forced outside into dreamland for a fitting expression of the keenness of delight.

But going into dreamland is going altogether beyond the reach of photography—at least beyond its present reach, for possibly some future Röntgen may bring about the possibility of impressing "the unsubstantial fabric of a dream" upon a photographic plate, and oneiro-photography be as well recognised a division of the art as micro- or tele-photography. But this is a feature for the future, photography halts as yet in the power of giving a full impression of the airy, dreamy, beauty of May, is less

suitable for the particular purpose probably than many other means, the of the word-painter and artist, for instance. Still, it can do a great deal and the wider the range of effort the more may unsuspected capacities unfold themselves, and the better will be the result. Light, airy, fleetly grace are the qualities that would go to make characteristic pictures of May. They are unfortunately those wanting in the majority of photographers. Presumably they are those most difficult to render photographically, inasmuch as many able and appreciative workers must have tried to express them.

For our comfort, it should not be forgotten that they are very high qualities and difficult to express in any fashion. The trained artist, expert writer, and eloquent speaker find them the ones most difficult to incorporate into picture, book, and speech. They have the feeling of what they want, but the expressing media are too gross to do justice to such delicate impressions. The photographer, with a soul above a developed formula, experiences much the same feeling and disappointment when taking a walk in the country on a May morning, or lingering along the riverside on a May evening. The impressionist picture is an effort to solve the difficulty, but by wrong methods. The feeling that leads to the attempt is most elevating, the result is emphatically nothing of the sort, but, on the other hand, most depressing.

The strong point of photographic work, extreme mechanical fidelity of execution, must not be ignored, but made proper use of, if a true result is to be gained. If allowed, however, to act without a refinement of judgment, the result is the one we are familiar with in the good photographic picture, a frameful of perfectly rendered detail, texture, and light and shade. We ought to admire it to the full, as coming as near to perfection as possible, and, had Adam not eaten the apple, we would probably do so. As it is, we unconsciously resent something about it, much the same way that we do the occasionally lucky man we know who, born without any hereditary tendencies to skip over the boundaries of the orthodox, and, further, reared with an educational comprehensive all-roundness, also fills his frame, from corner to corner, with uniform coloured perfection.

It is ticklish walking. We cannot say that we wish for a fault; but anything out of focus; but we would like a blank space here and there as a relief—and, probably, a sop to our own less perfect clay—a little air, grace, and suggestion, in place of closed-in solidity. Instead of the perfect whole we should aim for a perfect part—much less difficult to gain—but let that part be so essential a one, and all pertaining to it naturally arranged, that it will suggest the symmetrical whole. We may prefer the richly laden hawthorn, that carries its bloom in such thick heavy clusters; but, remembering that it will not impress itself upon the negative as it does upon the eye and mind, it will be wiser to select a smaller tree, with sparser bloom-sprays a little more apart, and surroundings that will not detract from it. Photographically, the result is sure to be far more satisfactory.

Alas! it is in May, the month of flowers, that we have occasion to regret most deeply the colour limitations of our art. Flower form is very beautiful, and can be rendered to perfection, but without colour it is but a beautiful body without a soul. A classical statue of perfect marble beauty is most beautiful, but a living commonplace man is more interesting, after all. We will, doubtless, gain colour life in time; so the photographic Pygmalion will suddenly find his Galatea endowed with life one day. As it is, flowers in a photograph, however well arranged, and however well depth and kind of colour may have been translated into shade, have markedly lack of life and soul about them.

But regretfully leaving flowers as beyond our true range, most suitable though they would prove to illustrate the point in favour of suggestive and lightness, there are many other things within practicable range that end. May, with every corner full, but not too full, of life, perfect light, and fair weather, offers the best opportunities of the year for the suggestive piecework advocated. The stile with the path beyond, the half-open door with the sunny scrap seen through, the turn in the lane bend in the river, bit of cathedral cloister, or abbey interior, are all very much to the purpose.

Vignetting and local development are both legitimate means of helping out, by keeping back excess of subject and emphasising particular parts to the concentrating of interest upon the leading thing it is desired to present. There are accepted means, in rules and lines of composition for doing the same thing in a picture. But it must be remembered that these are ones that the artist has evolved to suit his own special practice. They cannot apply regularly to the very different conditions under which the photographer works. If the artist finds a tree or rock in a spot where they would break upon a leading eye line, and introduce discord and irritation when he would have easy gliding, he can leave them out

he photographer, short of chopping down the tree or blowing up the clock, has no alternative than to admit them. The one can suppress as he likes in his foreground, and emphasise in his middle distance, the other cannot.

The compensation the photographer has, and which he should not be slow to avail himself of, is the fidelity and ease with which he can reproduce an essential part, and the extreme pleasure which the imagination experiences in working out for itself the full scene. This leaving a space blank is the photographic alternative to the rules of artistic composition when they cannot be applied. Provided the right space be left blank, it will prove more than equally effective. That this is so will be readily admitted by most, if the simple experiment of looking actually, or mentally, over the pictures they have, or remember, be tried, and noting which give them the most pleasure.

One of the chief charms of tele-photography, and one that, apart from its other advantages, points to a lasting adoption, is, that it lends itself and aids this selective faculty. Many a photographer, before the new lenses came into use, looking through a telescope in his summer holiday, must have been struck with the charming pictures often seen, and wished they could have been preserved for future consultation, remembrance, and pleasure. May, as the best photographic month of the year, be the one for anybody who may elect to start with the new type of work. The conditions are then at their most favourable point, and he will have acquired mastery and confidence in the new field before the less favourable months come in. If, however, so conservative that he will hold to the attempt at a complete picture, let him pay some homage to May by using his largest aperture, giving the shortest exposure, and so on, so as to convey some feeling and suggestion of the sunshine and glad, young freedom of every living and growing thing. Let him not, in the too close effort after the perfection of detail that, however truly present, is never really noted anywhere but on a photographic plate, make no difference between a sunny day, or month, and a dull, grey one.

#### SPRING AND SPRING LIGHT.

DURING the past two or three weeks we have received different negatives from correspondents asking the cause of their lack of brilliancy or flat appearance. In every instance the cause has been over-exposure, pure and simple, though the fault has been, in some instances, attributed to the plates. Many amateurs do not appear to realise the difference in the actinic quality of the light now from what it was when they laid aside their cameras last autumn. Just now the light may be said to have reached the zenith of its actinism, and it may be mentioned that, after a May shower has passed, it is more highly actinic than many may surmise, and this should be taken into consideration when making exposures at this season.

By the way, referring to spring light, we may again remind our readers, as we have done on many previous occasions, that pictures are to be had now that are not obtainable at any other season of the year; for example, shaded glens, in which it is impossible to obtain detail in the deeper shadows when the foliage is at its full. To take them with leafless trees and shrubs would give the scene a wintry aspect. Again, many buildings and ruins that are surrounded by trees, and are almost, or entirely, hidden when they are in full leaf, may be well shown now, though the trees will not be depicted as leafless, as they would be if the photographs were taken earlier. The trees, while the foliage is light, will not, in most instances, impair the view of the buildings, while they will enhance the beauty of the picture. It is for this reason that we again remind our readers that no time should be lost in securing the pictures. Spring is late this year, but, now that it has commenced, it will proceed rapidly, and we shall probably soon have summer with its foliage, and what is not secured now in spring effects will have to be waited for till next year, a long time to wait to get a picture.

#### THE NEWCASTLE CONVENTION.

At one of the meetings of the Camera Club in March last, Mr. S. B. Webber, an accomplished goldsmith of long practical experience, kindly gave the members a demonstration of gold working, a brief account of which is printed in this Journal of April 6 last. We understand that Mr. Webber, who is a staunch supporter of the Photographic Convention of the United Kingdom, has been good enough to promise a repetition of this demonstration at the Newcastle meeting of the

Convention in July next. Those intending to be present may rely on having a delightful discourse on some of the properties of the precious metals.

In addition to Mr. Webber's demonstration, the programme as we have already announced will include papers by Sir J. Benjamin Stone, M.P.; Dr. P. H. Emerson, M.A., M.B.; Mr. C. H. Bothamley, (Past President of the Convention), and Mr. J. Bridges Lee, M.A. Photography at the Seat of War, is also expected to prove an attraction at one of the evening meetings.

The Newcastle Meeting of the Convention is the fifteenth of the series. Last year the Council issued a small pamphlet giving a short history of the Convention since its foundation. From that pamphlet we extract the names of some of those gentlemen who, either as Presidents or as readers of papers, have lent their practical support to the Convention during its existence. A study of the appended list will show that, with few exceptions, it includes the names of the men most prominent in British Photography during the last fifteen years.

T. N. Armstrong.	Sir Howard Grubb, F.R.S. (Past President).
R. Child Bayley.	F. B. Grundy.
Thomas Bedding (President, 1900-1901).	A. Haddon (Past President).
Gambier Bolton, F.G.S. [1901].	A. L. Henderson.
Thomas Bolas, F.I.C., F.C.S.	A. Horsley Hinton.
C. H. Bothamley, F.I.C., F.C.S. [(Past President).	Messrs. Hurter & Driffield.
F. A. Bridge (Hon. Sec. & Treasurer)	W. Jerome Harrison, F.G.S.
W. K. Burton.	Professor Joly, F.R.S.
Arthur Burchett.	Rev. F. C. Lambert.
William Bedford (Past President).	W. Lang, F.C.S.
F. P. Cembrano (Ex. Hon. Sec. and Past President).	Percy Lund.
William Crooke (Pres. 1899-1900).	Alfred Maskell.
Lyonel Clarke, C.E.	George Mason (Past President).
George Davison (Past President).	Dr. Hill Norris.
T. R. Dallmeyer, F.R.A.S. (President Royal Photographic Soc.).	Andrew Pringle, F.R.M.S. (Past President).
R. P. Drage (Ex Hon. Sec.).	Rev. S. J. Perry, F.R.S.
W. E. Debenham.	H. P. Robinson (Past President).
B. J. Edwards.	Dr. Paul Rudolph (Jena).
E. Howard Farmer.	F. M. Sutcliffe.
J. Guardia.	John Stuart (Past President).
W. Friese-Greene.	J. Traill Taylor (Past President).
William Gamble.	E. J. Wall.
	H. Snowden Ward.

#### PAPER-MANUFACTURE, WITH SPECIAL REFERENCE TO ITS PHOTOGRAPHIC USES.

[Paper read before the Edinburgh Photographic Society.]

I HAVE been frequently asked by members of this Society and others, What relationship exists between photography and paper-manufacture? For the present I do not intend to answer this question directly, as I hope the result of my remarks this evening will convince all my hearers that without good paper there could be no good photography. One of my questioners, however, would not be put off till this evening, but wanted an explanation at once. I tried to satisfy his curiosity by saying that his prints were made on paper. Yes, he replied, my negatives are made on glass, and yet we don't wish to have a lecture on the manufacture of window glass. The inconsistency of humanity was manifest when my too previous critic frankly admitted that a lecture on the manufacture of celluloid films would be both interesting and instructive.

Photographers should be interested in paper and its manufacture for many reasons, but chiefly because of the necessity for absolute purity, essential to good or even passable, work. If purity and cleanliness are necessary in the processes employed by the photographer, it is equally necessary that the paper to be used for printing purposes shall have been carefully made, so as to ensure absolute purity in the finished article. Besides the paper upon which the photographs are printed, we must not forget that purity is necessary in the mounts, and in the envelopes, tubes, or boxes used for the storing or packing of the papers, plates, and films in the factory, sale-room, or studio.

The principal constituent of a sheet of paper is a somewhat inert body, possessing physical properties indicative of the source from which it has been derived. This substance, known as cellulose, imparts peculiarities to all the numerous varieties of paper, from wrappers through all kinds of news, printings, arts, lithos, writings, to photographic papers, this last class being that to which we shall devote most of our attention to-night.

The materials now used as sources of cellulose for the manufacture of paper are so numerous that it would be hardly possible to enumerate them. But, as we are chiefly concerned at the present time with the manufacture of papers intended to be used for purposes connected with

photography, I shall ask your attention to the three principal sources of fibre used for paper-making in this country and on the Continent. The e are :—

1. Rags, including linen and cotton new cuttings, and worn-out garments.

2. Esparto grass (Spanish and African).

3. Wood fibres (commonly called wood pulp).

The methods of reducing these substances to a condition amenable to proper treatment in the various stages through which they must pass in the process of manufacture into finished paper are much the same in the case of rags and esparto grass. In the case of wood cellulose, however, all the preliminary processes have been gone through in mills situated at or near the forests from which the wood is obtained, and the material is supplied to mills in this country in the form of a sheet of pulp. I shall have occasion to return to the subject of wood pulp in papers, but in the mean time let us return to the consideration of the other cellulose-yielding bodies, namely, rags and esparto. We shall run over as rapidly as possible the various stages through which these bodies must pass in the course of their conversion into paper.

The first or preliminary operations are picking, cutting, and dusting. In the case of worn-out garments, all buttons, hooks and eyes, pieces of elastic, or other foreign materials, must be removed. The rags are then put into a duster, willow, or devil, in which they are subjected to a considerable amount of tossing about, with the object of beating out the dust, which falls or is drawn by means of fanners into a dust chamber, the rags being at the same time filled into boxes or sacks, ready to be transferred to the boiler-house. Here the rags are treated with a weak solution of caustic soda in specially constructed boilers; these may be either spherical or cylindrical. The duration of boiling depends upon two factors, namely, quantity of caustic soda used per hundredweight of rags, and pressure of steam per square inch in the boiler. After boiling, the rags receive a thorough washing, are withdrawn from the boiler and transferred to a washing and breaking engine, where the last traces of caustic soda and dirt are removed, while the rags are reduced or torn into very small shreds. In this condition the rags, if necessary, are treated with a small quantity of bleaching solution, for the purpose of removing any colouring matter which may still cling to the fibres. The bleaching agent employed consists of a solution of chloride of lime. It is not desirable that I should enter into the chemistry of this process at the present time, but I wish you to keep in mind that chlorine, in a certain form, has been used for bleaching the fibres. Though chlorine is a very useful substance in the production of paper, it is absolutely necessary that no trace of it shall exist in the finished article, especially if such paper is to be used for any purpose connected with photography. For the present I shall leave this subject, in order to complete the short account of the manufacture of paper; but I shall have occasion to return to it. The rags, after boiling, washing, breaking, and bleaching, are mixed with a large quantity of water, and passed over a suitable machine, called a *presse pâte*, whereby a further removal of dirt is effected, and the rags are obtained in the form of a sheet of what is called "half-stuff." This half-stuff is now placed into an engine provided with a large roll, upon which are fixed a number of knives or blades. As the roll revolves, the blades pass over a number of stationary blades securely fastened to the bed of the engine. The name given to this type of engine is a beater, and the function which it has to perform is implied in the name. The half-stuff is put into the beater with a quantity of water. The rapidity with which the roll revolves causes the pulp to pass between it and the bed plate, and in this manner becomes reduced to its ultimate fibres. All chemicals which it is desirable to retain in the finished paper are inserted here. These include—

1. The colouring materials which it is necessary to add in order to impart the required shade to the paper.

2. Sizing materials, the object of which is to make the paper more or less impervious to water, thus enabling us to write upon paper with ink, or, in the case of photographic papers, to subject the prints to prolonged washing without injury.

3. Filling materials are also added to the beater. These materials may be of mineral origin, as China clay, or any of the numerous forms of precipitated sulphate of lime; or of vegetable origin, as in the case of starch, which is also largely employed as a filling agent. The object of these is to fill up the intervening spaces between the individual fibres, and thus impart to the sheet a more solid surface.

After the fibres have received the necessary amount of beating, and the colouring, sizing, and filling materials have been added, the pulp is run into suitable chests, from which it is pumped as required for final conversion into paper. The paper machine is rather complicated

for description here. The principle involved, however, is simple, depending upon the fact that you cannot cause fibres suspended in water to pass through a sieve. The water itself will run through the meshes of the wire cloth, leaving the fibres behind in the form of a thin sheet. In actual work the pulp, thinned with water, is run on to an endless travelling wire cloth, through which the water passes, leaving the fibres on its surface as a sheet of paper. As the wire cloth travels forward, the sheet of "felted" fibres is induced to leave it, by being made to pass under a roll covered with felt and kept constantly wet. The paper now passes through a number of rolls, each having its own function to perform, and upon their efficiency depend many of the qualities of the finished sheet of paper. After drying, calendering and cutting, each sheet is examined by girls, counted out into quires, and reams, ready for the market.

I hope I have made this short account of the methods of paper-manufacture sufficiently clear to my hearers. Although the principles involved are simple, the processes employed are very complex, and a small deviation from the proper treatment in any of these processes has a very decided influence on the finished article. In my description of the manufacture of paper from the raw material I have only referred to rags as the principal source of cellulose. The methods of reducing other fibre-yielding plants are similar to those just described.

Assuming that you have now grasped the essential principles of paper-manufacture, we shall now turn our attention to the subject of paper for photographic purposes, and of the various chemicals used in the manufacture of paper, and which are liable to be retained in the finished paper.

As it will now be evident to all that the manufacture of paper is largely a chemical process, and that the chemicals employed are various, each having its own function to perform, and, having performed that function, it is desirable that any excess should be removed as speedily and as effectually as possible. The permanence of a sheet of paper is undoubtedly dependent upon the care with which all chemicals employed in the transitional stages of the process have been removed from the pulp before it has reached its final stage. At any point of the process it is possible to leave traces behind which, if persisting in the paper, may render the work of the photographer very distressing. There are certain qualities which we, as photographers, are desirous that all paper used by us should possess, such as strength, hardness, and pliability, permanence of colour, and finish. These important qualities, which, from our present point of view, may be considered as essential to good paper, can only be retained if the chemicals employed in the processes already mentioned have been neutralised, and the resulting compounds eliminated from the stock.

Let us now consider in what way residual chemicals in paper may affect photographic work. The first wet process to which the raw paper-making material is subjected is, as we have seen, boiling with caustic soda solution. But, in the manufacture of all ordinary papers, the subsequent processes involve such drastic treatment that it is impossible for any of this chemical to be retained in the paper. In many papers, however, where purity of colour is no object, then the alkali is sometimes not fully eliminated from the stock, and the result is that the paper will contain an amount of soda sufficient to cause harm from a photographic standpoint. Such papers as I am referring to are largely used by the makers of plates and papers for the purpose of wrapping and packing their goods, with the result that, if the alkali comes in contact with silver emulsion, either in plates or papers, a decomposition of silver compounds takes place, with a corresponding degradation in colour. I have often seen printing-out papers (which are usually supplied in cardboard tubes) having a dark border round three sides of the sheet, something like a sheet of mourning notepaper. The edge of the sheet inside the roll is not thus affected—indeed, it will be observed that only those parts of the paper which are in contact with the containing case are thus darkened in colour. If the cardboard or paper of which these tubes are made be carefully examined, it will be found that it is strongly alkaline. Of course we know that, if the instructions of the makers are carried out to the letter (I refer chiefly to the clause, "Keep in a dry place"), such minor calamities may not occur, or they may be encouraged to take place by keeping the tubes in a place which is too dry. This apparent paradox depends upon the hygroscopic property possessed by paper. Assuming that the tubes of printing paper left the maker's premises in an absolutely dry condition, which is not likely, these tubes lie in the dealer's shop in a place which probably contains air having a considerable amount of water vapour. The paper now absorbs moisture from the atmosphere, even to the extent of ten or twelve per cent. The purchaser now may keep his tube of paper in a dry place, with the result that a portion of this moisture is expelled partly into the tube, and during the

process the chemical action already referred to takes place. We know that, tubes and paper are kept constantly dry, such chemical reactions will not take place, but the intermittent absorption and expulsion of moisture causes the residual alkali of the cardboard tubes to act upon the silver or the gelatine of the emulsion. The same remarks apply to the envelopes used for cut papers and for bromide papers. In many cases it would be an advantage if as much care and selection were exercised in the cardboard boxes, envelopes, and wrappers as upon their contents.

The manufacturer of brown wrappers does not usually anticipate that his paper will be employed for purposes other than are implied by the name, and yet, according to a certain present-day standard of artistic excellence, prints must have the smallest possible amount of detail, of brown tone, and stuck on mounts to match, these mounts being frequently nothing else than a bit of brown paper. Such printing and mounting may look well for a time, but we cannot be surprised if their beauty vanishes, caused by the appearance of yellow spots or other blemishes on the print. These defects could, no doubt, be obviated by the manufacture of a brown paper of the necessary degree of purity; but, if the paper-maker is not duly advised regarding the purposes for which the paper is required, then the photographer will have no cause of complaint against the paper-maker if things do not go as he desires. There is yet another action which brown paper in particular has upon a sensitive emulsion. If brown paper is kept in contact with the emulsion side of a plate or film, an action seems to take place, and a developable effect is obtained. As far as I am aware, it is unknown whether this effect is due to chemical or electrical action. This phenomenon is well worth investigating.

We shall now pass on to other residual chemicals which may possibly exist in the finished paper, and which are, perhaps, of greater interest to the photographer because of their liability to exist in the paper or mounts with which he is in daily contact. The second chemical process to which the paper stock is subjected is bleaching. This process, as I have already stated, consists of the treatment of the "stuff" with a solution of chloride of lime. As it is impossible to obtain perfect bleaching without using an excess of the bleaching agent, there is a possibility that some of this excess may exist in the finished paper. The effect of the existence of an excess of these unstable chlorine compounds in the paper is that they exert a powerful action upon the cellulose, thus causing the paper to lose its strength. The object of treating raw cellulose materials with bleach is to oxidise all non-cellulose matters, converting them from insoluble compounds to soluble substances, which can be easily removed by washing. If this is properly done, the cellulose will not be acted upon by the bleach; but, if too great an excess of bleach has been used, then the cellulose becomes attacked, forming insoluble chlorine substitution compounds, which become fixed upon the weakened fibres, causing degradation of colour and loss of strength. I need not dwell upon the effect which this would have upon paper and mounts used by the photographer. The presence of any unstable compound of chlorine, or even of chlorine itself, in a photographic paper would soon make itself manifest, either in the gelatine or the silver compounds of the emulsion. But the trouble would be much greater if these compounds existed in the paper of the mounts, where the action would be on the finished print, causing loss of its tone, and the production of all shades of yellow spots. Any excess of chlorine, beside acting on the paper, causing a destruction of fibres, would also be liable to attack the iron of the drying cylinders on the machine, thus allowing iron compounds to penetrate the paper, producing what are commonly known as "rust spots" or "specks."

As we are all aware that any unstable compound of chlorine, existing either in paper or mounts, will sooner or later have a very detrimental effect on our photographic work, it is evident that the paper-maker must do his best to remove these last traces. There are two methods whereby this may be accomplished. These are: (1) Washing out the chlorine compounds with water; and (2) the addition of a substance which will neutralise the activity of the chlorine. The former method is undoubtedly the best, but would require a water supply such as no paper-maker dare even dream of. The latter method is therefore the only remedy which can be employed in daily work. The substances used for the purpose of counteracting the evil effect of chlorine are called "antichlors." Several antichlors may be used, the most common being hyposulphite of soda, sulphite of soda, pentasulphide of lime, and ammonia. I have mentioned them in the order in which they are most commonly employed by paper-makers, the first place being given to the photographer's great friend and enemy. The second on the list is also a powerful photographic chemical, though we cannot say that its presence has any harmful effect as possessed by hyposulphite of soda. Indeed, sulphite of soda is employed in photographic preparations solely to

prevent oxidation of other chemicals. Of the other antichlors mentioned, pentasulphide of lime and ammonia, the former is never employed in good papers; but, as I have already mentioned, some photographers like to choose their own mount, even though that mount be a sheet of brown paper. Such æsthetic taste may yet receive a sudden check by the discovery of the evolution of sulphuretted hydrogen between the æsthetic mount and the æsthetic frame which support and surround the æsthetic picture. I may say in passing that I have had some not altogether pleasant acquaintance with this antichlor. The last antichlor which I mentioned was ammonia, and, if it alone were used, the photographer would have no cause for complaint against the paper-maker. Why is it not employed?—(1) Smell; (2) cost—both of which reasons are prohibitive.

For the present we will turn our attention to hyposulphite of soda when used as an antichlor. If this substance is used in excess for papers which may be used in any photographic process, we must certainly be prepared for trouble. Hypo is the most powerful chemical which the photographer has to employ. If it exists in his dishes or on his fingers, stains will inevitably be produced on his prints or negatives. Hypo destroys the value of all other photographic solutions into which it finds its way. It is always used as a final solution in the treatment of photographic prints, and, if not thoroughly removed by washing, invariably causes the prints to fade or become discoloured. When using hypo as an antichlor, the calcium hypochlorite remaining in the pulp is decomposed, with the formation of more stable salts, such as calcium sulphate, sodium chloride, and hydrochloric acid.

If the water in which the pulp is suspended only contains a very small trace of chlorine compounds, then the decomposition may take place with the formation of sodium tetrathionate, sodium chloride, caustic soda and lime.

The first reaction is the principal one. The presence of hydrochloric acid as a product of the decomposition is in itself a source of considerable trouble for the photographer, even when there is no free hypo.

As the last process to which a photographic print is subjected is a bath of hypo followed by prolonged washing, it will be evident that, if the presence of hypo, or any of the products of its decomposition, were present in the paper, they will now be removed, and all tendency to further damage will cease. Hyposulphite of soda employed as an antichlor, and an excess remaining in the finished paper, may spoil the silver emulsion but it will not spoil the print after fixing and washing. Not so, however, with the mount, for the print will now be brought into contact with a paper which is liable to contain an excess of hyposulphite of soda or the products of its decomposition. In which case these, if present in any appreciable quantities, will cause the appearance of spots on the print, possibly accompanied by a general fading or degradation of tone. If, then, the presence of hyposulphite of soda can cause serious results, either in the paper or mounts, it is most desirable that the photographer should know how to detect their presence. A simple and efficient test easily carried out by any photographer, even without a special knowledge of chemistry, is to take a quantity of the suspected paper, boil with distilled water, and, after evaporating to convenient bulk, add a few drops of a solution of silver nitrate. If excess of hyposulphite is present, a brown colouration or brownish-black precipitate will be produced, the absence of which may at the same time be taken as conclusive evidence that excess of hyposulphite is not present in dangerous quantity.

There is still another substance which may be present in paper, and which acts injuriously upon a photographic print. This is ultramarine, used as a colouring agent, and very largely used by paper-makers. Ultramarine is a very complex body, and, if treated with alum or any acid substance, loses its blue colour, accompanied by the evolution of sulphuretted hydrogen. Ultramarine is occasionally present in the paper of mounts, and, as the mountant employed is frequently acid, this decomposition will take place, and the sulphur compounds thus liberated will almost certainly attack the silver of the print, producing yellow spots or other discolouration. A recognised test for the presence of ultramarine in the paper of the mount is to add a small quantity of acetic acid to the mountant, and paste a silver print upon the suspected mount. If ultramarine is present in injurious quantity, yellow spots will appear on the prints in the course of two or three days. You will, no doubt, observe that I have only referred to the mount as liable to contain ultramarine as a colouring matter, because a paper which been manufactured for photographic printing is always coloured with cobalt blue or smalt, which is not acted upon by acid bodies. Of course, if a photographer

wishes to use a paper which has not been made for photographic purposes, then he must first of all determine for himself whether the colour of the paper will remain fast, after being subjected to treatment with dilute acid.

I fear I have only done scant justice to my self-imposed task, because so much can be said on the subject of photographic paper and mounts. Photographers may, with benefit to themselves, give a little consideration to the subject of the paper upon which their prints are made, as it is of great interest to them. It is, no doubt, astonishing that, with all the processes, both chemical and mechanical, through which cellulose must pass before it can be formed into a sheet of paper of sufficient purity to meet the demands of the great army of users of photographic papers. Paper-makers of all countries have spent much time and money upon the production of a paper possessing all necessary requirements; but the difficulties of making a paper chemically pure, regular in thickness and weight, with suitable surface, were so difficult that most mills gave up the matter. The qualities required in a photographic paper can only be obtained by using the very best and carefully sorted linen rags, perfectly pure and free from iron or other substances which might cause spots to appear in the paper afterwards. It must be most carefully sized, so as to enable it to resist the softening action of the several baths to which it will be subjected. The surface must be even; all sorts of marks, specks, or pinholes, must be absent. Speaking universally, the paper trade has scored one of its greatest successes in the production of a paper which may be considered as practically faultless, for photography requires a paper which possesses only good qualities and no bad ones. There is, however, one great cause for regret, namely, that the British paper-makers have not been able to supply the demand, so that the photographer must go the Continent for his paper. The reason is, not that the British paper-maker cannot manufacture a paper possessing these necessary qualities, but rather because the photographer can get a thoroughly good paper abroad; he does not care to try experiments on a paper which may or may not meet his requirements.

J. EDINGTON AITKEN.

#### FOREIGN NEWS AND NOTES.

**Photography with a Fly's Eye.**—Particulars of an interesting experiment are given in the German periodical, *Mutter Erde*. The eye of the fly is of a composite nature, and consists of some 8000 lenses; but each of these only forms an image of a point perpendicular to the facet constituting the lens. The pictures upon the retina of a fly therefore resemble a mosaic. As the facets are in different planes, and are of various sizes and shapes, they do not all correspond in focus, and it is thus possible for the fly to see objects at various distances, although its visual organs have no power of accommodation. It is no easy task to mount a fly's eye suitably for photographic purposes upon a metal plate without injuring its form or structure; but, after many failures, satisfactory results were secured. It was found that 20 cm. between object and lens gave the sharpest results, and that the definition was more or less impaired at other distances; but negatives of bright objects, such as street lamps, the brilliant reflections of water, &c., were obtained up to a distance of 8 metres. To obviate the difficulties presented by the short extension of an ordinary camera and dark slides, a tubular camera, about one metre in length, was tried, but the intensity of the image was so much reduced, that three hours' exposure was necessary to obtain a passable negative.

**The Vienna Technical School and the Paris Exhibition.**—We learn from the *Photographische Chronik* that the exhibit of the Vienna Technical School will be of the most interesting kind. Among other novelties an improved process of printing in natural colours will be shown. This process is a modification of the three-colour printing process, but the greys, the deepest tones and shadows, are reproduced by a fourth printing by photogravure. The result obtained at the first trial of the process was so successful that it will be included in the exhibit. This work is a copy of H. Bartel's *Youth and Old Age*, and is said to be exceptionally perfect in its gradation and true rendering of the colours. Numerous other specimens by the same process, representing works by Alma-Tadema, Blaas, Darnaut, Schäffer, Pettenkofen, &c., will also be exhibited. It seems probable that this process will take premier rank for copying works of art. The exhibit will also include specimens by a number of other printing processes, such as photogravure, photogravure in colours, collotype, combined collotype and lithographic

printing, collotype from aluminium plates, process work, &c. Pure photography in portraiture and landscape will also be shown in a its numerous printing processes from albumen to gum-bichromate. The services of photography to science will also be represented by micro-photographs, spectrum photographs, radiographs, &c.

**A Test for Gilt Edges and Lettering.**—The *Photographische Chronik* recommends the following test: Remove any trace of grease from the stamping, lettering, or gilt edges to be tested, and apply a few drops of a ten per cent. solution of nitrate of silver. Real gold will not tarnish, but ordinary bronze and gold of very inferior quality (8 carat) will turn grey.

**Purifying Gelatine.**—The *Journal de la Société Chimique* recommends that gelatine should be purified by treatment with successive baths of water, diluted solution of potash, diluted acetic acid, water, and, finally, alcohol. Most of the mineral impurities will thus be eliminated. The gelatine should then be dissolved in warm water, filtered, precipitated with alcohol, dried, pulverised, and treated with ether. In this way the mineral constituents may be reduced in certain cases to twenty-five per cent., and the sulphur compounds to two per cent., of their original quantities.

**Discoloured Platinum Prints.**—The imperfect elimination of the iron salts from platinum prints causes the paper to turn yellow in the course of time, and Herr Gaedicke recommends a bath of 15 grammes of soda and 20 grammes of chloride of lime dissolved in 200 c.c. of water as a bleaching agent. By a curious mistake chloride of calcium was printed originally instead of chloride of lime, and, as Herr Gaedicke remarks, it would have saved some trouble if a handful of salt had been taken instead. Such a solution is quite useless for the purpose. A solution of soda and chloride of lime will precipitate carbonate of calcium, but the supernatant fluid is a powerful bleaching agent.

**The Studio Roof.**—The *Camera Obscura* contains an article upon this subject from the pen of Herr Alfred Parz-r-Mühlbacher. To those who think of building their own studios he recommends the use of good ordinary window glass, and, as it is generally slightly curved, care should be taken in glazing that the curves are in the same direction, preferably with the concave side upwards. If T iron is used for the rafters, there is great advantage in using the pattern with underneath channels, as it carries off any excessive condensation of moisture or drip. The durability of a roof depends largely upon the material used for fixing the glass in position. Changes in temperature cause unequal expansion of the glass and rafters, and the desideratum is a putty that combines sufficient elasticity and adhesiveness to keep the joints water-tight. The best putty is stiff and dries yellowish. If soft and white, it should not be used for the purpose. The following is recommended as an excellent composition instead of putty. Tear ordinary newspaper into small pieces, place it in an enamelled vessel and cover it with caustic potash lees. Boil it and add with constant stirring one-third the quantity of turpentine. Thoroughly mix and keep the solution hot; then add the following ingredients, which must also be dissolved in boiling turpentine:—

Ordinary pitch .....	10 parts.
Resin .....	3 "
Gutta percha .....	10 "
Wood tar .....	2½ "

The solution should be well stirred and boiled till it becomes a stiff paste, and should be used whilst still warm. The composition may be good; but we should advise considerable care in its preparation, as it must be highly inflammable.

#### SHIELDING.

THE many advantages that can be conferred by the simple operation of shielding are seldom thought of by those who at times are face to face with difficulties in photography. Speaking generally, most workers look upon a shielding operation as one more particularly connected with the printing of negatives, and seldom or never realise that in many other ways it proves of great value in producing results otherwise impossible of attainment without having recourse to its aid.

In the exposing of a sensitive plate even, many instances will be found in which, were it not for the simple operation of shielding, nothing like successful results could be obtained, and this applies not merely to a certain class of outside subjects, but to a large number of indoor operations as well. A striking example of the latter class of subjects may be given as showing what can be done by merely shielding a sensitive plate during exposure. The writer some little time ago was asked for his advice *re* the photographing of what undoubtedly appeared a difficult subject to reproduce by means of photography and half-tone process blocks. The subject in question was an oil painting possessing a charming sky effect of great delicacy, linked to a distinctly difficult tone of colour forming the rest of the picture, and the problem to solve was how to photograph the painting so as to retain the delicacy of the sky and at the same time bring out the detail in the darkest parts of the foreground. Several attempts had been made by different makes of plates, and quite a number of exposures given with the view of ascertaining what yielded the best results, the outcome of which showed that, whenever a sufficiency of time had been allowed to bring out the detail in the darkest portions, the sky became hopelessly clogged up, and, when exposure was made to suit the latter, the former was much undertimed. In addition to isochromatic plates, various coloured screens were tried at the back and front and between the lens, but without success, and on studying the painting the writer immediately suggested that the only means of accomplishing the feat was to resort to an operation of shielding, and on making such a suggestion he was informed that such had been already attempted without success. On making further inquiries as to how the shielding had been conducted, it soon became evident that an error had been committed even in this apparently simple operation, and this proves that there is even in shielding a good deal to be learned by those not possessed of much photographic experience.

In this case the failure was clearly attributable to the employment of a wrong shield. Now, many may imagine that the introduction of an opaque shield between an object that is being photographed and a sensitive plate can only have one effect, viz., the prevention of light reaching the plate; but this is clearly an error, as was proved by old collodion-workers forty years ago, when it was fully recognised by photographers that there was such a thing as at that time was termed auxiliary illumination, and this fact was actually used to advantage when very dark portions of an object had to be photographed simultaneously with lighter parts of the same subjects. At that time it was not uncommon to introduce *white* shields between the lens and the darkest portions of the object being photographed, the result of the introductions of such light-coloured shields being a distinct gain in the reduction on the sensitive plate where such dark objects should appear; this simple operation can be tried by any reader, and will be found to yield surprising results. It therefore follows that some consideration must be bestowed upon the colour of the shields employed whenever this operation is being resorted to.

In the case of the oil painting already mentioned a white opaque shield was the worst possible medium to employ, simply by reason that the white colour acted as an auxiliary illuminant, taking practically the place in a slightly lesser degree than the white sky of the painting, and, of course, yielding an out-of-focus, fuzzy effect.

The exposure that was found necessary to bring out the darkest parts of the picture was nearly four times that required for the cloud effect in the sky, and this difficulty was eventually overcome by the use of a transparent screen or glass shield wafted continually at a distance of about five or six inches in front of the lens in such a position as tended to intercept the pencils of reflected light emanating from the sky portion of the painting.

On development, the first plate exposed under such treatment yielded a perfect result, and from which a satisfactory half-tone block was produced.

It stands to reason that some consideration must be bestowed upon the colour of the transparent shields employed. The colour selected for this particular subject was signal green, and the plates used were isochromatics of medium speed, the lens being fitted with various coloured screens inserted between the combinations. These, of course, increased the time of exposure, which was over an hour.

The photographing of oil paintings requires a good deal of thought so as to render correctly the various colour values. It may be taken for granted, however, that judicious shielding of difficult portions plays a most important part when dealing with such subjects, and opaque shields are not by any means as serviceable as coloured transparent mediums. What the colour should be, or density of the same, is a matter that can only be left to the judgment and experience of an operator.

The advantages of sky shades or shields in outdoor work was more appreciated years ago than at the present day. Doubtless, the extreme sensitiveness of plates that are now in use makes their employment less practicable than was the case even twenty years ago; but it cannot be said that the bulk of the work shown as the result of rapid exposures is any better than was produced by even a dry plate, such as Wratten & Wainwright's splendid slow plate of about 12 sensitometer yielded when used in conjunction with a shield, a striking example of which may be mentioned as designed by Mr. Charles Parker, and drawings of which were given in THE BRITISH JOURNAL OF PHOTOGRAPHY under date

November 9, 1883. As I write, examples produced by means of this simple little instrument lie before me, and they are charming.

Shielding, however, may be said to enter into every branch of photography, in none of which, perhaps, does it prove more efficient than in daylight enlarging. Here it will, when judiciously employed, work wonders, for thin portions of a negative are, with the greatest ease, kept back until the denser portions of a negative are brought out.

As a rule, this class of enlarging is generally conducted in rooms having an abundance of space, and it is quite a luxury for an operator to be able to move comfortably about between the easel and lens, and carefully scan the projected picture on the easel, seeing where the slightest improvement could be effected by merely wafting, in some instances, his finger across the denser part. In conducting this same work by means of artificial light the same thing holds good; in fact, some negatives could never be made to yield passable results were it not for shielding some parts of them.

In the making of lantern slides we find another fruitful source of improvement by means of shielding, both when making slides by contact and the more perfect method of reduction by through the camera.

Innumerable instances will be found, when making slides through the camera, that merely wafting a piece of cardboard in front of the ground glass that is interposed between the light and the negative will give very superior results to when such wafting was not conducted, and there are very many instances, especially with negatives that have been produced by rapid-shutter exposures, in which it would be next to impossible to make lantern slides from at all were it not for having resort to a suitable method of shielding. An example may be mentioned such as is quite common when, say, a paddle steamer has been photographed whilst going at full speed. In subjects of this kind the water is always represented as of much greater density, by reason of the churning into a white foam of the same, than the other parts of the picture, such as the hull, and, without shielding off the entire parts of the negative that does not contain the water until such time as the white water is exposed fully up, no passable result can be produced.

In a case of this kind a useful plan to follow is to first pull off a silver print, and cut out, slightly within the water run, the portions of the print showing the white water. This cut-out shield is then fastened to a sheet of glass the same size as the negative, and, by means of studs, is placed in front of the negative for the necessary time required to print up the water; it is then removed, and the rest of the negative exposed. This is a most important factor in lantern-slide making, and is the only means whereby some difficult printing negatives can be made to yield anything like pleasing results.

In copying, again, it will often be found that it is only by shielding some parts that any good can be done, and it is well to bear in mind, when intercepting any shield between a lens and an object, especially at any distance from the lens, that a white shield will affect the plate somewhat; therefore attention must be given to the colour of the shield employed.

A. T. NEWTON.

#### THORNTON'S IMPROVEMENTS IN CAMERAS.

[Patent No. 6754 of 1899.]

MR. THORNTON says: All the rigid parts of the camera I make from aluminium sheets stamped out by a press or other means to the desired shapes. Thus the body or case, *A*, the front or lid, *B*, the lens-carrier or support, *C*, are all stamped from or made of sheet aluminium, *a*.

The aluminium sheet is rolled or formed in the usual way, and is preferably on one surface, printed, coated, or enamelled with a covering composition, *b*, to exactly represent in appearance mahogany or other wood. It is then stamped to the desired shapes for the different parts of the camera, and the blank is covered on the plain side with leather paper cloth or similar flexible material, *c*. The cover leather paper or cloth, *c*, is cut a little larger than the corresponding aluminium metal blank, the edges, *d*, of the cover extending or overhanging beyond the edges of the blank all round.

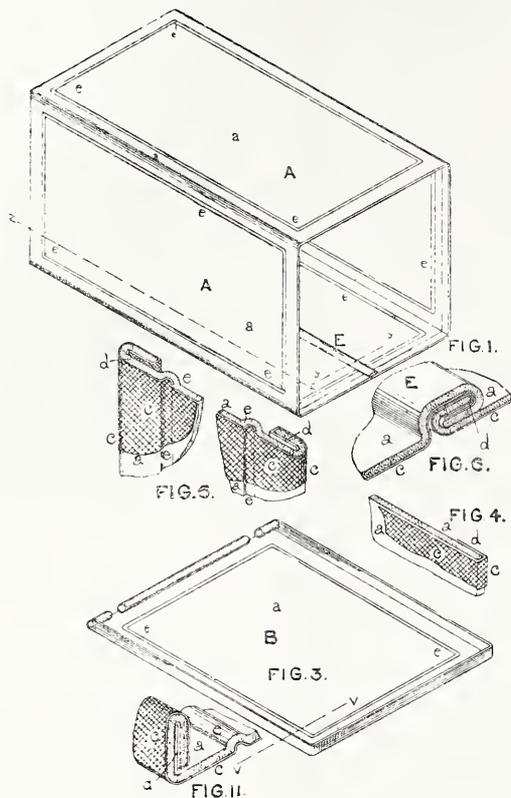

The flexible covering, *c*, is secured to the aluminium blank, *a*, by any suitable adhesive material applied all over the surface or to the edges only as desired. The overhanging edges, *d*, of the flexible covering, *c*, are turned over on to the opposite side of the aluminium blank, *a*, as shown in fig. 4.

The edges of the covered aluminium blank, *a*, are next turned over upon themselves and upon the flexible cover, *c*, to produce a rim of double thickness, along each edge, for the purpose of giving stiffness and rigidity to the article. By this construction comparatively thin aluminium sheet can be used whilst obtaining great strength and rigidity at the edges.

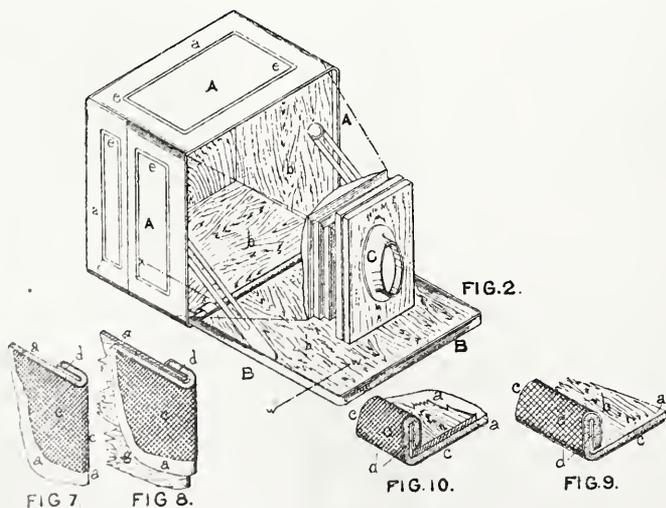

The flexible cover, *c*, of leather or other material is by the same operation turned over into the interior, and is there gripped between the two surfaces of the aluminium. It thereby presents a complete cover or finish to the edges and is also perfectly secured in position. Paste or adhesive material may in some cases be dispensed with between the cover, *c*, and the aluminium, *a*, the cover being alone secured by the gripping of its overhanging and overturned edges, *d*, by the metal.

The turning over of the aluminium, *a*, and cover, *c*, together, to stiffen the edges, stretches the leather tightly on the metal and presents a very good finish.

In this way an aluminium blank, *a*, has been formed covered with leather or other flexible material, *c*, preferably manufactured to resemble or look like leather, and it is now only necessary to shape or bend this into proper form for the various parts of the camera, and to secure the joints finely together to complete the finished article.

This operation is done by the aid of formers, dies, jigs, or other suitable means, such as are well known and understood. The jointing may be done in various ways according to the shape of the blank and of the finished article. For instance, in making a camera body of elongated box form open at the two ends, as in fig. 1, the join or seam, *E*, would be produced either by hooking the adjacent edges into each other and then clinching them together, or a lap joint riveted, screwed, or other-

wise secured, may be used instead. These ordinary methods are well understood.

The box, or other article, is afterwards ornamented at the corners, joints, and other desired places, by heated press tools or other convenient means.

In order to stiffen the body, *A*, baseboard, *B*, front, *C*, box, or other part of a camera, I form indented or raised stiffening ribs, *e*, by pressing

in suitable dies. This may be done either before or after the metal has been bent into shape.

In some styles of camera it is desirable to make certain parts, such as the inside of the body, *A*, the inside of the baseboard, *B*, and the front or lens-carrier, *C*, look like polished mahogany. This may be done by printing, enamelling, or colouring the surface of the metal, or by covering same with paper or other similar flexible material made to imitate or resemble the grain of the mahogany, or by covering with or inserting a thin veneer, *g*, or layer of polished mahogany or other ornamental wood, as in figs. 8 and 10.

The enamel or printing will preferably be applied to the aluminium sheets before being cut or shaped, but, if so desired, may be after being cut or shaped.

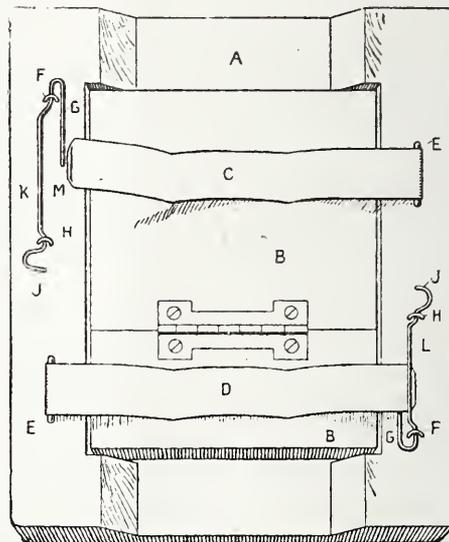

The metal being first leather-covered, the finished effect will be that of a piece of polished mahogany covered with leather on the opposite side, and having a narrow border of leather round the edges of the polished sides. If desired that the turned-over edges shall be flush with the polished surface of the veneer, the latter may be rabbeted round the edges for metal to fit into. The whole is clenched in a press to complete. It produces a cheap and yet first-class finished result, and warping and bending is entirely prevented.

### HUDSON'S PRINTING FRAME.

[Patent No. 25,657 of 1899.]

INSTEAD of looping the two ends of the swivel round the eye or small staple, which secures it to the side of the printing frame, the inventors make the swivel at one end with a bend, and pass it through the staple or eye, then we further bend the extremity in the form of an elongated *U* with the other portion of the swivel, bringing it to project under the bent lip of the flexible metal strap. At its other extremity the swivel is bent to pass through the staple or eye, and is then curved round into a loop or bend, so as to be capable of being manipulated by thumb pressure, as hereinafter explained, for releasing the strap.

When the swivel lies flat against the side of the frame in its inoperative position, its bent limb, which forms the *U* portion, stands up somewhat, and in such a manner that, when the flexible metal strap is pressed down, it forces the bent limb or *U* portion of the swivel down-

wards, which operation thereby raises the swivel portion, and brings it over the lip formed at the extremity of the flexible metal strap, securing or fastening the same in position automatically, or at one operation.

To release the strap, the loop or thumb portion at the opposite end of the swivel is pressed back, which disengages the same from the lip formed on the strap, and allows the latter to spring or fly back.

*A* is the photographic printing frame; *B* its back, which is secured in position by the flexible metal straps, *C* and *D*, pivoted at the respective sides of the frame, as shown at *E*.

Two of the new form of swivel, *K* and *L*, are represented for securing the ends respectively of the two flexible metal straps, *C* and *D*. These swivels, at the outer end of the frame, after passing through the eye or staple, *F*, are bent into a projecting limb, *G*, which forms with the swivel a kind of elongated *U*. When the swivel lies flat against the side of the frame, this limb projects upwards somewhat. At their other ends the swivels are bent and passed through the eye or staple, *H*, and then curved or curled to a suitable shape to admit of thumb pressure, as shown at *J*.

The swivel, *K*, is shown in its inoperative position, whilst, on the contrary, the flexible strap, *D*, is represented as being secured by the swivel, *L*.

When the end of the flexible strap, c, is pressed down, it forces down limb, g, of the swivel, k, and thereby brings the latter over the lip, m, of the flexible strap, c, which thereby becomes secured in position in an exactly similar manner, as shown by the strap, d.

The flexible straps, c and d, are instantly released by thumb pressure on their curled ends, j, which action causes the flexible straps to spring or fly back, and the back, B, may then be removed, and also, if need be, the picture.

### THE FORTHCOMING EXHIBITION OF THE ROYAL PHOTOGRAPHIC SOCIETY.

THE Forty-fifth Annual Exhibition of the Royal Photographic Society will be held at the New Gallery, 121, Regent-street, London, W., from October 1 to November 3, next. The Exhibition will be divided into five sections, namely: I. Selected pictorial photographs; II. General professional work; III. Photographic apparatus and material; IV. Photo-mechanical processes of reproduction; V. Scientific photography and photography in its technical applications. We subjoin extracts from the prospectus relating to the manner in which it is proposed to administer these sections:

#### SECTION I.

##### *Selected Pictorial Photographs.*

The West Gallery will be set apart for this section. The same general lines which have characterised the Pictorial Section of the Society's previous Annual Exhibition, will be followed. Portraiture, landscape, architecture, figure studies, exterior and interior work, stereoscopic prints and transparencies, lantern slides, &c., by any process, will be included, and both competitive and non-competitive work will be admitted.

Medals will be placed at the disposal of the Judges. No exhibit will be eligible for an award unless, with the exception of mounting and framing, it is entirely the work of the exhibitor.

Lantern slides will not be eligible for an award unless both the negatives and slides are entirely the work of the exhibitor. If an award be made, it will be to an individual slide.

#### SECTION II.

##### *General Professional Work.*

The North Gallery will be set apart for a non-competitive Exhibition of general professional work, including portraiture, figure studies and groups, landscapes, architectural and engineering photographs, exterior and interior work, &c. No restrictions are imposed as to date of production, or as to the previous exhibition of work for this section.

The Section will be under the management of the Organizing Committee. Although it is wished, in this section, to allow the utmost latitude, the right is reserved to reject any work that is considered to be unsuitable.

Allotment of space and charges.—Two methods will be adopted:—

(A). Space will be let to exhibitors who wish to make a collective exhibit of their work. They may arrange and hang it themselves, or, at their request, it will be arranged and hung by the Committee. Drapery and other decoration will be allowed; but the scheme of decoration proposed to be adopted must be submitted to, and approved by, the Committee. Space will be charged for at the rate of 5s. per foot linear, payable on allotment. The Committee do not bind themselves to allot any particular position, but will duly consider priority of application in their decision. Application for space (specifying the amount required) must be made by letter, addressed to the Secretary of the Society, on or before Saturday, July 21. A plan of the North Gallery can be obtained on application to the Secretary.

#### SECTION III.

##### *Photographic Apparatus and Material.*

The Central Hall and South Gallery will be devoted to an exhibition of photographic apparatus and material of every description used in photography. The exhibits will be divided into two sub-sections—competitive and non-competitive. Apparatus entered in the competitive sub-section may also be exhibited in duplicate in the non-competitive section.

(A). Competitive.—The competitive exhibits will be displayed in the South Gallery, and will be dealt with by the Technical Selecting Committee. No apparatus that has been shown at any previous Annual Exhibition of the Society will be eligible for admission unless it possesses some new feature, which must be specified on the entry form. All exhibits must be concisely described, and any that have been already shown at a London exhibition may be refused. Every exhibit will be catalogued, and, where it is considered desirable, described and illustrated. Pulls of blocks illustrating such exhibits, which may be available, should accompany the entry form. A removable label must be attached to each exhibit, bearing the name of the exhibitor and the number to which it refers in the entry form. During the Exhibition the exhibits will be under the supervision of an attendant provided by the Society.

(B). Non-competitive.—The non-competitive exhibits will be under the management of the Organizing Committee, and will be shown in the Central Hall. The exhibits in this sub-section will not be catalogued. The Committee have set apart certain space which will be let for the erection of stalls, and applications for space, which must be made by letter, addressed to the Secretary, on or before Saturday, July 21, will be

considered in order of priority of application. Stall-holders will have to provide their own tables, stands, counters, show-cases, &c., and all structures, displayed signs, notice boards, &c., will be subject to the approval of the Committee. Attendants, if necessary, must be provided by the exhibitors. Orders for goods may be taken at the stalls, but no delivery at the Exhibition will be allowed. Catalogues, circulars, and price-lists may only be distributed from the stalls. Any special lighting of stalls required will be arranged for where possible, at the exhibitor's expense. No exhibitor will be permitted to transfer or sub-let any part of the space allotted to him, and no substance of a dangerous or explosive nature will be allowed in or on any such space.

#### SECTION IV.

##### *Photo-mechanical Processes.*

This Section will include all exhibits relating to or illustrating any process of photo-mechanical reproduction, viz., photogravure, line and half-tone photo-engraving, photo-lithography, collotype, photo-zinco-graphy, Woodburytype, polychromatic printing, &c.

Medals will be placed at the disposal of the Judges, but non-competitive work will be admitted.

#### SECTION V.

##### *Scientific Photography and Photography in its Technical Applications.*

This Section will comprise examples of work shown for its technical qualities, and apparatus used in photographic investigations: The various processes of colour photography, the photographic reproduction of paintings, drawings, maps and plans, photographs by artificial light, photography applied to industrial and educational purposes, astronomy, spectroscopy, geology, meteorology, microscopy, medicine, surgery and the Röntgen rays, surveying and engineering, zoology and botany, tele-photography, new processes, enlargements, photography applied to military purposes, recording instruments, &c., negatives, transparencies, stereoscopic prints and slides, lantern slides, and general work.

Exhibits may be excluded unless the points of special technical or scientific interest are distinctly stated.

Medals will be placed at the disposal of the Judges, but non-competitive work will be admitted.

### THE NATIONAL PHOTOGRAPHIC EXHIBITION.

THE Second National Photographic Exhibition, under the management of Mr. A. C. Brookes, opened at the Portman Rooms, Baker-street, on April 27, and closes to-morrow, Saturday, May 5. Music, lectures, and cinematograph exhibitions were provided for the entertainment of visitors for whose information and instruction in the more serious subject of photography about sixty firms had taken the opportunity of making a display of their specialities in apparatus and material. Compared with its predecessor of two years ago, the present Exhibition is decidedly larger, while it is more varied in nature, inasmuch as the element of manipulative photography is stronger, more than one firm giving practical demonstrations in the working of their printing papers, &c.

It would be absurd to pretend that the present Exhibition is the means of introducing any startling novelty to the photographic world, but of its comprehensive usefulness there can be no question. We go the length of saying that nobody interested in photography could fail to profit by an afternoon passed in examining the rich collection of photographic apparatus, &c., now to be seen in the Portman Rooms. Manufacturers and dealers may inspect the newest productions of their competitors; professional and amateur photographers can gratify their individual predilections by the careful scrutiny of the very latest efforts of those business houses whose aim it is to cater for the ever-increasing number of photographers.

When all is said and done, this is, or at any rate should be, the prime aim of such an Exhibition, and we are bound to say that the Portman Rooms display amply achieves that aim.

A detailed notice of the Exhibition would read very like a dealer's catalogue with a few adjectives thrown in, a literary production that is a weariness to the flesh of all concerned. We must therefore content ourselves by merely giving a list of the principal exhibitors and an indication of the dominant features of their displays. The Editorial Table pages of this JOURNAL for months past, and the "Novelties in Apparatus Section" of our 1900 ALMANAC have contained full descriptions of the newest introductions in photographic apparatus, &c., as they have appeared, so that on the present occasion we are absolved from going over the ground again.

We may say, however, that we have notes of several of the season's novelties that are being put forward by some of the exhibitors, and to these we shall devote separate references in our pages as occasion offers.

Amongst the exhibitors are Messrs. Seabrook, Bros., & Co., who have a good collection of the Manhattan Optical Company's Wizard Cameras on a tastefully decorated stall; Messrs. T. Illingworth & Co., who are to the fore with some capital carbon and bromide enlargements and a stand of apparatus; Mr. Frederick Boehm, who has a stand well filled with the chemical specialities of E. Merck and other houses; Messrs. F. H. Taylor & Co. (bottles and measures); J. Lancaster & Son, with many

new designs of cameras, &c.; Marion & Co., who show an admirable collection of prints on Mariona papers of various kinds, bromide papers, quick-print papers, demonstrate the toning of P.O.P. papers and development of quick-print papers, and have a very large stand stocked with an immense variety of apparatus; H. F. Purser, whose exhibit consists of the Busch aplanats and other lenses; The Thornton-Pickard Manufacturing Co., Ltd., whose well-known shutters and cameras give opportunity for a well-arranged exhibit; The Photo-chromosome Syndicate; Butcher & Son (a large stand loaded with apparatus appealing to amateurs); David Allan, with a capital collection of print-washers, &c., and dark-room furniture; George Houghton & Son, whose stand is one of the most crowded and artistically arranged in the room; William Tylar, with novelties in the shape of the Dreadnought acetylene generator, and a new acetylene gas-jet; Secco films; The Warwick Trading Co.; The Columbia Optical and Camera Co.; Morgan & Kidd, with beautiful specimens of printing and enlarging on their bromide papers; enlargements by the bromide, carbon, and platinotype processes; photo enamels, collotype printing, and half-tone process blocks; C. P. Goerz; Rogers & Webster, with specimens of artistic picture frames for photographs; Harrington Bros., chemicals; J. Lizars; Joseph Levi & Co.; O. Sichel & Co.; J. J. Griffin & Son, Ltd.; L. Gaumont & Cie.; R. W. Thomas & Co., Ltd.; W. H. Assender & Co., Ltd.; Prestwich Manufacturing Co.; &c.

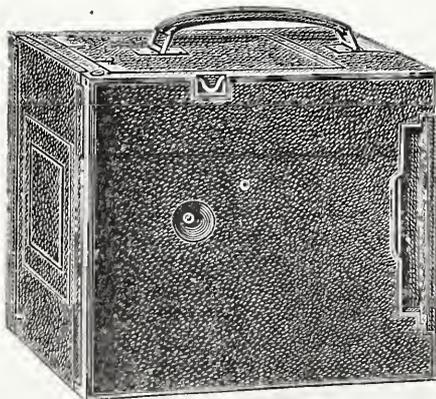

The Exhibition, which we trust to hear has been successful, is open today and to-morrow from 12 to 10, and we recommend our readers to pay it a visit. It is compactly arranged in a suite of rooms not too large for the purpose; and the person interested in photography who could not derive some knowledge or benefit from an hour or two passed in studying the varied contents of the stands must be a hopelessly dull individual. The greatest credit is due to Mr. A. C. Brckes for his work of organization

## Our Editorial Table.

### THE ADAMS REFLEX HAND CAMERA.

Manufactured and sold by Adams & Co., 26, Charing Cross-road, W.C.

IN March last some correspondence appeared in our pages on the subject of reflector hand cameras, several readers ventilating their ideas with respect to their requirements in the matter. The attention thus directed to the peculiar characteristics of this class of instrument invests the introduction upon the market of the camera now under notice with considerable interest. Without going so far as to say that in the Adams Reflex Hand Camera all tastes and idiosyncrasies are anticipated—a “large order” somewhat difficult of execution—we may yet allow ourselves to remark that a careful examination of the camera leaves us in doubt as to whether it omits the inclusion of any feature desirable in an instrument showing a full “sized finder image,” while we should be just

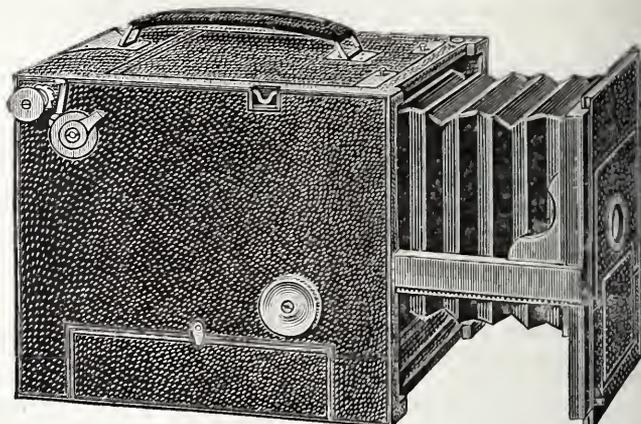

as much puzzled to suggest any respect in which the vital movements of the camera could be improved upon so as to afford the acme of convenience to the photographer with the minimum amount of mechanical outlay.

The Adams Reflex Hand Camera takes 5×4 pictures, and only measures 9 in. × 8½ × 6½, with a weight of 6½ lbs. The illustrations respectively show the camera entirely closed; extended for long-focus work, and with the funnel-shaped hood, 6½ inches high, opened for allowing of an examination of the finder image. The lens aperture is entirely controlled from the front of the camera, a small board being let down to allow of the diaphragm being revolved in accordance with an engraved scale. A focal range of from 6½ to about 13 inches is given by the camera.

The patent focal-plane shutter employed and the mirror are practically part and parcel of one system, for the movement that releases the mirror releases the shutter at the same time, virtual instantaneity and simul-

taneity being assured, and smoothness and noiselessness characterising the double motion. The method of controlling the shutter is exceedingly ingenious. The driving spring is always wound to its full tension, and the different speeds are obtained by varying the slit, command over which is obtained by means of a knob outside the camera. These speeds are marked on the “blind,” and are visible from the outside of the camera; they range from one-thousandth to one-tenth of a second, and time exposures are also available.

Double dark slides are used in the camera, space in the bottom of which is provided for carrying two not placed *in situ*, but a focussing

screen is also fitted for stand work. The rising front, which is available for either horizontal or vertical pictures, moves to the very great extent of one and a half inches, a long rise on a 5×4 plate.

In the foregoing brief description we have only outlined the main features of the Reflex hand camera, which, we need hardly say, has all the old familiar Adams excellence of construction and exquisite finish, but of the instrument as a whole it is right to say that it embodies the reflector principle to perfection. The serious worker will assuredly

appreciate the Adams Reflex, at once a high-grade and a high-speed machine. In all its parts and movements it bears skilled analysis and scrutiny. You see your finder image perfectly and to the full size, and the control of your lens aperture and your shutter speed are obtainable with the least expenditure of power. The remaining details of the camera have been carefully thought out, and we have no hesitation in recommending the Adams Reflex to the class of photographers for whom it has been designed.

### CATALOGUES RECEIVED.

Rae Brothers, Glasgow, Paisley, and Perth.

THIS is a well-printed and illustrated catalogue of about 160 pages, giving detailed particulars of an immense variety of photographic apparatus and material. Both amateurs and professionals will find it of use for consultation, for it makes reference to the requirements of both classes of photographers. Moreover, it has the added advantage of being well up to date as regards its contents.

The Columbia Optical and Camera Company, 42, Goswell-road, E.C.

In this catalogue we have particulars and prices of a large collection of American-made photographic apparatus, amongst which are Bausch & Lomb's Unicum shutters, Gundlach's shutters, the Turner-Reich convertible anastigmat lenses, the Recto, Monroe, Kozy, Korona, and other cameras, and a variety of other photographic apparatus.

Thomas Illingworth & Co., Willesden Junction, N.W.

THIS catalogue appeals both to professional photographers and the trade for it gives prices and particulars of Messrs. Illingworth's specialities in backgrounds, bromide enlargements and printing, canvas enlargements (bromide), carbon enlargements and printing, circle frames, collotype printing, copying or making negatives, developing, finishing enlargements, framing, gelatino-chloride printing, carbons on ivory, Kodak developing and printing, lantern slides, enlarged negatives, painting enlargements, oil paintings, orthochromatic photography, process blocks, platinotype enlargements and printing, retouching, silver printing, toned bromide enlargements, toning and fixing, Vigo enlargements.

#### SPECIMENS OF FRAMES FOR PHOTOGRAPHS.

Manufactured by Rogers & Webster, 161, High Holborn, W.C.

THE samples of frames for photographs which Messrs. Rogers & Webster have submitted to us, appeal to the most refined taste. We should like to see a more general employment of such aids, to showing off photographs to the best advantage, so that in time the common and gaudy gilt frames which are so prevalent nowadays, would no longer offend the eye, and disfigure our walls. Messrs. Rogers & Webster's specialities comprise walnut ovals and circles, with gold lines and square outside frames, and the surfaces are of a rich warm brown colour, a tint well suited to the majority of photographs irrespective of tone. The frames have keyed corners thus preventing shrinking, and the workmanship is English and excellent. Panels with relief designs are others of Messrs. Rogers and Webster's specialities, which we have pleasure in bringing to the notice of our readers, who wish to be in touch with the latest ideas in photograph framing. Many of the most prominent London professional photographers are adopting these coloured hard wood frames, which deserve very high praise.

## Studio Gossip.

MR. WALTER MACFARLANE has purchased the portrait business of Greenway, Brothers, of 339A, High-street, Cheltenham, and is conducting it under his own name.

ACCORDING to the *Daily Mail*, Mrs. Smith, of Blackpool, a medium who takes part in the *séances* of the new spiritualist church at Wolverhampton, told those assembled there recently that, on the previous day, after all arrangements had been made in the hall for the opening service on Sunday, she and one or two other friends sat quietly in the place for about an hour, indulging in spirit thought. The spirit forms of Dr. Berry, Ward-Beecher, and John Ruskin entered the hall. She saw and recognised each very plainly. This was corroborated by Mr. Aldridge, of Wolverhampton, who for some years has been connected with Spiritualism. An admirer of Dr. Berry in the audience asked whether it would be possible to photograph the "spirit" of the doctor, so as to convince the sceptical. It was explained, in answer, that spirit photographs were not unknown, but that certain conditions were essential.

"B.-P.'s" PHOTOGRAPHIC STAMPS.—We read that a prominent postage-stamp dealer was interviewed about "B.-P.'s" new stamps at Mafeking. Undoubtedly the stamps on photographic paper, reported to have been issued by Colonel Baden-Powell, will be accepted as genuine if they were issued of necessity. What the reported "surcharged" stamps are, however, is a mystery. Supposing the ordinary town postage at Mafeking to be a penny, the Colonel has no right, from a stamp-collector's point of view, to surcharge penny stamps a shilling on account of the extra risk in delivering letters under fire. The laws of philately may seem absurd, but they are immutable. If the postmaster at Mafeking ran out of 2½d. stamps, and surcharged other stamps, these would have a high value. Colonel Baden-Powell may increase postmen's wages, but any surcharged for this cause will not obtain acceptance among philatelists.

SHYNESS IN OUTDOOR PHOTOGRAPHY.—Writing in the *English Mechanic* on outdoor photography, a correspondent of that journal says: "I believe that shyness is one of the chief causes of failure. An operator must not fear being conspicuous, and he will often have to encounter some harmless public ridicule if he means to be successful. We will take street processions as an example. Frequently (due to the large number of sightseers) it is impossible to get a desirable position on the road or footpath. As to chamber windows, they are too high. My own method is to mount a pair of steps, or to stand on something else I provide which places me above the heads of the spectators, and usually I am fairly satisfied with the results. I get a friend or two to stand near my platform, to guard against accidental overthrow. There may be a slight measure of risk, but encounter of that is usually to be on the right side of the line between success and failure. Crafty, stealthy movements are, of course, sometimes desirable, in order to secure some subjects (so that the

subject is unaware of being shot at, and so driven to seek cover), but I am convinced that a too retiring disposition on the part of the amateur photographer accounts for very much of our commonplace, unsatisfactory work."

AMUSING THE BABY.—"When a baby doesn't want to have its photograph taken," writes an American journalist of a humorist turn, "it is a pretty difficult feat to persuade it to the contrary or to fool it. A baby knows when it doesn't want to be photographed, and it resents all efforts to the contrary on the part of its mother, father, grandmother, and aunt, who have come along to assist in the ceremony. Every one joins in the effort to persuade the baby to be good and be photographed, until it is tired out with the noise and the attention, and its little whimpering cry, with the wrinkled nose and distended cheeks and crossed eyes, gives way to a lusty bawl. At this the efforts of the baby's friends and the photographer are redoubled. The baby bawls the louder. The photographer blows whistles, beats a tambourine, stands on his head, and kicks his legs and shakes a rattle until his arm is tired. Occasionally the baby gets slightly interested and stops crying for a moment; but, as soon as the photographer sets to work to make the photograph, it begins to cry again. At this the photographer gives up, and is driven to his last resort to keep the baby quiet for a few minutes. He burns paper! No one knows why a baby will stop crying long enough to be photographed when it sees paper burning, but it does. When the baby grows up, he will stand and watch with some degree of enjoyment a building burning down—a sort of savage instinct, probably. However that may be, a lighted newspaper on the floor will cause a crying baby instantly to desist. His eyes will assume a beautiful baby stare, his baby lips will part in pleased wonderment, and, before the paper burns up or the gallery burns down, the photographer has made the picture."

## News and Notes.

THE Richmond Camera Club held a *Conversazione* in the Prince's Hall at the Star and Garter Hotel, Richmond, on Thursday evening, April 26.

HACKNEY PHOTOGRAPHIC SOCIETY'S EXHIBITION.—The dates fixed for the Hackney Photographic Society's Annual Exhibition are November 21-23.

THE Annual Dinner of the Camera Club will be held in the Club large room on Thursday, May 10, 1900, at 7.30 p.m., Sir William de W. Abney, K.C.B., F.R.S., &c., in the chair.

ROYAL PHOTOGRAPHIC SOCIETY.—May 8, Ordinary Meeting, at 66, Russell-square, at eight p.m. Mr. Chapman Jones, F.I.C., F.C.S., will read a paper on "The Effects of Colour on Gradation." The exhibition of photographs (mainly architectural) by Mr. F. H. Evans, now on view, can be viewed on presentation of visiting card.

MR. WALTER D. WELFORD writes: "A very little error in your paragraph last week as to my demonstrating the Thornton film, viz., the number of the road being printed as 168 instead of 166, has led to some inconvenience. If 'Warwick Lodge' is on the envelope, it is all right, but 166 is in the Stratford delivery, whilst 168 is in Forest Gate. Moreover, the occupier of 168 has expressed annoyance at the letters being delivered there. Will your readers kindly note that the number is 166, Romford-road, E. By the bye, I might mention that the film in future will be known as the Thornton film."

THE Ninth Annual Exhibition of the Brixton and Clapham Camera Club was held last week. For the best individual collection, the silver-gilt medal was awarded to Mr. Tryhorn for a series of remarkably fine architectural studies, the silver medal going to Mr. W. E. Dunmore for a set which included what, in the opinion of the Judges, was the best photograph in the room, a winter study in a London-street, an exquisite example of this class of work. Bronze medals were also awarded to Mr. F. W. Levett and Mr. R. Fisher. There was a loan collection, which included work by Messrs. Harold Baker, W. Thomas, W. T. Greatbach, and others, and, if not so large as some of its predecessors, the Exhibition contained some high-class work and very little indifferent photography.

THE COMMERCIAL SEPARATION OF PLATINUM FROM GOLD.—Scraps, filings, &c., of gold containing platinum are put on one side in minting operations, as the ordinary methods of gold refining cannot be applied to them with success. The following method has been successfully used by the author when dealing with large quantities of such scrap. The sifted filings are digested with nitric acid of 1.199 density, until no more silver is dissolved. During this operation a small quantity of platinum also goes into solution in the form of platinum-nitrite of silver. The metallic residue is washed and exhausted with aqua regia of the following composition:—Concentrated hydrochloric acid, 100 volumes; concentrated nitric acid, 43 volumes; water, 143 volumes. When the chloride of silver which deposits on the surface of the metal stops all further action, the solution of chloride of gold is decanted, and the chloride of silver removed by washing the metal with a little ammonia. The metal may then be treated a second time with aqua regia. After six successive treatments with aqua regia and ammonia, the metallic residue consists of pure platinum. The acid solution which contains the gold is evaporated down with an excess of hydrochloric acid, to drive off the nitric acid, until the chloride of gold crystallises. The chloride of gold is redissolved, and the small quantity of platinum present is precipitated by means of chloride of ammonium. Finally, the gold is precipitated by ferrous sulphate. The filings treated by the author contained:—Gold, 28.05 per cent.; silver, 10.56 per cent.; platinum, 45.46 per cent.; copper, 15.93 per cent. If the metals form a true alloy, it is preferable to previously melt this alloy with 3 parts of lead, or, what is even better, 3 parts of zinc. The metal is then granulated and treated with sulphuric acid, which dissolves the zinc, and the spongy residue is treated in the manner above described.—E. PRYWOZNIK in *Esterr.-Zeits. f. Berg. u. Hüttenwesen*, 1899, p. 356.

## Commercial Intelligence.

THE Thornton Film Company, of Altrincham, Cheshire, announce that they have in preparation, and will shortly issue, a new film, which will be supplied on daylight loading spools, and known by the trade name of "Dayroll," and will be supplied in flat cut pieces for all descriptions of cameras.

MR. W. O. STANLEY, having resigned his appointment as manager for Messrs. Stanley & Co., of 1, Clare-street, Dublin, begs to notify that he intends resuming business on his own account as photographic camera and scientific instrument maker, at 31, Lincoln-place, Dublin, on and after May 1, 1900, trading as William Stanley.

MESSRS. WERTHEIMER, LEA, & Co., inform us that, owing to the termination of their leases at London Wall, and the decision of the Corporation to widen that thoroughfare, they have been compelled to obtain new premises for their works, and to transfer their offices to 46 and 47, London-wall, first floor (six doors from Moorgate-street).

MR. ARTHUR RAYMENT, late of the well-known house of Perken, Son, & Rayment, Hatton-garden, E.C., informs us that he has taken up the wholesale agency for the United Kingdom of the celebrated firm of Steinheil & Sons, of Paris and Munich. All the optical and other productions of Messrs. Steinheil will be included in Mr. Rayment's agency, the new orthostigmats, the antiplanats, tele-objectives, shutters, &c., being listed in his catalogue. Messrs. Steinheil fit Kodak and other cameras with their lenses and shutters, a branch of the business to which Mr. Rayment intends devoting attention. Mr. Rayment has had over thirty years' experience in the photographic trade, and is well known and esteemed all over the country.

SPECIAL SERIES OF WAR PICTURES.—By special arrangement with the proprietors of the *Sphere*, Messrs. Eyre & Spottiswoode are publishing a series of photographic reproductions of "Scenes at the Front," from sketches made on the spot for the *Sphere* by special artists. This series comprises the following subjects, as opalines, size 8x6 inches, on plush or khaki:—1. The Fight for Spion Kop; 2. How Lord Roberts's son won the V.C. at Colenso; 3. The Brave Piper at Magersfontein; 4. The Dublin Fusiliers Crossing the Tugela; 5. The Attack on Spion Kop by the Lancashire Fusiliers; 6. The Queen's (Royal West Surrey) Regiment advancing at Colenso; 7. Sailors at the Front. Messrs. Eyre & Spottiswoode also announce that they have made arrangements to publish, in cabinet size, printed in first-class style by the Woodburytype process, a series of portraits of the Generals at the Front. The first set will comprise the following:—Field-Marshal Lord Roberts, V.C.; General Sir Redvers Buller, V.C.; Lieut.-General Sir George White, V.C.; Lieut.-General Lord Methuen; Major-General Hector Macdonald; Major-General Sir W. F. Gatacre; Major-General Hon. N. Lytton. The photographs will be suitably mounted upon titled mounts.

THE PATENT LAWS AND FOREIGN COMPETITION.—It is pointed out, in the current issue of *Feilden's Magazine*, that most of the injury done to British taxpayers by our patent system is the result of the disconformity existing between our patent laws and those of foreign nations. Thus, for instance, in Germany, France, or Austria, the patentee, during the lifetime of his patent, may take out supplementary patents relating to improvements. These additional patents, however, expire simultaneously with the main patent. In England such additions are not provided for. The foreign inventor consequently takes out ordinary patents for them, and the result is that his invention continues often to have a monopoly for many years yet after it has expired in his own country. The most unfair point, however, insisted upon by *Feilden's Magazine* consists in the injury done to the British taxpayer, arising from the fact that we grant annually about nine thousand monopolies in excess of those granted by Germany, which means that there are thousands of articles protected in Great Britain for which the Government of our commercial rivals refuse patents. The articles so protected are manufactured in Germany, without any restriction or royalty, at a cost considerably lower than they could be manufactured here. The German manufacturers, therefore, supply the British demand at their own prices without adding a penny to the imperial or local taxation.

### ROYAL PHOTOGRAPHIC SOCIETY.

APRIL 25,—Mr. Chapman Jones, F.I.C., F.C.S. (Vice-President), in the chair. "ONE-MAN" EXHIBITION BY MR. F. H. EVANS.

Mr. F. H. EVANS formally opened an exhibition of his architectural and other work, constituting the third of the Society's series of House Exhibitions. The collection comprises views of Kelmscott Manor (once the home of the late William Morris), the cathedrals of Lincoln, Canterbury, St. David's, Gloucester, Ely, Wells, and Bourges, Beverley Minster, the New Forest, Epping Forest, and Redlands Woods, lakeland, some fine studies of sea and sky, and some very striking portraits, including two of the late Aubrey Beardsley. In the course of his introductory address, Mr. Evans said that in his architectural work he was attracted by the beautiful and artistic aspects of the subjects rather than influenced by their architectural or antiquarian value. Architecture lent itself most readily to photographic reproduction, and the so-called mechanical exactitude of the camera was an element of importance in the rendering of far finer and more abundant detail than was possible to the painter or draughtsman. In the hands of an artist photography was capable of yielding true effects of light and shade, accurate drawing, good composition, and all the elements that architecture demanded, and it was certainly not a mechanical method. His chief aim had been to produce such effects of light and shade as would give an irresistible feeling that one was in an interior, with solidity and perfection of perspective, and atmosphere and massiveness of outline. All the prints were in platinotype, the variations of colour being due to the character of the negatives, and in some cases to the condition of the paper, the differences in the negatives arising from the nature of the subject and not from the method of development. They were all from untouched negatives, except that a little ordinary spotting had sometimes been necessary. When working on the back of a negative, he found it all but impossible to avoid upsetting the natural gradations of the subject and introducing false lighting, and it was useless to spend time in trying to make bad negatives yield good prints. Plain prints from plain negatives was, he thought, pure photography; he was content with pure photography, and it was not such a bad road to travel by towards the goal of art. Whatever printing process was adopted, success was dependent upon the quality of the negative and the conditions under which the photograph was taken; if these were correct, and exposure adequate, a platinotype or carbon or gum-bichromate print would be equally good. He urged photographers to be content with pure photography, and in architectural work especially deprecated dodging and altering the negative or the print; photographs that seemed to have been taken by a light that never was by land or sea, had no interest for him. The study of black and white would be found to greatly assist young photographers, and to help them to analyse a subject, and to see when it was best capable of adequate translation into monochrome. Referring to his landscapes, Mr. Evans said that most of them were taken with a Burchett colour screen, and the clouds were on the same plates. He could not bring himself to believe in the possible success or legitimacy of using cloud forms not taken at the same time and place as the landscape, and the method of printing in clouds could only be satisfactory by the luckiest of chances. If the clouds were in the negative, they induced the feeling that they were an integral part of the picture; but alien cloud forms, and working on the back of the negative, made a photograph incoherent, puzzling, and wearisome. The question whether photography was art had been much discussed, and was generally limited to intelligent assertion on the one side and ignorant assertion on the other; but might not photography, at any rate, be considered worthy of a place amongst the crafts? He had often tried to repeat some of his negatives, but invariably failed, and he challenged any one to go to any of the places depicted in the Exhibition and bring back the same thing with mechanical accuracy. If this did not mean individuality, it meant nothing, and individuality was the basis of all art. Nearly all his portraits were taken with a Dallmeyer-Berghem lens, in a studio formed by knocking two attics into one and adding a side light. The Spring Exhibition at Burlington House could show quite as many dreadful things as the Autumn Exhibition at Pall Mall, and he hoped he would never have to say, "I cannot draw, I cannot paint, and to photograph I am ashamed."

The CHAIRMAN was very pleased to hear Mr. Evans say that his pictures were pure photography, and not mixtures of photography and something else which no one could define, and for which mixture no one had been able to find a name.

Mr. J. C. S. MUMMERY was glad that Mr. Evans had spoken so strongly and so tritely about double printing and alien clouds, a subject which he had done well in bringing so prominently forward.

Mr. W. THOMAS entirely dissented from the assumption that the best and most truthful atmospheric qualities were always to be obtained by the use of only one negative; if falsities were introduced, they did not arise from the method of using two negatives, but from the ignorance of the person who introduced them. Every practical photographer knew that one negative could be made to render, and to render successfully, some phases of atmospheric conditions; but his opinion, based upon some little experience, was that improvements could be made, and more truthful reproductions sometimes obtained, by the employment of a separate cloud negative. This, however, must be done with skill and knowledge, and if one had not these one had better not try double printing.

The Exhibition will remain open daily during the present month, and tickets of admission may be obtained on application to the Assistant Secretary at the Society's rooms, 66, Russell-square, W.C.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 26,—M. S. Herbert Fry in the chair.

Mr. WALTER D. WELFORD, alluding to the fact that a statement of his some time ago, that he could develop a negative to full capacity in sixty seconds, was received with incredulity by one or two, said that he was now prepared to guaran-

tee to do the same in twenty seconds repeatedly. He was quite in agreement with a remark that it was a course not to be recommended in certain particular cases, but, in dealing with quantities of work which was just as well done one way as the other, the saving of time was enormous. The developer was a combination developer, and he proposed at an early date to give a demonstration of its rapid action, and also of the continuing action of the ortol developer, by means of which it was possible to finish the development of a plate removed from the solution just after the appearance of the image by holding it under running water.

Mr. H. C. RAPSON complained that ortol had a strong staining action upon his fingers, which were of a marked pink colour after a few hours' use of this developer at the weak strength of the normal solution.

Mr. WELFORD remarked that it was entirely without effect on himself, even after fifteen hours' continual use, and that therefore, as with other developers, it must be a personal question—some it stained and others not.

Then followed a long discussion of a conversational nature upon the characteristics and qualities of the various films which are now upon the market.

A great deal of the uncertainty and want of reliability in celluloid films was attributed by Mr. HADDON, in the first place, to imperfect washing of the pyroxyline used in the preparation of the celluloid, apart from defects of the emulsion itself.

The question of grain in negatives upon films having originally a paper support was alluded to, as well as that of the avoidance of cockled results after stripping, opinions for and against such films being freely expressed.

PHOTOGRAPHIC CLUB.

APRIL 25.—Mr. Charles Wallis in the chair.

Mr. E. A. NEWELL gave an exhibition of lantern slides, part of a series illustrating London, upon which he was engaged. Starting from the west and proceeding eastwards, he showed successively views of the statuary and other details of the Albert Memorial, Lambeth Palace and Bridge, the Houses of Parliament, Westminster Abbey, the Clock Tower, the lions in Trafalgar Square, Somerset House and the Embankment, Goldsmith's Tomb, Tower Bridge, and some pretty little bits on the river down to Rotherhithe. Other miscellaneous views were of Midhurst Castle, Canterbury, the country round Llanberis; Surrey; and, in Belgium, Dinant, Antwerp, &c., including a view of the old Steen Castle before restoration. The London views were all hand-camera work, bright, and picturesque, and reminding one that there is an endless store of subjects for the camera at hand, well worthy of attention, without the necessity to go far afield, as is so often imagined. The warm colour of the slides, produced by pyro-ammonia development, was very pleasing and suitable.

The SECRETARY read a communication from the Paris Exhibition authorities, stating that the use of hand cameras was allowed without payment, the charge for stand cameras, until, one o'clock p.m. being 25 francs per day, or 1000 francs for the season.

**Richmond Camera Club.**—At the meeting on the 23rd ult. Mr. W. E. Dunmore, of the Tella Camera Company, gave a demonstration of the various unique points of this most ingenious hand camera. By means of a model with glass sides the working of the changing mechanism was very clearly shown, and the manner in which the exposed film was transferred to one chamber while the celluloid separator took its way to another was studied with much interest. Mr. Dunmore showed some slides which well supported the claim of the Tella to be capable of turning out good work. Incidentally they also spoke well for the quality of the films used, viz., those supplied by the Tella Company, and of the Cooke lens fitted to the camera. A cordial vote of thanks to Mr. Dunmore and the Tella Company concluded the meeting.

**Aintree Photographic Society.**—At last week's meeting a large gathering met to take part in a descriptive tour through the "Lowlands of Scotland," by Mr. Daniel J. Niell, who proved to those present, by exhibiting some seventy lantern slides of places of interest closely associated with Sir Walter Scott and the "peasant" poet, "Bobbie" Burns, that there is ample material in this part of "bonnie" Scotland to satisfy the most fastidious "globe-trotter" photographer, and who might from his negatives make up a most interesting lecture, or even a series of lectures, not only of landscape, but many interesting architectural subjects, especially if he is lucky enough to secure a number of views of the elaborately beautiful Melrose Abbey.

FORTHCOMING EXHIBITIONS.

1900.

- May 23-25 ..... Plymouth Photographic Society. Hon. Secretary, W. H. Harris, 5, Clarendon-place, The Hoe, Plymouth.
- July 9-14 ..... Photographic Convention of the United Kingdom (Newcastle-on-Tyne Meeting). Hon. Secretary and Treasurer, F. A. Bridge, East Lodge, Dalston-lane, London, N.E.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

Patent News.

THE following applications for Patents were made between April 17 and April 21, 1900:—

- BACKGROUND.—No. 7042. "Improved Background or Screens for Photographic or other purposes." W. BROOKES.
- NEGATIVE DRYER.—No. 7065. "Improved Means of Drying Photographic Plates or the like." W. BROOKES.
- "PRODUCING PICTURES."—No. 7381. "Improvements in the Method of and Means for Producing Photographic Pictures." C. A. BURGHARDT.

Correspondence.

- \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

THE KEEPING QUALITIES OF PLATES.

To the EDITORS.

GENTLEMEN,—A letter received this morning seems to confirm the correspondence to you on the 18th inst. with reference to the keeping qualities of our plates. Please see from enclosed what Messrs. Lavis, of Eastbourne, say.—We are, yours, &c., MARION & Co. 22 and 23 Soho-square, London, W.C., April 28, 1900.

[The letter to which Messrs. Marion refer is from the well-known photographers, Messrs. G. & R. Lavis, of Eastbourne, who write that some time ago they developed a 12x10 Marion plate nine years after exposure and found it all right.—Eds.]

RENOVATING BLINDS.

To the EDITORS.

GENTLEMEN,—Like your correspondent, D. McFarlane, I have been troubled in the same manner. It is a difficult operation, and requires both skill and experience to do them well; here is the *modus operandi* as practised upon mine, they roll up flat and even.

After being washed and well rinsed, whilst wet, starch them, hang them out smoothly on a line to dry—not on a windy day; when nearly dry, place them evenly on a smooth ironing board, covered with a blanket; let them be ironed with a hot iron, they will then lie flat and even—patience and care will overcome all the bagginess.—I am, yours, &c., W. GIRLING.

Answers to Correspondents.

- \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street Strand, London, W.C. Inattention to this ensures delay.
- \* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

- A. Mallett, High-street, Christchurch, Hants.—Photograph of Lieutenant G. R. Stephens.
- A. B. Gardiner, 14, Grey-street, Newcastle.—Photograph of group of Boys' Brigade of St. Mary's, Newcastle.
- Rev. W. C. Johnson, Yaxham Rectory, East Dereham, Norfolk, and R. W. Howes, East Dereham, Norfolk.—Photograph of miniature of the poet Cowper.
- A. J. Webber, 41, Darlington-street, Wolverhampton.—Photograph of New Cross House, New Cross, near Wolverhampton. Photograph of the foundation-stone of the new Workhouse at New Cross for Wolverhampton.

VIEW.—The articles you mention may be obtained of such houses as Messrs. Marion, Soho-square, G. Houghton & Sons, High Holborn, W.C., and others, whose addresses you will find in our ALMANAC for 1900.

REFLEX.—The first-named camera is fully reviewed on another page; the other instrument was noticed in the JOURNAL for March 23 and 30. It is strictly against our rule to make recommendations of the nature asked for.

**BROMIDE.**—1. Messrs. Morgan & Kidd, Richmond, the London Stereoscopic Company, 54, Cheapside, and other firms whose addresses will be found in our ALMANAC, undertake such work. 2. Messrs. Sharp & Hitchmough, Dale-street, Liverpool, might be able to supply you. 3. For portrait work, pure and simple, we should advise a portrait lens.

**STUDIO-BUILDING.**—T. BETTS. A studio but twenty feet long is very inconvenient for general professional work. As you can get any length, we should advise you to have it from five to ten feet longer. Your suggestion to have five feet at either end as merely a small tunnel in which the camera can be run, as occasion requires, is excellent, and will answer every purpose.

**F. A.**—We have had no personal experience of the process, but theoretically either strength should answer, provided that your image has been thoroughly fixed and cleared. From the description of your trouble, we imagine you have failed in one of these respects. With a pure deposit of silver you should get the tone mentioned. A short washing after toning is all that is required.

**USE OF THE RULED SCREEN.**—AJAX writes: "I am asked to take a photograph of a silver-print photograph. A print from my negative will be used for making a half-tone block from, as a book illustration. Shall I get a better result if I use a ruled screen when making my negative?"—Better send the original print to the block-maker; or, if you copy it, send your copy. The block-maker will then copy it with the screen that suits his purpose best.

**POUNCEY'S OIL-COLOUR PROCESS.**—ARTIST writes: "Could you kindly inform me by what process Mr. Pouncey produced oil paintings direct on canvas without a photographic base? Is the process a patent, or have the rights expired?"—Pouncey's process was on a photographic base by the bitumen process. There were two patents, both of which have expired. They were numbered 267, 1863, and 3849, 1868. You can obtain the complete specification at the Patent Office for 8*d.* each.

**BLINDS FOR STUDIO.**—J. H. W. says: "My studio has a south-west light, and the sun, at times, gives trouble. The top blinds at present are white, and, when the direct sun is on the studio, there is a great glare in it. Would any other colour be better than white, as I must put up new blinds of some sort shortly?"—With a studio with such an aspect we should have a tolerably dark green for the blinds and curtains. These would avoid the glare complained of, and be a pleasant light for the sitters.

**PROCESS WORK.**—S. S. G. writes: "A local paper wants to reproduce four of my photographs. Will you please tell me how to make the blocks? also, whether one of the costly ruled screens is an absolute necessity for the work?"—Yes, and a properly arranged camera to take it. Our correspondent had better send his photographs to a process block-maker to do the work for him, as it would not pay him to purchase the necessary screen, and then learn how to use it, merely to produce four blocks.

**PROMISSORY NOTE.**—SWINDLE. If you gave a promissory note for the apparatus, we expect you will have to meet it when it becomes due. It will be no defence to an action upon it that you now find that the things are not of the value you were led to believe. You saw them beforehand, and had the opportunity of judging their value. Old and obsolete photographic apparatus should, of course, not be assessed at its original catalogue price; that you should have been aware of when you made the purchase.

**IMPROVED LIGHT.**—SNAP-SHOT says: "Kindly tell me what is the matter with the two negatives sent herewith, which I hope you will receive without breakage? All the negatives I have developed lately have turned out like these."—The only thing the matter with the negatives is that they are much over-exposed. The light during the last few weeks has much improved, and also become more actinic, and this has not been sufficiently allowed for in the exposures. Bear in mind that just now the actinism is about reaching its zenith.

**THE CHROMATYPE PROCESS.**—A. BIGNOLD asks what was the chromatype process and how was it worked?—A chromatype is a highly glazed carbon print produced in this way: The print is developed on a collodionised plate that has been previously waxed to facilitate its being stripped from the plate when finished. When the print is developed and dried, one or more thicknesses of softened double transfer paper are squeegeed upon it and allowed to dry, and the whole stripped off. Usually the name and address of the photographer was produced at the bottom of the picture by double printing.

**LENS FOR STUDIO WORK.**—W. W. J. asks: "Is there any great disadvantage in using a long-focus lens for portraits? My case is this: I have taken premises with a studio about thirty-five feet long, and the only lens I have at present is a '3A' portrait, but this requires about twenty-five feet between sitter and camera for a full-length cabinet portrait. Will that be a disadvantage?"—No; on the contrary, it will be a great advantage, as the pictures will be in better perspective and more pleasing than if a shorter-focus lens were used. The fault in so many portraits is that they are taken too near the sitter.

**COLLOTYPE PRINTING.**—COLLOTYPE writes: "Why cannot the necessary appliances for working collotype be obtained here, for I am told they can only be obtained from Germany? Is there no house here enterprising enough to supply it, and why? Can you give me the address of any house in Germany from whom I could get a small outfit, and the probable price?"—Messrs. Penrose & Co., Baker-street, Lloyd-square, W.C., supply all the appliance for the collotype process, and have done so for some years past. Better apply to them for a price-list. You see your strictures on lack of British enterprise are not warranted by facts.

**PHOTO-SCULPTURE.**—R. PARKER. So far as we are aware, there is no one in this country who is producing plaster busts by photo-sculpture commercially. Both the patented processes mentioned you are free to work, as the patents expired many years ago. We can offer no opinion as to whether you would find photo-sculpture take with the public at the present time, even if the prices charged were moderate. We should, however, be rather inclined to doubt it.

**THE COLLODION PROCESS.**—T. T. says: "I am an operator out of employment, and, like many others, find a difficulty in getting a job. Is the wet-collodion process difficult to learn, as I might, if I could work it, perhaps, get employment with some of the process workers?"—The wet-collodion process is not difficult to work to those who understand it; but it requires to be learnt, and it is very different from the gelatine process with the plates bought ready for exposure. All the old manuals give full working details of the wet-collodion process.

**RECOVERING GOLD FROM TONING SOLUTIONS.**—GOLD says: "After using sulphocyanide toning bath, I throw it away, and I am certain there is some of the gold in it, as I don't stint the gold when making up. Can you inform me how to reduce it? In the fifties, with albumenised paper, I used to reduce it with iron, but I suppose that will not act with the sulphocyanide."—The gold may be precipitated with the sulphate of iron as in the method you used to employ. It will be well to acidify the iron solution before adding it.

**LECTURES ON PHOTOGRAPHY AND THE SPECTROSCOPE.**—H. E. S. writes: "I read about two months ago that a course of lectures would be given at, I think, University College on photography and the spectroscope. I think the paragraph was in your paper, but cannot find it again. What I want to know is, Are the lectures published; and, if so, could I obtain a copy? If you could help me in this matter at all, I should be much obliged, as I have looked in vain in most of the photographic papers for a reference to the subject again. I venture to trouble you, as your paper always seems to me to deal with the scientific side of photography to a greater extent than any of the others."—In reply: We have not seen mention of the publication of the lectures in question, but perhaps this insertion of our correspondent's question may elicit definite information on the point.

**STUDIO-BUILDING.**—W. W. SMITH writes: "As I am troubled very much in getting my sitters dark in the hair, and also people with light blue eyes and sometimes brown eyes, I get very strong catch lights in their eyes, and they are always finding fault with same. Could you inform me, through your valuable JOURNAL, which way I could remedy these defects? Enclosed you will find photographs. I think the negatives are fully exposed; also I have drawn a plan of studio. Studio painted orange green, but I am thinking of painting same light gray. N.N.E. light. Blinds, white cotton. You see, between my side light there runs a dark wall, but between side light and dark wall, there will be about three feet space to let the light (side light) travel up. Top light open. Do you think whitewashing dark wall would be of any service? Length of studio, thirty feet. I have twenty feet of running glass top and side, and I use Imperial Sovereign plates; also their standard developer."—The fault in the portraits is that they are badly lighted. Too much direct front light has been employed, and the negatives are also under-exposed. The sketch shows that the studio is all that can be desired if rightly used. It might be a slight advantage to have the wall whitewashed.

**TONING, MOUNTING, &C.**—S. G. ELLIOTT writes: "1. The toning bath made up as follows: water, 20 ounces; sulphocyanide of pot., 20 grains; gold chloride, 2 grains, which, according to a leaflet I have, should tone twenty-four half-plate prints a purple black, only tones three or four half-plate prints when placed one at a time in a half-plate developing dish with a portion of the toning solution. The leaflet above mentioned says that several should be toned together, but this would appear to necessitate a very large dish, which is not altogether in keeping with an amateur's requirements. I purchased a combined bath (pint) some time back from a local chemist; this toned about thirty-six half-plate photographs a very dark colour, and kept well. Could you, please, quote a formula, either separate or combined, that would keep and meet the above requirements, or suggest a satisfactory method of carrying out above? 2. I have some difficulty in mounting P.O.P. photographs which have been polished on a ferrotype plate; they lose some of the gloss, and do not go down quite firm on the mount, but are somewhat blotchy and irregular. I have no difficulty in mounting photographs, when wet, with the aid of a roller and linen as advised; but, when mounting dry, the result does not at all please me. The mountant used is Higgen's; this I brush all over the back of P.O.P., which I then place on mounts and roll. Could you suggest a remedy, please, as I much prefer the polished surface, and am anxious to improve the mounting? 3. Can dry plates be made into positives? if so, how? 4. What formula is used for positive dry plates, and where are they obtainable?"—1. The bath should, if the chloride of gold was good, tone the number of prints mentioned, or, a proportionate quantity, a proportionate number. It is better to keep the gold and sulphocyanide in separate solutions, and mix when required for use. A formula for a combined toning and fixing bath is given on p. 1075 of the ALMANAC. 2. If you desire to retain the full gloss, you had better use the backing paper supplied, specially for the work, by all the dealers. 3. Ordinary gelatine plates are not suitable for positives. 4. Dry plates for positives are supplied by Fallowfield & Co. We do not know by what formula they are prepared.

\* \* \* Owing to exceptional pressure on our space this week, we are compelled to hold over many answers to correspondents, reviews, and other matter.

## EX CATHEDRÂ.

THE *Handbook* of Imperial plates and papers issued by the Imperial Dry Plate Company, of Cricklewood, London, N.W., is a decidedly instructive and useful publication which we can recommend to the studious attention of all photographers, be they "Imperialists" or not. The formulæ are expressed in both the English and metric systems, and there is added, for the first time, a developing table giving the time of appearance of image and the total time of development for the Company's plates and papers. In the section of the book devoted to exposure notes there are half-tone reproductions from photographs illustrating the subjects given in the exposure table: sky and sea, a light interior, a panorama, a dark interior, river scenery, and a glade under trees. Other articles in the book deal clearly and tersely with the after-treatment of faulty negatives, stops, home portraiture, &c., and, by way of supplement, there is given a series of half-tone reproductions of negatives illustrating the article first named. These illustrations show on transparent paper negatives before and after

intensification, and before and after reduction, while the positive results are printed on ordinary opaque paper. The *Imperial Handbook* is obtainable gratis of dealers and the Company, and the useful object-lessons it contains make it well worth having.

By the kindness of Mr. C. H. Talbot, of Lacock Abbey, Chippenham, we have received a statement of the present position of the Fox Talbot Memorial Fund. It is the first financial statement yet issued. The proposed memorial takes the form of the restoration of the chancel of Lacock Church, Wilts, and the estimated cost is 1000*l.* The following is a list of the subscriptions received since January 1, 1900: Mr. R. P. Brereton, 1*l.* 1*s.*; Mrs. Hamilton, 2*l.*; Miss Ellen Spedding, 1*l.*; Mr. G. P. Fuller, 5*l.*; Mr. Charles Awdry, 10*l.*; Mr. W. Steward Bell, 25*l.* The balance in hand on December 31, 1899, was 80*l.* 1*s.* 9*d.*, so that at present the fund amounts to 214*l.* 2*s.* 9*d.* We may again remind our readers that the following comprise the Committee: The Right Rev. the Lord Bishop of Bristol; the Rev. H. W. Armstrong, Lacock Vicarage, Chippenham (Hon. Secretary); Miss Awdry, Notton House, Chippenham; Mr. E. Eyres, Ray Mills, Chippenham; Mr. J. E. Gladstone, Bowden Park, Chippenham; the Rev. W. G. Clark-Maxwell, Clunbury Vicarage, Aston-on-Clun, Salop; Mr. T. Pike, Lacock, Chippenham; Miss Talbot, Lacock Abbey, Chippenham; Mr. C. H. Talbot, Lacock Abbey, Chippenham (Hon. Treasurer); Mr. A. J. Tanner, Lacock, Chippenham. Subscriptions may be paid to the account of the Fox Talbot Memorial Fund, at the Capital and Counties Bank, Chippenham, through any of the metropolitan and country branches of the bank, or they will be received by the Hon. Treasurer, Mr. C. H. Talbot.

\* \* \*

MR. W. G. COLLINGWOOD'S *Life of John Ruskin*, which has just been published by Messrs. Methuen, contains a paragraph relating to a meeting with Longfellow at Verona, which incidentally shows the great art critic to have been even more sympathetically disposed towards photography than is commonly supposed. The paragraph runs: "As I was drawing in the square this morning, in a lovely, quiet,

Italian light, there came up the poet Longfellow, with his little daughter, a girl of twelve or thirteen, with springy-curved flaxen hair—curls, or waves, that wouldn't come out in damp, I mean. They stayed talking beside me some time. I don't think it was a very vain thought that came over me, that if a photograph could have been taken of the beautiful square of Verona, in that soft light, with Longfellow and his daughter talking to me at my work, some people both in England and America would have liked copies of it." It is quite obvious from this that a good many years ago the author of *The Stones of Venice* and *The Seven Lamps of Architecture* had a great appreciation of the possibilities of pictorial photography, otherwise we can hardly imagine him indulging in reflections so eminently favourable towards it. Few modern art critics would care to put on record such an aspiration as the one which we have quoted. The fashion amongst these gentlemen is to decry photography whenever the chance offers.

\* \* \*

MR. W. H. PICKERING, writing in *Popular Astronomy* on the forthcoming eclipse, expresses the opinion—one, we believe, peculiar to himself—that direct photographs of the solar corona have not very much scientific importance. He is inclined to believe that their chief value is an æsthetic one. If well taken, he thinks they form attractive souvenirs of what is undoubtedly one of the grandest celestial phenomena on which the eye of man has ever rested, and it is this æsthetic enjoyment attained, which, it seems to him, will constitute the chief gain of the majority of the expeditions which will view the eclipse. But, if photographs are of little value, drawings are worse than useless, since it is quite impossible during the brief time available during totality to represent, with the least pretensions at accuracy, even a very restricted area of the corona. In Mr. Pickering's opinion the time spent in looking at the paper might much more profitably be expended in watching the eclipse itself, and he recommends those who visit the eclipse region at their own expense to spend but little time in attempts at scientific work. This is a strange and, of course, unconscious comment on the elaborate eclipse preparations by English observers, to which we briefly refer this week on another page. It will probably interest our readers to learn that the special correspondent of THE BRITISH JOURNAL OF PHOTOGRAPHY on this occasion will be Mr. Nevil Maskelyne, who has kindly promised us a series of descriptive articles on the work done by the British Astronomical Association's Expedition.

\* \* \*

MR. W. HOLT, of Fairholme, Manor-road, High Barnet, writes us: "After reading in your valuable paper the articles on 'Vignetted Negatives and Vignetting,' I think it may interest your readers to know that I have lately invented and patented a machine by which vignetted negatives can be obtained direct. Doubtless you will remember publishing a specification of same some few weeks ago, previous to which I wrote you, enclosing some proofs of half-tone results produced by the same machine. (No. of Patent, 5386, 1899.) I beg to enclose a portrait of myself (exposure of which was three seconds) merely as an example of its capabilities, also the negative for your inspection, which kindly return at your convenience." Those of our readers interested in Mr. W. Holt's vignetting machine will find it described at page 171 of the JOURNAL for March 16. We also perceive that it figures in the April number of *Process Work*, issued by Messrs. Penrose & Co., of Upper Baker-street,

E.C., who supply the machine for 16*l.* 16*s.* Judging by the half-tone pictures and the portrait Mr. Holt has been good enough to send us, the machine vignettes admirably. You may imagine, however, that its somewhat high price must restrict its use to engraving establishments.

#### PAPER AND ITS ADAPTABILITY TO PHOTOGRAPHIC REQUIREMENTS.

THE paper read by Mr. J. Edington Aitken before the Edinburgh Photographic Society, "On Paper-manufacture, with Special Reference to its Photographic Uses," which was published in our last issue, is one of particular interest to photographers. Many of them have but a vague idea of how paper is made, or of what modern papers are composed, and Mr. Aitken has enlightened them considerably on the subject. Paper used to be made exclusively of rags, but now comparatively little rag is used in its manufacture. Other materials, such as the cellulose from esparto grass, wood fibre, straw, &c., are now more generally employed. In his paper the author shows that he is thoroughly *au courant* with the manufacture of paper, and also with photography, which makes the essay doubly valuable, more especially where he points out the pitfalls that beset the photographer, not only with regard to the paper upon which the picture is printed, but also with respect to the paper in which the emulsions on paper plates may be packed. What is of really still more immediate importance to photographers, as he points out, is the paper employed for the mounts upon which the photographic plates are to finally rest.

So far as the paper is concerned, such as that used for albumenising, and turned out from the well-known factory in the Rives district, and that by the Steinbach firm in Malmø, both those papers are probably the purest in the market, and they may be implicitly relied upon for all photographic purposes; but other papers, which are not specially made for photographic work, though often used in silver printing, such as the rough drawing-papers employed by amateurs for "artistic" effects, may give rise to trouble. In these papers there are sometimes chemical impurities that are fatal to photography, though they are excellent in every way for the purposes for which they were specially manufactured.

For the emulsion paper of the P.O.P. type, the photographic paper just referred to is not employed, but a cheaper kind, though much, if not all, of it is made at the same two factories. In the case of the emulsion processes the same purity of paper is not so imperative as in the albumen silver process for the reason that it is usually "surfaced," "baryta-coated" and this coating, to an extent, insulates the emulsion from the paper itself, so that the latter is rendered more or less inert. "Baryta white" (sulphate of baryta) may be considered, practically, an inert body; it has, however, to be applied to the paper mixed with a vehicle such as size, starch, flour paste, &c. the like, to secure it to the paper. Now, this adhesive substance may not be an inert compound, and it may have a material influence on the keeping qualities of the emulsion film before use, and also on the stability of the finished picture. If the P.O.P. emulsions consisted of chloride of silver, pure and simple, the case might be different, but they also contain free nitrate of silver, as well as an organic acid, such as the citric or tartaric. These, with the silver, enter into combination with the sizing material that cements the pigment to the

paper, and often are the cause of the rapid discolouration of the paper. It is often found that the discolouration of P.O.P. is first noticeable on the back, though the emulsion on the front is still white. This is more marked in the case of collodion papers than it is with gelatine ones; but, in either case, it shows that it is not the emulsion that has become discoloured, but the coating on the paper and the paper itself. It may fairly be assumed that, if the pigmented coating and its combination with the constituents of the emulsion is the chief cause of the deterioration of printing-out papers, by keeping, it may also be inferred that it may have an important influence on the permanence of the finished picture.

Mr. Aitken, in his paper, did not touch upon this subject, but, of course, it has no reference to the manufacture of the paper itself, but he dwelt upon matters of equal importance to photographers. One of them was the effect that some of the commoner papers, brown paper and the like, used for parcelling plates and emulsion papers, may have on the keeping qualities of the emulsion film, even though it does not come in actual contact with them. Years ago we pointed out that the deterioration of plates packed with an air space between them was largely due to emanations, with changes of temperature, from the paper and boxes in which they were parcelled.

One of the most important points dwelt upon by the author of the paper was the paper of which mounts are composed, and the impurities they often contain. Ultramarine, it is mentioned, is often used to give a tint, or an artificial blueness. Ultramarine is a sulphur compound, readily decomposed by any acid. If a little dilute acid be added to some ultramarine, sulphuretted hydrogen is set free, and will be readily recognised by its smell, and one can easily realise the effect it might have upon a silver picture. A perhaps still more important subject in connexion with paper for photographic mounts is the presence in it of some of the antichlor used, in excess, to destroy the last traces of the chlorine employed in bleaching the pulp, which is hyposulphite of soda. It will be manifest to every one that it is very little use for the photographer to take every precaution to eliminate all traces of the fixing bath from his prints if they are to be afterwards mounted on boards the paper of which contains hypo. Mr. Aitken, in his paper, gives a simple method of testing for hypo, which we here quote: "Boil the suspected paper or mount in distilled water, then evaporate to a convenient bulk, and add a few drops of a solution of nitrate of silver. A brown colouration indicates the presence of hyposulphite." There are other tests for its presence that are perhaps more delicate, but this is a simple and practical one. There are, however, often other materials in paper and mounts than ultramarine and hypo that may effect the stability of silver photographs.

Some years ago Mr. E. W. Foxlee published a very simple method of testing photographic mounts that requires no chemical manipulation whatever. Briefly, it is this: Take an unmounted albumen print, and place it, face downward, on the suspected mount, over one half of which place some insulating material, such as two or three thicknesses of paraffined paper or a thin piece of celluloid, and over this lay a piece of pure paper, say the Saxe or Rives photographic paper, and bind the whole together at one end with a couple of paper-fasteners. Now put into a pressure frame with several thicknesses of moistened blotting-paper at the back, and a plate of glass on the top to prevent evaporation of the moisture, and

screw up tightly; keep in a moderately warm place for two or three weeks. We now have one half of the print pressed in close contact with the mount, and the other half protected from it, but all of it kept damp. A silver print, under these conditions, is bound to fade sooner or later; but, if that half which is in contact with the mount shows deterioration before the other, and it sometimes will in two or three days, it is obvious that the mount is the cause. In introducing this method of testing, Mr. Foxlee assumed that photographers were not so much interested in knowing what was the particular material that caused the deterioration, but in learning if the mounts contained anything at all that would injuriously act upon the silver prints put upon them.

---

**Further Eclipse Gossip.**—As the 28th approaches, the arrangements as to the eclipse expedition assume a more detailed form, and further official news becomes available. It is satisfactory to learn that most of the foreign Governments concerned are placing as many facilities as possible at the disposal of the observers passing through or into their territories: those of Spain and France form the exception, but official communications from them are daily expected. The Naval Department of the United States will permit instruments to be landed without examination and free of charges, and, if anything should pass into Canada, it will be similarly treated. In Portugal itself, the observer travelling by the State railways from Oporto to Valencia, and also by the narrow-gauge rail to Vezin will be carried free. All travellers going for eclipse observation purposes should be provided with a certificate stating that they are eclipse tourists. At a recent meeting of the British Astronomical Association, Miss Bacon gave details as to the expedition under the leadership of her father to the United States. Wadesborough is the station they have selected, and they are fortunate in having chosen the same locality as that selected by Professor Young, who has offered them the use of his camping ground, with every personal help he or his party can give. Professor Barnard has invited them to visit the Yerkes Observatory. As showing what can be done with comparatively slight photographic apparatus, we may note that at the same meeting one observer stated that he intended to take with him a one-and-a-half inch photographic lens with tele-photographic attachments, and also an ordinary "lantern lens" of ten inches focus. The same observer, Mr. Crommelin, intended to have a snap-shot at an effect not hitherto photographed—the disappearing shadow in the sky after totality. Mr. Evershed intended to use a reflecting telescope for his photographic work, and he believed this had not been done before. He converts his telescope virtually into a prismatic camera, which will have the advantage of giving all rays of the spectrum in focus with only the first adjustment. Using a reflector, he would experience the special advantage of having the aperture admitting the light to the prism close by the side of the plates, so that he could make the exposure with one hand and rack the plates along with the other. It is to be hoped that none of these hopes and plans may be marred by weather difficulties, and especially that the sirocco may not put in an appearance and spoil the observing by reason of the atmospheric haze it would bring about.

---

**A New Perfect Incandescent Burner.**—The *Scientific American* descants upon the merits of a new burner which it states is now in use by the Paris authorities. It points out the increase in light emission that follows increase of temperature in the Bunsen burner, which never arrives at a maximum possible, through imperfect mixing of the gases. The new burner obviates this difficulty, and, further, has an arrangement for heating the air before mixing, and so obtaining a higher temperature, which indicates 1800° C. The same article states that in a short time anybody will be at liberty to manufacture these burners, and so, of course, a decrease of price will result.

**Experiments with Albumen.**—In connexion with some agricultural experiments, Mr. J. Bertland Farmer, M.A., read at a recent meeting of the Royal Society a paper containing much matter of interest to photographers on the drying and coagulation of albumen. The sample he employed came from Merck, of Darmstadt, and was sent as egg albumen. The results he obtained were sufficient to prove that anomalous behaviour at times shown by albumenised paper might be accounted for by changes in the physical condition of the albumen brought about by dehydration. For example, if the albumen employed were put in or attached to a series of drying tubes, and then raised to a temperature of 80° C. for a short time, in two hours the albumen [was completely altered; it became insoluble in water, and, in fact, underwent a process of coagulation. If, however, the albumen be carefully dried before the heating is brought about, which it was stated might be readily done by placing it in an incubator at a temperature of 52° to 55° C., the results were entirely different. Thus dried, the albumen lost its shellac or glue-like appearance, and easily crumbled to small particles. Further experiments, which took the temperature beyond boiling point, still left the dried albumen quite unchanged. It is evident that it would be no difficult matter to expose quantities of albumenised paper to the specified temperature, 80°, which produces insolubility, and it might be worth while to try what would the result be like. The use of weak silver baths possesses certain advantages, but is impossible below a certain strength with ordinary albumenised paper, as the coating of albumen dissolves.

**Cellulith.**—This is the name given to a substance, lately frequently mentioned in several of our foreign contemporaries, which appears to have properties fitting it for use in the manufacture of photographic trays, &c. One description that we have read points out that, in the making of paper, it is known that, by beating the pulp for a long time, a transparent and elastic substance is obtained, which hardens rapidly on drying, covers the fibres, and imparts great strength to the paper. An amorphous colloidal cellulose hydrate, as supposed, is produced, being set free from the cells, and acting as an agglutinating substance. This is also the theory of the fabrication of vegetable parchment. In parchenting paper by means of sulphuric acid, the cellulose is transformed into amyloid, which yields, with an excess of water, a gelatinous precipitate, uniting the remaining fibres, and forming a translucent sheet. The description proceeds: "The cellulith is prepared by a process exclusively mechanical, the beating of the pulp for a much longer time than is necessary for the production merely of paper. According to the properties of the pulp and the velocity of the revolving cylinder, the duration of the operation varies from 40 to 150 hours, until all the contents of the vat are transformed into a homogeneous mass having no trace of fibres. In the state of extreme division the material still contains a good deal of air, which may destroy its regularity, so it is submitted to a new beating for about two hours. If the cellulith is to be coloured, the colours, soluble or otherwise, are added before the heating. The hot cellulose liquor is received into a reservoir perforated at the bottom, from which it drips. With ninety-six per cent. of water the consistence is that of thick honey. The water is evaporated either in the open air or in a stove at 40°. The pulp hardens gradually, and finally reaches the consistence of horn. Its specific weight is then about 4.5. The cellulith may be worked like horn, ebonite, and other similar substances, and is, as compared with celluloid, unflammable. In mixing the cellulith, at the moment of trituration, with sawdust and thirty per cent. of lampblack, a kind of very dark ebonite is obtained, dense and susceptible of a polish."

#### ON THINGS IN GENERAL.

THERE is no doubt that the Camera Club is a real live society, and some of the best work of the day has its results first published within its walls. Those who were not there have to take their enjoyment second hand, and read in the pages of their BRITISH JOURNAL OF PHOTOGRAPHY some original account of papers read or

discussions carried on, though, I doubt not, many would prefer, for example, to have personally witnessed Mr. Webber's interesting metallurgical experiments; and again he added fresh interest to the ever-green subject, the saving of residues. To my mind, one of the most extraordinary of the aberrations of otherwise trained and business-like minds takes place, and is to be noticed all over the country, on this very topic. "Save your waste toning baths," says Mr. Webber, knowing well, I feel sure, that there is every need to hammer such advice into the brains of the majority—I say, not only of amateurs, but of professionals. Nineteen out of twenty photographers who give any attention to the subject at all, save their print-washings, and the bulk of them pique themselves upon their 'cuteness in so doing. But—and this is a very old, stale tale, yet ever needing the telling—how many systematically save their gold or collect the silver that is to be found in their waste hypo? Yet here Mr. Webber can inform them what a large proportion of the gold bill is not utilised in the production of a print, but, all the same, it usually goes down the sink. Similarly is the used-up hypo solution put to waste. Let me once more point out that in the hypo used for fixing P.O.P., or any silver print, there has always been more silver from a given number of prints than can be extracted from the print-washing; and, what is of more importance still, the silver so extracted always contains a certain amount of gold. Sent to an honest refiner, the price per ounce given for silver from hypo will average ten per cent. (often reaching a higher figure) in excess of that given for print-washings. And again, now that so much ready-sensitised paper, especially the emulsion kinds, is very greatly in vogue, the silver going into the washing water is less than it used to be. Speaking from a practical point of view, my advice to photographers, however, who do not possess experience like Mr. Webber's is: Throw down all the precipitates you can from print-washings and hypo, throw your old toning solutions into the waste hypo jar, collect and dry your precipitates, and don't attempt to do anything more with them, but send them at once to the refiner. One of the largest metallurgical firms in the world charges a sum which does not exceed an average of five or six per cent.; others charge ten; but, even at the latter figure, it is the truest economy not to attempt any crucible work.

Then we had Mr. Burchett's lecture on composition, reminding one of a good old standard authority of somewhat similar name, Burnett, from which much advantage could be gained by the student, and yet he did not advise slavish adherence to rules. I am one with Mr. Humphery, who was delighted to hear from an artist of Mr. Burchett's eminence that picture-making was possible without sticking to absurd rules (I hardly think Mr. Burchett called them absurd). But I don't think Mr. Humphery intended to be taken literally when he said no one could seriously contend that the female form was either angular, pyramidal, or circular. He was, I apprehend, speaking of woman in the abstract, and not in the concrete, for I know a good many portrait photographers who would be excessively glad if they had no angular women before their camera, and would find others as nearly circular as makes no matter! The latter would be well enough if they would let the photographer have his own way, but it is well known they won't; they like to look at the sample album, and, selecting some particularly sylph-like girl, declare that that is how they wish to be taken. I will confess, though, that I do not seriously contend that there are any pyramidal women, they would be freaks indeed.

We have another fine society in the L.P.P.A., and Mr. Haddon's talk on balances was very interesting. He might perhaps have added with advantage that it was possible to buy sets of gram weights, stamped as correct by authority, at a cost of a few pence extra. Yet stay! It is questionable whether such stamping is as valuable as it sounds. I remember a case some years ago where a chemist was fined for having an incorrect measure in use in spite of his protest and pointing out that this very measure was stamped by the local weights and measures authority—had a Government certificate, in fact; and, further, I know a tradesman who had his doubt about the ability of his local authorities, who had a quarter-ounce weight stamped as correct, put away carefully, wrapped in tissue paper, presented it again for examination twelve months afterwards.

and was informed that it was incorrect. After that he was not surprised when, after sending a block-tin quart measure to be stamped, it really was stamped, stamped clean through the metal, leaving a hole, through which the liquid the measure was intended for steadily trickled out. No, perhaps Mr. Haddon was well advised, after all, to say nothing about "stamping." By the bye, speaking of balances, I have in use at the present time (the instrument having had no special care taken of it), and have had for about fifteen years, a small pair of brass-beam hand scales, which only cost a few shillings, but which will weigh with great accuracy and rapidity to one-fifth of a grain, the fractions of a grain being measured by a sliding rider on one side of the beam. I could not wish for a better or handier instrument for general rough use.

It is very satisfactory to know that the odious Copyright Bill has no chance of being passed this session. It is to be hoped that sufficient organized opposition may be brought into play against its next appearance that shall succeed in getting it rejected. Photographers should combine, and, above all, interview the local M.P.'s on the subject. So far as I can see, the effect of any effort of the Copyright Union has been absolutely *nil*. Speaking of copyright, I am rather surprised the Editor did not express his opinion on the offer of *Country Life* to pay from 5s. to 10s. 6d. for the use of pictures they publish out of sets sent in competition for the prizes that journal offers. True it is that there is some credit to be gained from a reproduction of a photograph in the pages of that splendidly printed journal; but, if a print is worth inclusion in such select pages, it is worth paying for, and 5s. is no payment at all.

There has been much talk lately about photography and the illustrated press. My own belief is that photography in that direction has been a curse to art progress. Of all the vapid, monotonous, unpicturesque, flat, inartistic illustrations ever put into a newspaper, commend me to the average "photo block." I suppose its cheapness has been so great that publishers have succumbed. There is the *Graphic*, at one time the very home and hotbed of high-class wood-engraving; but at the present time it is easy enough to pick up a number which has not a wood-engraving in it from cover to cover—no, I am wrong; we do find wood-engravings, and sometimes very excellent ones, in the advertisement pages. The reason of all this is not far to seek. It is an expansion of the 5s. idea. Some men are so delighted to see their name attached to some twopenny-halfpenny snap-shot that they are only too glad to get it printed for nothing. They would rather pay (not to speak of being paid) to have it put in, and so the papers fatten on their vanity—some papers, that is to say—the latter paper I named is a conspicuous example of honesty in this respect, as far as my knowledge carries me.

I read with much pleasure Mr. Tulloch's paper given before the Dundee Society, and with much of what he said I heartily agree. But surely, when he gave it as his opinion, speaking of double printing having "much to answer for," that "it is beyond the power of man to make a connected whole from parts," he did not remember—to name two artists only—what Rejlander and what H. P. Robinson have done. I have, in a place of honour in my home, a copy of *From Dawn to Sunset*, by the latter artist, which is, to my mind, superior to the work of many a painter both in unity and breadth, and it rings with the true poetic fervour. While speaking of this, I may mention a technical point about it that often strikes me. My copy—I believe it was almost, if not quite, the first finished copy produced (unmounted when I received it)—appears now as bright and free from fading as when it came into my possession, and that cannot be very much under a score of years ago. Yet it is an albumenised paper print. Can any one explain how it is that so many of the more recent albumenised prints fade so quickly? FREE LANCE.

#### THE PHOTOGRAPHIC WORLD AND THE WAR—AN APPEAL.

So far none of the various war funds that have been raised for the benefit of the sufferers by the prolonged struggle in South Africa has received the contributions of photographers, photographic manufacturers, and dealers as a class. No attempt has been made to enlist the active co-operation of the photographic world as a whole in the good and noble aim of alleviating the pain and suffering caused by the war, although

some satisfaction may be derived from the fact that photographic societies at Manchester, Croydon, and Redhill have held special optical lantern entertainments which resulted in the addition to various war funds of useful little sums of money.

But this is not enough. It has been represented to us that, as some branches of photographic industry have directly profited by the war, it is the duty of photographers, manufacturers, enlargers, &c., to make a special and concerted effort in the direction of materially aiding one of the war funds. That the three classes of photographic producers we have named have been doing increased business on account of the war admits, we believe, of no doubt. The slow movement of 200,000 British troops, and continuous strife for six months, with the consequent loss of thousands in killed and wounded, has laid innumerable claims on the services of photographers and enlargers, while the demands of the Government and private individuals for photographic apparatus and material have been exceedingly great.

The war may last for months, and probably will; but, whatever may be its duration, the further losses by death are bound to be great, and the long list of the widowed and fatherless is destined to be very largely increased. We have been asked to appeal to our readers for their contributions towards the well-administered War Fund of our powerful contemporary, the *Daily Telegraph*, which has made the care of the widowed and fatherless the objects of its special efforts. It is needless to say that we accede to this request with the heartiest pleasure, and we ask our friends and readers all over the country to join us in this noble work.

Every amount, large and small, will be acknowledged in our pages, and the total sums will be forwarded, week by week, to the *Daily Telegraph*.

We trust to receive the co-operation of the great manufacturing firms, professional and amateur photographers, *employés*, dealers, enlargers, and the many other classes to be found in modern photography, so that the total contributions which the photographic world will make to the *Daily Telegraph* War Fund will be both large and representative.

#### THE NEWCASTLE CONVENTION.

To the pages of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1900 Mr. S. Herbert Fry contributed a short article with the title "On Stopping at Home." It is so admirable a plea to professional photographers to attend the forthcoming Convention at Newcastle in July next that for their especial benefit we consider ourselves amply justified in reproducing it.

##### "ON STOPPING AT HOME."

"I wonder," wrote Mr. Fry, "how many professional photographers are members of the Photographic Convention? This question has been running in my mind since last July, when I met a professional friend—a veteran and an old friend of my late father's at Gloucester. He put the question to me in a slightly different form. Said he, 'Are there any professionals here?'"

"Well, of course there are. Some of the attenders of Convention are professional photographers, many are connected with the business of photography, and more—perhaps the majority—are amateurs. Nevertheless, I think it is a matter for regret that so few of the men who are making the production of photographs the bread-and-butter business of their lives should fail to attend a gathering where the very spirit of photography may be said to breathe.

"A photographer who attends the Convention finds himself an honoured guest in a town whose local authorities have invited him and bidden him welcome; a participant in a week's pleasurable picnic, surrounded by kindred spirits, he is, at his own option, a snap-shotter, a serious worker, or a lazy man watching others toil; and he has a unique opportunity of discussing the whole gamut of new and old methods with all classes of enthusiasts. There is a pass word which serves as an introduction to every one, namely, membership of the Convention, and its yellow badge is the sign of a hail-fellow-well-met.

"Without contrasting the methods and manners of our own Convention with those of our American friends, which Convention I believe to be as largely dominated by the professional as ours is by the amateur element, I believe the English photographer, especially the provincial photographer, would find himself benefited by a week's intercourse with his brethren.

"There are lions, too, at the show; live, pictorial fuzziographers; editors who speak as ordinary beings, and not as 'we'; cranks with patent cameras of all sorts, and lady photographers, all intent upon making as many exposures as is possible in the day; and the photographer who can't learn something from them, either what to do or what not to do, what is new and good or what is worthless, must know all there is to know, and more.

"But," says an objector, 'what good will all this be to me? When I take a holiday, I want to get away from photography altogether; I want a change of scene and a change of subject, to get upon an entirely fresh tack.' Well, I think you will do all this at the Convention. Nothing can be a greater change to a photographer than to be a disinterested and critical observer of other people's methods, of other people doing the work one is accustomed to do oneself. You have no idea how smart a man may be with his camera until you meet a better man than yourself. And there is some comfort, too, in seeing a man fumbling with his apparatus, you feeling sure all the time you could do it better and quicker yourself.

"Now, my contribution to the ALMANAC can be boiled down to a few words: Can you afford to stop at home? Can you afford to run along in the same groove year in and year out? Where will you get most ideas in the shortest time from your fellow-photographers? Well, I say, Can you afford to stop at home?"

#### AN OLD TELE-OBJECTIVE.

IN his interesting account of the history of the tele-objective, Mr. T. R. Dallmeyer\* attributes the priority of the principle of this instrument to P. Barlow, 1834, acknowledging, however, I. Porro's claims to be the first to introduce this instrument into photographic use.

By a happy chance, some weeks ago, I came across an old book, printed in Sir I. Newton's time, *i.e.*, A.D. 1686, the title of which I dare hope will be interesting to the readers of THE BRITISH JOURNAL. This title runs thus:

## R. P. F. JOANNIS ZAHN CAROLOPOLITANI.

*Sacri Candidi Canonici Ordinis Præmonstratensis in Superiore CELLA DEI Professi,*

PRO

EXPLICANDO ET DEMONSTRANDO

## OCULO ARTIFICIALI TELEDIOPTRICO

SIVE

## TELESCOPIO, FUNDAMENTUM II. MATHEMATICO-DIOPTRICUM,

in quo

Comprimis de materiâ & formâ Artificiali apti Diaphani ad perfectionem Oculi Artificialis Teledioptrici:

Deindè de variâ lentium diaphanarum tam inter se quam cum Oculo Naturali combinatione:

Tandem & de ipsius machinis sive instrumentis Teledioptricis cum Oculo Naturali comparatis Methodicè, Genuinè, ac Mathematicè tractatur.

ANNO M DC LXXXVI.

\* *Tele-photography* (an elementary treatise on the construction and application of the tele-photographic lens). London: William Heinemann, 1899. 148 pp., with 26 plates and 66 diagrams. Cloth, 15s.

The book forms the second part of the *Oculus artificialis teledioptricus sine Telescopium*, by the same author. As seen from the title, the author belonged to the order of the Præmonstratenser Friars, and is said to have become, some years afterwards, Canonius of this order at Würzburg.

It is remarkable that, at this time, so shortly after the Thirty Years War, and in a dreadfully devastated country, such an interest was being taken in a scientific pursuit. Of course there is no knowledge of highest importance contained in the large folio, but artifices and devices are mentioned which clearly show that the author was by no means devoid of insight and dexterity.

Of special interest for a photographic journal is the treatment of the camera obscura, or "cistula parastatica," as the author sometimes calls it. When I wrote the history of the camera obscura in my *Theory and History of the Photographic Objective*, I derived my knowledge of the prior stages of this instrument mainly from English sources, especially from J. Harris's talented Treatise; and there is no doubt that the final practical perfection and theoretical investigation of this instrument was effected by W. H. Wollaston and G. B. Airy. I had then no means of tracing the development of the camera obscura in Germany, but now the discovery of this volume, and some others found in the mean time, enables me to fill up the gap to a certain extent; we see that the camera obscura as show-box, and later on as drawing apparatus, had a rather wide-spread use in Germany during the end of the seventeenth and in the eighteenth century.

As far as J. Zahn's *oculus artificialis* is concerned we are surprised at the development of the tele-objective, *i.e.*, a combination of a convex lens of longer and a concave lens of shorter focal length. J. Zahn's theory may follow in the Latin original (the author's text being conscientiously copied with every mistake as well as with the peculiar accentuation), of which I give such a literal translation as I am able:—

#### COROLLARIUM I.

(*Insignis combinatio Lentis convexæ et concavæ ad majorem imaginem procurandum.*)

Specillum concavum ita intra Lentem convexam et ejus imaginem collocatum, dum imaginem trajicit, potest eam exprimere majorem, quàm alia Lens convexa sola qualiscunque ad eandem distantiam. Nam si Lens aliqua convexa sola adhiberetur ad imaginem in eadem distantia exhibendam, si esset plano-convexa, OR foret diameter convexitatis; si convexo-convexa aequaliter utrinque, OR foret semidiameter convexitatis utriusque: radii autem transeuntes per O centrum Lentis convexæ, qui determinarent diametrum imaginis forent BOP, AOQ: foret autem PQ diameter imaginis in eadem distantia multo minor diametro KL imaginis per combinationem harum Lentium procurata. Ergo, &c.

#### COROLLARIUM II.

Hinc discitur secretum et mirum artificium pro cistulis specierum et cameris obscuris in parvâ distantia plurimum imagines trajectas amplificandi. Sed de hoc artificio alibi plura.

#### COROLLARIUM III.

(*Quomodo Tubus brevior æquivalens majori confici possit.*)

Item patet hinc, quomodo per similem combinationem loco Lentis objectivæ longiori distantia imaginem formantis major nihilominus imago in breviori distantia procurari possit, itaque tubus contractior et brevior fieri, qui tamen æquivaleret, imò præstaret tubo longiori cum Lente ordinariâ objectivâ.

#### COROLLARY I.

(*A special combination of a convex and concave lens for producing a larger image.*)

A concave lens, thus placed between a convex lens and the image formed by it, can in transmitting the image produce it in a larger size than any single lens whatever at the same distance. For if any single convex lens be used in order to produce an image at the same distance, if it be plano-convex, OR would be the diameter of the convex surface; if it be a crossed lens of equal radii, OR would be the radius of each convex surface: but the pencils passing through O, the centre of the convex lens, and which determine the size of the image, would be BOP, AOQ; but the diameter, PQ, of the image at the same distance would be much smaller than the diameter, KL, of the image formed by the combination of these lenses.

#### COROLLARY II.

From this may be inferred the secret and wonderful artifice used in show boxes and camera obscura to greatly magnify the images transmitted at a short distance. But of this artifice more later on.

#### COROLLARY III.

(*In which manner a shorter tube could be made equivalent to a longer.*)

In the same way it stands to reason from the foregoing, in which manner it is possible to produce an image none the less larger by a similar combination at a shorter distance instead of using an objective forming the image at a longer distance; and so a tube which possesses not only the same but even a higher power than a longer tube with an ordinary objective can be made shorter and more convenient.

COROLLARIUM IV.

Quantò specillum cavum caeteris paribus (habito scilicet respectu ad centri ejusdem et imaginis Lentis convexae situm, ut dictum) propius accedit ad imaginem, tantò penicilli magis distrahuntur, et imago necessariò fit major in longiori distantia; et quantò remotius ab imagine Lentis convexae collocatur, ita ut propius Lentem convexam accedat, tantò minor imago procuratur in distantia breviori.

COROLLARY IV.

The nearer the concave lens *coeteris paribus* (we must, as already mentioned, take into consideration the situation of its centre and of the image formed by the convex lens) approaches the image, the more the pencils are lengthened, and the image necessarily becomes larger at a greater distance; and the further it be placed from the image formed by the convex lens, so that it approaches this convex lens, the smaller an image will be formed at a shorter distance.

The figure appended is a copy of the drawing to be seen on page 132 (fig. 2).

As to the practical use of these theoretical rules he gives some instances in the next volume, *Fundamentum III.*, pp. 219-221. From these we infer that, in accordance with the above Corollary II., the device was

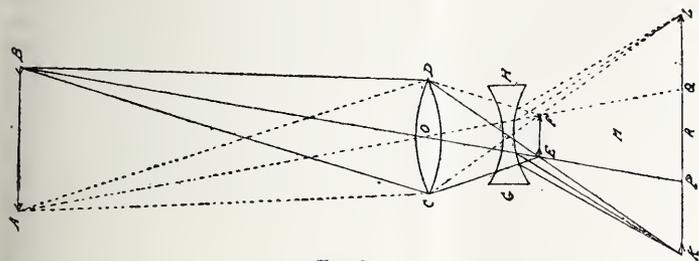

FIG. 2.

planned to magnify the primary image in a camera obscura of a comparatively small length. In order to accomplish this the positive and negative lenses were mounted in two separate telescoping tubes so that their distance could be altered at will. A third tube, holding the above-mentioned, was fixed to the camera obscura and allowed the focussing of the image on the matted surface.

In this way, the author concludes this chapter, we are able to obtain a larger or smaller picture, and at different distances, according as the concave lens is placed nearer or further away from the convex lens.

DR. VON ROHR.

FOREIGN NEWS AND NOTES.

**Thermography.**—An interesting communication by Dr. R. E. Liesegang appears in the *Physicalische Zeitschrift* concerning the action of heat as the means of obtaining an image. If equal parts of hydroquinone and anhydrous carbonate of soda be moistened with alcohol and rubbed to a thin paste, it will, in the course of a few minutes, turn an intense deep blue colour. This blue substance has the remarkable property of being sensitive to radial heat. By brushing the mixture upon thin writing-paper, and wiping away the excess which is unabsorbed, the blue substance is formed in the fibres of the paper. This paper, when exposed to heat in a gas oven, bleaches in about five seconds. By placing coins, &c., upon the paper, images of their shadows may be obtained. The formation of these images is only retarded a few seconds when the sensitive substance is wrapped in black paper. Dr. Liesegang remarks that he does not know of any substance which by exposure to light changes so rapidly. The normal oxidation of alkaline hydroquinone by exposure to air is characterised by deep brown discolouration. The blue substance seems to be an intermediate stage of oxidation. The colour immediately disappears when the substance is moistened with alcohol or water, and it does not reappear when dried again, ether does not affect it. The paper in the sensitive state will only keep a few days. Herr Gaedicke makes a few remarks concerning the above in the *Photographische Wochenblatt*. He says this intense blue compound may also be prepared by rubbing hydroquinone and calcined potash together in the dry state. If the dry mixture is rubbed upon blotting-paper and exposed to the radiant heat emitted through the windows of an anthracite stove, in about three minutes it will turn green. If a silver coin be placed upon the paper, it will quickly get very hot, and the compound will turn brown. The blue colour of the compound seems to be due to the presence of a certain amount of water, easily dissipated by heat. When this takes place, the colour changes to brown. Hydroquinone, rubbed down with efflorescent soda and moistened with a little alcohol (ninety-five per cent.), does not show any blue colouration when brushed upon paper, but remains colourless.

**Metol-hydroquinone.**—H. Quatz, writing in the *Atelier des Photographen*, recommends the following formula, which, subject to various modifications, may be taken as a stock solution for many kinds of development:—

	No. 1.	
Water .....	500 c. c.	
Metol .....	5 grammes.	
Hydroquinone .....	1 gramme.	
Bromide of potassium (ten per cent. solution) .....	60 drops.	
Hyposulphite of soda (ten per cent. solution) .....	60 „	
	No. 2.	
Carbonate of potash .....	20 grammes.	
Water .....	250 c. c.	

The addition of hyposulphite of soda has a retarding action, and keeps the shadows clear in the case of over-exposure. In development with ferrous oxalate its action is the opposite, being in that case an accelerator and producer of fog. For instantaneous exposures, take 3 parts of No. 1 and 1 part of No. 2. For time exposures, or where over-exposure is suspected, begin with a small quantity of alkali, say 10 parts of No. 1 to 1 part of No. 2, increasing the latter as may be thought desirable. Development begins at once in the case of instantaneous exposures, and it is complete in two or three minutes. Several plates may be developed in succession in the same solution, which does not lose its activity. A mixture of old and new developer may be used with much advantage for time exposures. The developer may also be used for Velox paper. For the carbon variety use 3 parts of No. 1 and 1 part of No. 2, and for special portrait add an equal quantity of water. In the latter case development is slower, and the pictures show more contrast than with the developer recommended by the makers of the paper. For bromide paper, take 3 parts of No. 1 and 1 part of No. 2, and dilute with five times the quantity of water. Lantern plates may be developed with 6 parts of No. 1, 1 part of No. 2, and 7 parts of water. The tone may be modified by varying the strength of the developer. Black tones may be secured with a concentrated developer, whilst the addition of water tends to warm brown tones.

**The Berlin Exhibition.**—We have been requested by the President of the Deutscher Photographen Verein to inform our readers that an Exhibition will be held at Berlin during the next Convention, to take place in the month of August. The Exhibition will be held under the patronage of T.L.H. the German Emperor and Empress, and promises to be of more than usual importance. We notice that a number of German manufacturers of photographic lenses, plates, and other photographic requisites are supporting the Exhibition in a liberal manner by offering prizes. The President, Herr K. Schwier, of Weimar, will be happy to forward programmes upon application.

**Copying Drawings and Engravings.**—The *Wiener Freie Photographen Zeitung* draws attention to an old process, due to Nièpce de St. Victor, but which is very little known. It may be used even for engravings printed on both sides. Soak the prints for a few minutes in water to which a little ammonia has been added, then draw them through water slightly acidified with sulphuric acid and dry them. Expose them for five minutes over a dish to the fumes of iodine at a temperature of 12° to 16° R. This impregnates the ink, but not the paper. The surface upon which it is desired to copy the engraving should be prepared with a solution of starch and dried. Before printing, prepare the starch surface by damping it with blotting-paper soaked in water acidulated slightly with sulphuric acid. Place the engraving face downwards upon the starched surface, lay several sheets of soft paper upon it, and bring the surface of the print in contact with the starch by means of pressure. An image is thus formed in iodide of starch, which may be fixed by first drawing it through a solution of nitrate of silver, exposing it for a few seconds to light, and then developing with a solution of gallic acid. Fix with hyposulphite of soda. The image is reversed. By this process negatives may be made upon glass coated with albumen or gelatine.

**Insurance by Picture Post Card.**—According to the *Revue Suisse*, the latest development of the mania for picture post cards is the insurance of the recipient against accident. By payment of a premium of 5 francs for a hundred picture post cards,

the addressee becomes entitled to an insurance for 50*l.* in the event of death, or 10*s.* per week in the event of injury. Bicyclists are only entitled to half these sums. The contract is worded as follows: "This card must bear the impress of a post office stamp, and entitles the person whose name it bears to the sum of 50*l.* in the event of accident, followed by death within three months, if the same shall have happened to him upon a journey for which money has been paid, whether by train, tramway, stage coach, omnibus, or steamer. In the event of injury, not followed by death, the Company will pay to the said person 10*s.* per week, whilst incapacitated for work, during the period of eight weeks dating from the fortieth day after the accident occurred. In the event of accident to bicyclists (racing excepted), the amount of compensation shall be reduced by one-half. The insurance shall begin at midnight of the date of the post-mark, and shall be valid for thirty days. It shall not take effect after the 1st January, 1903."

#### PORTERAGE OF IMPEDIMENTA FOR THE PEDESTRIAN PHOTOGRAPHER AND THE MAKING OF HIS CAMERA CASE.

To peruse the pages of the photographic press from week to week, a stranger to the ways of photographers (if such exists!) would go away with the impression that now the camera is not used apart from the cycle. One ingenious article after another appears claiming to put forward the latest "best" method of camera carrying on a cycle, but similar hints to the older-fashioned pedestrian brother of the camera are almost totally ignored, as though such an anomaly no longer existed. But we walkers are not in the British Museum yet—not yet there labelled as specimens of an extinct species for the eyes of the curious or antiquarian to gaze on. Some photographers are yet sufficiently conservative to prefer Shanks's mare to the most luxurious of cycles, and are even bold enough to hold the daring opinion that, whatever advantages may exist in the bicycle, still walking has also a few to compensate for any disadvantages of speed or some inconveniences the former may possess. The cycling photographer apparently does not go in for very weighty apparatus (as indeed how can he?), and presumably any camera over half-plate would be out of the question. As there are still some amongst us who prefer something originally larger than quarter-plate, and a camera with a larger sphere of usefulness than the hand variety, the majority of these, if not from choice, being debarred from the cycle for the above reasons, must do some walking, as trains do not go everywhere, and since the chartering of carriages or motor cars is apt to deplete the

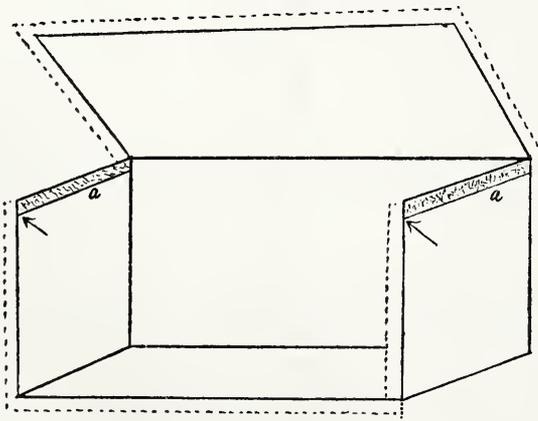

Fig. 1.—Box cut to serve as case. *a a* Here *only* edges of flannelette are glued down over the edge. Dotted lines represent free flannelette edge.

pockets for pedestrians, this article is written by one who for years has spent days and weeks on photographic tramps, and therefore can speak from practical and personal experience, of every kind of portorage for impedimenta weighing up to twenty pounds on occasion.

Now, there exists a good deal of choice as to the precise manner in which the camera shall be carried, and at the outset the first consideration is as to what shape the camera case shall take. For short excursions from home, undoubtedly the most convenient and lightest receptacle (if, at the same time, its unprofessional and not over-imposing looks be not considered an objection to its adoption) is one of those neat feather-weight rush baskets of which so many patterns abound. These well-known white ones can be had in any size (in fact, many seem just made for camera and slides side by side) and are very cheap; but, perhaps, more preferable and even lighter, yet equally as strong, are those open-work unbleached rush baskets with leather handles; they "look better" for the purpose, to the writer's mind, if looks ought to be considered. A visit to any basket shop will, however, doubtless reveal many suitable patterns, but perhaps it may be mentioned that such a one as the latter described, 14 × 10 inches, costing a 1*s.*, takes a half-plate camera, three

dark slides, lenses, note books, &c., and the tripod laying along the top easily, the basket being lined with the focussing cloth, to protect all from dust, &c.

Some persons, however, prefer to divide their load, and balance half of the burden against the other half. For them a couple of school satchels (waterproof, from 1*s.* a piece), one for the camera, the other for the slides, &c., are the things to purchase, and these can be carried in each hand, or slung one across each shoulder on either side. But, of course, these satchels, if affording slightly more protection than the baskets, are equally with them of no use for travelling about with, as, obviously, their construction (particularly of the open baskets) is not such as fits them for hard wear and tear as part of one's personal luggage. Therefore, for other than home use, a more substantial (and more orthodox!) article should be purchased, of which the most convenient shape will almost invariably be found to be that of the oblong in opposition to the square. Then, too, as this case is to be brought to withstand weather, all kinds of portorage, and every other vexation, a stout article should be chosen in preference to the lighter (and cheaper) limp canvas cases. Leather, if most durable, is rather too expensive for most pockets, but very serviceable stiffened canvas baize-lined cases can be purchased at a price by no means ruinous. But what is better than to make a case oneself, in the manufacture of which one's own particular requirements or likes can be studied, as in no other way, unless the expensive one of having a case made to order? The writer rejoices in an eminently respectable black home-made case, which cost a very small sum in the making, and is said by competent critics to be a very nice-looking article (which cannot *always* be said of "home-made" affairs); has stood any amount of buffetings, still being none the worse for them; is waterproof; can be made to look like new again, with a fresh coat of enamel; and which, finally, can be carried in the hand, slung over the shoulders, carried knapsack fashion, or can run on wheels at will, and

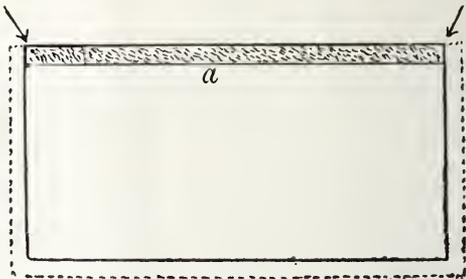

Fig. 2.—Outside of box lid to form side of case, and ready for sewing in position, as indicated by arrows. *a* and dotted lines as in fig. 1.

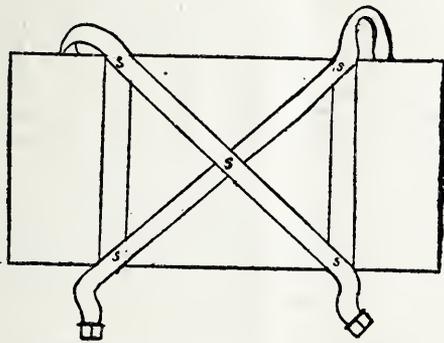

all with equal comfort. Perhaps it is only the maker's vanity which causes it to be regarded as an ideal camera case; but, be that as it may, it certainly admits of every possible method of portorage adapted to all circumstances and to every one's fancy, and on this account the reader may like to hear how such a one may be simply manufactured, and of course he can omit any feature which may not meet with his approval or wants.

By far the most convenient foundation—saving the expense of mill-board sheets and the subsequent trouble of cutting out—is a cardboard box of dimensions suitable to your camera (and it is wonderful how exactly suitable such boxes can be had), which your women-folk can get for you free of cost from the drapery establishment they patronise. Since of necessity readers of this article will be users of every size of camera, it seems the better course to speak generally, not confining oneself to any particular size, but writing in such a way as shall be equally useful to him who contemplates making a case for his whole-plate as for him who means to do the same for his quarter-plate. Obviously some recommendations would only apply to weighty cameras, but still, in the matter of the actual case-making, only the measurements will differ, the details being, of course, common to all sizes. But, just to give some idea of how far materials will go, it may be said that one yard of flannelette (costing 4*½d.* the yard at the outside, being named as the cheapest material which commends itself as suited to the purpose) will be ample to line a case large enough to take a whole-plate outfit; and the same quantity of "apron linen" (which runs wider), at the same outlay, will more than suffice to cover the same-sized case. To prepare the box for use, one of its long sides will have to be cut down at each end to form the lid of the case, while the original *box* lid will serve as the *side* of the case, as shown in the accompanying cuts.

It would be somewhat difficult to precisely describe how the case is to be lined and covered, and even if these proceedings were minutely detailed, they would appear to the reader so formidable as might possibly lead to discouraging him from the attempt. Therefore, since every one's own eyesight and common sense will be his best guide in the actual cutting of the lining and covering, minutiae as to the way will not be gone into, but just only what is necessary said in order to give a clear idea of what is meant, which will be all the assistance required. Perhaps it may be here remarked as some encouragement that the whole of the work is quite a

straightforward, easy, and speedily accomplished task. First of all, the box is to be lined with the flannelette, which is glued down piece by piece, wherever a join is necessary and no selvage available, turning in the material so as to make a neat finish. The glue should be thin, but not watery, in which case it would penetrate the flannelette and impart a dirty, untidy appearance to the whole. The best method is to allow the glue to just get tacky after spreading, before pressing down the flannelette upon it. About an inch of the stuff should be allowed to project over the edge of the box all round, quite free and not glued over the edges, save at the tops of the two ends (all shown in fig. 1), and for the following purpose. When the box is thus treated, it will be minus a front, as will the lid of the case lack the flaps it must have to complete it. The original box lid deprived of its edging (to be used hereafter) must now be lined to form the front of the camera case. The flannelette is turned back over what will be the top, or free edge of the front of the case, in the same way as was done at *a a* in fig. 1, but all the other sides have the projecting inch of material (see fig. 2). This side being lined as above is placed in position in the box (the arrows in figs. 1 and 2 being made to coincide), and then a needle and thread are brought into requisition to strongly stitch one to the other all the way round—a very simple proceeding, for the needle is simply passed in and out in the manner known as “back-stitching,” which expression, if the male reader does not understand, since it can hardly be explained in words, the nearest member of the opposite sex will be able to practically demonstrate. Then the spare piece of the underneath flannelette flap, which has just been sewn to the top one, is cut off close (but not so as to endanger the stitching), and the remaining (top) flap all the way round glued down over the sides to make a strong joint.

To complete the actual case itself, only the lid has to be finished, and in all probability the cardboard edge, which has been stripped off the box lid, will serve the purpose of its edging; or, if not long or deep enough a strip of cardboard (one inch wide) of a sufficient length to go right round the lid, must be cut, with a triangular piece cut off each end to slope in towards the case. This has to be lined in the same way as was the erst-while full front of the case with flannelette, pasting over the

Back view of knapsack attachment fitted to the camera case, sewed at *s*.

latter for the finished edge and the ends, and leaving a free margin at the top by which to sew it all round the lid by its free edge, to which it is stretched in precisely the same way as was the aforementioned side, and similarly finishing off by gluing down over the join. Before covering the case, a stout piece of millboard, and of the same size, should be glued to the bottom of the case to strengthen it there. Then the apron linen is to be glued on as a covering—not a hard matter. The joins should be made to come exactly at the edges of the case, as here they will be hardly noticeable, as the material permits of very neat manipulation, even when it has to be turned in.

Before putting the case into the hands of the saddlers and ironmongers, two strips of hard wood, about  $1 \times \frac{1}{2}$  inch, should be screwed at about two inches from either end of the bottom of the case. Now it is ready for the affixing of the straps, which the saddler will provide, as well as make the sling for carrying the case over the shoulder. Two straps will be required to run round the case; they are kept in place at the back by loops, and connected by a handle at the top, which handle should be riveted to the straps—not to the case lid of which they would then soon prove the destruction—to prevent its loss. (It is convenient if these straps be made long enough to take the tripod, lying on the top of the case as well.) At either end of the case buckles should be sewn for attaching the sling of broad webbing, which should be capable of alteration by having a buckle in the centre wherewith to loosen or tighten the length when slung, or about to be slung, as required. As the strap handle serves for general carrying, and, attached as recommended, does not wrench the lid, the sling may not always be required, wherefore its detachability. One half is used as the means of drawing along the case when mounted on its wheels. When the saddler has done his part, the ironmonger will rivet on a hasp and eye through which a letter lock can pass. This the writer considers the best securing for the purpose, as there is no fear of a lost key, and only the one in possession of the mystic word can open the lock.

Now for the affixing of the wheels, the use of which no one would believe was such a boon until one had made practical experience of

them on a long day's tour. Four small iron wheels about four inches in diameter, costing approximately *3d.* a piece, are first selected, and these are kept in their axles by split pins (as, of course, the wheels and axles must be detachable for convenience of packing), the axles being flat to admit of screwing them in to the bottom of the case, and having shoulders to the rounded ends, round which the wheels revolve to prevent them rubbing against the case. The axles (which, together with the wheels, should be enamelled to prevent rust) fit over two bolts a piece, screwed through the wooden strips and secured by nuts *outside*, which a spanner tightens up, unless winged ones be used—perhaps more convenient. The writer first tried thumb-screws, but these worked out in a very few moments though most tightly screwed, whereas with the bolts and nuts the camera case has been pulled along over rough roads for a day without a symptom of the nuts loosening. When not in use, the wheels, axles, pins, and spanner (through which a hole should be drilled) can most conveniently be strung together, and carried thus ready for use; they are affixed with no trouble, and quite quickly enough, and as readily detached.

To revert to the sling, which, it should be almost unnecessary to remark, should be sufficiently broad to prevent cutting into the shoulders, since this is why it is to be preferred to a strap for slinging, and the sling, with the straps, should be the same colour as the case is to be when finished. This latter, in its raw state, is quite “a gentleman in (pale) khaki,” but requires three coats of enamel to make it durable and waterproof. Of course the maker can select his own colour—to be patriotic and in the fashion, khaki (with perhaps his initials in the tricolour thereon); or, if one has not fashionable, though not necessarily unpatriotic, tastes, he will probably consider black or brown the best colours.

Before applying the selected paint, the apron linen must be sized, for which purpose a stiff starch paste serves very well, being handy and not having the evil smell of size; then, when this is dry, the enamel can be applied evenly and thinly, waiting till one coat is dry before proceeding to another.

It only now remains to describe a knapsack attachment, though this the writer confesses to have altogether rejected in favour of the wheels; but in a rough hilly country, where these, perhaps, could not be used, the knapsack would be the best thing to replace them. Buy as many yards as the measurements of your camera case (and your own proportions of chest) require of the same webbing of which your sling has been made, and with it four large buckles to complete the materials wanted for its construction. This will make a detachable attachment which will not pull out the back of the camera case, as those attached thereto not unfrequently do. Cut two lengths of webbing to go, like the straps, right round the case, and fasten in the front with a buckle a piece, these, of course, being sewn to one end (the top); then two more lengths, long enough, when affixed to the webbing at the back of the camera case (as in fig. 3), to go over the shoulder and under the arm, and fastening with the buckles in front. Though it is fairly obvious that, on a long day's tramp, it is a great advantage to be able to vary one's method of carrying, &c., to suit both the locality and one's moods, still, if every reader of this article only finds one method of these ways of portorage to his fancy, the writer will not have written in vain. SEMPER EADEM.

#### AN IMPROVEMENT IN PHOTOGRAPHIC ROLL FILMS.

[Patent No. 2770 of 1900.]

THIS invention of the Actien-Gesellschaft für Anilin Fabrikation, of Berlin, consists in coating the wrapper which comes into direct contact with the sensitised surface of the film with a thin layer impermeable to water. This layer prevents injuries to the film through atmospheric moisture, or through such ingredients of the covering body as might be obnoxious. It likewise prevents the marks and figures printed on the wrapper from being transferred to the sensitised surface.

In order to carry out the invention, the enveloping body is coated with collodion, or with such solutions of resin as, after evaporation of the solvent, yield a layer impermeable to water.

#### THORNTON'S IMPROVEMENTS IN THE JOINTING OF METALLIC BOXES, CAMERAS, SHUTTERS, &c.

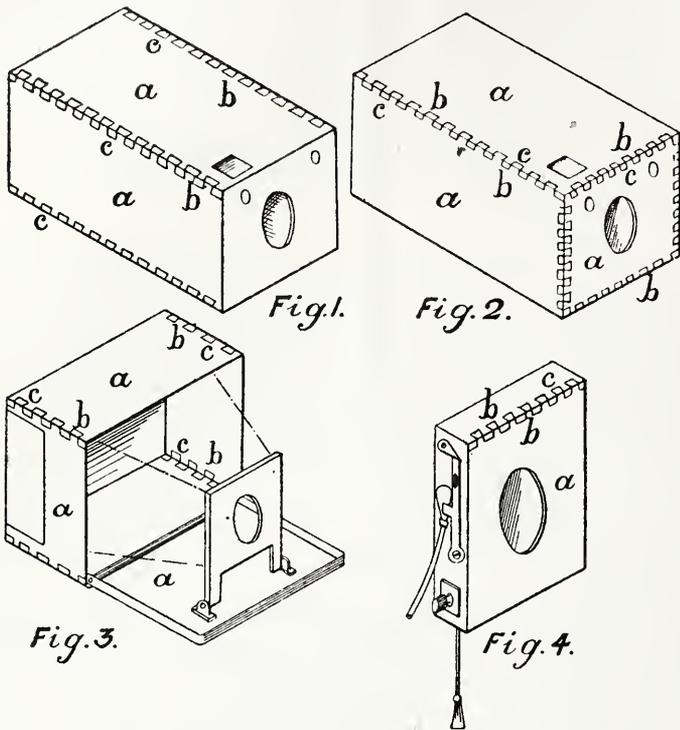

[Patent No. 7360 of 1899.]

THE invention consists essentially of a box, case, or the like, formed or constructed with curved or bent dovetailed corner pieces, which engage with each other (not in the thickness of the metal) in the same curved surface or plane.

The sheets, *a*, from which the case or structure is made, may be of aluminium, iron, steel, tin, brass, copper, or other metal or alloy, and are stamped out in blanks of the required shape.

The edges which are to come together to form the connexions or joints at the corners (or elsewhere) are stamped with interlocking or dovetail projections, *b*, alternating with recesses or notches, *c*, of corresponding shape.

When the blank is raised or stamped into shape for a rectangular case or structure, the interlocking dovetail projections, *b*, are bent or carried round the corner from one side, and the corresponding projections on the other edge are bent or carried round the corner from the opposite side,

the projections, *b*, on one side engaging and fitting closely into the recesses or notches, *c*, on the other side, thus forming a dovetail joint, not in the thickness of the metal, but flat, or in the same curved plane.

The two parts, after being fitted into position, are tightly pressed, and so rendered secure.

IMPROVEMENTS IN PAPER FOR PHOTOGRAPHIC PURPOSES.

[Patent No. 12,585 of 1899.]

THE patentees, the Rotary Photographic Co., point out, that, as usually prepared, papers for use in producing positives have one side coated or treated with a more or less solid dressing of baryta or lime for the purpose of supporting the sensitive layer which is to be afterwards applied. If this supporting medium be not used, the chemicals will penetrate the grain or fibre of the paper, with the result of producing an ineffective and indistinct picture.

In the Company's invention this supporting medium can be entirely dispensed with, for the reason that, once the gelatine or albumen solution, or the like serving as the support or vehicle for the sensitive salts, has become solidified on one side, the emulsion subsequently applied to the other side will be prevented by the first coating from penetrating the thin paper.

There is no difficulty in obtaining distinct copies in the printing-out process with the present paper, for the reason that, on exposing the front surface to the light, the transparency of the paper enables the light to practically simultaneously reach the emulsion on the back surface. The finished picture on one side of the paper is therefore enhanced by the finished image on the other side, though the latter is less intense than the former. A further result of this double treatment of the paper is that it allows of a reduction in the period of exposure, a fact which, in certain operations, as, for instance, for enlargements, is of considerable importance.

By using two emulsions of a different character the use of separate papers for negatives of different character or density may be avoided. For instance, one side of the paper may be prepared with a soft and highly sensitive emulsion, and the other with a highly contrasting and less sensitive emulsion, so that a substitute for two papers varying in sensitiveness is provided. Owing to the different densities of the shadows and depths of the images on both sides of the paper, it will, when looked through, present a very complete representation of the image upon it. In the case of such transparent positives the paper so treated acts as a deadened plate when seen through, so that the auxiliary devices which have heretofore been employed, such as ground glass, milk, or opal glass, or the like, to act as a base, may be dispensed with.

CAPTAIN DAVIDSON'S IMPROVEMENTS IN CAMERAS FOR THREE-COLOUR PHOTOGRAPHY.

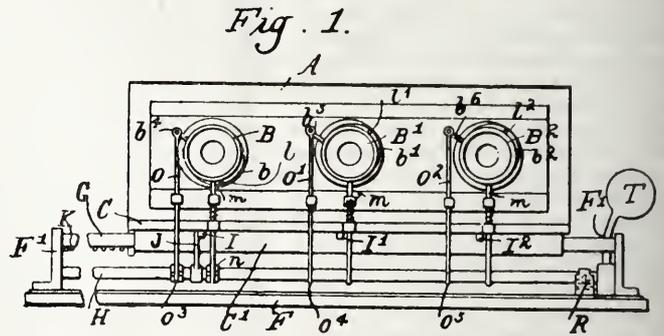

[Patent No. 15,444 of 1899.]

THE lenses are each applied with a different colour-filtering screen, in order to obtain negatives of the relative values of the colours filtering by the aid of the lenses and screens.

The colour-filtering screens—light red, blue-violet, and green or yellow respectively—are preferably of optical ground glass, but may be of dyed celluloid or other transparent material.

Each lens has a different-sized aperture, the lens with the red screen having the largest, that with the blue-violet screen the smallest, and that with the green or yellow screen a medium stop.

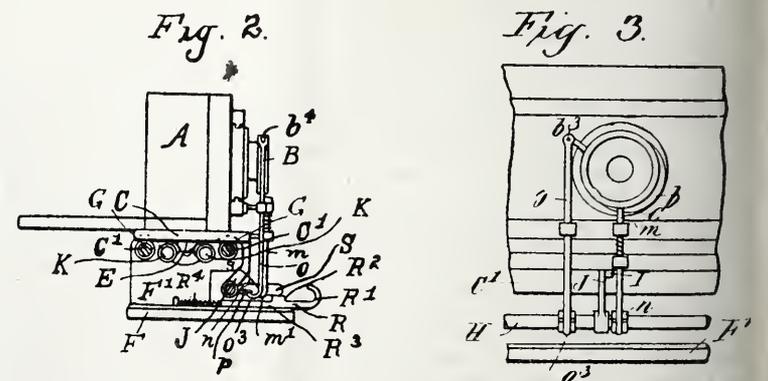

The camera, *A*, is provided with the three lens openings, *B B<sup>1</sup> B<sup>2</sup>*, and is divided internally into three compartments by partitions between the

lenses, so that three similar negatives can be obtained either on one long plate or on three separate plates fitted one behind each lens. The lenses, *B B<sup>1</sup> B<sup>2</sup>*, are provided with the requisite colour screens, as above described, and, by means of stops, the aperture in each case is regulated to give the required proportion according to the colour to which each lens applies. The colour screens may be slipped in suitable holders at the back of the lenses, or they may be passed between the combination in the case of rectilinear lenses, or in front or behind of the lens in the case of a single lens. The actual arrangement employed is not material to this invention, as the various arrangements indicated are well known.

The camera, *A*, is fitted upon a sliding carriage, *c*, attached by means of thumb screws, *E*, or the like. The baseboard, *F*, is provided with standards, *F<sup>1</sup> F<sup>2</sup>*, at each end supporting rods, *G G*. Tubes, *c<sup>1</sup> c<sup>2</sup>*, on the sliding carriage, *c*, are adapted to slide upon the rods, *G G*.

Lengthwise of the baseboard, *F*, a rod, *H*, is arranged, supported in suitable bearings, and operated by means of a rubber press ball, *T*, to

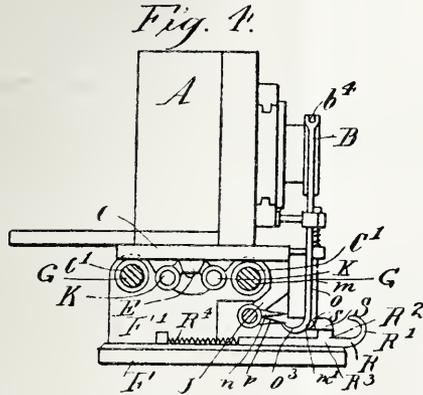

cause a vibration through a small angle. Three catches, *I<sup>1</sup> I<sup>2</sup> I<sup>3</sup>*, are arranged upon the under side of the carriage, *c*, and a side rod, *J*, is arranged upon the rod, *H*, in such position that the camera, *A*, being moved, it will be stopped at three different positions by means of the engagement of said rod, *J*, with one or other of the catches, *I<sup>1</sup> I<sup>2</sup> I<sup>3</sup>*, at the positions necessary to bring each of the lenses, *B B<sup>1</sup> B<sup>2</sup>*, in turn into the proper position for exposure. Spiral springs, *K*, attached at one end to one of the standards, *F<sup>1</sup>*, and at their other ends to the sliding carriage, *c*, cause the movement of the camera along from one position to another, as permitted by the rod, *J*, as will be hereinafter described.

The lenses, *B B<sup>1</sup> B<sup>2</sup>*, are provided with the shutters, *b<sup>1</sup> b<sup>2</sup> b<sup>3</sup>*, having an aperture which, as it passes before each lens, will give the necessary exposure. Springs in each case serve to cause the movement of each shutter when pressed in a manner well known. Each of the shutters, *b<sup>1</sup> b<sup>2</sup> b<sup>3</sup>*, is provided with a pin, *l<sup>1</sup> l<sup>2</sup> l<sup>3</sup>*, and, in order to stop each shutter at the exposing position, to allow for time exposure, spring rods, *m*, are mounted in suitable brackets, so that their ends will come in the path of the pins, *l<sup>1</sup> l<sup>2</sup> l<sup>3</sup>*, and will stop the shutters at the exposing position. The

lower ends of the spring rods, *m*, are provided with extensions, *m*<sup>1</sup>, upon which a projection, *n*, upon the rod, *h*, can press. The rods, *o* *o*<sup>1</sup> *o*<sup>2</sup>, are connected to the other shutter catches, *b*<sup>4</sup> *b*<sup>5</sup> *b*<sup>6</sup>, and side projections, *o*<sup>3</sup> *o*<sup>4</sup> *o*<sup>5</sup>, are provided, upon which another projection, *p*, upon the rod, *h*, can press.

At a suitable position on the framing, a sliding piece, *r*, is mounted,

having a finger piece, *r*<sup>1</sup>. At its other end it is cut away slightly, so that the portion, *r*<sup>2</sup>, is at a lower level than the portion *r*<sup>3</sup>. A spring, *r*<sup>4</sup>, serves to return it to its proper position after each operation. A projection, *s*, on the rod, *h*, is adapted to bear nominally on the higher portion, *r*<sup>3</sup>, but, when the sliding piece, *r*, is moved outwardly, will move through further until it bears upon the lower portion, *r*<sup>2</sup>.

ON THE PRODUCTION OF SILVER PRINTS WITHOUT TONING.

I.

A SILVER print, considered simply as such, and judged from a purely technical point of view, altogether apart from any value which may attach to it from extrinsic causes, is, I think, dependent upon two things for the place it is found to hold in popular estimation.

Of these the one is its appearance, whilst the other, of quite equal importance, is its permanence, a term here merely relative, no doubt, but none the less real.

Both considerations are, accordingly, of the utmost consequence to the printer. Knowing that, by reference to them, the merits, other than pictorial, of a print are usually estimated, the photographer, however much he may be disposed to depart from the traditional lines of manipulation, cannot afford to be neglectful of either. To them also, as a necessary consequence, other considerations not without weight, as, for instance, increased time and cost, and the difficulties attending the working of particular printing processes, are in practice largely subordinated. The latter are, we may suppose, looked upon as evils for which no remedy exists, and as restraints of which the printer would be glad to rid himself could he accomplish this without the sacrifice of the two characteristics which determine a good silver print.

Admitting this to be so, I have often wondered why the task of devising cheaper and simpler modifications of our existing processes for printing in this medium has received so little attention from those engaged in photographic work of an experimental character. One would think that the subject, being essentially of practical utility, would appeal to such investigators. Our ordinary silver processes, whilst much may be said in their praise, are both tedious and relatively costly. Our results, I grant, are remarkable for their excellence, but that, satisfactory though it may be to those of contented mind, is not the point at issue. The question really resolves itself into this, Cannot results equally excellent be obtained with less outlay, with less expenditure of time, trouble, or money, as the case may be? Of course, the answer may be in the negative as well as in the affirmative; but, in the absence of the experimental data necessary to decide this point, we are not justified in coming to either conclusion on *a priori* grounds alone. For this reason, then, it is somewhat to be regretted that there is so little tangible evidence at command to enable the photographer to speak with authority upon a point so vital to his interests. We must not, however, overlook the fact that, from indirect sources, it is possible to glean some information which may serve as a starting-point to beginners in this investigation.

Taking the matter of permanence first, let us avail ourselves of the facts furnished us by our daily experience. It is usually contended, and, I think, with much reason, that, of two silver prints, the first of which has been toned with gold, fixed, and properly washed, and the second merely fixed and washed without toning, that which has received the deposit of gold will prove the more lasting. There is, indeed, such an abundance of convincing evidence of an experimental character avail-

able in proof of this proposition, that it may well be regarded as incontrovertible. The evidence, in point of fact, dates from that period in the early days of photography when prints on paper supplanted collodion positives on glass.

Unfortunately, however, the proposition, simple as it appears at first sight, is not always rightly understood. It has already been said that the term, permanence, in the case of a silver print is merely a relative one. Unless we are careful to bear this fact always in mind, we may be tempted to argue that, because the "life" of an untoned print is admittedly shorter than that of one which has been toned with gold, in the first place, therefore, gold-toning is necessary to permanence, and in the second place, that untoned prints are necessarily evanescent. Neither conclusion is supported by experience. All that practice really teaches us is that the use of gold solutions for toning purposes serves to increase the permanence of the prints. We are not entitled to regard it as essential to that permanence unless proof is forthcoming in support of the assertion that silver prints not so treated are more than ordinarily short-lived. As a matter of fact, however, nothing in the nature of such proof can be brought forward. All the evidence points to a very different conclusion. Take, for instance, the deservedly popular gelatino-bromide paper printing process. In the vast majority of cases, prints in this medium are produced by simple development, without toning of any kind. Yet the permanence, always using that word in a relative sense, of these prints has, by the evidence of time, been very convincingly demonstrated, and is now, I think, pretty generally admitted.

Gold-toning, then is not essential to permanence, though it remains none the less true that a gold-toned print is, in general, more lasting than an untoned silver one, from the circumstance that, of the two, the more costly metal is less liable to suffer change through the operation of chemical agencies.

The question of permanence being thus disposed of, the matter of the appearance of the print next claims our attention. Viewing the subject in its practical aspect, it seems to be pretty generally agreed that some form of toning for silver prints (excluding, perhaps, those produced by development) is, on æsthetic grounds, a necessity. Such a conclusion, however, will hardly bear the test of rigid analysis. Its character is at best tentative and provisional. We may, notwithstanding, accept it in a restricted sense, making it an expression of the state of our present knowledge of the facts, and regarding it always as a proposition which we shall have to qualify in the light of a wider and more discriminating experience.

There is certainly a very intimate connexion between toning, using that word in its common acceptance, and the appearance of the finished silver print. It would, indeed, be strange were it otherwise. The existing printing-out processes in which silver is the sensitive medium do not exhibit much diversity of character. We find in each case that there is very little departure from certain hard-and-fast rules which have been formulated for us by our predecessors in the field, whether it be in the matter of the actual formulæ employed or in the conditions laid down for the working out of the process. The bearing of this on the relationship of toning to the appearance of the print is, of course, very evident. Amongst the rules given for the successful working of these processes, toning occupies a leading place, and this simply because, without its aid, it has been found impossible to produce a really good silver print upon paper prepared according to the orthodox formulæ. These formulæ being, as has been said, nearly identical in character, the result in all cases, is necessarily the same. Consequently, the process of toning has been somewhat unduly exalted, a recourse to it having come to be looked at as one of the conditions indispensable to success.

My readers (assuming them to have taken the trouble to follow me thus far) will readily see that such a conclusion cannot be regarded as inevitable, inasmuch as it rests upon insufficient data. All that can safely be said upon this head is that toning is found to be indispensable under certain defined conditions, from which we are careful not to depart. It by no means follows, however, that when we cease to observe these conditions, or that when we alter them, or substitute others for them, all of which things we are, of course, at perfect liberty to do, it by no means follows, I say, that, under the changed circumstances, toning will continue to occupy its old place as a determining factor. Let me here cite, as possessing a bearing on the point at issue, one or two facts which serve to demonstrate that, even in the case of a silver print produced in the usual way, the beauty of the result cannot be attributed to the toning alone. Take the case of an untoned print upon gelatino-chloride paper. Its appearance, when fresh from the printing frame, is, I venture to say, and I think most will admit, as rich and beautiful in its way as any gold-toned print can be. In a few cases, perhaps, the colour may not be so agreeable as that of a toned print, though this circumstance has of late years been much less noticeable than formerly. With the better brands of paper, and when printing in diffused light is the invariable rule, such crudeness is seldom apparent. Though not lasting, this beauty of what we may regard as the type of the modern silver print sufficiently shows that, in so far as appearances are concerned, silver compounds are as capable of holding their own as those of gold.

Conversely, let us for a moment consider that rarer type of the skill and intelligence of the photographer, the gold print. By the term I must not be understood to mean the silver print in its final state, after it

has been coated with gold by treatment in the toning bath. The expression is to be interpreted as indicating that species of picture obtained by the direct action of light upon paper sensitised with a compound of gold. As the action is comparatively slow when a gold salt alone is employed, it is generally found necessary to combine with the chosen compound a body of a more sensitive character, such, for instance, as ferric oxalate. On exposure to light, the oxalate undergoes speedy decomposition, as in the process of platinotype printing, the change being accompanied by the formation of an image in metallic gold, due to the simultaneous disintegration of the associated salt.

Now, the appearance of a print produced in this way is not of that surpassing degree of excellence which we might be led to expect by an experience derived merely from the use of gold solutions for toning purposes. Any merit that a gold print may possess must be attributed to its colour alone. In that combination of richness and depth with extreme delicacy of effect, with which all silver printers are familiar, a print in this medium is utterly lacking. The general effect, indeed, as often as not, is somewhat dull and flat, particularly in the half-tones. Weakness is another feature characteristic of the gold print, though, perhaps, this defect may in some measure be due to the difficulties of manipulation having been only imperfectly mastered.

In the gold print, then, we find a fresh proof in favour of the conclusion that the orthodox silver print is less indebted to the toning process for its appearance than is commonly supposed.

I pass now to a brief review of the advantages which would accrue to the photographer under an altered condition of things, assuming it were found practicable to simplify and improve our existing silver-printing processes. The first, and perhaps the most important, of these is the saving in cost which might be effected. Supposing it were found possible to produce a good silver print of the average type by means of a formula which should not involve recourse to gold toning, the saving effected from this source in the expenditure of the printer would be by no means inconsiderable. It is not necessary for me here to enter into any elaborate calculations. The cost of his chloride of gold, and the ratio which this cost bears to his whole outlay in the production of the print, are items which the practical photographer may very easily estimate for himself.

Hardly less important, from an economical aspect, would be the saving in time which would result as a necessary consequence of the disuse of the toning bath. In the ordinary course of things, working under the usual conditions, the amount of time spent in toning operations is large and indeed excessive. Under the circumstances, this can hardly be remedied. In the treatment of a batch of silver prints in the toning bath, it is found impossible, after a certain stage is reached, to maintain the rapid working of the gold solution without an addition of an extra quantity of the chloride. As this, however, means an increase in cost, the photographer in general deems it wiser to let things take their natural course, the result of which is that the process of toning, regarded as a whole, is apt to be unduly prolonged. Besides the time that is lost in the treatment of the prints, there is, in addition, that which is required for the preparation of the necessary baths as well as that which is expended in the recovery of the gold from the disused solutions. These items must all be taken into account in making up an estimate.

To the advantages, saving in cost and saving in time, a third may be added, namely, saving in labour. Under the system now practised, a good silver print is the result of a series of operations which, with one exception, make no great demand on the intelligence and executive ability of the printer. I say, with one exception, for the process of toning, necessitating as it does in a marked degree the exertion of the operator's skill, care, and patience, must be regarded as a case apart. Toning, in fact, is an art in itself, and as such cannot be carried out in a superficial and mechanical fashion.

The silver-printer's task, therefore, is in some measure an exacting and laborious one, though, no doubt, it will be contended that he is amply repaid for all his pains by the quality of the work he produces. The contention may be admitted, but does not serve to settle the question raised as to whether the trouble expended is, from the nature of things, a necessity.

Lastly, there is another advantage which would, I think, result from the simplification of our existing printing processes, and which, though perhaps not attainable in every case, must not be overlooked.

I refer to what in all likelihood would be the result of newer and simpler conditions of working upon technique, namely, a raising of the average standard of excellence in the matter of the appearance of the print. In saying this, however, I do not mean to convey the idea that we should be able to produce a better class of work than that turned out by the professional photographer now under the old system. All that is meant is that we should probably have more good prints by having fewer bad ones. In other words, the difference, frequently apparent to a painful extent, that distinguishes the work of the professional from that of the amateur, would tend to become less as the practical difficulties of the process were more easily overcome.

That this would be the natural result of the change there can be little doubt. With the disuse of the toning process, and with it of the accompanying necessity for observing that extreme care in manipulation which the average amateur seldom succeeds in acquiring, it is evident

that the risks of failure in working the process must be diminished, and the chances of producing good prints proportionally increased. To be sure, the amateur here would reap the benefit, rather than the professional photographer; but, in the other advantages which have been enumerated, each would be entitled to participate alike.

The facts mentioned in the foregoing short summary should suffice to convince the practical printer that the existing processes, while excellent in their way, are not without their shortcomings, and also that it is desirable that an endeavour should be made to introduce improvements in our methods of working, whereby the imperfections complained of would be either entirely remedied or reduced to a minimum.

In a second paper I propose to treat, in brief detail, of the remedies which would seem to be required to effect this end. I shall also give, as the result of careful experiment, a few jottings which may be of a little assistance to those who hereafter may turn their attention to an interesting and comparatively neglected branch of photographic research.

MATTHEW WILSON.

#### ANNUAL DINNER OF THE PHOTOGRAPHIC PLATE AND PAPER-MAKERS' ASSOCIATION.

The Third Annual Dinner of the Photographic Plate and Paper-makers' Association was held on Wednesday evening, May 2, at the Restaurant Frascati, Oxford-street, W. The chair was occupied by Mr. Frank Bishop, the Vice-Chairman being Mr. John Howson. Amongst the company were Mr. George Houghton, Mr. Edgar Houghton, Mr. F. W. Hindley, Mr. George Davison, Mr. F. K. Hurman (Newcastle-on-Tyne), Mr. Hubert Elliott (Elliott & Son), Mr. M. S. Berger (Berger & Co.), Mr. J. B. B. Wellington and Mr. H. H. Ward, Mr. J. Stevenson and Mr. C. Winter (the Imperial Dry Plate Company), Mr. H. M. Dennes (Morgan & Kidd), Mr. E. Schumann, Messrs. Whitfield (the Paget Prize Plate Manufacturing Company), &c. A very pleasant programme of songs, violin solos, and recitations had been provided, and the entertainment, combined with the admirable dinner provided by the renowned Restaurant Frascati, appeared to afford the highest enjoyment to all present.

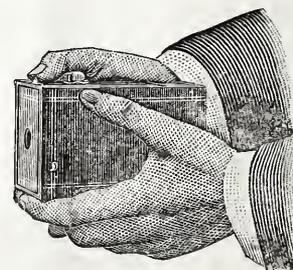

The toast-list was short, and brevity characterised the speeches. The Chairman having submitted "The Visitors," Mr. Houghton and Mr. Bedding replied. In proposing the toast of the Association, Mr. Hindley said that he strongly supported its aims. The toast was replied to by Mr. Howson. The health of the Chairman was the last toast on the list. The speeches were chiefly congratulatory of the Association and the continued success of its aims in the regulation of discounts; and Mr. Howson took occasion to point out that, while at the first dinner there were no guests, the Press was represented at the second, and the Press and the trade at the third. An enjoyable evening terminated with the singing of "Auld Lang Syne."

### Our Editorial Table.

#### THE BROWNIE HAND CAMERA.

Manufactured and sold by Kodak Ltd., 43, Clerkenwell-road, E.C.

WE doubt if the famous Kodak Company "can go one better" than the Brownie Camera for combined cheapness and utility. Measuring only  $4\frac{1}{2} \times 3\frac{1}{2} \times 3\frac{1}{2}$  inches, it weighs  $8\frac{1}{2}$  ounces. The lens has a focal length of 4 inches, and the size of the image given is  $2\frac{1}{2} \times 2\frac{1}{2}$  inches. It takes daylight changing cartridges, transparent film or paper film being had as desired at 7d. and 5d. per spool of six exposures respectively. The instrument is neatly covered with leather cloth, the external fittings

are of nickel, and in loading and exposing the film the well-known Bullet and Bull's-eye Kodak movements are availed of. And all this for 5s.! The Brownie is simply a marvel at the price. The Company say that they think this new departure will have the effect of making thousands of new users of photographic apparatus of all kinds, as has been the case with their other and previous simplifications of photography and perfecting of film products. The Brownie is called a camera "for boys and girls." We know several young people, as well as numerous "grown-ups," who were immediately smitten with the ambition to possess the specimen instrument the Kodak Company kindly sent us. Altogether, the Company may be congratulated on one of the surprises of the spring season; success, of course, will follow.

MESSRS. MARION & Co., of Soho-square, London, have placed on the market a series of post cards sensitised by the ferro-prussiate process. For use with these cards there is also a specially arranged collection of floral masks and discs in great variety. These are sold at sixpence the packet, and will be found of service for general work as well as for printing on post cards. Three special lists also reach us from Messrs. Marion: one devoted to specialities in projection lanterns and accessories; a second to the Radial camera; and a third (temporary list) to process apparatus and miscellaneous photographic materials.

#### CATALOGUE RECEIVED.

MR. JONATHAN FALLOWFIELD, of 146, Charing Cross-road, W.C., sends us his season's list, 1900. In the course of twenty-four large, closely printed pages it gives the reader a priced and illustrated review of the newest introductions to the photographic market in the way of apparatus and material. We can recommend our professional and amateur readers to procure a copy of this list: it contains something to suit all tastes.

*A Handy Guide to Photographic Requisites* is the title given to the list of photographic apparatus, materials, and chemicals issued by Messrs. Reynolds & Branson, Limited, of 14, Commercial-street, Leeds. It extends to over eighty-eight pages, and is a very well-compiled production.

## Studio Gossip.

FIRE.—The studio and stores of Messrs. Johnston & Co., photographers, of 60, High-street, Stoke Newington, were destroyed by fire on Thursday night, May 3.

"PICTURES OF THE YEAR 1900," with nearly 250 reproductions of the leading pictures in The Royal Academy, New Gallery, &c., was published at the *Art Journal* Office, on the opening day of the Royal Academy, Monday, May 7. It contains, as usual, only pictures which are accepted and hung. The price in paper covers is 1s., and, as affording a second-hand glimpse at a selection of the year's art, is well worth possessing.

In his studies of slow motions, Professor Charles S. Slichter, by means of kinetoscope pictures, has so magnified the motions that the growth of seedling peas and beans during three weeks is shown in a few seconds. The plants were photographed on the kinetoscope film by artificial light at intervals of a few minutes to a few hours during the three weeks. On projecting the pictures upon the screen at the usual rate, the motion of growth was magnified about 500,000 times, and the different rates of development of the various parts were brought out very clearly. Among the striking results was the curious behaviour of a pea struggling to enter impenetrable soil, the root curving and writhing much like an angle worm, while the pea was rolled about very grotesquely.

LARGE CAMERAS.—Messrs. Penrose & Co., in *Process Work* for April, say that they have never experienced before such a run on big cameras as during the past three months, and it has taxed all the energies of their factory to turn out the number required in addition to the smaller sizes, which are in constant demand. Five 20 x 16 and four 24 x 20 cameras have been sent out since the beginning of the year, and three more of each size are in course of construction for orders in hand. Very few people realise the enormous amount of work in these large cameras. It is a very different matter from the way the small hand and stand cameras are being turned out nowadays. The tendency of process work seems to be towards bigger sizes, and it is natural this should be so with the greater ease with which the half-tone process is now being worked. Besides, big sizes pay if you can get the orders and can execute them properly.

THE "Woman's Exhibition" at Earl's Court, which was opened to the public last Saturday, is decidedly worth a visit. Its features include a Fine Art Section, which occupies nearly the entire space of the large building by the lake, known as the Queen's Palace, and contains a collection of close upon a thousand pictures all painted by women of various countries. In the Queen's Palace are also to be seen many examples of the achievements of woman in the Applied Arts, examples of every imaginable decorative piece of handiwork being contributed. In the Handicraft Hall, which is situated near the to Royal Galleries, many interesting and beautiful "crafts" are seen in operation. The intention of the Woman's Exhibition, on its historical side, is to illustrate, by actual memorials, the most famous and distinguished of womankind, to exhibit their portraits by contemporary artists—the actual dresses they wore, their personal ornaments and feminine belongings, letters written by their hand—and similarly intimate details. The typical classes of womankind embrace all sections of society, preference being given to portraits of royal personages as best recognised; ladies of the historical aristocracy; women who have made famous reputations by their social charms, or have been traditionally celebrated for personal beauty; women whose names have become universally familiar, owing to their gifts as great singers, actresses, painters, writers, and in the various avenues to fame wherein womankind has left enduring marks.

## News and Notes.

THE members of the Alpine Club are now holding an Exhibition of Alpine photographs in their Club Rooms, 23, Saville-row. The Exhibition will remain open until the 26th of the month.

THE Exhibition of photographs, mainly architectural, by Mr. F. H. Evans, is now on view at the Royal Photographic Society's rooms at 66, Russell-square, W.C., and can be viewed, on presentation of visiting card, from ten to four.

ON Tuesday last the Prince of Wales presented, at Marlborough House, the Albert Medal annually granted by the Council of the Society of Arts, to Sir William Crookes, F.R.S., "for his extensive and laborious researches in chemistry and physics, researches which have in many instances developed into useful practical applications in the arts and manufactures."

THE GREAT TELESCOPE AT PARIS.—The *Malin* states that an examination of the sun made at the Exhibition last week through the gigantic telescope at the Optical Pavilion gave unlooked-for results. The sun's image, as seen, was one of surprising clearness, and flame prominences, such as have hitherto been visible only on the sun's edge, were perceptible on the surface itself.

WE are informed that the Fourth Triennial Exhibition of the Ashton-under-Lyne Photographic Society will be held from November 12 to 17 inclusive in the Town Hall. It will be an invitation Exhibition, offering no prizes, and having no competition, but lectures, &c., will given each evening. The carriage of pictures will be paid by the Society each way, and the exhibits will be insured whilst in their possession.

THE FORTHCOMING ECLIPSE.—The Astronomer Royal and his assistants have left for Ovar, in Portugal, in order that they may have plenty of time to make the necessary preparations for the observations they have in view. They have taken with them apparatus weighing in all about two tons for the purpose of photographing the eclipse during various phases. These photographs will be on a larger scale than those which were taken by the Astronomer Royal a couple of years ago in India.

MR. F. W. HASELGROVE sends *Nature* a photograph of a robin's nest in a water can, with the bird sitting upon its eggs, now to be seen at Finchley Cemetery. Our contemporary remarks that robins are well known to build their nests frequently in curious places, one of the most remarkable instances on record being that of a nest in a battered beer can between the rails over which trucks were continually passing at Worthing railway station. Flower-pots and water cans appear to be favourite nesting places of the birds.

At the fortnightly meeting of The City of London Tradesmen's Club, on May 3, the feature of the evening was an extremely interesting lantern lecture by Mr. G. J. Clark, entitled "From Cairo to Khartoum." For many years Mr. Clark has been collecting views of Egypt and Palestine, and he explained that a number of the slides were prepared from views brought to England by a tradesman of the City of London. The lecturer took his audience from Alexandria, along the Mamoudia Canal, to Cairo, and thence up the Nile to the Isle of Philæ by the First Cataract, concluding with the exhibition of several slides illustrating the campaign leading to Lord Kitchener's victory at Omdurman. Mr. Clark dwelt upon the historical, religious, and social aspect of Egypt, as illustrated by the existing monuments and customs, and greatly interested his audience.

HOW WE SEE.—The essential nature of the action exerted by ether waves is still undetermined, says the *Chemical News* in the course of a review of Professor Shelford Bidwell's *Curiousities of Light and Sight*, though the old belief that the sensation was produced by a series of mechanical beats similar to the action of air waves on the ear no longer carries any weight. Ether waves can bring about chemical changes as in photography; they can also produce electrical effects, as, for example, when they are allowed to fall on a piece of prepared selenium; but it is inconceivable, and, further, there is no evidence, that they are able to impart their own vibrations of such enormous frequency to any part of the human organism. Many guesses at the truth have been made, but it is most likely that the effect is both electrical and chemical. Again, the range of sensibility of different eyes may vary in the same manner as do different ears, and it is by no means probable that all animals, and especially insects, have the same limits of vision as man; further, the same vibrations falling in different places will give very different results. A chemical action will be caused by the ray falling on the leaf of a plant, an electrical action if it falls on a selenium cell, and the sensation of light if it falls on an eye.

PROPOSED NEW ART CLUB FOR LEEDS.—A number of gentlemen interested in the furtherance of pictorial photography and art in Leeds and the West Riding of Yorkshire met on Friday evening last, at the Vegetarian Restaurant, Boar-lane, Leeds, to receive and discuss a scheme prepared by a sub-committee, with a view to the formation of an Arts Club for the City of Leeds. There were present Messrs. W. E. Tindall, R.B.A.; J. H. Gash, R. Bourke; Percy Sheard; T. Carter; W. M. Coultass, and others. The scheme is only yet in a chrysalis stage of existence, but, from the well-known activity of the gentlemen interested, it may be fairly anticipated that such a Club will be formed. As foreshadowed in the report read at the meeting, the name of the proposed Club will probably be "The Arts and Crafts Guild," and the idea is to limit the membership to thirty, with a subscription of one guinea per annum. A further proposition is to hold an annual exhibition, probably in December of each year, of pictorial work, paintings, and it is also intended to include in the scheme representative workers in wood and metal. The question as to whether ladies should be admitted was allowed to stand over. There being only a small attendance at the meeting, the whole matter was left in the hands of a sub-committee, to convene a further meeting, and a proposition to invite likely exhibitors now showing in the Leeds Art Gallery was unanimously carried.

WHERE KNOWLEDGE ENDS.—"I suppose it is true that nobody exactly knows what happens when you drop a piece of sugar into your teacup," writes Dr. Andrew Wilson in the *Scotsman*, "or how the particles and molecules of sugar are taken to pieces by the molecules of the water, or what is the ultimate relationship of sugar and water when all is done. A stone is thrown into a pool, and we watch the ever-widening circles which gradually disappear and leave the pool surface as placid as before. Where do the vibrations end, or do they ever end at all? I suppose science would say they are endless, and pass...

out into the Ewigkeit, and mingle with the other vibrations which constitute part of the 'force' of the universe. After all, how little do we know of the real essence of anything. It is a profitable thought this, even if it tends somewhat to discouragement. But it has one great advantage, that, if it teaches the scientist humility of the best type, it should also impart a like lesson to the people who are not scientific, and who are never weary of airing their stupidity in denouncing scientific aspirations. Only it will never teach such people any such lesson. Nothing is known to them save the sense of their own importance, which is very extensive. That which really comforts the man of science is that his methods of research grow year by year in completeness and accuracy, and he does succeed in explaining many things whereof his fathers were ignorant. The spirit of true science is that it sees as in a glass darkly, and it waits, patiently and hopefully, for the days to come when will dawn the fuller light and the more perfect understanding.

THE monthly lantern-slide competitions, instituted by the Borough Polytechnic Photographic Society amongst its members at the commencement of the late winter session, have just been concluded. Mr. E. J. Hoar takes first place and the silver medal, scoring 114 points out of a possible 180, whilst Mr. F. W. Gregg secures the bronze medal with 99 points, and Mr. E. G. Hawgood the certificate with 88 points. Messrs. F. W. Bannister and R. R. Rawkins officiated as Judges throughout the season, and have rendered valuable service by their candid criticism of every slide submitted. These competitions have met with considerable success, and have, doubtless, been the means of infusing much interest in pictorial lantern slide-making throughout this Society. One result has been the formation of a set of "picked" slides, numbering about sixty, which the Society will be glad to lend to other societies, with descriptive notes, as soon as ready.

## Commercial Intelligence.

THE FOLDING APEK CAMERAS.—Mr. W. Emery, of Soho-street, sends us a new list of his folding Apek cameras, and informs us that at the new and reduced prices they will be maintained at their former grade of excellence. The reductions in price are as follows: Folding Apek cameras, one camera, twenty per cent.; magazine Apek cameras, three or more cameras, twenty-five per cent.

Husson's Safety Acetylene Syndicate, of 28, Victoria-street, Westminster, S.W., are issuing a catalogue of acetylene generators, purifiers and fittings, for lighting towns, villages, railways, factories, hotels, private houses, &c.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
14.....	Bradford Photo. Society .....	Varia. P. E. Newstead.
14.....	Stafford Photo. Society.....	Prize Slides. Reader, Mr. Rostance.
15.....	Ashton-under-Lyne.....	{ Demonstration: <i>Velox Printing</i> . D. A. Nightingale.
15.....	Gospel Oak .....	{ Prize Slides.
15.....	Hackney .....	{ Demonstration: <i>Glass in its Photographic Aspects</i> . Thomas Bolas, F.C.S., F.I.C.
15.....	Redhill and District .....	{ <i>Intensification and the Improvement of Negatives, with Experiments</i> . The President.
16.....	Croydon Camera Club .....	{ Demonstration: <i>A New Method of Counteracting Excessive Contrast in the Negative</i> . Benjamin E. Edwards.
16.....	Woodford .....	{ Demonstration: <i>Platona</i> . F. G. Emler.
17.....	Liverpool Amateur .....	{ American Slides.
17.....	London and Provincial .....	{ <i>Rapid and Wholesale Development</i> . Messrs. Welford and Human.
18.....	Croydon Microscopical .....	{ Photographic Chat.
19.....	Bootle .....	{ Excursion: Raby Mere. Leader, H. G. Page.
19.....	Brentford .....	{ Excursion: Burnham Beeches with Stoke Poges. Leader, Mr. Squires.

### ROYAL PHOTOGRAPHIC SOCIETY.

MAY 8,—Ordinary Meeting,—Mr. T. R. Dallmeyer, F.R.A.S. (President), in the chair.

#### COLOUR AND GRADATION.

MR. CHAPMAN JONES, F.I.C., F.C.S., read a paper on "The Effect of Wave-length on Gradation." It had, he said, generally been taken for granted that the character of the gradation given by a photographic plate is not affected by the character of the light that produces the developable effect, except, perhaps, that red light has a greater tendency to produce reversal than blue light. It appeared that the trichromatic printing processes of to-day depend for the accuracy of their results upon the similarity of the gradation produced by the red, green, and blue-violet lights employed in getting the three negatives. Although there might be theoretical grounds for saying that the gradation is independent of wave-length, it was desirable to practically test the question, and the paper consisted of a detailed account of experiments conducted with this object. A strong light being necessary for these experiments, magnesium

ribbon was employed, the exposures being regulated by noting the weight of magnesium burned, or the length of ribbon when the weight per unit length was uniform. To isolate the colours, carefully tested coloured screens were placed close in front of the burning magnesium, the plate exposed being at a distance of three feet, with a rotating sector immediately before it for giving the proportionate exposures, while the space between the plate of the screen was enclosed by a brown-paper tube, in which were diaphragms to prevent reflected light from the surface of the tube from impinging upon the plate. The first experiment described was a comparison of the effect of blue light with that of green light, the green giving a steeper curve than the blue. The general tendency of white light was undoubtedly to give a steeper curve than ultra-violet, and, when green was compared with ultra-white, there was again a markedly greater steepness shown by the green, the less refrangible light. There was a greater steepness also in going from red to green, and an apparent tendency to reversal in the higher densities was here clearly set forth, there being also a marked tendency to less steepness in the lower densities. The ordinary plates, which showed no difference between green and ultra-violet, showed a steeper curve when red was compared with green, so that, if a plate did not show a steeper gradation in passing from ultra-violet to green, it did if one went on the red, and, if the red and green were alike, they were both steeper than the ultra-violet. The fact was thus emphasised that, as one got longer wave-lengths, or went farther towards the red end of the spectrum, steeper curves were produced. A second series of experiments was carried out with specially sensitised isochromatic plates developed with metol, with the exception of three which were developed with pyro and ammonia, the ammonia being found to decrease the steepness of the gradation given by the red as compared with that of the blue, or to increase the blue as compared with the red. Summarising his results, Mr. Chapman Jones said they showed that gradation is not constant with varying wave-length or varying colour; that, the longer the wave-length, the more one approached green or red, the steeper would be the gradation, except that it became less steep in the higher densities, the tendency to reversal being possibly greater, and also probably less steep in the lower densities. The differences in gradation were not due to different compounds in the film when specially sensitised, because the same differences were shown by ordinary plates, an increase in the difference of wave-length giving a difference in the increase of gradation. The experiments also demonstrated the fact that the use of pyro and ammonia leads to irregularity in this respect, as in others, making the curve produced by the light of longer wave-length less steep than it otherwise would be, or that of shorter wave-length more steep than it should be. It seemed probable that it was the ammonia that caused this irregularity.

#### COMING EVENTS.

MAY 22, Technical Meeting, subject to be announced. JUNE 12, Ordinary Meeting, a paper by Mr. H. L. Aldis, B.A. JUNE 26, Technical Meeting, a paper by Mr. J. H. Agar Baugh.

ON MAY 29, Dr. P. H. Emerson will open an exhibition of his works in the Society's rooms, and will deliver an address. The present Exhibition of photographs by Mr. F. H. Evans will remain open until May 26.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 3,—Mr. A. Mackie in the chair.

MR. J. E. HODD brought forward the "Volvo" apparatus for developing, fixing, washing, and drying rollable films. It consists of a wheel, a stand for same, and two specially shaped dishes. The quantity of film one is enabled to develop depends, of course, upon the diameter of the wheel, as the film is wound upon the rim. The width of film depends upon the width of the rim also, but wider wheels can be had to fix to the same spindle. The rotation of the wheel carries the film through the developing solution until the images are complete, when a similar action performed in another trough fixes and finally washes the film, which may be dried whilst still on the wheel.

MR. W. F. CRAWFORD showed his Express rotary developing machine, constructed to take either quarter or lantern plates, twenty-four in number, and accommodating equally well glass plates, celluloid or paper films, and bromide prints. It serves also for toning and finishing silver prints, and forms an excellent washing apparatus. Mr. Crawford claimed that two dozen average exposures could be developed in twenty-two minutes and washed in ten minutes, resulting in a great saving of time over methods involving the handling of only one or two plates at a time.

MR. PHILIP EVERITT thought the apparatus would serve very well for stand development with dilute developer. The usual methods available for stand development had the great objection and drawback that a bright line was caused round any deep shadows, due to a creeping action, arising perhaps from the stagnant condition of the solution. If, by means of a small motor or other arrangement, the machine could be kept slowly rotating, the application to the purpose he had outlined would be quite feasible.

The statement that forty-eight ounces of solution was required in any event, for the working of the apparatus, was discussed from the point of view of the expense in the case of developers not commonly usable more than once.

MR. CRAWFORD said he had used pyro ammonia for three batches of plates, and that a little citric acid would remove any stain that might be caused.

MR. R. BECKETT thought that, if sufficient sulphite were used, this would not mark the limit of use, and that five or six times would probably be safe.

MR. J. E. HODD passed round a stoppered bottle having on its outside a ground surface to serve in place of the ordinary paper label, a celluloid holder for small plates to prevent contamination of the fingers with chemicals, and two of Wynne's locket exposure meters. Mr. Hodd also passed round a bundle of prints on an American self-toning paper, all of which were frightfully marred by blotches and spots of an unaccountable nature. He toned before the meeting a print on some of the same paper, with the same result. The paper, it appeared, was packed face to face with nothing intervening, but between the backs of the papers were pieces of

paper which it was considered might have caused the trouble. No explanation was offered, the defects being somewhat strange and unusual.

Mr. T. E. FRESHWATER passed round silver prints from negatives taken through Joly screens, and an enlarged photograph of a piece of gold quartz.

Mr. R. H. PRIMAVERSI brought forward a photograph taken with a single lens, with an exposure of thirty minutes, at nine p.m. on a May evening, the subject being a marine pier by electric light. From each arc lamp lines of electric influence proceeded to the foreground of the picture, every line having similar curves. The brightness of the lines decreased with the distance of the lamps from which they proceeded. Wherever the lines changed their direction, a bright spot appeared. He wished to know at what time in the exposure did the occurrence take place. It was instantaneous in his opinion. Since taking this photograph, he had tried repeatedly with three cameras to get a similar result, but unsuccessfully.

Mr. A. HADDON said that the thing was due entirely to a mechanical origin, and not electrical as suggested, caused by an oscillation of the camera.

Mr. BECKETT suggested that a pinhole in the shutter blind would easily explain the appearance. After closing the shutter the camera might have been moved before the dark slide was closed, and the path travelled by the camera was registered by the pinhole images of the lights upon the plate.

The subject will be again brought up at a later date.

#### PHOTOGRAPHIC CLUB.

MAY 2.—Mr. Frank Haes in the chair.

Mr. F. A. BRIDGE brought to the notice of the meeting a case of platinum poisoning of which he had been informed. A girl who was set to tone lantern slides with platinum was found to be so sensitive to its effects that something in the nature of paralysis of the arm had set in. To show how small a quantity was sufficient to give rise to these symptoms, it was mentioned that a jar which had contained platinum toning solution was rinsed out with water and given to the girl to finish washing, but even the minute trace which was still present caused her the same paralysis.

Mr. A. MACKIE mentioned the case of a chemist who had been experimenting with platinum, and said that his hands were in a terrible state as a result.

It did not transpire what salt of platinum was used in the case mentioned by Mr. Bridge.

Upon the recommendation of the Committee it was agreed that during the summer months the meetings should take place at 7.30 p.m. instead of 8 as at present.

Mr. W. F. CRAWFORD said that, returning two years ago from New Zealand, and travelling about England, he had amassed some 600 exposures in a comparatively short time. Wishing to develop them expeditiously, he worked out as a developing machine an apparatus made and used in New Zealand by him as a washing machine. This apparatus he now showed. It was constructed for quarter-plates, and could be used for developing glass plates, celluloid films, paper negatives, and bromide prints, fixing and washing, and for toning and finishing silver prints. The apparatus consists of a stout glass trough provided with bearings, upon which are supported, by means of a spindle, two glass discs provided on their inner surfaces with radial grooves. Glass plates may be inserted directly in the grooves; films and prints are supported there in carriers of celluloid or other material. There is provision for twenty-four exposures at a time. The developer having been placed in the trough, the discs charged with the twenty-four exposures are lowered with rotary movement into the solution, and kept revolving by means of handles attached to the spindle. In reply to a question, Mr. Crawford said that it worked at its best with exposures of a similar nature. Violent under or over-exposures would manifest themselves as the development proceeded, and it was an easy matter to remove any that required special treatment. After development was complete the discs were removed and placed in another tank to wash, and the fixing bath poured into the first trough. Finally a stream of water is allowed to play, water-wheel fashion, on the film sides of the plates, for about ten minutes, which was found sufficient to free them from hypo. Mr. Crawford showed negatives so developed at the R.P.S., also prints toned therein.

**Croydon Camera Club.**—Wednesday, May 2.—The PRESIDENT gave a short address upon the forthcoming Exhibition of the Royal Photographic Society at the New Gallery, Regent-street. Mr. MACLEAN reminded his hearers that the Exhibition in question promised to be a great step forward as regards the attention it will attract and the facilities it will possess for the effective and orderly display of a much larger number of photographs than was possible at the Pall Mall Gallery. In connexion with the new regulations and conditions which had just been issued, he trusted he would be pardoned for reminding them that the Royal Photographic Society were now carrying out the advice given by the speaker in his paper read at the Photographic Congress in 1893, which, under the title, "Photography in Compartments," strenuously advocated that "the bewildering mixture" of all sorts and kinds of photographic productions should be shown at the Society's Exhibition in well-defined groups. This has at last been carried out, so that in the forthcoming Exhibition classes have been formed for (1) pictorial photography, (2) general professional work, (3) apparatus, (4) photo-mechanical, (5) scientific photography. Leaving this portion of his subject, the President spoke of the desirability of members who proposed exhibiting making immediate arrangements to produce their pictures, which, on account of the large dimensions of the New Galleries, should preferably be either direct enlargements or from enlarged negatives. He strongly advised intending exhibitors to prepare what they thought suitable and bring their prints to the Club, so that they might be fully criticised, and suggestions made for amendment or improvement before the prints were finally sent up to the institution for judgment. He also gave a short account of the National Photographic Exhibition now open, advising members not to lose the opportunity of seeing a comprehensive collection of up-to-date apparatus, &c. In connexion with this advice, a party of members arranged to visit the above on Saturday afternoon next. A description of a new blind shutter, which works

in front of the lens, drew forth the opinion of Mr. Maclean that the brevity of exposure was not directly proportional to the width of the slit in the shutter. This was debated, and subsequently, by means of the optical lantern, Mr. ISAAC demonstrated that, unlike a "focal plane" shutter, such a one as that under consideration permitted light to reach the whole of the plate, while the opening was passing in front of any part of the lens. Subsequently a number of lantern slides by Mr. Willcocks were inspected, the President taking the opportunity of announcing that a bronze medal offered by the Thornton Heath Photographic Society for lantern slides had been awarded to their member, Mr. G. W. Watson, the second position being gained by another member of the Club, viz., Mr. A. Willcocks.

**North Middlesex Photographic Society.**—May 7.—At the lantern slide competition held at Jubilee Hall, Messrs. Crane and Rawkins tied for first place out of a good collection of slides. The second general competition, and the prints from the Rochester outing on Easter Monday were a very good collection. Mr. Beadle was first and Mr. Mummery second in the general competition, and in the Rochester outing Mr. Mummery was first and Mr. Broad second. Twenty-one prints were sent into the latter. Mr. Crane showed some Wellington stripping films which he had just tried, one of which was stripped at the meeting. They were good negatives, and free from defects.

**Leeds Camera Club.**—The concluding meeting of the winter session was held at the Club Rooms, Grand Restaurant, Boar-lane, Leeds, on Wednesday evening last, when the awards in the Club's recent competitions were made. Mr. H. Stockwell, who was awarded the silver medals in two classes, being Hon. Secretary of the Club, had generously decided to waive his claim, and the first prizes were therefore withdrawn. A bronze medal for lantern slides went to Mr. H. Laverack, and a similar award for prints to Mr. Bell. Mr. SKILBECK afterwards entertained the members by a description of how to construct a reliable exposure meter for tenpence, and at the same time explained the working principles of Wynne's actinometer. A resolution was agreed to, seeking affiliation with the Yorkshire Photographic Union, and Messrs. Rust, Skilbeck, and Stockwell were appointed delegates for the first fortnightly meeting of the summer session. Mr. C. GREYSON also exhibited a handsome pedestal stereoscope containing a large number of views. During the summer season the meetings will be held the first and third Wednesday in each month only.

#### FORTHCOMING EXHIBITIONS.

- 1900.
- May 23-25 ..... Plymouth Photographic Society. Hon. Secretary, W. H. Harris, 5, Clarendon-place, The Hoe, Plymouth.
- July 9-14 ..... Photographic Convention of the United Kingdom (Newcastle-on-Tyne Meeting). Hon. Secretary and Treasurer, F. A. Bridge, East Lodge, Dalston-lane, London, N.E.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Patent News.

The following applications for Patents were made between April 23 and April 28, 1900:—

- FULL-SIZE FINDERS.—No. 7470. "Improvements relating to Full-size Viewfinders for Twin-lens Cameras." C. B. WINTER.
- CAMERAS.—No. 7474. "Improvements in Photographic Cameras." Complete specification. J. GAUT and J. J. ROUSE.
- ANIMATED PHOTOGRAPHS.—No. 7560. "Improvements in the Production and Reproduction of Animated Photographs." A. SINCLAIR.
- PAPERS AND FILMS FOR X-RAY WORK.—No. 7653. "Improvements in Photographic Papers, Films, and Plates for use in Röntgen or X-ray Photography." J. W. T. CADETT.
- CAMERAS.—No. 7664. "Improvements in Dark Slides for Cameras." W. F. STANLEY.
- STEREOSCOPIC PHOTOGRAPHS.—No. 7684. "Improvements in Means for Exhibiting Animated Series of Stereoscopic or other Views." R. BÜNZLI.
- CAMERAS.—No. 7722. "Improvements in Photographic Cameras." Complete specification. O. THIEMANN.
- CAMERAS.—No. 7867. "Improvements in and connected with Magazine Cameras." M. E. BANGER.
- SHUTTERS.—No. 7920. "Improvements in Apparatus for Controlling the Exposure of Photographic Sensitised Films." Complete specification. A. HOFMANN.
- FILMS.—No. 7921. "Improvements in or relating to the Marking of Photographic Films." Complete specification. A. HOFMANN.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE PHOTOGRAPHIC CLUB.

To the EDITORS.

GENTLEMEN,—I beg to inform you that, in consequence of continued ill health, our Secretary (Mr. W. R. Stretton) has reluctantly been compelled to resign the position, which resignation has been accepted by the Club with regret.

I have undertaken to carry on the work as Secretary and Treasurer *pro tem*.

It has been decided that, in order to meet the wishes of the majority of the members, during the summer months the meetings will commence at 7.30 p.m. sharp.—I am, yours, &c.,  
E. A. NEWELL.  
4, Maiden-lane, Queen-street, London, E.C., May 4, 1900.

### A HAND-CAMERA CHANGING MECHANISM.

To the EDITORS.

GENTLEMEN,—I am advised to patent a changing mechanism I have constructed for a hand camera for my own use.

Before doing so, I should be glad of your opinion of its commercial value.

I first made it for twelve plates, but found I could eliminate certain objectionable features by making it for eight plates, which I consider enough for the class as distinguished from the fifty-film or roll class. The size is  $5\frac{1}{2} \times 5\frac{1}{2} \times 10$  for a five-inch lens, but the weight is less than the ordinary camera.

1. A plate is changed by a half turn of a nut.
2. No sheaths, only light rims.
3. Nothing can touch the sensitive surface, for one rim cannot touch the next.
4. Nothing loose to rattle, and no falling plates.
5. Changing, being independent of gravity, can be effected in any position of camera, and the latter may be even sent spinning in the air without displacing anything.
6. Additional weight of mechanism for stereoscopic as compared with quarter-plates practically *nil*.
7. Rapidity. The whole eight plates can be changed in four seconds (not four seconds each).
8. No levers, pulls, racks, wheels, or springs.
9. Changing mechanism of such a nature that it can be made of celluloid or vulcanite.
10. Without bringing into action additional mechanism, a plate already in the focal plane can be moved aside to substitute another, and afterwards brought back; thus the plates may be of different brands, speeds, or colour-sensitiveness, and any one can be exposed at will and in any order, for the indicator is for the purpose of showing *not* how many plates have been exposed, but *which* plate is in the focal plane.

With your unique knowledge you may be able to kindly tell me (1), Is there such a camera already on the market? (2), Would there be a commercial demand for such?—Thanking you in anticipation, I am, yours, &c.,

R. B. HUGHES.

Green Bank, Bangor, May 7, 1900.

[We know of no plate-changing mechanism exactly similar to that described by Mr. Hughes. With regard to ascertaining its commercial value our correspondent's best plan will be to submit it to some manufacturer of hand cameras.—EDS.]

## Answers to Correspondents.

\* \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street Strand, London, W.C. Inattention to this ensures delay.

\* \* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPH REGISTERED:—

T. M. Barbour, 1, Brierley-street, Bury, Lancs.—Photograph of the Bury football team and English cup.

A. G. B.; J. McCONNAN; R. HOLDEN; WATER.—The answers to these and other correspondents are unavoidably held over.

MONOCHROME.—Robert Johnson's work on *Retouching*, published by Messrs. Marion & Co., Soho-square, W., contains many helpful chapters on the subject.

CASTLE.—Yes; we believe, if you take legal proceedings, you can recover in such a case. But, before deciding to sue, you had better take a solicitor's advice.

KHAKI.—We presume that the gentleman you invited to sit did not pay you anything. In that case the copyright is yours, and you can proceed against the infringers.

B. L. E. asks us to tell him the best developer for bromide paper.—In reply: We might make many suggestions, but we do not think we could do better than advise him to use the developer recommended by the makers of the particular paper.

DIRECTORY OF PHOTOGRAPHERS.—E. B. writes: "Is there a directory of photographers published? If so, where can it be obtained, and what is the cost?"—In reply: Messrs. Percy Lund & Co., Bradford, publish such a directory, price, we believe, 7s. 6d.

ELECTROTYPING.—W. WISDEN. Your query in no way applies to photography, and our space is too limited to admit of giving practical details for making electrotypes from bronze medallions. Better get a manual on the process of electrotyping.

TOWER.—1. We believe Messrs. Marion & Co., of Soho-square, supply such goods. 2. Messrs. Poulton's address is (or was) Lee, S.E., but we understand that the business was taken over some time ago by Messrs. Hazell, Watson, & Viney, 1, Creed-lane, E.C. Better write that firm.

J. McLEISH.—The Aerograph may be described as a kind of pencil carrying finely divided pigment in solution, which is directed by air pressure to the surfaces of bromides, carbons, platinotypes, &c. If you write to the Aerograph Company, 30, Memorial Hall, Farringdon-street, E.C., they will send you full particulars.

YEARLY AGREEMENT.—C. W. The *verbal* agreement, even if a witness was present, is not binding on either side, and you are liable to be dismissed at a week's notice. You also can, if you wish, leave at any time by giving a week's notice. An agreement on either side, to be binding, must be in writing, and duly stamped.

A. J. JACOBS.—The process is fully described in a book on heliographic printing by Mr. G. E. Brown, published by Dawbarn & Ward, Farringdon-avenue, E.C. Again, at pp. 994-1008 of our ALMANAC for 1900, a complete series of formulæ are given. Consult one or both, and you will have all available information.

RESTORING DAGUERRETYPES.—X. Y. Z. says: "I have an old Daguerreotype (on glass) which is very much faded. Can I restore this in any way?"—As the picture is on glass, it is not a Daguerreotype. It is a glass positive by the collodion process, and there is no method of restoring these pictures when they have faded. If it were a Daguerreotype, the case would be different.

MARKING ON A NEGATIVE.—W. THOMPSON writes: "Would you kindly let me know what is the cause of mark down the enclosed 12×10 negative? The dark slide is a new 12×10. I put two plates in this slide, and they are both marked in the same way. It was the first time I had taken this slide out. After exposure they were left in the slide (securely wrapped up) for a week before developing."—In reply: The markings appear to us to be such as would be caused by the leather hinges of the dark slide's draw shutter. The exhalations from the leather, probably caused by heat, were of a nature to partly obliterate the image.

SPOTS ON PRINTS.—ALEC CHAMBERS says: "If you will tell me the reason of the black spots on prints enclosed, through your valuable columns, I should be greatly obliged. It is such a waste of time to have to get fresh prints off, owing to these spots."—The spots are caused by particles of foreign matter coming in contact with the prints while they are wet, and so reducing the silver at that point. Probably this occurs in the operation of washing the prints before they are toned. It may, however, occur after that. Particles of pyro, or other reducing agents, would cause the spots; so would particles of iron in the washing water.

PATENT INFRINGEMENT.—H. PRADEAN writes: "I should be obliged if you could let me know the best course for one to take in the following matter. In 1896 I was granted a patent for a hand camera (No. 23,840), and during a visit to the photographic exhibition I saw the hand camera, and find that the movement is an exact copy of my patent. The exact date of patent is October 27, 1896, and I granted in the same month manufacturing rights to Messrs. ———."—In reply: We recommend you to place yourself in the hands of a respectable solicitor, who will advise as to whether you have a clear case. Much will turn on the claims made in both cases.

FAULTY ALBUMENISED PAPER.—E. A. SWEETMAN says: "I herewith enclose some prints made on enamel albumenised paper, and should esteem it a favour if you would give me, in the columns of your JOURNAL, your opinion as to the cause of the mealiness shown in the prints. The paper was sensitised for three minutes on a fifty-five grain bath, and the peculiar part of the matter is, that out of, say a dozen sheets floated on the same bath, ten will be perfectly free from the defect and the other two faulty. Sometimes all will go well for weeks together, then this mealiness crops up again, and, although I have tried using a weaker bath and floating for a shorter time, the result is practically the same."—The mealiness in the samples sent is due to the silver bath being too weak. It may have been of the right strength when the sensitising was commenced, but each sheet of paper floated makes it weaker on the surface by robbing it of its silver. This it will do, though the strength remains nearly the same towards the bottom of the dish. After three or four sheets have been floated the solution should be stirred up, or otherwise agitated, to maintain an equal strength throughout the bulk.

### EX CATHEDRĀ.

THE Secretary of the British Optical Association, writing from Clifton Chambers, West-street, Blackpool, sends us the current number of the official publication of the transactions of the Association, *The Dioptric and Ophthalmometric Review*, which is sent out monthly. "Some few years ago," writes Mr. Sutcliffe, "and to a certain extent even at the present time, the public and the trade generally suffered so very much from the many unscrupulous and incompetent quack opticians travelling the country, that it was felt that any scheme having for its main idea the classification and qualification of the optician would be readily welcomed. With this intention the British Optical Association was founded about four years ago, with the idea of improving, educating, examining, and certifying our sight-testing opticians. That this scheme has proved an unqualified success will be apparent when I tell you that not only has it been found necessary to make admission by examination a *sine-qua-non*, but that, up to the present date, out of eighty candidates nearly two-thirds were unsuccessful, thus showing the necessity for examination. The members of the Council,"

adds Mr. Sutcliffe, "are working hard to place the Association on a basis somewhat akin to that of the Dental and Medical Association, and are confidently looking forward to the time when by charter, legal enactment, &c., the eyes of a so far long-suffering public will be attended to and cared for by competent and duly qualified refractionists." We have much pleasure in giving publicity to this statement of the Association's objects. *The Review* is brightly and ably written, and the information it imparts to refractionists appears to be carefully selected. It is a large question whether sight-testing should or should not fall within the scope of ophthalmic surgery; but, putting that matter aside, the B.O.A. is deserving of encouragement in its efforts to exact from those who make the care of people's eyes an affair of business some evidence of possessing the necessary knowledge of what is required.

\* \* \*

READERS of the copious war intelligence printed in the newspapers have, no doubt, seen occasional references to a unique specimen of journalism produced at Bloemfontein, viz., *The Friend*, "edited by the war correspondents with Lord Roberts's Force." A copy of this publication, dated April 11, has been kindly sent us for our inspection. It is a large sheet of four pages, three of which consist of advertisements, the remaining page being made up of news and telegrams relating to the war. There is a contributed article headed "The War Artist of To-day," by Mr. H. Owen Scott, war photographer for the *Illustrated London News*. Mr. Scott most ably states the case for the new school of war artists, photographers, and says that, as long as the men practising this art are honest and do not attempt to foist faked work on the public, their efforts are bound to be acceptable. The article contains matter which, in the opinion of the editorial directorate of *The Friend*, is of a controversial nature, for some replies to Mr. Scott from well-known artists at the front appear to be anticipated. We are much obliged to Mr. G. W. Scott, of Fulham, for letting us see this copy of *The Friend*. The present conflict in South Africa has given photography an opportunity of proving what a valuable aid it can be to war correspondents, and it was quite in the fitness of things that attention should be directed to the point by one of the new school of "specials" writing, practically on the field of hostilities for purely local readers.

SINCE writing the previous paragraph we have received another copy of the *Friend*, dated Easter Monday, April 16. About that time Lord Roberts was beginning to move his army northwards and the editorial article in the paper tells the reader that the war correspondents with the Field Marshal's force can no longer be responsible for the conduct of the journal. Our interest in this particular copy of a unique newspaper lies in the fact that Mr. Scott's letter above referred to appears to have evoked a reply from the well-known artist, Mr. W. B. Wollen, R.I., who, if we mistake not, represents the *Sphere* in South Africa. Mr. Wollen clearly holds a brief for art *versus* actuality, and, although his letter is not before us, it is not difficult to imagine his line of argument. He discounts the claims of the photographer to a place amongst war "artists," and is persuaded that the readers of the illustrated papers prefer hand-made sketches of war history to photographically produced records. Mr. Wollen's belief that the war artist, as opposed to the war photographer, will "come out on top" draws a very spirited reply from Mr. H. C. Shelley, the able war photographer and correspondent of our contemporary, the *King*, whose success is due in chief measure to the photographic enterprise and journalistic ability which Mr. Shelley has shown while he has been following the British forces in South Africa. The old Glasgow camera enthusiast puts the case for the war photographer as against the war artist with great skill and forcibility, and makes it abundantly clear to his readers six or seven thousand miles away what is clear to the newspaper-reading public in Great Britain to-day, and what has so often been insisted on in these pages, viz., that the war correspondent of the future will be the photographer-journalist. The descriptive writer, however able, will stand small chance of employment unless he be a skilful photographer, for his services are sure to be in demand in both capacities. As for "the man with the pencil," the "artist" *per se*, we are convinced that he is a doomed personality on the battlefield, however valuable his services may be in Fleet-street or St. John's Wood. We reprint Mr. Shelley's able and cogent letter in another part of the JOURNAL.

\* \* \*

THE following paragraph appeared in some of the daily newspapers at the beginning of the present week: "The Lord-Lieutenant of Ireland is desirous of purchasing and presenting to the Queen a collection of photographs of incidents connected with Her Majesty's visit to Dublin, and will be much obliged if artists who have taken any such photographs would kindly submit them to him through the Ulster King of Arms, Dublin Castle, in order that the collection may be made as complete as possible. All copies which are not selected will be carefully treated and returned immediately to their owners." We reproduce Earl Cadogan's request for the benefit of several photographic friends whom we know to have been in Ireland during the recent Royal visit, and who possibly might not see his Excellency's request in the ordinary newspapers. It is a distinct compliment to photography, at a time when the illustrated journals so largely avail themselves of its aid to fill their pages, that the Viceroy of Ireland is anxious to secure a series of direct prints for the purpose of presenting the Queen with a pictorial memento of her visit to the Sister Isle. Evidently the innumerable half-tone reproductions from photographs that are published week by week have far from destroyed popular appreciation of direct photographs. Indeed, the poorly produced blocks that are so lavishly given in the

newspapers and periodicals appear to be creating a reaction in favour of photographic prints of popular subjects, which some few years ago it was confidently expected would no longer command public interest in face of the all-pervading phototypic illustration.

\* \* \*

THAT a photographer has no right to use the negatives of sitters without their consent was again established one day last week. At the Westminster County Court the Taber Bas-Relief Photo Company were sued for damages by two actresses (sisters) for selling their portraits without permission. According to the reports in the Press, the ladies had their portraits taken in the ordinary way of business. Later, when touring in the country, they found them on sale everywhere. The portraits appeared on Christmas cards and on handkerchiefs, chief and glove boxes, &c. For the defendants it was said that the ladies paid reduced prices, it being usual for professional ladies to do this; also that there was nothing on the photographs to indicate the names of the ladies. In the end the Judge found for the ladies with ten guineas costs each and granted injunctions restraining further sales. It has been established over and over again that the negative is the property of the photographer. It has also been established that he has no right to use it for any purpose of his own without the consent of the sitter. That point was first decided in a law court, if we remember rightly, in the case of Pollard *versus* The Photographic Company, many years ago. We call special attention to this case, because we know that some photographers imagine that, as the negatives are their property, they have the right to do as they like with them. They have not, however, even to the extent of exhibiting them in their show-cases, without permission of the sitters.

#### PHOTOGRAPHING AT THE PARIS EXHIBITION.

OUR readers are, no doubt, aware that the hand camera is to be admitted free to the Paris Exhibition, and, as some doubt may arise in the mind of many as to what is to be understood by hand camera, we may quote from an editorial article in our contemporary, the *Photo-Gazette*, which sets at rest any speculations on the interpretation of the official declaration. Monsieur Mareschal says: "It would have been more explicit if the term 'camera held in the hand' had been used, for a photographer will not, for example, consider that a camera taking plates 10 x 8 inches is likely to be regarded as a hand camera." We therefore approached the General Commission of the Exhibition for a further explanation, and learnt from Monsieur Chardon, the General Secretary, to whom we were referred, that the restriction was to be interpreted absolutely literally. Any apparatus, whatever its size or shape, must pay the twenty-five francs fee if it is supported on a tripod or other device, whilst, on the other hand, any camera, of whatever size, is exempt from payment so long as it is carried in the hand. It may be a 10 x 8 instrument, or the smallest folding camera. It would be labour lost to discuss this regulation, for there is no possibility of its being altered. It remains to consider how the best results may be obtained.

Those who wish to work with the stand camera can only do so in the morning. They must first apply to the Administration Department (Quai d'Orsay, near the Pont d'Alma) for the necessary permit, for which they will pay twenty-five

rances, and which authorises them to photograph to their heart's content until one hour after noon.

Those who use a camera without a stand are free to work from morning to night. These will do well to provide themselves with a hand camera provided with a rising front and a lens embracing a tolerably wide angle, for many of the monuments, &c., in the Exhibition are so placed that the photographer must take them, if at all, at comparatively short range. La Rue des Nations, which presents some of the most interesting features, runs almost exactly from east to west. It will therefore get the sun in the morning and evening; but, as it is almost straight and planted with large trees, it will be almost impossible to make instantaneous views in it. The photographer will find things better arranged for him in the palaces on the north side, the main façades of which point towards the Seine. The whole of them can thus be taken in the morning from the Pont des Invalides, a lens of long focus being advisedly employed. More detailed views will also be obtainable early in the morning. Le Palais de la Belgique, which is one of the most notable, and which represents the Hôtel-de-ville d'Audernarde, can be obtained by means of a good rise of front. Le Palais de la Hongrie is likewise of great interest, but only part of it can be obtained at a single exposure, as other buildings intercept the view. Those who dislike rising early in the morning can obtain a good view of these palaces from the Pont de l'Alma close on sunset, but they should not attempt le Palais Belgique, the main façade of which will then be illuminated from behind. All the right bank of the Seine, being due south, will be easy to photograph. The parts to be specially noted are Old Paris and the Palais de la Ville de Paris. On the Esplanades des Invalides, the principal artery of which runs almost exactly from north to south, it will be difficult to get a lighting other than one which gives one side sunshine and the other shadow. If the best time is to be taken advantage of—about noon—turn the back on the Dôme des Invalides, and arrange, if you can, to have a clouded sky, not sunshine. Behind the principal galleries of the Esplanade will be found many interesting features: to the east, les Mas Provençal, la Maison Bretonne, &c.; to the west the various foreign buildings will be found to present difficulties in photographing.

Le Pont Alexandre can be taken from various points along the left bank of the river. The front of the bridge, on the side of the Champs Elysées, can be taken at any time. The statues and decorative work make it a most interesting subject; to include these, the camera should be placed on one side of one of the footways. The two palaces on the Champs Elysées stand behind it. The larger is well lighted up to mid-day, the smaller all the afternoon.

The position of the Champ de Mars is south-east and north-west; good lighting can therefore be obtained at almost any time, but in sunshine the waterworks in the background do not come out well; for these diffused light should be chosen.

Le Trocadéro will be fully lighted most of the day, and by taking one's stand in the central roadway the different construction of the two sides can be obtained. Russia stands out prominently, and behind it, by the left wing of the Palace, is China, where, with a wide-angle lens, an excellent view is obtained.

These few notes from our contemporary will show there is much to be done even with a hand camera. One hint may be added: As plaster enters largely into all the buildings, backed plates will be found of special value in securing negatives free from halation.

**Astronomical Light Filters.**—The image given by a refracting telescope, like that from a photographic lens, especially of the older type, is accompanied by a secondary image. The latter rarely gives any trouble, but that in a telescope may be a source of difficulty, as the quality of definition is required to be so much greater. Thus a star which to the eye represents a point of light may show, when examined through a telescope of low power, as two separated stars, while a more powerful instrument will again split up these new stars, and so on, a refinement of definition never looked for in photographic instruments. Yet each of these stars is really defined, not as a point, but as a disc, surrounded by another fainter coloured disc, the secondary image. Messrs. T. J. J. Lee and G. H. Peters, of the U. S. Naval Observatory, have been making experiments to get rid of this violet secondary image by using screens or light filters arranged as a cap to fit outside the eyepiece of the telescope. They tried several screens, and found the definition to be improved, as anticipated. A parallel to this plan is found in microscopic work. These experiments refer more particularly to eye observation, but it is naturally to be expected that similar beneficial results would be obtained in a photographic direction, though the *modus operandi* would need changing. Here the ordinarily most photographically active portion of the spectrum was excluded. If a photograph were to be taken, it would, with most stars, be better to utilise this part and exclude the other, a suitable adjustment of the focus being made.

It is interesting to note the kind of screen adopted for such a one would suggest itself as being a suitable one for a dark-room light filter for ordinary photographic operations. The actinic material found best was a solution of picric acid and chloride of copper in alcohol, which, in the case in point, was placed in a small cell and fitted as mentioned above.

**The Value of Photography in Astronomy as shown in American Work.**—We need scarcely point out that of late years telescopic objectives have been constructed with curves specially adapted to utilise to advantage the more actinic part of the spectrum, thus showing that the chromatic aberration is not entirely got rid of. Of the immense value that photography has been to the astronomer there cannot be two opinions. Most worthily and splendidly has his work been seconded in America—the home of the finest observatories in the world—by the munificence of private individuals. The first star photograph was taken in America by Professor Bond in 1850, while Rutherford and Draper have given lustre to Transatlantic records by their early work—the former by his early photographs of the sun, moon, and stars, and the latter by his stellar spectra pictures, which were the first photographs of value in depicting lines which gave some idea of the actual composition of the stars. Coming to a later period, photography has been of inestimable value, under Professor Barnard's direction, in recording details of comets, nebulae, the Milky Way, &c., while Professor Pickering's Draper Memorial stellar spectroscopic photographs are a monument of skill and scientific adaptation of photographic means to an end. The work done at the Lick Observatory is mostly photographic, and, indeed, to put it in a few words, most of the important astronomical discoveries of late years in America, as elsewhere, owe their value to the negatives they have been able to produce since the development of the gelatino-bromide dry plate.

**Aurora Spectro-photographs.**—In a recent number of *Comptes Rendus* M. Paulsen gives a description of some successful work in photographing the spectra of the Aurora Borealis. The negatives were taken by him in Iceland, where, he reports, the displays last December and January were very vivid. He employed two spectrographs in his work, and was so successful as to obtain records of twenty-two lines, sixteen of which are photographed for the first time. One of his instruments had glass prisms, but in the other quartz was used so as to avoid the absorption of the ultra-violet rays, that part of the spectrum being very inefficiently dealt with when the dispersion is brought about by glass.

**Experts and the Value of Paintings.**—The opinions of experts, and their evidence in law-suits, is often largely discounted, and, in many instances, not without justification. Some months back we alluded to an application in the Appeal Court with reference to the sale of the Peel heirlooms, amongst which were a couple of fine paintings by Van Dyck. For these 11,250*l.* had been offered privately, and the Court was asked to sanction the sale, for it was said that, in the opinions of experts, they would not realise more than from six to seven thousand pounds at auction. The Court, however, and wisely, decided that these pictures must be sold at auction, and not privately. At the time we insinuated that the sum offered was much below the value of such fine works as were these two examples of Van Dyck's powers. On Friday last the pictures came "under the hammer," and realised the substantial sum of 24,250*l.*, about double the sum offered for them privately, and nearly four times what the experts had estimated them at if sold by auction. An offer had been received for them from Belgium of 20,000*l.* before the sale. It will be interesting to see what is the ultimate destination of these two pictures; we could have wished that it was one of our national collections. Amongst the pictures sold on [Friday were some by W. Collins, Greuze, Van der Weyden, Landseer, Sir P. Lely, Hoppner, Mulready, Sir Thomas Lawrence, and other well-known artists, most of which fetched good prices. The day's sale realised 53,350*l.*, and included other works of art besides paintings.

**Keeping the Roof of the Studio Waterproof.**—In the Foreign News and Notes a fortnight ago we gave a method, recommended in the *Camera Obscura*, of keeping the roof of the studio impervious to water. It consists of employing, instead of putty, a compound consisting of paper pulp, pitch, resin, gutta percha, and wood tar, for cementing the glass to the sash bars. It is said to answer well. Leaky studio roofs have always been a *bête noire* to photographers, and many suggestions, from time to time, have been made for avoiding them, with more or less success. A professional friend of ours, when in business, made it a practice to periodically give the sash bars and the outside wood work a thin coating of gas tar, to which a little tallow had been added. He told us that, since he had adopted that plan, he had not been troubled by water finding its way through the roof. Possibly this method of avoiding leaky roofs may be of service to many of our readers.

**End of the Lantern Season.**—The lantern season may now be said to be over, and secretaries of photographic societies are by no means to be envied in the task before them of providing pabulum for the meetings during the summer months, supposing, of course, their societies meet during the summer season. The task is somewhat lightened, it is true, by some of those enterprising houses that have demonstrators who will attend at meetings to practically illustrate the working of the novelties of which they make a speciality. Not only do the meetings by this means have the opportunity of seeing the latest novelties put upon the market at their own doors, but often an instructive discussion follows which has [nothing directly pertaining to the novelties exhibited, and thus a pleasant evening is spent. But for the lantern and these practical demonstrations, it is a little difficult to imagine how many of the hundreds of photographic societies there are in this country could possibly exist, let alone continue to flourish as they do.

**Vesuvius.**—After a period of inactivity this volcano has again awakened from its slumbers, and created some alarm amongst the dwellers in its neighbourhood, notwithstanding that the authorities at the Observatory on the mountain assured them there was no immediate danger. A Reuter's telegram last week stated that four English tourists, who went beyond the limit indicated as dangerous by the guides and gendarmes, had been seriously injured by masses of incandescent stone, and were lying in Naples in a serious condition. It is scarcely likely that nowadays there would be four tourists from England without one or more cameras, and we know

that enthusiastic photographers will, at times, run risks that but for photography they would not do, and that naturally occurred to our mind. A few photographs of this volcano in violent eruption, when the wind was favourable, would make grand as well as interesting pictures, hence many when in the district would be tempted to incur some risk to obtain them. From later telegrams we are pleased to learn that the first report that four Englishmen had been seriously injured was inaccurate. These telegrams also state that the violence of the eruption is subsiding.

#### "THE BRITISH JOURNAL OF PHOTOGRAPHY" WAR FUND.

An excellent start has been given to the Fund which it has been suggested we should collect from our readers for inclusion in the larger Fund on behalf of the widows and orphans of soldiers killed in the war that is now being so ably organized and administered by our contemporary, the *Daily Telegraph*.

With characteristic kind-heartedness, Mr. Thomas R. Dallmeyer, F.R.A.S., President of the Royal Photographic Society, at once came forward with sympathy and help. Mr. Dallmeyer wrote:—

"I have read your appeal to the photographic world in aid of the War Fund with much interest and sympathy, and have great pleasure in enclosing a cheque for 5*l.* 5*s.* in support of your excellent object. I venture to think that photography, pre-eminently, has enabled us to grasp the terrible earnestness of the war, and to realise, more clearly than the most vivid descriptions alone, its hardships and difficulties, and the valour displayed in overcoming them.

"All who have contributed to photographic knowledge, and all who have worked to further photography, either as an art or an industry, may feel some pride in the part their efforts have played in the present war. I sincerely wish your appeal every success, and hope that it may be widely read and unanimously supported, despite the fact that it is probably an 'extra turn' that is now being asked for."

The distinguished photographer, Mr. H. Walter Barnett, of 1, Park-side Hyde Park Corner, S.W., also wrote us:—

"Concerning the article in your *JOURNAL* of the 11th inst., appealing for subscriptions from the photographic world, I have no reason to doubt that manufacturers, photographers, dealers, &c., have individually done their part in giving funds for the benefit of the widows and orphans, poor sufferers by this war, which is for the good of humanity as a whole; but I am glad to see your suggestion that we should, as a class, do something more, and have much pleasure in enclosing my cheque for 10*l.* 10*s.*, and also a cheque for 3*l.*, the latter being the result of a collection amongst my employées."

The first list of subscriptions is as follows:—

Messrs. J. H. Dallmeyer, Limited, 25, Newman-street, Oxford-street, W.....	£10 10
Mr. H. Walter Barnett, 1, Park-side, Knightsbridge, S.W. ...	10 10
The Proprietors of THE BRITISH JOURNAL OF PHOTOGRAPHY ...	10 10
Mr. T. R. Dallmeyer, F.R.A.S., President of the Royal Photographic Society .....	5 5
Employees of Mr. H. Walter Barnett .....	3 0

Our thanks are here tendered to the above-named gentlemen for the ready help. We have forwarded a cheque for 39*l.* 15*s.* to the *Daily Telegraph*, in the columns of which journal an acknowledgment will doubtless appear simultaneously with this announcement.

We sincerely hope that the admirable precepts and examples which are supplied by the above-quoted letters and the accompanying contribution will have the greatest weight and influence with our readers, all of whom we cordially invite to send us a subscription, large or small—but the larger the better. It is probably true that various war funds have successfully appealed to the generous instincts of most of those who read this appeal; but the fact remains that there are strong reasons, as pointed out by Mr. Dallmeyer and Mr. Barnett, why the photographic industry and profession should, as a class, participate in the good work of helping those upon whom war has cast the burden of loss or suffering.

Cheques, postal orders, &c., that are sent to us should be crossed and made payable to "The Editor, BRITISH JOURNAL OF PHOTOGRAPHY."

#### MR. F. H. EVANS'S EXHIBITION AT THE ROYAL PHOTOGRAPHIC SOCIETY.

The spirit of uniformity pervades the photographic atmosphere at 60 Russell-square, where Mr. F. H. Evans has his exhibits on view just now. That the prints are well worth a visit goes without saying; the

mounts and frames are in keeping with the subjects is worthy of comment in these days of incongruous collections of variegated mouldings, and that the whole show is quiet, and careful, and of uniform quality speaks well for the exhibitor. There is no effort to achieve greatness, and yet the exhibits touch the point above mediocrity—mediocrity here so many of our exhibitors either stop short or stoop to eccentricity to keep up their reputations. There is nothing, however, in this Exhibition that borders on the eccentric, although one or two of the figures, perhaps, might be considered by some to transgress the usual limits of conventionality.

There are no large pictures, the exhibits are uniform in size, which is small, the granulated canvas paper, two yards long by six inches high, conspicuous by its absence, and in its place are several sober-toned dry prints, technically as perfect in their particular province as photography can make them. The interior architectural work is even daintier in many instances, and cannot be too highly praised for its cleanly handling, its delicacy of detail, and its beautifully manipulated light and shade. The external landscape combined with architecture did not, however, impress us so much as the more careful studies in stone.

The Kelmscott series of pictures were interesting, and we will notice them *seriatim*, as they will, no doubt, command more than passing attention. The view from the Thames is the old familiar one, and is a landscape of little merit. The *Entrance from the Road* demands more careful scrutiny, the fine old elm tree being not the least picturesque part of the print.

The *Front Entrance* looks rather dangerous, and we imagine the fault lay with one of the camera legs, which might have been groggy in the knees. *From the Orchard* is a study in shadows: the rugged branches of the apple trees cast their shadows on the grass and break the foreground into reticulated patches of light and shade. *In the Garden* contains a cookery, and the rooks appear to have been having a game at seesaw whilst the photographer was timing his exposure, for the tree-tops are a mass of twiggy blurs. This picture is interesting from its associations merely, and the next, *The Garden Front*, is very flat. *In the Tapestry Room* is rather nice in light and shade, and the two armchairs are certainly *sans reproche*. The *Bedroom of Mr. Morris* contains an antique four-poster, which looks very shabby about its two front posts; in fact, we should require a heavy insurance premium paid before we ventured to sleep under its canopy. Who was it that described one of these old bedsteads as antiquated heaps of mustiness? *In the Attics* was fuzzy-wuzzy when viewed within a few feet, but the effect was very charming at a greater distance, and we must assume that the expressive words of a great artist long since dead and gone were in the mind of the operator when he perpetrated this picture. Those words were, perhaps, more expressive than polite, but one inferred that the picture "was not painted to be smelt at." *A Study in Contrasts* takes us above the attics into the ancient timbered roof, where light is streaming in upon the rafters, making a very strong chance in favour of halation, which, however, has been cleverly avoided by Mr. Evans.

The church comes last. This is a landscape with trees. We can well imagine the photographer on his way to divine service casting a longing eye on those fine old trees, forming a splendid background for the church. We can still further imagine during the lengthy sermon that his mind would revert to the scene outside, and it wants but a little greater stretch of the imagination to bear the parson say towards the close, "What went ye out for to see?" here the photographer fidgets in his seat and tries to look outside. "The trees (*sic*) shaken by the wind?" at which our friend starts visibly recalled to place and season. But the mischief is done, for, when he photographs the church, he takes the trees "shaken by the wind." At any rate, the trees in this picture have either moved or the camera legs caught cold and shivered.

But there is much to interest the lover of landscape in this Exhibition. Let us take, for example, the scenes in Redland Woods. As a rule, their names afford an index to their character. Look, for instance, at *An Avenue in Fairyland*; the title is perhaps a trifle far-fetched, but it is fairly descriptive of the original. *Evening under the Pines* and *Primeval Giants* are equally expressive; *A Study in Greys* says little, but in the original indicates much that is "tender" and delicate. *Easter Snow* is also a beautiful bit of work.

The forest scenes hardly need any description of the prints other than that conveyed by their titles. What could be better than these: *Evening in Epping*, *A Quiet Wood*; *An Honourable Old Age*, *New Forest*; *A Woodland Nave*; *Hot Sun and Welcome Shade*; *An English Glade*; *A Lane in Sun-light*. All these are perfect little pictures, quite in keeping with one's ideal of the scenes they represent.

Several of these woodland pictures excel in the beauty of their treatment, their tones are exquisite, and more like the delicately pointed bits one sees in the illustrations to some of Ruskin's works. Lakeland is more sombre, but cloud-storm and sunshine have each received their mead of attention with good results. The seascapes are not so interesting. *Loneliness* is not a prepossessing title to start with, and the picture does not belie its name. *Evening Clouds* is slightly better, but wanting in life. *Where the Sky dipt down to Sea and Sand* (Tennyson)—Well—There no man could live, or move, or have his being.

Finally, *Sea and Sky and Sand*, and here the description:—

A still salt pool locked in with bars of sand,  
Left on the shore, that hear all night  
The plunging seas draw backward from the land  
Their moon-led waters white.—TENNYSON.

The reader expects much from reading the title, but gets about a  $3\frac{1}{2} \times 2\frac{3}{4}$  with two little notes of exclamation between the sea and sky, a bit of distance and a lot of seashore.

Now, as to the portraits, there are several good examples of untouched work—some of them look rather coarse and fuzzy, and have not the same careful handling that characterises the majority of the work displayed. Mr. Storey's face will be familiar to most visitors, and Mr. Aubrey Beardsley's portraits will cause comment for several reasons.

Mr. Todhunter looks a studious gentleman, and might have invented the puzzle published by his great namesake, viz., that of the *pous astinorum*.

The female face and figure hath no charms for the talented exhibitor, or, if so, he fails to display them to the greatest advantage.

CRITICUS.

## THE WAR ARTIST OF TO-DAY.

[Reprinted from the Bloemfontein *Friend*.]

CAN you inform me whether there has been a sudden exodus from Bloemfontein of war correspondents armed with cameras? There ought to have been, and yet I have inquired in vain whether such an event has taken place. For, look you, the judgment has gone forth from the pen of Mr. Wollen that the "war artist," meaning the man with a pencil as opposed to the man with a camera, "will come out on top." Truly, this is most disheartening. No one likes to be thrust to a bottom position, and, if that is to be the fate of the man with a camera, why should he any longer endure the hardships of campaigning and the sorrows of separation from the comforts and companionships of home?

But the war correspondent with a camera has not gone home, he has no intention of doing so. He is unrepentant enough to believe that he, and not the man with a pencil, is going to "come out on top."

Let us have the point at issue clearly defined. War correspondents are with the army to report the war—some by word pictures, others by camera or pencil pictures. Sightseeing is a passion with humanity. Every inhabitant of the British Isles would like to have a personal vision of the conflict in South Africa, but, save for two or three irresponsible persons whose presence at the front no one can understand, those inhabitants are compelled to rely upon the eyes of others. Now, leaving aside the correspondents who devote themselves to word pictures solely—the question to be decided is, Does the man with the camera surpass the man with the pencil in depicting the actuality of warfare?

An astounding claim is made on behalf of the man with the pencil. He can, we are told by Mr. Wollen, show the public "an accurate bird's-eye view of what a battle is like." And he does it by "a few lines to indicate the background and characteristics of it." The same authority assures us that "the brain of the camera cannot take in all that is going on. The man with the pencil does so." Such is the case for the man with the pencil. Now for the test of cross-examination.

Modder River and Magersfontein may be cited as two representative battles of the war, and so may be honestly used as touchstones to try the claim Mr. Wollen makes on behalf of the man with a pencil. In each case there was a battle line of some five or six miles; in each case the enemy was invisible; in each case it was physically impossible for any one man to see more than a small portion of the battle. A spectator on the right flank at Modder River could have no personal knowledge of incidents which were happening in the centre of the bridge, or down the river on the left flank. Even of his own particular section on the right flank that spectator could not attain to a perfect knowledge; but the man with a pencil is untrammelled by such minor matters as time and space, he takes in "all that is going on." Or, if he does not take it all

in, he puts it in his sketch. The result is no more "an accurate bird's-eye view of what a battle is like" than a photograph of Oom Paul is like a photograph of Mr. Chamberlain. In short, the facility with which the pencil man can jot down what he did not see is his ruin.

It will be obvious that the man with the pencil, not being ubiquitous, cannot "take in" all that happens on a battlefield; he sees just as much as, and no more than, the man with the camera; for the rest, which forms so large a proportion of his sketch, he has to rely upon the testimony of others. Now, when the public have in their hands a result attained by this method, what is its value as an "accurate bird's-eye view of what a battle is like?" Absolutely *nil*. People at home want to see a battle as they would have seen it if they had been present, and no sane man will contest the assertion that the best medium for giving them that vision is the camera rather than the pencil. Try as he may after the actual, the man with the pencil thrusts his personality between the event he sees and the people at home for whom he wishes to reproduce it, and consequently his sketch becomes a miserable failure when considered as an "accurate bird's-eye view of what a battle is like."

On the other hand, what does the man with a camera do? He and his lens see at least so much of a given battle as any man with a pencil, and what they see they see with unflinching accuracy. Take that battery in action which Mr. Wollen chooses to cite as a subject wherein the powerlessness of the camera is supposed to be illustrated. The camera man does not fear the test. He can show the guns coming into action, record their unlimbering, depict the preparation for firing, and time a photograph at the actual moment of firing. It is true that his picture will not show quite such a volume of smoke as the sketch of the man with the pencil. But why? *Because the smoke is not there.* The man with the pencil puts it in because other men with pencils have been putting it in for generations. Perhaps, too, the public would not mistake the sketch for a battle scene if the smoke were absent. Any how, what becomes of the boast of *accuracy*? Moreover, the man with a camera will not present his public with a twelve-pounder firing from the carriage of a howitzer.

There is something more to be said for the man with a camera. Nowadays he is in the habit of screwing a tele-photo lens to the front of the camera, and with that lens he can immensely out-distance the vision of even that all-seeing man with the pencil. Objects a couple of miles off are brought near, and groups of men can be photographed at such distances as prevent them assuming any posing attitudes. In this way actuality takes on the added charm of natural grouping, and I shall be greatly surprised if some of the tele-photo pictures of this war do not take rank as the most artistic as well as realistic records of its incidents.

After all, the man with a camera may safely leave his case in the hands of others. Take a negative and a positive witness on the question in the abstract. Mr. Julian Ralph writes that "the pictures of our battles which are coming back to us in the London weeklies are not at all like the real things," and then he adds: "I saw the other day a picture in one of the leading papers by one of the best illustrators. It showed the British storming a Boer position. In the middle ground was a Boer battery, and the only gunner left alive was standing up with a bandage round his head, while smoke and flame and flying fragments of shells filled the air in his vicinity. In the rush of the instant he must have been bandaged by the same shot that struck him, and, as for smoke and *débris* in the air, there was more of this in the corner of that picture than I have seen in all the four battles we have fought."

Now for the positive witness. He is no less a person than the art critic of the *Pall Mall Gazette*, who can no more be charged with a predilection for photography than Messrs. Steyn and Kruger can be saddled with a predilection for truthfulness. This critic dwells, as Mr. Scott did in the letter which opened this discussion, upon the old and new methods of war illustration, and then candidly adds, "I would like to say that the artists score off the photographer, *but they do not.* The public wants the facts as near as may be, and are too deeply stirred to be put off with melodrama."

One other witness may be called to give Mr. Wollen an idea of how he work of the man with the pencil is faring at home. Here is a recent private letter from England, which makes merry in the following fashion over those sketches which are so inclusive and accurate: "There is a picture of two gunners standing to attention after having exhausted their ammunition. The man nearest the gun is looking straight in front of him, with a bandage round his head, a bullet wound in his face (close to the left ear), two in the right side of his chest, and one in his right leg, some distance above the knee. Within a yard of him is a bursting shell. But that man ignores such trivial things. Still he stands. I suppose

the weight of so much lead in him keeps him up. One wonders whether he is hollow inside, so that the bullets all drop down into his feet."

No wonder, worthy editorial sirs, you have not witnessed an exodus of men with cameras from Bloemfontein; they are staying to "come out on top."

H. C. SHELLEY.

#### PICTORIAL COMPOSITION IN PHOTOGRAPHY.

[Paper read before the Edinburgh Photographic Society, and awarded the Society's Bronze Medal.]

IN view of the magnitude of this subject, and the frequency with which it has been treated in photographic literature, in a rudimentary as well as in an elaborate, manner, it might seem impossible in the compass of a short essay to set forth anything of value, or that would not merely be an echo of what has been repeated a hundred times. I am well aware it is almost impossible to say anything absolutely new on the subject of pictorial composition, but I hope by elaborating to some extent certain well-known rules, and by examining and analysing some distinctive examples of different styles of composition, as found in the works of acknowledged masters, to arrive at a somewhat clear perception of the various qualities that go to the making of a well-composed picture. It must, of course, be understood that this subject, although resting on simple foundations, rises into great complexity and subtlety, and in the highest reaches of art its laws become almost intangible, and elude analysis. It is, however, impossible in photography to carry extreme subtlety into composition; we must rest content to have the stronger elements of the picture correct. The painter may, indeed, carry purpose into every touch of his brush, but the photographer knows that his efforts in the direction of composition cannot descend to minute detail. Notwithstanding this limitation, the task of the photographer is no easy one. Granted that he has got a subject that is everything that can be desired, the choice of point of view, of manner of lighting, of atmospheric conditions, and of the distinctively technical methods by which he arrives at his result—all these things demand the exercise of his best skill, and it is only in the most favourable circumstances that he can congratulate himself on his success.

For a long period photographers seem to have been content with qualities demanding little more than manipulative skill. As we know, some of the early workers were men of cultured taste and had high ideals; but, as the art became easy of acquirement, and cheapness of production brought popularity, almost all efforts after excellence were in a short time submerged by the tide of philistinism. For some years past it has, however, been the aim of thousands to produce work distinguished by artistic feeling, and, if the impossible has been sometimes vainly attempted, it must be admitted that astonishingly fine results have frequently been produced by means of the camera when the nature of the subject admitted of artistic treatment.

In speaking of architecture, Ruskin says that the good designer must *begin* like the owl, and *finish* like the eagle. The necessity of attending in the first instance only to broad masses when designing a building appears to apply equally when the object is to design a good picture. To illustrate how little the quantities of broad and pleasing composition were in the past sought for and obtained, there is now thrown on the screen a representation of a show-case of landscape photographs, such as we have been accustomed to see suspended on shop fronts, contrasted with a number of pictures in which graceful composition is very apparent. I am aware that this is rather a contrast of extremes, not only on account of the practical impossibility of composing photographs that would be as thoroughly harmonised as the best paintings, but also because commercial and artistic considerations do not always coincide. Yet there can be no doubt that the public, which delights in topographic detail, does not object to a little art thrown, as it were, into the bargain; and there is now a large number who can appreciate and will buy good pictures for their art quality exclusively. It must be a matter of common observation that of late there has been a considerable improvement in purely commercial photography, although much more is still to be desired. Perhaps it is not too much to say that the best work of that kind which we see here at present is produced in our own city, and by one of our own friends.

On examining the sketches that appear on the screen, it will be seen that, in order to be pleasing, a picture regarded as a whole must have—

1. Unity of motive.
2. Breadth of effect, or harmonious disposition of the masses of light and shade.
3. Balance, and harmony of line.

There are other desirable qualities which must characterise pictures, *e.g., variety* in the lighting, lines, surfaces, &c., and *suggestiveness*

mystery, purity of colour, &c., but it is not my intention to deal with these at present.

1. *Unity of Motive.*—No picture is altogether satisfactory that fails in the quality of unity. It is an oft-repeated truth that the simplest pictures are the most powerful, but it is naturally impracticable to lay down rules for the attainment of this quality. The photographer should know, in every case, what attracts him to a subject, and he ought absolutely to reject whatever counter-attraction may exist in the field of view. It is no uncommon thing to find two distinct pictures, or, it may be, a picture and a half in one photograph. It requires no small amount of courage to reject what we are tempted to convince ourselves may possibly turn out to be beautiful accessories to the main theme. The possession of lenses of different focal lengths, by enabling the photographer to fill his plate with exactly the subject he desires, should take away the chief temptation to retain extraneous matter. The well-known expedient of adjusting slips of paper on the margins of a print for the purpose of determining experimentally the best size and shape as a guide to trimming should never be neglected. Whilst giving this caution, I think it well to say that it appears to me this principle of restriction, like many others, is sometimes carried too far, and, as a consequence, the subject is presented with objectionable baldness. This is naturally a point on which no rule can be absolutely laid down—the true guide can only be feeling the result of culture gained by observation, and study of the best models.

2. *Breadth of Effect, or the Harmonious Disposition of the Masses of Light and Shade.*—The amount of space occupied respectively by light and shadow varies greatly even in the best pictures. It was laid down as a general principle by Sir Joshua Reynolds that a fourth of the picture should be light, another fourth dark, and the remaining half of middle tint. But, as has been said, these proportions are widely departed from, notably in the work of those pre-eminent artists, Rembrandt and Turner, the pictures of the former consisting largely of shadows, those of the latter chiefly of light. There must, however, be something of the nature of balance in the opposing parts of a picture. The slide now to be placed on the screen will, to some extent, illustrate the manner in which lights or shades may be said to balance each other, a small strong mass being the equipoise of a large weaker mass.

The figures represent (1) a dark disc balanced by a larger faint one; (2) ornaments balanced against each other; (3) the same principle applied in the case of an irregular mass, which is also broken up into parts; (4) the principle applied to clouds; (5) a foreground tree, balanced by a mass of wood in the distance; (6) cottages balanced by a tree; (7) sketch of Bass Rock, with boat near the shore.

[These principles were further illustrated in diagrammatic form by a slide showing Turner's *Fighting Téméraire*, M'Culloch's *Inverlochy Castle*, and Orchardson's *Napoleon on Board the Bellerophon*.]

A slide by Mr. George Cleland was also shown to illustrate how the difficulty of getting a fine, well-diffused light over sky, water, and earth can be overcome.

The next slide shows pictures by Orchardson, which are remarkable for the simplicity and beauty of the disposition of the light. It will be noticed that the principal figures are in a very light colour, and it is instructive to observe the manner in which the light is carried with so much delicacy and beauty through the picture.

In the pictures we have just been examining we are struck with the beautiful modulations of the light and shade, and the harmonious way in which the lines melt into each other. It is in landscape we most frequently miss this sense of symmetry, and, paradoxically, it is in landscape we find it sometimes unduly developed, as, for example, in Turner's later work, which strongly suggests formal and conventional treatment, with a consequent air of unreality. As illustrating this characteristic of the somewhat formal treatment of landscape, the next slide, representing work by B. W. Leader, has been chosen. The work of this artist is undeniably captivating in composition, and it is impossible for the photographer to be led too far astray in the imitation of his methods, because nature will not allow it. It will, however, be felt that the *waywardness* of nature, which is one of her charms (certain modern schools of art perversely esteem it her chief charm), has been unduly eliminated. If nature is rich in harmonies, she certainly does not allow them to fail of full effect for want of "accidentals."

The next slide illustrates work by the late Sir J. E. Millais. It seems to me that the landscape work of Millais may be accepted as illustration of sound practice in composition. Those who have observed the reproductions of his work can hardly fail to have been struck by its resemblance to a well-composed photograph. He chose the most characteristic example he could find of a particular kind of scenery, and repre-

sented it as forcibly as he could, not making his work easy by elimination of all the material which a weaker man would have deemed foreign or unharmonious, or by scamping the detail of foliage, reeds, grass, &c. There was nothing partial or affected about his impression of a landscape, and the consequence is that scenes such as *Murthly Moss*, *Chill October*, *The Vale of Rest*, and *The Old Garden*, along with his many famous pictures in other branches of art, take their place in the memory as the work of no other modern master has done. If, as we were recently told on high artistic authority, a photograph is to be defined as "an imperfect impression of nature gone wrong in the fixing," it is to be feared that this striking resemblance of the landscape work of Millais to photography and to unsophisticated nature must, in the estimation of many artists, place it under a similar double derogation. It is, however, possible that the high-toned landscapists of to-day may allow some more or less faint traces of merit in the rude landscapes of Millais, although they smack so strongly of nature, and not at all of Hokusai or even of Corot. Doubtless the work of the impress on schools is, much of it, extremely beautiful, valuable, and unique, and it would be only absurd to speak in depreciation of the masterpieces in that style, yet one cannot but say that, on the whole, an exhibition of the work popularly called impressionist is of so spiritual an essence that it leaves, with most people, little more permanent mental residuum than a visit to a carpet warehouse. As a rule, the ordinary impression picture is not, directly at least, very valuable to the photographer, while realistic pictures, such as those of Millais, may be studied with great advantage. Photographs can never be too bright nor good for human nature's daily food.

This slide gives pictures to illustrate breadth of effect as opposed to "spottiness." In the first two cases the effect is due largely to choice of subject; in the other the boats are grouped in an effective manner to this end.

3. *Balance and Harmony of Line.*—The common rule is that lines running in one direction must be compensated by lines running in a contrasting direction, as in the example shown in this slide, where in each case B represents lines complementary to A, and it will be observed that a short, strongly defined line will balance a long one weakly defined, also that a short, strong curve will be a set-off against a long one of slight curvature. The other outlines are taken from pictures by eminent artists. The word line must not be used in too restricted a sense, as breadths of shadow, when they in connexion with pictures extend in a linear way over a picture, must be treated as if real lines.

The next four slides are shown to illustrate the fact that it is usually more easy to secure the balance of the lines of a picture when the subject is close than when dealing with landscape on the large scale.

*Hill Stream, Aberfeldy.*

*A Bit on the Burn at Gifford.*

*Ferns at Loch Vennacher.*

*Wayside Flowers at Aberfeldy.*

*Glen Croe.* In narrow and winding glens we find the same facility of composition that obtains in foreground subjects.

Doubtless, photography has many fields of more importance than those dealing with foreground, but in none are its peculiar excellences more evident. Where the principal charm is wealth of beautiful detail, we are constrained to admire rather than to criticise, for the camera puts all our unaided faculties of imitation to shame.

All portraits that are at the same time works of art possess harmonious lines in a marked degree. A slide is now shown containing several portraits by artists of eminence to illustrate this fact.

The next slide, which has reproductions of G. Paul Chalmers' *Legend* and Terris's photograph, *The Ghost Story* (well known to most of us as the Society's presentation print of 1893-94), has been chosen to illustrate the necessity of avoiding too great formality and any appearance of the picture being made by rule. *The Ghost Story* is a fine composition as regards light and shade, but the rule of the pyramid is too obvious, and, if we contrast the random-looking but yet graceful grouping of the figures in the *Legend* with the somewhat mechanical grouping in *The Ghost Story*, we will have no difficulty in learning a needful lesson. There should not be too much plane geometry in a picture. Another point to be noted is the somewhat huddled grouping that characterises almost all photographs as compared with the free arrangement of the figures in paintings. Of course, the technical difficulty of free grouping is well known to all photographers.

We hear the maxim constantly repeated that "the art is to conceal art." This principle of concealing the means by which an effect is produced is of great importance, but, like many another principle, it is not at all times desirable to carry it to an *extreme* length. We often find poetry of the highest rank in prose composition, notably, for example, in

the works of Ruskin, yet we love not poetry the less but rather the more when the words run in numbers with the added charm of rhyme. So, when we find in a picture the sweet harmonies of line, and the pleasant balancings of light and shade—those analogues of rhyme and numbers—we need not be ashamed to confess our delight in their visible presence, if, as in the case of the good poem, *they are skilfully and not superficially employed*, and so become the evidence of an added genius. I have thought it necessary to repeat this idea, because, as already indicated, some of the modern schools of art seem by their practice to hold a firm conviction that only the picture that is the parallel of the prose poem is the expression of true enlightened art. It seems to me the well-composed photograph avoids two opposite extremes; it is the staff of art life, equally removed from the caviare of the decadent and ultra-impression schools on the one hand, and from the confectionery of the purely decorative men on the other. There are Worths and Redferns in the world of art, and their words seem to have the weight of eternal verities—till the fashion changes. Their little systems have their day, they have their day and cease to be, but a robust common-sense art will survive when that which is merely pretentious and vapid, or at best esoteric, will have vanished into obscurity.

Photographers are not quite free from the weakness of following some prevailing fashion, but they do not, or cannot, go to the same extremes as the artists. The pendulum of photography vibrates in measured arcs; that of painting is seen to strike out in wild erratic excursions. Let us set our own watches by our own clock—let us follow our own sober counsel as photographers.

Perhaps I may be allowed a word or two on the subject of vignetting. The making of vignetted pictures was submitted some years ago by a dogmatic writer on photographic art to unmitigated condemnation, and his dictum was taken as so sound and incontrovertible that many photographers, doubting apparently the grounds of their own taste, fell in with his ideas, and ceased to make or admire vignetted pictures. The almost universal delight in a vignette rests on much too solid a foundation to be blown away by one puff from a conceited mouth. It is a fact, that in the ordinary exercise of vision we are constantly looking on vignetted pictures, and it is only by looking from a port hole that we can do anything else. Even good paintings which are not *apparently* vignettes are so in the effect obtained, for, though they seem to fill the square frame up to its corners, the feeling of intelligibility (which is at times not too oppressive, even in the centre) fails entirely as the margins are approached. It would, of course, be as foolish to recommend the universal adoption of the vignette as it was entirely to veto it, but there can be no doubt that many photographs otherwise unrepresentable on account of distracting or unbalanced marginal matter may be rendered perfectly delightful by resorting to a method of treatment to which no natural or honest exception can be taken.

Before closing, I feel constrained to say that, even when the rules of composition have been mastered, there is a branch of the photographic art where the difficulty of producing a satisfactory picture is extreme. I refer to idealised figure subjects. It is the terrible, uncompromising truth-telling of the photograph that is the chief cause of this, perhaps the only unsurmountable cause. We may bury our pictures in utmost depths of Rembrandt shadow, but we cannot entirely succeed in our highly idealised subjects. A little cynical demon lurks in the bellows of our cameras. His delight is to thwart all our efforts after the ideal, and never yet has he failed. After an infinitude of painstaking posing, and draping, and backgrounding, and lighting, and waiting for the right expression on the sitter's face, we expose a plate, we expose two plates, to avoid all risk of failure we expose three plates on our grand ideal subject, *The Soul's Awakening*. We get three perfect—technically perfect—negatives, but, alas! alas! the demon has been at work, and our every trick has been made transparent. Then how foolish it seems of Miss Brassey—for it is, and can be no other than Miss Brassey—to be dressed so absurdly, and to gaze at the ceiling in such a meaningless and silly way. Seriously, there is no help for it. This kind of subject must be avoided. Before deciding on any figure subject, let one ask himself the question, Is this make-believe? If it is, let him be sure that in the result it will be seen to be so, and, in that case, where can be the pleasure of looking at the picture? Like the little boy in the story, the camera demon is always threatening to *tell you*, and, like the boy, he will be as good as his word.

In all the ordinary pursuits of life, in work or in play, the camera may be successfully employed, and, if we avoid all strained attempts at artificial posing, for the most part only, watching for and seizing the fine natural attitudes and groupings that occur spontaneously, we need not sigh because it is denied to us to deal with the distant in time or the ideal in art.

The most precious gift of our life, that gift without which all the others are almost valueless, is memory. Whatever enhances that gift is of the highest service to us, and so I feel that photography has a value higher than its mere art value. I feel that the making and the preserving of those visible records that will recall after many years the images of well-loved friends, and bring back to us again and again the hours and the scenes when our lives were at the brightest and the best, need not be the trifling pursuit it is by many deemed to be; and with the lapse of years we shall be all the better, all the happier, if we can at will bring into the living present what to ourselves, if not to others, are the precious memories of a vanished past.

JAMES CRAIG.

#### SPA—A LIGHTLY TRODDEN PHOTOGRAPHIC PATH.

A PRETTY little village, about three hours' ride east of Brussels, with about 8000 permanent inhabitants, largely supplemented in the season, Spa, it is said, originated the name to all watering-places called Spas. One has only to get into one of the Great Eastern Railway carriages at Liverpool-street, and travel *viâ* Harwich, Antwerp, and Brussels, and in about seven-teen hours he is at Spa, at an extremely small cost, viz., return, second class, 42s. 2d. He is amidst lovely mountain scenery, which, to judge from present appearances, has not been well or over-photographed, perhaps the pleasures of the gaming tables usurp all the attention of the visitors. Unlike Monte Carlo, visitors wishing to partake of the so-called vice must give notice of their intention to become members, and in forty-eight hours get a ticket, and pay twenty francs, which entitles them to win or lose as much money as they can, with free entry into the theatre, concert room, regatta, horse-racing, velodrome, golf gardens, &c. The gambling rooms are fairly well patronised, although the season is not in full swing until late in the summer. It is said to commence on May 1, but at present very few hotels are open. The gambling rules are much more liberal than at Monte Carlo, *i.e.*, at roulette the minimum stake is two francs, maximum 6000 francs, and at certain hours of the day Zero on all stakes gives another chance for your money; the *systemists* should win, but they must have the capital and courage (?); which of these qualifications I lack your readers must form their own conclusions. The bathing arrangements are pretty complete. One may have a *bain à la Champagne*, *à la Russe*, not *à la Turc*, or a peat bath, said to be very efficacious in gout. I tried the latter, and, on my emerging, I had an unpleasant idea that I looked like a resurrected nigger; the most unpleasant sensation I had was a desire to use my *mouchoir* to wipe the perspiration from my brow or whisk a fly from my nose, but this was nearly out of the question on account of my sanguinary *noir* covering. I am getting out of my latitude.

I have only seen one hand camera, and there seems to be only one professional photographer here who advertises apparatus and materials, general, with use of dark room. I have just seen the greatest enthusiast (stereoscopic) I have ever had the pleasure to meet—le Comte Alberic du Chastel. I had an invite to his Castle. Until I visited him I was under the impression that my stereoscopic apparatus was the most perfect in the universe, now I will have to sing small. The Comte, as I have already mentioned, is a profound enthusiast—stereoscopic cameras, lenses by the best English makers. One particularly beautiful camera, and evidently his favourite, was made in Belgium. He takes all his negatives on 13 × 18 cm., prints them on *glass* only by development in the camera. The latter's dark slides have got double shutters so that one may remain open longer. His field camera has some unique points—the usual twin lenses, a rack to separate if desired, a rising front, a scale for focussing, a rack and pinion for focussing on ground glass, revolving dark-shutter slides, and, by turning a pin outside the camera, the stereoscopic partition is moved towards the end. A finder and a view-meter complete the camera. I suggested that it should have a swing back. He immediately exhibited an English camera, remarking "that, as the rising front was greater than is usual, it was unnecessary." The Comte is not exclusively a landscapist, but his studio is adorned with group studies, enlargements, bromides, ten to twenty diameters, that would make many professionals blush. The studio is quite detached, and in itself is a large villa. The Castle can only be compared to Eaton Hall or Chatsworth. Although the Comte cannot speak English and I am at a disadvantage with French, we got on well together. He gave me a pressing invitation to revisit him, and I am sure he would extend his hospitality to any artist or photographer who pleased to call. I was almost forgetting to say that hotel prices are very moderate. Excellent *pension* may be obtained from eight francs. I am sure that any one interested in photography will only cry encore, which I will echo with my camera.

Hôtel de Laeken, Spa, Belgium.

A. L. HENDERSON.

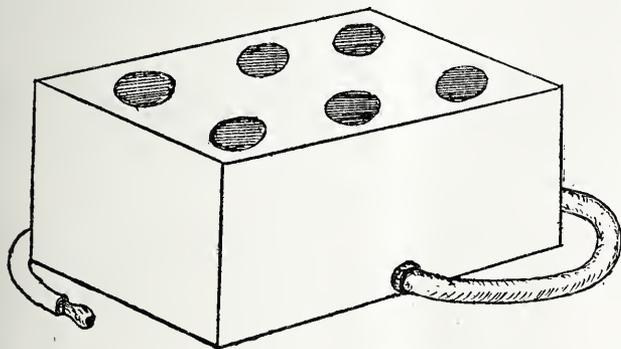

IMPROVED METHOD FOR MOUNTING PRINTS.

[A paper read before the Photographic and Microscopic Branch of the Franklin Institute.]

OFTEN the troublesome part to the amateur photographer is the mounting of the print. The cause of this is that, by the old method, it requires some practice, which he has not had, for the number of prints he has to mount is so small that he prefers to get them in shape for the album, especially after he has tried his hand at mounting the first few prints in the old way and making a mess of it.

Now, to remedy this trouble, I have contrived the device I have here this evening, and of which I will give you a brief description and a practical demonstration.

This invention is for the mounting of squeezed or other dry prints. The method has several advantages. It is very simple, neat, and clean; stops all daubing of the prints and leaves them and the hands quite clean. The mounts have less tendency to curl, and as the prints are quite stiff, they are more readily handled, and, if they are to be coloured, it may be done before they are mounted, and there is therefore less

danger of soiling the mount. To the inexperienced person this method is well adapted, since it requires but very little skill to make quite a neat job of it.

The arrangement consists, first, of a block of wood, which is called the squeezed print-mounter. This block is made about one-eighth of an inch smaller than the print to be mounted, and its upper surface is formed with a series of circular grooves, each of which is in communication with its neighbour, and the whole system in communication with the outlet pipe near the bottom of the mounter. To this outlet is attached a piece of rubber hose, and, to facilitate the handling of the prints, a small paddle is also added. To keep the prints more firmly in place, the upper surface of the mounter is coated with a solution of rubber cement, made quite thin with benzine. This coating must be renewed whenever the surface gets too smooth to hold the prints firmly.

To use this mounter, place the print upon it, face down, with the edges projecting all around, and on it, to hold it in position temporarily, place the paddle, then prepare the brush with as much paste as needed, after which place the rubber hose in the mouth and exhaust the air, this holds the print whilst applying the paste; after the print is pasted, apply the paddle to it, so that it may be readily transferred to the mount, place one edge in its proper position on the mount, and with the left hand hold it there until you remove the paddle, after which proceed as in the older method.

JOHN G. BAKER.

PHOTOGRAPHING A SPLASH.

"It would be difficult to imagine anything more commonplace to the ordinary observer than the splash of a drop, yet Professor A. M. Worthington's researches, extending over many years as they have done, and the first series of which were but recently completed, show that this apparently simple occurrence, when examined by the refined methods which science makes possible, is really a succession of bewilderingly beautiful phases, which, for their complete interpretation, require the resources of higher mathematical analysis. The same distinguished investigator has demonstrated that a variety of allied phenomena, while fundamentally dependent upon the same properties of matter, are all characterised by their individual peculiarities of changing forms, which can be reproduced at will by the experimenter." So says an anonymous writer in the May number of *Knowledge*. We can only afford space for one short extract, but those interested in the subject will find ample material, well illustrated, in the original article contained in the magazine referred to. "It is necessary to point out that the form of the splash depends very much upon the condition of the surface of the sphere. When a polished sphere of marble, rubbed very dry with a cloth just beforehand, is dropped into the water, the water spreads over the sphere so rapidly that it is sheathed with liquid even before it has passed below the general level of the surface. The splash is insignificantly small and of short duration; but, if the sphere be roughened with sand paper or left

wet, the water is driven away laterally, forming a ribbed, basket-shaped hollow, which, however, is now prolonged to a great depth, the drop being followed by a cone of air, while the water seems to find great difficulty in wetting the surface of the sphere completely."

SMITH'S NEGATIVE-WASHER.

[Patent No. 3382 of 1900.]

THE invention relates to the use of a revoluble water wheel, in connexion with and forming a part of a photographic washing machine, the construction and combination being such that the negative plates may be readily and conveniently placed there-in, removed therefrom and securely held in position during the process of washing, the machine being equally well adapted to hold plates of varying size within predetermined limits.

*a* represents the base of the machine, which is preferably formed from bent wire, the base being oblong in shape as shown, the wire being bent upwards at the sides to form supports, *b b*. Attached to the upper ends of the supports are plates, *c c*, the plates being centrally bored to receive and support the ends of a shaft, *d*. A water wheel, *g*, consisting preferably of a series of buckets, *h*, rigidly attached to each other at the front and rear, is mounted upon the shaft by means of plates or bars,

FIG. 1.

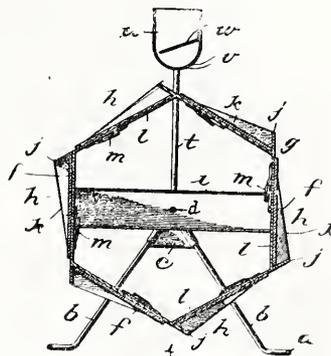

FIG. 2.

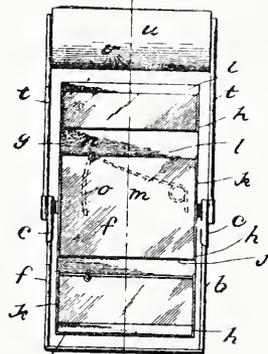

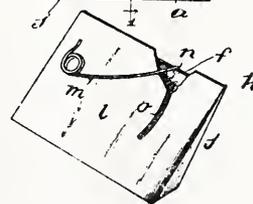

FIG. 3.

(fig. 1), extending diametrically across said wheel, and soldered or otherwise attached thereto. Each of said buckets is provided with a flat bottom, *l*, formed from sheet metal, and outwardly extended flanges, *j k*, the latter being tapered towards the front as shown.

Bent springs, *m*, are soldered at one end to the bottom of each of the buckets as shown, each of the springs having formed upon its free end a catch, *n*, which is projected through a slot, *o* (figs. 2 and 3), formed in the bottom of the bucket, said slot being curved to conform to the path of movement of the free end of the spring. The ends of the catches which project through the slots are bent so as to engage and overlap the edges of the negative plates, *f*, and to press the plates back against the flanges, *j*, or other suitable stops, so as to hold the plates in place during the rotation of the wheel. The flanges, *j*, preferably consist of extensions of the plates, *l*.

Vertical bores formed in the plates, *c c*, are adapted to receive detachable vertical wire supports, *t t*, to the upper ends of which is attached a trough, *u*, having a row or rows of perforations, *v*, in the bottom thereof, extending throughout its length. The trough is intended to be placed beneath a faucet, from which it receives a water supply. A

baffle plate, *w* (fig. 1), is formed in the trough, the plate extending from end to end, and nearly across the same, as shown, for the purpose of causing a more uniform distribution of the water than would otherwise occur. The object in making the trough removable is to render the device more compact for shipping purposes.

In placing the negatives in the buckets, the spring, *m*, is drawn out to the position shown in dotted lines in fig. 3. The negative, *f*, is then laid upon the bottom of the bucket, which is in effect the equivalent of an ordinary tray, with its rear edges against the flange, *j*, when the spring is released, which causes the front edge of the plate to be engaged by the catch upon the end of the spring, thus securing it in place.

## PRODUCING MULTIPLE PHOTOGRAPHS.

[Patent No. 7431 of 1899.]

THE invention of Herr Szczepanik.

An opaque plate, *d*, possessing suitably distributed holes (see fig. 2), is arranged between the objective and the image-receiving screen, consisting, by way of example, of a matt or ground-glass disc, *c*.

The figure or object of which a multiple representation is to be made may be formed by the diaphragm opening itself, or a transparent negative or diapositive of the object may be arranged in place of the diaphragm.

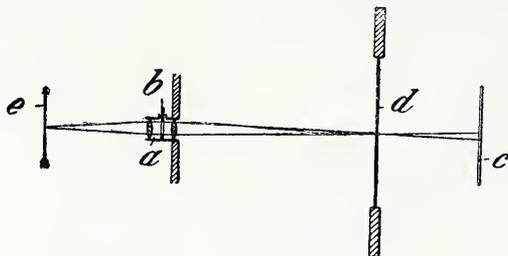

FIG. 1.

On illuminating, an image of the object appears on the matt or ground-glass disc for every hole in the plate; thus there are formed just as many copies of the object as there are holes in the plate, *d*.

If the openings in the plate, *d*, are near enough together, the diaphragm images combine to form a pattern, design, or ornament, as is shown in fig. 5.

The negatives or diapositives to be placed in the objective instead of

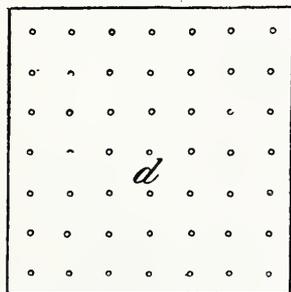

FIG. 2.

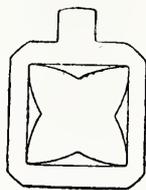

FIG. 3.

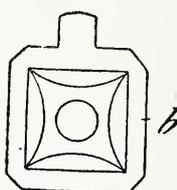

FIG. 4.

the diaphragm may consist of paintings on glass plates. If a sensitive photographic plate be used instead of the matt or ground-glass disc, then from one object, and by a single impression, as many photographs of the object can be obtained as there are holes in the plate, or a repeat design or ornament (fig. 5) can be produced.

It is possible to produce, by the method described, photographs that

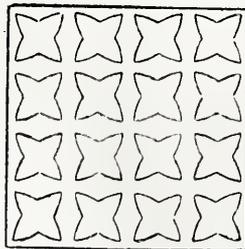

FIG. 5.

can serve different purposes, for example, for the production of prints as groundwork for documents, bonds, securities, &c., in so far as it is a question of multiplying or forming patterns with repeat designs or figures. As these impressions depend not only on the diaphragms, but also on the arrangement of the openings in the perforated plate, imitation is almost impossible.

## MACAIRE'S NEW PHOTOGRAPHIC FILM.

So much interest is just now being taken in film matters that we append the specification of Mr. Macaire's patent (No. 12,152 of 1899) in full:—

The object is to produce a film which, without the employment of a glass plate or carrier, shall be free from grain and possess other advantages, as hereinafter explained.

Films of this class have hitherto, as is known, been mounted either upon glass, or upon carriers, or backings of paper, or other material, and, when backings of the latter class are employed, it is impossible to produce satisfactory enlargements of photographs taken upon the films, or pictures suitable for projection, on account of the transference of the grain of the backing to the gelatine of the film, which on enlargement or projection has the effect of spoiling the picture.

Now, I am able, while still retaining the advantages of the paper backing, to produce a film entirely free from grain, and from which satisfactory enlargements to any desired size, or pictures entirely suitable for kinematographic or lantern projection, can be obtained.

The films are particularly useful for film cameras and for kinematograph negatives and positives, since they can be made in any length, and, in the preferred construction, are cheaper than celluloid, though celluloid may be employed in their manufacture if desired. Further, the improved films, in their preferred construction, are entirely unflammable, and thus render kinematographic projection perfectly safe.

It is possible to obtain equally sharp impressions from either side of the film, which will be found useful for carbon and process work. Further, the positive made upon the improved films can be used for crystoleum work without any preparation.

I take a sheet, band, or reel of backing paper, which should be of good manufacture, and made from pure rag pulp. Upon this I spread, by any convenient means or apparatus (such, for example, as the machines employed in the manufacture of fancy papers, which are so well known as to require no further description), a coating, or it may be two or more coatings, of a mixture of gelatine and barium sulphate, the gelatine being rendered insoluble by chrome-alum or other suitable agent; or, instead of gelatine for this coating, I may use any other suitable colloidal substance capable of being rendered insoluble; or I may first apply a coating or coatings of a mixture of soluble gelatine or other suitable colloidal substance, and barium sulphate, and, when this is dry, superpose thereon a coating of insoluble gelatine or insoluble colloidal substance. After allowing the coating last applied to dry, I apply an impermeable coating of wax, rubber, gum, resin, or the like, dissolved in benzine or other solvent, and, after allowing the solvent to evaporate, I apply a coating of collodion, or, by preference, alternate coats of collodion and gelatine or casein until the desired thickness has been obtained. This may be effected by dissolving the gelatine in water or casein in alcohol. The gelatine or casein should be rendered insoluble in water by the addition of a suitable agent, such as formalin. The outermost coating should contain the sensitising material or serve as the carrier therefor.

There is a special advantage in applying alternate coats of collodion and gelatine or casein in the manner above described, since I thereby obviate any stretching of the film lengthwise or transversely.

I prefer films having upper coatings of collodion and gelatine or casein as described above the impermeable layer above referred to, but I may employ celluloid in place of the coats of collodion and gelatine or casein. For this purpose I may apply one or more coats of celluloid upon the impermeable layer, according to the thickness desired. The celluloid will be applied in solution in a suitable medium such as acetate of amyl and acetone with benzine. The outer layer is sensitised as before.

The paper backings which I employ are by preference black or of non-actinic colour. This has the great advantage of enabling rolls of film to be introduced in broad daylight into or removed from film cameras, and in the case of packets of film of preventing the daylight passing through the paper or other backing of a film exposed thereto and injuring the films behind. Halation, which is so serious a matter in producing photographic images for enlargement and the like as hitherto upon glass backings, is also thus prevented.

Any suitable apparatus may be employed for applying the various coatings to the paper backing, and when these have all been applied the band or sheet may be cut up into sizes suitable for the requirements of the photographic trade.

The films, after being exposed in the camera upon their backing, may be stripped therefrom and developed, intensified, reduced in intensity, fixed, washed, and finished, just as if they were upon glass, so that it is possible to readily follow and control the progress of these various operations, and thus obtain greatly improved results.

After washing and finishing the exposed film I prefer to pass it into a solution consisting of glycerine *five per cent.*, formalin *five per cent.*, water and alcohol. The film is then placed upon the original paper backing, which may be retained for the purpose, and allowed to dry in the air; this will impart perfect rigidity and smoothness to the film. When it is dry, it may be again stripped from the backing, and the result is a perfectly bright and rigid film entirely free from grain.

The films are particularly adapted for advertising and decorative purposes, since the difficulty experienced hitherto of enlarging transfers such

are required for the purpose, and which difficulty is due to the transference of the grain of the paper backing, is obviated. In employing my improved film for advertising or decorative purposes, it is only necessary to moisten the film and cause it to adhere to the desired surface, say, a painted iron tablet, by placing the gelatine face inwards thereon, and applying pressure. The paper backing may then be stripped off, leaving the film adhering firmly and evenly to the surface. The film should then be varnished.

The film may, if desired, be strengthened after exposure and finishing, by a surface layer of gelatine applied thereto in the well-known way.

## Our Editorial Table.

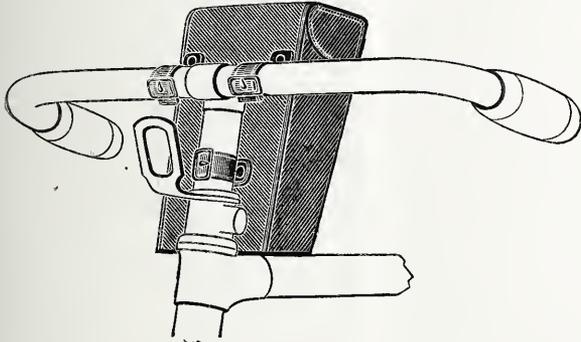

MESSRS. GEORGE HOUGHTON & SON, of 88 and 89, High Holborn, W.C., are issuing a clearly written pamphlet descriptive of the special features of the Sanderson Hand Camera, which we recently noticed in these columns.

MESSRS. R. & J. BECK, LIMITED, of 68, Cornhill, E.C., are issuing a special catalogue descriptive of the Beck-Steinheil orthostigmatic and other photographic lenses, prisms, &c.

### THE NO. 8 PRIMUS CAMERA.

Manufactured and sold by W. Butcher & Son, Blackheath, S.E.

THIS little instrument, which, with three double slides and a case, sells for two guineas, is especially designed for cycling photographers. In the illustration it is shown so attached to a cycle that it may be removed from the case without unstrapping the latter from the machine. Of field-glass shape, the body of the camera, which is morocco-covered, may be compressed by the movement of two internal supports. It is made for

quarter-plate pictures, and the slides are of the metal form devised some years ago by Mr. B. J. Edwards. The single lens, of about five inches focus, is controlled by a rotating diaphragm with three apertures, and the shutter, which is of the go-and-return variety, admits either of time or instantaneous exposures. The camera is light, portable, and well made, and the cycling photographer who requires a simple form of instrument should find the No. 8 Primus to his taste. It has a view-finder, and the slides may be packed inside the camera when the latter is not in use.

### THE BARNET PLATES AND PAPERS.

Elliott & Son, Barnet, N.

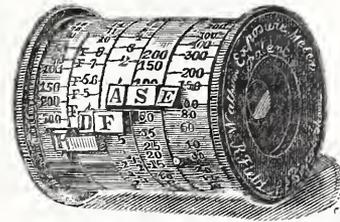

WITH many pleasing illustrations made from negatives taken on the Barnet plates, this little book in its striking coloured cover has yet other claims on our favourable notice. The developing and other formulæ are expressed in both the Imperial and the metric systems on a basis of 1000 c. c. of water throughout. The latter point is one that should always be borne in mind by those compiling formulæ on the metric system. Moreover, the approximate speed numbers of Messrs. Elliott's plates are given for the H. & D., Wynne, and Watkins systems. The price-list is of general as well as particular service, and we must congratulate Messrs. Elliott on its taste and utility.

### THE WATKINS STANDARD EXPOSURE METER.

Manufactured and sold by R. Field & Co., 142, Suffolk-street, Birmingham.

THE latest pattern of this beautiful little instrument, the utility and ingenuity of which will assuredly perpetuate the name of Alfred Watkins in photography, lies before us. Messrs. Field draw our attention to the fact that the instrument has been greatly reduced in length and weight

without compression or curtailment of the scales, and, while being quite as complete as before, it is now more portable; in fact, the meter has been given the utmost possible portability without impairing its efficiency, and it may be carried in a waistcoat or ticket pocket with no inconvenience. It is so long since the Watkins exposure meter was reviewed in our columns that a brief description of its functions and the manner in which they are exercised may not be out of place. It is taken from the explanatory pamphlet: "The instrument consists of a simple actinometer for testing the light, a chain pendulum for counting seconds or half-seconds (for timing both the actinometer and camera exposures), and five movable calculating rings carrying pointers, P, D, S, F, and A, which, when adjusted to the numbers representing the value of each factor, causes a sixth pointer, E, to indicate the correct exposure. It is a means of calculating variations from one test exposure. The basis of the calculation is a test of the light which is actually illuminating the shadiest part of the subject to be photographed, and the first thing to do, therefore, is to test the light: Unfasten the lid of the pendulum box, and allow it to swing, then hold the actinometer to face the source of the

light which falls upon the subject, not to face the subject; pull out a fresh surface of sensitive paper under the aperture, and at the same instant count 'nought'; continue counting 'one, two,' &c., in time with the swing of the pendulum (counting at one end of the swing only for seconds). The number of seconds taken for the paper to darken to the standard tint is the actinometer or A number. In testing the light the depth of tint is the important point. The paper darkens rapidly in light; up to a certain point it is lighter than the standard tint, after this point it is darker. The point when it is neither lighter nor darker is that to be timed."

In photography, of all the vital conditions for success not one ranks with such importance as accuracy of exposure. This little meter, with its five factors, and the simple manner in which they may be estimated conjointly with the darkening action of light on a thin strip of excited paper, places at the command of the photographer a most valuable power, for, intelligently used, he need scarcely ever spoil a negative, lantern slide, copy, or enlargement, by gross error of exposure. Our experience and our opinion of the meter is that it ought properly to form part of every photographer's equipment. It is well worth the 15s. charged for it.

### CATALOGUE RECEIVED.

J. Lizars, 101 and 107, Buchanan-street, Glasgow; London, Edinburgh, Aberdeen, and Belfast.

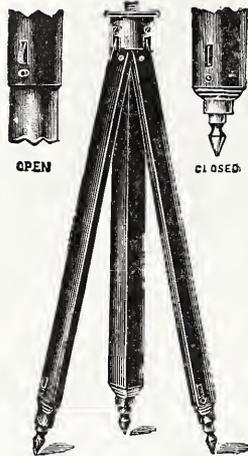

THE handsome catalogue of Mr. Lizars, which extends to nearly 200 pages, is especially noticeable from the fact that it gives many half-tone illustrations made from negatives taken in the well-known Challenge cameras. These negatives were obtained by about a dozen clever photographers, amongst whom such expert workers as Mr. W. M. Warneuke, Dr. J. Cowan Woodburn, Mr. C. Chapman, and Mr. W. L. Primrose, are prominent. A glance at the photographs, some of which have been medalled, shows that the Challenge cameras could not have a more eloquent series of testimonials, for the work throughout is of the highest class, including, as it does, examples of landscape, seascape, group, and portrait photography. The catalogue itself is a comprehensive guide to the selection of photographic apparatus, and it contains, besides, much information relating to formulæ and practical hints, thus constituting it a useful reference book for amateur photographers. A special feature is made of illustrating and enumerating the more recent forms of Mr. Lizars' cameras. The catalogue appeals alike to professionals and amateurs, and is sent free on application.

### CAMERA TRIPOD OF ALUMINIUM OR BRASS.

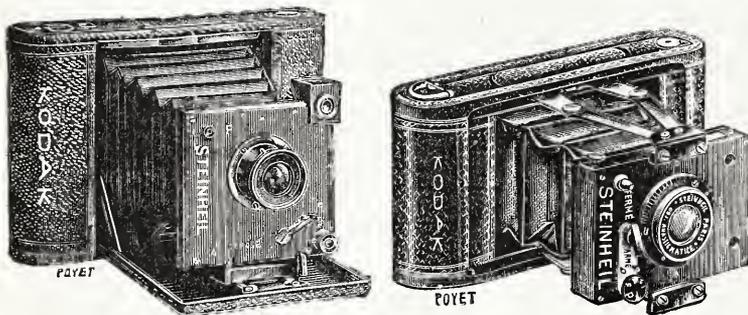

Supplied by Arthur Rayment, 125, Earlham-grove, Forest Gate, London, E.

THE stand shown overleaf may appear familiar to our readers, but upon close inspection it will reveal the fact that a new and decidedly advantageous locking and releasing device has been substituted for the well-known form, with internal and external springs, hitherto employed. The old form of outside spring is very liable to be pushed out of its place or broken. The method of opening the new stand is by simply drawing out the tubes telescopic fashion, when a duplex catch secures the rigidity of the jointed connexions. The closing is effected by pressing the duplex catch, which simultaneously releases all the jointed connexions, and permits the instantaneous closing of the legs to their minimum length

of 14½ inches, so making this a most portable as well as light and convenient camera stand, which, from personal examination, we can strongly recommend to those of our readers who appreciate portability and compactness in photographic apparatus.

Mr. Rayment has also brought under our notice two Eastman's Kodaks, Nos. 1 and 4 of the Folding Series, fitted by Messrs. Steinheil & Son with their orthostigmatic lenses and patent shutters. The lenses, though working with very large apertures, render crisp definition to the margins of the field, this important desideratum being ensured by an efficient

arrangement for obtaining exact focal adjustment. The shutters give prolonged exposures as well as varying speeds of instantaneity. Mr. Rayment asks us to add that he is agent for the Paris branch only of the firm of Steinheil & Son.

\*\* Great pressure on our space this week again obliges us to hold over several reviews, notices, &c.

## Studio Gossip.

**THE TANQUEREY FREE-PORTRAIT SCHEME.**—We have to thank Mr. J. Thomson, of 70A, Grosvenor-street, W., and Mr. F. Ralph, of Dersingham, King's Lynn, for batches of "Tanquerey" literature. We have over and over again drawn the attention of readers of the JOURNAL to the nature of the Tanquerey free-portrait scheme.

**PHOTOGRAPHERS ON NAVAL BRIGADE DAY.**—Writing of the crowd assembled in Trafalgar-square to welcome the Naval Brigade on Monday week, Dagonet, in the *Referee*, says: "From my point of vantage I had an excellent opportunity of studying the kodakers. I had no idea they were such an adventurous body. They climbed lamp-posts, they hung over the parapets of seven-story buildings, they balanced themselves on railings at the imminent risk of impalement. In the centre of the Square, in a spot commanding a view of the approach from Whitehall, one kodaker had improvised a human ladder. A big, broad-shouldered man was at the base, on his shoulders a second man was seated. The kodaker climbed up the men and seated himself on the shoulders of the second. It was a daring feat. At any moment there might have been a serious accident."

**PHOTO BUTTONS.**—Our contemporary, the *Professional Photographer*, gives the following outline of the method for producing photo buttons, which are very popular just now in the United States:—"A 5×8 plate is generally used to the best advantage, placing upon same from one to forty-five exposures of the standard-size buttons. The celluloid used in covering costs seventy cents a sheet (this is sufficient for about one thousand small-sized buttons); the backs used for same can be had from forty cents a gross up. The prints are dipped into a solution of alcohol; they are then united to the

celluloid by the aid of an adhering roller, which works on the same principle as a burnisher. After once united it is placed on a block and cut out by a circular die; it is then placed in a machine that is so simple that it can be operated by any child almost able to stand on its feet. The machine has the capacity of turning out twelve thousand buttons a day. When not in operation, no expense is connected with it whatever, and the space it occupies is so small that any vacant corner in a room would be sufficient. The different sizes made to-day range from one-fourth of an inch up to nine inches in diameter, most of them being round, but some of the late additions being oval-shaped."

**THE SPEIGHT GALLERIES.**—The whole of the well-known building, known as 178, Regent-street, has just been entirely redecorated, most of the work having been done at night so as not to interfere with the general carrying on of the business. The woodwork of the staircase, like that in other parts of the building, is painted ivory white, the doors being picked out in a peculiar shade of dark green. Each door has fixed to it a carved tablet with the purpose for which the room is used written in gold. The walls of the staircase, which are painted a rich Indian red, are covered with numerous pictures. The colour of the stair carpets and draperies harmonise with the colour of the walls in a capital manner. There is a fernery outside the galleries on the first floor, with a fountain playing. The whole of the first floor is occupied by the galleries. The walls are painted a soft sage green, frieze having been formed by a shelf fixed round the walls, about three feet from the ceiling, upon which have been arranged some pieces of pottery. The second floor is reserved for the lady artists; the third floor for the dispatch, mounting, finishing, and housekeeper's rooms; on the fourth floor one comes to the various dark rooms, the Peacock and Rose dressing-rooms, and then the visitor enters the Divan, where clients are served with afternoon tea previous to entering Mr. Richard Speight's studio. Special accommodation is arranged on the roof of the building for the printing from the negatives, all the photographic printing being done on the premises.

**A WELL-KNOWN BIRMINGHAM PHOTOGRAPHER.**—The current number of the *Birmingham Magazine* is, as usual, beautifully produced, and contains, among many other articles of local interest, one devoted to Mr. H. J. Whitlock, Birmingham's first photographer. "There are few," says our contemporary, "who have such a record as Mr. Whitlock. To be appointed photographer to both Her Majesty the Queen and His Royal Highness the Prince of Wales are exceptional honours, and to be commanded to photograph a series of views of and about the royal residence at Balmoral, and of the royalties there, is a pleasure enjoyed by few. Some of the pictures thus taken illustrate the Queen's own book, *Leaves from a Highland Journal*; and, when in 1874 His Royal Highness the Prince of Wales visited Packington, a further Royal command was issued for another series of views and portraits at that stately home of Warwickshire. Mr. Whitlock's studios have been visited by a long series of mayors and the Lord Mayors and other governors of the city. The portraits of all the Judges and other notables who have visited Birmingham form a magnificent gallery of prominent people. In fact, in no other studio than that of Mr. H. J. Whitlock, have so many important portraits been taken. Very largely has Mr. Whitlock's work been that of taking photographic records of not only the principal places and buildings of the city, but an innumerable variety of business and private establishments, which together form such a collection as to constitute a picture history of the progress of the city for the period embraced. Further, his collection of photographic records of public and private functions is unique—laying of foundation-stones, openings of public buildings, royal and other receptions, processions, banquets, weddings, and, most recently, groups of khaki-clad warriors for South Africa. These latter include a very fine group of the Warwickshire Imperial Yeomanry, taken at Warwick Castle on the day previous to their sailing from Liverpool. In addition to the New-street establishment, Mr. Whitlock has a branch studio at 201, Broad-street, under the management of his son, who is the representative of the third generation of photographers of that name, and here again is a record, for photography itself has only just completed its second generation."

## News and Notes.

**THE Annual *Conversazione*** of the Society of Arts will be held at the Natural History Museum, South Kensington, on Wednesday evening, June 20.

**THE Annual Dinner of the Camera Club** was held on Thursday, May 10, in the Club-room at Charing Cross-road, under the chairmanship of the President, Sir W. de W. Abney, F.R.S.

**PHOTOGRAPHIC CLUB.**—Anderton's Hotel, Fleet-street, E.C., Wednesday evening, May 23, 1900, at 7.30 o'clock, Mr. G. J. T. Walford, "Control in Photographic Printing," illustrated by lantern-slide examples.

**THE older readers of this JOURNAL** will be interested to know that one of its most valued supporters, Mr. W. J. Stillman, who has been obliged to drop photography during the past year from press of literary work and instability of residence, has permanently located himself in Surrey, and has resumed photographic pursuits.

**THIS year's Special Summer Number of the *Studio*** is to be devoted to "Modern British Water-colour Drawings." The illustrations will include examples of the work of all the most prominent contemporary water-colour painters, and an important feature of the number will be the coloured reproductions, of which there will be no fewer than twelve.

**ROYAL PHOTOGRAPHIC SOCIETY.**—Tuesday, May 22, a Note by Mr. Alfred Watkins, entitled "Hydroquinone and Colour Impressions," will be read. The Exhibition of pictures by Mr. F. H. Evans will remain open until

Saturday, May 26, from ten to four p.m. (Wednesdays, eight p.m.). On Tuesday, May 29, Dr. P. H. Emerson will open an exhibition of his work, at eight p.m., and will give an address.

HOW EX-PRESIDENT STEYN TREATED HIS BURGHERS.—Prior to the Boer exodus from Kroonstad, ex-President Steyn vainly implored the Free Staters to continue their fight for freedom. Threats and cajolery were alike futile. Finally Steyn became quite mad with rage, and kicked and cuffed the faint-hearted burghers. An enterprising photographer in the town took a snap-shot of the scene, which plainly shows Steyn striking his burghers.

MESSRS. G. WEST & SON inform us that their well-known entertainment, "Our Navy," will be given at the Agricultural Lesser Hall at the same time as the Military Tournament, which opens next week. We are pleased to learn that this exposition of life in the Royal Navy has greatly stimulated recruiting throughout the various towns in the country. It has also been exhibiting for the past eight months at the Royal Polytechnic, Regent-street.

PROFESSOR RÖNTGEN.—*Nature* states that the U.S. National Academy of Sciences has decided to award the Barnard medal to Professor Röntgen for his discovery of the X rays. This medal is awarded at the close of every quinquennial period for a discovery in physical or astronomical science, or novel application of science to purposes beneficial to the human race. The first presentation of the medal was to Lord Rayleigh and Professor Ramsay for their joint discovery of argon.

PHOTOGRAPHY WITHOUT LIGHT.—At the meeting of the Photographic and Microscopic Section of the Franklin Institute, on April 3, a communication was presented by Dr. Martin J. Wilbert on "Photographing Without the Aid of Light." Among the experiments shown was one in which a coin was heated and then enclosed with a sensitive plate in such a way as to entirely exclude light, with the result of producing a negative in which the heat waves are supposed to have been the active agent.

THE MEISENBACH ARTISTIC DISPLAY IN ADVERTISEMENT COMPETITION, 1900.—The following are the Judges' awards: 1. "Rex," W. S. Wilson, with Messrs. R. E. Thomas & Co., White-street, Moorfields, E.C., first prize, 20*l.* 2. "Nubian," W. S. Wilson, with Messrs. R. E. Thomas & Co., White-street, Moorfields, E.C. (disqualified from taking second prize of 10*l.*, owing to being first prize-winner). 3. "Galley," S. Martin, with Messrs. Cooper & Budd, Limited, McDermott-road, Peckham, S.E., second prize, 10*l.* 4. "Peckjoy," George Joyner, of Messrs. Joyner & Wenham, 27, High-street, Peckham, S.E., third prize, 5*l.* An exhibition of the specimens will be on view at the St. Bride Foundation Institute, Bride-lane, Fleet-street, London, E.C., till Saturday next, May 19. Admission is free. The whole of the 220 designs submitted in this competition, together with the Judges' reports, will be published in book form, price 1*s.*, post free. Application for copies should be addressed to The Secretary, The Meisenbach Company, Limited, West Norwood, London, S.E.

MR. CHARLES HYATT-WOOLF.—*The Disptric and Ophthalmometric Review* for April contains an excellent portrait and a brief biography of Mr. Charles Hyatt-Woolf, the editor of the *Optician and Photographic Trade's Review*, from which we learn that he is thirty-six years of age. Mr. Hyatt-Woolf devoted some portion of his career, subsequent to his undergraduate days, to the study of medicine and law, his inclinations leading him ultimately into journalism. He has owned a variety of newspaper properties, and nine years ago inaugurated the *Optician and Photographic Trade's Review*, in the editing of which his early training in physics stood him in good stead. Almost simultaneously with the appearance of this publication Mr. Hyatt-Woolf produced *Science Stiftings*, a weekly paper which conveys science to the general reader in a popular form. Its success has been very remarkable. Mr. Hyatt-Woolf is also the author of a book on alimentary chemistry, which has passed into its fifth edition, besides other works of varied nature. In addition to his labour of editing the two newspapers already mentioned, he writes many of the technical and trade articles and paragraphs in them, and finds time for contributing to the political and social press. His optical work, however, gives him the greatest satisfaction, and he ranks himself proudly as an optician of ten years' standing, this being the period when the *Optician and Photographic Trade's Review* was first projected.

PHOTOGRAPHIC CLASSES AT THE GOLDSMITHS' INSTITUTE, NEW CROSS, S.E.—We are informed that a class for elementary and advanced students of practical photography will be held by Mr. W. T. Wilkinson on Saturday afternoons, from 4.30 to 7.30; and on Monday evenings, from 7.30 to 9.30. The Saturday afternoon meetings are for the purpose of doing daylight work at the Institute on printing in P.O.P., carbon, platinum, &c.; copying, portraiture, &c.; and for the purpose of practical instruction in landscape, architectural, and snap-shot photography in Greenwich Park, Blackheath, the river-side, &c. The Monday evening meetings are for dark-room work, such as developing the Saturday exposures, printing in bromide, Gravura, retouching, intensifying, and reducing negatives, enlarging, toning, mounting, &c. The class dates are May 21 to July 7. The photographic studio and dark room are fitted with electric arc lamps for copying and portraiture. The department is provided with studio, landscape, lantern slide, and copying cameras, an enlarging lantern, and a powerful electric projection lantern. It also possesses complete outfits for photo-lithographic and colotype work, for platinotype and carbon printing, and for retouching and other branches of modern photographic practice. Students provide their own sensitive paper and plates, but all chemicals required are furnished by the Institute. The fee for the course (twelve meetings) is 12*s.*

THE BLAIRGOWRIE EXHIBITION.—We had occasion to comment very favourably on the last Exhibition promoted by the Blairgowrie and District Photographic Association, and, if enthusiasm and ability for hard work tend to success, the forthcoming Exhibition, which the Association has arranged for January 14-19, 1901, ought to rival its predecessor. Messrs. John B.

Maclachlan and D. J. Monari, who were in the thick of the work at the last Exhibition of the Association, have been appointed joint Secretaries. The schedule of classes is as follows:—Open to all: A, Champion (open to prints which have previously taken a first prize in an open exhibition); B, Architecture, exterior and interior; C, Instantaneous work, subject showing evidence of motion; D, Flowers, Fruit, and Still Life; E, Stereoscopic work, in sets of three (award for best individual print or transparency); F, Lantern slides, Champion (open to slides which have previously taken a first prize in an open Exhibition); G, Lantern slides, in sets of four (award for best individual slide); H, Lantern lecturette (particulars on application to the Secretaries). Open to professionals: J, Landscape or Seascape; K, Portraiture or Figure Studies, including animals. Open to amateurs: L, Landscape or Seascape; M, Figure Studies or *Genre*, including animals. Open to members: N, any subject. Enlargements may compete in any class. A silver and a bronze medal and a diploma are offered for competition in each class. The Association also offers as a special prize a gold medal, value five guineas, for the best picture in the Exhibition, the picture to become the property of the Association for addition to the permanent collection in the Association Club-room.

THE Royal Cornwall Polytechnic Society's Sixty-seventh Exhibition will open at Falmouth on Tuesday, August 21, 1900. With a view to encourage workers in arts and crafts, a considerable amount of space will be set apart in the Exhibition for the display of specimens of handicraft by members of classes associated with the Home Arts and Industries Association, exhibitors under the Arts and Crafts Exhibition Society, students in Technical Instruction Classes under County Councils (especially in Cornwall), and others. Medals and prizes are offered in several departments, including photography (photographs by professionals and by amateurs, and photographic apparatus). The following is the schedule: In all cases state whether the work is professional or amateur, and name process of production. All work sent for competition must have been executed within eighteen months of the date of this Exhibition. *Carte-de-visite* portraits are excluded from exhibition, except when illustrating some special process or novelty. All enlargements for competition must be the work of the exhibitor. Regulation 5 does not apply to the Photographic Department. Information respecting the Photographic Department may be obtained from Mr. W. Brooks, Laurel Villa, Wray Park, Reigate (member of the General Committee). Professional.—Medals in the following subjects: Outdoor Photography—1, Landscape, not less than 20×16 inches; 2, Landscape, 12×10 inches and under; 3, *Genre*; 4, Architectural (exterior); 5, Instantaneous, including marine; 6, Animals; 7, Enlargements. Indoor Photography—1, Portraits, not less than 20×16 inches; 2, Portraits, 15×12 inches and under; 3, Home Portraiture; 4, Still Life, flowers, &c.; 5, Interiors, architectural or otherwise; 6, Enlargements. Amateur: 1, Landscapes; 2, Architectural, exterior or interior; 3, Alpine Scenery, including Caucasian; 4, Hand-camera Work, not less than twelve examples, quarter-plate; 5, Instantaneous, including marine; 6, Still Life; 7, Enlargements. Apparatus: Photographic apparatus generally, including the lantern and its appliances.

## Commercial Intelligence.

THE AUSTIN-EDWARDS MONTHLY FILM-NEGATIVE COMPETITION.—The prize-camera for the current month has been awarded to Mr. Theodore Harris, Belhaven, Shepherd's Hill, Highgate, for his negative, *Procession entering Canterbury Cathedral*.

In the Westminster County Court last week Judge Lumley S. Smith, in the case of Newman *versus* The Taber Bas Relief Co., at the instance of Miss Ethel Newman, recently engaged in the *Belle of New York* Company at the Shaftesbury Theatre as under-study to Miss Edna May, granted an injunction against the defendants to restrain them from publishing Miss Newman's photographs on Christmas and birthday cards.

*Re* A. H. COX, photographer, Weymouth.—This debtor made an application for his discharge at the Dorchester Bankruptcy Court on Wednesday last, before his Honour, Judge Philbrick. It appeared that the receiving order was made in 1893, and, on the whole, the debtor's conduct under the bankruptcy proceedings had been satisfactory, but the Official Recorder called his Honour's attention to the fact that the debtor, at his public examination, refused to answer a question, with the result that the Registrar threatened to adjourn the examination *sine die*. In allowing the examination to be closed, the Registrar expressed the opinion that the debtor was a man totally unfit to go into business again. He did not oppose the discharge, but he thought his Honour should be made acquainted with the facts. His Honour said he noticed that the debtor executed a deed of assignment in 1891, and in 1892 he obtained an administration order. Under the present bankruptcy proceedings the creditors had only received a dividend of 2*s.* 11*d.* in the pound. Debtor was questioned by the Official Receiver as to certain goods he had in his shop when he filed his petition. Debtor explained that they belonged to his mother, but had been taken by his sister, Julia. She had also taken other articles belonging to his parents. He did not know her present address. His sister claimed the things under a deed of gift. His Honour remarked that, if the Official Receiver thought the goods belonged to the debtor's estate, he must get the deed of gift set aside. As matters stood, the debtor had, no doubt, offended against the Bankruptcy Act in more than one respect, but his conduct under the proceedings had been generally satisfactory, and he only intended to suspend his discharge for six months more than the statutory period, therefore he should grant the certificate subject to a suspension of two and a half years.

## Patent News.

THE following applications for Patents were made between April 30 and May 5, 1900:—

- PHOTO-MECHANICAL PRINTING.—No. 8088. "An Improved Photo-mechanical Process for Producing Printing Surfaces." Complete specification. E. Vogel.
- FOCUSING.—No. 8099. "New or Improved Method of and Means for Focusing in Photographic Cameras." A. L. ADAMS and W. WATSON.
- PROJECTION.—No. 8137. "A Method of Showing Titles Beneath Lantern Slides and other Transparencies, and for the Projection of Titles to Appear in White on Screen." THE PHOTOGRAPHIC ASSOCIATION, LIMITED, and J. LE COUTEUR.
- LIGHT FILTER.—No. 8171. "Improved Light Filter or Screen for Photographic Purposes." H. RHEINLANDER.
- FILM-HOLDER.—No. 8039. "An Improved Photographic Film and Print-holder." W. F. CRAWFORD.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
21.....	Cripplegate Photo. Society .....	Prize Lantern Slides.
21.....	South London .....	How a Lens is Made. C. P. Goerz.
22.....	Hackney .....	Pictorial Photography in Practice. A. Horsley Hinton.
22.....	Isle of Thanet .....	Exhibition of Members' Work.
22.....	Leeds Photo. Society .....	Demonstration: The Carbon Process. R. Stockdale, M.A.
22.....	Royal Photographic Society .....	Hydroquinone and Colour Impressions. Alfred Watkins.
23.....	Croydon Camera Club .....	Demonstration: A New Make of Collodion-chloride Print-out Paper. C. Woodhead.
23.....	Photographic Club .....	Control in Photographic Printing. G. J. T. Walford.
24.....	Ashton-under-Lyne.....	Meeting to Examine and Discuss the Results of Ramble to Hattersley.
24.....	London and Provincial .....	Open Night.
25.....	Croydon Microscopical .....	Photographic Chat.
26.....	Ashton-under-Lyne.....	Excursion: Delamere Forest. Leader, H. Rausch.
26.....	Borough Polytechnic .....	Excursion: Crohamhurst. Leader, E. G. Hawgood.
26.....	Liverpool Amateur .....	Excursion: Eastham. Leader, E. Simnett.
26.....	South London .....	Excursion: Claygate and Oxshott. Leader, S. Whiteman.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 10.—Mr. J. S. Teape in the chair.  
 Mr. WALTER D. WELFORD showed some negatives reproduced in carbon on celluloid films, and pointed out a crowd of blotches which covered the whole of the negatives. There was considerable discussion as to whether they were the result of faulty tissue, deterioration of good tissue, or blisters, which, drying down, had taken a double edge.  
 Mr. T. E. FRESHWATER projected on the screen some of his experiments in colour photography by the Joly process. The chief difficulty that he had encountered was in registering the viewing screen with the positive transparency. An interesting slide shown by him was one of a piece of gold quartz tinted in the colours of the original. Finally he exhibited some lantern pictures of the Paris Exhibition, showing the various styles of the buildings of the different countries taking part in the show, and many general views particularly interesting at the present time. The slides, he explained, were albumen slides.  
 Mr. J. W. HODGES contributed some slides of Winchester, Bournemouth, Christchurch, &c., including one of the Great Globe at Swanage, standing sixteen feet high.  
 Mr. H. C. RAPSON showed a collection of miscellaneous slides by the carbon process in red chalk.

### PHOTOGRAPHIC CLUB.

MAY 9.—Mr. Hans Müller in the chair.  
 Mr. E. A. NEWELL showed one of the Continental picture post cards now so commonly used, in order to ascertain by what process the view and decoration was produced. Some interesting facts concerning these cards were elicited in the discussion which took place. It appears that in some districts people make a practice of selling these cards in the summer months to the tourists, who have acquired a habit of addressing from every place they visit postal mementoes in this form to their friends. On the Continent so greatly has the custom grown, that the sale of the unstamped cards, at prices ranging upwards from a penny, is sufficiently lucrative to go a long way

towards the keep of the vendors in the winter months, when little business of the sort is done. The wholesale prices are from fifteen to seventeen shillings a thousand upwards.

The CHAIRMAN related a tale, from which it appeared that, as the result of a wager made by some officers in Baden-Baden, 120 differently illustrated post cards of the immediate vicinity were collected in fifteen minutes, showing the popularity of the custom.

Mr. NEWELL, referring to the process of copper toning recently brought forward by Mr. W. Bates Ferguson, spoke of it as most fascinating and easy to work. Very inferior bromides were greatly improved by its treatment, and the range of colour was considerable. During the first minute a light sepia tone would prevail, extending gradually to the reds in the space of three or four minutes. He noticed that the colour went right through in some cases to the back of the print. He did not look on the process as one suited to landscape work, but for some classes of photograph the colours were very appropriate.

Speaking of colour in prints brought up the question of colour in negatives and their estimation in printing.

Mr. MACKIE said that some ortol negatives were very similar to pyro negatives. He did not consider that in the long run ortol was any more expensive than pyro.

Mr. F. A. BRIDGE considered that the task of estimating the printing value of a brown negative when accustomed to blue-back, was as difficult as when dealing with a brown-tinted background after long being accustomed to grey or neutral tints. The question of colour in these matters was a very deceptive one, and wanted a lot of experience.

### Croydon Camera Club.—May 9.

#### THE HAND CAMERA IN 1900.

This was the subject which engaged members of the above Club. It took the form of a series of descriptions of various patterns, mainly new, of hand cameras, together with the exhibition of a considerable number, and much discussion on the efficiency of various expedients for obtaining splendid snapshots. The PRESIDENT, somewhat paradoxically, stated that, in order to obtain an excellent result with a hand camera, the desiderata were small stops, slow plates, slow shutters, but a fast light; but, as a rule, at least two out of the four factors were usually perforce sacrificed, hence most snap-shots had to be considered as compromises; and, because small stops were not usually possible for this class of work, it became necessary to employ a lens possessing brilliant definition to the edge of the plate. But he warned his hearers that not even the most expensive of anastigmats would produce a negative showing depth of focus unless stopped down. Amongst the many hand cameras described, Mr. BEN E. EDWARDS brought forward a magazine box camera, which seemed to possess capital features, including that saving virtue of a reliable changing mechanism. It was said to be possible to expose and change twelve plates in thirty seconds. The above, known as the Cyko, costs but 35s. Mr. DUNMORE gave an exhaustive description of the Tella hand camera, which surely must include all that is best in a hand camera if one may believe this enthusiastic advocate. Any how, his hearers envied him the facilities which the camera lately offered him of taking 500 negatives in five days. The No. 1A Pocket Kodak was shown and explained by the PRESIDENT, and elicited favourable opinions, but more interest was shown in the remarkable little Brownie hand camera, which, made by Kodak, Limited, will take an excellent snap-shot two and a quarter inches square upon a daylight cartridge, and yet lens, instantaneous shutter, film-winder, and all cost but 5s. Pictures taken with it were handed round, which were a good deal better than most of the photographs as printed in our weekly newspapers. A big step was taken in passing from the Brownie camera to the Goerz-Anschütz camera, which is an instrument not only made in the most perfect fashion, but fitted with a lens which alone costs a matter of 6/. A handsome album of reproductions from negatives taken by the above spoke most eloquently for the splendid efficacy of lens and shutter. The latter, by the way, is of the focal-plane type. The camera, which may be carried in the pocket and brought into use at a moment's notice, was considered the best pattern shown for high-class work, requiring extreme shortness of exposure and sharpness of definition. Another Goerz hand camera shown by the President, which provoked deserved admiration, was the Photostereo Binocular, which, usable as a first-class field glass, is transformable in "half a mo'" into either an opera glass, a stereoscopic camera, or an ordinary hand camera. The whole concern is carried in a sling case, and is in appearance and size almost identical with any ordinary race glass.

Aintree Photographic Society.—At the meeting of this Society last week, one of the Vice-Presidents (Mr. WILLIAM LOCKIER) gave a demonstration intended more especially for beginners, still one which was also very interesting to those who have had some experience. He had an assortment of cameras, and explained the whole of the working parts, in fact, demonstrated in a brief way the making of a negative and on to the finished print, pointing out how necessary it was for a beginner to know something about stand-camera work before undertaking the more difficult hand camera. The Ilford Company kindly sent a number of their *Every-day Book*, which so clearly shows what dangers await the unwary photographer, and explains how to avoid them. Messrs. Elliott & Son also sent some of their bi-monthly journals for distribution.

### FORTHCOMING EXHIBITIONS.

1900.  
 May 23-25 ..... Plymouth Photographic Society. Hon. Secretary, W. H. Harris, 5, Clarendon-place, The Hoe, Plymouth.

July 9-14 ..... Photographic Convention of the United Kingdom (Newcastle-on-Tyne Meeting). Hon. Secretary and Treasurer, F. A. Bridge, East Lodge, Dalston-lane, London, N.E.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### GAUGES.

To the EDITORS.

GENTLEMEN,—It is surely to be greatly regretted that the British Committee of the Paris Photographic Congress should seek to oppose the efforts being made to establish a thorough understanding on the important matter of gauge of photographic plates.

Year by year photographic apparatus is becoming more elaborate as ingenious ideas are evolved, and the usefulness of these ideas depends largely upon the accuracy of the workmanship in making, finishing, and fitting the relative parts, so that, if the proposed resolutions of the plate-makers were to gain general approval, which I think highly improbable, a very serious discouragement would be offered to British inventors and apparatus-makers at a time when every reasonable effort should be made to free them from the trammels of obsolete ideas. Is not gauge the very keystone of American manufacture? Has not the foreigner come over to us with his magnificent *uniformity* in high-class goods? Contrary to the proposed resolutions, I hold: (1) That it is quite a mistake to cut plates less than the nominal size; (2)  $4\frac{1}{4} \times 3\frac{1}{4}$  should not mean  $4\frac{3}{16} \times 3\frac{3}{16}$  inches—there should be no difficulty in reducing the limit of error to one per cent.; (3) That a proper limit of thickness should be fixed, and prices adjusted accordingly; (4) That the custom and experience of the trade in the above matters have not been amply sufficient to satisfy all requirements.—I am, yours, &c.,  
WM. HUME.

1 Lothian-street, Edinburgh, May 12, 1900.

### THE JOLY PROCESS—A CORRECTION.

To the EDITORS.

GENTLEMEN,—I should esteem it a favour if you would make a correction with regard to my name, which appeared in your issue of May 4 as C. B. "Howdice," under the heading of "The Joly Process Practically Applied," it should have been C. B. Howdill; in every other particular the report was correct.

I expected your attention being drawn to the error or misprint by the reporter, hence my not writing last week.

I should be pleased to correspond with any amateur who is working the "Joly" process, as, up to now, I have not come across any one with whom to compare notes.—I am, yours, &c.,  
CHARLES B. HOWDILL.

24, Albion-street, Leeds, May 14, 1900.

[We insert the correction with pleasure; will those of our readers working the Joly process take cognisance of the last paragraph in Mr. Howdill's letter?—EDS.]

### THE STEINHEIL LENSES.

To the EDITORS.

GENTLEMEN,—In your issue of April 27 you inserted a note to the effect that Mr. Arthur Rayment was English agent for Messrs. Steinheil's famous lenses. We wish to point out that our firm have the sole British licence for these lenses.

The arrangement with Mr. Rayment was due to a misunderstanding. We beg to say, on Dr. Steinheil's authority, that it will be immediately cancelled.—We are, yours, &c.,  
R. & J. BECK.

68, Cornhill, London, E.C., May 14, 1900.

[We understand that Mr. Rayment received his agency from the Paris house of Messrs. Steinheil. Both parties, no doubt, acted in perfect good faith in the matter.—EDS.]

### COPYRIGHT.

To the EDITORS.

GENTLEMEN,—In your JOURNAL of May 11 I observe an article by "Free Lance," in which the writer states as follows:—

"It is very satisfactory to know that the odious Copyright Bill has no chance of being passed this session. It is to be hoped that sufficient organized opposition may be brought into play against its next appearance that shall succeed in getting it rejected. Photographers should combine, and, above all, interview the local M.P.'s on the subject. So far as I can see, the effect of any effort of the Copyright Union has been absolutely nil."

It is very funny that "Free Lance," who writes about copyright matters, should be so ignorant of the present position of affairs. The "odious Copyright Bill, which, he says, "has no chance of being passed this session" is really defunct, and is replaced by another draft of the Bill, which has been read the second time in the House of Lords this session, and is now before a Committee of the House of Lords. This redrafted Bill is, in my opinion, eminently satisfactory. Photography is placed in the same class and enjoys the same rights as any other artistic work. The very production of a photograph secures a copyright; there is no registration required, and the duration of copyright is for the lifetime of the photographer and for thirty years after his death.

"Free Lance" says, "So far as I can see, the effect of any effort of the Copyright Union has been absolutely nil." I am not surprised that he should say so, for, if a man doesn't look, how can he be expected to see? If "Free Lance" would really take the trouble to look up all the facts about the Copyright Bills, I am convinced he will change his opinion, and say the Photographic Copyright Union has achieved a very great success.—I am, yours, &c.,  
FRANK BISHOP.

London Chamber of Commerce, Botolph House, Eastcheap, May 15, 1900.

## Answers to Correspondents.

\* \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street Strand, London, W.C. Inattention to this ensures delay.

\* \* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

J. Yeoman, Bedale, Yorkshire.—Photograph of a group of cricketers.

Hellis & Sons, 211, Regent-street, W.—Photograph of 1st M.R.E. for South Africa.

M. Senior, 6, Church-street, Inverness.—Photograph of Service Co. of Cameron Highlanders Volunteers.

A. Paterson, 32, Church-street, Inverness.—Photograph of Trooper P. H. Smart. Photograph of Trooper D. Smart.

J. B. Scott, 18, Devonshire-street, Carlisle.—Photograph of group of H.R.H. Princess Victoria of Wales, Sir Richard and Lady Musgrave, Mr. Tom Musgrave and Master Courtney Musgrave. Photograph of H.K.H. Princess Victoria of Wales.

NELL.—1. The Photographic Copyright Union (Hon. Secretary, Henry Gower), London Chamber of Commerce, Botolph House, Eastcheap, E.C.  
2. Yes.

WATER.—We had the water tried for washing gelatine negatives and prints, and the report we received was that it appeared to have "no harmful effect on the films."

COPYRIGHT.—A. Z. The copyright is undoubtedly yours; but, as you have not registered it, you can take no proceedings. If you register it, you may be able to prevent the further sale of the piracies.

AJAX.—The negative should be left in the solution until it assumes a deep brown colour, but all depends upon the extent to which it is required to intensify. The solution will keep well in a weak light.

DRYING ENAMEL QUICKLY.—R. HOLDEN asks the method of drying enamel quickly.—There is no better way than to place them where there is a dry and slightly warm atmosphere. Heat should not, of course, be used.

W. H. C.—Our recollection of the camera (which we do not think is now on the market) is that it was a good and practicable one. Probably you will not be far wrong in purchasing at the price named, but we cannot give a more definite opinion without seeing the actual instrument.

A. G. B.—We imagine that the application of your theory would only hold good in the case of both sides of the film—which are not of equal sensitiveness—being subjected to the action of light, and admitting of reduction by development; but this would not be the case in actual practice.

**ORTHOCHROMATISING PLATES.**—C. WARMAN writes: "Is there any method known of converting ordinary plates into isochromatic ones, as I often require one or two, and I do not want to buy a dozen every time?"—Yes. Formulae for doing it will be found on pages 1083-4 of the ALMANAC.

**LESSONS IN X-RAY WORK.**—NERROW writes: "Could you kindly inform me where I can obtain lessons in X-ray photography.—In reply: We know of no special instructors in radiography, but, possibly, if our correspondent inquires of Isenthal, Potzler & Co., Mortimer-street, Cavendish-square, W., they may be able to meet his requirements.

**HYPHO-ELIMINATOR.**—HYPO writes thus: "Will you please tell me which is the best hypo-eliminator to use, as I have read of several, and I want to use the one that is *really* the best?"—The best hypo eliminator is water, pure and simple. If the negatives are thoroughly fixed in the first instance, the hypo is readily got rid of by the use of plenty of running water.

**VARNISHING GLASS POSITIVE.**—J. COLEMAN. If the glass positive has been made so many years, it will be somewhat risky to varnish it with a spirit varnish. Sometimes, in these old pictures, the collodion film has become altered in character, and quite soluble in strong spirit. If the picture is varnished at all, it should be done with a varnish in which benzole is the solvent.

**F. L.**—We are in doubt as to whether we can be of any assistance in such a case; but (1) we should think there would be no restriction as to the use of the symbol; (2) probably, if you sought to protect it as a trade mark; (3) we should think not if not so used, but your better plan will be to consult a trades-mark registration agent, as we are not quite sure of our ground in this matter.

**RESTORING SPOILT ENGRAVINGS.**—ENGRAVER writes: "A client of mine has brought me an engraving very much spotted with yellow damp spots, and wishes to know if it is possible to get rid of them. I shall be glad of the address of a firm (if there is such a one) that would restore the engraving."—In reply: We know of no such firm, but perhaps some reader will help our correspondent.

**DISCOLOURED PYRO SOLUTION.**—S. R. says: "I have made up two lots of ten per cent. solution of pyro with the usual quantity of sulphite, and both are of quite a sherry colour. What I have made before has been almost colourless. What is the cause?"—Probably the sulphite was not a good sample—been badly kept. Try the solution; it may possibly work all right at present.

**BLACKENING THE EDGES OF LENSES.**—T. BOWERS writes: "I have read several times that the edges of lenses should be blackened. I have an old portrait lens of rather a large size, the edges of which do not seem to ever have been blackened. Will you please tell me the best medium to use for the purpose?"—Nothing is better than the ordinary dead black varnish sold for photographic purposes.

**PYROXYLINE.**—N. JOSEPHS says: "I made some pyroxyline, or rather tried to do so—according to Hardwich's formula, but, after the cotton had been in the acid for a few minutes, it all dissolved. Can you kindly tell why it did so?"—Evidently the acids were not the full strength given in the formula, or too much water was added. Or it may be that the cotton was not thoroughly dry at the time of its immersion.

**THE CHADWICK STEREOSCOPE.**—WILLIAM DREW writes: "Will you please inform me where I can purchase the Chadwick stereoscope, or similar instrument, as recommended in the ALMANAC, also the best instrument for viewing transparent stereoscopic slides?"—In reply: The stereoscope referred to is the invention of Mr. W. I. Chadwick, 26, King-street, Manchester. It is adapted for viewing transparencies as well as slides.

**COPYRIGHT.**—IBEX writes: "Do you mind telling me how I stand with regard to the risk of copyright under the following circumstances? A customer sends me a photo to enlarge or copy. He paid for it in the ordinary way of business, but I see the mount has upon it the word "Copyright." Under what circumstances may I or may I not copy a photograph?"—In reply: If the photograph is registered at Stationers' Hall you run the risk of an action for infringement. In such cases an indemnity should be obtained from the customer, though it is seldom, if ever, done. Still, the law of the matter is as we have stated.

**STUDENT.**—Your best plan, perhaps, will be to address Dr. J. M. Eder, the Technical High School, Vienna, who will acquaint you with the terms for the photographic courses at that institution. Some years ago Mr. Leon Warnerke read at the Royal Photographic Society a paper descriptive of the establishments at Vienna, Berlin, Brussels, &c., at which photography can be studied. If you call at 66, Russell-square, W.C., you may be able to consult that paper in the library. As to the cost of living we can give no idea; but we believe a knowledge of English and French would carry you through so far as languages go in almost any part of the Continent.

**MOISTURE ON LENS.**—GEO. BETTS says: "The other day I had to photograph the interiors of three greenhouses, and on coming to focus—a wide-angle lens—I found I could hardly see the image. On examining the lens I found it covered with moisture. When I had wiped it off, I found that it came again, and also between the lenses. Finally I got the negatives, but they were anything but brilliant ones. Is there anything that I can put upon the lens to prevent the moisture in greenhouses from condensing on the glass?"—The condensation may be prevented from gathering upon the lens by simply making it slightly warmer than the atmosphere of the building—say by standing it close to the hot-water pipes for some time before it is used; then no condensation will take place.

**IRON IN WATER.**—T. SAUNDERS. If the water, after being drawn from the tap and allowed to stand for a few hours, deposits a yellowish-red precipitate, it looks as if it contains particles of iron in suspension. If that be the case, the spots on the prints are fully accounted for. The only way to avoid them is to filter the water. A flannel bag, filled with cotton wool, tied over the tap, will, to an extent, mitigate the evil. Probably the pipes, if of iron, are rusty on the inside.

**RIGHT TO PHOTOGRAPH.**—R. C. A. asks: "Can a rector legally prevent me from taking a photograph of the church? The other day I was about to do so, and the parson came out of the rectory and told me he would not allow it, although I was going to take the picture from the road—a highway. He told me he had given the sole right to photograph the church to a local man, who allowed a percentage of the profits to the schools."—The Rector cannot prevent you from photographing the church from the highway, and you were foolish to pay any heed to his "bluff," which was unworthy of a clergyman.

**COMBINED TONING AND FIXING.**—C. BEST writes: "Will you kindly give me your opinion on this point? Are prints toned in the usual combined bath, containing alum and lead, as permanent as those toned in the sulphocyanide bath and fixed afterwards? I find that the former is far less trouble and more economical, as it takes a great deal less gold, and that is an item in toning a number of prints."—We should certainly say no, unless it is ensured that the tones are obtained by gold, and gold only, and not by sulphur. As our correspondent says that a deal less gold is required for the combined bath, it seems that, in his case, sulphur is a prominent factor in his toning.

**JAMES MCCONNAN.**—1. In *Platinotype*, by Sir W. de W. Abney and Mr. Lyonel Clarke, published by Sampson Low & Co., Fetter-lane, a special chapter is devoted to the subject. Mr. Clarke strongly recommends a matt paper and the following bath:—

STOCK SOLUTION.

Chloro-platinite of potassium..... 60 grains.

Distilled water up to ..... 2 fluid ounces.

Toning bath: 1 drachm of stock solution, made up to water with 2 fluid ounces, to which is added 2 or 3 drops of nitric acid. 2. An uncommon occurrence nowadays. Alum would act as a preventive, but probably the temperature of your developing bath was too high. 3. Inquire of Messrs. A. & M. Zimmermann, St. Mary-at-Hill, E.C.

**LANDLORD AND TENANT.**—L. M. writes: "I am in a bit of a fix with a studio I rent here. It is a quarterly house, and it has been in such a disgraceful state that we cannot live there, and the studio itself is a ruin, being a puddle half the time. Several of my backgrounds and other things have been spoilt. Matters were so bad that I gave notice in March to leave in June, and now the landlord says I must stop till next March, being the same month that I entered the premises. Will you tell me if I really am liable, considering what a disgraceful wreck the place is? I may say that a builder was brought to see what he could do to the studio, but he refused to touch it, saying it could not be repaired."—In reply: Yes; as we understand the law of landlord and tenant, you are liable for the rent till next March. But an almost similar case came under our own observation recently, and legal advice was given to threaten an action for damage caused by the ingress of rain. It had the effect of causing the premises to be repaired.

**SPOTS ON PRINTS.**—SPOTS writes: "Can you tell me the cause of these spots, they have been a great nuisance to me for some little time, and I have tried to trace them, but do not feel satisfied? I always use same strength bath—1 drachm sulphocyanide, 16 ounces of water—and am as clean in working as one can possibly be. I sometimes mount at night, and one cannot possibly see these spots at night. I wrote the manufacturers but they could only tell me what I know already, that was, that there must be some foreign matter somewhere. I think myself that they are caused by the water, or else I use my alum bath too much. I should be much obliged if you could possibly help me, I see so much of what you do for others in your JOURNAL that I have felt encouraged to trespass on your kindness."—The cause of the spots is that indicated by the manufacturers, namely, foreign matter; but where it comes from it is impossible for us to say. It may be from the water, or it may be from other sources, such as dust, &c. If you suspect the alum, why not omit its use with a few batches of prints, and see the result? We should not think, however, that these spots are due to the alum, but there is no reason why it should not be omitted by way of experiment.

**COPYRIGHT.**—ALBION writes: "We have in our town two printers' stationers, &c., who are issuing post cards with views of the town printed on them. These views are printed from blocks made from our photographs, without our permission or ever mentioning the matter to us at all. Is this legal, and can we stop them from using these photographs, being from our original prints, or can we take legal proceedings of any kind? These pictures were not copyright or registered; they were bought for sale as either ordinary photographs or opalines, not to be reproduced. Some time ago we gave, for the benefit of an institute, some pictures to be reproduced as decorative pictures for an illustrated programme, to be used for no other purpose. We have an idea these blocks are being utilised for this post-card business; if so, is this legal? Can they stand by reproducing prints from our negatives at all without permission? If not, what can we claim as damages?"—In reply: If our correspondents took the original photographs, the copyright is theirs, and proceedings can be taken provided that registration has been effected at Stationers' Hall. The Copyright Act is printed in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1900. We would suggest that our correspondents should consult a solicitor; it is not clear, according to the terms of their letter, if they really have copyright in the photographs.

## EX CATHEDRÁ.

IN a sympathetic article on "Science for the Love of It," our contemporary, the *Scientific American*, makes the timely remark that it is because the work of the pure scientist is so self-sacrificing and unselfish that he commands our special regard. "With but little prospect of material advancement, he is content to labour long years for the sheer joy of adding something to the sum total of human knowledge. Not to mention that most conspicuous example of disinterested scientific research, Faraday, what adequate pecuniary reward has Tyndall derived from the arduous research that culminated in his brilliant theory that heat is a mode of motion? What personal advantage has accrued to Crookes and Lockyer in their endeavour to prove that the seventy odd elements known to chemists are but the modifications of one matter, even as our various forms of energy are but the manifestations of a single force? What commensurate reward have Darwin and Spencer received for their investigations in the theories of natural selection and evolution, or Röntgen for the discovery of the rays that should rightly bear his name?" Science very

rarely wins many of the material prizes of life; like virtue, it is its own reward. In our own branch of science, that which concerns itself with photography, there are many earnest workers who are, and have to be, content with contemporary acknowledgment and recognition as the sole return for their labours. And it will be an ill day for human progress when men of this kind will no longer be found amongst those whose principal aim in life is to add to the sum of our knowledge.

\* \* \*

PROFESSOR FLINDERS PETRIE'S paper on "A National Repository for Science and Art," which was read at the Society of Arts on May 16, contained the very valuable suggestion that the nation's artistic and scientific treasures should be arranged in a plain and specially erected building to be located on suitable ground twenty miles or so out of London. In brief, the Professor would shut up the costly and inadequate museums in South Kensington and Bloomsbury, and would make his rurally situated range of cheaply constructed galleries the nucleus of a unique village to be called Sloane, which would become the Mecca of those seekers after knowledge whose pilgrim instincts would survive the expense and worry of a twenty-five mile journey on the London and South-Western Railway. It is plain to all that the National Museum accommodation is becoming, year by year, painfully taxed, and that in time to come the adoption of some such plan as that advocated by Professor Flinders Petrie will be lifted out of the region of mere plety of opinion and become an absolute necessity.

\* \* \*

ONE of the subjects dealt with by the Professor in his very thoughtful and reasonable paper related to the registration of the objects in a museum. By the present system, he remarked, the solemnity of registering every object, with drawings and full description, is said to need a costly staff. But, as he pointed out, we have learned to register the stars by the thousand photographically instead of registering each separately, and so, in his opinion, we must do for the contents of our store-house. A photographic register of groups could be done by cheap artisan labour, and very rapidly kept up. The use of photography for this purpose is a capital suggestion, no doubt, though we are unconvinced that "cheap artisan labour"

would be found satisfactory from a technical point of view. Museum photography demands a very high degree of skill indeed, as the distinguished Professor's experiences long ago very likely taught him. In a later reference to the subject, Professor Petrie also stipulates that the objects, and all information about them as to source, donor, &c., should be photographed on a fixed scale, in a special camera house, at the time they arrive. The cost of plates and labour to photograph double the annual exhibiting area would be under 50% a year. This estimate strikes us as exceedingly low; at a venture we should hardly think that the photography of one year's additions to the London museums could be done for so small a sum as 50%; however, these are minor points. What we are pleased to observe is that the Professor, in the scheme for his museum at Sloane, recognises that photography is capable of playing a valuable part. To repeat the concluding words of one of the most interesting papers recently read at the Society of Arts, "May we all meet twenty years hence at Sloane."

\* \* \*

*Mr. Punch*, during the fifty-nine years of his merry existence, has poked fun many times at photographers and photography, but never in an unkind manner. In the last few years the gaiety of the nation has been added to by the issue of cheap reprints of the first fifty years' volumes of our contemporary, while Mr. Spielmann has written the great jester's history, and Mr. Holt Schooling, in the pages of the *Strand Magazine*, has given us a selection of *Punch* pictures, with explanatory notes, extending over a period of half a century. Now come the publishers, Messrs. Bradbury, Agnew, & Co., Ltd., of 10, Bouverie-street, E.C., who send us a volume of 200 pages, entitled *An Evening with "Punch,"* made up of random selections in prose, verse, and illustrations. The book is dedicated to the unfortunate man, woman, or child in whose home there is not a set of the *Punch* volumes. *Mr. Punch* is a national institution of which it is difficult to write too favourably, and we are happy to be the means of informing our circle of readers that this *Evening* with such a delightful companion may be had for the modest sum of two shillings and sixpence. It is a book which gives us a taste of the best English wit, humour, and pathos of fifty years.

\* \* \*

WE have received from the well-known photographers, Messrs. John Patrick & Sons, of 52, Comiston-road, Edinburgh, a supplementary catalogue of their local views, about ninety of which are devoted to Edinburgh itself, while there are series illustrating the land of Burns, the Trossachs, and celebrated golfing links. Another series comprehends the homes and halting-places of the Carlyles, and yet another illustrates the early homes and haunts of the late Robert Louis Stevenson. The last-named author at the present time stands high in popular esteem, and there is apparently no limit to the enthusiasm of his admirers in collecting reminders which bear upon his short and busy life. Messrs. Patrick's Stevenson photographs are the outcome of great skill and assiduity, and they include a portrait of the deceased writer. The Carlyle series is also complete and interesting. This mention of Messrs. Patrick's catalogue may be useful to many readers who may desire to know the source from which photographic memorials of two great Scottish literary men may be obtained.

THE fourth of the series of One-man Exhibitions in the rooms of the Royal Photographic Society, 66, Russell-square, W.C., will be opened at eight o'clock on Tuesday evening next, May 29, by Dr. P. H. Emerson, who will deliver an address. About 140 photographs will be shown, and they have been specially framed for the purpose. Presumably this Exhibition, which remains open till the end of June, will complete the series until next autumn, when, no doubt, the One-man Exhibitions will be continued. They have been very popular features at Russell-square this spring. Previous contributors were Mr. Craig Annan, Sir J. Benjamin Stone and the National Photographic Record Association, and Mr. F. H. Evans, whose Exhibition closes this week. Admission to these exhibitions is free, a card being easily obtainable from the officials of the Society or a member.

\* \* \*

WE are indebted to an American contemporary for the report of a case which is interesting from the fact that the United States Judges sustained a photographer's contention that, when negatives are injured or destroyed by carriers and though the negatives were neither good nor valuable, damages may be recoverable. It appears that the plaintiff, who was a passenger upon the steamship *Alleghany*, of the Atlas Steamship Company, plying between South America, the West Indies, and the port of New York, took on board a box of photographic negatives and views in the harbour of Port Limon, and gave them in charge of one of the cabin stewards. The box was an old brandy case, which the plaintiff had utilised as a receptacle for his negatives. He had also with the box of negatives three demijohns of mineral water. When the vessel arrived, neither the box nor the demijohns could be found, and the Lieutenant left the wharf without them. The next day he learned that the demijohns had been found, but not the box. He went several times to the wharf during the following three weeks, and was always told that the box was missing. It was found, however, in a locker in the forepeak of the ship some months after Mr. William E. Wamsley, as assignee, began suit for its loss. Four or five boxes of signals had been moved to the locker. They were old cases, similar in shape to the box of negatives. The chief officer, who had directed them to be put there, ordered one of the boxes of signals to be brought up to him on the bridge. On being opened, this box turned out to be the one containing Lieutenant Massey's negatives. A dismissal of the complaint on the first trial was reversed by the Appellate Division upon the ground that sufficient had been shown to require submission to the jury of the question whether the Company had converted the box of photographs, or whether its excuse for not delivering it upon Lieutenant Massey's demand was a sufficient one. A judgment for the plaintiff on the second trial for a substantial sum as damages was lately affirmed by the Appellate Division of the New York Supreme Court, in an opinion by Justice Rumsey. The Court held that, though these articles had no market value, the plaintiff was entitled to recover as damages for their conversion their actual value to him. Though the fact that the negatives were not good ones was to be considered, the jury might also consider that, "when one has gone a long way to obtain photographs of the scenery of a foreign land which is difficult to reach, or where the photograph is of some incident which is not likely to be repeated, even a poor representation may be of considerable value if a picture can be printed from it, because, as far as it goes, it is a correct-

presentation of what occurred." Given a set of similar circumstances in this country, we doubt whether a photographer could recover damages for what were virtually admitted to be indifferent negatives, especially in view of the fact that the plaintiff obviously treated them as such!

### IMPURE PHOTOGRAPHIC MOUNTS.

IN the article in our issue of a fortnight ago, a correspondent asks the following question, "Why does not some enterprising firm put upon the market mounts that are guaranteed to be pure, and such as will have no evil effect on the pictures mounted upon them?" There may be several answers to this question. One is, that mounts put upon the market with such a guarantee would necessarily be much higher in price than the usual commercial articles, and the question naturally arises as to whether amateurs, and we may include many professionals, would pay the necessarily enhanced price for that guarantee? We venture to say that we doubt if any firm who put such mounts upon the market would find the idea a commercial success. We, a few years ago, consulted one of the oldest and most renowned firms of card-board makers in this country on this very subject, and this, in substance, was the reply: We used to make a speciality of photographic mounts that could be depended upon, but foreign houses came into the market with showy goods at much lower prices, so we let this branch of the business drop. We still make the boards, and cut them up to photographic sizes, but we do not catalogue them as "photographic mounts."

Now, the question arises, Do amateurs as a rule, and some professionals, really care "two straws" about the permanence of their pictures? We are induced to put this query from the number of letters we are continually receiving from correspondents, sending stained and fading prints, asking if the mounts are the cause of the deterioration. One would almost have thought, after all the simple methods of testing the suitability of mounts for photographic purposes which have appeared in the JOURNAL during the past few years, that all photographers who take any interest in the stability of their work would have tested their mounts before taking them into use, because the trouble is so trifling. That being the case, it is very doubtful if they would pay an increased price to secure mounts that would be guaranteed inert on silver prints mounted upon them.

There is another point in connexion with this matter that may weigh with mount-makers. It is this: A mount may be perfectly pure, and yet a silver print mounted upon it will fade, though that may not be due in any way to the mount, but to the imperfect fixation and washing of the picture. This, of course, might lead to litigation between the manufacturer and the purchasers, with the usual *pro* and *con* evidence of experts and the expenses following. With these facts before us, it is not to be surprised at that no enterprising manufacturers do put upon the market photographic mounts of guaranteed purity. However, the photographer who values his reputation can, if he will take the trouble, easily test his mounts and thus prove their quality before using them.

In connexion with the above-mentioned article, and the methods for testing the purity of photographic mounts, a correspondent calls our attention to the fact that, if many of the chocolate and other coloured mounts were submitted to Mr. Foxlee's test, they would show a discolouration in a day or so.

That is quite true. But it is simply a colour stain on the prints, and it need not in any way impair the *stability* of the photograph itself. When Mr. Foxlee described his method of testing photographic mounts before the Photographic Club some years ago, we remember that he showed some examples in which the coloured mounts had stained the picture within a few hours, yet, after the lapse of some weeks, the image remained intact. This could be seen by viewing the picture by transmitted light, though it was almost obliterated by the stain when seen by reflected light. The colouring matter on a surfaced mount, though it may stain the paper, may be quite inert on the permanence of the silver image itself. Sometimes this colour is so soluble that, if the picture is made very wet in the mounting, it will come through the paper and produce a stain on its surface, which is seen at once. The method is to detect latent causes of the deterioration of silver prints by the use of unsuitable mounts.

**A new Storage Battery.**—That the capabilities of electricity are not sufficiently realised in photographic practice is in all probability due to one of two causes: either the initial outlay for a complete electric installation is not justified by business expectations, or the experience with accumulators is unsatisfactory. There are, however, numerous minor uses for electricity, if a ready means of generating it were available. Every one is familiar with the electric bell, which an average schoolboy could erect at an expenditure of less than a sovereign; but when it becomes a question of dark-room lights, fixed or portable, difficulties arise. An accumulator is beautifully simple in theory: you have your battery, make your connexions, turn on the tap as it were, and the light appears. There is, however, an unfortunate "but." An accumulator quickly spoils if not kept regularly charged, the plates buckle, the battery short-circuits, and expense is quickly entailed. There are, it is true, several dry batteries in the market, that are capable of regeneration when exhausted by passing the current the reverse way through them, and there are many small portable accumulators, capable of working for from five to twenty-five hours, but they have not had much vogue amongst photographers. We note, however, in the *Scientific American* particulars of a new form of accumulator, which if the claims made for it should prove to be just, should make the use of electricity a very simple thing in any studio. It is claimed for this battery (made by the United States Battery Co.) that it can be kept in stock by dealers fully charged, and that it will not deteriorate by keeping. It is by no means heavy, the positive element in a five-ampère hour cell weighing only six ounces, while the whole battery of positive and negative elements charged with the suitable liquid only weighs seventeen ounces. It is further stated that it can be recharged by passing the current through it in a shorter time than with most others. Finally, it is stated to have a discharge of 2.65 volts, a record power.

**Solar Eclipse Duration.**—The length of time during which a solar eclipse remains visible depends upon a variety of conditions, which *Nature* last week tabulates on the authority of Mr. C. Whitmell (President of the Leeds Astronomical Society). Five conditions are given under which the duration is extended, but two of them cannot be fulfilled, the most important being that the observations be made from a station on the equator, the linear velocity of the observer then being greatest, besides having the sun in the zenith, and so giving an umbra as large as possible. *Nature* states that Mr. Whitmell gives, on the authority of Mr. Crommelin, who calculated them from Oppolzer's data, six long-duration eclipses during the next century, the longest being "7 hours 24.5 minutes." This is, no doubt, a misprint for minutes and seconds. Over the signature of Charles P. Butler will be found, in the same number of that periodical, a detailed account of the expeditions that are being sent out by various observatories, and the work they have arranged to carry

on. We note that the kinematograph to be worked by Mr. and Mrs. Maskelyne will be provided with a tele-photographic lens. Professor Cambell, from the Lick Observatory, will use an instrument of forty feet focus, and thus obtain a direct image of the sun four inches in diameter. Amongst other novelties, a kite will be sent up by Mr. Bacon to observe the temperature, and compare it with that at the ground level. A tele-photo arrangement will be used by Mr. Dyson at Ovar, the positive lens being the nine-inch refractor of the Thompson photo-heliograph at Greenwich. At Tripoli a most ingenious system of electrical exposures is to be worked by Mr. Percevell Lowell, of Arizona, and Professor Todd, of Amhurst College Observatory, U.S.A. A great number of photographic cameras will be automatically exposed for varying times, all of them being operated from one revolving drum with delicately fitted electrical contacts.

**Photography and Art.**—Photography has done much in instructing painters in many ways. It has given them many hints with regard to the movements of animals, and enabled them to depict them according to their correct attitudes while in motion; also with regard to the human figure divine. There is, however, a type of "artists" to which it has not yet appealed: we allude to those who draw for the fashion papers. They still seem to ignore alike anatomy and drawing, as they have done for generations past. If one takes up a fashion plate, one cannot but feel amused at the grotesque drawing of the figures—all angles, and the proportions ridiculous. A member of our household recently called our attention to an illustration in a weekly paper that has a column devoted to the latest fashions which bears out our remarks. It was supposed to depict a female figure clothed in a tight-fitting costume, but how the arms could possibly have got into the sleeves of the dress, unless it was sewn upon them, it is difficult to conceive, and, if that were done, it is a mystery how they could possibly be bent without bursting the fabric. The figure was posed full front, with the usual "artistic" angles of the lay figure, and the most noticeable feature in the drawing was that the arm, when measured with a pair of fine compasses, midway between the elbow and the shoulder, was just a trifle larger than the waist. Other proportions, according to the *Venus de Medicis*, were equally ridiculous, if not more so. We have often wondered that the fashion papers do not illustrate them with direct photographs—process blocks are cheap enough—so as to give their readers a fairly correct idea of what is meant. At fashionable costumiers there are usually attendants with good figures, in flesh and blood, upon whom a mantle or other garment can be shown to its best advantage, and why should not similar *life* figures be depicted in the fashion journals? They, one would surmise, would appeal more directly to their readers than the ridiculous lay-figure impossible attitudes and proportions that now appear in them.

**A Photographic Risk.**—Photographers, at times, run great risks in the pursuit of their art, as is well known. Last week a new one cropped up in the Divorce Court of quite a social character. It was this: It was stated in Court that the respondent had taken to amateur photography, and was in the habit of taking a lady into the dark room with him. To this the petitioner objected, and it brought about a serious quarrel. Not much evidence was reported on this point, but it was sufficient for one of the evening papers to head its report, "Dark-room Divorce Suit." We allude to this case simply to point out the trouble that a gentleman may get himself into if he gives instruction in photography to a lady friend and he happens to have a jealous wife. Professional photographers run a similar risk if they give instruction to lady pupils, as they frequently have to do in the course of business, and so do the sellers of photographic apparatus, who give practical instruction in its use. Of course, it is impossible to teach a pupil photography without the instructor and the learner being shut up together in the dark room.

**The Royal Academy and the Tailors.**—Our contemporary, the *Tailor and Cutter*, has paid a visit to the Royal

Academy Exhibition this year again, and, as usual, takes the exhibitors severely to task for not knowing how to do justice to the tailor's art. It complains that the artists do not paint the garments in a proper way, &c. It is to be hoped that the R.A.'s and A.R.A. and other artists will in future profit by the criticisms of our sartorial contemporary, and duly study the dummies to be seen in every clothier's window, so as to learn how the different garments should be represented in a picture. At present they too often represent them as comfortable every-day raiments such as people generally wear, and this does not by any means accord with the ideas of the *Tailor and Cutter*, hence its condemnation. If the artists would only study the aforesaid dummies, they might possibly be able to paint coats, vests, and trousers so as not to entail the censure of "sartorial artists," but we fear that they are obdurate in the matter. Perhaps the advice we have proffered to painters might also be extended to photographers; they, too, often do not arrange the dress in strict accordance with the notions of those who made it.

#### "THE BRITISH JOURNAL OF PHOTOGRAPHY" WAR FUND.

THIS week we have to acknowledge the receipt of a further sum of 51l. 5s. to be handed over to the *Daily Telegraph* War Fund; but though gratifyingly large, by far too great a proportion of the total amount is traceable to one source. We should be very pleased indeed to see the Fund more numerous supported, and, as we said a fortnight ago, will welcome small as well as large amounts. So far the sum contributed range from 50l. down to 4s., and they proceed from representative sources. The *Daily Telegraph* Fund, large as it is, will require to reach to more than double its present amount in order that the claims that have been made upon it may be met; so that the scope for further help in the matter is only too wide. Again we say that the photographic industry and profession has benefited largely by the war, and it is peculiarly appropriate that, as a class, they should do something to help those whose loss has resulted in their gain.

In sending us the very handsome sum of 50l. for the Fund, Mr. J. J. Elliott, of the eminent firm of Elliott & Fry, 55 and 56, Baker-street, W., writes as follows: "I am glad you have started a fund for the benefit of the widows and orphans of soldiers killed in the war, and, as a photographer who has benefited pecuniarily by the war, I have pleasure in forwarding you, enclosed, my cheque for 50l."

Mr. Henry M. Ward, Trade Photographer, of 41, Belgrave-avenue, Leicester, writes: "Herewith I beg to enclose my mite for your excellent War Fund. Judging from my own experience lately, photographers have been well patronised by officers and men 'ordered south,' and should welcome this opportunity of showing what photographers as a body can do."

Mr. T. Stokoe, Photographer, of Clare, Suffolk, writes: "Though I have subscribed to numerous war funds, I should like to have a little share in *our own*, and send P.O. 4s. for that purpose."

The following is the list of subscriptions to date:—

Received last week and acknowledged in the *Daily Telegraph* of Friday, May 18:—

Messrs. J. H. Dallmeyer, Limited.....	£10 10 0
Mr. H. Walter Barnett .....	10 10 0
Proprietors of THE BRITISH JOURNAL OF PHOTOGRAPHY .....	10 10 0
Mr. T. R. Dallmeyer, F.R.A.S. ....	5 5 0
Employe's of Mr. H. Walter Barnett .....	3 0 0
	£39 15 0

Received this week:—

Messrs. Elliott & Fry, 55, Baker-street, W. ....	50 0 0
Mr. Henry M. Ward, Trade Photographer, 41, Belgrave-avenue, Leicester .....	1 1 0
Mr. T. Stokoe, Photographer, Clare, Suffolk .....	4 0
	Total £91 0 0

We thank those gentlemen who have come to our aid this week. An acknowledgment of their contributions appears in the *Daily Telegraph* to-day.

Cheques, postal orders, &c., that are sent to us should be crossed and made payable to "The Editor, BRITISH JOURNAL OF PHOTOGRAPHY."

## MAGNALIUM.

W. G. T. LANDER & SON, the well-known opticians of Brunswick, have just issued a new portrait lens with a working aperture of  $f\cdot2\cdot3$ , which was originally calculated by Professor Zincke (*genannt Sommer*), but which has been altered by Dr. Hans Hartig. Another novel point about this lens is that it is mounted in a new alloy called magnalium, which has been discovered by Dr. Ludwig Mach, consisting of magnesium and aluminium.

The idea of utilising these two metals as an alloy is by no means new, having been suggested, according to Dr. Hartig, in a paper read before the Photographic Society of Vienna, by Wöhler, over forty years ago. His first mixture was in the proportion of the equivalent weights 28 : 12, and was a tin white, extremely brittle mass, which, when heated to redness, burnt with a white flame like magnesium. The second alloy contained eighty per cent. of magnesium and twenty per cent. of aluminium, and was a half-ductile mass which had the peculiar property of falling into thin leaves without the evolution of hydrogen when left in water for a day. In 1870, Parkinson, after a long series of experiments, came to the conclusion that magnesium-aluminium alloys would be of no value in the arts, and Richards, in his work on "Aluminium" (1890), appears to look unfavourably upon such alloys.

According to Mach's experiments, the failure of all these alloys was due to the presence of impurities such as sodium, carbonic acid, and hydrogen, and the presence of these substances produced the ready destruction by water, whilst Mach's magnalium is absolutely stable in air and water. As long as aluminium was prepared by the reduction of its salts by sodium it was not possible to avoid these impurities; but, now that aluminium and magnesium is prepared by electrolysis, absolute purity is possible. Magnalium is a silver white metal, unaffected by air and water, and it can withstand oxygen acids, such as sulphuric acid, to a great extent, but alkalis attack it. Its specific gravity is less than that of aluminium, which is 2·7, whilst that of magnesium is 1·7, so that the alloys range from 2 to 2·2, according to the proportions of the metals. It is therefore about twice as heavy as water. The melting point lies between 600° and 700° C., according to the proportion of magnesium.

As regards the value of the alloy in the arts, this differs enormously, and according to the proportion of magnesium. Pure aluminium, like iron, copper, and silver, is extremely unpleasant to work; on the other hand, brass, steel, or nickel silver work up well and they never "strip" aluminium does, a fact which is known to all who have used lenses mounted in brass and aluminium. The metal which works best is brass, and anything which is to replace it must be as like it as possible, and alloys of aluminium, zinc, and copper have been tried, but their specific gravity is comparatively great, so that they have been but little used.

By the addition of magnesium, aluminium gains considerably in hardness, and the alloy can be rolled in sheets or drawn into wire; 100 parts by weight of aluminium and 10 parts by weight of magnesium give the working qualities of rolled zinc, with 15 parts of magnesium, that of cast brass, with 20 parts that of soft copper, and with 25 parts of hard copper. The actual metal used contains from 10 to 15 parts of magnesium to 100 of aluminium; it works well and is free from tipping or softness, the surfaces are smooth and even, and the small screw threads may be cut with the greatest fineness, and it is so hard that a piece of sheet aluminium can be cut with a magnalium knife.

Although the experiments have not yet been finished, it is believed that by admixture with other metals the alloy may be made to have a greater hardness than cast iron, with a fracture like steel.

A mixture of 100 parts by weight of aluminium and 30 parts of magnesium is very hard, and for working this is the extreme limit. If we add more magnesium, however, it becomes more brittle, but gains considerably in its capability of being polished, till it reaches its maximum in this respect when the metals are mixed in the proportion of their atomic weights, or as 24:27, but the limits between which the alloy will polish well are 2 parts of aluminium and 1 part of magnesium, and 1 part of aluminium and 4 parts of magnesium.

The reflective power is very high, about that of silver, and far above that of other speculum compositions, all of which especially absorb the ultra-violet part of the spectrum, and for which reason glass mirrors are preferred, but even these must be considered inferior to magnalium mirrors, which reflect almost without any absorption. As is well known, all speculum alloys are very heavy, having a specific gravity of from 7 to 8·5, they are, therefore, about three times as heavy as glass, whereas magnalium is lighter than glass; it is also less liable to flexure, and therefore has no ill effect on the image. As regards price, it is, bulk for bulk, the same price as brass in the raw state, but it is rather more costly to work.

## A PHOSPHATE OF SILVER COLLODION PAPER.

In the current number of the *Photographische Correspondenz* Professor Valenta describes his experiments with phosphate of silver, and says that in 1839 Fife\* described a method of preparing a photographic paper with phosphate of silver. He treated paper with solution of phosphate of soda and silvered it after drying in a silver bath, or painted over the paper a solution of silver nitrate in ammonia or ammonium carbonate solution. This process, however, found no practical use, nor did a somewhat similar process, published by Maxwell Lyte,† which was used with albumen paper. Conduchee‡ stated that the prints thus prepared showed fog in the shadows. Later, Lyte§ treated paper with a solution of sodium phosphate, Rochelle salts, sugar of milk, gelatine, and water, and silvered it after drying. He stated also that there was no insoluble silver precipitate formed as when a chloride was used to salt the paper.

Quite recently Dr. J. Meyer,|| of New York, has again directed attention to the phosphate of silver printing process by utilising the solubility of phosphate of silver in organic acid, such as tartaric and citric acid, and has thus formed a gelatinous solution of silver phosphate, which solution is spread on the surface to be sensitised. On paper thus prepared vigorous prints can be obtained, which are readily toned with gold, and also without gold toning, and merely washing and fixing give brown tones on pleasing shade.

The experiments made by Valenta with Meyer's process on Rives paper, unprepared and also sized with arrowroot, gave similar results as were obtained on Arndt & Troost's sepia printing paper, which is prepared with ammonio-citrate of iron, tartaric acid, silver nitrate, and some gelatine.¶

Paper prepared according to Meyer's process is rather insensitive, and, when tested with a Vogel photometer and albumen paper as the standard, was found to be less than one-third the sensitiveness of ordinary albumenised paper.

The phosphate paper showed, however, a very short scale of gradation, whilst the albumenised paper showed about two and a half times as much, and ordinary collodion paper about double.

The paper prepared according to Meyer's process appears, therefore, hardly likely to replace the normal papers, and experiments were made to modify it by adding gum and starch to the acid phosphate solution, but without the wished-for results.

Further experiments were then made in the direction of replacing the silver chloride by silver phosphate in the ordinary emulsion process with astonishing success; and a paper was thus prepared which excelled the best commercial collodion paper in sensitiveness, and also gave vigorous prints which were easily and evenly toned in the ordinary gold bath, and which, without gold toning, also gave beautiful sepia to black prints.

When using the silver phosphate with citric acid or silver citrate in collodion emulsion and keeping the proportion of citric acid low, or an emulsion is used without citric acid, the colour of the prints without gold toning is black, and the colour becomes browner the higher the proportion of citric acid.

With these emulsions the organic acids, as in the case of citric acid in the chloro-citrate emulsion, give greater brilliancy and clearness to the pictures, but lower the sensitiveness, which latter circumstance in this case is of no importance, because even a tolerably high proportion of citric acid does not so far lower the sensitiveness that it does not exceed that of the most sensitive commercial collodion paper.

For preparing a silver phosphate emulsion of this kind, place in a bottle 1500 c. c. of a four per cent. collodion with from 250 to 300 c. c. of ether, and to this solution add from 20 to 25 c. c. of phosphoric acid of specific gravity 1·265 at 15° C., corresponding to a proportion of forty per cent. of  $H_3PO_4$ , to this then add from 50 to 60 grammes of citric acid dissolved in 100 c. c. of absolute alcohol. Now dissolve from 70 to 75 grammes of silver nitrate in 75 to 80 c. c. of water, and add 150 c. c. of alcohol. The silver solution thus obtained is added in the dark room by yellow light to the collodion, the bottle being vigorously shaken all the time.

The phosphoric acid combines with the silver nitrate, and the silver phosphate formed is suspended in the collodion, and forms a yellow emulsion, which contains, besides phosphate of silver, citrate of silver.

¶ *Ibid.*, 1895, p. 541.

order to make the nitric acid set free harmless,\* from four to eight grammes of finely powdered lithium carbonate should be added to the emulsion, and the whole well shaken till there is no longer an evolution of carbonic acid gas. Then there should be added 20 c. c. of a solution of equal parts of glycerine and alcohol, and the emulsion filtered through cotton-wool.

The coating of paper with this emulsion can be effected as easily and regularly as with any good collodio-chloride of silver emulsion, and a printing-out paper is obtained which has, according to the kind of baryta paper used, either a glossy or matt surface.

This paper is about three or four times as sensitive as the best commercial collodion papers, and therefore it should be placed in the printing frame, and the toning, washing, &c., of the prints should be effected by yellow light, and not by diffused daylight.

The silver phosphate collodion paper requires somewhat dense and plucky negatives, and must be deeply printed. The prints have a dark brownish-black colour, and can, after washing in soft water, be easily toned in the usual toning baths.

The toned prints are very similar to the ordinary collodion prints, and sepia-toned to blue-black tones may be obtained as with albumen prints.

For toning, an ordinary borax gold bath is recommended, consisting of water, 1000 parts; borax, 10 parts; chloride of gold solution (one per cent.), 50 parts. Still, any other gold bath can be used. With the borax bath brown to purple-brown tones can be obtained, whilst sulphocyanide baths give bluish tones.

A sulphocyanide bath which tones very quickly and regularly consists of water, 500 parts; ammonium sulphocyanide, 10 parts; sodium hyposulphite, 1½ parts. For use, 100 parts of this should be mixed with 100 parts of water, 20 parts of one per cent. solution of chloride of gold.

After toning, the prints should be washed and fixed in a ten per cent. solution of sodium hyposulphite, and then treated exactly like ordinary collodion paper.

If it is desired to work without gold toning, the prints should be washed in soft water, then laid in a two and a half per cent. solution of citric or tartaric acid till the yellow colour has quite disappeared and the silver phosphate is dissolved, they should then be well washed and fixed in a five per cent. solution of hypo and then well washed. The colour of the prints thus obtained is a beautiful deep brown.

Although this paper prints very quickly, it may be developed, when only faintly printed with aqueous solution of pyrocatechin or hydroquinone which contains a little citric acid, and the results obtained are quite equal to those obtained in this way with the ordinary papers.

### PHOTOGRAPHY ON WOOD BLOCKS.

[Translated from the *Photographische Correspondenz*.]

For preparing photographic pictures on wood blocks instead of drawings, the wood block is usually prepared with a white ground, and on this, by a suitable printing process, the picture printed. Another way, which, under certain conditions, gives extraordinarily exact and beautiful results, is that in which, on a black ground, a thin collodion skin is transferred, this collodion being prepared by the wet-collodion process in the usual way on glass, and thence stripped by sulphuric or hydrofluoric acid, and transferred to the black surface.† In this way pictures similar to the well-known ferrotypes are obtained.

The black film is rather troublesome to the wood-engraver, as it presents some resistance to the graver. On the other hand, the transfer of the picture, as described in the directions, may easily cause trouble, as it is not easy, and also gives rise to distorted pictures; and it only succeeds with a somewhat stout film, which, again, makes the work difficult for the engraver, and prejudices the clearness of the picture.

As a help for the first trouble, I have found a very simple means. This is nothing more nor less than colouring the surface of the wood block with aniline black. To effect this colouring, the surface of the wood block is painted several times with a concentrated solution of aniline sulphate, and, when dry, is oxidised into aniline black by treatment with a solution of potassium bichromate containing cupric chloride.

In this way an intense black is obtained with matt shiny surface, which affords an excellent ground for the collodion negative image.

\* An obvious alternative plan would be to precipitate carbonate of silver from the given quantity of nitrate, collect and wash the same, and then add this to the phosphate collodion. This would certainly obviate the presence of lithium nitrate, which probably has no good effect, and might crystallise out.—EDITORS.

† M. V. Roux, *Manuel de Calcographie*; Lainer, *Phototypographie*, p. 42; and *Traité de Photographie Industrielle*, by Féry and Burais, Paris, 1896, p. 326.

The wood surface, thus coloured, is freed from excess of bichromate solution by rubbing with a wet pad, and when dry is well rubbed with a flannel coated with solution of gum, and allowed to dry. It is thus prepared to receive the collodion film.

The picture is prepared in the camera by the wet-collodion process in the usual way on a well-cleaned sheet of glass, which should be rubbed with a benzine and wax solution.

The exposure should be full, the development short, and then fixed with potassium cyanide, then reduced with iodo-cyanide solution till the shadows are clear glass and a sufficiently thin image obtained. The iodo-cyanide solution is made by adding to a four per cent. solution of potassium cyanide a few drops of solution of iodine in potassium iodide. The plate should be then washed, allowed to dry, and then placed in a three per cent. solution of sulphuric acid, wherein it should be left till the film begins to strip from the glass. Then the plate should be taken from the solution, the film cut round the edges, a sheet of well-sized, smooth paper squeegeed on to it, and the picture and the paper carefully lifted from the glass and then transferred to the damp wood block by squeegeeing it on to the black surface and lifting off the paper. The result is a vigorous positive, with bright lights and beautiful half-tones.

Instead of gumming the wood block, the surface may, just before the transfer of the picture, be coated with aqueous shellac varnish, and the picture transferred before the varnish has dried in. E. VALENTA.

### DAGUERRE, TALBOT, AND NIEPCE AT AN AMERICAN PHOTOGRAPHIC SALON.

OUR contemporary, the *Photo-American*, has lately published various amusing satires at the expense of some of the American photographic salons and their principal supporters, and in its last number laid the scene of the following midnight drama in the gallery of the Chicago Photographic Salon of 1900, in the course of which the three fathers of photography are made to disown some modern outcomes of their labours:—

(Enter three shades: the first of Daguerre, the next of Niépce, and the third of Fox Talbot.)

Daguerre: Well, gentlemen, we're in the wrong pew. Go back to the door, Fox, and ask that fellow where the photographs are.

(Exit Fox Talbot, while the others look around the room out of curiosity.)

Niépce: Pardon, bard, but how do ze dink zese pictures war made, and what are ze of?

Daguerre: Drop your English until Fox comes back. (In French): This thing here was evidently made by a painter who didn't know anything about painting. It's a regular daub. There isn't a good thing in it. The most of them are just as bad. In France we wouldn't have hung such paintings for a moment in our day. As to what they are pictures of, I should say from the colours that some of them are Chinamen; these, I mean, with the yellow faces. Some of them are Indians, a purely American race, which you have never seen; and these with the brown faces are half-breed negroes—mulattoes, they call them in this country. In fact, most of them seem to be of this latter class. They haven't any Europeans in the lot.

(Enter the shade of Fox Talbot on the run.)

Talbot: The man at the gate says this is the photographic exhibition we came to see. They don't call it that; they call it a Salon. That sounds French, and you fellows ought to know what it is. He gave me a catalogue. Here it is.

Daguerre: These photographs?

Niépce: This a Salon?

Daguerre: Well, I'm glad that it's pretty well settled now that I didn't discover photography. Niépce, it's up to you. Johnny Tennant says that you discovered it.

Niépce: He don't know what he's talking about. You discovered it yourself. There are half a dozen monuments to you all over the world. You can't put it on me.

Daguerre: Well, I didn't do it. Talbot must have done it. I didn't believe those articles in *Photogram* and the *Photographic Times*, but I'm beginning to believe them now. Talbot, you're to blame for this.

Talbot: May I never eat another shade of a saddle of Southdown if I did. Daguerre, you are to blame for this. One of the first things you ever said was that you were going to discover photography in colours, and now you've done it.

Daguerre: But I haven't. These aren't colours, they are smears. No man, woman, or child ever had such a colour as this thing (pointing to one of *Litstig's* masterpieces).

(Talbot has meanwhile picked up a magazine, April *Camera Notes*, from which he reads all about the process of local development, and proceeds to translate the same in French to the others.)

Daguerre and Niépce (in chorus): And they call that photography?

Talbot: They do; but I don't. And I move that we make a formal protest against it.

Daguerre and Niépce: We will.  
(The three shades get their heads together and produce the following document, which they duly sign and seal):—

STATEMENT.

We, the undersigned, the discoverers of photography, hereby certify that we have examined the within collection of so-called photographs, and that we never discovered or intended to discover any such thing.

While we are always glad to see discoveries made in connexion with photography which will assist in the ease and certainty of results, and feel that, if intelligent efforts are made in that direction, photography will, in the course of time, become an independent one of the fine arts, and the means of the fullest expression of all that is artistic in the worker, we do not feel that any efforts are for the real good of photography which make it in any way subservient to a sister art, like that of painting, and which require the methods, skill, and training of the painter to produce desired results in colour or tone.

We think that the man who paints with a brush, be his medium pigment or a chemical, is a painter, and not a photographer. And we think that a picture, the lines and shades of which are produced by the application of a brush charged with either a chemical or a pigment, is a painting or drawing, and not a photograph.

We think, moreover, and finally, that every effort which makes the latent photographic image merely subsidiary to the exercise of talents apart and aside from pure photography, and clearly within the domain of a sister art, is an effort in the wrong direction, and destructive of the status of photography as an independent art.

[Signed]

DAGUERRE,  
NIÉPCE,  
TALBOT.

The shades affix this statement to the walls of the galleries and sadly depart.

Curtain falls.

RECENT PATENTS IN COLOUR PHOTOGRAPHY.

THORPE'S METHOD.

[Patent No. 11,466 of 1899.]

We print Mr. Thorpe's specification in full:

When transparencies of photographs taken separately through red, green, and blue-violet screens on isochromatic plates are viewed by transmitted light in such a way that the three photographs appear superposed and only the respective colour of each is transmitted to the eye, a picture of the object is seen in its natural colours as for example in the apparatus known as the kromscop.

For the purpose of transmitting only the respective colour of each of the transparencies to the eye, it has been proposed to impress by means of photography diffraction gratings of different spacing for each colour upon the respective transparency, and illuminate them in combination with a lens by parallel rays of light directed upon them from one direction, the different spacing for each colour displacing the spectrum formed by the respective diffraction grating to a different extent so that the spectra overlap, and, if the eye is placed at a point where the red of the spectrum from the transparency taken through the red screen, the green of the spectrum from the transparency taken through the green screen, and the blue of the spectrum from the transparency taken through the blue screen coincide, the photographed object will appear in its natural colours.

My improvements in the method of and means for rendering photographic and other pictures visible in their natural or other colours, consist chiefly in producing diffraction transparencies from isochromatic photographic transparencies, said diffraction transparencies having gratings of the same spacing for all colours, but the lines of the grating placed at a different angle for each different colour, and rendering them visible in the respective or any other colour by illuminating them from different points, the positions of which are in planes perpendicular to the lines of the gratings on the respective transparency, but can be varied to alter the angle of incidence of the rays, so as to obtain spectra overlapping, and at the same time crossing, each other; and in the method of producing such diffraction transparencies from photographs and for some purposes without the aid of photography.

On the sheet of drawings appended hereunto, figs. 1 and 2 show a diagrammatic view of the apparatus employed for rendering the diffraction transparencies visible in various colours in elevation and plan.

Figs. 3, 4, and 5 diagrams of the positions of the spectra for viewing the objects photographed in their natural or other colours.

Fig. 6 shows a design in colours; figs. 7, 8, and 9, the three diffraction transparencies produced from photographs through, say, green, red, and blue screens, and fig. 10 the three transparencies superposed.

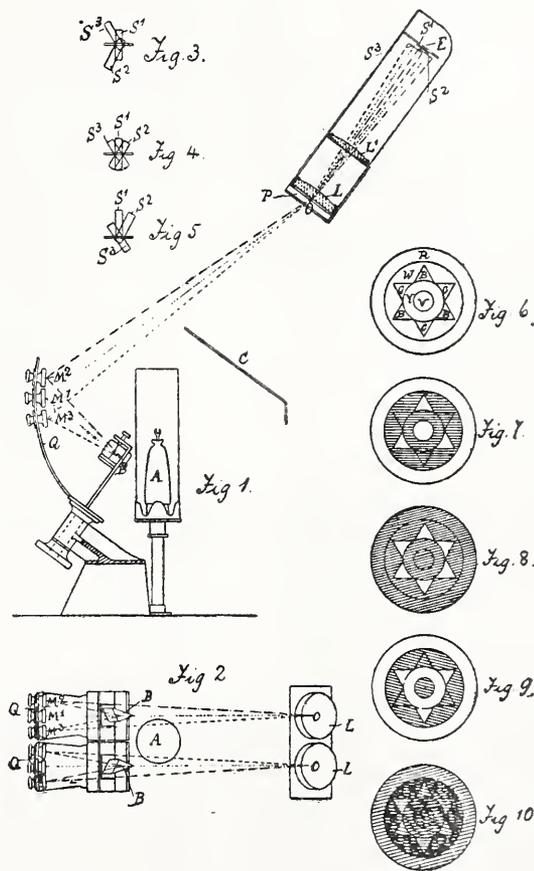

In carrying my invention into effect, in the case of natural objects to be rendered visible in their natural colours, at least three separate photographic negatives, taken through coloured screens, and positive transparencies printed from them, are necessary; but I do not limit myself to this or any number of such photographs or transparencies, as for

certain purposes more are advantageous. These transparencies, however, are only used for printing other diffraction transparencies, the following manner of performing this operation being a convenient one.

A glass, or other suitable transparent plate, is coated with a sensitive film of bichromated gelatine, which is kept in a somewhat soft state until exposed to light by the addition of a small percentage of some suitable substance, such as glycerine. On this film is mounted a celluloid or other suitable replica of a diffraction grating, of preferably from 10,000 to 40,000 lines to the inch, the ruled side being in contact with and, preferably, impressed into the gelatine film, so as to produce the grating lines on the film by mechanical action.

One of the original isochromatic transparencies being now laid over the plate prepared as aforesaid and exposed to sunlight or other suitable source of light, the portions of the gelatine film under the clear parts of the transparency will be rendered more insoluble in water than those parts which are under the opaque portions of the transparency. The celluloid or other grating being now detached or dissolved by a solvent having little or no effect upon the gelatine, such as acetone, and the plate washed in water, the reproduction of the grating is found upon the gelatine, varying in the intensity of its diffractive action according to the proportion of light each part has received through the transparency.

In making these diffraction transparencies from the different original

isochromatic transparencies, the lines of the grating are placed in each of them at a different angle to the picture, so that each transparency is lined in a different direction from the others, all the gratings, however, having the same spacing, which preferably is as fine as possible.

In order to make this method of preparing the diffraction transparencies perfectly clear, I will now refer to the drawings. Fig. 6 represents a coloured plaque or design to be photographed and rendered visible in colours, R denoting red, W white, G green, B blue, Y yellow, and V violet. Of this plate three negatives are taken through green, red, and blue screens, and positives printed on glass or other transparent plates in the ordinary way. It is obvious that in these positives only those parts of the plaque will be quite clear that contain the pure colour corresponding with that of the respective screen, and more or less clear in the parts of a colour into the composition of which the colour of the screen enters, and be opaque on those parts the colour of which does not contain the colour of the screen. Thus, in the transparency taken through the green screen, the parts marked G on fig. 6 will be clear, and those marked W and Y more or less so, while the rest will be opaque. When this transparency is placed upon the plate coated with a sensitive film of bichromated gelatine, into which a replica of a diffraction grating has been impressed, and exposed to light, as described above, the parts marked G, W, and Y, on fig. 6, will transmit light, and the bichromated film be rendered more or less insoluble, while under the other parts it will remain soluble, and, after being washed, a lined transparency, as shown by fig. 7, will be obtained,

the grating lines on this transparency being placed, say, horizontally, as indicated.

In the same way the diffraction transparency obtained from the transparencies taken through the red screen will be as represented by fig. 8, the celluloid replica of the diffractive grating being in this case impressed upon the bichromated film at an angle to the horizontal as shown, the angle of the lines being preferably ten degrees or less, but shown exaggerated on the drawing for the sake of clearness.

The diffraction transparency obtained from the transparency taken through the blue screen will be represented by fig. 9, the diffraction grating being in this case impressed upon it at an angle inclined to the horizontal in the opposite direction to that used for the transparency (fig. 8).

If more than three transparencies, obtained through other coloured screens, are used, the lines on the diffraction transparencies made from them are preferably placed at intermediate angles corresponding to the position of the respective colour in the spectrum.

The three diffraction transparencies (figs. 6, 7, and 8), hereinafter called the green, red, and blue plate respectively, are now, preferably, permanently superposed with the picture or image coinciding, as shown on fig. 10, and when viewed or projected in a suitable manner, either by reflection or transmission, are seen in colours; and, where the isochromatic photographs are taken from natural objects, with the natural differences of light and shade.

For the purpose of viewing, preferably the first order of spectra from transmitted light is used and brought to a focus at the eye by means of a lens placed immediately above the transparency, and when the picture is in good definition as seen by an eye lens such as is used in the stereoscope, each transparency being illuminated only by direct or reflected light in a plane perpendicular to the direction of the lines upon it, while the actual light is screened from the eye, the picture on each transparency is seen uniformly coloured according to the portion of the spectrum yielded by the grating, and, when the lights or mirrors reflecting the light are moved into such positions that the diffracted pencils from each transparency transmitted to the eye are of the same colour as the screens through which the original photographs were taken, the picture appears in its natural colours.

By figs. 1 and 2 an apparatus suitable for viewing is represented diagrammatically in elevation and plan.

In this apparatus the points of illumination, lenses, and images on the transparencies are duplicated so as to obtain the respective spectra and images at two eyeslits, for the purpose of showing the photographed object stereoscopically.

On the drawing, A represents a Welsbach incandescent burner from which the light falls through slits upon two totally reflecting prisms, B, which reflect the rays of light to the reflectors, M. Instead of the burner, A, and prisms, B, in some cases two incandescent filaments in the position of the prisms may be used with advantage. The light from the mirrors falls upon the combined diffraction transparencies, P, and passes through the lens, L, and the picture is viewed through the stereoscopic lenses, L<sup>1</sup>, and narrow eyeslits E. C is a screen to shield the transparencies from the light of the burner.

For the purpose of causing the rays of light to fall on the respective diffraction transparencies lined with gratings of uniform space but different inclinations to the picture, in a plane perpendicular to the inclination of the lines, and to vary the angle of incidence, the reflectors, M, are attached to the surface, Q, of an ellipsoid of revolution, the major axis of which is in the line of the reflecting point of the respective prism, B, and the centre of the lens, L, which are in the foci of the ellipse, the rotation of which round the axis forms the ellipsoid. It is evident that the light rays from the prism will be reflected to the centre of the lens in any position of the reflectors, M. Slots radiating from the axis are formed in the surfaces, Q, so as to vary the position of the mirrors, M, and the angle of incidence. The inclination of these slots to the vertical is the same as the inclination of the grating lines to the horizontal, so that the rays, B, M<sup>1</sup>, O, are in a vertical plane perpendicular to the lines on the green plate, the rays, B, M<sup>2</sup>, O, in a plane perpendicular to the lines on the red plate, and the rays, B, M<sup>3</sup>, O, perpendicular to the lines on the blue plate. The three gratings diffract the rays transmitted by the mirrors into spectra in the same planes as the rays, and, if the respective angle of incidence is so arranged by shifting the mirrors that the green part of the spectrum, S<sup>1</sup> (fig. 3), formed by the green plate, the red part of the spectrum, S<sup>2</sup>, formed by the red plate, and the blue part of the spectrum, S<sup>3</sup>, formed by the blue plate, fall upon the eyeslit, the photographed object will be seen in its natural colours, the eyes being preferably placed at a short distance from the eyeslits.

If the position of the mirrors is changed, the colour received into the eye from the different plates will be changed. By placing the mirrors, M<sup>2</sup> and M<sup>3</sup>, into the line of mirror, M<sup>1</sup>, for instance, the green part of the three spectra will be transmitted through the slit, as represented by fig. 4, and the object will appear all green; by shifting the three mirrors to the top it will be shown all red, and by shifting the three mirrors to the bottom it will appear all blue. By shifting the mirrors, M<sup>1</sup> and M<sup>2</sup>, to the bottom and the mirror, M<sup>3</sup>, to the top, the blue parts of the spectra from the green and red plate, and the green part of the spectrum from the blue plate, will fall into the eye, as represented by fig. 5, so that the

green and red portion of the photographed object will appear blue, and the blue parts green. It will be evident that by altering the positions of the mirrors any part of each spectrum can be made to fall into the eye, and any variety of different colourings besides the natural colours rendered visible.

In some cases the mirrors, M, may be replaced by incandescent filaments movable in the same way, and the prisms and burner, or other source of light, omitted.

In the case of flat objects, such as designs of wall papers, for instance, or where a stereoscopic effect is not to be produced, of course only one set of reflectors and one source of light and diffraction transparent photographs are required.

In the case of designs in two colours, of course only two diffraction transparencies and two reflectors will be wanted. The diffraction transparencies for such designs, and the like, can be produced without the aid of photography, by placing a celluloid replica of a diffraction grating over the design, or drawing it upon such replica, and painting for each colour the parts having a different colour with varnish to fill up the grating spaces, placing the grating lines at a different angle for each colour. Thus the three plates (figs. 7, 8), and 9, can be obtained by placing three celluloid gratings over the design (fig. 6), at the respective angles, and painting the white parts in figs. 7, 8, and 9 with transparent varnish, which, when superposed and inserted into the apparatus, will show the design in its original or any other colours, in the same way as the gelatine diffraction transparencies obtained from photographs taken through isochromatic screens in the manner hereinbefore described. The transparencies may likewise be produced by printing on the celluloid gratings with varnish or like filling, and making transparent replicas of them in the manner hereinafter described.

It is obvious that where the photographed object is a design, or where a design is specially prepared as a transparency in the manner herein last described, from one to a considerable number of transparencies, with gratings of the same spacings but different inclinations, may be used, and that an unlimited variation and combination of colours may be produced by the means hereinbefore described.

Instead of using the gelatine diffraction transparencies obtained from the photographs, or those obtained directly without the aid of photography, by the processes hereinbefore described, celluloid replicas of them may be made, mounted, and superposed in the manner adopted for the gelatine transparencies. This can be done by smearing the original with a thin oil, such as watchmakers' oil, and pouring the celluloid solution upon it; when set, the replica can be readily pulled off.

#### SZCZEPANIK'S METHOD.

[Patent No. 7729 of 1899.]

If a plate, *e* (hereinafter for shortness called a line plate), provided with fine transparent lines, is placed between a matt screen, *a* (fig. 1), on which the image of the object, *b*, is to be projected, and an objective, *c*, in which a diaphragm, *d*, provided with a square opening, has been placed, then the image appears on the matt screen in bands or lines which correspond to those of the line plate. If the line plate is moved further and further from the matt screen, then the bands forming the image become broader and broader, until, when a certain distance is reached, the lines or bands of light unite to form a sharp, unbroken image, which is, of course, less illuminated than an image projected without a line plate. If, instead of the diaphragm with the square opening (fig. 2), a diaphragm (fig. 3) is inserted, the opening of which has the same height as that of the diaphragm shown in fig. 2, but has a less breadth, then, again, the image is less illuminated. If, whilst the other conditions are kept the same, a diaphragm is inserted which, in the vertical direction, is only one-third open (figs. 4, 5, or 6), there are, again, formed on the projected image black lines or bands, which are twice as broad as the light ones. Thus the width of the lines or bands of light is in direct proportion to the height of the opening in the diaphragm if the distances of the line plate from the objective and the matt screen remain the same.

A consideration of fig. 1, in which are shown the limiting rays corresponding to the several diaphragms shown in figs. 4, 5, and 6, will make the phenomena just described completely clear.

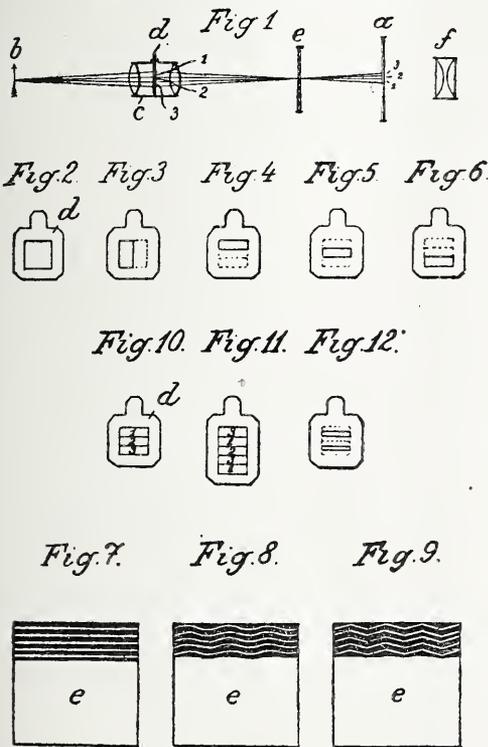

The transparent lines, or the line plates themselves, may have any desired positions (for example, vertical or oblique) if the diaphragm be arranged to correspond. The line plates, instead of having straight transparent lines (fig. 7), may be provided with wavy or zigzag lines (fig. 8 or 9 respectively).

As has been stated, when a completely open diaphragm (fig. 2) is used, a complete image is obtained. A complete photographic image can also be produced by means of the three partly open diaphragms (figs. 4, 5, and 6), if they are used one after another in the manner hereinafter described.

Together with each separate diaphragm, a colour filter (1, 2, or 3) of the kind used in three-colour printing is arranged in front of the objective, and in the end a sharp negative is obtained, which, in consequence of the employment of three diaphragms, exhibits three times as many lines as the line plate. The picture will thus consist of successive groups, each composed of three lines, which, on the negative, are of course monochrome, but in different shades corresponding to the red, yellow, and blue colour filters 1, 2, and 3 respectively.

The same result is attained if, instead of three diaphragms one after another, a single diaphragm (fig. 10) is used, the opening of which is provided with filters of like height for the red, yellow, and blue rays, arranged one above another.

If a diapositive or transparency (hereinafter called a diapositive) is produced from the negative that is obtained, a coloured image, representation, or picture, can be projected by means of the apparatus shown in fig. 1. In this case, *a* represents the diapositive, *e* (as formerly) the line plate, *c* the objective, *d* the diaphragm (with red, yellow, and blue plate). In front of the diapositive a condenser, *f*, of known kind, is arranged, and *b* the coloured image, representation, or picture, is produced. It is evident that the line plate, *e*, must occupy exactly the same position in relation to the diapositive as it did in relation to the negative during taking, since otherwise it might come about that, for example, the yellow rays impinged on the red filter. To remove this defect by adjusting the line plate is very difficult. Another device is therefore, provided by means of which the correct adjustment can be effected without displacing the line plate. This device consists of a diaphragm which, as is shown in fig. 11, possesses, in addition to filters for red, yellow, and blue (1, 2, and 3, respectively), as shown in fig. 10, two other filters, one above and the other below this group of filters, the upper one being for the blue, and the lower one for the red. By shifting such a diaphragm inside the objective vertically, the defect hereinbefore mentioned can be removed,

As this diaphragm permits of three different serial arrangements of the colour filters—namely, red, yellow, blue (1, 2, 3); yellow, blue, red (2, 3, 1), and blue, red, yellow (3, 1, 2). The shifting of the diaphragm may be effected by means of a screw or in any other suitable way.

As already stated, an image or picture projected in the manner described contains three times as many lines as there are in the line plate, and each three successive lines appear in the three fundamental colours red, yellow, and blue. These lines are, however, so closely packed together that the eye cannot distinguish them separately, and thus the desired colour effect is attained.

The image or picture is the better the more closely the lines are packed together on the plate, *e*. The production of such closely lined plates, however, is limited by commercial and technical considerations. On the other hand, the number of lines composing the image can be increased by further division of the diaphragm. The opening in the diaphragm may be divided, for example, into six or nine parts, instead of three, so that two or three times as many groups of lines (each consisting of three-colour lines) appear as in the case of the tripartite diaphragm. A single diaphragm having its opening divided into six parts is provided with two groups of colour filters, one above the other, and each such as shown in fig. 10; fig. 12 shows by way of example one of three separate diaphragms to be used one after another instead of a single diaphragm provided with six colour filters as just described, the diaphragm shown being provided with two colour filters for yellow rays. A negative produced with a single diaphragm having six colour filters, or with three diaphragms of the kind illustrated in fig. 12, thus contains six times as many lines as there are in the line plate, and is therefore much more accurate than a negative produced with the tripartite diaphragm.

If the line plate is made of suitable thickness and provided at the back

with a layer sensitive to light, this plate can serve at the same time as a photographic plate. Inversely, the photographic plate can be provided with fine transparent lines on a dark ground on the side away from the light-sensitive layer. Such a plate also forms a means of producing pictures or images in natural colours. When employing such a photographic line plate the distance of the light-sensitive layer from the lined surface is always the same; the plate must therefore be kept exactly at the same distance from the objective when projecting as when taking.

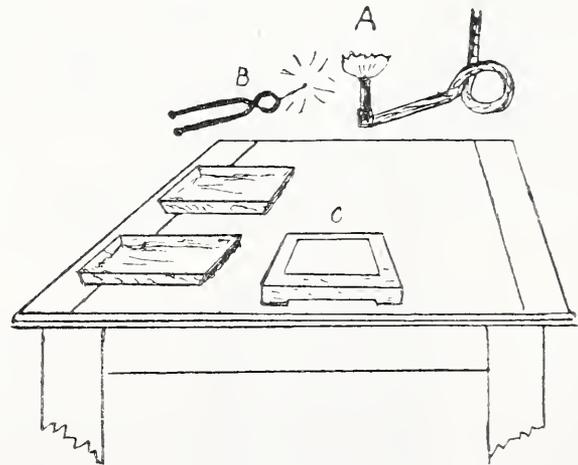

HOW TO WORK VELOX IN QUANTITY QUICKLY AND CHEAPLY.

LET it be understood at the outset that the paper we are dealing with is Carbon Velox, as the other varieties require different treatment to that given below.

An essential condition to success with Velox is *correct exposure*, therefore we will give a few hints on the same.

The most convenient and accurate means of printing Velox is by magnesium ribbon, and, for an average unstained negative, a length of about half an inch, burnt at a distance of one foot, is about correct. The best plan is to always burn the ribbon at one fixed distance from the printing frame, and there is only one variable factor in determining the length of ribbon required for exposure, *i.e.*, the density of the negative.

In most houses a sliding gas jet is to be found, and a table either under it or very handy. Put a table or other suitable stand underneath the jet, and pull it down as far as it will come; you will then have a most ready way of burning the magnesium at a fixed distance. For you have only to place the printing frame containing negative and paper on the table, nearly, but not exactly, underneath the gas-burner, light the gas (not turning it too high), and then take a piece of magnesium ribbon of the right length for the negative in use, hold it with an old pair of pincers or the points of a pair of scissors, put it in the flame till alight, then withdraw till just over the flame, and move it to and fro while burning, taking care to keep the same height as the gas flame. This operation is in practice performed very quickly, as the ribbon burns at the rate of one inch in two and a half seconds. The accompanying sketch will convey the idea of position, &c.

A, gas flame. B, pincers, with ribbon burning. c, printing frame.

You can thus produce any number of prints easily and quickly, as you can place two empty plate boxes (with lids on) at your left hand, one for the unexposed paper and the other for the prints. (See that the lids are on during the exposure.)

To make a good vignette on Velox it is necessary to place the vignetting screen about one and a half inches above the negative, cover the opening with the tissue paper in which the Velox is wrapped, and exposure as above, giving about three times the ordinary exposure for the same negative.

We now come to the developing. I give two methods of doing this, so that the reader can choose for himself which to employ.

The following is the developer used in both cases (I am aware this is contrary to the Company's instructions, but its use is justified by results):—

- Rodinal ..... 1 part,
- Water ..... 16 parts,
- and add 10 grains of sodium sulphite to every 10 ounces of water.

Before developing, make up the fixing bath either according to the Company's formula, or a plain hypo bath of 4 ounces to the pint, with which I have never had any stains when working as below.

Now, for developing, get two dishes, pretty deep ones; in one put clean water, and take your prints and put them one by one into this.

water, taking care not to let them stick together. When you have put them all in, pour your developer in the other dish, allowing about 6 ounces of developer to a dozen half-plate prints, and, as quickly as possible, transfer your prints from the water to the developer, one by one and face up, taking from the water with one hand and pushing down into the developer with the other; at the same time keep them moving, and prevent them from sticking, in fact, treat them in the same manner as toning P.O.P., only you will have to handle them much quicker, as they develop fast. If they come up slowly, you have under-exposed, and to try to bring them up will very likely result in stain.

As soon as any one is fully developed (do not overdo it), take from the developer and throw in the fixing bath, face up, either direct or after a slight rinse in cold water, pressing it under with a glass rod, bone spoon, or anything which will not injure the print and is long enough to prevent the hypo from touching the hands. After all the prints have been placed in the hypo, let them fix for ten to fifteen minutes, then wash well for about an hour.

Let me again emphasise two essential conditions of success, viz., correct exposure and freshly made-up developer; also allow plenty of fixing bath.

#### SECOND METHOD.

This method, though rather slower than above, is practically free from any liability to stain.

One dish only, in addition to the fixing bath, is required, and this would preferably be a shallow, flat-bottomed porcelain dish.

Take one print and place it face up in the dish, flood with water, and allow to stand while you put 4 or 6 drachms of the above developer into a measure (4 for a cabinet size and 6 for a half-plate print), then pour the water off the print, which will leave it perfectly flat on the dish bottom; take the developer and pour it at one sweep over the print, taking care it covers the print well; watch carefully, and, when completely developed, pour the developer off and again flood with water, which will lift the print from the bottom of the dish; take it out and throw in the hypo, pressing under with a glass rod, &c., as before, washing and fixing same as mentioned above.

I may point out that the cheapest size of Velox is the cabinet size, which is just the right size for cabinet mounts without any trimming. Mounted on a plate-sunk, half-plate mount, it gives a very pleasing width of margin.

The other varieties of Velox I have not referred to in detail, as they are quite so easy to work, nor as certain in results, as the carbon.

The Special Portrait Velox has a splendid matt surface, but requires far more care in exposure and handling, as it is about four times as sensitive as Carbon Velox, while the Glossy Velox is extremely liable to surface markings. Therefore, for all-round work, the Carbon Velox is to be recommended, and, if treated as described, the results will be practically indistinguishable from platinotypes.

I do not claim novelty for these methods, but I have not yet seen a similar method described, and, as they are the result of much experiment and experience, I think it will commend itself to your readers.

R. N. HEPWORTH.

#### RETOUCHING, AND ITS ABUSE.

We often hear old stagers tell of the excellent portrait work they remember in the 'fifties and 'sixties; how there was a virility and force about some of it that is seldom excelled now, with all our added knowledge and improvement in apparatus. Looking through a collection of the earlier examples of photographic art, what is it that strikes most of us at first sight? Probably, in nine cases out of ten, the absence of any retouching, or, at most, the very slight amount of such. Our predecessors were not so terribly afraid of a truthful presentation of their sitters as most of us are nowadays. And so, though their accessories and backgrounds, to say nothing of their ideas of posing, are, in our modern eyes, grievous and heart-breaking, yet what life and character these fast-fading old prints possess!

It is the fashion now, the public demand it, and will have it—or so at least the *à-la-mode* photographer will tell you—to smooth the face into marble-like evenness and coldness, extracting in the process nearly all those lines and expression marks that indicate personality. It is positively appalling to look at some of the specimens of so-called "high-class retouching," such as will be sent in answer to any ordinary advertisement for an assistant. The demand, of course, creates the supply, and so we get lovely feminine faces by the dozen, impossibly lovely, insipid and unnatural, and masculine lineaments, or what should be so, robbed of every vestige of manliness and decision by a similar process of over-flattery. The hoary-haired septuagenarian smirks with the even and placid visage which, perhaps, was his three decades ago; or the happy matron, *passée* and not too slender, smiles at us with the beauties of "sweet seventeen" and a sylph-like figure!

Now, we must not wholly blame the retoucher. As has been said, the demand creates the supply. An inartistic race of photographers, realising the power that retouching often has to atone for bad lighting and operating, have demanded a certain article, and have, in many cases, got more than they bargained for. At the same time the supply has assisted

the demand. Employers, seeing constantly nothing but the usual variety of retouching, have got accustomed to it, expect it, and require it. The man who can make their negatives smoothest and cleanest, who can most successfully extract all lines and wrinkles, and deduct ten years from the sitter's age, passes with them for the best retoucher, and is engaged accordingly.

It may be useful in connexion with this subject to have a perfectly clear idea in our minds of what retouching essentially is. The correct technical definition, probably, will be that it is pencil or other work on a negative, rendered necessary by the fact that the camera exaggerates and emphasises any imperfections in the face, and tends to render the shadows too heavily, giving also an undue importance to spots and freckles. If retouching were simply confined to rectifying the exaggerations of the camera and the inherent imperfections of a photograph, there would not be much ground for complaint. As, however, the photographer does not exist to preach theoretical perfection to an indifferent public, but has to remember his banking account, this, of course, is practically impossible, be it never so desirable. A certain amount of flattery, and making up for Nature's omissions in the bestowal of good looks, must inevitably be practised if the goodwill of our clients is to be gained.

There is, nevertheless, a wide gulf between a little legitimate flattery and a wholesale destruction of likeness and identity. Some of us have got so used to this latter that a little reflection often becomes necessary to convince us of its existence. We have only to compare a typical highly finished photograph of one of our friends with that friend in person, and conviction will generally follow that the former is about as lacking in candour as it well could be.

At Scotland-yard a sort of register is kept of all criminals and suspects coming under police attention, illustrated with photographs of these interesting individuals. It is only necessary to mention that these portraits are preferred by the authorities in an untouched condition, and it becomes evident that some one at least is aware of the deceitfulness of "the usual thing."

Of course, no one wishes to insist on unalloyed truthfulness in a portrait; this would be often extremely undesirable, even from an artistic point of view. We want to see the sitter at his best, with his unpleasant features, if there are any, just sufficiently held back, and his good points relieved and shown to advantage by judicious lighting and after-treatment, under which head we include a legitimate amount of pencil work.

It is more than likely that much of our bad retouching is due to bad lighting and operating. It is quite possible, with the better opportunities we now possess, to obtain negatives which shall require a very slight amount of working up, more especially if isochromatic plates are used. It really seems, however, to be the settled opinion of many operators that they have simply to expose and develop the plate and the retoucher will do the rest, making amends for all errors of lighting, exposure, and the like. If the negative is under-exposed, what matters it so long as it is not utterly unrepresentable? The pencil-wielder will tone down all the heavy shadows which result and matt-varnish it for him. What if it is over-exposed and flat? This quite indispensable individual will work up the high lights, and bring sparkle and brightness where none before existed. And so with defects of lighting, often the most serious, and all the ills that a negative is heir to; the same magician is trusted to have a panacea that will cure them.

The natural result of this is that retouchers get so used to doing much work when it is wanted, that they end by indiscriminately overworking everything, without rhyme or reason; and the operator does not use his best endeavours to obtain as nearly perfect a negative as possible, having learnt to be content with a second-rate result.

The over-retouched print satisfies the public, for the simple reason that their taste is not yet sufficiently educated to appreciate better things.

They are not, however, by any means so Philistine as they are often represented to be, as is amply proved by the generous recognition always given to genuinely artistic work. It is an infallible truth that good taste always conquers in the long run, be the reign of the ugly and vulgar never so seemingly secure. As an instance of this near to hand, let us note how our furniture and interior decoration has undergone such radical change since the day, not so long gone by, when hideous solidity and stiffness held their own triumphant. So may we be well assured that, near or distant, the time is surely coming when the public will scorn the type of portrait which now delights their souls and will insist on having a genuinely truthful and satisfactory work of art. Why should we not try to anticipate, to be a little ahead of our generation, rather than a good way behind?

It goes without saying that the best portrait work of our leading men is beyond the reach of any reproach on the score of over-finishing. We have only to recall the productions of such pioneers as William Crooke, Craig Annan, W. M. Warneuke, and Caswell Smith, to mention a few whose names are household words in the camera world, to perceive, more plainly than any amount of critical teaching could impress on us, how much room for improvement there is in the average show-case.

There are already, fortunately, many gratifying signs of a change for the better in our sitters' ideas on this subject. It is not so rare now to have them request that their negatives may not have much retouching bestowed on them, and that their lines and wrinkles be not interfered

with. In many ways they now show an intelligent understanding of the good points and defects of a photograph, as many careless workers are daily finding out to their cost. Perhaps it is written in futurity that the time may even arrive when the photographer will refrain from excusing anything tawdry or tasteless in his work by what he evidently considers the clinching argument that the public like it, and must on no account fail to be gratified by a plentiful supply of it. It would probably be difficult to name any other profession or business where this semi-apologetic remark is so often heard. On the whole, it is certainly a remarkable libel on the public, who are ever quick to perceive what is good, and to adopt and patronise it accordingly, to the best of their ability.

A. LOCKETT.

#### NOTES ON MOUNTING PRINTS.

I HAVE several times noticed, when reading through practical works on photography, that the chapter devoted to the mounting and finishing of the photograph never looks as if it had been written with the enthusiasm so conspicuously a feature of the other chapters, and, in bad cases, there is a deliberate intention to shelve or burke the subject, as if really too simple a matter to write about, whereas we all recognise it to be a most important subject. I really think the mounting of photographic prints has been little better than a nuisance from the earliest days. Prints on albumenised paper certainly gave less trouble than the modern P.O.P., but the paper was thin, and stretched considerably, and, unless great care was exercised in the selection of mounts (referring more particularly to large sizes), the surface showed up any defects little or much, all which difficulties present themselves to a more or less degree to-day, for we have all of us, for instance, to keep an eye open for the elusive bristle.

I think something might be done on lines similar to the old (and satisfactory) method of mounting the prints face down to good-quality glass plates. This old method still has its uses, and for filling up panels and covering our walls there is no simpler or better plan. Where only one or two prints are wanted, or where one wishes to show results quickly and display them to the best effect, the glass-mounted photograph easily surpasses the cardboard presentment. Now, of course, the objections to the method are on the score of weight, and bulk, and risk of breakage, but why not do something with a thin, but not too thin, celluloid film, to which we could squeegee the print for permanent support?

I judge by the sale of ready-made mountants that the average amateur seldom uses the home-made starch paste. Starch paste freshly prepared, which fairly thick, squeezed through muslin, and put on with a brush, has shed all its roving bristles, is probably the safest preparation to use as regards the permanent character of our work; and, if it would only stick a little better at the corners and along the edges, what a boon and a blessing starch would be. On the enamelled surfaces a starched print adheres without the least difficulty; but, with the plain Bristol board, troubles are liable to crop up. These troubles are due partly to the fact—the usual fact—that the prints are unevenly dry. If a print is curly at the edges, and most of them are, it denotes a dryness which has not reached the centre. Such prints may be mounted upon an enamelled board easily with any good mountant; but, if Bristol boards are used, they are best sized beforehand with a solution of gelatine (five per cent.) applied hot by means of a Blanchard brush, viz., an appliance somewhat in the form of a squeegee, the rubber being replaced by two or three folds of lint. The board, when dry, should show no signs of glaze, and, on application of the starched print, breathing also over the mount, we may generally secure the adhesion of the print.

A great deal of care is requisite in order to get perfect results when the richly glazed variety of print is required. I know that amateurs use plate glass freely for the purpose, and some few of them get very clean results. Examine with a lens the surface of some glazed prints, however, and you will find many evidences of tiny pieces of fluff, dust, and other extraneous matters. This is scarcely surprising when we consider how the operator works away at his glass or vulcanite with silk handkerchief or flannel. The surface is, of course, rendered highly electrical, and every tiny, microscopic piece of matter in the immediate vicinity is at once attracted, and the man wonders what the Dickens is the reason he cannot get a clean surface. A well-washed leather is by far the best to use with which to wipe the glass, but reason points rather to the use of separate glasses for each print, as then the two surfaces can be brought together under water, and the dust fiend altogether eliminated.

Whatever the mountant—starch the commercial mountant, or rubber solution—difficulties are bound to be met with if the prints are not uniformly dry over the whole surface. Prints which have been glazed and thus exposed to practically a uniform desiccation are, I think, certainly easier to mount than those which, after the usual drying, have been stored one on top of the other unevenly, exposed to whatever degree of moisture or dryness there may be in the atmosphere. Although we may secure this uniformity, in some degree, by keeping prints rolled tightly round cylinders, face out, with a piece of clean white paper folded outside, the glazed print will always be the better and most uniformly dried, and consequently the easier to mount.

J. PIKE.

## Our Editorial Table.

PYRAXE.

Agents: Fuerst Brothers, 17, Philpot-lane, E.C.

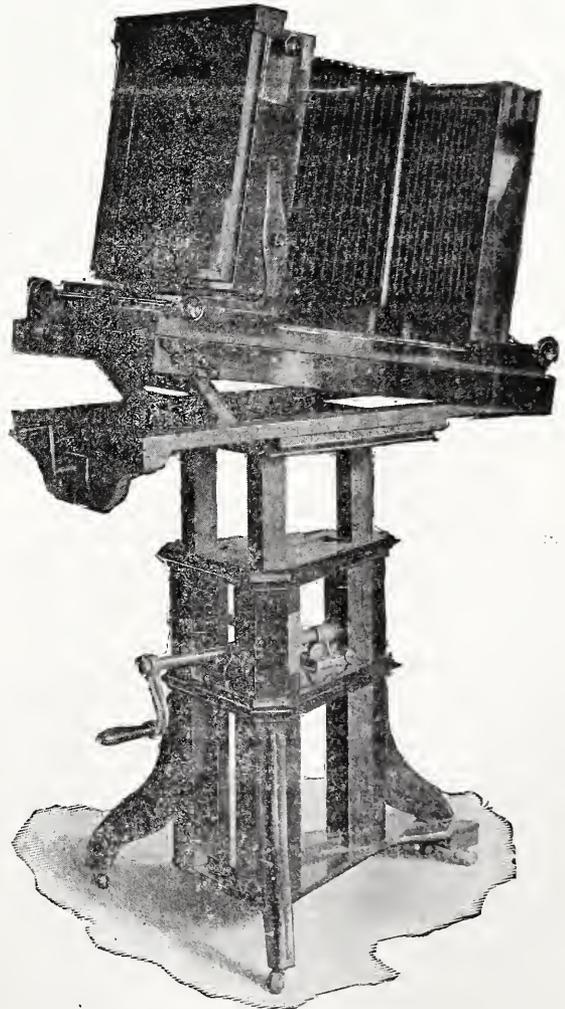

PYRAXE is the name given to a form of solid pyrogallol (or, as it is still erroneously called, pyrogallic acid), which is manufactured by Messrs. Hauff & Co., and a sample ounce of which was sent us by Messrs. Fuerst Brothers. Produced in fine white crystals, one ounce of Pyraxe occupies the space of a one-ounce bottle, whereas, as is well known, an ounce of the flocculent sublimed pyrogallol requires bottle space of about twelve-ounce capacity.

One shilling an ounce is charged for Pyraxe, which we found freely soluble, and, so far as we have been able to judge, quite as suitable in development as the older form of pyrogallol.

#### THE "FORWARD" STUDIO CAMERA AND STAND.

Manufactured and sold by O. Sichel & Co., 52, Bunhill-row, E.C., and 47, Oxford-street, W.

WE do not hesitate to say that this handsomely built camera, which we examined recently, would form an ornament to any photographic studio, whilst its efficiency as a practicable instrument for portrait work, &c., is undoubted. The camera is made in mahogany with brass bindings, but the particular one we inspected was of walnut with nickel fittings, and we were much struck by its excellence of finish and construction. Whether in walnut or mahogany, it is fitted with a double swing and repeating back, which takes one back for slides, holding carriers for  $8\frac{1}{2} \times 6\frac{1}{2}$  and cabinet plates, and another back with roller

shutters containing carriers for larger plates. The backs are easily fixed and removed by turning a screw or pressing them into a spring. The smaller back is fitted with a hinged focussing glass, and a focussing glass is supplied for the larger. It fixes in the same way as the back itself. The front part is movable. The lens can be lowered or raised, and is fixed in a very simple and ingenious way. The square bellows is supported by an arrangement, which prevents sagging. The camera extends to double its natural length. The stand is of black ebonised wood, and is fitted with an easily controlled tilting system.

This bare outline of the Forward camera's principal features will

show the professional reader that it is well adapted for all-round studio work. Our own opinion of it as a piece of apparatus is that it would be a difficulty to surpass it in convenience and usefulness. It has a range from a very short focal length to fifty-four inches and works with the utmost ease and smoothness.

#### KELLY'S DIRECTORY OF CHEMISTS AND DRUGGISTS. 1900.

691 pp., price 20s.

London: Kelly's Directories, Limited, 182-184, High Holborn, W.C.

THE ninth edition of this invaluable work has been issued. In addition to chemists and druggists, the names of manufacturing chemists, dentists, veterinary surgeons, wholesale druggists, drysalters, mineral water manufacturers, photographers and photographic material dealers, surgical-instrument makers, and other trades are given. In this edition the names of the Isle of Man and Channel Islands are included for the first time, and it should be said that besides England and Scotland the Directory also extends to Ireland, which has only been included in later editions. The names of over 49,000 persons are given in the Directory, of which it is the bare truth to say that to the members of the various trades with which it deals it is quite indispensable. It is obviously compiled with Messrs. Kelly's usual care and accuracy.

#### PHOTOGRAPHY IN COLOURS.

By R. CHILD BAYLEY, F.R.P.S. 74 pp., price 1s.

London: Liffé, Sons, & Sturme, Limited, 3, St. Bride-street.

IT is no easy thing to write a book on colour photography in such terms as shall make the subject clear to the general reader; but Mr. Child Bayley in the volume before us has quite successfully accomplished the task of giving a perfectly simple exposition of his theme, almost wholly avoiding, at the same time, its more abstruse physical and chemical aspects. The author's well-known faculty of discoursing lucidly upon highly involved scientific topics comes to his aid in his description of the processes with which the names of Lippmann, Ives, Joly, and R. W. Wood are associated, while the chapters on the nature of colour, the undulatory theory of light, colour vision, and other matters of underlying theory are equally interesting and explanatory. The author's final conclusion is that photography in natural colours has never been accomplished and never will be, "pigmentary" colour photography being understood in the reference. The book is admirable in its explicitness and conciseness.

## Studio Gossip.

WE are sorry to learn that an old and esteemed friend of the JOURNAL, Mr. John Stuart, of Glasgow, a Past-President of the Convention, has lately been in poor health. It is hoped, however, that a rest and change will fully restore him to his usual vigour.

THE QUEEN AND WAR PHOTOGRAPHY.—Her Majesty the Queen is collecting portraits of the soldiers who have distinguished themselves in South Africa. She has a likeness of every general in the field, and is getting one of every officer who especially distinguishes himself. She has the portraits of several private soldiers, and is to obtain photographs of all the soldiers recommended for the Victoria Cross. Lady Roberts has presented the Queen with a portrait of her son.

THE NATIONAL BAZAAR.—Messrs. Langfier (Limited), of 23A, Old Bond-street, W., have been appointed the sole official photographers to this week's National Bazaar, and have also been intrusted with the preparation and publication of a very handsome souvenir in connexion therewith, which, besides containing photographs of all the prominent people interested in the promotion of the Bazaar, will also include contributions by persons eminent in literature, science, art, and music. Messrs. Langfier have presented the Committee with 10,000 coupons (entitling the holder to three photographs), which are to be sold by them at 10s. 6d. each, the entire proceeds to be handed over to the Fund in Aid of the Sufferers by the War.

THE ROYAL ACADEMY.—A contemporary writer prints the following unfavourable criticism of this year's Exhibition at Burlington House: "I have been prowling about the Royal Academy for some days past, and have been made exceeding sorrowful, not so much by what I have seen there as by the hopeless acquiescence of the critics in the present deplorable condition of English art. The Academy Exhibition never has been, and could never hope to be, a display of wholly fine and worthy work. It has from time to time afforded us great art, but it is frankly impossible that all its pictures, drawings, sculptures, modellings, and the rest should be high above the level of mediocrity. That is an inescapable thing. The Academy is not to blame for the fact that there are not 500 craftsmen of the first rank alive in any given year. It is to blame for the feeble aid it affords to the art it is supposed to cherish, and so neglects and even stultifies, that wealthy London offers about the worst school in which an ambitious and capable young painter may study. It is to blame for the ridiculous and selfish conservatism which has excluded from its walls the works of men who have achieved brilliant reputations in spite of it; it is to blame for the spirit which has turned a national institution into a coterie. For all these things it has partly to thank the terms of its charter and partly the inherent determination of human nature to make the

selfish best of a good thing which cannot be taken away from it. But the Press, which has the power to shake it from its apathy, seems itself asleep, and dozens of monstrosities go unrebuked annually, as if they were hedged about by a sort of divinity because of their surroundings. It is the current and the natural belief that the Academy is open to meritorious work alone; it is the current and the natural belief that it is made up of the work of Englishmen, or that in the main at least it represents the English school. Both these ideas are illusory. In the Exhibition of this year the most notable portraiture is from the hands of Mr. Sargent and M. Benjamin Constant, an American and a Frenchman. In historic painting there is nothing to compare with the work of another American, Mr. Abbey. In criticism it would seem to be essential only to have mastered a certain cant. We appear to have done with our ancient friends 'brio' and 'chiaroscuro,' but we have got into another jargon about a painting being 'wrought' and 'observed with insight' and the 'vivid gesture' of a painted little finger. As I happen to know personally, a great number of the men who criticise the art-shows of the year are thoroughly acquainted with the traditions and principles with which they profess to deal; but they do not express their genuine opinions. Whether, from mere kindness or a timid desire to avoid offence, they write smooth things, and, partly as a result of their amiable banalities, the chief artistic association of the country is steadily going backward."

## News and Notes.

IN consequence of so many astronomers being away with the object of seeing the solar eclipse of May 28, the annual "visitation" to the Royal Observatory, Greenwich, will be postponed until the end of June.

MESSRS. TENNANT & WARD, of 289, Fourth-avenue, New York, inform us that the increasing demand for the *Photo-miniature* has necessitated third editions of No. 1 ("Modern Lenses") and No. 2 ("The Pose in Portraiture"), and a second edition of No. 6 ("Orthochromatic Photography"). These three numbers thus reach their 8000th each.

ROYAL PHOTOGRAPHIC SOCIETY.—The exhibition of pictures by Mr. F. H. Evans will close on Saturday, May 26, at four p.m. On Tuesday, May 29, at eight p.m., Dr. P. H. Emerson will open an exhibition of some 140 examples of his work. It will remain open until June 30, on presentation of card, from ten till four p.m., Wednesday ten to eight.

AINTREE PHOTOGRAPHIC SOCIETY'S EXHIBITION.—One of the features at this Society's Seventh Annual Exhibition, in November next, will be a lecturette competition, open to photographers at home and abroad. The lecturette may be on any subject, the lantern slides not to exceed twenty-five, and the descriptive matter to be limited to not more than twenty minutes in delivery. One of the awards in this class went to a member of a society in Perthshire last year.

THE "CASTLE" PLATE ON THE SOUTH AFRICAN BATTLEFIELDS.—One of the photographic gifts sent to Dr. John Hall-Edwards, who has been engaged in radiographic work at the military hospitals in South Africa, was a consignment of Messrs. Mawson & Swan's plates. In a recent letter to Messrs. Mawson & Swan Dr. Hall-Edwards writes: "Your splendid gift of plates arrived in splendid condition, and I have done some excellent work with them. I am using your 'Castle' almost exclusively for my X-ray work, and find it to act as perfectly here as at home."

WE are sorry to learn of the death of Mr. H. E. Farmer, one of the Vice-Presidents of the South London Photographic Society, which took place on the 10th instant, in the thirty-eighth year of his age. For a period of about eight or nine years he had suffered from consumption, and at Easter complications set in. At the formation of the Society he became a member of the Committee, and remained in that position until the state of his health obliged him to remove from London. He was a frequent exhibitor of architectural work and lantern slides, and was the recipient of many medals at home and abroad. Mr. Farmer, who was highly esteemed by a large circle of friends, leaves a widow and three children.

BRITISH ENTERPRISE.—It is extremely interesting to note that our genuine British firms can compete with their American brothers in the matter of smartness when they become determined to do so. The enterprising firm of Messrs. R. & J. Beck (Limited), of 68, Cornhill, E.C., sent one of their operators to photograph the crowd in front of the Mansion House celebrating the relief of Mafeking at 11 o'clock last Saturday morning, and at 12.15 the same morning this firm showed a print from the negative in their window. Also this same firm showed two 30×20 enlargements, and one 20×16 enlargement (from negatives taken at different times on Mafeking Day) at two p.m. on Monday. These attracted universal attention and admiration, the work being of the usual high standard of this well-known firm. We understand that the largest enlargements are from negatives taken with the new Beck-Steinheil lens, and it gives us very much pleasure to commend Messrs. Beck for their promptness and enterprise.

THE FORTHCOMING ECLIPSE.—A Reuter's telegram from Madrid, of the 18th instant, says that Sir Howard Grubb has arrived at Plasencia to observe the impending eclipse of the sun on behalf of the Royal Dublin Society, of which, it is well known, he is the Vice-President. Another telegram from Santa-Pola, in the province of Alicante, states that the English and Scotch astronomers have arrived there. The eclipse on the 28th, only partial in this country, begins at an early hour in the afternoon, so that the viewing of it does not entail sitting up, or rising, to some, at "unearthly hours." The eclipse here is only partial, but it is a good partial, and we have little doubt that, even here, there will be a goodly number of cameras brought to bear upon it. To secure photographs of it, lenses of long foci should be used, and it may be borne in mind that all combinations, if one of its components only

are used, has its focus about doubled. Thus a rapid rectilinear of ten inches focus will become a lens of about twenty inches focus, and yield an image approximately double the size that it will if the instrument be used intact.

**SIR WILLIAM ABNEY ON MODERN SCIENTIFIC INSTRUCTION.**—At the Annual Dinner of the Pharmaceutical Society Mr. Michael Carteighe proposed the toast of "Science," which, he said, might be regarded from two main points of view, first, the enormous strides which it had made during the Victorian era; and, secondly, the effect of scientific teaching in connexion with education. In his early days the teaching of science was hardly contemplated, and was certainly not recognised as a method of intellectual training; but the men who fought for it, such as Huxley, Tyndall, and Herbert Spencer, and those who gathered round them, were ultimately successful, and science was now recognised by the two old Universities, and long before was recognised by the Scottish Universities, as a proper method of culture. The idea which was current for some time, that examinations would do everything, was falling into disfavour, and the proper teaching of science was being greatly developed. He had the greatest pleasure in associating with the toast the name of Sir William Abney, the head of the Science and Art Branch of the Government and the Controller of the General Elementary Education and Science throughout the country. He was not only a man of science, but an experimental philosopher of the highest type, and distinguished for his researches in various branches of physics. Sir William Abney, in reply, after thanking Mr. Carteighe for what he had said of himself personally, said that this toast really was unnecessary, as it was implicitly contained in the three previous ones, though he must admit that a little more science in Parliament would be welcome. It was with the greatest satisfaction that he found that scientific instruction was increasing so largely throughout the country. When he first had to do with scientific instruction under State control, he found that all the laboratories he could muster up for the instruction of the poorer classes could be counted on one hand; at the present time there were nearly 700 scattered throughout the kingdom, giving instruction to between 18,000 and 20,000 students. That was something to boast of in fifteen years, and, although Parliament did not quite understand all scientific subjects, it was always ready to vote money for the purpose. Science was not out of place even in military matters, and was very useful, and had proved as useful in South Africa as the dogged perseverance and bravery of our soldiers, and it was also capable of revealing facts hitherto undreamt of in the realms of industry and commerce.

## Commercial Intelligence.

We understand that Kodak (Limited) have opened a wholesale distributing depôt, with a retail shop, at 96, Bold-street, Liverpool, and they will open a similar warehouse and shop at 72, Buchanan-street, Glasgow. The Liverpool depôt will ensure the more prompt supply of Kodak goods to the trade in the north-west provinces, and Glasgow will serve the same purpose to such dealers in Scotland as wish to take advantage of the centre. Statements which have been made as to further extensions in the United Kingdom out of London are entirely without foundation.

**AN OLD-ESTABLISHED RESIDUE BUSINESS.**—After being established for a period of over fifty years, the business of J., J. J., & T. G. Blundell has recently been removed from No. 162 to No. 199, Wardour-street, London, W. This removal has given opportunity for the erection of premises specially designed for the varied purposes of the business. To our readers Messrs. Blundell will be particularly known for the speciality which they make of dealing with gold and silver residues, in which connexion they have been so long and favourably appreciated by a world-wide circle of clients. The premises are large, light, and lofty, and the furnace-room is a model of completeness and efficiency. For obvious reasons, the business of residue reduction is not so extensive as formerly, but the firm of Messrs. Blundell is perfectly equipped to meet all the requirements of modern photographers in this regard. The supply of nitrate of silver and chloride of gold are also among the departments of the business.

In last week's JOURNAL we printed a report relating to an application made at the Dorchester Bankruptcy Court for his discharge from bankruptcy by Mr. A. H. Cox, photographer, Weymouth. The report which reached us from a press agency originally appeared in a Dorset newspaper. From correspondence that has been addressed to us it appears that Mr. A. H. Cox, the gentleman above referred to, was incorrectly described as a photographer in the reports, the fact being that he is, or was, a tobacconist, and has never been in business as a photographer. It further appears that at Weymouth there is a photographer named Mr. Walter G. Cox, of 3, St. Mary-street, who has been in business for the last twenty years, and is well known in England and abroad. We very much regret if any annoyance has been caused to Mr. Walter G. Cox (who has never been bankrupt) by our publication of a report incorrectly describing Mr. A. H. Cox, tobacconist, as a photographer, and trust that the publicity we are giving to this explanation of the matter will remove any misconception of which he may have been made the object.

**THE WARWICK COMPETITIONS.**—The following is the list of awards of the Warwick Competition for May:—10l. prize, Mr. Alfred Shaw, Photographic Dealer, Ashton-under-Lyne, *Cows in River Stour*; 5l. prize, Mr. C. T. Holland, 2A, Princes-road, Liverpool, *Radiograph of Boy's Hand*; 1l. prizes, Mr. W. Arkless, Victoria-road Studio, Bensham, *Landscape with Clouds*; Mr. E. G. Ballard, Photographer, Welsh-street, Chepstow, *Bromide Print of Baby*; Mr. A. M. Bosdet, Dowsett-avenue, Southend-on-Sea, *Carved Oak Porch*; Mr. W. Bridgford, Windsor-road, Rathmines, Dublin, *Snap-shots of Queen's Procession*; Mrs. Broughton, 4, Embankment, Bedford, *An Old Font*; Mr. W. G. Buchanan, 17, Sandyford-place, Glasgow, *A Misty Morn*; Rev. E. T. Clark, Brunswick-road, Gloucester, *Monks' Washing Place*; Mr.

F. Crew, Lyncroft-mansions, Finchley-road, N.W., *Golden's Hill, Hampstead*; Mr. N. Fordham, 4, Poster-lane, Cheapside, E.C., *A Study of Cattle*; Miss L. Harvey, Duddington-avenue, Smithdown-road, Liverpool, *White Clematis*; Mr. John Hummel, 88, Salcott-road, Wandsworth Common, S.W., *Departing Winter*; Mr. A. J. Keith, Courtlands, Ealing, W., *Laddie*; Mr. H. M. Lomas, 3, Selborne-villas, Minehead, *Going to the Meet*; Mr. H. V. Mitchell, 17, Brunswick-street, Cheetham, Manchester, *Marble Reredos*; Mr. S. Yates Omerod, 64, Forest-road, Southport, *Interior of Old Church*; Mr. E. A. Russell, Southgate College, New Southgate, N., *Rock a Nore, No. 1*; Mr. J. Spavin, Photographer, New Brumby, *via Doncaster, Avenue of Trees*; Mr. C. J. Thompson, Warren Bank, Brampton, Cumberland, *Rural Scene*; Mr. A. Waterall, Brighton Grove, Flixton, Manchester, *Watching for Daddy*; Mr. J. A. Wilson, 53, Kenilworth-road, Egremont, Liverpool, *Pals*.

**THE THORNTON FILM COMPANY, LIMITED.**—The first meeting of the shareholders of this Company was held on Tuesday, May 15, at the Victoria Hotel, Manchester, Mr. J. E. Thornton in the chair. The Chairman reported that the shares of the Company had been considerably over-subscribed, although the issue had not been publicly announced. A suitable building for the works had been secured at Alfrincham, and its equipment with the special machinery required was now almost completed. Although the Company had only been formed four months, their preparations for manufacturing were so advanced that they would be turning out their films for the market almost immediately. Dealing with the prospects of the Company, Mr. Thornton stated that the Company's films would be as easy to use as glass plates, and would be sold at a similar price. They were very much lighter in weight than plates, this being a distinct advantage where a large supply had to be carried, for example, in outdoor work. The development of the film would be as easy as the development of a plate. The transparent backing of the new film was designed both as a support for the film when in use and to prevent its curling up during development. It admitted of the progress of development and density being easily seen when held up to the ruby light, and could be readily removed from the film when dry. Satisfactory arrangements had been made for bringing the merits of the film before the notice of all prospective users. In reply to inquiries by several shareholders, Mr. Thornton explained that there had already been an enormous number of applications for the new film, both from photographers and dealers, at home and abroad. Mr. E. H. Williams, of Bolton, stated that he had been over the factory, and was much impressed with all he saw. He thought the Company had a capital factory, thoroughly up to date and splendidly equipped, with everything of the newest and best. Captain Williams, of Southport, thought that there would be a good market for the new film for cinematograph work, on account of its non-inflammable nature. Mr. J. H. Boydell, of Manchester, wished to express his pleasure and surprise to find on visiting the factory a few days ago that it was almost ready for work. From what he saw there, and his general business experience, he could say that great ability had been shown by some one in the mechanical and chemical arrangements for manufacturing the film. Mr. Rothwell, the Technical Manager, reported that, in spite of the difficulty experienced in obtaining machinery and plant, owing to the brisk state of trade in engineering businesses, the equipment of their works would be entirely completed by Whitsuntide, when they expected to be in full running order for turning out the film for sale. Mr. Slater, of Southport, moved a vote of thanks to the Chairman for presiding and congratulated the Company on the progress made with its arrangements, which was seconded by Mr. Boydell and carried unanimously.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
28.....	Bradford Photo. Society .....	Exhibition of Members' Work.
28.....	Southampton .....	<i>Faking Negatives.</i> Mac Mills, sen.
28-31 .....	Southport .....	Exhibition of Members' Work.
29.....	Bootle .....	Prize Slides.
29.....	Darwen .....	Excursion: Chatsworth and Matlock.
29.....	Hackney .....	Developers. W. F. Fenton-Jones.
29.....	Royal Photographic Society ...	{ Opening by Dr. P. H. Emerson of an Exhibition of his Works.
31.....	London and Provincial .....	{ <i>A Few Notes on Photographic Optics.</i> J. W. Hodges.
June.	Southsea .....	Paper: <i>Portraiture.</i>
1.....	Liverpool Amateur .....	{ Excursion: Eve-ham and District. Leader, C. F. Depree.
2-5.....	South London .....	{ Excursion: Tunbridge Wells. Leader, Messrs. Regers and Slater.

### ROYAL PHOTOGRAPHIC SOCIETY.

MAY 22,—Technical Meeting,—Mr. Chapman Jones, F.I.C., F.C.S. (Vice-President), in the chair.

Mr. ALFRED WATKINS sent a note on the subject of

### HYDROQUINONE AND COLOUR IMPRESSIONS.

At the Technical Meeting in March last, Mr. Watkins read a paper entitled "Some Developers Compared," and, in the discussion which followed, a reference was made to statements by Mr. Ives and others to the effect that hydroquinone showed a reluctance to bring out the red impressions, and that for that reason it should not be employed for developing three-colour negatives, but that metol did not share this defect. Mr. Watkins thought that, if this observation was correct, it was an exceedingly interesting point that one developer should be able to differentiate between the light impressions formed by different colours, and he had therefore made some experiments the results of which were detailed in the present communication. A

Lumière panchromatic plate was exposed in different parts through three screens—blue, green, and red, for the relative times which previous trials had shown to be necessary to give equal light impressions. On development with metol, without bromide, the red, green, and blue strips appeared simultaneously in eighteen seconds; with hydroquinone development the same result occurred in seventy-five seconds, and with a mixture of metol and hydroquinone all appeared in twenty-four seconds, there being no lagging of the red impression with hydroquinone. Cadett spectrum plates, exposed through the three screens in the Hurter & Driffield exposing apparatus, did not show that hydroquinone failed to do justice to the lower tones of the red exposure, and a successful attempt with the same plates to obtain speed readings through the red and blue screens by daylight also showed that the red tones did not lag. Both with metol and hydroquinone the red impression gave a steeper gradation than the blue, both being developed for the same period, a fact which threw a doubt upon the usual presumption that all three-colour records must be developed for the same time to secure the same gradation in each. Mr. Watkins came to the conclusion that Mr. Ives had drawn wrong deductions from his observations. A weak tone appeared to lag behind with hydroquinone, but not with metol. It was probable that Mr. Ives's observation of the red tones lagging behind when the hydroquinone developer was employed arose from the fact that they were weak tones, not because they were red, and that, if the red tone had been strong, he would have found that the blue appeared to lag.

Mr. SANGER SHEPHERD explained some experiments which were made in connexion with the Cadett Spectrum plate. When developing with metol it was found that the images of four colour patches—red, green, blue, and white—all came up equal in density and in the same time; but, with a hydroquinone developer, the blue appeared first, and the red came up about half a minute afterwards; if development was continued for about two minutes, and the negative fixed, the red (which appeared far lighter than the blue) was really more dense than the blue which appeared before it.

Mr. C. J. THOMPSON, who had recently been travelling in Russia, said that the Czar was devoting a great deal of attention, to three-colour photography, and was personally making some investigations upon the subject, the results of which he (the speaker) hoped to be able to ascertain and communicate to the Society.

Mr. SANGER SHEPHERD added that, as the result of long experience in practical three-colour work, he was of opinion that metol had a very great advantage over hydroquinone; with it one could govern the density of the negative by the time of development, but with hydroquinone the tones would differ according to the duration of development.

Mr. T. E. FRESHWATER said he had not made many experiments in this direction, but those he had made had been with the pyro-soda developer, and the density under the red and blue screens appeared to be relatively equal.

Mr. SANGER SHEPHERD said hydroquinone was exceedingly useful for black-and-white work, but the quality that made it so valuable in that case unfitted it for three-colour work, where it was necessary to obtain every range of gradation with very little density. Metol, and similar developers, gave beautiful negatives, full of gradation, and without the objectionable blocking up of the whites. Blue and red both gave the same gradation.

The CHAIRMAN said that, as stated in his recent paper read before the Society, he got a difference in almost all cases, and the experience of Sir W. Abney and Mr. Watkins was the same. He thought Mr. Shepherd must have been using plates of an exceptional character.

Mr. SHEPHERD replied that the Spectrum plate was exceptional in character, and he attributed his results to its very high speed.

#### IMPROVEMENTS IN CAMERAS.

Mr. AGAR BAUGH exhibited two cameras in which he had had certain improvements made, especially with regard to their use with a variety of lenses, the extent of rising front and swinging back, and their extension for tele-photography. He also referred to the method of focussing with tele-photo lenses, and strongly advocated the use of a telescope for the purpose of detecting the presence of mist or moving objects, invisible to the eye, which would interfere with the sharpness of the picture.

#### COMING EVENTS.

The Exhibition of pictures by Mr. F. H. Evans closes to-morrow (Saturday). On Tuesday next, May 29, Dr. P. H. Emerson will open an exhibition of his works, and will deliver an address; and, at the Ordinary Meeting on June 12, Mr. H. L. Aldis, B.A., will read a paper on "The Construction of Photographic Objectives: Mathematical Investigation."

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 17.—Mr. R. P. Drage in the chair.

Mr. PHILIP EVERITT showed a new form of plate-carrier or sheath that has been just brought out by Newman & Guardia. It is made in one piece, two edges being turned over on the back and stamped with a ridge to give greater stability to the whole. It was, he considered, a great improvement and a neat piece of workmanship.

The CHAIRMAN reviewed the particulars of the recent arrest of a photographer, near one of the fortified towns in France, on a charge of spying, and expressed his surprise that there were still so many people who so incautiously photographed in the vicinity of military posts.

Some discussion took place on the announcement of a new platinotype paper with which no calcium was wanted, or any special precautions in the matter of storage. Its supposed similarity to the old Pizzighelli paper was also referred to.

Mr. A. HADDON showed the results of some experiments he had been making with some samples of collodio-chloride self-toning paper, some very bad prints upon which had been shown at a previous meeting. He showed a print fixed according to the instructions issued by the makers, which was in a very blotchy state. His experiments went to show that the fault would be eliminated, however, and that the instructions were inadequate to the successful working of the paper. Further prints were passed round, which had

been subjected to a treatment particulars of which Mr. Haddon reserves for the present, showing a practically complete removal of the bad tendencies of the paper which arose in the substratum.

#### KEEPING QUALITIES OF FILMS.

The CHAIRMAN, in answer to an inquiry, repeated some of his former experiences with films in hot climates, such as one had to go through in a tour round the world. He found that in such cases the latent image was practically falling off from the moment after exposure. Films that would keep a long time before exposure soon began to deteriorate in the sense that the light effects did not last, although he had found that, given a sufficiently long time after exposure, the film could be again exposed without much fear of the former image asserting itself. The emulsion, it would thus appear, was still good, but its power to retain the latent image was very slight. Under similar circumstances, he should certainly develop films within a short time of their exposure.

Mr. A. HADDON reminded the members of the difference between cut films and rollable films. The former were sliced from a block, and the latter coated on glass. Much trouble arose from imperfect washing of the pyroxyline. Some time back he went through a smokeless-powder factory. Smokeless powder was made from sawdust, which, after being nitrated, takes a fortnight to wash, and during that time it is washed continuously with hot water and cold water again and again. The whole object of the treatment is to get rid of the merest trace of acid, which would be fatal to the success of after-processes. He was quite sure that no user of pyroxyline for photographic film purposes went to this trouble, it was too expensive, and the chief trouble with cut films was due to the presence of this acid and the decomposition it set up. Cotton-wool used for making the pyroxyline consisted really of a series of minute tubes, and the amount of washing required to clear these of the acid was immense. In the rollable film, where, of course, the same state of things might originally exist, the solvents used tend themselves to remove by decomposition that which, left in the other film, causes its early deterioration.

Croydon Camera Club.—All amateurs, and most professionals, have, at one or another time, been plagued by photographs lacking in half-tone. Especially is this liable with interiors, such as include brightly lit windows. A new ingredient to be added to the ordinary developer has been discovered by Mr. BEN E. EDWARDS, who on Wednesday, the 16th inst., explained how this latest addition to the photographer's collection of chemicals is advantageously usable in the making up of developer designed to reduce contrast. Introducing Mr. Edwards, the PRESIDENT stated that every addition to the power of controlling or varying the result of an exposure by altering the scale of gradation in a negative was a great gain to the art side of photographic procedure. Further, he was disposed to welcome every fresh complication or specialisation in photographic practice. Of late years photography had been inclined to become cheap and nasty—easy and profitless. By making it less so it would be the more worth while for clever people to devote their best attention to the calling. Mr. EDWARDS handed round a large number of negatives and prints in pairs, in which one of the pair was developed with the normal amount of bromide, while the other had the bromide replaced by about  $\frac{1}{4}$  drachm per ounce of a ten per cent. solution of boro-tartrate of potassium. The boro-tartrate seems to act as a retarder of the chemical action set up by the reducer, but, instead of checking a deposit in the shadows and lighter half-tones, it appears able to stop an excessive deposit in the high lights. Hence, although, like bromide of potassium, it slows down a developer, it does not induce hardness, but rather the reverse. Whether the resulting negative would materially differ from one in which an unrestrained reducer was used no visible evidence was adduced. However, in cases of bright windows and deep shadows, as found in interiors, probably a restrainer of some sort is a *sine-qua-non*, in which case there seems no room to doubt but that Mr. Ben E. Edwards's discovery is of distinct value. A considerable amount of discussion ensued upon the subject of the lecture, and on the use of restrainers generally. Mr. SALT contended that bromide only shortened the scale in the earlier stages of development, and was, at any rate, useful in keeping down general fog. Mr. WRATTEN considered that the leaving out of bromide from the developer was a passing fad, and that there was no good reason shown for doing without it, it was a convenience in controlling development and checking fog. Mr. WILLCOCKS stated that he never used any restrainer, most of his exposures being very full ones. He had never found any need for a restrainer. In answer to the President, he stated that his practice was confined to the use of medium rapidity plates. With a "fast" plate he should think a restrainer needful. Mr. SCHAEER stated that he had used the Cadett lightning plate without a restrainer, and found no ill effects follow; but he did not state whether in any case over-exposure had to be reckoned with. Other members having taken part in the talk, at the instance of the PRESIDENT, who said the Club was much honoured by their fellow-member having made what was apparently an important contribution to photographic knowledge, a hearty vote of thanks was accorded to Mr. Ben E. Edwards.

Hackney Photographic Society.—At the meeting on the 15th inst., Mr. T. BOLAS gave a lecture and demonstration on

#### GLASS-BLOWING.

Mr. Bolas dealt with his subject in a most thorough way, and showed a number of beautiful experiments. Among other things he described the various kinds and methods of manufacture of the glasses used for light filters in photography.

Redhill and District Camera Club.—The winter session of the Redhill and District Camera Club was brought to a close on Tuesday, May 15, when Mr. T. PERCIVAL PADWICK gave a lecture and demonstration on

#### THE INTENSIFICATION AND IMPROVEMENT OF NEGATIVES.

Mr. William Brooks, the President, was to have given a lecture on this subject, but was too unwell to attend. General regret was expressed by the members at the continued indisposition of the President. Mr. PADWICK

demonstrated and described various methods of intensification and of reduction, both general and local. Mr. HENRY SPEYER gave some practical hints on retouching, and on local reduction by the aid of methylated spirits of wine. He also showed a remarkably fine photograph of an approaching storm on the Alps, taken under most trying circumstances, for so great was the force of the wind that, in the very act of making the exposure, Mr. Speyer and his camera were blown to the ground.

FORTHCOMING EXHIBITIONS.

1900.  
 May 25 ..... Plymouth Photographic Society. Hon. Secretary, W. H. Harris, 5, Clarendon-place, The Hoe, Plymouth.  
 July 9-14 ..... Photographic Convention of the United Kingdom (Newcastle-on-Tyne Meeting). Hon. Secretary and Treasurer, F. A. Bridge, East Lodge, Dalston-lane, London, N.E.  
 August 21..... Royal Cornwall Polytechnic Society. W. Brooks, Laurel Villa, Wray Park, Reigate.  
 October 1-Nov. 3 ... Royal Photographic Society, New Gallery, Regent-street. The Hon. Secretary, 66, Russell-square, W.C.  
 November 12-17 ..... Ashton-under-Lyne.  
 ,, 21-23 ..... Hackney Photographic Society.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

Patent News.

- THE following applications for Patents were made between May 7 and May 12, 1900:—  
 CAMERA.—No. 8615. "The Williams Double-action Camera." A. H. WILLIAMS.  
 PANORAMIC CAMERAS.—No. 8674. "Photographic Apparatus for Taking Panoramic Views." Communicated by A. Luino & Co. O. IMRAY.  
 BACKGROUNDS.—No. 8810. "Improvements in Photographic Backgrounds." J. MARTYN.  
 DARK SLIDES.—No. 8815. "Improvements in Photographic Dark Slides or Plate-holders." W. F. GILES and F. P. WHITEHEAD.

Correspondence.

DARK ROOM IN PARIS.

To the EDITORS.

GENTLEMEN,—It may interest your readers to know that I have induced the proprietor of this hotel to arrange a dark room for the free use of visitors. There is an ample and constant supply of water and a sink, and so arranged that all ordinary photographic operations may be conducted. Many hotel keepers provide cycle accommodation, but are in ignorance of the importance of a well-arranged dark chamber. The usual excuse is, "Oh, they only want to change plates." I notice Mr. York hard at work in the Exhibition, and, doubtless, he will have a good set of negatives. At present I am resting after my winter campaign.—I am, yours, &c.,  
 A. L. HENDERSON.  
 Hôtel Britannique, 20, Avenue Victoria, Paris, May 19, 1900.

WATKINS STANDARD EXPOSURE METER.

To the EDITORS.

GENTLEMEN,—In your very appreciative notice of the new pattern, you inadvertently convey the impression that five pointers have to be moved. There are only three pointers (for plate, diaphragm, and light) to be set before the final pointer indicates the exposure. The two extra scales for subject and copying are ready to hand when wanted, but have no pointers, and are passed over for all ordinary work.—I am, yours, &c.,  
 ALFRED WATKINS.

ENGLISH VERSUS FOREIGN PHOTOGRAPHIC ART.

To the EDITORS.

GENTLEMEN,—I am writing to you as I see articles speaking about a probable invasion by the French, but what about the actual invasion in an art sense that I see everywhere I go, offering to make portraits for nothing—at any rate, getting people, if possible, to send to a foreign country away from English jurisdiction? We have in trade, as in everything else, to compete, and are the foreigners going to beat us in quality, correctness, and cheapness, and so take the trade abroad?

It is some years ago when, at the Art Schools of South Kensington, one of the masters there told me, in speaking of a pupil who neglected the antique and was painting from life, that we should never hear of him again. Now, what has that to do with the above? I will tell you. Last summer I was away in the country, and I set to work to read again Flaxman's lectures to the Royal Academy on sculpture, and in one of them he says: "When we look upon the ancient Egyptian sculpture, stiff in form, lacking in perspective and drawing, and far from what was obtained at a much later date, yet it had thus one element of perfection—that the statues were invariably seven heads in height; that seems to have been one of the first correct standards of the human form." Now, we are told nothing happens by chance; all is corrected by measure, and the antique Greco-Roman sculptures are used at the Royal Academy's Art Schools (where I was seven years a student). South Kensington Art Schools use those works to teach students the further and more perfect development of the human form which centuries have pronounced perfect. Now I set to work to follow out the principle of proportion; and if you follow out, as I enclose, you will find drawings can now be made without much mental effort with a rapidity and correctness and truthfulness of proportion that I think may go far to beat Mr. Foreigner on his own ground. I invite you to call on me and let you see for yourself, and others, what may be unknown to many: quicker, cheaper, and better than enlargements, using them as an aid occasionally rather than a basis, my life-size heads costing in time, ten minutes.—I am, yours, &c.,  
 86, Warwick-street, Belgravia, S.W., May 16, 1900. JOHN BOOL.

[Perhaps some of our readers may be interested in Mr. Bool's theories, and will feel disposed to avail themselves of the invitation contained in his letter.—EDS.]

THE STEINHEIL LENSES.

To the EDITORS.

GENTLEMEN,—The letter of Messrs. R. & J. Beck, in your issue of the 18th inst., forces me to obtrude upon you and your readers a reply.

Messrs. Beck's statement reads thus: "In your issue of April 27, you inserted a note to the effect that Mr. Arthur Rayment was English agent for Messrs. Steinheil's famous lenses. We wish to point out that our firm have the sole British licence for these lenses.

"The arrangement with Mr. Rayment was due to a misunderstanding. We beg to say, on Dr. Steinheil's authority, that it will be immediately cancelled."

I find in your issue of May 4 (not April 27) a notice to the effect that I am (not that I was) agent for the United Kingdom for the celebrated firm of Steinheil Fils of Paris (Munich being added in error).

In confirmation of your statement I hold a document signed by Messrs. Steinheil Fils of Paris. This document cannot be regarded by Messrs. Steinheil Fils as a misunderstanding, since it arose out of their invitation, and two months elapsed between their invitation to me and the exchange of signed documents, wherein a definite term is set forth as the minimum life of the agency. I cannot, therefore, understand Messrs. Beck's assertion that it will be immediately cancelled, *i.e.*, unless by my consent, which up to this moment, I have not given. Permit me to point out, for Messrs. R. & J. Beck's information, that the agency conferred upon me cannot affect their interests since the lenses, &c., which I offer are manufactured by Steinheil Fils in their own workshops. Obviously, they cannot be confused with the lenses of Messrs. Beck, which, according to their catalogue, are not made by Steinheil Fils at all, but by themselves at their factory in Holloway and upon which they have acquired a licence to engrave the name of Steinheil coupled with their own, and which they issue under the style Beck-Steinheil. Much regretting to trespass thus upon your space, I am, yours, &c.,  
 ARTHUR RAYMENT.

125, Earlsam-grove, Forest Gate, May 21, 1900.

A PROGRESSIVE PHOTOGRAPHIC SOCIETY.

To the EDITORS.

GENTLEMEN,—Herewith I have pleasure in sending you our summer programme of arrangements. You will notice I have at length been successful in forming a ladies' section, which promises to be a great success. A special course of lectures has been arranged for them, and on the first excursion last Wednesday to Liphook they turned up in force. A very enjoyable day was spent, and many excellent photographs taken, the tea, of course, being quite the feature of the day's outing.

This year promises to be the most successful in the annals of the

Society. The membership is steadily on the increase; the expenses are kept down; there is a good balance in hand and no debts, and I hope to be able to record further progress in time.—I am yours, &c.

F. J. MORTIMER, *Hon. Sec.*

*Southsea Amateur Photographic Society, 10, Ordnance-row, Portsea.*

## UNDER-CUT PHOTOGRAPHIC GLASS AND EXTRA FULL-CUT PRINTING FRAMES.—THE RESULT!

To the EDITORS,

GENTLEMEN,—I, too, like Mr. Hume in his letter to you last week, would insist that photo dry plates should not be cut smaller than their normal size. Then add to this the fact that our printing frames are all extra full made to their respective sizes. With these combined errors our negatives are often too small to catch the frames all round, and so with careless or rash printers a plate is not seldom broken while being pressed out of part of the frame. In this way we have lost many valuable negatives, the subjects of which were hundreds of miles from us, and, in many cases, not retakable, owing to either natural or artificial alterations.—I am yours, &c.

J. P.

May 21, 1900.

## Answers to Correspondents.

\* \* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street Strand, London, W.C. Inattention to this ensures delay.*

\* \* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\* \* *Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.*

### PHOTOGRAPHS REGISTERED:—

T. Everitt Innes, 108, Wellington-road, Heaton Chapel.—Two photographs of Miss Robinson's wedding party.

E. Binns, 69, Sadler-street, Durham.—Photograph of presentation of freedom of City of Durham to Captain Lambton.

G. Morrison, Birr, Ireland.—Photograph of John's-place, Birr. Photograph of Cumberland-square, Birr. Photograph of Episcopal Church, Birr.

BEGINNER.—A perfectly practicable instrument.

AGREEMENT.—W. The agreement is of no good as it is. It must be stamped. The cost will be sixpence only. Then it will be binding.

J. BROWNING.—Caramel may be obtained of Messrs. Litchenstein & Co., Silvertown; but the prepared backing may also be had of that firm, and of Messrs. Gear, Chidley, & Co., Great Portland-street, and other houses.

DRIED ALBUMEN.—A. C. asks; "Can you tell me how much dried albumen should be used for photo-litho transfers to be equal to the white of one egg?"—Eggs vary considerably in size. Dried albumen dissolved in six or seven times its weight of water will give a solution about the consistence of white of egg.

ILLUSTRATING CATALOGUE.—BIRMINGHAM. The best process for illustrating the catalogue, as process blocks are objected to, will be the colotype process. For the small edition required, it will not be very much more costly than if process blocks were used, because they, of the size required, would be somewhat expensive.

PHOTOGRAPHING IN THE NATIONAL GALLERY.—S. MINNS. You will not be allowed to use a camera in the National Gallery without the permission of the Trustees. This, we believe, is only granted to professional photographers who publish their work, so that the public get the benefit of the reproductions. The same regulation, we think, applies to the Tate Gallery.

AN OLD CLARENCE B.C. MAN.—I. Since its introduction commercially, about nine years ago, we have repeatedly seen the system worked, and excellent results produced by it. 2. In the first case, a lens of the anastigmatic type; in the second, one of the old rectilinear form. Write again if we can be of further help. Our recollection of your Club goes back twenty years.

LENS FOR PORTRAITURE.—A. A. A. says: "I have the offer of a No. 3 D group lens of sixteen or seventeen inches equivalent focus, cheap. Will you please tell me what length it would require for full-length cabinets and groups? also if it will be much slower than the B cabinet lenses?"—The distance required for a full-length with a lens of that focus will be about eighteen feet between camera and sitter, and for full-length groups a greater distance according to the number of figures. The D series require about four times the exposure of those of the B series when both are used with their full aperture.

THE MACAIRE FILM.—H. COLEBROOK writes: "I see in your last issue you give the specification of Macaire's photographic film. The idea seems so good, I should be much obliged if you would tell me if the film is made commercially yet, and, if so, by whom?"—In reply: The film is made commercially. If you write Mr. G. Macaire, Nightingale-road, Rickmansworth, he will probably send you a sample.

SPOTS ON PRINTS.—AJAX writes for our opinion as to the cause of spots on some enclosed prints. The (albumenized) paper is sensitised on a bath standing at about 55 grains.—We regret that, with only the strength of the silver bath to enlighten us, we can give no opinion as to the cause of the spots beyond that they are due to faulty manipulation at one stage or other, but which it is impossible to say on such meagre data.

COPYING GLASS POSITIVES.—B. & Company write: "We have a glass positive brought to us to copy and make an enlargement from, but there are no whites in it, what should be white is nearly brown. Can you give us a hint on the subject?"—If the picture will not yield a good copy in the camera, try removing the varnish from the back and using it as a negative to make a transparency on a dry plate. That is the best way to copy some glass positives.

PAINTING STUDIO.—TENANT. If the studio requires painting, and the landlord declines to have it done, we expect you will have to have it done at your expense. You want it done for your convenience or idea, and not for the landlord's. He, of course, does not care whether it is done or not, as he has no interest in the matter—whether it is shabby or not. If there was an agreement that the landlord should have the studio painted, &c., at periodical times, the case would be different.

BROWN TINTS ON P.O.P.—P.O.P. asks: "Can you tell me how to avoid a brown tint in the whites of P.O.P. prints? I have used the ordinary sulphocyanide bath and the formalin toning bath recommended in the JOURNAL some months ago, but cannot avoid this trouble."—Without seeing an example of the stains we cannot offer an opinion, as there are so many causes that may conduce to degrade the whites of prints. One very prolific one is washing the prints in dishes that are not perfectly clean, imperfect fixation, contaminated water, &c.

INSOLUBLE CARBON TISSUE.—CARBON asks: "How can one tell whether carbon tissue is insoluble or not until it is printed, if there is any method of doing so? I have often printed tissue and failed to obtain a picture, and this I have attributed to insolubility in the tissue?"—The solubility or otherwise of carbon tissue is easily tested. Place a piece of the suspected tissue in cold water for a few minutes, then put it into water at a temperature of from 90° to 100° F., and, if it is soluble, the coating of the paper will begin at once to dissolve.

TRANSFERRING FILMS TO COPPER.—H. J. JAMES says: "I wish to transfer films from dry plates to copper plates, but I find, when they begin to get very dry, in most cases they peel off again. Can you tell me how to make them stick to the copper? I have tried cleaning the copper with chalk and have soaked the films in methylated spirits before removing them from the dry plate and do not soak them in alum?"—We doubt if you will get the films to adhere unless you employ some adhesive as a substratum on the copper. Make the metal perfectly clean and coat it with a thin solution of gelatine, allow it to set and then float the films on to it.

DYNAMOS FOR CINEMATOGRAPHIC PROJECTIONS.—A ZASLISA asks: "What horse power is required and what sized dynamos for light to suit projections of cinematographs, and what would be the cost of dynamo, and where made?"—It will all depend upon the light required, and that is dependent upon the scale of the projection. A small screen will require far less light than a large one. Any of the electrical engineers will quote you for a dynamo and, at the same time, inform you the power that will be required to drive it. The power will, of course, be dependent upon the size of the machine. If you can get the current from the mains, you will find it far more economical than having your own electrical installation.

SPOTS ON PRINTS.—B. F. C. R. writes: "I enclose three silver prints, and should esteem it a favour if you would give me your opinion as to the cause of the spots which show after they are mounted. The silver bath is kept up to sixty, and the paper is floated for three minutes. I may say that sometimes we have a large batch of prints, and they are washed in a dish. The size of dish is twenty-four inches by fourteen, the depth of dish is only four inches. Would the cause be here?"—We can only give the same reply as that to "Ajax." The vessel in which the prints are washed seems a somewhat small one for a large batch of prints, unless they receive careful attention all the while and the water being constantly changed and the prints closely drained between each change.

COPYRIGHT.—J. H. writes: "I shall be very glad if you will kindly inform me if it is a rule for publishers who pay for the right to reproduce a copyright picture to sell duplicate blocks to other publishers without paying anything further to the holder of the copyright? A few years ago Messrs. Cassell & Co. paid me 12s. 6d. each for the right to reproduce two pictures, and I find they have supplied duplicate blocks to music-sellers, and my pictures are printed on sheet music. [Cassell & Co. say that, when they pay for right to reproduce a picture, they have also the right to sell blocks to other firms. I feel sure this is not the rule; is it? Messrs. Cassell say they do not claim the copyright, but the right to use and sell as they like."—In reply: There is no rule in the matter. In granting the right of reproduction, you probably did not specify that it was for one issue only; hence Messrs. Cassell's action. For years we have included in our ALMANAC forms to be used in giving the right of reproduction. These were drawn up by the Photographic Copyright Union, and designed to obviate such cases as yours.

### EX CATHEDRÀ.

THE declared object of the *Ilford Every-day Book*, a copy of which has been sent to us by the Britannia Works Company, of Ilford, is to show in brief what dangers await the unwary photographer, how he may recognise them, and how avoid them in future. Were it not that many years' experience in the examination of photographic failures, and the indication of their causes, has persuaded us that a liability to mistakes in camera work besets the majority of plate-users, we should be less strongly convinced than we are of either the utility or the necessity of this book; but, in familiar language, it supplies a felt want—a want that will continue to be felt so long as photography itself relies primarily upon the exposure and development of sensitive salts in gelatine. The *Ilford Every-day Book* consists of fourteen pages of notes relating to common faults, their causes and prevention, illustrated by fifteen phototypic reproductions of negatives showing blemishes and defects of an only too familiar kind. Photographic instruction is never so certain of reaching its mark as when it is founded on the principle of parallelising bane and antidote;

and, in the case of the *Ilford Every-day Book*, the principle is carried out to perfection. Every plate-user should get a copy of this really useful book.

\* \* \*

MR. RUDYARD KIPLING's popular set of verses, “The Absent-minded Beggar,” has been the means of raising so much money for the benefit of those who have suffered by the South African war that their faults of taste and style may well receive the forgiveness of the most hypercritical. The song reaches us this week in a very attractive form. It is set out in a sixteen-page book, printed in colours on the Orloff press, which simultaneously prints several colours, and it is illustrated by eminent artists, whose work is supplemented by pictures of the arms and flags of the three kingdoms and other national symbols. The Printing Arts Company, of Holbein House, 119–123, Shaftesbury-avenue, London, W.C., who are sending out this Royal Edition of the poem, price it at one shilling, and state that for every copy sold threepence will go into the “little tambourine” of our contemporary the *Daily Mail*. From a letter on the subject received from Mr. William H. Ward, the managing director of the Company, we gather that 100,000 copies of the book have been produced. It is very beautifully printed indeed, and, as a souvenir of the war, it will probably be valued by many to whom the ingenuity of the Orloff machine is of comparatively little account. We may say that we have seen the machine at work, and it struck us as destined to have a vast influence on the future of colour-printing—although trichromatic half-tone work offers it little or no scope.

\* \* \*

THE Morelograph is the name given to a machine for rapidly exposing bromide paper, which has been invented by one of our professional readers, Mr. H. L. Morel, of 126 Wellbeck-terrace, Mansfield-road, Nottingham. To show what the machine will do, Mr. Morel sends us two lengths of paper bearing a considerable number of developed bromide prints; these are uniform and of good quality. From a series of illustrations that are before us it is easy to perceive the main principles of construction adopted in the machine. It is of box form, and the negative is inserted upon the uppermost

side. A roll of sensitive gelatino-bromide paper having been placed inside the box, it is engaged in a spindle controlled by an external handle, and the source of light, gas or incandescent electricity, having been adjusted perpendicularly to the negative, all that it is then necessary to do is to draw the paper forward under the negative, intermittently shielding the latter from the light, of course, and the exposed roll of paper is subsequently withdrawn from the machine for the purpose of development. In so far as we can judge from the illustrations, the machine appears to be a simple affair; and it should be found of very decided service by photographers having considerable numbers of bromide prints to produce.

\* \* \*

THE Handbook of the Newcastle gathering of the Photographic Convention of the United Kingdom was issued to members this week, and in another part of the JOURNAL we reprint the arrangements that have been made for the meeting, which takes place from July 9 to July 14. The book has a stiff cover, the colour of the cloth suggesting khaki, and it contains several illustrations, the frontispiece, by Messrs. Wellington & Ward, being an excellent specimen of bromide printing. The obvious care taken in the compilation of the historical notes relating to Newcastle, Hexham, Durham, and Alnwick deserves special recognition. The programme, no matter in what aspect it presents itself, has an attractive appearance, and those who attend the meeting should be able to rely on passing a pleasant holiday, agreeably punctuated by photography. The best reward that could attend the efforts of the local Committee and Mr. Bridge, the general Hon. Secretary, to ensure such a desirable result would be a large gathering and a successful meeting. If our opinion is worth having on the matter, we should say that the Newcastle Convention—the last of the century—will fulfil the highest expectations in both respects.

\* \* \*

ON more than one occasion we have adverted to the enterprise of Messrs. Underwood & Underwood, of London and New York, in quickly securing stereoscopic photographs in those parts of the world upon which the eyes of the public were for the time being riveted, and only a month ago we gave some details of the efforts they were making to employ binocular photography at the seat of war. Now, whilst Lord Roberts's soldiers are marching across the Transvaal, and the end of the war still keeps out of sight, we are the recipients of a set of stereoscopic slides from negatives taken by Messrs. Underwood's operators on the battle-fields between December and February last, when the tide of success began to turn in favour of our arms. The set of slides numbers about seventy; they are entitled, *For Empire, Queen, and Flag*, and they are appropriately packed in a box covered with khaki. These slides do Messrs. Underwood signal credit, for we do not hesitate to say that they are some of the best war photographs we have seen. They illustrate most realistically many of the most striking of the earlier phases of the campaign, in some cases showing fighting actually in progress; and, when it is remembered that they have the additional feature of being stereoscopic, an idea may be formed of the immense interest attaching to them. We shall attach great interest and value to these slides, and shall be surprised if the public does not show an equal degree of appreciation.

## PHOTOGRAPHIC PATENTS AND THE PATENT ACTS.

THAT photographic inventors are more or less interested in the Patent Acts is proved by the lists of applicants for patents that appear in our columns weekly. The Patent Acts have, from time to time, been amended, but they are still in a very unsatisfactory state so far as patentees are concerned. The fees are very high, and the patentee, when he has paid them, has no official guarantee that his invention is really protected. It may have been anticipated, in fact may be as old as the hills, yet the Patent Office will take the fees; they ask no questions. They do that even if other patents have, only shortly before, been granted for precisely the same thing; though, of course, a patent granted under these circumstances will be invalid, yet the Patent Office has taken the money and granted it. At present it rests entirely with the applicant for a patent to find out for himself if his invention has or has not been anticipated. The case is different in most other countries.

We are pleased to see that the Board of Trade are now taking this matter, to some extent, into consideration. It has appointed a Committee to inquire into the working of the Patent Acts with reference to the following questions: "(1) Whether any, and, if so, what, additional powers should be given to the Patent Office to (a) control, (b) impose conditions on, or (c) otherwise limit the issue of Letters Patent in respect of inventions which are obviously old, or which the information recorded in the Office shows to have been previously protected by Letters Patent in this country; (2) whether any, and, if so, what, amendments are necessary in the provisions of Section 22 of the Patents Acts of 1883; and (3) whether the period of seven months' priority allowed by Section 103 of that Act to applicants for Letters Patent under the International Convention may properly be extended, and, if so, on what conditions?" These are the points to be inquired into by the Committee. It is stated, however, that "Her Majesty's Government do not think it desirable, and do not propose, to establish any general system of examination as to the novelty of inventions in respect of which applications for Letters Patent are now made, and do not require any inquiry into any such system of examination."

It will be noticed that, whatever the report may be, the patentee will still have to take the responsibility of his invention being *really* novel, as the inquiry is to be confined only as to whether patents are to be issued for inventions which are "obviously old," or have been previously protected by Letters Patent in this country. Now, there are very many old inventions in connexion with photography that have never been the subject of patents, though they have been worked, and the details of them have been published, perhaps, several times in the journals; yet any one can now, and, it seems, will still, be able to obtain patents for them by paying the fees, though, of course, the patents would be invalid if contested. Patents are being continually taken out that are invalid, yet they prove profitable because no one cares to contest them, as it is well known that litigation in patent cases is a very costly affair. Therefore, a monopoly is sometimes secured and maintained entirely by bluff, threatened application for an injunction, an action for damages, &c. An old photographer, who is often consulted, and engaged in making searches in reference to photographic patent matters, once told us that probably seventenths of the patents taken within the last few years would not stand if they were contested.

In America and in Germany the case is different. In these

countries not only are searches made in their Patent Offices, but in other directions, so as to ascertain what has really been done before. Thus, when a patent is granted, the patentee has some reasonable guarantee that it is a valid one, and one that is not likely to have to be contested, or, if it were, upset. Although a patent here is very costly—for fourteen years the fees are just upon a hundred pounds, they used to be more—no inquiry is made as to the originality of the invention for which it is granted. In America a patent for seventeen years costs less than ten pounds, and for that sum due search is made as to what has been done before, and the patentee has some assurance that the patent he obtains is one that is valid.

Here is another important difference between the Patent Acts of England and America. In this country, if the specification contains, say, ten claims and it is contested, if a single one of them proves bad, the whole patent becomes void. In America, under similar circumstances, if even nine of them were proved bad, the tenth would stand, and the patent, as regards that claim, would remain valid. It is true that here a patentee can disclaim any of the claims made in the specification; but, if the case is under litigation, the other side can oppose the disclaimer, but that again involves additional costs on both sides.

That photographic inventors are, at the present time, interested in the Patent Acts there is no question, as witness the list of applications we publish weekly. It seems now that any one who makes an improvement, perhaps only a change, in a process or in a piece of photographic apparatus, at once makes for a patent, and no one will deny that an inventor is justly entitled to profit by his invention. The Patent Office should therefore assist him in doing so by saying, to some extent at least, that he has, when he has paid for it, a reasonably valid patent.

In the early days of the art, when new and really original inventions and improvements were continually being made, the number of applications for patents for them during an entire year were often less than are now made weekly. In 1851, for example (the year that Scott Archer published the collodion process), there was but one, and that one was not for this process. In 1874 (the year that Dr. Maddox published the gelatine process) there were but fourteen applications for patents in connexion with photography, and those did not include Dr. Maddox's invention. It is noteworthy that the two most valuable processes in photography, the collodion and the gelatine processes, were not patented, but were freely given to the public by their inventors.

We are pleased to see that the Board of Trade have appointed a Committee to inquire into the working of the Patent Acts, but, at the same time, we regret that its inquiries are to be so much restricted.

**Aerial Photography.**—Some of the peculiar difficulties of this uncommon branch of photographic work are pointed out in the course of a short article in the *Scientific American*, which tells us that the aeronaut who secured a photograph which illustrates the article has, on several occasions, ascended in a balloon with his camera fully loaded with forty films, and has exposed the whole of them at varying altitudes, yet, when they were developed, they were found to be absolutely useless. The atmosphere, adds the writer, plays an important part in the success of an aerial photograph. At an altitude of 300 feet a magnificent result may be obtained. You ascend another 100 feet, and expose a second plate, exactly under the same conditions regarding speed, light, etc., as the first, yet the plate ultimately turns out

a dismal failure. The exposure proves to be many seconds too short, and the picture is scarcely visible. But ascend another 200 or 300 feet, expose again, and you get a result equal in every respect to that obtained at an altitude of 300 feet. There seems to be a thin, filmy cloud (not of vapour) that floats above the earth, which appears to have a non-actinic effect upon the plate, and therefore it is under-exposed. This phenomenon is apparent to the naked eye.

**The Indian Society's Journal.**—The last two or three numbers of the *Journal of the Photographic Society of India* show such marked improvement in the nature of their contents that we are glad of the opportunity of congratulating the new editor upon the changes he has made in his paper. As it was formerly conducted, the *Journal* contained, perhaps, too large a proportion of matter having a purely topographical interest. We imagine that in the new arrangement this element will not be so prominent, and that greater insistence will be placed upon information designed to be of service to practical photographers. The new editor chats pleasantly with his readers, and gives them two or three useful articles on subjects of current interest. "What they say in England," "Our London Letter," "Foreign Notes and Notions," "New Lamps for Old" and "Entre Nous" are headings which clearly convey an idea of what is printed below. The "pictorial policy" of the *Indian Journal* appears to have been sought in the "mud-flat school," which our contemporary may be interested to know, commands little or no notice nowadays in England. With the exception of this and some other solecisms concerning pictorial photography, which would cause many of our readers to smile, the *Indian Journal* is well up to date, bright, lively, and useful.

**Zomo.**—We had a visit this week from Mr. Mark Blow of the Crown Studios, Sydney, New South Wales, who, besides being a photographer, is opening a business as a wholesale dealer in photographic goods. Sydney appears to be conspicuous for the severity of its competition in portrait photography; but it is described to us as an excellent centre for the business of supplying amateurs with their photographic requirements. The term "Zomo" which appears at the beginning of this paragraph has been applied to a printing process adopted by Mr. Blow for portrait purposes, and some of the results were submitted to us for our inspection. They resemble smooth-surfaced bromide prints with rich black shadows, delicate half-tones and soft lights; but the process does not rely upon silver for the sensitive medium. From the indication given us of the method of producing these Zomo pictures we should expect them to be as permanent as a photographic print could be. And we know that in Sydney where the business methods of photographers are somewhat more dramatic than here in London—the "blessed word" permanence possesses very high significance.

#### DR. EMERSON AT THE ROYAL PHOTOGRAPHIC SOCIETY.

[FIRST NOTICE.]

THE Exhibition of Dr. Emerson's photographs at No. 66, Russell-square, W.C., coincides with the author's removal from East Anglia, the field of so much of his literary, photographic, and natural history work. The world at this time is closing many old chapters and opening new ones. It is so with that branch of photography of which Dr. Emerson was once the chief student and exponent. Regret collides with reason as we write in the past tense, for the photographic work which Dr. Emerson put aside some ten years ago will not be taken up again, and on June 30, when the Exhibition closes and the one-hundred-and-forty photographs are taken down from the walls, they will be scattered in many directions, in all probability not to be gathered together again and publicly shown. The negatives and photogravure plates have been destroyed, so that in a very little while a direct photograph by the most intellectual figure in modern photography will be a very rare thing indeed.

The last decade of the closing year of the century has witnessed many curious happenings in photography, and especially in that section of it which we have in immediate contemplation. It has produced salons and "schools," fuzzipters, astigmatographers, Artigueites, gum-bichromate

worshippers, photo-fakers, the *f-64* man, the diffusion-of-focus man, the mud-flat person, and other phenomena. And then we have read, alas! about pictorial photography by the mile without perceiving anything but printed words in the whole mass of it. There have been forewords to catalogues, accusations of implacable hostility to pictorial photography, and angry references to a mysterious "B. J." cast of thought, of all things in the world! The comicality of these little tempests seen retrospectively is irresistible. But now at the end of all this absurd and wearisome farce-acting comes the sincere and earnest worker, to whom for his arresting thoughts and examples photographers owe so much, to show by the simplicity and truthfulness of his printed productions what is most abiding and convincing in pictorial photography.

Ten and twelve, in some cases fifteen, years have passed since Dr. Emerson produced these photographs, and to-day they teach us several lessons: One of them is that in the matter of pictorial photography we have been moving in a circle, and that, after all the varied experimentation to which we referred just now pure unfaked photography as a means of producing a truthful pictorial result, gives a photographer wonderful powers. Neither Dr. Emerson's negatives nor his prints were ever worked on, and yet in some cases the very striking contrasts of light and shade, and the delicacy of some of the finer gradations would appear to be impossible of production without careful handwork on the negative. But, no; Dr. Emerson has always taught, and followed out his own doctrine in practice, that in delicacy of rendering of certain subjects, pure photography excels painted work and other means of making pictures. And this is amply borne out in the present Exhibition.

There is no colour in these 140 photographs, the platinotypes, photo-gravures and carbon prints being uniformly in black pigment. It is probable that the hanging scheme chosen by Dr. Emerson will excite discussion. The walls have been covered with a yellow fabric, and the frames are of thin moulded wood coloured green, whilst mounts of a very light green tint have been chosen. In no single case has close-up framing been adopted, and, for so pointedly declining to recognise a fad which in recent years has been carried to excess, we think Dr. Emerson deserves special thanks. Who that remembers the vast expanse of stained woods of which some of the recent exhibitions in London mainly consisted can do so without feeling that they had a killing effect on many of the photographs and a most distressing effect on one's nerves? Dr. Emerson shows us that an exhibition of photographs need not be as depressing to contemplate as a suburban undertaker's window on a wet afternoon. Seen in the evening especially, the total effect of his Exhibition is bright to the eye without being violent and obtrusive, and, as you walk round the rooms and examine the photographs one by one, you are conscious that the tender scheme of mounting and framing exercises no distracting effect upon you while you are looking at them. By daylight, owing to the illumination coming in from side windows, a certain harshness and garishness is seen in parts of the Exhibition, but this is an unavoidable matter. The rooms at Russell-square fall short of the ideal gallery in which to show pictures or photographs.

But the most remarkable feature of this Exhibition, if we may make use of a convenient "bull," is what it does not contain—the "fuzzy" photographs. Of all the stupid mendacities of which Dr. Emerson was at one time made the object—and we are obliged to say that our own pages were formerly abused in this way—none clung so tenaciously to his name as that of being the inventor of "fuzzy" photography. We can even recall such a phrase as "defunct Emersonism at the Salon," as if to say that some of the foolish blurs that were shown at the latter Exhibition were the results of Dr. Emerson's example or teaching. Nothing of the sort. Fuzzy photography is not on view at Russell-square just now. In one picture only is the background designedly thrown out of focus, but of the evil thing whose only claim to notice lay in its being hopelessly blurred there is no trace. Truth to tell, some of these photographs of Dr. Emerson's would in parts do credit to a perfectly corrected anastigmat, and yet they are full of pictorial qualities.

We mentioned above that Dr. Emerson's work in East Anglia has been brought to a close. We can permit ourselves to feel some share of personal regret at the severance. It is about thirteen years since the placid natural charms of the English Holland first exerted themselves over us, and many is the hour, by night and by day, that we have passed near the dreamy broads and rivers which have given Dr. Emerson so much of his inspiration. Properly to understand and appreciate the charm, the fidelity of the work he is showing at Russell-square, you must have lived in the land and amongst the people; you must have seen the wisps of mist rising up over the bland marshes, and have listened to the incomparable music of the wind in the reeds; have sailed over the serpentine rivers, and seen the shy coot disappear at the sound of your

voice; you must have dipped deeply into that East Anglian charm life, the precise nature of which mere verbal description finds it difficult to convey.

It is this fact of our long and intimate association with the scenes Dr. Emerson's photographic work that may explain in some measure the keen admiration we feel for it, an admiration that grows with the years, but, of course, the principles of pictorial photography as laid down by Dr. Emerson in his writings are not to be regarded as susceptible of geographical restriction. He could just as well have translated his theories into practice in the West Highlands of Scotland, or amongst the Yorkshire dales, as in Norfolk and Suffolk; but he had to make a choice of scene, and the selection was a happy one. Some pictorial photographers have identified their work with Dedham, others with Canvey Island, Paul's Cray, Walberswick, the River Thames, and so on. Painters have done the same thing, and the humble photographer can scarcely be blamed for following so admirable a lead.

The Exhibition is to remain open until June 30, so that ample opportunities offer themselves for a visit of inspection. Next week we shall print a few detailed notes on many of the individual photographs. From a small catalogue that is issued it is apparent that nearly the whole of the photographs exist only in Dr. Emerson's books, a form in which they can scarcely be said to be so accessible to photographers as could be wished; but the greater number of those shown at Russell-square, W.C. are for sale. By the way, it is interesting to note that several of the photographs were printed in platinum fourteen years ago. Looked to-day in the bright spring daylight, they have all the bloom and richness of deposit of carefully produced prints made last week!

#### THE "BRITISH JOURNAL OF PHOTOGRAPHY" WAR FUND

To the total of 91l. which we have received for the *Daily Telegraph* War Fund, we are this week enabled to add only the sum of 10s. from the employees of Messrs. E. S. Baker & Son, Bristol Street, Birmingham. The result, we must confess, causes us some disappointment, for we were induced to hope that the magnificent example set by Messrs. Elliott & Fry, Messrs. Dallmeyer, Mr. H. Walter Barnett, and others, would not be without a similar effect upon other firms equally in a position to contribute to a representative photographic War Fund, while the presence of smaller sums in the list impressed us with the belief that photographers and others all over the country would be similarly inclined to participate in the movement. What we particularly wished to print was a column or two of names with small sums, such as shillings, half-crowns, and so forth, set against them.

However, we will keep the list open a little longer, and will gladly forward any sums that are sent to us to the *Daily Telegraph*. It is a melancholy thing to reflect that this week, which witnesses the ailment of the rank and file of photographic workers to help a Fund to alleviate the sufferings caused by a war which has greatly benefited photography, also sees the final extinction of the Photographers' Benevolent Association, which was started many years ago to benefit photographers, so many of whom have profited by it, so few of whom, alas! have supported it. The pity of it all!

#### THE PHOTOGRAPHER'S YEAR.

JUNE.

"After her came jolly June, arrayed  
All in green leaves, as he a player were."

MAY has not by any means proved the idyllic dream month, nor the month of flowers we had anticipated. There must have been something wrong either with the popular conception that gives it such a character, or the seasons have shifted onwards into the year, and winter lingering late delays the coming of summer. Upon first thought we are more ready to accept the latter reason, for it is a very common thing to hear people beyond middle age saying, upon a chilly day in April or May, that spring and summer are later in coming now than when they were young. There may be something in it, but it must be noted, upon the other hand, beyond the natural "praise of times that have been," that scientific observers, dealing with average results, that make but indifferently palatable reading to the majority—say that in reality June in our climate is what poets dream May to be. An agreeable outlook, now that June is with us, for we can expect a double amount of seasonal pleasures. However about the arrears of May, there is one feature about June in

pic description that there is no need to turn to science for an endorsement of, as it is so evident to an ordinary eye every year, viz., that it is a safe month. "Leafy June" sounds as natural as "spring cleaning," or "honest poverty." The trees are in their full wealth and glory of dress, and richly deserve being pictured. Still, trees as trees do not appeal to the ordinary imagination. There is a pleasure in the fulness of their presence, and a restful satisfaction to the eye in the large masses of green; but it requires something of a Ruskinite cast of soul to go further, and endow the tree with sentient life. To see in the spread and general disposition of branches and leaves a perfect arrangement for getting a due share of the necessaries of light, and rain, and air to every part. An order that varies markedly in each kind of tree, but which in each is equally effective for the purpose.

Another feature about trees that does not strike the casual observer is that of age. Unconsciously measuring by the brief span of human life, he fails to realise without an effort how long it takes forest trees to attain maturity, how long they retain their vigour, and how humanly gracious they are in clinging to waning life. Many an old tree by the side of an important road may have looked down upon historic doings that we only know of in the misleading patchwork of book description written long afterwards. They may have seen roystering cavaliers riding and singing the music-hall ditties of the day, and sober fighting Puritans chanting psalms, archers marching to French wars, baronial retainers loyal upon home forays, nay, even have cast their youthful shadows upon mailed crusaders on the way to the port of embarkation for the Holy Land. And probably, nowadays, when a breeze freshens up their cooling faculties, their grave head noddings may be reminiscences conjured up and discussed, or possibly the usual ones of aged doubt as to the lower order of things, the safety of a high-g geared bicycle or motor car running by, for instance.

But, if these tree suggestions are not to be gained in looking at the tree itself, they are still less likely to be in looking at its photograph. On the whole of it, trees would not seem very difficult to photograph. Nor are they up to a certain point of merit, but a downright good picture of a tree is a greater rarity than one would suppose until he sets about finding it. The one in which characteristic arrangement of bough and leaf is given in masses of light and shade, in which there are not over many reflections upon the infinite leaf surfaces, but yet with a sufficiency of detail and crisp sparkle in the right place. It is work for early morning or late afternoon, when the light is clear. A fairly large stop, the slowest practicable rate, and a quick exposure, will also be best, owing to the lower light, the need for density, and the fact that small twigs are rarely still long.

But the great essential about trees in pictures is that they be in the right place. If it be too much to expect the more deeply sympathetic interest in them referred to above, they are unconsciously and universally regarded as objects heightening human interest in very many ways. There is a great difference in the view seen through a window, if there be trees in it or not; in the appearance of the house, if its immediate surroundings are bare of trees, or modified and softened by their presence. A field or lawn with a large, spreading tree in it is far more satisfying to the eye than if bare, and trees doubly improve the river bank in their actual and reflected presence. The same acknowledgment of worth is made by the more general planting of trees in towns, as the old-fashioned gardens, courts, and closes, where they once grew naturally, are eaten into by the brick-and-mortar cancer. In short, we appear to need splashes of green before we can truly thrive—a useful instinct, probably surviving from times when our ancestors lived altogether in the open, and in the midst of green.

The highest opportunity of the photographer comes in fitting the human interest with trees in his picture. So will he most effectually appeal to the feeling of instinctive fitness, and stir up interest to its best point. Spenser, in the couplet at the head of this article, expresses the same thing unconsciously by referring to

"June, arrayed  
All in green leaves as he a *player were*."

The manner in which to do this must vary with place and taste of worker. Trees with a village church behind them, or spreading over rustic benches in front of old-fashioned taverns, look well. So they do forming avenues leading up to lordly country houses, or singly, shading a path in the park, throwing grateful shade over a resting team or gipsy van in the lane, fringing the river bank and overhanging the fishing punt. It is a true photographic question of judicious selection, for, whichever may be chosen, it is certain to be appropriate, and strike an observer soothingly as such without his being able to say exactly why. If given anything of a chance, trees never make a mistake in selecting

suitable growing places. There are no square pegs in round holes. The pines, spruces, and firs keep to the bare and sterile uplands, lower down in richer soil come oak, ash, elm, and beech, and still lower in moisture bottoms the poplars, willows, and alders. Incidentally a tree may thus be used to emphasise any more far-reaching suggestion it may be desired to convey. Pictures with trees and still water in them have, further, a higher quality of lasting interest than any others. They can be looked at day after day for years without palling upon the taste or fancy. Action, colour, glitter, arms, and soldiers possess an attraction which we feel keenly at such times as the present. They stir up the blood healthily and patriotically at critical seasons. But critical seasons, by comparison, are rare. Such appreciative violence of emotion cannot be long sustained without a break-down or safe-guarding reaction, and the most satisfactory pictures, all round, are those of quiet natural scenes and objects in middle shades and colours. A hay-laden waggon in the rickyard is a far more satisfying picture to have on the wall through twenty years than a cavalry charge, a ploughman leaning against his plough handles, than an officer, sword in hand, at the cannon's mouth.

The reference to the hay waggon leads us naturally to another characteristic feature of June that requires no recommending, viz., hay-making. He must be a very rare and peculiar individual indeed who does not find a willing pleasure in leaning over a gate to look at the hay-making in the field beyond. There is a peculiar and universally felt charm in gathering in the fruits of the earth—hay-making, corn-reaping, blackberrying, apple-gathering. Of all these hay-making is the pleasantest and most popular, both to the dweller in country and town. To the former it means evident and palpable gain, and, although it may be "more blessed to give than to receive," to the majority of us it is pleasanter, any way, to receive. With the townsman no item in the imagined prospective delights of a visit to the country figures so spontaneously as hay-making. Warmth and sunshine must be present as essentials; the grassland is easy and elastic to the tread after city pavements; the scent delicious, and the cider keeps divinely cool in its jar in the running water of the brook for the slacking of thirst with an unaccustomed Spartan twang of urgency about it. Something of added vividness, too, may be given to mental pictures of hay-making presenting themselves in after-life from the fact that the first impressions were formed in childhood, for the hay-field is emphatically the place for children. But, whatever the cause or causes, it is very clear that pictures of hay-making are very popular. Few possessors of a camera are there who have not tried their hands at it. The conditions are all favourable—good light, slow action and movement, and suitable photographable colour. Still it would be harder to find one satisfied with his result than dissatisfied. The two mistakes made as a rule are: taking the picture in the open field (where the workers naturally are most of the time), and allowing the latter to be conscious that they are being photographed. As a remedy for the first, the opportunity of taking the waggon in a corner, or, at least, with a hedge, or a tree as a background, should be carefully watched for. Better would be snapping it off as it comes through the gate into the lane; or, better still, the best spot in the lane itself should be chosen, and everything made carefully ready for releasing the shutter when waggon, team, and driver have moved on to it on their homeward journey. A load of hay with a setting of living green, horses moving slowly, and the waggoner walking alongside, are elements that, rightly handled, go to make a very effective picture. But, whether in field, lane, or home-stead, let them be taken without giving a chance for conscious arrangement. The pose of a rustic labourer need not necessarily be worse than that of one higher up the social or intellectual scale, possibly of the two it may be better, for he does not know enough to attempt too much. But, even if it were good, perfect indeed, it cannot but detract from the value of the picture in being incongruous. People do not go into hay-fields to pose.

Thus, with two readily accessible subjects, trees in full beauty and haymaking, both admitting of such wide and varied treatment, there should be no lack of characteristic material for photographing in June. Not that the choice need be limited to these, for, with everything at its very best in country and town, there is unlimited minor material of all sorts available.

#### TELE-PHOTOGRAPHY.

[Translated from *Die Umschau*.]

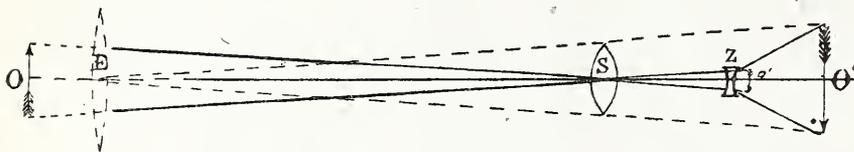

It is necessary sometimes to make photographs of considerable size of objects at a distance. It has been stated that during the war between China and Japan photographs were taken of wrecked Chinese vessels.

situate in inaccessible places, so that the effect of the artillery and torpedoes might be studied. Problems of a similar kind also presented themselves during the war between Spain and the United States, as photographs were wanted of large masses of moving troops, from a considerable distance. But we need not refer merely to the incidents of war to illustrate the importance of an instrument which permits of such photographs being obtained.

The ordinary photographic lens depicts distant objects on a scale proportional to its focal length. There would be no difficulty in photographing distant objects if lenses of suitable focus could be used. This is actually done in astronomical photography. The beautiful photographs of the moon made at the Paris and Lick Observatories were taken with lenses of ordinary construction and very long focus, exceeding, in fact, ten metres. In other words, the photographic plate was more than ten metres distant from the lens. In ordinary photographic practice such a solution of the difficulty is impossible, because insuperable obstacles stand in the way when cameras of such enormous extension are used. The problem to be solved in constructing an instrument for tele-photography is, consequently, to find the means of obtaining an image of considerable size with a camera of workable dimensions.

Such an instrument is now made by combining a collecting lens,  $s$ , with one of considerable diverging power,  $z$ , so that the distance between them upon the optical axis may be altered at will within certain limits.

If we take the collecting lens,  $s$ , alone, the distant object,  $o$ , will be represented by a small inverted image at  $o^1$ . This may be seen at  $s$  under the same angle as the distant object,  $o$ . If we now interpose the diverging lens,  $z$ , as shown in the diagram, an enlarged image of  $o^1$  will be formed at  $o^2$  instead of the smaller image, and this may be projected upon the ground glass. If we find the print,  $E$ , upon the axis, by means

of a simple geometrical drawing, so that  $o^2$  shall appear to be under the same angle as  $o^1$  is in relation to  $s$ , the distance,  $E o^2$ , will represent the focal length of a simple collecting lens, which will give an image of the same size as  $o^1$ . By means of our combination we thus obtain the larger image and reduce the camera extension by the distance  $s E$ .

We may here observe that the image,  $o^2$ , may be further enlarged, within certain limits, according to the relative positions of  $z$  and  $o^1$ , without unduly increasing the camera extension,  $s o^1$ , and this leads us to the second advantage of such a combination, which enables us to obtain, within considerable limits, an image of any desired size by means of moderate camera extension, however distant the object.

Such advantages must, however, be bought at the expense of certain disadvantages, in comparison with the lens of ordinary construction. There is a loss of rapidity, and the length of the instrument reduces the field of view to such an extent that it seldom exceeds  $10^\circ$ . The want of intensity is easily explained. We will assume that the collecting lens,  $s$ , requires an exposure of one second to form the image at  $o^1$ , and that the interposition of the negative lens,  $z$ , enlarges the image at  $o^1$  to six diameters. It follows that the amount of light which was concentrated to form the smaller image at  $o^1$  has been spread over an area  $6 \times 6$ , or thirty-six times larger, to form the image,  $o^2$ , and it is therefore necessary to multiply by thirty-six to obtain the correct exposure, which should now be more than half a minute instead of one second.

The combination of a collecting lens of long focus with a diverging lens of shorter focus is called a tele-objective in the proper sense of the term. Such an instrument was constructed by the Italian engineer, Ignazio Porro, in Paris, in 1851, and shortly afterwards recommended for photographing buildings. It was practically forgotten, but forty years afterwards it reappeared as a new invention and came to the front in the domain of photography.

If distance be an important factor, the atmosphere with us is seldom clear enough for using the tele-photo lens; but, in Italy, Professor G. Roster has taken photographs with it in which houses, seventeen kilometres distant, may be clearly seen. Other uses for the lens are to be found in the sphere of architectural photography where details of buildings can only be photographed, with an ordinary lens by erecting stages of considerable expense.

Specially constructed tele-objectives may also be used for instantaneous photographs at a distance, and these have been used for studies in

natural history. Tele-photo lenses have been little used, as yet, for portraiture, although certain advantages in perspective would be secured in consequence of the size of the image being independent of the distance of the sitter.

DR. MORITZ VON ROHR.

## PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

FIFTEENTH ANNUAL MEETING, NEWCASTLE-ON-TYNE,

July 9 to 14, 1900.

PRESIDENT: THOMAS BEDDING, F.R.P.S.

THE meetings and exhibition of apparatus, pictures, &c., will be held in the Grand Assembly Rooms, Barras Bridge.

### RECEPTION COMMITTEE.

The Right Rev. the Lord Bishop of Durham; the Right Hon. the Earl of Durham; the Right Rev. the Lord Bishop of Newcastle-upon-Tyne; the Very Rev. the Dean of Durham; the Rev. Canon Gough, D.D., Vicar of Newcastle-upon-Tyne; the Right Worshipful the Mayor of Newcastle-upon-Tyne, Riley Lord, Esq.; the Sheriff of Newcastle-upon-Tyne, John J. Forster, Esq.; H. E. Armstrong, Esq.; Cuthbert Bainbridge Esq.; H. Benson, Esq., Under-Sheriff of Newcastle-upon-Tyne; Robert Blair, Esq., F.S.A.; W. D. Cruddas, Esq., M.P.; James D. Farquarson Esq., M.B., C.M.; Dr. George Foggin; J. Pattison Gibson, Esq.; William Gray, Esq., Deputy Mayor of Durham; the Rev. Principal Gurney, M.A., D.C.L.; Thomas Hodgkin, Esq., D.C.L., Litt.D.; Alexander Laing, Esq.; B. Lupton, Esq.; C. W. Mitchell, Esq.; Joseph M. Moore, Esq.; Alderman Henry Newton, M.D., J.P.; W. Parry, Esq.; J. B. Payne, Esq.; the Rev. Jevon J. M. Perry; Professor G. Hare Philpson, M.D., D.C.L.; W. R. Plummer, Esq.; Frank W. Rich, Esq.; R. Straker, Esq.; Professor Stroud, M.A., D.Sc.; J. W. Swan, Esq., M.A., F.R.S.; Aaron Watson, Esq.; Richard Welford, Esq., M.A., J.P.; Lionel Williamson, Esq.; Professor Mark R. Wright, M.A., &c.

### LOCAL EXECUTIVE COMMITTEE.

Messrs. Geo. B. Bainbridge, C. E. Barkas, James Baty, J. S. B. Bell, Dr. Blacklock, W. Parker Brewis, T. Maltby Clague, Walter S. Corder, Percy Corder, W. E. Cowan, J. W. Dyson, G. Elphick, Wm. Fenwick, A. B. Gardner, Godfrey Hastings, R. O. Heslop, J. J. Kirkwood, P. M. Laws, Edgar G. Lee, William Milburn, Rev. J. W. Ogden, Frederick Park, Sydney Reid, John Scott, G. L. Snowball, C. J. Spence, John Watson, and W. C. Way.

Sunderland Society.—Messrs. W. J. Pope, W. Bartram, and C. E. Cowper.

Durham Society.—Mr. R. Hauxwell, Major E. White, and Mr. Frank Cluff.

South Shields Society.—Messrs. A. W. Hoare, J. Davenport, and M. H. Sadler.

Committee for Compiling Notes on City, &c.—Messrs. J. P. Gibson, R. O. Heslop, W. P. Brewis, and Percy Corder.

Excursion Committee.—Mr. J. J. Kirkwood, Major White, Messrs. R. Hauxwell, Walter S. Corder, C. E. Barkas, G. Elphick, and John Watson.

Local Hon. Secretary.—Mr. W. Thompson, 22, Campbell-street, Newcastle-on-Tyne.

Assistant Hon. Secretary.—Mr. Edgar G. Lee.

### ARRANGEMENTS.

MONDAY, JULY 9.—For the benefit of those members of Convention who will be in Newcastle previous to, or early on Monday, members of the Newcastle Association will arrange to be at the meeting room to act as guides, and parties will, at convenient times, be conducted over the old Castle, Black Gate Museum, Cathedral, Natural History Museum, and generally inspect the most interesting features of the city.

*Conversazione.*—The opening *Conversazione* will take place in the Grand Assembly Rooms at 7.30, when the members will be officially welcomed to the city by the Right Worshipful the Mayor of Newcastle-upon-Tyne, Riley Lord, Esq., who will be supported by an influential Reception Committee, the officers and members of the Newcastle and Northern Counties Photographic Association, and neighbouring Photographic Societies. The Convention will be declared open, and the President will deliver his address. After a short interval, there will be an exhibition of specially selected lantern slides, followed by a collection of slides by members of the Newcastle and Northern Counties Photographic Association, illustrative of the places to be visited by the members during the meeting. Honorary Lanternist—The Rev. J. W. Ogden.

TUESDAY, JULY 10.—*Excursion to Hexham, the Roman Wall, &c.* Leader, Mr. J. Pattison Gibson. The train will leave the Central Station 9.50, arriving at Hexham 10.45. Lunch at the Town Hall at 1.30. Brakes will leave the Town Hall at 2.30. Trains from Hexham at 8.3 and 8.53, arriving at Newcastle at 8.58 and 9.35. Tickets, including train, luncheon, brake, &c., 7s. On arriving at Hexham, the party will

be conducted to the Abbey, &c., permission to photograph inside the building having been kindly given by the Rector, the Rev. E. S. Savage. After lunch, brakes will leave as above for the pilgrimage along the Roman Wall, &c. W. D. Cruddas, Esq., M.P. for Newcastle, has kindly given permission for a limited number to visit Haughton Castle. Special tickets, to the number of sixty, will be provided for those wishing to avail themselves of this invitation, and will be distributed either by priority of application or ballot, as may be found most convenient. Those of the party who have these special tickets will drive by Hums-haugh to visit Haughton Castle. Haughton is one of the thirteenth-century Border castles, and was formerly held by the ancestors of the poet Swinburne. The remainder of the party will drive back to Hexham by way of Chollerford and St. John Lee. There will be no meeting at the Assembly Rooms on this evening.

WEDNESDAY, JULY 11.—The Annual General Meeting and election of the new Council at the Assembly Rooms at 10 o'clock. There will be a meeting of the new Council at 11 o'clock. In the afternoon there will be a reception of the members by the President of the Newcastle-upon-Tyne and Northern Counties Photographic Association, G. B. Bainbridge, Esq., at Jesmond Dene. Jesmond Dene is a pleasure ground about two miles from the city. It was formerly the town residence of Lord Armstrong, and is quite an unique spot, affording as much opportunity for pictorial photography as could be obtained by going many miles from the city. All trams marked "Jesmond" or "Osborne Road" from the Central Station or the Assembly Rooms go near the Dene. The reception will be held in the Banqueting Hall at 2 o'clock. The official group will be taken by Mr. W. Parry (of South Shields), at the old Water Mill, at the top end of the Dene, at 3 o'clock. Refreshments will be provided in the Banqueting Hall at 4.30. At the Assembly Rooms, at 7 p.m., the Annual Dinner and Smoking Concert will be held. Evening dress optional. Tickets (not including wine), 5s. 6d. Lady members are invited to be present at the dinner and concert. Mr. W. S. Corder has arranged that during the dinner a selection of typical north country and border ballads shall be played on the "Northumbrian Small Pipes."

THURSDAY, JULY 12.—*Excursion to Durham.* Leaders, Mr. Robert Hauxwell and Major E. White. The train will leave the Central Station at 9.30, arriving at Durham at 9.50. Luncheon at 1 o'clock. Train leaves Durham at 6.5, arriving at Newcastle at 6.50. Tickets (including luncheon and admission to Castle), 5s. 6d. On arrival at Durham the members will be divided into two or more parties with a leader to each, so that photographic work can be more easily accomplished. Dr. Kitchen, Dean of Durham, has kindly promised to give every facility to members for photographing the interior of the Cathedral, except during the hours of Divine service (morning, 10 to 10.40; afternoon, 4 to 4.35. N.B.—The usual Visitors' Fee of 6d each (in aid of the Restoration Fund), will be charged. Durham Castle will also, by special permission of Dr. Plummer, Master of Durham University, be available to the Members of Convention; he has also kindly granted the use of the large and splendid Banqueting Hall of the Castle for luncheon. At the Assembly Rooms, at 8 p.m. A paper on "National Photographic Records," by Sir J. Benjamin Stone, M.P., also a paper by Mr. J. Bridges Lee, M.A., on "Photogrametric Methods as applied to Record and Survey Work," after which there will be an exhibition of specially selected lantern slides.

FRIDAY, JULY 13.—*Excursion to Alnwick, Hulme Abbey, &c.* Leader, the Rev. Jevon J. M. Perry. The train will leave the Central Station at 9.30, arriving at Alnwick at 10.39. Lunch at the White Swan Hotel at 1.30. Train leaves Alnwick at 4.10, arriving at Newcastle at 6.30. Tickets (including luncheon, brakes, &c.), 8s. On arrival at Alnwick, brakes will be waiting to take members for a drive through the Park, visiting the spot where William the Lion was taken prisoner while besieging Alnwick Castle in 1174, Brislee Tower, Seven Streams, Hulme Abbey, &c. After lunch the party will be conducted to the Castle, dairy grounds, the churches of St. Michael's and St. Paul's, &c.

At the Assembly Rooms, at 8 p.m., a paper entitled "Bubbles," by Dr. P. H. Emerson, M.A., and a paper on "Some Residues, and what to do with them," by Mr. S. B. Webber, followed by an exhibition of specially selected lantern slides.

SATURDAY, JULY 14.—Various short excursions to places of interest in and around Newcastle will be arranged to suit the requirements of the members.

GENERAL INFORMATION.

Application for membership of the Convention should be made through the Hon. Secretary, Mr. F. A. Bridge, East Lodge, Dalston-lane, London, or the Local Hon. Secretary, Mr. W. Thompson, 22, Campbell-street, Newcastle-on-Tyne. The annual subscription is 5s. The privileges of membership include invitations to the Official Receptions, admission to all the meetings, to the Exhibition of Apparatus, Pictures, &c., at the Assembly Rooms, with special rates for excursions, &c. Non-members are admitted to the Exhibition of Apparatus, Pictures, &c. (which is open each day from nine a.m. to nine p.m.) on payment of 6d.

Railway Time Tables, &c.—The times of trains for the various excursions are as nearly as can be ascertained at the date of issue of this programme. Should there be any alteration, it will be posted on the notice board, but in any case the correct time will be printed on the coupons. The Tyne Steam Shipping Company's s.s. *New Londoner* or

*Tynesider* leave Free Trade Wharf, Ratcliffe, London, E., and Quay-side, Newcastle, every Wednesday and Saturday. Fares (single), first class, 12s.; second class, 8s. Return, 18s. and 12s. Average passage twenty-three hours. The Tyne river steamers for Shields and Tyne-mouth, calling at all piers, leave the landing stage every half hour. Fare to North Shields, 3d.; return, 5d.

DARK ROOMS.

The Thornton-Pickard Company have again this year very kindly promised to send a commodious portable dark room with the excursions. It will, as on previous occasions, be in charge of Mr. Hesketh, one of their representatives.

*Dark Rooms in Newcastle.*—Messrs. Mawson & Swan, Moseley-street; Messrs. Brady & Martin, Moseley-street; Mr. R. Clark, Moseley-street; Mr. F. Park, Collingwood-street; Messrs. Hurman, Limited, St. Nicholas Buildings; Messrs. Wilkinson & Simpson, Newgate-street; Mr. John Watson, Grainger-street; Mr. Kirkup, Westmoreland-road; Mr. Dixon, Elswick-road; Mr. A. B. Gardner, 12, Grey-street; and at the Assembly Rooms.

*Hexham.*—Messrs. Gibson & Sons, chemists and opticians.

*Durham.*—Mr. Wilkinson, photographer, end of Framwell-gate Bridge, near the Cathedral; Mr. Edis, photographer, Sadler-street, close to the Castle.

*Alnwick.*—Mr. Ruddock, photographer, Bondgate Within; Mr. Robson, photographer, Finkle-street; Mr. J. L. Newbegin, chemist, Narrowgate; the Rev. Jevon J. M. Perry, St. Paul's Vicarage.

HOUGHTON AND SALMON'S BACKGROUND STAND.

[Patent No. 11,043 of 1899.]

This consists of an upright rectangular frame of wood, *a, a* (figs. 1 and 2), of sufficient dimensions to receive the largest background that may be required.

The frame is strutted at the lower corners to ensure strength, and is furnished with cross feet, *b, b* (figs. 1 and 2), to which are fixed castors to enable the stand to be moved about freely. On the lower inner surfaces of the uprights of frame are fixed fillets of wood, *c, c* (figs. 1 and 2), to which are screwed a series of brackets, *d, d, d, d* (figs. 1 and 2), for the purpose of storing the pivoted rollers, *e, e* (figs. 1 and 2), to which the backgrounds are attached.

The uprights are slotted in their upper parts, *f* (fig. 2), to receive a

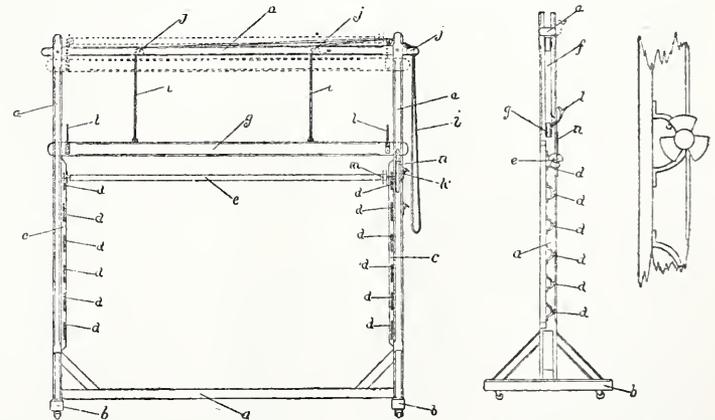

FIG. 1.

FIG. 2.

FIG. 3.

sliding rail, *g, g* (figs. 1 and 2), which is sufficiently long to extend across and through the frame, and to engage in the slots, in which it is made to run up and down freely by means of a double cord, *i, i* (fig. 1), running on pulleys, *j, j, j* (fig. 1), in the manner of Venetian blinds. The friction is reduced by sash rollers inserted in sliding rail. The double cord is operated from the side of the frame, where it is made to engage on a stud, *k* (fig. 1), to retain rail in required position. The sliding rail is provided with a bracket at each end, *l, l, l* (figs. 1 and 2), placed at the proper distance apart, to receive pivots on background roller, and are branched outwards, as shown in fig. 2, to allow background to run free when in use.

The method of operating is as follows: The roller on which the required background is fixed is lifted from the rack and placed on the brackets of sliding rail, each roller being furnished with a winding cord, which runs on the pulley, *m* (fig. 1). This cord is passed under a tension plate, *n, n* (figs. 1 and 2), which exerts just sufficient pressure on it to prevent background from unwinding before required.

The double cord is now pulled, causing the rail to rise to the position shown by dotted lines (figs. 1 and 2), where it is retained by twisting said cord round stud, *k* (fig. 1).

Each background is weighted by having an iron rod hemmed in its lower border.

On releasing winding cord from tension plate the background may be lowered or raised at will, in the manner of an ordinary blind.

When it is desired to remove background and store it in the rack, it is first wound on roller, and the winding cord held in one hand, whilst the double cord is released from stud, and the rail lowered with the other.

The background is then lifted from the rail brackets and placed in the rack, where it is prevented from unwinding by means of a stud (fixed in upright), which engages in one of the slots cut in flange plate of roller, as shown in fig. 3, a stud being provided for each roller.

#### COPYRIGHT IN PHOTOGRAPHS.

At the Photographic Club, on May 16, Mr. A. Mackie addressed the meeting on the subject of copyright in photographs, referring at the outset to the existing Act of 1862 (The Fine Art Copyright Act), the provisions of which, whereby photographs and paintings were classed alike, were considered by photographers, as a whole, to be very fair. This act, after a lapse of some forty years, and in which no considerable alteration was deemed necessary by the body of photographers, it was now proposed to supersede, and it was of the new Bill that he desired to speak. The law relating to copyright in engravings, prints, sculpture, photography, and the fine arts is at present contained in no fewer than ten Acts which, under various names, have the dates 1734, 1766, 1777, 1814, 1836, 1844, 1852, 1862, 1875, and 1886. The new Bill proposes to supersede all of these Acts of Parliament, and very truly commences with a note to the effect that "the Statutes are so confused that it is useless to enter into their details." Mr. Mackie thought it was a step in the right direction to have one Act for all classes of copyright, but at the same time the existing Act suited photography very well, and there was no particular desire on our part to have it altered. Painters, however, found that it no longer suited them, and they have taken the matter into their hands and drafted a bill, which has been read a first time in the House of Lords, and referred to a Committee for amendment. The Bill was originally drafted by the St. John's Wood Committee of Artists, and in that form was entirely inimical to photographers, who were apparently considered as outcasts.

The original draft was very hard upon photography, and even absurd; but, as redrafted by the House of Lords, a marked alteration had been made. It was the re-drafted Bill which he had before him, and he thought it had been drafted in a spirit of great fairness to everybody. Photography was by no means badly treated. Whatever defects the Bill contained were due rather to a lack of acquaintance on the part of those who drafted it with the requirements of photography as distinct from the other classes of fine art. In the new Bill the term of the duration of copyright has been altered from life and seven years in the present Act to life and thirty years after the end of the year in which the owner dies. Of course, there was no objection to this. Of particular interest to photographers were the regulations under the heading, "Special Provisions." It was obvious that rules which might be applicable to paintings might not all be applicable to engravings. A painting was a definite thing in itself, and an engraving was created from something else. In photography we must have the negative and the print, and the special provisions deal with the differences between these. Copyright exists from the date of production, but under the new Bill nothing is said about registration, which is required by the present Act. He thought that there was a great deal in favour of continuing the clause providing for registration. It may be a pity that one should be called upon to pay for what is already his, but the fact remains that millions of photographs are taken with no prospect of their acquiring any exceptional value, until one day circumstances render them of considerable marketable value and they are registered. Registration provides a ready means of proving title to a photograph. Under the new Bill a man may come across a photograph, with no name or owner, which he wants to reproduce; yet, while he may have every honest desire to pay for its use, he cannot do so, and it is not safe for him to attempt to publish it for what might be the benefit of the community, for fear of consequences. When a photograph is of such value that the author desires to ear-mark it as his possession, registration should be his means of so doing. Its value should counter-balance any trouble or expense.

Under the new Bill the owner for the time being of the negative shall be deemed to be the author, and an assignment of the copyright may be made by delivery of the negative or by the assignment of the copyright in writing. Now, if the owner is the author and the photograph keeps changing hands, it becomes possible that the copyright may never cease, being in existence for the life of the author and thirty years. This was absurd, of course, and assignment of copyright by delivery of the negative would be found impracticable. As one present remarked, quite a number of copyrights would fall to the share of the dustman. Copyright under the new Bill belonged to the author, even though he may receive valuable consideration for his work. The right to print photographs in the latter case, however, does not go with the copyright. Permission must first be obtained from the party for whom the work was done. On the other hand, the person who pays for the photograph must go for further copies to him who took it, as the copyright belongs to the latter. Personally, Mr. Mackie thought the man who paid for a photo-

graph should be entitled to the copyright in it, and should not, in order to secure it, have to get it assigned to him, probably at further expense. His reason for this was best put in the form of a question, How much less would a photographer charge you for a photograph if you assigned to him the copyright? Not sixpence, he felt sure. The copyright would be worth nothing to him, as he could not deal with the photograph without your permission.

There was an interesting discussion of a conversational character, and a committee was ultimately appointed to examine and report upon the Bill.

#### ON THE PRODUCTION OF SILVER PRINTS WITHOUT TONING.

##### II.

In my former paper I endeavoured to show that the merits of a good silver print, including under that heading the qualities of permanence and appearance, are not, as is often supposed, inseparably connected with the particular means employed in its production. In the development of my argument I had occasion to make special reference to gold toning. I showed that, in regard to this, the common view is in all probability erroneous, there being no real evidence forthcoming to support the assertion that the retention of the toning process is necessary to success in silver printing. I then proceeded to point out the advantages which would be likely to result from the disuse of the toning bath were it found possible so to alter the conditions of working as to ensure that the quality of the prints would be maintained unimpaired.

In the present article I have to deal with the problem thus presented to notice. It is a problem of considerable magnitude, and one for which a satisfactory solution has still to be sought.

A few timid attempts have been made recently with the laudable object of improving the existing printing processes. Unhappily, the majority of these are of very little practical importance, but one or two display considerable ingenuity and a certain degree of merit. There is, for instance, what is known by the name of self-toning paper, an article of which several brands are now in the market. The particular advantage claimed for it is that no toning bath is required, as the gold salt is already present in the paper, and is reduced to the metallic state during the exposure of the print to light. Having had no opportunity of trying this paper, I am unfortunately unable to speak of its qualities from personal experience. Whatever its merits or otherwise, its use would, at all events, tend to effect a saving in time and a reduction in the amount of care and labour required, two of the advantages mentioned in my former article. On the other hand, the need for the employment of a salt of gold for sensitising purposes would not, I fear, permit of any reduction being made in the cost of the materials, a matter of the utmost importance from the point of view of the professional printer. The same objection will apply in an equal degree to an older and better-known substitute for the usual system of treatment. I refer to the combined bath for toning and fixing. Even were it not so, however, the latter would be disqualified on other grounds, there being, as most readers will be aware, serious objections, mainly of a chemical nature, to the use of the combination.

A few attempts have been made to improve the quality of the prints, and so get rid of the necessity for toning, by the introduction of special reagents into the sensitising formulæ. The ferric salts have been pressed into service for this purpose, as well as those of uranium. These attempts have not been attended with success, for, though the quality of an iron or uranium print may be improved by the addition of a silver compound to the sensitising bath, the converse operation is found to produce a silver print of a very inferior description.

I shall now proceed to say a few words as to what would seem to be the fundamental principles involved in the matter, as, were these more generally recognised, the solution of the problem would be to some extent facilitated.

At the outset, what seems to have been quite overlooked in most of the attempts that have been made to improve the existing printing processes is the fact that it is to the silver compound, or compounds, present in the paper that the beauty of the result must be mainly attributed. A just perception of the practical value of this dictum is of the greatest consequence. Its importance lies in this, that only when it is fully realised does it become possible to exclude the operation of secondary causes, and thereby to advance towards a knowledge of the conditions favourable to success.

Regarding the matter from this standpoint, it will be perceived that there is nothing to be gained by employing as a sensitiser a mixture of metallic salts. Obviously, a suitable silver compound is all that is required. The question as to what constitutes suitability cannot, of course, be answered off-hand without recourse to experiment. A condition is, however, of necessity imposed upon us in making this choice. The silver salt selected must be of such a character that, in the subsequent manipulations, the operation of fixing shall not be destructive to the beauty of the image. This, in turn, naturally leads us to consider the nature of the fixing process, and to pass in review the various salts and other compounds that are available as fixing agents.

Fixing may be briefly defined as a process of solution whereby the unaltered and superfluous silver salts remaining in the print are removed

order to ensure its permanence. Now, it will be evident, on consideration, that the solubility of the silver compound, or compounds, which have to be got rid of will vary according to the special nature of the fixing agent employed to effect their removal, or, in other words, that the different substances employed as fixing agents will be found to possess different degrees of solvent power. Moreover, it will be seen that, in choosing a salt for the preparation of the fixing bath, we are, *ceteris paribus*, at liberty to select that which will permit of the operation being carried out with least detriment to the appearance of the print. The importance of this fact, regarded from a practical aspect, will be readily apparent.

Under any circumstances the choice of silver salts available for sensitising purposes is necessarily limited. It is therefore all the more desirable that the liberty of selection, such as it is, should be in no wise curtailed. Any restriction in the nature of a rigid adherence to one particular fixing formula will evidently tend to defeat this end, whilst, on the other hand, greater freedom of choice in the matter of fixing formulæ will serve to increase the number of silver compounds which may be used as sensitisers.

Upon the right apprehension and right application of the principles which have just been enunciated the attainment of success in any attempts that may be made to simplify and improve the manipulations of silver printing will, I incline to think, ultimately depend.

As a small contribution to the literature of the subject, I propose now to describe in a condensed form a few experiments in silver printing which were made by me about a year ago, and which, though of no great value in themselves, serve to show that, under conditions differing much from those that have been laid down for the printer's guidance, fairly good results may still be obtained.

The choice of a suitable silver compound was the first object of my inquiry. In the process of investigation it was found necessary to reject, as unsuitable for sensitising purposes, several well-known salts. Of these the most important was chloride of silver. The quality of the chloride image was found to suffer so much in consequence of the operation of fixing that, after an unsatisfactory trial had been made of a variety of fixing baths, it was thought inadvisable to make any further use of the salt as a sensitiser. A trial was then made of succinate of silver, the salts used for the purpose of sensitising the paper being nitrate of silver and succinate of soda. Paper so prepared gave, on exposure in the printing frame, a rather crude brick-red image, which, when fixed in the usual way, assumed a weak yellowish-brown hue. Oxalate of silver, employed as a sensitiser, gave a somewhat better result, but, as in the case of the succinate, the quality of the print produced was much inferior to that of a toned silver print upon plain paper. For fixing these prints a hyposulphite bath of the usual strength was employed. After making without success a number of trials with other silver salts, principally those of the commoner organic acids, some experiments were made with the neutral tartrate of silver. Employing this salt as a sensitiser, it was found possible, under certain conditions easily complied with, to obtain excellent prints which might be fixed in the ordinary way with very little loss of appearance.

The quality of the image produced by the exposure of the tartrate to light is such, indeed, as to warrant the assigning of a special place to the salt among photographic reagents. In richness and vigour it is scarcely to be surpassed. The abnormal intensity of the silver deposit enables the print to resist the reducing action of the fixing bath to a much greater extent than is found to be the case with the image due to chloride and to most of the other salts of silver. Three conditions would seem to be indispensable to success in working the tartrate printing process. In the first place, unsized paper only must be used. If this precaution be overlooked, and an albumen paper, or one sized with starch, arrowroot, or other similar substance, is employed, it will be found impossible to fix the print produced on such a paper without seriously impairing its beauty. The reason, no doubt, is this, that in such a case the image formed is due, not merely to the reduction of the tartrate, but also to that of certain compounds of silver, which have been formed by the action of the sensitiser upon the organic body used as a size.

In the second place, it is necessary that the sensitiser should be free from acidity. In experimenting with the tartrate, a sensitised paper neutral to test papers was treated with a wash of a weak solution of tartaric acid and dried. On exposure only a feeble image resulted. This, on further examination, was found to be composed of minute crystalline grains, which exhibited a strong tendency to detach themselves from the surface of the paper. The appearance, too, of the print after fixing was much inferior to what would have been produced had the acid treatment been omitted.

The third condition essential to the satisfactory working of this process is that the operation of printing be conducted in diffused light. When the printing is conducted in sunshine, red streaks are very apt to make their appearance, and, unless the utmost care has been taken to secure an even coating when sensitising, wavy lines and irregular markings are also likely to result. The loss of contrast, too, due to exposure in sunlight, is much more decided than it is in the case of a gelatino-chloride or albumen silver print.

For fixing this paper, the usual hyposulphite bath answers well. It may with advantage be used in a rather more dilute form than is com-

monly recommended. A very interesting fact in connexion with the tartrate printing process is that the fixing may be successfully performed by the immersion of the prints in a solution of ammonia.

In an article entitled "Ammonia as a Fixing Agent," which appeared in this JOURNAL on November 3, 1893, I described at length the course of treatment which I had found necessary to follow in using this reagent for the purpose of fixing prints produced by the ordinary chloride process. I showed that, in order to obtain good results with the ammonia bath, the prints must be toned in the usual gold bath before fixing. The process, therefore, it was seen, could not be carried out so as to effect any appreciable reduction, either in the cost of the materials employed or in the amount of time and labour demanded of the printer. In spite of these admitted disadvantages, however, it was felt that the introduction of the ammonia bath could be justified on practical grounds, seeing that, as a first step towards the production of permanent prints, it seems requisite that the use of sulphur compounds for fixing purposes should be abandoned. By employing tartrate of silver as a sensitiser instead of the chloride, I find it is possible, using the ammonia fixing bath, to produce excellent prints *without any toning whatever*. The image is of a somewhat warmer colour than that which is produced when the hyposulphite bath is used.

For the benefit of those who may desire to test for themselves the merits of the tartrate printing process, I give below the formulæ for the preparation of the sensitising and fixing solutions:—

#### Silver Nitrate Solution.

- (a) Crystallised silver nitrate ..... 280 grains, or 18 grammes.  
Distilled water ..... 7 fluid ounces, or 199 c. c.

#### Ammonium Tartrate Solution.

- (b) Ammonium tartrate ..... 250 grains, or 16 grammes.  
Distilled water ..... 10 fluid ounces, or 284 c. c.

#### Hyposulphite Fixing Bath.

- Hyposulphite of soda ..... 2 ounces, or 57 grammes.  
Water ..... 14 fluid ounces, or 397 c. c.

#### Ammonia Fixing Bath.

- Ammonia (sp. gr. = .880) ..... 2 fluid ounces, or 57 c. c.  
Water ..... 14 " " or 397 "

With regard to the reagents employed in sensitising, I should here mention that ammonium tartrate is a salt which the photographer may experience some difficulty in procuring. Luckily for him, it can be very easily prepared at home, and this is the course I should recommend to those who may be unable to obtain it at the chemical dealers'. The only reagents required for the purpose are tartaric acid and ammonia. A saturated aqueous solution of the former having been made, ammonia is added thereto, drop by drop, until the acid reaction has entirely disappeared, this point being determined by testing with litmus paper. The liquid is then to be evaporated to a small bulk, and, when sufficiently concentrated, set aside to cool. When the whole has become solid, the crystals must be removed and spread on a sheet of blotting-paper to dry, after which they may be transferred to a bottle for preservation. The paper used for printing should be of tough quality, and should possess a smooth, close-grained surface perfectly free from size. In the case of the nitrate bath the operation of sensitising may be performed by floating the paper in the usual manner. After draining, the sheet should be laid aside in a dark place until superficially dry. While still damp, care being taken to coat the paper as evenly as possible. In order to guard against any excess of nitrate being left after sensitising, a second coating of the tartrate solution should be applied once the first has had time to soak into the paper. The sensitised paper will keep for about a fortnight if preserved from air and light in a dry place; but it should be used as soon as possible, otherwise the purity of the high lights may become impaired.

In the operation of printing an ample exposure should be given, as the loss of density on fixing is rather greater than in the case of a chloride print. If it is thought necessary, the prints may be well soaked in water before immersion in the fixing bath. In my own practice, however, they have invariably been fixed without this preliminary washing, and no bad results have ensued. In fixing with the hyposulphite bath half an hour's immersion will be required; with the ammonia bath an immersion of fifteen minutes should be sufficient, as its action is more energetic. On their removal from the fixing bath the prints should be washed in the usual way.

In the hands of careful workers the process just described is capable of affording results little, if at all, inferior to those obtained upon plain paper under the old system of printing and toning. Still better results might, perhaps, be obtained by the use of a stronger nitrate bath. As it is, the prints exhibit a range of tone, and warmth, and richness of colour which is remarkable, bearing in mind the circumstances attending their production and the simplicity of the means employed.

I recently made a few additional experiments with the tartrate, my object being to ascertain whether or not the valuable properties of the salt might be utilised for the purpose of preparing a gelatine emulsion. I made use of a formula very similar to that of the excellent one recom-

mended by Mr. J. Barker, but containing a little additional tartrate in place of the chloride of silver.

Unfortunately, through a want of proper attention at the stage when the silver nitrate solution was added, the resulting emulsion was not quite homogeneous, and, owing to the loss of silver tartrate due to this cause, the prints obtained were weak and somewhat mottled in appearance. These prints, without further treatment, were duly fixed in the hyposulphite bath. When removed from the solution, they were found to have lost considerably in vigour. On the other hand, the colour was fairly good, and, though lacking the richness and warmth of a print upon plain paper, possessed nothing of the unpleasant quality characteristic of an untuned and fixed gelatino-chloride print. On the whole, the result seemed to favour the conclusion that a process might be devised which would permit of the use of gelatine in the form of an emulsion. It has already been mentioned that, for sizing the paper, starch, arrowroot, and, in fact, most colloid bodies, are not available. I have not tried gelatine, but, from what has just been said the probabilities are that it might be employed for this purpose were due care taken to prevent its coming in contact with the nitrate of silver used in the sensitising operations.

This, of course, is a point which could be very easily settled by experiment.

In conclusion, I would recommend the readers of the JOURNAL to study this subject for themselves, and to endeavour by every practicable means to gain a fuller knowledge of the conditions governing the operations of printing, toning, and fixing.

In this way it will be possible to arrive at results which will be of real value, and at a solution which will be accepted as final.

MATTHEW WILSON.

### RAPID AND WHOLESALE DEVELOPMENT.

[Paper read before the London and Provincial Photographic Association.]

It has been said, and no doubt with a considerable amount of truth, that concerning photographic discovery the amateur has taken the lead. We may qualify the assertion, and we will, by asserting that this was in the early days of photography. Nevertheless, the impression is distinct that we owe so much to the amateur, and you must pardon me a little if, for a wee bit, I champion the professional and the trade worker. Without doubt the professional runs in as many set grooves as he can, 'twere folly otherwise, from a business point of view. Chopping and changing to the amateur is pleasure; to the man earning his living by photography it spells loss—loss of time, loss of material, loss all round. The amateur has just as much fun and enjoyment over failures as with successes, but the professional cannot, in justice to himself, view failure with the same amount of equanimity.

Thus it comes that in the past, and even in the present, the amateur is the one who dares, who departs from handbook precepts, and who, in so doing, benefits his fellows by finding out something. All praise to him for it. At the same time let us not forget the professional worker, who consolidates by actual work what the amateur has merely skimmed over. I grudge the amateur nothing, I only plead for a slightly better recognition of the professional and trade worker's services. An invention remains an invention, a discovery no more than arouses interest, until one or the other has been put to a practical conclusion. It is the man who earns his living by photography that proves the case. The amateur may find the skeleton, but he leaves the professional to provide the body.

I am myself both in the skeleton and the full body line of business. You will, doubtless, remember my championship of ortol as a developer, both in the photographic press and at meetings of societies. My first impressions were gained, in the amateur profession, by the trial of a few plates; but I was afterwards able to confirm these from the commercial point of view. You may remember that a large amount of fun was produced by more or less sarcastic hits at what I may call my "table of quantities." In the article in one of our photographic journals upon "Ortol," I gave a list of plates, films, &c., that I had developed with that reagent. The only idea I had in so doing was to show that the remarks I made, and the conclusions I had come to, were not founded upon the two or three trials that the ordinary amateur might make; rather, that they were the results of sufficient experience to justify conclusions. The "table of quantities," however, was not, I am afraid, taken in this light, and considerable ridicule followed.

But my idea then was, as it is now, that, whilst a few trivial experiments may prove the possibility, it is to the practical carrying out of the idea that we should look for the probability—in other words, it is the practical worker who proves absolutely whether there is anything in the matter at all.

And here I feel I must have a go at the scientific expert, and I go for him in precisely the same way as I have already described the amateur's function. He does not test by practical rules. Test tubes, and conclusions carried out to the seventh or eighth decimal, prove but the germ.

The professional who exposes and develops two or three thousand plate or films can gauge the value of the new developer, or whatever he may be trying, very much better. Failure with him means serious loss; failure with the scientific expert, perhaps, merely provides him with copy for his next article in one of our periodicals.

Now, the point with which I am concerned to-night, viz., rapid and wholesale development, is just one which has shown me pretty clearly that we may learn much from wholesale work—that is to say, using a method or process upon a very large scale. In my own case time was an important item, as it cost money and inability to supply lost orders. Therefore our efforts for some time have been mainly directed towards turning out the work at a greater speed. Of course, conveniences for washing and drying were soon devised; and by the abolition of printing frames altogether, and printing four negatives on to a film at one time, we gained further rapidity. You will, perhaps, gauge our efforts best when I tell you that we found it pay better to do away altogether with our original transparencies and to substitute larger ones containing four each, the difference being simply that of having, say, a single whole-plate to handle as against four quarter-plates. At first thought you would deem this a very slight matter indeed; nevertheless, we found it worth three or four dozen extra negatives in a day's work. I may say here that our ambition was to turn out two gross of half-plate negatives per day, two persons only doing all the work up to hanging up to dry.

But all these details were quite secondary to development. We could push on in the exposing or in the washing and drying, but right in the middle we were compelled to jog along at the mercy of the tyrant developer. So then we settled down to quicken that process. We were using ortol soda at the time, and making use of the strong feature of that developer, its continuing action. I perhaps ought to explain that absolute density had to be coupled with the quick development, and that is where the difficulty lay. Our experiments merely proved that development to the density required took the same time practically whether a normal or an energetic solution was used. With an energetic mixture of one part ortol solution double strength, two parts carbonate of soda solution double strength, no sulphite of soda or bromide, the image appeared extremely quickly; but, alas! we had to soak for density—that is, we had to continue the development just about as long as with a normal solution.

I shall have the pleasure, later on, of showing you the continuing action of ortol, and at the same time Mr. Human will be able, I hope, to show you the development of a negative to full printing density in 18 to 20 seconds. We do some of ours in 10 seconds, but will keep to our original assertion of 20 seconds.

The developer he will use is a combination, but at present I am not at liberty to tell you anything about it. Not only does this developer act so quickly, but it gives greater density. If it should be thought that my idea of density, perhaps, goes hardly far enough, let me add that in our work we require absolute opacity in some parts. Take a border negative for instance, the part into which the portrait is printed in must be left a pure white when printing from the border negative, and that means, of course, great density.

A question you may ask is, how this quick development can be made useful to others. Some of you, no doubt, fail to see any advantage in it, and I dare say there are many to whom development is a pleasure to be drawn out and prolonged as far as possible. They like adding minims of bromide to restrain, a few drops of soda or ammonia to quicken, breathing on a part of the plate, and all the little dodges. It adds, in their estimation, to the value of the finished result. All I can say is, I don't. I should prefer my plates to come out of the camera developed, fixed, and ready for printing. Therefore, provided I get good results, the quicker I can develop the more I am satisfied.

But to any one who has the opportunity to expose correctly (or within a reasonable range of correct exposure), a number of plates, quick development will appeal. To the trade worker, the professional photographer who, knowing his studio light can take forty or fifty portrait negatives in a day quite near enough to correctness, or even the amateur who comes home with a few dozen plates, which by a preliminary test he finds are all about right, to all these speed in development will prove a boon. The tentative, and what I call the "patting on the back" methods, are all very well for a dozen plates, but, when it comes to hundreds, we get tired and want to work quicker.

I do not claim for this new developer that it will do everything. The very fact of its energy proves it to be unsuitable for over-exposure, and even for under-exposure it would require to be diluted with water in order to make it act more slowly.

To those who have no need for such quick work, but who yet wish to push on their development, I would strongly recommend ortol. In the

experiment I will show you I take an exposed film and develop it until the image is well out, then I shall cut it, placing one half in the fixing, and leaving the other in plain water. Personally, I use the stream from a tap, but, as I cannot do that here, soaking in plain water will show you, when contrasted with the half that is fixed, how enormously the action of ortol is continued; and, if this be taken advantage of, it helps considerably in getting through a big batch of negatives.

In conclusion, to refer back to the trade worker and the professional, it is when we are told that some thousands of negatives have been produced by a process that we place some reliance upon it. The two things in development I have spoken about, I can assure you, have been thoroughly tested for three or four months and in constant use daily upon—well, never mind how many million negatives.

This paper is really only a few notes strung together somewhat hurriedly, and forms part of a series of development experiments that I am engaged upon, but I thought they might interest you, and perhaps provoke some discussion. I can, however, describe the whole idea in a nutshell. A friend said, "Is it wise to develop quickly when you can do it slowly?" To which I replied, "Is there any sense in developing slowly when you can do it quickly?"

WALTER D. WELFORD.

### PLATES VERSUS FILMS.

WITH many photographers, especially professional workers, there exists a strong prejudice against the use of films; and these are found pinning their faith exclusively to glass supports for their sensitive emulsion. In a great measure this prejudice is fostered by the experience of those whose work is chiefly confined to an interior practice, and who, as a rule, do a large amount of portraiture. On the other hand, there are a large number of professional workers whose calling lies in what may be termed a more "general run of work," very much of which consists in supplying photographs for special trade purposes, entirely outside a studio portrait practice, and with such workers films are looked upon with favour when any particular kind of commission has to be executed. At the same time it would be going too far to say that for every kind of subject films are as suitable as glass supports.

The first real attempt to introduce films for all-round general work, may be said to have originated with the Eastman Company; in fact, for many years, this firm has expended no end of money and labour in bringing to the present high state of efficiency, not only their continuous rolls of sensitive material, but likewise the cleverly conceived apparatus for utilising it; and hardly a season has passed, during the last ten years, in which some fresh advance in their apparatus has not been placed upon the market.

Their first stripping films are still remembered by many old workers, and not a few of them can still be found who look with satisfaction on the negatives secured by these strippers. The method of working them, at the time of their introduction, was, however, by many amateurs and semi-professional workers, looked upon as too messy. Still, they were a step in the right direction, and undoubtedly have led to the production of the more modern "non-stripping" films, which have, during the last number of years, become such a feature in hand-camera work with journalists and amateur workers throughout the length and breadth of the world; and now we see numerous makers catering for the public's support in this material. That there are many first-rate qualities of films now on the market is a fact well known to all those workers who have experience in developing for the trade, and those other amateur workers, who merely press the button and send the rest to be done by their dealer, or professional developer. At the same time it is often painfully evident to a professional developer that much useful material, in the way of high-priced films, is so carelessly manipulated, and which turn out so large a percentage of failures, even under the most careful system of development. Of course the quality of the films, in nearly every case, is blamed for such failures; whilst, in point of fact, the blame lies at the door of the worker who has exposed them. This, no doubt, has tended to give films a bad reputation, as compared with plates. There is so much what is termed snap-shot work done nowadays, with novices who seem to look upon hand-camera work as the most simple thing in the world, that it is little wonder many professionals have come to form quite a dread when asked to develop a number of rolls of sensitive films, the treatment of which, as far as subject and exposure is concerned, is quite unknown to them.

On the other hand, there are those workers who from the very first have seen the advantage which lies in films for various classes of subjects, and these, it is only fair to state, have carefully studied the special treatment necessary when using them, and who invariably turn out as large a percentage of good negatives as would have been acquired with glass.

Of the many forms of hand cameras specially designed for the use of films, it would be out of place to speak of any one pattern in preference to another. That a patent monopoly should rest with any manufacturer for a particular method of exposing films, or rolls of such material, is only a fair recompense, considering the great outlay they have expended

in experimenting, and bringing to such a state of perfection, the various forms of apparatus we now see designed for the purpose.

Every monopoly, however, does undoubtedly deter others from entering on similar lines, and hence we see so many forms of cameras limited to the use of films only, the outcome of which is seen in the exceedingly fine qualities which are now placed before the public; in addition to which there are several makes of films designed more particularly for use with special forms of cameras which are only available for them, and which form a striking contrast to the form of camera capable of exposing glass plates as well as films.

For quite a number of years it would appear as if most of the experiments conducted by manufacturers in the production of sensitive films lay in the direction of adopting that material only as dispensed entirely with the operation of stripping, and therefore, at first sight, it would appear a bold step for any one to suggest a return to the almost original idea of producing a film that required stripping of its paper support before it was in its best condition for printing; yet it is a patent fact that two, if not three, of the latest productions, and for which improvements are justly claimed, are actually "strippers."

These new forms of stripping films are a long way in advance of the original form of strippers, and even during the short time they have been before the public have gained a splendid reputation for negative working. The first of these later-day strippers was placed upon the market by Mr. Wellington, and this was soon after followed by a special class of material termed *secco*, and for which a limited company has been formed. As yet, the extreme simplicity in working of both of these films is not as well known to the public as they deserve. This, no doubt, is due to many causes, one of which being that many workers who use films are tied down by the form of their camera to some particular class of film that is specially required for same. That these modern strippers will, however, continue to make headway with the general public is a certainty.

The treatment of *secco*, for instance, is in reality quite as easy, in fact, easier, than the development of a glass plate, and, for the benefit of those readers who have as yet neither seen nor heard of the manipulations necessary, the following particulars may prove interesting.

The films are supplied in packages like bromide paper, each packet contains twelve films and twelve strengtheners. The latter are laid aside when the packet is opened, and only the sensitive films retained in the dark enclosure. The sensitive film is placed in any dark slide, and exposed as easily as a glass plate. Any formula in development can be used, and, if exposure is about right, the image comes along beautifully, and fine density is secured, as well as a nice range of half-tones, provided the lighting of the subject has been right. The film is then fixed in the usual form in hypo. In fact, up to this stage all the manipulations may be likened to the development of a bromide print on paper. After being well washed the negative is placed in a weak solution of glycerine and water for about one minute, and one of the strengtheners is also immersed in the solution at the same time. After a short immersion the negative is taken out and placed face upwards on a clean sheet of glass, a strengthening film is placed over the same, and both are squeegeed in contact.

In this condition the sensitive portion of the film is enclosed between two sheets of paper; it is, when still damp, pulled off the glass, and pinned up to dry in any suitable position. The drying does not take so long as with glass plates, by reason that the air has access to both sides of the negative, and when quite dry both papers will peel off the film with the utmost ease and certainty. Should intensification or reduction be required, either is as easily effected as with glass plates, and the tooth of the film is very suitable for retouching. For carbon work, where double transfer is shirked, these films are particularly well adapted; and they are just what is desired for the production of sky negatives, especially when exposed in conjunction with a black mirror. The emulsion is quite rapid enough for shutter exposures, and it is the writer's intention at an early date to make a few experiments in orthochromatising these films for colour work. In commercial photography they prove a great boon in many cases where glass plates would be of no avail, and when used in conjunction with one or other of the clever envelope contrivances, whereby only one dark slide is required, and this is capable of being filled and emptied in broad daylight, by reason of the opacity of the containing envelopes, they at once take a place in the first rank of up-to-date clever contrivances, getting rid of weight and the necessity of changing in the dark room, when a fresh supply is required, for any number can be carried in envelopes in the breast-pocket.

That a return to stripping films should have taken place will, no doubt, surprise many, but the fact remains that a distinct advance has recently been made in them, and, if the manufacturers continue to supply them in the excellent form and quality as at present, the public will most certainly get accustomed to their use, and much of the existing prejudice be dispelled.

A. T. NEWTON.

### THE STUDIO OF THE FUTURE.

[Translated from the *Bulletin de la Société Française de Photographie*.]

At the establishment of one of the most skilful provincial photographers—M. Boulland, of Mâcon—I recently saw an installation of artificial light, a description of which will be of interest to all professional por-

traiturists with the camera. It is a fact that M. Bouilland no longer uses daylight for any of his portrait work, and therefore the name which he has given his studio, *L'Atelier du XX<sup>e</sup> Siècle*, is well chosen, for there can be no doubt that the next century will see artificial light in universal use. In giving a complete description of his plant we feel that the question is of interest to the amateur as well as to his professional brother, because the former is prevented from doing more in portraiture by the considerable expense entailed by a suitably glazed studio.

The studio is an elegantly furnished room, which may be furnished in any fashion, and is not lighted from without. The only condition is that the upper part of its principal accessory—the lamp—shall be capable of connexion with a chimney or flue. This lamp is a specially designed piece of apparatus, the back of which is shaped to certain curves which numerous trials have shown to be the best for diffusing the light as in an ordinary studio. The lower part is vertical, the middle portion is above the level of the model's head, whilst the upper part sends the light on to the ceiling of the apartment. Above is one white reflector and another on the shadow side of the sitter. The dimensions of the apparatus are: height, 9 feet 9 inches; breadth, 8 to 9 feet 9 inches; depth, 2 feet 6 inches. It is pivoted on its centre, so that its position in relation to the sitter can be altered.

Some idea of its internal construction will be gathered from the following description: The series of shelves are arranged behind the glazed portion for the reception of the lamps containing the flash powder. By thus varying the position of the lamps, the lighting can be modified as desired. The ignition of the combustible mixture is carried out by completing an electric circuit. Each lamp consists of a saucer-shaped receptacle, made of unflammable and non-conducting material. In the centre of each the electric "igniter" is arranged, a thin circle of platinum wire, mounted on two metal supports. These "igniters" are commercial articles, and can be replaced after each exposure with the greatest readiness. As soon as the circuit is completed, the platinum becomes sufficiently heated to ignite the mixture, whatever number of lamps may be in use. The current is supplied from accumulators giving a current of eight to ten volts, and, in order to produce the magnesium light at exactly the same moment that the shutter is opened, the closing of the circuit is arranged in connexion with the mechanism which opens the shutter.

The question of the powder used as the source of light is one of great importance, as it is necessary to combine extreme rapidity of combustion with great actinic power. Without detailing the very interesting researches which M. Bouilland has made, it may be said that he has prepared a mixture of extremely rapid combustion, inasmuch that the eyes of the sitter never exhibit any trace of movement, and the operator can succeed perfectly with portraits of children. The actinic power of the compound is such that it is possible to take portraits natural size in a time which is only a small fraction of a second.

As will be seen from this brief description, the arrangement has been devised from the point of view of its industrial use. The apparatus is in regular use, not only in the inventor's establishment, but in those of several photographers who have realised the enormous advantages of not being dependent on daylight.

It is some time since that I stated at a conference that a day would come when, instead of estimating the value of light at the time of use, we should actually weigh it out.

This prediction is now fully realised, for the use of given weights of the magnesium powder allows results to be obtained under various conditions with a certainty impossible with daylight. In other words, the problem of what exposure to give no longer exists, and, with this simplification of exposure, development likewise becomes a much more automatic operation. To the amateur this will mean no difficulty from incorrect exposure; to the professional it will mean a much greater uniformity of result, and the avoidance of the duplicate exposures so frequently necessary.

The weight of the magnesium mixture to be employed depends on the aperture of the lens, the size of the plate, and the dimensions of the object thereon. A few preliminary experiments will enable the operator to decide the amounts necessary under the several conditions. As an illustration of this plan, the weights taken by M. Bouilland, when using an applanatic lens for large heads, may be given.

Lens Aperture.	Plate.	Powder Used.
		grammes.
<i>f</i> 8	<i>Carte-de visite.</i>	1.5
<i>f</i> 12	Album.	2
<i>f</i> 12	7 × 9½	4
<i>f</i> 12	9½ × 12	6
<i>f</i> 12	12 × 16	8
<i>f</i> 15	16 × 20	10
<i>f</i> 20	20 × 24	12

These quantities correspond to what one would call a normal exposure. Development takes place rapidly and easily. Less powder can

be used if a smaller image is produced, or, if development is pushed further. Apart from its professional use, there is no doubt that artificial light will enable photography to be of great use to, say, medicine. It will be easy to obtain photographs of interesting cases in the most unfavourable (as regards light) situations.

A. LONDE.

## Our Editorial Table.

"BURMA."

By MAX and BERTHA FERRARS.  
237 pages, with a Map, Index, and Appendices, and 455 Illustrations from Photographs.  
London: Sampson Low, Marston, & Co., Limited.

THIS magnificent book, we are sorry to say, has no preface. A note, introductory to the list of illustrations, tells us that some of the latter are by Bertha Ferrars, by whom all the plates were developed, and that the remainder, with few exceptions, are by Max Ferrars. These few modest words leave unsatisfied our natural curiosity as to the circumstances in which the authors came to write and illustrate the book. For *Burma* is not the hastily written production of the literary tourist, it is a minute and painstaking study of the manners and customs of the Burmese from the cradle to the grave, penned in the restrained and carefully chosen language of trained observation. The authors, we must perforce conclude, lived for a lengthened period in Burma, and their book is therefore to be looked upon as the outcome of a premeditated design to record not merely a series of impressions of a deeply interesting and original living people, but as a scientific chart of the characteristics of a race observed, so to say, under a microscope. Childhood; Adolescence; Manhood and Occupation; Trades and Professions; Alien Races; Political; Pageants and Frolics—these are the headings of the principal chapters. They indicate the scope—the angle of view of the book—but nothing short of actual perusal can give an idea of the wonderful devotion to detail which the authors display in their work.

For ourselves the immediate interest of the book centres round the fact that it is illustrated by considerably over 400 photo-typic reproductions from photographs. When a book is illustrated in this manner, one of two things usually happens, either the original photographs are bad, or, if they are good, the reproductions are not. Frequently both are poor. In the present case neither one thing nor the other happens. The original photographs, it is obvious, were marvellously good, and they have not only been well reproduced by the Swantype Company, but are flawlessly printed. In the whole of our experience we have not come across a book so well illustrated by means of photography as is this fine work on Burma. After many hours spent in its study we are left regretting that no explanatory preface is given, but this does not detract in the least from the sincerity of the praise we are anxious to convey to authors, printers, and publishers alike for their share in the production of one of the best books of the year.

### THE SANGER SHEPHERD UNIVERSAL DEVELOPER.

Manufactured and sold by Sanger Shepherd & Co., 5, 6, and 7, Gray's Inn-passage, Red Lion-street, Holborn, W.C.

THE intimate knowledge of photographic theory which Mr. Sanger Shepherd has long manifested, and the evidences he has given of a thorough practical acquaintance with the manipulatory requirements of successful development in many branches of negative work, qualify him in an especial manner to undertake the preparation of many photographic materials. His firm announce themselves as manufacturers of scientific apparatus, light filters for orthochromatic work, three-colour filters, apparatus and materials for process work, and every requisite for the photography of colour, and a glance through our pages for the past seven or eight years will show that the photography of colour has given Mr. Shepherd many opportunities for making useful contributions to our knowledge of the subject. The firm should have a great future before it, for Mr. Shepherd's researches and experiments in colour photography have been the means of equipping him with a wealth of knowledge that must possess very great practical value. The Universal developer that has been sent to us has been compounded for portrait, landscape, and hand-camera work, lantern slides, black-and-white, and bromide paper, and is claimed to be the only developer for orthochromatic or three-colour photography.

Messrs. Sanger Shepherd & Co. supply the following descriptive notes:—

"The complete developer is packed in two tubes, about four inches long by one inch diameter; the tubes are corked and sealed at both ends, and the contents may be forced out by a wooden plunger given with each box; all the constituents of each tube are in fine powder, and dissolve almost instantly in water. There are no complicated formulæ to worry about, no weighing or measuring is necessary, and, as the chemicals used are carefully tested, both in bulk and in every batch put up, pure, fresh, and energetic solutions are instantly obtainable. The complete developer consists of three solutions. No. 1 is obtained by dissolving the contents of a No. 1 cartridge in 20 ounces of water. Cartridge No. 2 has a cork

division near the centre of the tube, marked by a heavy cross, and the larger portion is dissolved in 10 ounces of water to form the No. 2 solution, No. 3 being made by dissolving the remaining portion of a No. 2 cartridge in 10 ounces of water."

In the pamphlet sent us directions are given for the use of the developer in the eight or nine different classes of work mentioned above. Each tube makes 20 ounces of concentrated, or 40 ounces of normal, developer. We have no doubt that Mr. Sanger Shepherd's high reputation will ensure his firm's preparations great favour at the hands of photographers.

#### THE CEBERITAS DEVELOPING POWDER.

Prepared and sold by William Tylar, High-street, Aston, Birmingham.

THESE developing powders are put up according to the familiar seidlitz method. The contents of two paper packages are separately dissolved in water, and a few ounces of developing solution so obtained. Mr. Tylar remarks: Those people who only do a small quantity of plates at a time will, I think, appreciate this form, as the developer can be mixed, used, and thrown away. I am willing to send a sample packet to any inquirer on receipt of three penny stamps, or four kinds post free for 9d. We have now ready four kinds of powder, viz., hydroquinone, pyro soda, a one-solution compound, and hydroquinone and metol.

#### SPECIMENS OF PHOTOGRAPHIC PRINTING AND ENLARGING.

By Messrs. Morgan & Kidd, Richmond, Surrey.

TWENTY-one years have passed since the establishment of Messrs. Morgan & Kidd's business, which in that time has grown in variety and extent as well as age. We believe that the firm has the distinction of being the oldest makers of gelatino-bromide paper in Great Britain, if not the world. Vast, indeed, have been the changes made in manufacturing photography since 1879, but the Richmond house in 1900 possesses and shows every bit as much vitality as in the days when the late R. L. Kidd and Mr. W. T. Morgan were at the head of affairs. Quite recently we had an opportunity of examining a series of the different kinds of prints and enlargements which are sent out from the Richmond works. We saw collotype prints of the trade or commercial type being turned out in great numbers, whilst on other machines the most delicate kinds of prints for book illustration were being produced. A magnificent catalogue, containing over 100 10 x 8 prints, which the renowned engineering works of Charles Cammell & Co. (Limited), of Sheffield, is sending out, was shown us; it owes its fine collotype illustrations to the presses of Messrs. Morgan & Kidd. Post cards, local view books for photographers, imitation albumen prints, memoranda headings, reproductions of works of art, and many other branches of work are carried out in Messrs. Morgan & Kidd's collotype room, which, with the half-tone department, we have much pleasure in bringing to the notice of those of our professional readers who must have many opportunities of offering prints by these processes to their clients.

In the department of bromide enlarging Messrs. Morgan & Kidd have excelled for many years. We saw some magnificent life-size pictures of Miss Julia Neilson and other well-known ladies from negatives by Alfred Ellis, Van der Weyde, and others. These gentlemen know what is required in *clichés* of this kind, and they are fortunate in intrusting them to a firm like Messrs. Morgan & Kidd, who in the enlargements show a richness of shadow, delicacy of half-tone, and purity of light which do the most thorough justice to subject and process. A great feature of the business is the carbon enlargements, while a speciality known as the "Mulready" or cream crayon bromide finished with chalk should be especially attractive to those who appreciate tinted work. In catering for the photographic profession, Messrs. Morgan & Kidd have command of unequal skill and resources, and the quality of their work is such that it leaves little room for surprise that it is in very great demand.

#### DIE PHOTOGRAPHIE IM HOCHGEBIRG.

EMIL TERSCHAK.

Verlag von Gustav Schmidt, Berlin, W.

ALPINE photography is one of the most difficult branches of landscape work, and the book before us will be welcome to many who wish to visit the Tyrol or the Alps in pursuit of subjects for the camera. The text is well illustrated with views taken by the author, and as it is written in an easy-going, popular style, the tourist will find it not only a book of reference, but a pleasant companion. We are glad to see that Herr Terschak condemns, in unqualified terms, any faking of the negative, and advocates photography in its purest style.

## Studio Gossip.

THE TANQUEREY PORTRAIT SCHEME.—Mr. W. Blakeley, of 4, Seedley-crescent, near Manchester, is the latest photographer to send us a batch of Tanqueray literature. In time, no doubt, the energetic M. Tanqueray will have circularised the whole of the photographic profession in the country.

WE are sorry to learn of the death, on the 19th ult., of Mrs. Ada Isabella Stuart, the wife of Mr. F. G. O. Stuart, the well-known photographer of Southampton. The deceased lady was in her fifty-seventh year. We offer our sincere sympathy to our old and esteemed friend in his bereavement, and are sure that many readers will do likewise.

THE STUDIOETTE.—Mr. C. Parsons, of 48, Moffat-street, Nottingham, sends us a photograph and drawing of his invention, the Studioette, which consists of a box to hold backgrounds, fitted to hang anywhere at a moment's notice. It is principally intended for amateurs and outdoor photographers generally who cannot afford a studio. "Thumbscrews are fitted to the rail, which works in slots, and can be raised or lowered at will. The blinds are on rings, which also move backwards or forwards on the rails. The parts all fold into the box, the door at bottom then fastening with buttons, and the box can then be left hanging outside or taken under cover at will."

WHEN writing last week of the illness of Mr. John Stuart, of Glasgow, we had little thought that the genial Past-President of the Convention had been so ill as appears to have been the case. In a letter subsequently received from him he writes: "I regret to tell you that ever since my attack of influenza I have never thoroughly rallied or felt my old self; one thing after another seems to have come upon me and added 'fuel to the fire.' First, my fall from the scaffolding; then, a few days ago, got tripped up with some causeway stones which were being taken up at the crossing in Buchanan-street, and fell prone with a smash on the very hard causeway stones which you piteously deplored when you were in our city. As yet I hardly know what to say in regard to the visit to Newcastle, but you may rest assured that I will leave no stone unturned to join you there and cry 'Hurray!' for the President-elect. At the present time there are two of my operators in the Royal Infirmary, one operated upon for peritonitis and the other laid up with a broken leg, while your humble servant himself is in a very shaky condition. However, I hope to improve through time." We are quite confident that Mr. Stuart's numerous friends in all parts of the country will echo the latter aspiration.

## News and Notes.

THE Yorkshire Photographic Union's annual excursion to Ripon and Fountains Abbey will take place on Saturday, June 23.

MR. GEORGE MASON.—We are very pleased to learn that Mr. George Mason, of Glasgow, who has recently been somewhat unwell, is recovering, and hopes to be present at the Newcastle meeting of the Convention next month.

"DEVELOPERS AND DEVELOPING" is the title of No. 11 of the *Photo-Miniature*, published by Messrs. Tennant & Ward, 289, Fourth-avenue, New York. It skilfully condenses most of the available information on the subject.

THE BLAIRGOWRIE EXHIBITION.—Messrs. J. Craig Annan, Glasgow, and William Crooke, Edinburgh, who judged the last Exhibition, have again consented to act in that capacity. Mr. H. Snowden Ward has agreed to judge the Lecture Class.

THE PHOTOGRAPHIC "RED BOOK."—This is the title given to a little book designed for the use and information of the members of affiliated societies, to whom it should prove serviceable. It is issued by the Affiliation of Photographic Societies, 66, Russell-square.

RESTORING SPOILT ENGRAVINGS.—Mr. William Borough, of 2, Myrtle-terrace, Old Southgate, writes: "In answer to 'Engraver,' re restoring spoilt engravings, if advertiser will forward same to my address, I shall be pleased to undertake the restoration of them, it being quite in my line."

A CHANGE in the arrangements of the *Practical Photographer* and the *Junior Photographer* will take place in August next. It has been decided to combine the two magazines. The title of the magazine will then be the *Junior Photographer*, with which is incorporated the *Practical Photographer*.

THE Röntgen Society's next Ordinary General Meeting will be held on Thursday, June 7, at St. Bartholomew's Hospital. Dr. Lewis Jones will show an influence machine of American design. Mr. James Wimshurst, F.R.S., will give a short statement of his work in the design and perfecting of the several forms of his influence machine. Dr. Rémy, of Paris, will show a new localising apparatus.

THE report of the Patent Office for 1899, recently issued, gives some interesting notes on the fluctuations of inventive genius. Towards the close of the year, as a result of the war in South Africa, there were several applications for shields for infantry; the extreme heat of the summer produced a few inventions for sunshades for horses; after a fatal accident in Ireland to a passenger on an electric tramcar there were several applications for safety arrangements for such cars; and the passing of the Shop Assistant Seats Act gave rise to over fifty applications for patents for seats. The largest number of applications on one day was 127, and the smallest fell as low as 50. From women there were no fewer than 574, of which 149 were for inventions connected with articles of dress, and 42 relating to cycling.

THE following appears in the current number of the *Harmsworth Magazine*: "100l. for a photograph. The Editor of the *Harmsworth Magazine* offers the following prizes in competition for photographs: 1st prize, 100l.; 2nd prize, 20l.; 3rd prize, 5l.; and twenty prizes of 1l. each. No restrictions of any sort as to size or subject are laid down, but an interesting or curious picture will be preferred. The competition is open to either professionals or amateurs. A selection of the photographs will be published in the Magazine, and all will be at the disposal of the Editor. No photographs will be returned, for those not used will be sent to Netley Hospital for the amusement of the wounded soldiers. All photographs must be sent in by the last day of September, this year, addressed, Competition, Photograph Editor, *Harmsworth Magazine*, Harmsworth-buildings, Embankment, London, E.C."

**AFFILIATION OF PHOTOGRAPHIC SOCIETIES.**—At a meeting of the Executive Committee, held on Tuesday, May 15, Mr. H. Snowden Ward in the chair, the preliminary report from the sub-Committee appointed to consider a proposal to prepare a lighter collection of pictures for circulation was adopted. The pictures will be uniformly framed, and the prints will not exceed 10 x 8 in dimensions, while there will be a celluloid front in place of the usual glass, in order that carriage may be reduced to a minimum. The collection will probably be ready in time for the exhibition season. Business relating to further lectures, and the arrangements for a proper geographical and time sequence of exhibitions, relying upon the inclusion of work from the bigger shows, was transacted. The amended rules adopted by the recent Conference of Judges were brought forward, together with the list of signatories. The attention of exhibition authorities is specially directed to these rules, copies of which can be had on application to the Secretary at 66, Russell-square, London, W.C. The Committee had before them the suggestion of the Liverpool Conference that the rule, giving as a right to members of affiliated societies the privilege of using dark rooms, &c., of other societies, should be modified. The Committee desire it to be understood that there is no rule on the subject, and that the privilege is intended only to be temporary to members visiting districts other than their own.

## Commercial Intelligence.

MR. F. P. WELLS has opened an establishment at 105 Cannon-street, E.C. (opposite Cannon-street Station), for the supply of all photographic requisites.

THE Autocopyist Company, of 64, Queen Victoria-street, London, E.C., write: "We notice in last week's JOURNAL that for small numbers of prints you recommend collotype in preference to half-tone blocks. We would like to mention that for small numbers the photo-autocopyist would be found to answer the requirements of your correspondent, and give results equal to the best of collotypes at a minimum of cost. We enclose you a few specimens, which speak for themselves." The specimens sent are exceedingly good.

THE Board of Trade have appointed the Right Hon. Sir Edward Fry (Chairman); the Right Hon. Sir Richard Webster, Bart., G.C.M.G. (Master of the Rolls), the Right Hon. Sir Edward Carson, Q.C., M.P. (Solicitor-General); Sir Wm. H. Houldsworth, Bart., M.P.; Mr. F. J. S. Hopwood, C.B., C.M.G.; Mr. S. E. Spring Rice, C.B.; Mr. J. Fletcher Moulton, Q.C.; M.P., Colonel Thomas W. Harding; Mr. Edward Carmichael; and Mr. Herbert Hughes to be a Committee to inquire into the working of the Patents Act. Mr. A. Paget, barrister-at-law, is to be Secretary to the Committee.

At a meeting held on May 15, for the purpose of deciding upon the form of testimonial to be presented to Mr. A. C. Brookes, in recognition of his services to the photographic trade in organizing the late Exhibition at the Portman Rooms, Mr. S. L. Goldman in the chair, Mr. Dunn proposed and Mr. Ponce seconded, that some of the exhibitors at the Portman Rooms agreed that a present should be given to Mr. A. C. Brookes as a mark of their esteem, and in recognition of his untiring efforts and zeal in getting the Photographic Trade Exhibition together. The motion was carried unanimously. Mr. Ponce proposed, and Mr. Taylor seconded, that the present should take the form of a silver tray suitably inscribed. This was also unanimously carried. On May 23 the presentation was made at Mr. Brookes' office by Messrs. Goldman, Taylor, Ponce, and Dunn.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

### ROYAL PHOTOGRAPHIC SOCIETY.

MAY 29,—Mr. T. R. Dallmeyer, F.R.A.S. (President), in the chair.

#### EXHIBITION OF PICTURES BY DR. EMERSON.

The Exhibition of photographs by Dr. P. H. Emerson, B.A., M.B. (Cantab.), was formally opened, the whole proceedings occupying only five minutes. Contrary to general expectation, Dr. Emerson did not give an address of any length, but simply made a few remarks relating to the pictures; and, a very cordial vote of thanks having been given to him in acknowledgment of the

time, trouble, and expense which he had devoted to the preparation of the Exhibition, the members present devoted themselves to a preliminary inspection of the exhibits. We say preliminary advisedly, for they demand more careful and detailed examination than they could have been subjected to on Tuesday evening, and will amply repay the earnest study of every photographer.

The collection comprises 140 examples of Dr. Emerson's work, and includes 35 platinotypes printed in 1886, and published in *Life and Landscape on the Norfolk Broads*; 19 photogravures published in *Pictures from Life in Field and Fen*; 24 photogravures (one by the author) from *Pictures of East Anglian Life*; 7 autogravures from *Idyls of the Norfolk Broadland*; 21 photogravures from *Wild Life on a Tidal Water*; 12 photogravures from *On English Lagoons*; 15 photogravures from *Marsh Leaves*, and a few others. Dr. EMERSON said that all the photographs were taken before the end of the year 1891, and many of them in the early eighties, with the exception of the only portrait shown, which dated from 1892, and was the first portrait taken with a tele-photo lens. The last-mentioned picture was the original print exhibited at the first Salon, in 1893. The platinotypes were printed in 1886, and their quality was well maintained. The photogravures were produced by Goupil, Lemerrier, the Autotype Company, and W. L. Colls. The conditions of publication of most of Dr. Emerson's books necessitated the destruction of the negatives and copper plates immediately after the advertised numbers had been pulled, so that there had been no opportunity of making fresh prints in platinotype, a course which, if it had been possible, might have had an interesting result. Many of the works did not fulfil his ideals, but he thought they possessed certain instructive qualities; they would at all events prove how unfair were those critics who described his photographs as "fuzzytypes," and show that many so-called new departures were forestalled years ago. He did not claim that any single one of them was a work of art; they were all naturalistic photographs, constructed in accordance with what he regarded as the true principles of art, and free from the fakes and mischievous dodges of the charlatan.

The Exhibition will remain open until June 30, from 10 to 4, and on Wednesdays from 10 to 8. Admission is free on presentation of card, and everybody should go.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 24,—Mr. R. P. Drage in the chair.

The general instruction that plates should be washed after development and before fixing was the subject of a short discussion, in which several advantages and disadvantages attending the practice, and the alternative one of omitting the washing, were mentioned.

Mr. WALTER D. WELFORD believed that the omission of the washing only gave rise to a possible discolouration.

Mr. E. J. WALL held that there was very little difference whatever course was adopted.

Mr. A. HADDON said that a slight increase of density, as a rule, was the result of no intermediary washing.

Mr. R. CHILD BAYLEY, on the contrary, said that density was increased by long washing after development and before fixing.

Mr. WALTER D. WELFORD read a paper [see pp. 346-7] on

#### RAPID AND WHOLESALE DEVELOPMENT.

The two experiments were then made, Mr. Child Bayley acting as time-keeper of the twenty-seconds' trial. The negative was removed at eighteen seconds, but it was thought to be of full density, and that less time would have served. The experiment showing continuing action conclusively demonstrated the power of ortol in this respect.

Mr. WELFORD agreed that most developers continued their action in water, but his point was that with ortol the power was so very much stronger as to constitute a distinct feature.

Surprise was evinced at the entire absence of fog with such a quick developer, and it was generally agreed that the developer was one that would prove a boon in certain classes of work, for which no more was claimed for it.

Mr. W. F. CRAWFORD showed in action his Express photo-developing machine, exhibited on another occasion, developing by its means simultaneously twenty-four quarter-plates in a very short space of time. The form of the machine was described at a previous meeting. The negatives were all satisfactory, and, being very similar exposures, developed up regularly and together. With varying exposures or uncertain ones it would be necessary to watch carefully for any flashing up of the image, and to transfer any that wanted special treatment to a dish for that purpose.

### PHOTOGRAPHIC CLUB.

MAY 23,—Mr. A. Mackie in the chair.

The CHAIRMAN passed round a negative which had been spoiled during drying by falling dust. It had been placed to dry upon a shelf in a room, the ceiling of which had been newly lime-washed, and specks of this falling upon the negative had dissolved the gelatine. Under a magnifying glass a transparent spot could be seen, and in its centre a nucleus of foreign matter.

Mr. G. J. T. WALFORD read his Affiliation lecture, entitled,

#### SOME METHODS OF CONTROL IN PHOTOGRAPHIC PRINTING.

The paper, which deals only with non-chemical expedients, was illustrated with a number of comparative slides, showing, firstly, direct and unmanipulated prints, with all their faults; secondly, the means thought suitable for their modification, such as ground or partially ground glass with pencillings, intended to mask too prominent features, applications of stained varnish, &c.; and, thirdly, the print as modified by the various methods touched upon in the paper. Pictures without skies were shown with the defect suitably remedied, harsh contrasts softened into harmony, objectionable details altogether removed, and many other corrections the need for which continually arises.

## Patent News.

THE following applications for Patents were made between May 14 and May 19, 1900:—

- DEVELOPING TROUGH.—No. 8869. "Trough for Developing or Fixing a number of Photographic Plates Simultaneously." D. J. H. SIMONS.
- CAMERAS.—No. 9015. "Improvements in Photographic Cameras and in Appliances to be Used in Connexion therewith." H. W. JAMES.
- CINEMATOGRAPHIC APPARATUS.—No. 9112. "Improvements in Apparatus for Photographing and Exhibiting Cinematograph and Mutoscope Pictures." H. W. H. PALMER.
- CINEMATOGRAPHIC APPARATUS.—No. 9141. "Improvements in or connected with Apparatus or Mechanism for the Exhibition of Animated Photographs or Pictures." Complete specification. O. MESSTER.
- COLOURED PRINTS.—No. 9202. "Improvements in the Production of Coloured Photographic Prints, Plates, Films, and the like." Communicated by A. Schwarz. THE ROTARY PHOTOGRAPHIC COMPANY, LTD.
- CINEMATOGRAPHS.—No. 9122. "Improvements in Cinematographs." C. J. D. OPPERMANN and O. R. OPPERMANN.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### MOUNTING GELATINO-CHLORIDE PRINTS.

To the EDITORS.

GENTLEMEN,—In your issue of May 4 inst., S. G. Elliott complains of his difficulty in mounting P.O.P. prints that have been squeezed on ferrotype plates.

If, after the prints are toned and fixed and slightly washed, he gives them a bath for about ten minutes in a fairly strong solution of tannic acid, afterwards completing the washing, he will find no difficulty. He can even wipe off any of the mountant that may have got on the surface of the print with a wet handkerchief, without any injury to the gloss. *Crede experto.*—I am, yours, &c., JOSEPH RAWLINS.

Templeport Rectory, Co. Cavan, May 23, 1900.

### THE STEINHEIL LENSES.

To the EDITORS.

GENTLEMEN,—With reference to the letter in your issue of May 25, from Mr. Arthur Rayment, we wish to point out that the Beck-Steinheil orthostigmat lenses made in our factory are made from the curves and specifications supplied to us by Dr. Steinheil, of Munich, and are identical with those made in his establishment.

These lenses are manufactured under license from Dr. Steinheil, who owns the British patents, and we also beg to inform your readers that we are the sole agents in Great Britain for orthostigmat lenses made by Messrs. Steinheil themselves.—We are, yours, &c., R. & J. BECK, LIMITED.

London, May 26, 1900.

### SALE BY PUBLISHERS OF PHOTO-BLOCKS, ETC.

To the EDITORS.

GENTLEMEN,—Are you not in error in thinking that "J. H." (see last paragraph on page 336) cannot prevent the music publisher from using reproductions of his photographs from the blocks sold them by Cassell & Co.? We have hitherto managed either to extract a new fee for such transactions or to disallow the blocks being used.

It is quite a common thing for publishers of illustrated papers and magazines to sell duplicates of their photo-blocks, and at the same time to acquaint the buyers of their necessity before publishing to ask the charge and sanction of the photographer.

This may not be the law on the subject, but it is a fair, common-sense view of the matter.

Perhaps some one of your numerous readers will be able to put the matter in a legal light.—I am, yours, &c., J. P.

The Rev. F. C. LAMBERT remarked that the question of control in printing is one of the highest importance, and congratulated the reader of the paper on the systematic and exhaustive manner in which the lecture had been prepared. The lecture was most instructive and useful, and should be read by every society in the country. He wished to know the best method of colouring matt varnish for the purposes alluded to in the paper.

Mr. WALFORD replied that he bought his ready-made. Mr. E. W. FOXLEE said that any of the Judson dyes which were soluble in the solvent of the resins of which the varnish was made would answer. Almost all the coal-tar colours were so soluble.

Mr. F. A. BRIDGE said a little turmeric added to the varnish was frequently used, letting the sediment go to the bottom and using only the top.

Mr. LAMBERT believed that iodine was generally used, but that it was rather apt to produce a sediment. He wished that a method of applying matt varnish for this purpose by means of a brush could be found, as it was a great trouble to have to coat the whole of a surface and scrape away what was not required.

Mr. E. DOCKREE spoke of persulphate of ammonia as a method of control. Some time ago he took a negative in a hospital, and the whole of the subject was absolutely blocked by some windows. Persulphate alone would bring back the hidden detail. In reducing hardness of pieces of water in a picture it was so a valuable aid.

Mr. BRIDGE thought that, instead of troubling about partially ground glass, it would save time to take a piece of ordinary ground glass, and render transparent those parts which were so required by the application of oil, glycerine, or other similar body.

The CHAIRMAN suggested an alternative method, that of varnishing the back of the negative with white hard spirit varnish, and producing a matt surface where desired by rubbing the dried coating with resin, pumice, cuttle-fish, or like substance.

Mr. BRIDGE said that a negative varnished with a mixture of gold size and turpentine would be found able almost to defy the effects of water or damp. It could also be put on with a brush, but its drawback was that it required two to three days for drying.

Mr. FOXLEE, referring to the treatment of carbon prints, about which some useful hints were given by the lecturer, said that clouds were usually put in by water colour applied to the back of the negatives instead of by double printing.

The CHAIRMAN, in reply to a question by Mr. Dockree, said that *papier minéral* was so called because it was waxed with mineral or paraffine wax. As regards the substitution for it of waxed tissue paper, he added that the paper sold as *papier minéral* was of a very fine grain, and tissue paper was, as a rule, very coarse in texture. Tracing paper would be better than tissue.

Some discussion having taken place regarding papers suitable for this purpose, Mr. E. A. NEWELL remarked that it was getting more and more difficult every day to say what any paper was, it might be pine wood or any things.

Mr. FOXLEE expressed surprise that the paper used in photography should continue still to be made by only two firms, and his astonishment that competitors did not step into the field.

Mr. BRIDGE thought that when one remembered that, notwithstanding the consumption of paper in photographic pursuits, its bulk was merely a fractional part of that used in other industries, there was little cause for wonderment.

Mr. NEWELL said that the water used in making photographic papers must be absolutely free from iron. He did not believe that there was such a thing to be found in England.

Mr. BRIDGE mentioned a new series of sky negatives introduced by Mr. Walter D. Welford, which were graded off into perfect opacity at one end, and were likely to be very useful. They were on celluloid, and could be had with the opaque portion merely at one end, or reaching nearly into the middle, to suit different classes of foreground negatives.

Mr. LAMBERT said he had prepared graduated shields by fixing a plate and dipping in a picric acid bath repeatedly, a little further at each immersion, until the required depth was obtained. He thought, however, that such plans as these were never used for other than particular purposes, and that many were able to do all that was required with the usual brown-paper shade.

A vote of thanks was given to Mr. Walford.

### FORTHCOMING EXHIBITIONS.

1900.

- July 9-14 ..... Photographic Convention of the United Kingdom (Newcastle-on-Tyne Meeting). Hon. Secretary and Treasurer, F. A. Bridge, East Lodge, Dalston-lane, London, N.E.
- August 21..... Royal Cornwall Polytechnic Society. W. Brooks, Laurel Villa, Wray Park, Reigate.
- October 1-Nov. 3 ... Royal Photographic Society, New Gallery, Regent-street. The Hon. Secretary, 66, Russell-square, W.C.
- November 12-17 ..... Ashton-under-Lyne.
- "   21-23 ..... Hackney Photographic Society.
- 1901.
- January 14-19..... Blairgowrie and District Photographic Association. The Hon. Secretaries, Blairgowrie, N.B.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

H. B. Collis, Westgate Studio, Canterbury.—Two photographs of crypt of Canterbury Cathedral.

T. Everitt Innes, 108, Wellington-road, Heaton Chapel.—Photograph of Miss Robinson's wedding party.

L. Varney, Bridge-street, Buckingham.—Photograph of Parish Church, Buckingham. Photograph of Market Hill, Buckingham.

The Worthing Portrait Company, 4, Railway-approach, Worthing.—Photograph of Lord Roberts's letter to schoolboy W. Treagus, with the toy reading same.

THE GLOBE ENAMELLER.—F. W. GLADISH writes: "Can you tell me where to get a Globe enameller or burnisher?"—In reply: It would have to be ordered through a dealer, as we do not think Messrs. Smith & Co. have an agent in this country.

STUDIO-BUILDING.—H. C. R. The design for the studio is all that can be desired; but, if you can get five or six feet more in its length, you will find it a great advantage. Twenty-one feet is really too short for professional work, as it entails the use of lenses of short foci and their attendant evils.

FAULTY CAMERA.—E. WILSON says: "I have two hand cameras, but only one lens, a R.R. f-6. When I use one camera, I always get the negatives perfectly sharp, but with the other they are always more or less fuzzy. Can you suggest why?"—It is perfectly clear that, in the latter camera, the dark slides are not in register with the focussing screen. The remedy is obvious.

ENAMELLING PRINTS.—GEORGE SNOWE says: "I have been in the habit of enamelling my prints in the usual way with collodion and gelatine. Do you think there would be any advantage in adding a little chrome alum to the gelatine on the score of increasing the permanence of the prints? They are albumen prints."—We should say not, as the alum would not add to the permanence of the picture.

SCRAP PHOTOGRAPHS OF BANK-NOTES.—C. C. asks: "Would there be any objection to my making scrap photographs of Bank-notes, for very large amounts, for sale? Of course, the copies would be of small size, and could never be passed off as the genuine notes?"—Yes; certainly. It is illegal to reproduce a Bank-note in any form or size, and if you did so you would get yourself into trouble.

MARKINGS ON DEVELOPED BROMIDE PRINTS.—E. B. writes: "Will you kindly save cause of marks on enclosed piece of bromide paper, and remedy. All prints, vignettes, and white grounds are the same, no matter what precautions I take."—Some bromide papers are very prone to give these markings where there are large white spaces. They, however, are easily rubbed off with a clean rag moistened with a little alcohol.

WIDE-ANGLE LENSES.—THOMAS BROWN. The optician referred to makes two forms of wide-angle lenses—one a landscape lens and the other a rectilinear, and we fancy you are confusing the two. The latter gives the marginal lines perfectly straight; the former, if used for architectural subjects, would render them somewhat curved. For pure landscape this is to be preferred, though it does not include quite such a large angle of views.

CARBON TISSUE.—HANTS asks: "Can you please tell me where I can get some carbon tissue that will yield pictures of the colour of the enclosed piece of silk?"—So far as we are aware, there is no carbon tissue in the market anything like that colour, and we should say there would be no demand for it if it were. If you want it, we expect you will have to get it made specially, or make it yourself. The Autotype Company or Messrs. Elliott & Son will possibly make it to your order.

BARYTA PAPER.—BARYTA says: "I want some enamelled paper (baryta paper), such as is used for P.O.P. I have tried that used by lithographers and others, and, although the surface answers, the paper itself gets so rotten when washed that it will not hold together. I only want a quire or two."—Messrs. Otto König & Co. are agents for the paper, but whether they supply it in retail quantities we cannot say. Apply to them. Their address is 27, Cross-street, Finsbury, E.C.

SAVING WASTE TONING BATHS.—X. Y. Z. says: "In a recent issue you publish an article by Mr. Webber, on 'Saving Waste Toning Baths,' in which he says, 'Throw your old toning solutions into the waste hypo jar.' I should be obliged if you will give me the formula for solution that will precipitate the gold and silver in the mixed baths."—The silver and gold should be precipitated with a solution of sulphide of potassium—"Liver of sulphur." No more should be added than is sufficient to throw down the metals, as any great excess has a tendency to redissolve the precipitate.

LENS.—H. W. The lens you have is evidently a couple of simple meniscus lenses mounted in a tube. Some of the cheapest kinds of R.R.'s, made abroad, are of this kind. Of course, its optical and chemical foci are not coincident.

VARNISHING PRINTS.—FADING writes as follows: "Can nothing be done to render silver prints more permanent than they are? They all seem to fade after a few years. Could not some sort of varnish be applied to them so as to quite protect them from the air?"—Varnishing a print would not prevent its fading if it contains within itself the elements of decay, as it does when imperfectly fixed and washed. If it does so according to some the varnish would rather hasten the fading than otherwise, as witness some pictures mounted in optical contact with glass.

GOLD PRECIPITATED.—W. PLUMMER writes: "I dissolved a fifteen-grain tub of Johnson's chloride of gold in fifteen drachms of water, and it soon turned dark, and next day there was a brown sediment at the bottom of the bottle. On making up a sulphocyanide toning bath with it, the bath would not tone at all; but, when I used it for a combined bath with alum and acetate of lead, it went all right. Can you kindly enlighten me why the two baths behaved so differently with the same gold?"—The reason is this: In the first place, the gold was dissolved in impure water or in a dirty bottle, and so became precipitated. Hence there was no toning agent in the sulphocyanide bath, nor was there any gold in the combined bath, but here the tones were got by sulphur toning.

FIXING.—AN OLD SUBSCRIBER writes: "It has come under my notice that, after having used the fixing agent, hypo, for prints many years, ammonia fixing is also used. Will you kindly inform me what quantities are used, and if it is suitable for large quantities? I am now using collodion-chloride paper, and find my prints metallic in the shadows. Will you kindly inform me the remedy?"—Ammonia is a very old fixing agent; it was used in the later "fifties," for plain paper prints, but it was not found suitable for albumen ones, as it has a tendency to dissolve the albumen. We have not tried it with collodion papers. We should say that it would be inconvenient to use for large quantities of prints on account of its fumes. By metallic do you mean bronzing in the shadows? If so, that should disappear in the toning and fixing of the pictures.

WHITE SPOTS ON PRINTS.—LUX writes: "I am enclosing portions of mounted print, on which you will notice a lot of white spots. I have of late been troubled by having several prints in every batch with the same spots on them, and cannot trace the cause. If you can indicate it, I shall feel greatly obliged. There is not the least trace of them until the prints have dried after mounting. I never get them on unmounted prints, and yet you will see that the mounts cannot be to blame, as the spots come whatever mounts are used. There can only be one other cause, unless it is inherent in the paper, and that is the paper the prints are covered with. Have you had similar inquiry to this made to you?"—As the unmounted prints do not show spots, and the mounts are not the cause, it would seem that they must be either due to the mountant, or, what is more probable, to particles of pernicious matter, as dust, settling on the prints after they are mounted and are still wet. It may be from particles detached from the paper with which the prints are covered.

MAGNESIUM CYLINDERS, &C.—PHOTOPHILUS writes: "1. I shall be grateful for information as to where cylinders of magnesium (mentioned in Lewis Wright's *Light*, and to be used like lime cylinders, with oxyhydrogen jet, for giving spectrum rich in violet rays) can be procured or how made. I tried with gum water, but, as I apprehended, the ones thus made flew in pieces under the heat. Would silicate of soda serve to knead the magnesium oxide with? 2. I should be glad also to know how to prepare that kind of bromide paper which discolours rapidly under the action of light without any developing process, and is used in some kinds of actinometers."—In reply: 1. Possibly Messrs. Newton, 3, Fleet-street, E.C., might procure these magnesium cylinders for our correspondent if, which we doubt, they are articles of commerce. For their preparation the following formula has been given:—

Precipitated chalk ..... 4 parts.  
Magnesium carbonate ..... 1 part.

Mix to paste with gun water and mould to form.

2. Treat ordinary bromide paper (in the dark room, of course) with a thirty-grain solution of potassium nitrate, and dry in the dark.

OZOTYPE AND MARIOTYPE.—J. MACARTNEY writes: "Would you kindly inform me whether ozotype materials are on the market yet, or, if not, could you furnish me with Mr. Manly's address, and if he would be likely to supply me with materials for the process? 2. I tried mariotype by contact and pressure as described in THE BRITISH JOURNAL OF PHOTOGRAPHY in November 1897, but could make nothing of either process, neither with formulæ given nor slight variations of same; in fact, the tissue, which was in good condition, seemed to become almost insoluble, so that I had to use boiling water for development, and any slight image I got seemed to be tending more to the negative than positive. Do you know of any who have managed to work mariotype successfully according to directions given in THE BRITISH JOURNAL OF PHOTOGRAPHY? I used regular transfer paper and tissue, then prepared paper myself, but could not get a developable image in either case."—In reply: 1. Mr. Manly wrote us on the 27th ult. that the materials for his process would be obtainable in about a month from that date. Better watch our columns. 2. The formula we published was that given by Mr. Marion when he read his paper and demonstrated the process before the Photographic Society. We do not think either of the processes have been much experimented with in this country, though there is food for it. We do not know any one who is working it.

### EX CATHEDRÁ.

THE Paris Exposition, which was formally opened by President Loubet on April 15 last, is, we learn, not yet complete in parts, a matter which is, perhaps, not of the greatest concern to intending English visitors, the majority of whom have probably decided to make the trip to Paris in the holiday months of August and September. This, if we remember aright, was the case with the Exposition of 1889. In reference to that event, it may be of interest to recall the circumstance that photography was denied admission to a place among the fine arts, but was placed in the Industrial Section, "Class 12, Photography and Photographic Apparatus." For photographs, medals were awarded to the following British exhibitors: Messrs. John Thomson, Henry Van der Weyde, Walery, gold; Messrs. Frith, J. Pattison Gibson, F. Hollyer, J. Lafayette, H. S. Mendelssohn, F. M. Sutcliffe, Werner & Son, West & Son, silver; Messrs. W. J. Byrne, James Burnside, J. B. Scott, and York & Son, bronze. In the Photographic Apparatus Section gold medals were awarded to Messrs. J. H. Dallmeyer,

Messrs. Watson & Sons, and Messrs. Ross & Co.; and silver medals to Messrs. Sands & Hunter and Messrs. Shew & Co. At the present Exposition, we may remind our readers, there are to be no medals awarded for photography, a fact which, we are aware, has robbed the Exposition of much of its interest in the estimation of British photographers. The space devoted to British photography at the Exposition is so small that it was found impossible by the Royal Photographic Society and the Camera Club, who were originally asked to undertake the work of organization, to get together a thoroughly representative collection of British work.

\* \* \*

GENERAL WATERHOUSE and Mr. R. W. Craigie co-operated with the Royal Commission for the British Section of the Exposition in selecting photographic work for Paris, the first-named being responsible for the Scientific and Technical Section, and Mr. Craigie for the Pictorial. Both gentlemen, we are sure, did their best for the important interests committed to their charge, and it is their misfortune, and not their fault, that British photography is so inadequately represented at Paris. In 1889 the Photographic Class was placed in an upper building, but it attracted very few visitors, although, as a French writer at that time remarked, "there were a great many pretty things to be seen in the succession of gorgeously got-up salons, where the most celebrated photographers of Paris and other large cities tastefully displayed the finest specimens of their work." Moreover, in those days, "lifelike" portraiture and landscapes "minute in detail," were in almost universal favour. In the space of eleven years photographic tastes and fashions have changed—greatly changed. At a future date we shall commence a series of notes on the Exposition, the result of a personal visit. Meanwhile, we draw the attention of intending photographic visitors to a letter in our Correspondence columns from Mr. A. L. Henderson, who encountered some slight difficulties when photographing at the Exposition, which may be easily obviated, as he points out. We also desire to acknowledge the receipt from the well-known architectural photographer, Mons. Albert Lévy, of Paris, of a series of large views of the principal buildings comprised in the

Exposition. These admirable photographs very finely illustrate the gorgeous nature of some of the structures that have been erected on the banks of the Seine.

\* \* \*

A FEW years ago, as our readers are probably aware, the Worshipful Company of Spectacle-makers, following the example set by some of the old City Guilds in encouraging and furthering the crafts they are supposed to represent, inaugurated a scheme of granting certificates and diplomas, after examination, to those who proved themselves to be competent to act as qualified opticians. The Company did this with the view that the public, when requiring aid to impaired vision, could go to a duly qualified man who understood the theory and practice of optics as distinguished from a mere seller of spectacles. The outcome of this has been the formation of the Optical Society, which, in the course of a year's existence, has secured a membership of some three hundred amongst the leading opticians. Last week the Society held its third social meeting, at which Mr. W. E. H. Thornthwaite, the President, and immediate Past-Master of the Worshipful Company of Spectacle-makers, and the main promoter of the Company's scheme for the certification of opticians, was presented with a telescope, manufactured by Sir Howard Grubb, of Dublin, at a cost of 200*l.*, while Mrs. Thornthwaite was also presented with a handsome opera glass. The presentation was accompanied by an illuminated address, including the names of Mr. Christie, the Astronomer Royal, Sir Robert Ball, the Irish Astronomer Royal, the Earl of Rosse, Sir Reginald Hanson, and many others well known in connexion with optical matters. It is very gratifying to see that many of the old City Guilds, which have money at their disposal, are now expending it with such good results, as witness the Spectacle-makers, the Carpenters, Plumbers, and several others, in furthering the interests of their crafts. Unfortunately, at the time these ancient City Guilds were formed, there was no photography, otherwise we might have had a Worshipful Company of Photographers.

\* \* \*

IN a leading article last week we referred to the Board of Trade having appointed a Committee to inquire into the working of the Patent Acts with reference to the granting of patents for inventions that are "obviously old," &c., and regretted that its scope was to be so limited, *i.e.*, to what the records of the Patent Office show to have been previously patented in this country. We learn that, with the sanction of the Treasury, some reforms are now being carried out in the administration of the Patent Office. These reforms are the outcome of a report of a Departmental Committee, what conducted an inquiry early this year, and whose report will shortly be published. One important point is that the Committee have come to the conclusion that, although it is unnecessary and impossible, on the ground of the cost, to reprint the nearly 9000 specifications that are now out of print, a public benefit would be conferred by giving the Comptroller-General authority to reprint such as there is a demand for. It is suggested by the Committee that he should do so on the understanding that the applicant for them should take not less than six copies at 8*d.* each. This will be a great convenience to the public, inasmuch as now those who wish to have a copy of a specification that is out of print must attend at the Patent Office and there make one. Another recommendation of the Committee is that, as the

illustrated abridgments of specifications have proved so useful to searchers, the old specifications should be abridged at the earliest possible date. It is therefore recommended that illustrated abridgments be prepared of the whole of the specifications from 1617 to 1883 on modern lines, and that the work should be done with all reasonable expedition. The more ancient ones will prove interesting reading, and the later ones, some of them, will prove valuable to intending photographic patentees, as showing what has been done before, and thus give them the opportunity of avoiding repatenting something in which they have been anticipated. There are already abridgments of photographic specifications, but it is only the more recent ones that are illustrated. There are in the report other suggested reforms, but they more immediately concern patent agents than inventors who take out their own patents.

\* \* \*

MR. H. P. ROBINSON'S many friends in all parts of the world will be sorry to learn that in October last he was stricken with paralysis and forbidden by his doctors to write or engage in work of any kind. However, this week we have received a letter written by Mr. Robinson himself, in which he tells us that he is getting better in many ways—an item of news which we are sure will be received with widespread pleasure. Mr. Robinson will not be able to attend the July meeting of the Convention (of which he is Past-President) at Newcastle, but he sends his best wishes for its success. He has been in bed nearly the whole of the time since last October, and he therefore characteristically remarks: "It is fortunate that I prepared my Exhibition pictures last autumn." The forthcoming Exhibitions of the R.P.S. and the Salon will, no doubt, contain some of his work. Within the last few months, it may be remembered, the Council of the Royal Photographic Society conferred the Hon. Fellowship of the Society upon Mr. Robinson. He has been having a very bad time indeed during the winter, but his letter convinces us that he has so far recovered as to be able to resume his active interest in photographic matters, and we are confident we are but voicing the general wish that he should be speedily and fully restored to robust health.

\* \* \*

THE New Gallery, Regent-street, W., which next October is to be the scene of the Forty-fifth annual Exhibition of the Royal Photographic Society, will witness several striking innovations in the classification of the exhibits, to two of which this is a favourable opportunity of making a brief reference. Section II. is to be reserved for general professional work. The prospectus states that the North Gallery will be set apart for a non-competitive exhibition of general professional work, including portraiture, figure studies and groups, landscapes, architectural and engineering photographs, exterior and interior work, &c. No restrictions will be imposed as to date of production or as to the previous exhibition of work for the section, which will be under the management of the Organizing Committee, by whom the right is reserved to reject any work that is considered to be unsuitable from any cause whatsoever. In the allotment of space and charges two methods will be adopted. (a) Space will be let to exhibitors who wish to make a collective exhibit of their work. They may arrange and hang it themselves, or, at their request, it will be arranged and hung by the Committee. Space will be charged for at the rate of 5*s.* per foot linear, payable on allotment. Application for

space must be made by letter, addressed to the Secretary of the Society, on or before July 21. (b) One or more works may be sent to be displayed in the space devoted to general exhibits. The charge for space will be at the rate of 1s. per square foot occupied, with a minimum of 5s., the amount to be sent with the entry form.

\* \* \*

THE foregoing quotations from the Exhibition prospectus should be interpreted as a strong invitation to that much-discussed individual "the bread-and-butter man" to take advantage of the special opportunity that has been created for him to exhibit his work at the R.P.S., let it partake ever so much of the characteristics of the much-derided "usual thing" or "show-case" varieties. Photography of this kind has not had much chance in recent years of manifesting itself at Pall Mall; but the *amende* is to be made at the New Gallery, where special provision is to be put forth for its reception. But let those photographers and others who intend exhibiting bear in mind that applications for space must be made *on or before July 21*. This is a point upon which, in the interests of those concerned, we specially lay emphasis—the decision to exhibit must be made within the next six weeks. For years past we have been the recipients of complaints that the R.P.S. exhibitions excluded what may be termed high-class commercial photography. Now, after this autumn, the ground will have been cut from under the feet of all objectors, for the prospectus has been drawn up on such very comprehensive lines that no class of photography is excluded. The Exhibition, if supported by those in whose interests it is held, should, for the first time in a very recent years, be a thoroughly representative one.

\* \* \*

ANOTHER class, "the trade," which has not hitherto been considered at these annual exhibitions, is also to have an opportunity of showing photographic apparatus and material not necessarily new or novel. Section III. of the Exhibition is reserved for apparatus and material, and that part of the prospectus which is of particular interest to the trade is as follows: "The non-competitive exhibits will be under the management of the Organizing Committee, and will be shown in the Central Hall. The exhibits in the sub-section will not be catalogued. The Committee have set apart certain space which will be let for the erection of stalls, and applications for space must be made by letter, addressed to the Secretary, on or before July 21. Stallholders will have to provide their own tables, stands, counters, show-cases, &c., and all structures, displayed signs, notice boards, &c., will be subject to the approval of the Committee. Attendants, if necessary, must be provided by the exhibitors. Orders for goods may be taken at the stalls, but no delivery at the Exhibition will be allowed. Catalogues, circulars, and price-lists may only be distributed from the stalls. Any special lighting of stalls required will be arranged for at the exhibitor's expense, where possible. No exhibitor will be permitted to transfer or sub-let any part of the space allotted him, and no substance of a dangerous or explosive nature will be allowed in or on any such space." This sub-section of the Exhibition has been arranged for purely in the interests of the trade, who, as pointed out above, should make applications for space *by July 21 next*.

\* \* \*

WE may remind the photographic trade and profession, on whose behalf we have this week made such pointed references to the special inducements held out to them to take part in

the R.P.S. Exhibition next October, that the New Gallery is in all respects superior to the Pall Mall premises for the purposes of a photographic exhibition. The Water Colour Society's Gallery was admittedly too small for what it is now proposed to do. Moreover, it is situated in a thoroughfare which may best be described as leading from nowhere in particular to a destination just as vague. Still, even with these drawbacks, an average attendance of over 11,000 at the Exhibition was annually obtained. We are justified in anticipating a far greater number of visitors to next October's R.P.S. Exhibition at the New Gallery, one of the most commodious, popular, and successful suites of public rooms in London, situated in a brilliant and crowded thoroughfare, and therefore possessing exceptional facilities for attracting a very large number of people to a well-organized photographic Exhibition. We do not believe the photographic world has yet realised the full significance of the magnificent new departure which the R.P.S. has made in selecting the famous New Gallery as the scene of its annual Exhibition; but, when it is brought home to the minds of those interested that, for the first time, exhibition photography is to find a home amid surroundings not to be excelled in any other part of London, we shall be surprised if all classes of photographers and the trade do not come forward to support the Royal Photographic Society in its efforts on their behalf.

#### SOME RESULTS OF JENA GLASS.

THE knowledge of the use of Jena glass in photographic lenses is now virtually universal among all users of cameras; but, thanks to the vagaries of the English language, which permits such a word as glass to possess both a singular and a plural sense, there are many who are under the impression that Jena glass is one particular kind of glass, of novel composition, that turns out to be very useful to opticians. To most of our readers, however, it will be well known that really, instead of one kind only, there are made at the Jena works many scores of kinds possessing refractive and dispersive powers of different degrees, relatively and absolutely, each one of which is tabulated and its properties set out with exactness. Some of them are practically useless by reason of their susceptibility to atmospheric action, though that, in some cases, is remedied by sandwiching them between glasses of a more permanent nature. With such variety of optical possibilities the production of lenses of qualities which years ago were said to be impossible is now a reality, and, provided his purse is long enough, the present-day photographer can purchase instruments which, to borrow Dr. Johnson's words, possess potentialities of qualities beyond the wildest dreams of perfection of his immediate ancestors.

During the last decade some of the acutest intellects of the day have been engaged in the most intricate, laborious, and protracted mathematical calculations in the evolution of these new lenses, and for every year of that time one or more lenses of an entirely new type has been launched.

So great has been the change in the principles of construction that many old and familiar lenses have become superseded in actual practice, and, in some instances, no longer find a place in the maker's advertisements or price-lists. In some respects this is unfortunate, for there are some lenses of special convenience which for crisp definition and extent of field when well stopped down—a condition so often absolutely unimportant—are not excelled by any of the modern types.

The qualities that a photographer wishes his lenses to possess are freedom from astigmatism, flatness of field, extended covering power, rapidity, and "depth of focus;" beyond these, if his lens will break up into two of differing foci, he is all the more satisfied. Before briefly adverting to the first four of these qualities, let us again point out that the so-called "depth of focus" is a function of aperture only; it has nothing to do with the shape or construction of any lens, and is simply a question of diaphragm. It is as well to lay stress on this trite advice, for to this day there are makers of high standing who do not hesitate to describe their lenses as possessing depth of focus, thus leading the ignorant to believe that this depth is something inherent to the construction of the lens in question.

With regard to the other *desiderata*, the new lenses are a very long way in advance of their predecessors. In flatness of field (though this is not always an advantage) the correction is almost perfect, so that now a picture can be taken with the full aperture of the lens that shall be quite sharp from corner to corner, over a fairly large field, without using a diaphragm. Accompanying this quality is a freedom from astigmatism, of a most marked description. All the older lenses, when nearing the margin of a somewhat restricted field, were unable to give sharp definition in that part of the field, owing to astigmatism, and the only resource was to "stop them down," which is, really, evading the difficulty, not remedying the defect. We thus get extended covering power, though working at full aperture, and, so, the capabilities of the lens are increased. Those of the old lenses were listed to cover plates whose longest side was double the focus; but now lenses are constructed capable of doing that well, and with a diaphragm by no means small. One well-known lens will give, with a medium stop, a circle with a diameter of double the focus and yet give sharp definition on a flat field, with complete immunity from astigmatism.

Finally, we may refer to the single drawback possessed by most of these new lenses, their high price. This is not to be wondered at, as, apart from the extra care needed in manufacture, their components are greater in number. One well-known type is composed of cemented back and front lens, each of which is made of four single lenses. But even this drawback is in a fair way of disappearing, as the makers are introducing a fresh series at low prices, but yet unastigmatic and fairly quick. We wish our readers the good fortune to possess one or more of these invaluable triumphs of the optician's craft.

#### Acetylene Generation and Purification on a Small Scale.

—A very useful and practical communication from the Have-meyer Laboratories, Columbia University, upon this subject, appears in the *Journal of the American Chemical Society*. It starts by pointing out that for most purposes the purification is unnecessary, providing that the gas has been generated in a proper manner, the chief factor being that the action upon the carbide is not allowed to produce heating. This cannot be done by the slow drip of water, which often causes frosting and ejection of solid particles into the reservoir of gas. The carbide, preferably contained in a wide bucket or a wide-mouthed bottle, is covered with ninety-five per cent. alcohol. Slow generation at once begins, and enough gas is produced to expel all air present. Water now being added drop by drop, a gradual generation of acetylene occurs without material rise in temperature. Where economy is desirable, the alcohol can be distilled off and collected again. As to purification, the account states that no single one of the many published methods is sufficient, and a combination

of some of them is recommended. The gas produced as above is passed through an aqueous solution of 15.6 per cent. cupric sulphite to which has been added five per cent. of twenty per cent. volume sulphuric acid, the mixture absorbing the alcohol, ammonia, and hydrogen sulphide and phosphide. The gas may be further passed through one or two columns of pumice stone, saturated with an acetic or sulphuric acid solution or chromic acid. A small amount of these purifying minerals serves for a large quantity of gas. When properly carried out, the product is dry powder, and in lieu of the well-known nauseous odour possesses a faint and agreeable smell.

#### Sir W. Crookes on the Radio Activity of Uranium.

—We have from time to time brought before our readers accounts of the interesting researches of a small band of Continental workers on the remarkable radiations known from their first discoverer as Becquerel Rays. He first showed that uranium compounds emitted rays that affected a sensitive photographic plate through bodies actually considered opaque to light; they also discharge an electrometer when brought near them, and, unlike the Röntgen rays, are deflected by a magnet. Further investigation by M. and Mdme. Curie and M. Bémont resulted in a widening of the source of these rays, the conjectural discovery of an impurity which was the actual main source of the rays and its ultimate separation in an impure form. Sir William, whose investigations into the rarer earth metals are of world-wide fame, has taken the matter up, and recently read a paper upon his work before the Royal Society. Some idea of his indefatigable industry and of the labour involved may be formed when we state that of the specimens in his immense collection of minerals every individual one was experimented upon, large plates being covered with black paper, the samples placed upon them, numbered and registered for reference, and then allowed to act for various lengths of time to forty-eight hours and the plates then developed. This was a mere preliminary to the after-investigations, which were naturally of considerable interest. It is impossible to find space for a *résumé* of all the work done, but those photographers who are following up this subject will find the paper *in extenso* in the paper of the *Chemical News*, the first instalment appearing last week.

#### Experiments upon the Aberration called Coma.

—Spherical aberration has always been a crucial difficulty to the lens-maker and not alone the photographic lens-producer. For axial rays it was not difficult to meet it fairly successfully, and the power given by the use of the various glasses from the Jena Works has greatly facilitated the cure. The most difficult aberrations are those arising from the rays striking the lens at an angle; the result has been that the central and the external rays do not meet at a point, the focus of the former lying beyond that of the latter, the result being instead of a point of light a point accompanied by an elongated patch, shaped like an oval extended at one end to a point, this effect being termed "coma." At a meeting of the Physical Society, held last week, Professor S. P. Thompson showed some experiments upon this subject, and among other things a most instructive string-d model illustrating the paths of light rays in the formation of coma. He described coma as being a unilateral distortion, the "tail" of which pointed in a direction depending on the side of the lens presenting to the light. It was due, he stated, to unequal magnification from different zones of the lens, a fact which was shown by covering the lens with a zone plate of three or four rings, and viewing on a screen the distorted images of the several zones. The form of the coma varied greatly with the distance of the screen from the lens. The use of a diaphragm gets rid of this and other aberrations; but for photographic work the problem set before the lens-maker is to avoid coma while yet using a large aperture.

**The late Professor Piazzi Smyth.**—We gather from several of our contemporaries that, by the will of the late Professor Piazzi Smyth, the executors are instructed to repay to the Government Grant Committee of the Royal Society all of the advances, estimated at 300l., made by the Society to Professor Smyth for the purchase of scientific instruments after he went to Ripon. The will

bequeaths to the Royal Society of Edinburgh the portrait of Professor Smyth, by Faed, R.S.A., and all his books of original drawings and journals, and his boxes of glass photographs. The residuary estate is to be in trust for certain legatees for life, and subject to their life interest for the Royal Society of Edinburgh, if agreeable to receive the same as a trust, whereof the income is to be employed by that society, first, in printing for a limited free distribution and a small sale to the public, at a cost of about 600*l.*, the spectroscopic MSS. offered by Professor Smyth to the Government in October 1857, and then to assist or promote, every ten or twenty years, an exceptional expedition for the study of some particular branch of astronomical spectroscopy in the purer air of some mountain elevation of not less than 6000 feet above the sea-level, as tried and found feasible by him in the first experiment on the Peak of Teneriffe in 1856. If the residuary estate is not accepted by the Royal Society of Edinburgh, it is to be distributed amongst the pecuniary legatees.

### THE SOLAR ECLIPSE OF 1900.

[The following interesting communication, which should have reached us in time for publication last week, was delayed in transit.]

In our country there are probably millions of people who have never heard of Wadesboro. Such is fame. Yet Wadesboro is favoured of the gods, and exalted above many great cities. I am going there. It is not suggested that the latter event necessarily implies the former. The two circumstances are mutually independent, though both are due to one cause and will culminate simultaneously. The final result, so far as I am concerned, will be photography of some kind; but what is to be represented in the photographs must necessarily depend upon the amount of cold water which J. Pluvius intends to throw upon the undertaking. In any case, however, a few details will not be out of place here.

The geographical situation of Wadesboro is approximately 35° N. lat. and 80° W. long. From New York, by rail, *via* Philadelphia, Baltimore, and Washington, the distance is about 650 miles. It stands at an elevation of 300 feet above the sea level, and commands an uninterrupted view of the State of North Carolina for a distance of twenty-five miles in all directions; and we have it upon authority that the climatic conditions of that region are "sultry."

From the foregoing details the experienced reader will readily deduce two facts: Firstly, Wadesboro stands upon the central line of totality of this year's solar eclipse; secondly, its immediate vicinity presents many advantages for the establishment of an observing station. Herein we have the secret of its sudden accession to celebrity.

The British Astronomical Association originally organized two expeditions to view the eclipse, one in charge of Mr. E. Walter Maunder, F.R.A.S., of Greenwich Observatory, bound for the shores of the Mediterranean; the other, under the leadership of the Rev. J. M. Bacon, F.R.A.S., whose destination is Wadesboro. The former expedition has been divided into various parties, which will be stationed at a number of points between Ovar, in Portugal, and Algiers. The American party maintains its original organization, and of this party I have the privilege to be a member. We are now ploughing our way across the Atlantic, enjoying the scenery (fog exclusively) off the Great Bank of Newfoundland, and cheered by the incessant melody of the hooter, superadded to the seductive charms of the syren. By the time these lines reach England we shall, I trust, have reached our destination, and have completed all preparations for observing the phenomena of the eclipse.

It is anticipated that a party of American astronomers, under the leadership of Professor Young, of Princeton University, will also be quartered in the neighbourhood of Wadesboro, in which case the situation should be eminently congenial.

Of the courtesy and kindness displayed by the American authorities, technical and official, it is impossible to speak too highly. Everything that could be done for the comfort and convenience of the expedition has been done with characteristic thoroughness; to take one instance only, information likely to be of service in selecting a site for the camp.] It might be thought that, if we received

particulars of a few suitable localities, nothing more need be done; but that is not the view which our American cousins take of the whole duty of man; far from it. Anything and everything at all calculated to be of assistance has been sent over. Such insignificant trifles as trouble and expense have been disregarded entirely. Of books, pamphlets, charts, maps, and tables, geographical and meteorological, everything one could desire has come to hand, and the general excellence of these publications is worthy of note in every respect. The fact is, in science as in most other things, the Americans mean business, and they leave no doubt upon the subject. Would that it might always be so in our own country! But—

It is rather disheartening to think how other countries foster and encourage the work of investigation and discovery, whilst, save for private enterprise, such matters receive only the cold shoulder in England. The present is, of course, only a small instance, but there it is. Think what America has done for our expedition; then reflect that our own Government would not even help us in the matter of chronometers, notwithstanding the fact that we were prepared to accept responsibility for everything in the nature of risk or possible damage.

The work to be undertaken at Wadesboro will be, of course, mainly photographic. Direct observations of an eclipse are as useful as ever they were, and are made freely, but in no department of science has photography effected a greater revolution than in this. Formerly, if used at all, photography merely supplemented the more direct methods of research. Now the case is reversed. We are no longer mainly dependent upon what can be seen by the eye and indifferently recorded by the hand; we now place our chief reliance upon the record made by the sensitive plate. To the casual observer the most striking change would lie in the instrumental outfit of a modern observing party, as compared with the apparatus used years ago. In the majority of cases, what used to be the eye end of the telescope is now the camera end. Most of the observations are not made *during* an eclipse; they may be made days, weeks, or even months afterwards. Let the exposure and development of the plates be satisfactorily carried out, and the actual results can be determined at leisure. In fact, as a rule, all the observer has to do during an eclipse is to "press the button;" he "does the rest" subsequently. The advantages gained by the adoption of photographic methods may be summed up as convenience, simplicity, and accuracy. It is not too much to say that nowadays it would be possible to learn more from the observation of a single eclipse than was ever known of the subject before the advent of photography.

The following details will serve to give some idea of the outfit with which the expedition to America is equipped, and will roughly indicate the work which, weather permitting, it is intended to undertake. It will be noted that none of our instruments can be said to attain to large dimensions. Nevertheless, taken altogether, they represent a considerable bulk of luggage for one small party to carry ten thousand miles in the hope of observing an occurrence which will be visible for about ninety seconds.

Our leader, the Rev. J. M. Bacon, is taking (1) a sixty-inch telescope camera, 4.1" o.g., for photographing the inner corona. (2) A photometric camera for making a comparison between the actinic luminosity of the corona upon this occasion with that of the full moon at a similar altitude. With this instrument exposures have already been made upon the zenith, illuminated by the full moon, one half of each plate being shielded. During the eclipse identical exposures will be made upon the unexposed halves of the plate. In this way the plates upon development will give a comparison of the actinic intensity of the two sources of light. This is a point upon which exact data are of considerable value. (3) Mr. Bacon is also taking with him apparatus for observing the reduction of temperature during the eclipse in strata of the atmosphere somewhat removed from immediate contact with the surface of the earth. (4) An automatic recording actinometer completes Mr. Bacon's outfit. The purpose for which this is to be employed is to decide an extremely interesting question. It has frequently been noted that after totality the light appears to return much more quickly than it dies away as totality approaches. The question is, Does this appearance represent an actual fact, or is it merely an optical illusion, due

to increased sensitiveness of the retina acquired during the comparatively dark period of totality? Many persons have held the latter view, and it is extremely difficult to conceive what can be the cause of this singular fact, if fact it be. At Buxar, however, during the last eclipse, Miss Bacon made a series of equal exposures at regular intervals upon the landscape, before and after totality. This series seems to prove conclusively that the light returns far more quickly than it dies away. Knowing how careful a worker Miss Bacon is, I cannot feel any doubt that her records are substantially accurate, and the differences are so marked that it is impossible to conceive that any accidental error could account for them. It is hoped that the present device, which I have had the privilege of designing, will serve to settle the question one way or the other.

The automatic arrangement consists of a clock-driven mechanism, which causes a sensitive ribbon to travel, at a uniform rate, across an opening, through which the prismatic image of a slit is projected. At a given moment, say, five minutes before totality, the moving ribbon is punctured by a steel point, actuated by means of a key, under the control of the operator. At the exact moment of totality (second contact) the ribbon is again pierced. At the conclusion of totality (third contact) a third puncture is made; and, finally, the ribbon is punctured for the fourth time five minutes after totality has ended. Upon development, the impression upon the ribbon will represent a dark band, whose width will vary with the intensity of the illumination. The brighter the light, the greater will be the distance extended by the image towards the red end of the spectrum, and *vice versa*. The four punctures serve to check the rate of travel of the ribbon. If the movement is uniform, the punctures will be situated symmetrically on either side of the central point of totality. If not, the error will be readily calculable. Assuming that the mechanism is found to run truly, any lack of symmetry in the record can only be due to variation in the intensity of illumination.

Miss Bacon is taking with her a battery of cameras, all mounted upon a single equatorial axis, clock-driven, and with a sliding arrangement for changing the plates. The object of this apparatus is to secure a number of comparatively long exposures, in order to record the outer extensions of the corona to as great an angular distance from the sun as possible. The present being a period when sun-spots are at a minimum, very wide coronal extensions may be looked for. Miss Bacon is also taking a fixed camera for obtaining a sequence of landscape views for comparing the gathering and departing darkness—in fact, repeating the observations already referred to as having been made at Buxar.

Mr. G. Dixon is taking three instruments: (1) a fixed telescope camera, with forty-four-inch Dollond objective; (2) a fixed ordinary camera, with nineteen-inch Ross lens; (3) a hand camera with five-and-a-half-inch Wray R.R. lens. This latter instrument will be used in making an attempt to photograph the so-called shadow bands or ripples of varying intensity of illumination, which follow the course of the moon's shadow over the surface of the ground. These bands are a curious phenomenon, the origin of which is doubtful, and it is hoped that we may be successful in obtaining some representation of them, but they will require something in the nature of a quick exposure.

Miss E. K. Dixon is taking only one instrument, but one in the use of which she is skilled, having had previous experience with it in observing eclipses. That instrument is a slitless spectrocope. It will be employed for eye observations during totality.

The rest of our party, myself excepted, will, for the most part, be concerned in making eye observations of various kinds before, during, and after totality. All, of course, have cameras; and, no doubt, a number of exposures, for various purposes, will be made. These, however, must be dealt with subsequently, when we come to a description of the work actually done. We hope to impress a number of strangers into our service when the time arrives. To this end we have come provided with a supply of minor accessories, such as dark glasses, &c., which will be distributed to any persons who may be desirous of assisting in the work. A specimen of the form containing questions to be answered by those who undertake eye observations is appended *hæretico*. It is not intended that any one observer should answer all the questions put down. Each will select for himself the

particular observations he would prefer to make, and will confine his attention to those points exclusively.

As to the share which I, personally, shall take in the work of the expedition, I can only say, at present, that it remains to be seen. I have just received the cheering information that the case containing the bulk of my instruments cannot be found. It is believed to be on the vessel, but no record of it appears in the baggage list, and it is not manifested in the vessel's manifest. If it should not turn up at New York, I am afraid the messages sent across the Atlantic will be calculated to cause a breakdown in the cable by which they are transmitted. The ship's officers are all very much concerned about the matter; but that does not help very much, under the circumstances. The chief engineer, I hear, has suggested that, if the worst comes to the worst, he can lend me an indicator, which will accurately record the horse power of the eclipse, and give reliable information concerning the variation of pressure during each stroke of the piston. I am going down to say a word or two to that officer presently.

NEVIL MASKELYNE.

#### BRIEF OR PROLONGED EXPOSURES.

THE almost universal tendency of photographers, especially amateurs, to-day seems to be in favour of what is called instantaneous work. I can understand that, for certain subjects, such as running water and animals, &c., in motion, the exposure cannot be too brief, and some of my own best negatives of landscape subjects with foreground torrents have been made with exposures of the five-hundredth to the thousandth of a second, and, where the torrent is an important part of the subject, this brevity is imperative; but, the moment that we come to other conditions, as where the general definition is important and the distances great, demanding an exposure which necessarily sacrifices the detail of form in the torrent, as in an exposure of the tenth of a second, the best policy is to hide the moving water, or treat it as a simple mass of light in the picture, for the water comes as well with ten seconds' exposure as with the tenth of a second, no form being rendered in either case. In fact, I do not care for a photographic rendering of water, really plunging with an exposure of less than the five-hundredth part of a second.

To get this, or anything approximating to it, you must have a very rapid, and therefore large and heavy, lens; by preference, beyond debate, in my own experience, the Goerz double anastigmat, and everybody who has used that lens knows how ponderous it is for large sizes, and how limited in the range of field it is unless stopped down, when it becomes no longer available for the fractional exposures I have indicated, and torrents of breaking sea are out of the question with it. "Instantaneous" is a vague and relative term, for, in reality, the thousandth of a second is no less a time exposure than is one of ten seconds, but the deficiency of our optics and our material makes the record in that fraction of any natural phenomenon satisfactory for all practical purposes, and we may even regard the five-hundredth of a second as instantaneous in the photographic use of the term.

In hand-camera sizes the optical defects are so concealed that we may consider even the fifth of a second as brief enough to be called an instant, but in the rendering of falling water we see how far it is from the ideal. In large sizes, which I am considering as the indispensable field for the attainment of the highest qualities of photography, the tenth of a second is inadmissible for even moving figures in the streets, and beyond that the prolongation of exposure is a matter of indifference, and I consider the longest possible the best; and, in such places as the public squares on the Continent, and landscape in general, I prefer an exposure long enough to allow all moving objects to obliterate all impression of themselves on the plate. Photographing the Piazza of St. Mark at Venice, for instance, I used to give the smallest stop, and interrupt the exposure by putting the cap on the lens when anybody stopped before it, so that in the negative there appeared no people in the square. My friends wondered when I found the Piazza so empty, but there was no intrusion of those absurd passers-by whose ambition it is to get themselves, *per fas aut nefas*, into everybody's sight and notice, and

to make it a rule to get in the field whenever they see a camera up in a public place.

The professional photographer, doing his professional work, knows that he wants much better than I can tell him, but for those who want to do good work on their own requisition, I should say, Do good quick, or good slow work, but don't confound them. Recognise the limitations in either kind, and, if you want the former, devote yourself to the class of subjects best suited to it; get a powerful lens, a focal-plane shutter, and the quickest plates in the market and reconcile yourself to many failures to one complete success, which, however, will be a wonder of its kind and repay you. If you want a charming landscape or architectural subject, use a slow plate, a landscape lens (I find the concentric by far the best for general landscape work or architecture), and with a small stop give maximum exposure and a restraining development; but don't try to attain both objects in one negative, for you will certainly fail, and produce only a compromise, which is always detestable except in politics, and even these they are always unsatisfactory.

W. J. STILLMAN.

#### DR. EMERSON AT THE ROYAL PHOTOGRAPHIC SOCIETY.

[SECOND NOTICE.]

It should not escape mention that the work now being shown at No. 66, Russell-square, was produced by the only man who so far has received the Progress medal of the Royal Photographic Society, in recognition of his efforts as a teacher and exponent of pictorial photography, and it therefore possesses exceptional interest on that account. There is another feature of the Exhibition that gives it a distinctiveness of character which, if it tells very largely in its favour with those who are familiar with Dr. Emerson's many-sidedness as an observer of nature, may, to those who only know him in his photographic aspect, appear as a drawback. With few exceptions these photographs were made for the purpose of illustrating the author's books on East Anglian life and customs, and consequently without the guidance of explanatory text the special qualities of the photographs are not so obvious to the chance spectator as they might be.

This perhaps is only another way of saying that Dr. Emerson, like his two predecessors, in these interesting one-man exhibitions at Russell-square, Mr. Craig Annan, and Mr. F. H. Evans, might with advantage have reduced the number of his exhibits. All three gentlemen diluted their collections of photographs with a number of specimens of good photographic quality but lacking in sufficient interest to entitle them to a place in a collection of work representative or at any rate expressive of their author's best powers. On the other hand, it must be allowed that it is an exceedingly difficult thing to draw the line between work which should find a place in a one-man show, and work which should not. There is no getting away from the fact that the maintenance of a uniformly high level of productive or creative power is a phenomenon not often met with in intellectual workers. The best of us, no matter what our bent may be, are mixtures of the good, the bad, and the indifferent; and the same thing holds good with regard to our work.

With the exception of these somewhat superfluous pictures, such as *A Fisherman at Home*, and *On the Baulks*, to name two typical examples of the least interesting work sent by Dr. Emerson, there is scarcely a photograph here hung that does not possess its own special interest or offer a lesson to the photographer willing to learn one. Three or four impressions left after repeated study of Dr. Emerson's work may be usefully set down here. In the first place, look where you may amongst these 140 photographs, there is no apparent striving after effect. The subjects, obviously simple in themselves, have been given simplicity of treatment, the evil hand of the photo-faker being absent all through. Then, again, if the values of the photographs are carefully studied, it will be seen that in by far the majority of cases they have been correctly rendered in the prints. Where, however, there is an apparent falsification, it is probably due to the printing of the photogravures, which, in some cases, are clearly overdone.

Two other points are worthy of special attention: first, the natural manner in which most of the groups and the figures are posed; second, the really marvellous suggestion of motion which Dr. Emerson has succeeded in imparting to some of his subjects. We may quote as effective illustrations of both these points, No. 20, *Rowing Home the*

*Schoof-stuff*, and No. 55, *The Poacher*, the most celebrated of all his photographs. In No. 9, *Gathering Water Lilies*, we renew acquaintance with a glowing photograph which provoked a great deal of imitation at the time of its production. At the present day, when sheep studies are engaging considerable attention, it is interesting to note Nos. 42, 50, and 64, in which Dr. Emerson's dexterity makes itself apparent—here he shows us that he had thoroughly anticipated one of the latest departures in pictorial photography. In all these and many more we perceive complete command over figure and animal work—no stiffness, no awkwardness is visible in them, while in one, No. 46, *At Plough—the End of the Furrow*, there is a simply wonderful suggestion of natural forward movement, alone sufficient to make the author's reputation in this respect.

Dr. Emerson's versatility is illustrated by No. 142, *Portrait of a Lady*, taken with a tele-photographic lens in 1892. Only last year an eminent French photographer wrote about tele-photographic portraiture as if it were a very new thing indeed. In No. 106, *A Yarmouth Row*, we have a pleasing study of unique domestic architecture. The series Nos. 122 to 136a, which illustrate *Marsh Leaves*, are realistic photographic studies of winter phases in Broadland, snow and mist predominating, and they reveal the author's faculty of translating his observations into photographic records. The predominant impression of the student that East Anglian life and landscape are being illustrated in these photographs should not, indeed, obscure the great fact that the eight walls are covered with work intended to prove that pure photography has been employed to produce pictorial results true to nature, simple in sentiment and treatment. Nothing is shown in an exaggerated or aggressive aspect. Clouds do not overbalance the rest of a photograph, and, where rippling water is shown, the rest of the picture is not made wholly subordinate to it. The "models"—the wherry-men, boatmen, fishermen, and field workers—have, it is clear, not been specially prepared for the occasion. They have been photographed in their working habits and as they work, and, excepting in the few cases to which we above referred, a centre of interest is maintained in all the figure studies.

A one-man show hardly calls for criticism of the particularising kind demanded by exhibitions to which a great number of photographers contribute, and in the present case the circumstances are so peculiar that one's remarks must necessarily harmonise with the spirit which guided Dr. Emerson in organizing his Exhibition. It is a farewell show, in fact. We have therefore to bear in mind that the photographs are the outcome of six or seven years' close study and observation of the possibilities of producing pictorial results by the aid of the lens and the dry plate. That work was long ago completed, and Dr. Emerson is now content to let his writings and photographs speak for themselves. Both should be studied simultaneously in order that perfect justice should be done to one of the most thorough-going and earnest workers photography has yet produced. We hope to hear that the Exhibition at Russell-square, which closes on the 30th inst., has been largely visited. As we remarked last week, the photographs will never again be seen in collected form.

Some months ago, while reviewing the third edition of *Naturalistic Photography*, we expressed the hope that a fourth edition would one day be called for, and we made some suggestions for the omission of some not wholly essential information of a technical kind. If our suggestion is acted upon, we trust the chance will be taken of illustrating the volumes by carefully made copies of some of the photographs now to be seen at Russell-square. Thus theory and practice would go together, and the result would be a valuable contribution to the history of British pictorial photography.

#### DOES BACKING SLOW THE PLATE?

[A Paper read before the North Middlesex Photographic Society.]

A QUESTION has been raised as to whether a backed plate requires longer exposure than one which is not backed, or, as it has been shortly put, "Does backing slow the plate?" Some have not hesitated to affirm that backing does necessitate an increased exposure, and I think that the proportionate speed in the two cases has even been stated as generally applicable. The question is one to which a simple yes or no answer, universally applicable, cannot properly be given, as, although the cases in which any gain in rapidity can be detected from the use of an unbacked plate may be very rare, and even then accompanied by loss of quality, yet in the interest of strict accuracy a qualified reply should be given.

The idea that an unbacked plate will work faster than a backed one, doubtless, originated from a knowledge of the fact that what is known as auxiliary exposure may be employed to aid the more faintly illuminated

portions of the image in registering themselves on the plate. Auxiliary exposure was employed to some extent in the collodion days, and is effective in some cases with gelatine plates, although not generally advisable.\* Amongst the methods suggested in the collodion days was the use of a looking-glass behind the plate—a method resembling the use of an unbacked plate in that the auxiliary light acts chiefly close against the high lights, and not on large masses of shadow.

The method generally adopted when any auxiliary exposure was desired was the exposure of the whole surface of the plate to a weak light for a definite period. This plan is much more to be recommended, as it is a recognised maxim that the exposure should be fixed as sufficient to bring out the faintest radiations that we desire to register, or, as it is sometimes put, "Expose for the shadows, the lights will look after themselves;" and these faint radiations commonly exist as weak lights, breaking up large masses of shadow, out of reach of what is reflected in halation.

As the effect of backing is to prevent reflection into the film of that light which would cause halation, and so act as auxiliary, it follows that, if a plate is coated sufficiently thickly to prevent halation without backing, the presence of backing can have no effect on its speed. The same may be said of any ordinary plate, when the contrasts in the subject are not so great as to cause halation.

Let us now consider the cases in which halation may come in as a factor rendering a shorter exposure desirable with an unbacked than with a backed plate. In the first place the contrasts may be so strong that the high lights and the parts immediately surrounding them will be blocked up and appear over-exposed with an unbacked plate before the large masses of shadow are sufficiently exposed to show the desired detail in them. In this case a compromise may be effected and a shorter exposure given to save something of the lights, whilst sacrificing the shadows. Of course, the result is inferior to what would be obtained on a backed plate with exposure sufficient for the shadows. Another case is where the lights are evenly distributed throughout the picture, and the shadow details nowhere distant from them, as in the case of a window with the groining or device separating and immediately surrounding the panes of glass. Here halation will act as auxiliary exposure, and allow of a shorter exposure being given, although, as before, with inferior result. Another possible case is in copying a black-and-white line subject, when with a thinly coated unbacked plate a shorter exposure than will suffice to get density in the lights must be given, to avoid filling up the lines, both by irradiation and halation—again with inferior results.

Leaving these exceptional cases, it may be said that, with a fairly coated plate, on an ordinary subject, no difference of speed can be detected between a backed and an unbacked plate. I have here four negatives, all of which are on plates that were backed on one half only. The first is on a sensitometer, and no trace of difference can be discovered between the backed and the unbacked halves. The second is exposed on some trees in a garden, and there is no difference in the two halves, except that, at the top of the unbacked half, the twigs and leaves suffered slightly from halation, whilst on the backed half even a telegraph wire is distinct. The third is a window, and, though the lace curtain is clearer in the backed half, there is no difference in the detail either of the furniture below or of the cornice above it. The fourth is of a drawing-room, with window in the centre. Here the table in front of the window and the ornaments upon it show lighter in the unbacked half, and the same effect is noticeable in the music stool and end of the piano, which come in front of the white lace curtain. At a short distance from the window, however, the dark corners of the room are alike in the two halves.

To sum up, then, backing does not affect the exposure, save in a few exceptional cases, and in those cases the exposure is only shortened by submitting to a sacrifice of the better quality which backing would have secured.

W. E. DEBENHAM.

#### HANGING THE ROYAL ACADEMY EXHIBITION.

MANY of our readers who are occasionally represented by their work at photographic exhibitions may read with some interest the following brief account of the method adopted by the Royal Academy of Arts in selecting for exhibition the many thousands of paintings, &c., annually sent in to Burlington House. We abstract the article from *Knowledge* for June:—

Works in sculpture, oil and water colour, black and white, and architectural designs pour into the cellars of Burlington House during the three days granted to would-be exhibitors until they total some 14,000. The names and addresses of the authors of each work have to be re-

\* Some experiments by the late Professor Burton and myself on the effect of auxiliary exposure on gelatine plates were published in the early eighties.

corded, and the thousands of pictures or framed works have to be sorted and arranged, more or less according to size, in order that they may be viewed.

When the viewing day comes, a Council of ten members of the Academy sit and see the whole of these works. It is obvious that men of the highest standard in their art, trained in eye and mind, are able to reckon up the relative merits of very many of the works brought before them in a moment. A Council of Examiners conducting a *viva-voce* examination on some hundreds of students seeking to pass in French would dispose in an instant of such as could not speak three words of that language. Thus fall some thousands of works, which their authors and friends esteemed highly, no doubt on the principle "where ignorance is bliss 'tis folly to be wise." Tolerable works receive more attention, but the greater number of these follow the multitude downstairs into the cellars. Anything that the eagle-eyed Council regard as good work is set aside as doubtful (that is, accepted to be hung if space permits), and these works are so numerous that it is utterly impossible for anything like the whole of them to obtain a place upon the walls. A very small quantity of exceptionally good works—seldom more than eighty—are "accepted" to be "placed" in excellent positions.

The labour of viewing some 14,000 works is enormous. A procession of bearers carry the pictures in a stream before the Council, the names of the various artists not being mentioned. Sometimes the stream rolls on, dull and heavy, at other times it sparkles with "good things." Woe to the mediocre work that finds itself amongst the pearls; had it appeared in the midst of the dull and heavy, it might have had a chance, but in all things comparisons, if odious, tell. A very small part of a second can be given to the larger number of the works, as here described.

A vast number of the works have now to return to the cellars. As the works leave the large gallery where the Council sit, they are classified at once by a staff of commissioners stationed in the various galleries, and are thus alphabetically registered. Some thousands of cards are issued to the authors of these works, the educational effect of which should be to make each recipient "a sadder but a wiser man."

The first part of the Council's labour is now over, and so great is the strain of the concentrated attention given to the work that most of its members are exhausted. This portion takes from seven to eight days.

Then there comes a selection of the selected works—a second viewing. The "doubtfuls" are far too numerous for the space yielded by the walls of the Academy, and hence this fresh sitting.

The duty of the Hanging Committee, consisting of five members, now begins.

The Academicians, whose works have been passed in outside the turmoil of the 14,000, have first to be considered. This year the Academicians are particularly strong, and their works are, as a whole, such as have not been seen for many years. Each Academician is entitled to have four only of his pictures upon "the line," a graceful act to the outside artists, who otherwise would hardly ever obtain this desired position. Places of honour are apportioned to the finest works of members, and, after that, places of honour and position are given to the "accepted" works, and the best of the doubtfuls.

The mass that is left is picked over for the remaining space. The sizes of pictures tell for or against their being hung, as also does the subject, and the colour of the work. Let any one sit down in a room of the Exhibition, and observe how well balanced in size, subject, and colour, most of the walls are, and consider the labour of the Hanging Committee.

No member of the Council (with the exception of the President and Keeper) is allowed in the galleries until the hanging is complete. Then the other half of the Council, together with the President and Keeper, go through the rooms. They pass the work of the Hanging Committee, should it be approved, but it very often happens that what is considered an injustice in the hanging of a picture is, at this final viewing, altered by the Council.

But the labour is not yet over. First and foremost, the endeavour of the Hanging Committee has been to give as good a show as is possible; still, errors may have crept in. Has any "accepted" picture, with its red star, been overlooked? Has an old exhibitor who once earned fame for himself been lost sight of? If such is the case, the Committee orders such works to be hung, and down must come other works to make room. No alteration can take place after this.

Everything that can be done to act justly and generously has been done, but there are hundreds of "doubtfuls" for which no place can be found, and some, no doubt, are better than works that are hung. Perhaps these did not fit, perhaps they were overlooked. Also, as it is impossible to satisfy every one whose work finds a place in the Exhibi-

ion, there must always be a considerable amount of annoyance caused to exhibitors whose work is poorly located.

The Royal Academy of Arts holds itself highly. On the Press day none of its members appear. The critics are left severely alone to say their worst or best. The critic who finds fault is less likely to be laughed at for his ignorance than he who falls into the error of lauding an inferior piece of work.

#### A COMPACT OXYGEN GAS-METER AND HOLDER.

ACCORDING to the June number of the *Camera Club Journal*, at a recent meeting of the Club Mr. Simmelkjær and Mr. Abrahams showed an apparatus, invented by Mr. J. R. Rutter, limelight expert at the Opera House, Capetown, for making and accumulating oxygen gas without the aid of bulky gas-holders, and without the costly and heavy reservoirs which are the only means of carrying oxygen from place to place. The machine was conveniently small and compact, the outside measurement being only eighteen inches by fourteen inches, and it was capable of furnishing a continuous supply of gas for any length of time. By the substitution of glass retorts and the provision of additional wash bottles, it could be used for generating gas sufficiently pure for the work of dentists and others. The nature of the apparatus may be gathered from the following extracts from the directions for use:—

The tank is filled three parts full with water, and the gasometer inverted in it. To the right of the tank is hung a carrier, on the upper portion of which is placed a pipe, to which four retorts are connected. Immediately at the back of the retorts, and about six inches lower down, in the carrier, are holes in which are placed the supporting rods, the former forming a rest for the retorts, and the latter a support for a spirit lamp. Each retort having been filled with a quarter of a pound of black oxide of manganese and crystal chlorate of potash, mixed in the proportion of three ounces of black oxide of manganese to a pound of chlorate of potash, the several parts of the apparatus, gasometer, wash bottle, ether saturator, &c., having been connected, the spirit lamp is placed under the first retort, and from one retort to another, as each in turn is exhausted.

#### THE NEWCASTLE CONVENTION.

##### HISTORICAL NOTES ON THE PLACES TO BE VISITED.

[Reprinted from the *Official Handbook*.]

STANDING on the line of the Roman Wall, which stretched from Bowness-on-Solway to Wallsend-on-Tyne, Newcastle had its focus in the walled military camp, whose site it has entirely obliterated. The family name of the Emperor Hadrian, who visited Britain in A.D. 120, was given to the Roman bridge crossing the Tyne at this point; and the great stationary camp, which occupied the hill above as a *tête-du-pont*, shared with the structure the name of Pons Aelii. It is the second station, counting from the eastern extremity of the Roman Wall at Wallsend, and its site is located to the south and west of the Cathedral Church of St. Nicholas. Pons Aelii was the "Old" Castellum as distinguished from the "New" Castle of Norman times, in which originated the distinctive name of Newcastle-upon-Tyne.

*The Castle*.—The remains of the Norman fortress still extant are: (1) A Postern, with portions of the southern face of the outer wall, on the Castle Stairs, at the descent below the Moot Hall. (2) The Great Tower or Keep in the Castle Garth, built by Henry II., A.D. 1172 to 1177. It is now occupied by the Society of Antiquaries, of Newcastle-upon-Tyne. A Fore-building carries the outer stairway, by which entrance is gained through a machicolated turret. Original lamp niches are seen in the ascent, and at the stair head is an apartment with decorative Norman features on its inner wall faces. On the left the ascent is continued through a rich doorway leading into the Great Hall. Here are hung banners of the knightly families of the north; around are weapons and armour used in the defence of the town, with many pieces of ancient artillery and other antiquities. Stairs from here lead up to the battlements. Immediately below is the Library, enriched with specimens of armour, weapons of offence, and many other objects. Below this the basement floor is reached. Here the great central apartment possesses an original Norman column with radial vaulting. Numerous missiles of stone, used in the defence of the castle, together with relics of the later adaptation of the place as a County prison, lie around. An intramural chamber leads to the Chapel of the garrison, a fine example of late Norman work, exhibiting many characteristic decorative features in which the appearance of the volute in the capitals will be noted.

Further interest will be found in the mural chambers (in two of which the original fireplaces are extant, and in one of which the Castle Well is placed), and in the labyrinth of newel stairs, passages, and galleries throughout the building, whilst the view from the battlements reveals a prospect of the city and river below. The Castle and Black Gate Museum are open daily from ten to four. (3) The Great Gate, commonly known as the Black Gate, built A.D. 1247. The gateway, showing its portcullis grooves, has an arcading on either hand, with doors giving access to semi circular guard-chambers. These present fine examples of thirteenth century vaulting. The superstructure, modified early in the seventeenth century (when it was converted into a dwelling), is now used as the Museum of the Society of Antiquaries. Here are many interesting relics of the past, several pre-Conquest fragments, and the Society's unrivalled collection of inscribed and sculptured stones from the military stations and the line of the Roman Wall.

*Town Walls*.—Considerable remains of the Town Walls are visible, including Towers, Turrets, and a Gateway. These were built at various dates from the thirteenth century. (1) At Hanover-square (foot of Westgate-street, behind St. Nicholas Parish Room) a length of wall remains complete with parapets and embrasures. It was the locality of one of the breaches made during the siege of 1644. (2) At the West Walls (opposite Westgate Police Station) are Durham Tower, Heber Tower, Morden Tower, Ever Tower, with examples of Garites, or watch towers, upon the connecting walls. (3) North side of St. Andrew's Churchyard with an example of the Garite. (4) Plummer Tower, in Croft-street, opposite the Free Library. (5) Sallyport Gate, in City-road. The two last are greatly modernised for use as meeting halls of the Incorporated Companies, in whose possession they remain. During the rising of 1745 the Walls and Gates of Newcastle were put into a state of defence to resist the Highland army of Prince Charles—the last occasion of their use in warfare.

#### CHURCHES.

*St. Nicholas*, the Cathedral Church of the new Episcopal diocese of Newcastle, founded in 1882. It replaced an Early English structure of a much more ornate character; for, with the exception of the tower and lantern, the existing architectural features are meagre. The arcades spring from plain octagonal columns without capitals. The Nave and transepts are of A.D. 1359, and the Choir of about 1368. The tower and spire, the great triumph of the Church and the boast of the people of Newcastle, are of late work dating circa 1450. Among many interesting monuments within are those of Admiral Lord Collingwood, who was born in an adjacent house A.D. 1748, and a recumbent effigy of the late Dr. Bruce (died 1892), historian of the Roman Wall, and equally eminent as archaeologist and philanthropist.

*St. Andrew's*, in Newgate-street, contains a chancel arch of transitional Norman A.D. 1175 to 1185, also Early English and later work. It stands just within the town wall, and has suffered much during the sieges of the town. According to tradition, it was without the wall at this part that occurred the challenge from Earl Douglas to Harry Hotspur, which resulted in the battle of Otterburn, the Chevy Chase of the ballad, August 15, 1388.

*St. John's*, in Westgate-road; some Norman work remains, but the structure is mostly of fourteenth-century work, showing columns without capitals, and in character similar to those of St. Nicholas.

*All Saints'*; a modern church, built in 1786, on the site of an early structure. It is typical of the classical style in late and decadent development; and the interior presents an example of the eighteenth century abandonment of the outward traditional accessories of religious worship. This extreme plainness has lately given place to some fittings of a modern type. In the vestry is preserved a monumental brass of Flemish workmanship, a relic of the ancient church. It commemorates Newcastle's great merchant adventurer, Roger Thornton and Agnes his wife, with their seven sons and seven daughters. He died A.D. 1430.

*St. Mary's, Gateshead*; a church greatly modernised. Some Norman work appears in the South Door of the Nave. The remaining parts are of late fourteenth century and more recent periods. It stands near the scene of the murder of Bishop Walcher. The Angles of these parts resisted the Bishop whom William the Conqueror had set over them. As he left the church the cry was raised: "Short rede, good rede; slay ye the Bishop!" (Short counsel's good counsel, &c.). Whereupon Walcher was slain and the church set on fire, May 14, 1080. At the river margin, immediately below the church, is the site of the great fire and explosion which destroyed large portions of Newcastle and Gateshead in 1854.

*Sandhill*.—Here are illustrations of the domestic architecture of the seventeenth century. Surtees' house is a prominent example of the half

timber construction then in vogue. It is dated A.D. 1657-1658. A mural tablet on its outer face records the fact that it was through a window of this house that Jack Scott, afterwards Lord Chancellor Eldon, eloped with his bride, Bessie Surtees. In the street called the Side, which adjoins, over-hanging buildings of the same period will be noted. In a house in Akenside Hill the poet Mark Akenside was born, A.D. 1711.

*The Guildhall.*—This is an ancient structure refaced in 1791 and otherwise modernised. It includes the Assize Court of the town and county of Newcastle-upon-Tyne, the Town Chamber, or Mayor's Chamber, the Merchant's Court, containing oak panelling, a carved overmantle, dated 1636, and the names and Heraldry of the various Governors of the Incorporated Company of Merchant Adventurers. The basement is used as the Commercial Exchange—High Change 11.30 to noon, afternoon Change, 3.30 to 4 p.m.

*The Trinity House.*—Entrance is from Trinity Chare Quayside, or by way of Broad Chare. The Master Mariners, who formed the Fraternity or Gild of the Blessed Trinity, represent an ancient foundation, and the precincts of their House are in keeping with their venerable character. The residences are grouped in a series of quadrangles, and the Hall, Court Rooms, and Chapel contain many objects of interest belonging to the Master and Elder Brethren of this Corporation.

*Jesus Hospital,* in City-road, east of Pilgrim-street, was built for aged Freemen and their widows. The building is an example of late seventeenth century work. A piazza extends along its entire length and in front is a pant or water fountain.

*Keelman's Hospital,* eastwards in City-road, beyond the Sallyport Gate; built by the Fraternity of Keelmen at their own charge, A.D. 1701.

*The Friars.*—From Charlotte-square, or from Low Friar-street by way of Monk-street, access will be found to the cloister-garth of the house of the Dominican or Black Friars. In the church of this house Baliol did homage for the Scottish Crown to King Edward III., on June 19, 1334. The conventual buildings were granted in 1552 to several of the Incorporated Companies of the town, and their meeting places now surround the quadrangle. The Hall of the Company of Smiths is especially interesting; but the locality is dirty and disappointing.

#### MODERN NEWCASTLE.

*Grey's Monument* was erected, 1838, to Charles, Earl Grey, in recognition of his Reform Bill of 1832, and surmounted by a statue of the Earl by Baily. From the Monument, as a focus, the chief streets of modern Newcastle radiate. The great structures, all of polished ashlar work, here seen in Grey-street, Grainger-street, Market-street, with the connecting streets, including the Market, Central Exchange, Lambton's Bank, Theatre Royal, and Clayton-street, &c., as well as the Arcade, Eldon Square, Leazes Terrace, and minor streets, were the works of Richard Grainger, and the architects, John Dobson and Benjamin Green. Grainger began the reconstruction of the centre of the town after the year 1832, and is said to have erected a mile and a quarter of new streets in five years.

*Central Station* designed by Dobson; opened by the Queen and Prince Albert 1849.

*Stephenson Monument,* Westgate-road, a bronze statue of George Stephenson, by Lough, erected 1862.

*High Level Bridge.*—By Robert Stephenson, engineer; begun in 1846 and finished in 1849. It is noteworthy as representing the transition from cast iron to wrought iron for structural purposes which followed its erection.

*Swing Bridge.*—Opened 1876; the central portion is 281 feet long, and 1450 tons. It is raised off the blocks and swung round for the passage of vessels in about a minute and a half.

*The Moot Hall.*—A massive structure overlooking the bridges from the hill above. It was built in 1810, and here are held the courts for the county of Northumberland.

*The Quayside.*—There are few more picturesque sights than are here presented in busy times when the long line of deep water berthage is fully occupied. At the eastern extremity the Grain Warehouse is a prominent object. Its machinery and elevators discharge grain in bulk from the steamer's hold, which is elevated, carried, weighed, and distributed to the storage floors of the building at the rate of sixty to eighty tons an hour.

*The Town Hall.*—This structure faces the Cathedral, and is probably the least esteemed building in the city.

*Thomas Bewick.*—The workshop of the wood-engraver, whence issued his innumerable "cuts," is in St. Nicholas Churchyard, at its south-east corner. It will be recognised by a wall tablet.

#### INSTITUTIONS.

*Durham College of Science.*—Barras Bridge, established 1871, is an offshoot in connexion with the University of Durham. Its chemical, physical, and engineering laboratories are among the finest in the country, and its course of instruction is widely comprehensive.

*Medical College,* Northumberland-road, is also an institution affiliated with the Durham University.

*Rutherford College.*—Bath-lane.

*Hancock Museum,* of the Natural History Society, Barras Bridge, open daily, ten to four. The magnificent Hancock collection of British birds, the mineralogical and geological collections, and the examples of Thomas Bewick's engravings are of special interest.

*Literary and Philosophical Society.*—Westgate-road, founded 1793; one of the most popular institutions in the city. It has participated in the munificent gifts of the late Robert Stephenson, and of its present President, Lord Armstrong. Its library and lecture courses are its specialities.

*Institution of Mining and Mechanical Engineers,* adjoining the premises of the Literary and Philosophical Society. The Wood Memorial Hall and Library commemorate Mr. Nicholas Wood, mining engineer, advocate and exponent of George Stephenson's claim for his locomotive in the controversies attending the introduction of railway traction. Died 1865.

*Free Library.*—New Bridge-street, including a reference library of 50,000 volumes, with branch libraries built by Alderman W. H. Stephenson in Elswick and Heaton Parks.

*Young Men's Christian Association.*—Blackett-street.

*Geographical Society.*—Lovaine Hall.

*Society of Antiquaries.* (See "Castle.")

#### PUBLIC PARKS AND GROUNDS.

*Armstrong Park,* Jesmond Dene; *Brandling Park,* North-road; *Leazes Park,* Castle Leazes; *Elswick Park,* Elswick and Westmoreland-roads. In the Mansion here are placed the large collection of models of sculpture, chiefly by Lough. The Town Moor and Leazes form the great play-place of Newcastle, extending over an area of between eleven and twelve hundred acres of open country.

*Saltwell Park,* Gateshead, forms a beautiful adjunct to the sister borough.

*Note.*—A.D. 1900 marks the five-hundredth year of the city's separate existence, its charter having been granted by Henry IV. in the year 1400.

#### NOTES ON THE EXCURSION TO HEXHAM AND THE ROMAN WALL.

By J. PATTISON GIBSON.

Members will assemble at the Central Station, leaving by train for Hexham at 10.20 a.m. from one of the western platforms. Half a mile from the station the works of the Elswick Ordnance and Engineering Company lie to the left, and extend towards the river; the railway passes through and alongside of them for over a mile. These works employ over 15,000 men. The railway follows the course of the River Tyne, which it crosses to the south at Scotswood. About two miles beyond, on the north bank of the river, lies Newburn, where General Leslie, with a Scotch army, defeated a small English force, in the time of Charles the First. The great steel works of Spencer & Sons, Limited, are now the prominent objects of the battlefield.

Ten miles from Newcastle, on a commanding knoll, quarter of a mile to the left, stands Prudhoe Castle, the Norman Keep of the Umfravilles. It was often besieged during Scottish invasions, and repulsed an attack made on it by William the Lion, King of Scotland, 1174 A.D. After passing Prudhoe the colliery smoke is left behind, and the line passes through a fertile and beautiful agricultural district. On emerging from a tunnel, Corbridge, the Roman Costoptum, is seen half a mile distant on the right, with its mediæval bridge, which alone, of all the numerous bridges on the Tyne, withstood the great flood of 1771 A.D. On the left, about the same distance from the railway, Dilston Castle stands on the steep banks of the picturesque Devil's Water. It was the residence of James the Third and last Earl of Derwentwater, the popular hero of Northumbrian romance, who was beheaded for his share in the rebellion of 1715. Three miles beyond, Hexham stands on a plateau elevated about 100 feet above the level of the river, from which it is separated by a belt of haughs, covered with nursery and market gardens. Its foreign-looking sky line shows prominently its three oldest buildings—the Abbey Church, the Manor Keep, and the Moot Hall, formerly the Court House of the Archbishop of York, to whom the Manor and Regality of Hexham belonged. Early British and Roman remains have

been found on its site, but the town itself sprang into importance when Etheldreda, the Queen of Elfrid, in A.D. 671, gave it, along with many adjacent lands, to St. Wilfrid to establish a bishopric and found a monastery. The bishopric ceased in A.D. 814, being merged in that of Lindisfarne. The only part remaining of St. Wilfrid's Church is the underground crypt. It lies below the present church, of which the choir was commenced about A.D. 1200, and the transepts completed about A.D. 1240, the work in them being pure Early English. The Early Saxon church had been repaired, and remained in use as the nave. The erection of monastic buildings was carried on during the thirteenth century—a fragment of beautiful early decorated work, forming part of the lavatory, still remains in the cloister square. In 1296 a Scottish army, under the savage Earl of Buchan, burnt and destroyed the abbey, the monastic buildings, and the school, in which 200 scholars had been fastened up.

Scottish invasions and border raids made Tyneside a lively place of habitation until the seventeenth century, no man of substance in it knowing, when he went to rest at night, whether he might awake ere morn to find his cattle driven off, his people slaughtered, and his pele tower in flames. In 1536, although the Austin Canons, who held the abbey, at first resisted by force the commissioners sent down by Henry the Eighth, and initiated the rebellion known as "The Pilgrimage of Grace," they were finally driven out by the Earl of Norfolk, and their lands and goods were sequestered.

Until the first half of the present century hatting, gloving, and tanning were the leading industries of the town; the introduction of the silk hat and the kid glove destroyed the two former, and three only of its numerous tanneries now remain. Among the most notable objects inside the abbey church are the tombstone of a standard-bearer of Roman cavalry, the Saxon Frith Stol or Chair of Sanctuary, the night stair leading from the dormitories into the south transept, the wooden food-loft, with its screen of flamboyant woodwork, which is the only one remaining in any English monastic church, and the quaint chapel and tomb of Roland Leschman, one of the fifteenth century priors.

In driving to the Roman camp at Walwick Chesters, the road crosses the South Tyne by the suspension bridge at Warden, and follows the valley of the North Tyne, passing St. Michael's, an early English church at Warden, with a tower of Saxon masonry, and climbing Warden Hill, which, on its western flank, has a large early British camp.

Walwick Chesters, the Roman Cilurnum, lies on the west bank of North Tyne, and is the sixth camp on the line of the Great Wall, counting from its east extremity at Wallsend. It was garrisoned by an ala of Spanish cavalry. There are remains of its six gateways, and the foundations of the Pretorium and many of the streets have been excavated and cleared. Between the Camp and the river are the ruins of a Roman villa, some of the walls of which are still ten feet high.

#### NOTES ON DURHAM CITY.

The chief town of the county of Durham is situated on the river Wear, about fourteen miles south of Newcastle. It dates from the tenth century, when the monks of Lindisfarne rested there with the body of St. Cuthbert, after their long wanderings in the north of England. Soon after, a church was built, and the removal of the See from Lindisfarne, together with the growing fame of the body of St. Cuthbert, led to the rise of the city.

The church stands some eighty feet above the river, on a rocky peninsula, which was called Dunholme (Hill Island), whence Durham. In 1093 Bishop Canleple commenced to rebuild the Cathedral, and his grand Norman work, and that of his successor, Flambard, yet exists as the main part of the building; but, of course, numerous additions and alterations have been made, the chief of which are:—

*The Galilea*, or Western Chapel, built by Bishop Pudsey, 1153–1195. This is a fine transitional Norman work, and is very similar to that of the chapel in the Keep, Newcastle-upon-Tyne.

*The Nine Altars*, or Eastern Transepts, Early English, 1242–1280, which contained the shrine of St. Cuthbert, who is buried here.

*The Central Tower*, Perpendicular, 214 feet high; the upper portions of the western towers; several decorated and perpendicular windows, &c. On the door of the north porch the Sanctuary Knocker recalls how the church once interposed between the aggressor and the avenger. It consists of a fine grotesque head, with large ring in the mouth serving as knocker, and probably is contemporary with the door itself. Having entered the nave by this door, looking towards the east, we have before us a vista of the noblest and most impressive of the Norman churches in England.

Stretching across the nave between the piers, just west of the north and south doors, there is a line of dark-coloured Frosterley marble, with two short limbs at the centre, forming a cross. Eastward of this no

woman was allowed to go, for St. Cuthbert is said to have had a more than usual monastic dislike to women, and it was thought that to have allowed them nearer his shrine would be distasteful to him. The Chapter House has been recently restored as a memorial to the late Bishop Lightfoot. The banks of the Wear below the Cathedral are crossed by four bridges, and innumerable photographers find on them a happy hunting-ground.

*The Castle*, founded by William the Conqueror, 1072, upon the neck of land guarding the approach to the Cathedral, was for long the chief residence of the Bishops of Palatinate, but is now appropriated by the University, with the exception of some State apartments, which are reserved for the Bishop and Her Majesty's Judges. The Great Hall is one of the finest in the kingdom.

#### NOTES ON ALNWICK.

*Alnwick* (town on the Aln), the county town of Northumberland, is about thirty-eight miles north of Newcastle by rail.

To the right, on leaving the station, will be noticed a column, called "Farmer's Folly," eighty-three feet in height, erected by the tenants of the second Duke in 1816, in return for a remission of rent during a period of agricultural depression. Further on we pass through Bondgate, built in 1450, now the only one of the four gates of Alnwick remaining, and along Bondgate Within to the main attraction of Alnwick,

*The Castle*, which was founded by Ivo de Vesci, who became Baron of Alnwick in 1096. After many vicissitudes it was almost entirely rebuilt by the first Percys between 1310 and 1350, and was for long chief of the border strongholds. It was besieged by Malcolm Canmore, who was killed before its walls. David I. captured it, and William the Lion was here taken prisoner. In 1854 it was restored at the cost of nearly 250,000*l.*, but yet remains one of the finest baronial structures of England. The curtain wall, defended at intervals by towers, encloses an area of about five acres.

Entering by the *Barbican* (1315), one is at once impressed by its grandeur and massive strength. On the battlements may be seen some quaint stone figures, commonly supposed to have been taken by the enemy for watchmen.

*The Keep*, part of which dates from 1350, consists of a number of towers surrounding an inner court, upon entering which, to the right, there is a curious well, which descends in the thickness of the wall. A wooden axle crosses above it, with wheels at each end set round with pegs for winding up the water buckets.

Descending a steep hill from the Barbican to the river, we come to the *Lion Bridge*, built in 1773. It derives its name from being surmounted by the Percy Lion, with poker tail. From here a fine view of the Castle may be obtained.

In the beautiful parks beyond are the ruins of *Alnwick Abbey*, founded in 1147, of which little remains but an outline of the foundations and the gatehouse.

A fine drive leads to the ruins of *Hulne*, a small Carmelite Abbey, built about 1240.

#### THE SPECTACLE-MAKERS' EXAMINATION.

DR. G. LINDSAY JOHNSON writes us as follows:—"As it might be interesting to your readers to know the kind of questions, which are set by the examiners at the Spectacle-makers' examination for the certificate, I beg to enclose a copy of the questions relating to "general optics," and "special subjects," which have just been put before the candidates." The following are the questions kindly sent us by our esteemed correspondent.

WORSHIPFUL COMPANY OF SPECTACLE-MAKERS.—EXTRA EXAMINATION.

#### SPECIAL SUBJECTS.

Wednesday, May 30, 1900. Time 8.30—10.

The candidate may select any one of the four subjects he pleases, but only one set of questions is to be answered.

*Photographic Optics*.—1. Describe with a sketch the general arrangement of a tele-photographic lens. Why does a change in the distance between the front and back components alter the magnification of the lens?

2. How would you find the focal length of a single meniscus lens? What would be the equivalent focal length of a rectilinear lens the front combination of which is 6.5 inches, the back combination 6 inches, and the distance between the centres 0.75 inches.

3. Landscape lenses are usually arranged with the concave side outwards and the stop in front of the lens. Give a diagram to show (a) how, if there were no stop, an oblique pencil would not form a sharp image. (b) How, if the stop were placed behind instead of in front, it would fail to remedy the bad definition at the margins.

*Microscope*.—1. Explain exactly what you understand by multiple

colour illumination, and by dark ground illumination. How can these effects be obtained and in what cases are they useful?

2. What is meant by the numerical aperture of a lens? How does it differ from the angular aperture? Three lenses, a dry objective, a water immersion, and an oil immersion have each an angular aperture of  $100^\circ$ , what is the N.A. of each of them ( $\text{Sin } 50^\circ = 0.766$ )?

3. Explain by means of a diagram the action of a screw collar adjustment to an objective. State how and when it is to be used and the effect the rotation of the collar has on the image.

*Surveying and Nautical Instruments.*—1. Describe a Gunter's chain in detail. What tests would you make to ascertain whether the length is correct?

2. The mirror of a sextant is sent you to ascertain whether its surface is a true plane. Describe the methods you would adopt to find this out.

3. Describe the prismatic compass, and state what it is used for and how you would use it.

*Projection.*—1. State very clearly what it is that the condensers of optical lanterns are required to do; or, in other words, state the precise optical problem to be solved in the design of lantern condensers. Also explain by help of sketches how in good modern lanterns these requirements are fulfilled.

2. Describe with sketches an arrangement for projecting objects or slides that are laid horizontally instead of being set vertically as slides ordinarily are.

3. Solve the following problems:—

(a) A lens of 6 inches focal length is placed  $6\frac{1}{2}$  inches from a luminous disc  $3\frac{1}{2}$  inches in diameter. At what distance will the image be formed and what will the size be?

(b) It is required to form on a screen an image, 9 feet in diameter, of a luminous disc  $3\frac{1}{2}$  inches in diameter. The distance of the screen from the lens being 32 feet, what must be the focal length of the lens, and how far from the lens must the luminous disc be placed?

#### GENERAL OPTICS.

Wednesday, May 30, 1900. Time 7-8.30.

1. How would you distinguish between a shadow and a reflection; for instance, of a tree standing at the edge of a still pond?

2. Explain why it is that in using an ordinary convex lens as a magnifying glass the object you are examining must be placed nearer to the lens than the principal focus of the latter. Give a sketch showing this.

3. If you look through the large end of an opera glass, objects appear much smaller and further away than when seen by the eye alone. Explain by means of a sketch why this is so.

#### HEAT.

1. What do you understand by the term "coefficient of expansion of gases?" If 46 cubic inches of air measured at freezing point expand to 50.6 cubic inches when warmed to  $78^\circ\text{F}$ . at constant pressure, what is the coefficient of expansion of air per degree Fahrenheit?

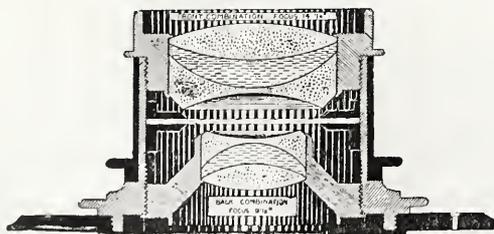

2. Mention three different ways in which heat can pass from a hot body to a colder one; give an example of each, and point out what is the distinction between the three methods.

3. Travellers sometimes ascertain the height of a mountain by placing a thermometer in boiling water when at the summit. Explain the rationale of this experiment, and state how you would conduct it yourself.

#### THE NEW BECK-STEINHEIL CONVERTIBLE ORTHOSTIGMAT.

Messrs. R. & J. Beck, of Cornhill, are now in a position to place on the market a series of orthostigmats hitherto unknown, either in this country or on the Continent, of which they send us the following particulars:—

The orthostigmatic lenses which Messrs. Beck manufacture under licence from Messrs. C. A. Steinheil Sohne, have, up to the present, been merely issued in this country as a very rapid symmetrical doublet, each of whose combinations can be used separately as a perfectly corrected landscape lens of about double the focal length of the original, but

each combination has the same focal value. Having this principle used in the construction of the Orthostigmats, Series I., as a basis, lenses can be constructed of either two similar halves (the Orthostigmats, Series I.), or two similar, but not symmetrical, halves, as in the case of the new series of lenses which Messrs. Beck, of Cornhill, are now placing on the market under the name of the Beck-Steinheil convertible Orthostigmats, Series II. The new series is so compiled that, while allowing of a great

range of foci, it, nevertheless, possesses a rapidity of from  $f-7$  to  $f-7.7$  in the case of the complete combination, and of  $f-12.5$  in the case of the single combinations. Any lens of this new series is really four lenses in one, and therefore universal.

(1) When the two combinations are used together at full aperture, they become a very rapid doublet.

(2) When the doublet is used with a small stop, it becomes a wide-angle lens.

(3) When the front combination is used alone it becomes a perfectly corrected landscape lens of a longer focus than the original.

When the back combination is used alone it becomes a landscape lens, perfectly corrected, of a longer focus than the original, but shorter than the front. The front combination must always be screwed into the back for use. To give a concrete example of this remarkable lens Messrs. Beck cite the performance of the No. 3B, Series II.; as a whole it is a doublet of about 6 inches focus working at  $f-7.7$ ; when stopped down it will cover a plate 9 by 7 inches, giving an angle of about  $87^\circ$  degrees. The front combination is of about  $14\frac{1}{2}$  inches focus, and the back of about  $9\frac{1}{2}$  inches focus, each of these simple combinations, moreover, will cover a much larger plate than that for which they are listed, thus becoming wide-angle lenses for landscape work. The variety of the range in the application of a really high-class landscape lens of the single type is not

very widely appreciated; but for landscape, pure and simple, many photographers give them the preference, as they produce the most brilliant and evenly illuminated pictures. For seascapes, again, they are most suitable, and even for architecture, when a moderate angle only is required, they can be used with eminent success. Of late years also single lenses have become deservedly very popular, for portraiture and the half-combinations of the larger Orthostigmats may be used with great success for large figure studies. The reason for the popularity of the single lens is, no doubt, partially due to the low price of this form of lens as compared with the doublet, together with lightness and portability; also the fact that, when used at extreme apertures, there is a certain softness of result in the modelling which cannot be obtained with the anastigmatic doublets.

The optical qualities of this new Beck-Steinheil Orthostigmat are similar in all respects to the Series I. The mount, it might be added, is clearly engraved with the three foci and the various standard diaphragm numbers for each separate use of the lens. The lenses are also adapted for all hand-camera work, and can be fitted to almost every camera in the market.

The Orthostigmats are issued in nineteen sizes, varying from  $3\frac{1}{2}$  focus to  $23\frac{1}{2}$  inches, and covering plates from  $3\frac{1}{2} \times 3\frac{1}{2}$  inches to  $28 \times 28$  inches.

#### PLYMOUTH EXHIBITION.

THOUGH the Plymouth Photographic Society has had an existence of six years, and has held several exhibitions, they have hitherto been members' shows. On Wednesday, May 23, an Exhibition was opened in the spacious gallery of the Plymouth Institution—the Athenæum—at which there were classes for members and open classes. This was quite a new departure for the Society, but it proved to be a very excellent one and most encouraging for the members, who could thus compare their work with that of outsiders, though it may be said that the best-known contributors to photographic exhibitions were not in strong force.

There were, however, examples from workers who will, no doubt, in coming days, be heard of. The work of the local men was of higher grade than they have hitherto risen to, and it is likely that they will still improve with such incentive as was given them at the Exhibition. Plymouth and the district has plenty of amateur photographers, but they are not much known as exhibitors, which is a pity, because they must have secured many charming pictures in a district where the scenery is beautiful and in many cases striking. The Exhibition consisted of about four hundred frames and a good lot of lantern slides. The general average of the prints and slides was of excellent quality, and the Judges were complimentary in their references to them. They were Dr. P. H. Emerson, Dr. Chas. Aldridge, and Mr. W. H. Babbe (Head Master of Plymouth School of Art). An advantage in the trio was that all were acquainted with photographic work, and two were artists of reputation in the West of England.

The following is the list of awards:—

Class A (Landscape, Seascape, and River Scenery).—Silver medal, A

*Hazy Morning* (31), W. Grist; bronze medal, *A Devon Estuary* (74), D. Adair; certificate, *The Promenade, Kingsbridge* (84), W. H. Mayne.

Class B (Figure Studies).—Silver medal, *In Doubt* (132), C. H. Dymond; bronze medal, *Betty* (117), G. F. Treleven; certificate, *One of the Olden Time* (125), H. J. Hissett.

Class C (Architecture).—Bronze medal, *Ruins, Okehampton Castle* (144), W. H. Mayne; certificate, *Prior's Doorway, Ely* (155), E. G. Turney.

Class D (Enlargements).—Silver medal, *Trawlers, Sutton Pool* (211), W. Grist; bronze medal, *Hereford Bridge and Cathedral* (189), F. E. Turney; certificate, *The Wetterhorn* (191), T. J. Dunstan.

Class E (Lantern Slides).—Bronze medal, C. H. Dymond; bronze medal, W. C. Johns; certificate, F. Johnson.

The foregoing are Members' Classes.

Class F (Landscape, Seascape, and River Scenery).—Silver medal, *Resting* (235), E. A. Price; bronze medal, *Victims of the Cornish Coast* (226), W. H. Harrison; bronze medal, *A Moorland Hut* (245), T. Allworth Courts; certificate, *Joe's Ship* (217), Graystone Bird.

Class H (Architecture).—Silver medal, *In Wirksworth Church* (272), W. R. Bland; bronze medal, *Capital in Chapter House, Southwell Minster* (285), A. J. Loughton; certificate, *Crypt, Gloucester Cathedral* (270), S. A. Pitcher.

Class G (Figure Studies).—Silver medal, *Catching the Breeze* (335), T. A. Sands; bronze medal, *A Colonial* (307), W. H. Harrison; certificate, *When Eyes grow Dim* (346), F. G. Tryhorn; certificate, *A Village Worthy* (353), J. B. Maclachlan.

Class G (Still Life).—Silver medal, *Fruit Study* (339), J. M. Whitehead; bronze medal, *Gladioli* (352), Miss Maclachlan.

Class I (Lantern Slides).—Silver medal, A. T. Crane; bronze medal, *Grayscale Bird*; certificate, J. Gunston; certificate, A. E. Smith.

Class J was devoted to pictures not for competition, and these were contributed to by the members in a most praiseworthy way, as well as by some other well-known workers. It is clear that, from the good beginning made by the Society in attracting outsiders, in future years more will be found to contribute to the Exhibition, and the Society has the duty thrust upon it of working up the West country generally to attempt high-class photographic pictorial work. The Exhibition was continued on Thursday and Friday, May 24 and 25 respectively, concluding with a *conversazione* on the evening of the last-named day. This was a very enjoyable function. During the evenings of the Exhibition lantern-slide exhibitions were given, and the attendance was good throughout the whole of the proceedings. On the first day the Judges and some of the officers of the Society lunched at the Duke of Cornwall Hotel, at the invitation of the President, Mr. H. S. Hill, M.J.I., who has always been very hearty in his support of the Society, and who has done much to help its progress and success. Those who had worked assiduously to bring about this first open Exhibition of the Society are to be congratulated upon the result of their efforts, and it is to be hoped that the work begun may be continued without break, so that so important a district may rely upon having an exhibition of good quality and excellent proportions at least once a year, and it is clear that the choice of date was rather happy than otherwise.

## Our Editorial Table.

### A PROFIT AND LOSS CHART.

MR. ARTHUR PAYNE, F.C.S., of Newcastle-on-Tyne, sends us a copy of a little book entitled "Profit and Loss Chart, for the use of works managers and others interested in the profitable conducting of a factory." Briefly, by the aid of the system of charting recommended by Mr. Payne it may be seen at a glance how a factory is paying. Works managers should find the book of the greatest assistance. It is published at the price of one shilling by Messrs. Percy Lund, Humphries & Co., the Country Press, Bradford.

### VERSCHIEDENE REPRODUKTIONEN-VERFAHREN.

By August Albert. Wilhelm Knapp, Halle a/S.

WITHIN the compass of 180 pages, Professor August Albert of the Vienna Technical School, gives a valuable treatise on the numerous applications of photography and similar processes to illustrations. The work deals especially with lithographic and typographic printing, and particularly with photo-mechanical work. Although many obsolete processes have been purposely omitted, Professor Albert has been careful to include those which may be of importance to the student. The subject is treated theoretically and historically and numerous illustrations assist the reader in forming an opinion of the advantages and limitations of the many processes described.

### THE YEAR BOOK OF PHOTOGRAPHY FOR 1900.

Edited by E. J. Wall, F.R.P.S., 647 pp., price 1s. London: The Photographic News, 9, Cecil Court, Charing Cross-road, W.C.

THERE is one article in the *Year Book* which is worth the shilling charged for the entire volume. We allude to that headed "P.O.P. by the Editor." In the course of considerably over a hundred pages Mr. Wall deals with the history of gelatino-chloride paper; the various

methods of making the emulsion, printing, toning, fixing and washing, development, &c. The article is a perfect storehouse of information on the subject, and as a piece of painstaking compilation does the author the highest credit. In our opinion it is worth reprinting and issuing in separate form. Besides many half-tone illustrations the *Year Book* contains articles on "Pictorial Composition," by J. T. Ashby; "Lantern Slide Making," by Mr. Vivian Hyde; "The Photographer's Gazetteer," by the Editor; a section devoted to "Novelties of the Year," formulae, tables, &c., and other information. The *Year Book* for 1900 is every bit as useful and readable as its predecessors and should be popular with the large class to which it appeals.

## Studio Gossip.

"PEACE WITH HONOUR."—An amusing story is told in *Macmillan's Magazine* in connexion with Disraeli's famous phrase, "Peace with Honour." In the course of a political lecture, illustrated with a magic lantern, in a country village, portraits of Lord Beaconsfield and Lord Salisbury, with the words "Peace with Honour," were thrown upon the screen. An old lady among the audience, whose head was full of recollections of a notorious criminal, innocently remarked, amid great laughter, "Which is Peace?"

SIR HENRY IRVING AND THE OXYGEN TREATMENT.—The celebrated actor, who recently returned from the United States, remarked to an interviewer: "Happy is the theatrical company that has no tale of mishaps. We met with nothing unusual. I was once the victim of a gentleman, who, emulating Sherlock Holmes, had published the startling report that I was only kept alive by copious libations of oxygen. He happened to see outside the theatre some fifty or sixty cylinders which were used for the limelight, and asserted that when I had finished my lines I was rushed off the stage to my dressing-room and there subjected to these draughts! He naively remarked that even the key-hole of my room had been stopped! I should add that the reason we carried our limelight about with us was because in some theatres there is no preparation made for its use."

## News and Notes.

THE "DAILY TELEGRAPH" WAR FUND.—We have received the following additional sums for this fund:—Mr. G. R. Baker, 5s.; Mr. J. W. Tourtell, Fowey, 2s. 6d.

THE SIEGE OF KIMBERLEY.—At the Camera Club, on Monday next, June 11, Mr. G. M. C. Luard (Reuter's correspondent) will give an illustrated lecture on "The Siege of Kimberley."

THE NEWCASTLE CONVENTION.—There will be a meeting of the Council at Anderton's Hotel, Fleet-street, London, E.C., on Wednesday, June 13, 1900, at six o'clock. The following is the agenda: To discuss the final arrangements for the Newcastle meeting; the nomination of members for the new Council; general business.

A ROYAL PATRONESS.—The Princess of Wales has consented to become the Patroness of the Alexandra Camera Club, Grimsby, a private organization of some dozen amateur photographers in the town. Mr. T. M. Williams (Port-Master) is the President, and Mr. W. H. Marris the Secretary *pro tem*. The Club is limited in membership.

THE General Architectural Congress begins on the 18th inst., and the Royal Institute of British Architects will give a *conversazione* in connexion with it on the 19th at Guildhall. As it is proposed to hold at the same time an exhibition of architectural drawings and photographs, there ought to be a good attendance of architects, artists, and students.

ROYAL PHOTOGRAPHIC SOCIETY.—Ordinary Meeting, Tuesday, June 12 at 66 Russell-square, at eight p.m. Mr. H. L. Aldis, B.A. (Cantab.), will read a paper entitled, "The Construction of Photographic Objectives—Mathematical Investigation." The exhibition of photographs by Dr. P. H. Emerson, may be viewed on presentation of visiting card, between the hours of ten and four; Wednesday, ten to eight.

AN EXTRAORDINARY NEWSPAPER.—The most up-to-date of all modern newspapers is the *Stereo-Revue*, published in Paris. This extraordinary newspaper gives the news of the day, or rather week, not in type, but in instantaneous photographs on a film like that of a cinematograph. A bobbin of this film is the journal, and the subscriber puts it through a portable stereoscope like a field glass, and looks at the pictures.—*Home Chat*.

HALF-TONE AT THE PARIS EXPOSITION.—*Process Work* states that the Paris photo-engravers have adopted a very good plan. They have formed themselves into a little syndicate, and make a joint exhibit, which promises to be very effective. There was some talk of one of the exhibits being a wondrous large half-tone block, made by joining together a number of negatives, and said to exceed in size anything ever before attempted.

ENTRIES will shortly close for the Ladies' Kennel Association Show, in the Royal Botanic Society's Gardens, Regent's Park, London. The large sum of 6000l. is offered in prizes for ladies' dogs, cats, poultry, pigeons, cage-birds, and ladies' amateur photography. The Show is limited to ladies, but not to members. H.R.H. The Duchess of Connaught is the President of the Association, and takes a keen personal interest in its welfare. Further particulars may be obtained from Mrs. Stennard Robinson, the Hon. Secretary, 5, Great James-street, London, W.C.

AN alarming fire broke out at one o'clock on Saturday, at the Photographic Studio and Cycle Works of Mr. Gude, High-street, Maidenhead. The outbreak was caused by the ignition of benzine vapours from the cycle works, on the lighting of a gas stove in the kitchen, and the whole of the back of the

premises was soon in a blaze. Mr. Gude, in endeavouring to check the fire, was seriously burnt on the arms, hands, and face, and was in a state of collapse when assistance arrived. Fortunately, Dr. Noble Smith, a London physician, was passing on a bicycle, and he rendered valuable surgical aid. Great damage was done by the fire, notwithstanding the efforts of the local fire brigade, but the adjoining premises were fortunately saved.

**PHOTOGRAPHING IN CHINA.**—It would seem, according to an evening contemporary, that the "heathen Chinese" is not in favour of photography when he knows it as such. The paper says that Mr. Ernest Hatch, M.P., has been working a cinematograph in Pekin, "and that the Celestials gathered round in silent adoration while the film was passing the lens; but, when two Germans came along with an ordinary camera, the Chinamen smashed it." Of course, we do not vouch for the accuracy of the report, but, if it be true, it seems that China is not a desirable place for amateur photographers to visit with their cameras. We know, however, that Mr. J. Thomson, some twenty years ago, did secure a fine lot of photographs in the Celestial Empire, with which he illustrated his work on China, and we do not think he met with much opposition while working.

**THE GREAT TELESCOPE AT THE PARIS EXPOSITION.**—"A picturesque ceremony," says the Paris correspondent of the *Daily Chronicle*, "took place on Monday at the Palais de l'Optique. Mgr. Lorenzelli, the Papal Nuncio, accompanied by his auditor and secretary, who was received by M. François Deloncle, the Abbé Odelin, representing Cardinal Richard, the Directors of the Paris and Meudon Observatories, Prince Henry d'Orléans, and Prince Roland Bonaparte, formally blessed the 'Siderostat,' or monster telescope, according to the ritual of the 'Angelic Teacher,' Thomas Aquinas. The prelate, who stood at the foot of the telescope, clad in rich vestments, with mitre and crozier, preached an eloquent sermon on the growing harmony between science and revealed religion. The benediction was then pronounced, and the 'Siderostat' was shown to those who had been invited."

**ANCIENT SUN-DIALS.**—"It is probable that the earliest sun-dial was simply the spear of some nomad chief, stuck upright in the ground before his tent. Amongst those desert wanderers, keen to observe their surroundings, it would not be a difficult thing to notice that the shadow shortened as the sun rose higher in the sky, and that the shortest shadow always pointed in the same direction—north," says Mr. E. Walter Maunder in *Knowledge* for June. "The recognition would have followed very soon that this noonday shadow changed in its length from day to day. A six-foot spear would give a shadow at noonday, in latitude 40°, of twelve feet at one time of the year, of less than two feet at another. This instrument, so simple, so easily carried, so easily set up, may well have begun the scientific study of astronomy, for it lent itself to measurement, and science is measurement; and probably we see it expressed in permanent form in the obelisks of Egyptian solar temples, though these, no doubt, were retained merely as solar emblems ages after their use as actual instruments of observation had ceased. An upright stick, carefully plumbed, standing on some level surface, may therefore well make the first advance upon the natural horizon. A knob at the top of the stick will be found to render the shadow more easily observed."

**THE BADMINTON COMPETITIONS.**—The proprietors of the *Badminton Magazine* (published by Mr. W. Heineman, Bedford-street, Strand) offer a prize of ten guineas each month for the best original photograph sent in representing any sporting subject. Ten other prizes will also be given away each month, each of them consisting of an original drawing by one or other of the artists who illustrate the magazine. The following are the conditions: Good, clear pictures are, of course, necessary, and, when possible, the negative should be sent as well as the print. Competitors may also send any photographs they have by them on two conditions: that they have been taken by the sender, and that they have never been previously published. A few lines explaining when and where the photographs were taken should accompany each negative. Residents in the country, who have access to shooting parties, or who chance to be in the neighbourhood when hounds are running, will, doubtless, find interesting subjects, and these will also be provided at football or cricket matches; wherever golf, cycling, fishing, skating, polo, athletics are practised. Racing and steeplechasing, including hunt meetings and point-to-point contests, should also supply excellent material. All matters of public-school interest will be welcome.

**ANOTHER "NEW" PHOTOGRAPHIC DISCOVERY.** The new discoveries in connexion with photography that from time to time appear in the lay press are really amusing to photographers. On Saturday last the *Daily Mail*, in all seriousness, published a communication from its own correspondent at Rome, under the date May 29, that "Captain Gentili, an Italian officer, who has been experimenting in long-distance photography, has discovered (the italics are ours) a means of taking photographs at a distance of twelve miles. By this means it has been possible to photograph fortresses from a distance of eleven miles, and masses of troops at a distance of nineteen miles." It is added that the Captain's invention is likely to become of considerable importance from a military point of view. Evidently the *Daily Mail*, or its own Rome correspondent, and, possibly, the gallant inventor, have never heard of the telephoto lens, which, thanks to Mr. T. R. Dallmeyer, has been in the market for some years now, and its results are well known. However, this "new" discovery of the Italian officer will, doubtless, go the round of the lay press, and professional portraitists will, no doubt, be duly informed of it by their sitters, as they are and have been for generations past, of the "new invention for taking photographs in natural colours."

## Commercial Intelligence.

"I. C."—*Photographic Scraps* for June contains the following mysterious paragraph: "We shall have something new to put before you next month. If you are interested, and want to have an early advice, send us a post card with the letters—I. C.—and your address on, and we will forward full particulars at the earliest moment."

The *Australasian Photographic Review* states that on Thursday evening, April 5, at Rubira's Café, Sydney, N.S.W., some sixty *employés* of the firm of Baker & Rouse, Limited, gave a presentation and farewell dinner to Mr. and Mrs. Baker and Miss Shaw, prior to their departure on an extended tour of the "Old Country." The house party consisted of the evening, Lady Brown and Mr. A. C. Shaw. The affair was in every way a success, and speaks well for the popularity of the head of the firm. The Chairman (Mr. Trowbridge), in proposing the toast of the evening, "Our Guests," referred to his first business with Mr. Baker fifteen years ago, and contrasted the business of that time with the present. He congratulated Mr. Baker on his untiring energy and perseverance in building up the Company to its present eminent position. He further remarked that, while Mr. Baker was most enthusiastically loyal, he never lost sight of the idea of Australia, for the Australians, as shown in a practical way, by his building and fitting, on unique lines, a huge factory at Abbotsford to enable them to supply the trade with Australian-made goods of every description. In replying, Mr. Baker spoke with evident feeling, and, in thanking the company for the reception they had given him, he hoped when he returned he would find all the old hands still with him, and, if he picked up any ideas that proved useful and profitable in the business, the whole of the *employés* would benefit thereby. The Victorian *employés* presented Mr. Baker with a gentleman's travelling case handsomely fitted. On behalf of the N.S.W. and Queensland *employés* a gold albert. The Chairman read a telegram from the Adelaide house sending congratulations and good wishes. Mr. Baker gave a garden party to the *employés* at Yarra Grange, on March 31. Nearly the full strength were present and had a very pleasant afternoon, all kinds of sports being indulged in until tea time, when refreshments were served on the lawn. An adjournment was then made to the house, and the balance of the time was filled up with music. Mr. Baker addressed a few kindly words, and said he hoped that everything would go on smoothly during his absence, and on his return he would find all the hands in their usual places.

## Patent News.

The following applications for Patents were made between May 21 and May 26, 1900:—

- FLASHLIGHT APPARATUS.—No. 9527. "Flashlight Apparatus for Photographing Purposes." S. D. ALTER and L. T. YOUNG.
- HALF-TONE NEGATIVES.—No. 9447. "Improvement in Processes of Producing Half-tone Negatives." Complete specification. G. D. ROCKWOOD.
- CAMERAS.—No. 9564. "Improvements in Photographic Cameras." S. N. TURNER and F. H. KELLY.
- SHUTTERS.—No. 9578. "Improvements in Shutters for Photographic Cameras. Complete specification. J. S. WRIGHT and C. S. GOODING.
- STEREOSCOPIC PHOTOGRAPHS.—No. 9672. "Improvements in the Method of Producing Stereoscopic Photographs and in Mechanism therefor." A. H. DUNNING.
- CINEMATOGRAPHS.—No. 9739. "Improvements in or relating to Kinematographs and like Photographic Serial Apparatus." H. SCHMIDT and W. HAENSCH.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
11.....	Camera Club.....	<i>The Siege of Kimberley.</i> G. M. C. LUARD.
11.....	Southampton.....	Print Competition: <i>Portraiture.</i>
12.....	Aintree.....	Royal Photographic Society's Paper: <i>Flower Photography.</i>
12.....	Birmingham Photo. Society.....	Demonstration: <i>Uses and Advantages of the Cristoid Films.</i> J. T. SANDELL.
12.....	Croydon Microscopical.....	Excursion: Beddington. Leader, H. C. COLLYER.
12.....	Hackney.....	<i>Practical Photography in the Field.</i> G. T. HARRIS.
12.....	Royal Photographic Society.....	<i>The Construction of Photographic Objectives: Mathematical Investigation.</i> H. L. ALDIS, B.A.
14.....	London and Provincial.....	Paper by E. T. WRIGHT.
15.....	Southsea.....	Paper: <i>Defects and their Remedies.</i>
16.....	Borough Polytechnic.....	Excursion: Round the Nore Lightship. Leader, R. R. RAWKINS.

16.....	Croydon Camera Club.....	Excursion: Godstone and Tanridge. Leader, Mr. HOLLAND.
16.....	Croydon Microscopical.....	Excursion: Caterham, Godstone, and Tiburstow.
16.....	Liverpool Amateur.....	Excursion: Chirk and District. Leader, T. E. CORNEY WILSON.
16.....	West London.....	Excursion: Hayes Common.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MAY 31.—Mr. T. E. Freshwater in the chair. Mr. J. E. HODD spoke favourably of the newly introduced Pyrax, or pyro in crystals. In this form an ounce could be contained many times in the old blue bottle that we were accustomed to, and the welcome reduction in bulk which the crystalline form permitted would be most convenient. It dissolved very quickly, and behaved altogether in a satisfactory manner. Mr. J. W. HODGES read a few notes on elementary

#### PHOTOGRAPHIC OPTICS.

His remarks, which were illustrated with diagrams and formulæ, touched

upon the diaphragms of photographic lens-s, the two principal systems of their measurement and numbering, and relative exposures. He concluded that a system like the U.S. system, which did away with all calculation and gave the relative exposures at a glance, was to be preferred to any. Many instruments really so marked, however, had no evidence that they were marked according to the system, the result being that people often misread them for the *f* numbers, and erred in exposure accordingly. He next alluded to depth of focus, a quality entirely dependent on the size of the aperture, although often said to be possessed more by lenses of particular construction than others. It has been claimed that the newer lenses possess this quality to a greater extent than the older forms, but in reality there is more depth of focus, if such it can be called, with a poor lens. Attention was next given to the determination of the distance which a near object must be removed from the lens in order that its image may be defined on the screen at the same time as objects at infinity; several measurements with a lens of five-inch focus with different stops were given. It appeared that, working at *f*-8 and set for infinity, objects up to twenty-six feet would be in focus, yet focussing scales were generally marked thirty feet, one hundred feet, and then infinity, with a considerable distance between the figures. One maker went to the extent of marking the scale one hundred yards, half a mile, &c. Mr. Hodges described the methods of finding the positions of object, lens and screen for enlarging, copying or reducing, passing on to a few words upon the modification of the focus of a lens by the use of supplementary lenses, or magnifiers, as they are often termed.

Mr. R. CHILD BAYLEY disagreed with the reader of the paper in his definition of the best system of numbering diaphragms as the U.S. system. The fact of the popularity which the *f* system enjoys amongst the more thoughtful of photographers was sufficient proof, on the principle of the survival of the fittest, that it was better fitted than a system based on an arbitrary unit which had to be remembered.

Mr. A. MACKIE said that the unit *f*-4 was chosen because at the time it was the common rapidity of the portrait lens—there was a great majority of portrait photographers in those days over others, and that was the reason for the choice.

Mr. P. EVERITT criticised the R.P.S. system of diaphragm numbering by which the focus was divided by the diameter of the stop. One should take the diameter of the cone of rays which enters the stop, as measured on the front of the combination, supposing the lens to be a doublet, otherwise the intensity is not properly obtained. The thing that should have been settled was the definition of "aperture."

Some discussion ensued regarding the use of the "magnifiers" and their title to their descriptive name; as also upon the new "Unar" lens, which Mr. Everitt claimed to be a modified Planar, while others saw in it a close resemblance to a well-known lens of English make and design. The diagrams of the lenses were compared and the essential points of difference discussed at length.

PHOTOGRAPHIC CLUB.

MAY 30.—Mr. Charles Wallis in the chair.

Mr. E. W. FOXLEE, alluding to the short discussion the previous week, on papers for photographic purposes, said that the Rives and Steinbach firms were the two which had practically a monopoly in this industry. He said that they made also a thick cheap paper for printing-out papers which was selling at 8½*d.* per lb., and it occurred to him that, as almost all of the P.O.P. papers were surfaced papers, one was rendered tolerably independent of the paper itself. As, therefore, it mattered less in this case whether our paper were of that purity required for other sensitive papers, it would, perhaps, be feasible for some English house to procure a fairly decent paper, coat it, and supply it to home users. A few years ago he experimented with papers for a collodio-chloride paper, having samples from the houses previously mentioned, and others who made a feature of baryta-coated papers. Some of the samples changed colour in a fortnight or three weeks, while others were good after as many months. Curiously, the best paper tried was of a very common make indeed. It was prepared in Germany for collotype printing; but, unfortunately, the foundation was so common that it would not stand water. By the time a print was fixed it could barely be handled; otherwise, the coating was well suited for the reception of the emulsion. It would seem, then, that a tolerably tough, cheap paper, suitably coated, should answer well for emulsion papers. We heard a good deal of fading of gelatine prints, but it was very probable that the cause was to be sought in the coating material with which the free silver combined. In reply to a question, he said that a pure paper was not so necessary for the platinotype process.

Mr. R. R. BEARD gave some particulars of a method employed by a friend in order to produce a pressure of gas of about eight or nine inches. A foot pump, with about an inch and a half stroke, was used to raise a column of water to a height, giving a pressure above that at which a regulator used would deliver the gas. The best pressure for the ordinary Bray burner was nine-tenths of an inch. He believed the device he alluded to had succeeded very well.

**Croydon Camera Club.**—In these days of pocket hand cameras, it is surprising that so few amateurs have provided themselves with apparatus available for the fascinating practice of enlarging, for, given a good negative and a clever worker, a surprisingly sharp picture of huge magnification is possible. Just to show how everything has been made easy, Mr. J. E. Lockyer, the well-known photographic chemist, of Deptford, exhibited and described the use of his enlarging, reducing, and copying apparatus at the club-room on Wednesday, 30th ult. In this, what is often the bugbear of the amateur, viz., the accurate focussing of a negative image preparatory to making an enlargement, is done away with by the simple expedient of providing a series of grooves into which lens-carrier and dark slide respectively are placed, according to the size of enlargement required, which may thus be produced, having the sharpest possibilities of definition. The apparatus will make enlargements, enlarged negatives, lantern slides by reduction, and may be used for copying

or for direct photography from nature. It evoked much interest and approval; and, in the course of proposing the thanks of the Club, the President said, not only should they, but all other amateurs, feel under obligation to Mr. Lockyer for placing this admirably designed apparatus at their disposal. Amongst interesting photographs shown by members were the following: A set of twelve platinotypes by Mr. Hector Maclean, being graphic studies illustrating the making of railway trains in the Brighton works. These have been prepared for the S.E.U. Science Congress Exhibition, which opened at the Brighton Pavilion on June 7. Mr. Stanley showed eclipse photographs, as did Mr. Ben. E. Edwards, who obtained some useful information respecting the suitability of various emulsions for eclipse photography. Finally, Mr. W. H. Rogers showed some charming little studies done upon Mr. Otto Schölzig's siennatype paper. They had been toned with a borax bath to a sepia tint. With the advent of June, the regular evening lectures, &c., are discontinued in favour of photographic outings. Of these ten have already been arranged for, most interest centering round a whole-day excursion which the President is organizing to Dickens' land. This will include Rochester, with its "Pickwickian" scenes, and others connected with "Joe Gargory," and "Pip," "The Seven Poor Travellers," &c. The Leather Bottle at Cobham, which is threatened with early destruction, will also be visited. Finally, the great man's last home, Gad's Hill, will be inspected. Should time permit, Lord Darnley's grand old palace at Cobham will also be photographed. Brakes will be provided at small fees, and everything done to ensure that only the right places are visited, to which end the Rev. C. H. Fielding, of Malling, has kindly undertaken to make all local arrangements, and act as the party's guide, philosopher, and friend. Members desiring to take part in this memorable excursion should at once register their names with Mr. Maclean, 34, Birdhurst-road, Croydon.

**Hackney Photographic Society.**—On the 29th ult., Mr. W. FENTON-JONES read a paper on

DEVELOPERS,

and gave the results of his experiments with the principal developers. The conclusion arrived at was that the different developing agents varied very little from one another as regards their developing powers, but they differed in the time required to produce their maximum effect.

FORTHCOMING EXHIBITIONS.

- 1900.
- July 9-14 ..... Photographic Convention of the United Kingdom (Newcastle-on-Tyne Meeting). Hon. Secretary and Treasurer, F. A. Bridge, East Lodge, Dalston-lane, London, N.E.
- August 21..... Royal Cornwall Polytechnic Society. W. Brooks, Laurel Villa, Wray Park, Reigate.
- October 1-Nov. 3 ... Royal Photographic Society, New Gallery, Regent-street. The Hon. Secretary, 66, Russell-square, W.C.
- November 12-17 ..... Ashton-under-Lyne.
- "   21-23 ..... Hackney Photographic Society.
- 1901.
- January 14-19 ..... Blairgowrie and District Photographic Association. The Hon. Secretaries, Blairgowrie, N.B.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

PHOTOGRAPHING AT THE PARIS EXHIBITION.

To the EDITORS.

GENTLEMEN,—Last week I had the pleasure of giving you an address at a hotel where a suitable dark room is fitted up. Now I have some further information that may interest photographers at the Exhibition. It appears that all the officials are not aware of the rules. A couple of days ago I placed my camera down on a settee with the knowledge and in sight of two officials when another made his appearance demanding to see my permit, which I had not got, believing that as I had no tripod, it was unnecessary, the result of this was that I was marched between two policemen the full length of the Exhibition grounds to the Bureau de Police, where I was introduced to a very polite gentleman who spoke pretty good English; he took my name, age, colour of hair, complexion, and full address in England and in Paris. Asking where my feet were, meaning the tripod, I replied that I was not in the habit of detaching them, but my camera legs were at my hotel. By pure luck I had the card in my pocket of a gentleman in a very high position in the French police, my passport was at the hotel; this, coupled with the statement that I had not had lunch, and "a hungry man was an angry man," and if I was not soon liberated I would get angry, I was told that I could depart, and with a mild apology was informed it was not the fault of the two first policemen.

Mr. York has been stopped on several occasions, but, as he carries about the regulations in French regarding photographing, he has fared better than yours truly,  
A. L. HENDERSON.

P.S.—I would advise all photographers visiting the Exhibition to carry the printed regulations. There is one very great hardship, viz., one has to pay twenty-five francs if he uses a stand for five hours' work, viz., from eight to one, and should the subject require an afternoon light he is powerless, and, as he has to get his permit the day previous, he has to run the risk of a wet or unsuitable day.

#### SALES BY PUBLISHERS OF PHOTO-BLOCKS, &c.

To the EDITORS.

GENTLEMEN,—The subject mentioned in "J. P.'s" letter this week, on p. 351, is one that has interested and puzzled me greatly, and I, like him and many others, would be glad if some of your legal readers would settle the question.

Last year I wrote a book on my travels, and, in addition to my own photographic illustrations, I bought about twenty blocks from six different weekly and monthly magazines, each of which, in reply to a special letter of inquiry, told me it was unnecessary to ask permission of the photographer who took the views; some of the editors, by the way, said it would be as well to acknowledge their origin.—I am, yours, &c., R. P.  
Cambridge, June 2, 1900.

#### LANTERN SLIDES FOR THE CONVENTION.

To the EDITORS.

GENTLEMEN,—The usual lantern display at the Photographic Convention at Newcastle-on-Tyne is this year under my management, and I am anxious to make it a really good one. I want to get a few really good slides from all our best workers, and therefore ask their kind assistance.

A few good slides, reaching me not later than June 10, will be much appreciated, and I'll do my best to give due credit to the gentlemen so obliging me. I do not want hundreds, but yearn for half-dozens of prime quality.—I am, yours, &c.,  
WALTER D. WELFORD.

Warwick Lodge, 166, Romford-road, London, E., June 2, 1900.

## Answers to Correspondents.

\* \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street Strand, London, W.C. Inattention to this ensures delay.

\* \* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

#### PHOTOGRAPHS REGISTERED:—

A. H. De'Ath, 32, Bank-street, Ashford, Kent.—Two photographs of Mrs. Moon.

E. E. Smerdon, 14, High-street, Newport, Isle of Wight.—Photograph of declaration of poll.

J. McNamara, 39, South-street, Romford, Essex.—Photograph of The Ford, Havering Well.

R. Ayton, 43, Bruntsfield-place, Edinburgh.—Photograph of English Football Team v. Scotch. Photograph of Scotch Team v. England.

J. KENNERELL.—We are much obliged by your letter.

TOBACCO SMOKE IN DARK ROOM.—J. ABBY. We suspect you must look for other sources of fog in the negatives than the presence of tobacco smoke in the dark room. That, you may rest assured, is not the cause of the fog, but what it is we cannot say.

COLIN TUCKER (Aldershot).—If the lens is one of Messrs. Dallmeyer's, we should advise you to take it to them; if it is one of the nameless variety, then, perhaps, Messrs. Sands & Hunter, of Cranbourn-street, Leicester-square, W.C., would undertake the work.

RESIDUES.—AMATEUR. As your expenditure for photographic material—plates and paper—is, annually, so small, we should say that it would not be worth your while to save the wastes, that is if time is of any value. The return would be so small—probably not more than three or four shillings a year—after the cost of reducing has been deducted.

STEREOSCOPIC CAMERA.—N. MASSEY. In reply to your inquiry we should say decidedly that the camera should be provided with the means of separating the lenses as may be required for the subject to be taken. It is also desirable that it should have a rising and falling front so as to regulate the foreground, which is an important item in stereoscopic pictures.

DURATION OF COPYRIGHT.—T. CARTWRIGHT writes: "I have a negative that, in the future, is likely to become very valuable. It was taken nearly three years ago, and made copyright at the time. How often should it be re-registered to keep the copyright alive?"—No re-registration is required. The copyright lasts during your lifetime and for seven years after your death.

FAULTY C.C. PAPER.—J. C. B. says: "Can you suggest the cause of the uneven tones on the enclosed C.C. prints? With this lot of paper I can get nothing else. I enclose two or three pieces of it unprinted."—The cause is that the paper is not evenly coated with the emulsion. This will be seen if a piece of it is exposed for a short time to light. As the collodion film is uneven, even tones cannot be expected.

ASCERTAINING COPYRIGHT.—W. & Co. write: "We have had brought to us to copy a dozen photographs. They are views of different watering places and we have a suspicion that some of them might be copyright, though they are not so marked. The man who bought them said they were not. How can we learn for certain?"—Only by searching the file at Stationers' Hall, unless, indeed, you apply to the photographers who took the pictures.

COLLODIO-CHLORIDE PRINTS.—NORFOLK says: "Will you please tell me, an amateur, if collodio-chloride prints can be blotted off and dried quickly like albumen paper? I am now using P.O.P., and am much troubled by dust sticking to the pictures while drying, and I am so situated that I cannot avoid the dust in the room."—Yes, collodio-chloride prints can be blotted off and dried before the fire if desired; the prints will not be injured by this procedure.

PATENT SPECIFICATION.—W. DAVY says: "I want the specification of a patent that was taken out some few years ago, but I live, as you see, far in the country, and cannot go to the Patent Office for it. How can I obtain it?"—At your Post Office you can obtain a form—Patents Form C I—for 8d. Fill that up and post to the Patent Office, and you will receive the specification in due course. You will have to give the number of the patent and the year that it was taken out.

FIXING.—ARISTO writes: "I have just been trying some American aristoplano paper, the fixing bath says 18 grains to the ounce of solution; would you consider this sufficient to fix, say, eighteen pieces half-plate size? If I use 6 drachms hypo to the 20 ounces of water, it seems a small quantity. I should fix fifteen minutes."—We should say that there is some misprint in the formula; 18 grains to the ounce is considerably less than an ounce to the pint of water, which is far too weak for a fixing bath with fifteen minutes' immersion.

BURNISHING PRINTS.—U. H. J. writes: "I am desirous of getting a high polish on my cabinets. The best result I get is with spermaceti wax and benzole rubbed on glass and the prints squeezed on and stripped off that. Sometimes they stick, and it takes a long time when I get a lot of cabinets. Can you tell me the best roller or burnisher or an easier method of getting a good burnisher?"—There are so many good burnishers on the market, supplied by the different dealers, and there is very little to choose between them so far as results are concerned. All are good.—It is quite opposed to our rules to recommend any particular manufacturer's goods. Better get prospectuses from the various dealers.

STEREOSCOPIC LENSES.—W. H. B. writes: "I have bought, second-hand, a pair, or what are supposed to be a pair, of stereoscopic lenses, but I find that their foci are not quite identical, there is nearly the thirty-secondth of an inch difference between them with their full opening; but the difference is not noticeable when they are stopped down to  $f/16$ . Can the lenses be used successfully for stereoscopic work?"—It is always desirable that the lenses should be of identical foci; but when the variation is so trifling, as in this case, it will, practically, make no difference if each is adjusted to its focus. A piece of cardboard, of the right thickness, under the flange of the longest-focus one, is all that will be necessary.

SQUEEGEEING GELATINO-CHLORIDE PRINTS.—PHOTOGRAPHIC CHEMIST writes: "Will you oblige by saying the best means to adopt in squeegeeing P.O.P. prints on to plate glass, so as to obviate their adhering to the glass? Have tried various means, but none are perfect. What I find to answer best is to clean the glass perfectly with Monkey-brand soap, and then polish with a solution of spermaceti dissolved in benzine, but even this allows of marks on finished article."—All the well-known published methods answer well if they are carefully carried out—the glass well cleaned, &c. The marks, in the case of the method our correspondent finds best, are due to the spermaceti coating not being evenly polished off. The remedy is obvious.

SUN'S ECLIPSE.—A. J. writes: "Being curious to know what results could be obtained by photographing the eclipse with ordinary apparatus and plates, I constructed a box sort of contrivance to my camera, to make extension enough to take the back combination of my half-plate R.R., which gave me a lens of about fourteen inches focus. I made four exposures, and was surprised on development that I received what I should presume to be a positive, instead of a negative; I gave a quick hand exposure in either case, and would suppose that my exposures were much too long, and hence the reversal. I have no practical knowledge, and know little of the theory of eclipse work. Is my surmise correct in the matter?"—Yes. Clearly reversal due to over-much over-exposure.

THE CARRIAGE OF NEGATIVES.—G. PARK writes: "A short time back I sent several negatives through the parcel post to a trade retoucher. On the return of same, I found three had been broken through bad packing in coming through the post. Will you kindly inform me whether I can claim compensation from the retoucher? I have written him asking for compensation, but he replies he is not responsible for damage done in transit, and that claims for damages must be made on the Post Office. I should add, the retoucher has no notice printed on his bill heads, price-lists, &c., that he is not responsible for any breakages or damage done to negatives. The retoucher also states that the negatives were very carefully packed before posting."—It is a universal custom of the trade that the senders are not responsible for damage during transit, so that the claim should be made against the carriers, whether the Post Office or others. The parcel should have been opened when delivered, and if any damage seen, its receipt should be declined at the time. Then the matter would rest between the carriers and the sender as to damages.

\* \* \* A number of Answers to Correspondents, Reviews, Notices of Apparatus, and other communications, are unavoidably held over.

### EX CATHEDRÁ.

Kew Gardens, beloved alike of the botanical student and the holiday-maker, also offers peculiar attractions to the photographer, who finds wide scope for making negatives in the numerous plant houses and gardens that form the main features of the celebrated botanic institution founded about 41 years ago by the widow of a former Prince of Wales. One of the latest to undertake anything like a systematic photographic study of the Gardens is Mr. E. J. Wallis, a member of the Royal Photographic Society, who has just issued a book entitled *The Royal Gardens, Kew, Illustrated*. Mr. Effingham Wilson publishes the volume, which is also obtainable, we understand, at the Gardens. Mr. Wallis includes in his book thirty selected photographs of about whole-plate size, reproduced in half-tone, separately printed, and accompanied in each case by explanatory notes by Sir W. T. Thiselton-Dyer, the Director, who, in the course of a brief preface, pays a tribute to the skill with which Mr. Wallis has photographed the most interesting and striking features of the establishment. The

book all through is distinguished by care and beauty of production. Mr. Wallis perhaps shows his best photographic work in the views taken of the Palm, Lily, and Temperate houses. The volume gives one a very good idea of the chief aspects of the Royal Gardens, and it should find its way into the possession of many visitors.

\* \* \*

ANIMATED photography is about to reach its inevitable, if not its ultimate, development. The Biograph Company will shortly open a studio in Regent-street for the purpose of exploiting animated portraiture. Amidst surroundings which the arts of the decorator, the upholsterer, and furniture-maker will render luxurious, people will move about in a light of 100,000 candle power (more or less), while a sensitive film passes rapidly behind the lens, and an impression of all the various phases of motion is secured. The possibilities of this interesting departure are, of course, very great, and, if Society (with a capital S) gives its patronage to the idea, animated photography in the Biograph studio will be assured of considerable success. The skill and resources at the disposal of the Biograph Company are so great, that we may be sure of this branch of photography being made to yield the best possible results for the delectation of those who are attracted to it. We have heard that Mr. Harold Baker is to have charge of the studio, which will therefore be under very competent direction. It will be an interesting experiment, and it is probably destined to excite much attention, although we do not share the sanguine opinion of a daily journalist that, in consequence of this departure, "the old-fashioned 'still-life' photography is to give way to the photographic living picture." Let not any of our readers be induced by such foolish writing to consider for an instant the desirability of converting their ordinary studios into brilliantly illuminated rooms, where thirty or forty exposures a second may be made on a band of sensitised celluloid. The demand for photography of this kind is not likely to be great, as its expensiveness obviously restricts it to a comparatively narrow circle. Still, this does not lessen our interest in the Biograph Company's experiment, which we hope will turn out successful.

WE have to acknowledge receipt of a copy of a recent issue of the *Effingham Democrat*, which is published at Effingham, Illinois, U.S.A. A large part of the issue is given over to a description of the Illinois College of Photography, and the exterior and interior of that structure are illustrated by five half-tone illustrations from photographs. We described the College at length in the *JOURNAL* a few weeks ago; it appears to be an institution where non-resident pupils may, for moderate fees, pass through a course of instruction in practical work, which, to judge by a study of the syllabus, might qualify them to take up portrait photography as a profession, provided they were proficient. Of Mr. Bissell, the founder of the College, the *Democrat* writes in the following manner: "Mr. Bissell deserves to be mentioned with Mergenthaler, the type-setting machine man, the type-writer inventor, and with the creators and discoverers of the numerous other inventions, for his College is as much of a creation, of an invention, as are the others. Six years ago the College of Photography started up with one instructor, a short curriculum, and the very humble quarters of a common photograph gallery. The course of study was thorough and covered the ground, but with its humble building and appurtenances nerve was the chief asset. Mr. Bissell possessed it, and, meeting difficulties, criticisms, and mutinies, and overcoming them, he marched steadily forward. Very soon what his friends thought was a dream, an hallucination, began to take shape as an active, tangible, living reality. The students increased, the College quarters grew, scientific papers began to notice it, its advertisements appeared in the leading and most expensive advertising mediums in the country, and in the course of a very few years the Illinois College of Photography was a marked educational and financial success. This is the achievement of President L. H. Bissell. We are proud of him and of his institution." Upon this exquisite specimen of high falutin' we need only pass the remark, the paraphrase of an utterance attributed to Abraham Lincoln, that "for those who like this sort of thing this is the sort of thing they like." Mr. Bissell teaches the ordinary stock subjects likely to advantage would-be operators, retouchers, printers, &c., and we wish him success in his enterprise. Here, in London, which perhaps is equal in size and importance to Effingham, Illinois, Mr. Howard Farmer for these many years past has been teaching almost every branch of photography at the Regent-street Polytechnic, and, such is man's ingratitude, nobody appears to have thought of bracketing him with Mergenthaler and "other creators and discoverers!"

\* \* \*

A COLLECTION of photographers' note and bill headings, we often think, would give material for astonishment, not unmingled with amusement, at the very great number of ways in which a photographer is able to describe himself. In most cases the unqualified designation, pure and simple, seems to satisfy the wants of those who feel it necessary to signify on their stationery the nature of their business or profession—they are content to call themselves photographers, nothing more, nothing less; but among the large minority there are many variations of the term, which, however striking or impressive they look, really carry no more significance. Thus there are photographic artists, artist-photographers, photographer-artists, pictorial photographers, art-photographers, high-art photographers, and so forth. It is just as curious to note the legendary references to the subdivisions of a business which are sometimes seen on note headings and memorandum forms. For example, "the

new instantaneous process" is still very often listed as speciality—a claim that surely presents a belated appearance in the year 1900. And then that rare and consoling old "stay-by"—"photographs by the new permanent process!" What tenacity it keeps its place amongst the literature photographic stationery! It even appears in the following note-heading schedule which we quote for the purpose of complimenting the correspondent, from whose letter we cut it, his enterprising readiness to do "anything to oblige." Captain Dudley Smooth, in *Money*, phrases it: "Appointments made for any hour, distance no object. Applications for estimates will be considered a favour. Studio open from 8 a.m. to 8 p.m., for day and artificial light photography. Photography in all styles and of all descriptions. Artistic results each person studied for. Characteristic positions. Children's photos a speciality. Photograms in platinotype highly recommended for artistic and permanent results. Copying from old photographs, no matter how small or faded, and enlarged to life size. Work finished in the new permanent process. Cricket, wedding, family, or other groups taken in or out of studio. Animals specially studied." The photographer who can accomplish all this satisfactorily to his sitters and clients reduces the question of success to a certainty.

\* \* \*

A FURTHER contribution to the study of the natural-colour photography problem has been made by M. Graby, who, it appears, has recently repeated some experiments on paper containing subchloride of silver and bichromate of potassium. Finding that in some cases prints were obtained which gave an appearance of the natural colours (*sic*), he came to the conclusion that, since this effect is obtained by the violet-blue of the subchloride and the orange of the bichromate, the next step would be to make a separate print of the blues and violets upon a blue paper, and one of the oranges and reds upon an orange paper, and that these prints, when superposed, would give, more or less, the desired effect. "His method of working is to make the first exposure upon a plate sensitive to orange, behind a red screen; the second exposure is made with a screen of bluish-green upon a plate sensitive to the blues and greens. By using a stereoscopic camera the two exposures may be made at the same time, besides obtaining relief."

\* \* \*

THE account from which we are quoting proceeds to inform us that in M. Graby's experiments the first plate is printed upon the ordinary ferro-prussiate, or blue print paper, the second upon a chloride of silver paper, which is not toned, but merely fixed in the hypo bath and washed, giving thus an orange-brown colour. The two prints are pasted upon a stereoscope card, and viewed through a stereoscope, a red screen being placed before the blue print, and a blue screen before the orange. In this case the colours of the object are seen with a greater or less approximation, and, if a stereoscopic camera has been used at first, relief is also given. A remarkable point observed, we are told, is the brilliancy with which the metals are reproduced; thus, in the case of gilding, the colour is not merely yellow, but a fine metallic lustre is given. This process is claimed to be one of great simplicity, as it requires but two exposures and two prints, which are made without toning. By making one of the prints transparent, the colours may be obtained by superposing one on the other.

We further learn that the process is now in an experimental stage, and is capable of further improvement to obtain a close approximation to the natural colours; it has the disadvantage of not reproducing the reds or violets to any great extent, but, as there are many subjects which do not contain these colours, the process may be used to advantage in certain cases. It is unfortunate that a properly authenticated record of M. Graby's experiments and the theories upon which they are based was not published instead of the above necessarily condensed translation. But, on the assumption that the account does not misrepresent him, we cannot hope that, by his combination of achromatic negative work, and a somewhat hap-hazard (or what appears to us such) system of printing, M. Graby is likely to add materially to our knowledge of the natural-colour problem. In parts his work appears to be purely empirical—we allude to the printing method. However, the experiments are interesting and curious.

### NEW APPARATUS.

ENGLISH-BUILT cameras enjoy a reputation the whole world over for the highest excellence and easy superiority over every rival, and, such being the case, it might be thought that, a piece of new apparatus once purchased, there was nothing to do but to shoulder the tripod or strap up and carry the outfit and set to work; but, as we will show, there are several points to consider before this can be done, and to start serious work with a new outfit without first overhauling it would be a mistake. In the first place, it must be remembered that it is not every one who cares to go to the expense involved in the purchase of instruments of the very highest class; indeed, we should imagine that, for one such outfit sold, there must be a hundred of the less costly kind—hand, stand, or magazine type.

In the course of a lengthened experience with cameras of many kinds, we have rarely met with one which—and more especially in the larger sizes—was not beyond improvement at our own hands, with an expenditure of labour rather than skill. A well-made camera is a beautiful example of the cabinet-maker's art, but a practical photographer wants something more, and especially in the case of his dark slides, for example. A set of slides are examined; the shutter, we will say, draws out and returns without a hitch, and is sufficiently tight to ensure complete light-tightness; but let the slides be used on what is termed a "muggy" day—a day with the atmosphere laden with damp, and investing every exposed cold surface with a thin, invisible film of moisture—and let them then be put away for a week or month or two. What will be the result? In nineteen cases out of twenty the shutters will either stick altogether or jamb so tightly that the focus will be displaced in the exertion of drawing the slide. Possibly the camera-maker would say, "My cabinet work represents a valuable scientific instrument, and should be taken care of as such—kept dry and free from these drawbacks," &c. But that is not the way to look at the matter. A camera is liable to be exposed to various atmospheric influences, neither day nor climate being invariably at the pick and choice of the user, and we do not hesitate to assert that a slide shutter may, and, indeed, ought to, work very loosely and still be light-tight. Hence our advice is, that every dark slide should be examined in this

direction, and, if, as will most probably be the case, the shutter should work a little stiff, it should be entirely removed, and very carefully rubbed with fine glass-paper in the tighter parts, and well wiped before being replaced. A little powdered talc should also be applied to increase the smoothness of working. With regard to the camera itself, there is less to be said; but, as, when the season is in full swing, it frequently happens that orders are in advance of possible turn-out, the press of work may lead to some trivial detail being defective—something that a workman could put right in a few minutes—it is better not to assume that everything is right, but to set the camera and tripod up, examine it well, and see that it will shut up properly. We remember a case where a man had bought a new camera, and taken it out untried, and, when he had exposed his plates and began to "unlimber," he found he could not shut his camera up except by main force, which, when applied to a good camera, generally spells disaster.

We now come to the most important aspect of our subject, which will be best dealt with by narrating a true experience. We were asked to diagnose the cause of fog on a dozen plates exposed under identical conditions. The dozen were a large batch, and all others used from the same stock, both before and after this defective packet, were in every respect perfect. The natural assumption was light fog. We examined the camera, a new one by a first-class maker, and of the magazine type, but we failed to discover a defect. We noticed, however, that the sheaths still retained a varnish-like smell, and we found that the plates had been put in the camera, exposed, and developed within twelve hours of the receipt of the instrument direct from the actual maker. Previous experience suggesting a possible cause for the disaster, we inserted a couple of plates in the camera, left it for twenty-four hours in the dark room, and then, without exposure, placed the plates in the developer with two fresh plates out of the same box. In a short time the plates from the camera were wholly fogged, while those direct from the box showed clear glass. The explanation was obvious. The liquid constituent of the black varnish, which had not entirely volatilised, gave off a portion of that residuum in the form of a vapour, which, in a manner explained before in these pages, very quickly brought about some change in the film that was developable into a strong "fog." We may at once say that such conditions have, in our personal experience, been brought about in many ways, but all traceable to emanations from the slide, the camera, or other surfaces. We have, as before mentioned by us, seen a lot of negatives spoiled simply by the cloth used for hinging the sections of the slide shutter. Only a fortnight ago we met with another instance.

The manager of one of the largest firms in the country showed us two negatives with two bands of, apparently, insensitiveness in the film, which had not developed at all. He informed us that they were caused by this hinging cloth in a slide that had been repaired three months before use. The plates were put in one morning, exposed, and developed before the day was over, and the results were as described.

We are aware that some makers advertise that their slides are hinged with a cloth that does not attack the plate, yet we consider that, as a matter of common prudence, no camera should be taken on trust as to this point. And, in conclusion we would say that with all new cameras, in addition to the recommendations already given, it is most desirable, we would go further, and say that essential to safety they should be set up with the focussing screen removed or thrown back; the

camera fully extended; the dark slides thrown open with shutters drawn; inner frames, if any, reared up on edge in some convenient place, and all left exposed to the air in a well-ventilated room for as long a time as can conveniently be given. There will then be every reason to expect a complete freedom from drawbacks in the newest of apparatus.

**Focussing and Focussing Eyepieces.**—There are at the present time, and have been for decades past, various focussing eyepieces to magnify the image as seen on the ground glass, all of which answer the purpose well, though they are not always used under their best conditions. The best of them is the old form, the "Ramsden eyepiece." This consists of two plano-convex lenses, mounted at a suitable distance apart, with their plane surfaces outward, the tube in which they are mounted being furnished with a screw and set nut to fix it when adjusted to the focus of the eyes of the user. Unless that is accurately done, the instrument loses the greater part of its value, and may become even misleading. This fact does not appear to be completely understood by every one. We will here quote an instance that recently came under our notice, and we might give others. Calling on an old portraitist the other day, he, in conversation, complained that his sight was failing him through age, and that he could not see to focus sharply even with his spectacles on. We suggested a Ramsden eyepiece, but he replied that he had used one for over twenty years, but, although he could at one time see well with it, and always used it, now it was of no use to him; in fact, he could do best without it. We asked to see the instrument, and found that it was set, as it probably was when first purchased, for a person of normal eyesight. We then made a small mark on the ground glass of the camera, and asked him to examine it with the eyepiece some little distance away, moving it backward and forward until he could see it clearly defined. This he could do distinctly when it was a full half-inch from its surface. Then we, after some difficulty, on account of corrosion, released the clamping screw, and set the tube some distance further back. A second trial showed that it was still too near. Finally it was got right for his sight, when he could focus with it as well as he said he could do twenty years ago. We mention this case to illustrate that, although focussing eyepieces may be used, they are not always used under the best conditions. Although our friend had found it necessary to from time to time change his spectacles through the focus of his eyes getting longer with age, it did not occur to him to lengthen the focus of his Ramsden eyepiece.

**Actinism of June Light.**—The number of letters we have received, accompanied by faulty negatives, clearly illustrates that it is possible for many amateur photographers to have "too much of a good thing." The trouble of those who have written and sent examples has been nothing more than very much over-exposure, and nothing else. The workers have not sufficiently taken into consideration the present improved quality of the light, actinically. Those who took up photography for the first time last autumn, for example, do not seem to realise the wide difference there is between the actinic quality of an autumn and a spring light, hence their failures. We notice that one firm of plate-makers—the Ilford—in their advertisement, say, "During the summer months don't use special rapid plates, or you will run the risk of getting over-exposed negatives." Amateurs, as a rule, particularly novices, seem to think that the fastest plates procurable and the most rapid shutter are essentials to success, more particularly with hand cameras; this is a great mistake. We have little hesitation in saying that the largest consumers of extra-rapid plates, during the summer months, are amateurs. Professionals and the more initiated avoid them, and prefer a slower plate, as giving better results and requiring less skill in their manipulation. When very rapid plates are used during the spring and summer months, a very rapid shutter becomes imperative to avoid over-exposure, whereas a slower-acting one would yield a better and more realistic picture. Again, for the same reason a

small stop in the lens must be employed. Where, then, are the advantages of employing the ultra-rapid plates, when all the extra precautions entailed in their working are considered? There are none—just the reverse. Some amateurs are under the impression that the smaller the stop employed in the lens the better will be the result, hence one of their reasons for using extra-rapid plates. That, as a rule, also is a mistake, though it is true that some of the cheap forms of lenses will not give good definition without one. The remark, however, does not apply to good instruments, they will cover the plates they are intended for with a wide opening,  $f/11$  or larger, for example. Incurring all these unnecessary extra difficulties to use the extra-rapid plates, when the same end may be better attained by the use of slower ones, seems very like employing a complicated steam engine to draw a cork, while a simple corkscrew would answer the purpose better.

**The New Physical Laboratory.**—The site selected for the National Physical Laboratory, in the Old Deer Park, evidently does not meet with the approval of some of the good people of Richmond. At the opening luncheon of the Richmond Horse Show on Friday last, the Mayor, in referring to the contemplated erection of this institution, is reported to have said that the company present were aware that it was proposed to erect the new buildings in what would be a very incongruous position, and interfering with the prospect over the park, adding that the Laboratory would be a useful institution, and they would be glad to see it in Richmond but some other site should be found for it. It may be fairly supposed that the Mayor, at the Horse Show luncheon, was echoing the opinion of Richmond, though most towns, we should have supposed would have felt highly honoured by having a national scientific establishment of this character in its neighbourhood, particularly considering that the grounds, upon a small part of which the building is to be erected, were but recently handed over to it as a public recreation ground. In the selection of a spot for a National Standardising Laboratory surrounding conditions are naturally an important factor in the case, and, doubtless, that is why the spot chosen was selected by the authorities. After all, the National Laboratory is not an unsightly factory, with tall chimneys emitting offensive vapours, and bringing together large numbers of workmen always an objection in residential neighbourhoods, but a building strictly for scientific purposes, and to be worked by scientific people. Though adjacent to the Kew Observatory, it is necessary that it should be some distance away from it, so that the various operations carried on in the two buildings should not interfere with each other. This might be the case, say, in some delicate magnetic and many other observations if they were closer together. However, it is possible that the Mayor, on the occasion referred to, did not echo the voice of the majority of the people of Richmond, which includes many scientific people, who are well aware of the absolute necessity for a suitable spot for such a national institution as this is to be. No doubt they feel more honoured than otherwise that the one chosen in the old Deer Park has been selected, even if it be not quite to the taste of some. They may also think that a Horse Show luncheon is not the most suitable place to refer to such matters as the position for a National Physical Laboratory.

#### WITH THE ECLIPSE EXPEDITION TO AMERICA.

THIS is the land of true progress. Things "move right along" here, as in no other country. Having had experience of this, I can speak with confidence. Probabilities point that way, at any rate. Surely, in no other country would it be possible that a law could be entirely altered, in the interval between the last thing on Saturday night and the first thing on Monday morning. And this without any effort on the part of the Legislature. But, in New York, I have seen that miracle performed.

With the British astronomical expedition on board, the good ship *Minneapolis* arrived at New York, a week ago yesterday. By the courtesy of the American Government, our instruments were to be admitted free of duty; and we had reams of documentary evidence

that effect, stamped, signed, sealed, and delivered. But, when our cases were brought up for review, the trouble began. The Custom officials were models of courtesy, and appeared disposed to give us every facility in their power. It appeared, however, that, although we had the courtesy of the port, the law demanded that our goods must be opened and examined, just as though they were ordinary merchandise. It was a deadlock. The officials were bound to do their duty; and we felt that, under the circumstances, we would see them something more than further before we would allow a single crew to be loosened. We spent a delightful five hours in trying to discover a *modus vivendi*, and left eventually, with all our goods and rattels marked "Hold." After leaving the docks, I wrote to an American friend, stating our dilemma. On Monday, I heard from him that he could "find no clause in the law that will allow them (the instruments) to be passed by the Custom House officers, unless you are entering as emigrants, and bringing your tools as instruments of your trade or profession."

According to appointment, I returned to the dock early on Monday morning, in order to continue the altercation; whilst Mr. Bacon went for help to the Consul General. Arriving at Pier 39, I met a courteous official, who said, "Come this way, please." We went upstairs to the place where our baggage was held in bond, and, without a murmur, every package was then and there chalked and passed out. What could have happened to the laws of the United States during the Sunday, I cannot say. I can only record the facts.

My missing case of instruments, I hear, was never put upon the vessel; so I have to do without them. The result is a makeshift, composed of anything that could be obtained by scouring New York, and put together here, with the aid of the local carpenter. Nevertheless, I hope to be able to expose a cinematographic film during the eclipse, and thus secure the longest series of photographs ever taken of such a phenomenon. All the rest of my projected work must be left for some future occasion.

Arriving here on Wednesday last, we found a welcome awaiting us such as we could never have anticipated. It is impossible to conceive anything more pleasant than our present surroundings. Of the warm-hearted hospitality displayed by the leading citizens of Wadesboro we shall carry with us a tender recollection to the end of our days. We are overwhelmed with kindness and sincere friendliness on every hand. From this hotel to our camping ground the distance is less than half a mile, but we are not allowed to walk to and fro. Carriages are always waiting to convey us wherever we may wish to go, and we do not even know whom to thank. All we can gather is that the carriages are ours, to use as we please. And that is only one instance of the extreme liberality of our good friends in this neighbourhood.

Turning to our fellow-visitors, we find every reason for self-congratulation. No man could wish for more genial or more intellectual society. Almost on the moment of our arrival, we were visited by Professor Young of Princeton University, who invited us to establish ourselves in his camp. Needless to say, that invitation was accepted with something more than alacrity. Proceeding to the camp, we found it situated upon the brow of a hill, overlooking a rolling, wooded plain, stretching for miles. The view, indeed, is superb, and the site chosen leaves nothing to be desired. At the camp there is yet another instance of the extreme courtesy and kindness universally displayed towards us. Side by side with the flags of the United States and Princeton University there flies the Union Jack! We learn that the Princeton party positively scoured the neighbourhood to find a British flag, and were vastly disappointed to find that it had not arrived before us. However, when we went to the camp on the second morning, there it was, floating gaily beside the others.

A few hundred yards from our camp is the station occupied by parties from the Smithsonian Institution, under Professor S. P. Langley, and from the Yerkes Observatory, under Professors Hale and Barnard. There is only one word which will describe the equipment of this camp. It is magnificent. Taking the two camps together, it may be safely said that there has never been gathered together in any spot so large and elaborate a collection of instruments for observing an eclipse. And never has such a number of cameras

been brought together upon any occasion, except, perhaps, in an exhibition of photographic appliances.

And there are many interesting things to photograph, apart from the eclipse. If I only had my cameras here, I could send home any number of subjects, both instructive and amusing. For instance, the spectacle of a party of distinguished astronomers chasing a cow would be distinctly classic. It appears that, on the ground occupied by the Smithsonian and Yerkes parties, there is a cow which was reared upon a farm some miles distant. One condition of the ground lease is that this cow shall not be allowed to escape. And the one aim in life of the cow seems to be to return to the place of its birth. Periodically, the cow contrives to get out of bounds; and, on such occasions, the entire staff turns out to "purwill upon" the animal to stop. So far the astronomers' efforts have been successful, and the terms of the lease have been faithfully observed. Again, the spectacle of a party of distinguished astronomers playing leap-frog, and "doing stunts" of various kinds, would be eminently soothing, as I have reason to know, but this, perhaps, should only be whispered with bated breath.

It would be interesting to know how many exposures have been made here by members of the various parties, to say nothing of the professional photographers with whom one collides at every turning. Certainly I have been photographed here more often than in all my previous existence. "Just a moment, please!" we hear every few minutes. Then there is a little snap, followed by "Thank you," and yet another group is added to the total. Naturally, those interested in the eclipse are always conversing more or less in groups, and the resulting permutations and combinations afford unlimited opportunities tempting to the snappers. As for Professor Young, his life here must be absolutely a burden to him. Everybody loves him, and I believe he is the most photographed man in the universe at the present moment. A most amusing scene occurred yesterday, whilst the genial professor was taking the local time. In the centre of the camp he sat, sextant in hand, and surrounded, apparently, by some hundreds of cameras, whose "business ends" were all directed towards him, with a view to taking him in the act. At the same time a further number of photographers were intent upon securing views of oppressors and oppressed.

This evening a most serious alarm was raised. Something had occurred which was calculated to shake the universe to its foundations. It was found that a firefly had obtained access to the exposing-room attached to Professor Barnard's large telescope. One can imagine what the consequences might have been had not this been discovered in time. As it was, however, after much exertion, the intruder was expelled with ignominy.

Among the negro population in these districts, opinion seems to be very much divided upon the subject of the eclipse. Those who have seen something of the equipment of our camps confidently predict fine weather for the 28th. "Dese folks know all 'bout it," they say. "Spouse dey come heah an' spens all dis money ef its gwine ter rain? Not much, dey don." From the outlying districts, however, we hear equally confident reports that "dey aint gwine ter be any 'clipse dis time, I reckon. Didn' dese heah 'stronomers say, las' yeah, dey was gwine ter be shootin' stars? An' dem shootin' stars didn' come off; so you kin bet dis heah 'clipse ain't comin' off."

At the present moment we are full of pleasant anticipations for to-morrow. The sky is faultless. The barometer is rising, and the forecast predicts that no eclipse has ever been observed under conditions more favourable than those that will prevail during the occasion upon which all our immediate hopes are centered.

NEVIL MASKELYNE.

*Klondik Hotel, Wadesboro, N.C., May 27, 1900.*

#### THE PARIS EXPOSITION.

WE stated last week that there would be no awards for British photographs at this year's Paris Exposition. As we have many times pointed out, they form a comparatively small and by no means representative loan collection. Exhibitors of apparatus, &c., are, however

classified as competitors. To them the composition of the "Jury for the French Section, Class XII," and the International Jury, will, doubtless, be of interest. According to the *Moniteur*:

By decree of the President of the Republic, given by request of the Minister of the Commerce, the following gentlemen have been nominated as members of the Jury: Braun (Gaston), photographer to the National Museums; Jury, Paris, 1889; Committee, Paris, 1900. Bucquet (Maurice), President of the Photographic Club; Committee, Paris, 1900. Demaria (Jules-Joseph), President of the Syndical Chamber of Photographic Manufacturers and Dealers. Fleury-Hermagis (Jules), optical instruments; Committees, Gold Medal, Paris, 1900; Honorary President of the Syndical Chamber of Photographic Manufacturers and Dealers. Marey (Dr. Jules Etienne), Member of the Institute and Academy of Medicine; Scientific Chron-ography; Honorary Member of the Photographic Society of France and the Paris Photographic Club; President of Committees, Paris, 1900. Nadar, junr. (Paul), portrait photographer, Gold Medal Paris, 1878; Grand Prize, 1889; Committees, Paris, 1900. Provost (Antoine), photographer, Toulouse; Silver Medal, 1889. Vidal (Léon), photographic journalist, Gold Medal, Paris, 1878; Jury, Paris, 1889; Committee reporter, Paris, 1900; Honorary President of the Syndical Chamber of Photographers. Wallon (Etienne), Professor of Physics at the Janson-de-Sailly Lyceum; Committee of Admission, Paris, 1900.

Substitutes: M. Bourgeois (Paul), amateur, General Secretary of the Paris Photo-Club; Committee of Installation, Paris, 1900. M. Geisler (Louis), papers, photogravure, various printing processes; Committees, Paris, 1900.

By a second decree, dated May 22, 1900, the following nominations were also made: As substitute: M. Boyer (Paul), portrait photographer, Gold Medal, Paris, 1899; Committee of Admission, Paris, 1900.

As member: M. Davanne (Alphonse), Vice-President of the Photographic Society of France; Committees, Jury, Paris, 1878 and 1889; Vice-President of Committees, Paris, 1900.

The investiture of the International Juries took place on May 23, under the presidency of M. Millerand, Minister of Commerce, in the large hall of the Trocadéro.

The following are the foreign members of the International Jury: Sir William Abney, England; Messrs. Cameron, United States of America; Desmazières, Greece; Dr. Eder, Austria; Engelsted, Denmark; Kawamura, Japan; Miethé, Germany; Pricam, Switzerland; X. ? Italy.

The Bureau of the International Jury was formed on May 26, and consists of the following members: President, M. A. Davanne; Vice-President, Dr. Eder; Reporter, M. Léon Vidal; Secretary, M. Pricam.

The work of the Jury will soon be started. At the inaugural meeting it was decided that the substitutes should have the same deliberative powers as the members.

#### THE COLOURS OF THE SILVER IMAGE.

METALLIC silver occurs in fixed photographic films in several very different forms, in gelatine negatives we have a pure black form, in printing-out paper, fixed and not toned, a bright yellow kind. Observations of the development of faintly printed gelatino-chloride pictures with nascent silver prove that, besides the above kinds, there are many others, such as red, brown, olive, green, each in several different shades.

As I have already pointed out, there is no doubt that the colour of the silver is only determined by the different sizes of the individual particles of silver, which are imbedded in the vehicle; the finer the grain, that is to say the fewer the molecules which combine to form a complex, the more the colour of the image tends to red or yellow.\* The black images are always considerably coarser-grained than the yellow and red.

I have made some observations which prove that the colour is only dependent on the size of the particles of silver.

\* *Photographische Physik*, p. 19.

If a faintly printed aristotype print\* is placed in an aqueous solution of gallic acid, there is obtained after short development and fixing a yellowish-red print, after long development brown, and finally green, to greenish-black images. The longer the print stops in the developer, the larger the grain becomes by the accession of nascent silver.

That in this case nothing else can happen is well seen if a print, which has been developed too long, is reduced with hyposulphite of soda, to which some potassium ferricyanide is added. The green form of the silver goes again into the brown, and then into the red.

In the development of Pan paper† there is no accretion of metallic silver on the exposed grains of the silver haloid. The yellow and red tones appear then, if the paper is exposed for a long time and if a diluted developer is used. The reduction of the silver haloid is then confined to the extreme outside of the individual grains. With short exposure and development with a strong developer, the silver haloid grains, on the other hand, are finally reduced through and through, and the brown or greenish-black form is produced.

It is possible moreover, as I have already‡ pointed out, even with dry plates which possess a very coarse bromide of silver grain, to obtain the red form of silver by confining the reduction to extreme outside of the silver haloid; sodium hydrosulphite develops a chloro-bromide plate which has been considerably over-exposed red, as do also some vanadium and molybdenum salts, but this last process is not suitable for practical work. R. E. LIESEGANG.

#### FOREIGN NEWS AND NOTES.

**Flat Negatives and Process Work.**—Professor A. Lainer, in the *Photographische Correspondenz*, draws the attention of the process worker and the collytoper to the use of hard-printing silver papers as an aid to obtaining good results. In Germany a series of hard-printing collodio-chloride papers is sold in three grades of intensity, and their effect may be enhanced or reduced by the process of toning. The combined toning and fixing bath gives most contrast. This may be somewhat reduced by washing the prints before toning. Intermediate effects are obtainable by separate toning and fixing baths. In the ordinary course a flat negative has to pass through the retoucher's hands before it is fit for process work, so that the gradation throughout the picture may be improved. Even then the result is often far from satisfactory, as hand work cannot rival the subtle tones of a good negative. Two process prints are given in the *Photographische Correspondenz* to illustrate Professor Lainer's point. The block for one of these has been made in the ordinary way, and gives a flat, unsatisfactory result. The subject is a river landscape, with high lights on the water in the foreground, trees in the middle distance, and some delicate half-tone in the distance. The second block has been made from a print upon a medium grade of these hard-printing papers, and gives the landscape all the requisite vigour in the high lights of the foreground and distance.

**Plate-sunk Mounts.**—An illustration is given in the *Photographische Correspondenz* of a simple piece of apparatus devised by Herr Kosel, Baron Albert von Rothschild's assistant, for producing the effect of a plate-sunk mount. A flat rule is fastened, by a hinge, to a board of suitable length. The other end of the rule is provided with a thumbscrew, by means of which it may be firmly secured to the board. The mounted print is firmly clamped between the rule and the board, so that the exact margin is left between the print and the rule, to represent the plate mark. A wooden block, resembling in shape the head of a claw hammer, is then passed along the surface of the mount, with some pressure, next the straight-edge. Each of the four sides is treated in this manner, and the effect is an impression resembling the mark produced by a plate in the press. According to

\* Gelatino-chloride of silver, with excess of silver nitrate.

† From the advertisements of this paper which have been introduced commercially by Ed. Liesegang, we imagine this to be similar in character to the now well-known "gaslight" developing papers.—EDS.

‡ *Photographische Archiv*, 1895, p. 284.

the illustration, a thin slip is fixed to the board underneath, half the length of the rule at the end provided with the thumbscrew. This slip of the rule is used for impressing drawing-paper, whilst the other is used for cardboard mounts. If a sheet of paper be laid upon the print before the pressure block is applied, the cardboard will retain its original appearance, but otherwise the surface will be furnished.

**Yellow Stains on Negatives.**—The *Photographisches Wochenblatt* states, on the authority of Professor Namias, that yellow stains may be removed by means of a two per cent. solution of ammonium persulphate. To eliminate the reducing action of the salt, a few drops of ammonia are added to the solution. The activity of the salt as a solvent of silver is only manifest when the solution is acid. In the neutral and alkaline states silver is not affected by it. The monoxide compounds of silver are, however, soluble in alkaline persulphate, and it therefore seems probable that the yellow stains are due to such forms of silver.

**Photography in Churches.**—Monsieur E. Mouchelet raises the question, in the *Photo-Gazette*, of the right to photograph in churches and similar edifices. His remarks, of course, only apply to France, but there are numbers of Englishmen who are seriously interested in church architecture, and carry the camera with them, when visiting our friends on the other side of the Channel, and naturally avail themselves of every opportunity of obtaining records of the many beautiful churches there. Monsieur Mouchelet admits that the question is a delicate one, but states that in the majority of cases the churches belong to the State or the parish. Private chapels, of course, are the property of the congregations. The priest, or curé, is only the usufructuary, and not the owner, but he is the guardian of order in the building. Should the taking of a photograph, when the building is not used for any kind of worship, be deemed an offence? Has the curé the right to exclude the camera any more than an umbrella, walking-stick, or similar impedimenta? The crime would seem to consist in taking the cap off the lens, but can such an act be stretched to the extent of assuming the proportions of an offence against decency or order? Monsieur Mouchelet holds that it cannot, and that the curé would exceed his duty in excluding the photographer under such circumstances. He recommends, nevertheless, as a matter of politeness, that permission be asked, and the archæologist will frequently find this to his benefit, as there are many objects of great interest in French churches which might otherwise escape his attention.

**Edouard Mantois.**—The *Photo-Gazette* records the death of this celebrated manufacturer of optical glass. The business, of which he was the leading spirit, was started by Guinand about sixty years ago in Paris, and was subsequently managed by Feil. The firm became noted for the excellent crown and flint glass it manufactured. In 1885 Mantois was brought into the business for family reasons, and two years after he assumed the entire management of the firm. Although he had been brought up as a notary, and had not received special education for the branch of manufacture he was called to, he, nevertheless, conducted the business with such signal ability that it became of marked importance to scientific opticians. Under Mantois' auspices the discs of glass for the Yerkes telescope and the present gigantic instrument at the Paris Exhibition were made. The lens of the latter is one and a quarter metres in diameter. It is curious to note that in 1880 the firm experimented in the manufacture of baryta glass, which has since become of such importance in photographic optics, but it seems only to have been used by makers of artificial diamonds, and then lost sight of until the lenses made with Jena glass became famous. Mantois recognised the danger which menaced the French trade in optical glass when the important innovations at Jena became known. He determined to compete, and, assisted by M. Verneuil, in the course of a few years produced a series of new glasses. In 1889 Mantois was awarded the principal prize at the Paris Exhibition. Similar success attended him in Brussels in 1897. In 1889 he was made

Chevalier de la Légion d'Honneur, and, doubtless, higher honours would have been conferred upon him in Paris this year had he been spared.

**German Patents.**—We recently drew attention to the unsatisfactory state of the British Patent Acts from the point of view of the patentee. The situation in Germany is not ideal, and we could point to cases of decided hardship which have arisen under German law, but the following statistics prove that numbers of doubtful, if not worthless, patents would have been granted if a similar system prevailed in Germany to that in our own country.

The *Deutsche Photographen Zeitung* states, on the authority of Mr. Alfred Joseph, of Hamburg, that, in the year 1899, 21,080 patents were applied for in Germany. Of these only 7430 were granted. The following figures relate to the photographic section:—

	1895	1896	1897	1898	1899	1877 to 1899.
Applications..	128	175	175	205	256	1970
Granted ....	50	46	53	44	73	766

On January 1, 1899, there were still  
 under consideration ..... 200 applications.  
 During the year 1899 there were .. 256 "

Total ..... 456 "

Deduct withdrawn, refused, &c. 108 "  
 Granted ..... 73 187 "

---

Still under consideration on Dec. 31,  
 1899 ..... 275 "

Of these 275 applications 8 date from the year 1897  
 56 " " " 1898  
 211 " " " 1899

Of the 766 patents granted from 1877 to 1898, 547 expired within that period, and 47 in 1899. On January 1, 1900, there were, consequently, 172 patents still in force relating to photography. The oldest of these relates to a process for printing coloured collotypes. It is No. 39,660, dated July 24, 1886, and was granted to J. F. Meisner, of the firm of Meisner & Buch, Leipzig.

**The Effect of Light on the Eyes.**—The *Deutsche Photographen Zeitung* states that a Russian physician has come to the conclusion that electric light is least, and candle light most, injurious to the eyes. This is based upon observation of the number of times the lids are closed in a given time under otherwise similar conditions. The more often the lids are closed, the greater the fatigue and consequent injury. The following figures represent the number of times the lids were closed per minute:—

Candle light .....	6½
Gas .....	2½
Sun .....	2½
Electric .....	1½

FILMS VERSUS PLATES.

AMONG a very large number of old and experienced photographers there has been, and still is, a considerable amount of prejudice against films, and this has greatly influenced many of the younger and less experienced, who look for correct advice from those who have made their mark long ago. Now, it seems a pity that, through a misapprehension brought about partly by prejudice, a good thing should become prohibited to those who otherwise would fully avail themselves of its advantages.

A young man starting in business was once given this wise advice, "If you want to be successful, take counsel with those who have been successful before you." The same applies to users of films, find out a successful worker with films and he will put you on the right track. Those who never do any good work with films cannot help you, but their prejudices will be catching, and then you will find it difficult to believe that you have blundered. The poor film will consequently get the blame.

It is my lot to have thousands of film negatives come under my notice during each year, some made by experts, but the majority by the ordinary amateur who works more or less in a mechanical sort of way.

My experience in investigating the causes of faults has led me to the conclusion that, in the majority of cases where unsatisfactory results have been obtained, they would have been avoided if a few simple rules had been adhered to.

Of course, I do not mean to say that films have no faults. A certain percentage of these will occasionally be met with, and the same thing applies to glass plates; but they are the exception and not the rule, as some seem to suppose.

When one considers that films weigh ounces as against pounds in the case of glass plates, that films are practically unbreakable, and that one hundred can be stored in the space of one inch without the chance of damage, the desire to use films grows stronger.

When also we remember that thousands of photographers are producing results on films that satisfy the most exacting expert, it seems well worth the while to carefully ascertain why we are not ourselves able to do the same. At a lecture I gave last year at the Athenæum, Manchester, I projected on the screen a number of lantern slides (which are a severe test for quality) made from Frena film negatives. A well-known photographer in the neighbourhood was present, and he has told me since that it set him thinking. He asked himself the above question, which has resulted in his adopting films for hand-camera work after years of prejudice, with first-class results.

Now for a few remarks about the films themselves. My knowledge lies chiefly in the direction of cut films, and it is of these I write.

A few years ago the treatment of celluloid as a support for the sensitive film was not properly understood, and how to avoid defects had to be learnt by mistakes, time, and experience. This want of experience, which time alone could give, was the cause of the bad films of days gone by. Now all this is changed. Time has made the manufacturers of today so well acquainted with defects and remedies that the chances of faults with any good brand of films are exceptional.

Choose therefore a brand of films by a maker who has had such experience, and who has made careful study to rectify the faults discovered. These brands are easily selected because they are few. They will be the well-known makers upon whose films good work has been recorded.

Do not expect to do rapid work on a slow film; there are as rapid films as plates for those who require them.

Do not develop with pyro and ammonia; this does not suit all brands of films; any other developer will do. I prefer pyro and soda.

Pour the developer on to the film, and shake the dish rapidly from side to side instead of rocking, and the film will lie flat at the bottom of the dish. Rocking is liable to cause the film to float occasionally.

Carry development rather further for films than for glass plates.

If you use rapid films, do not be sure your dark-room lamp is quite safe until you have tested it. Put an unexposed film about the same distance from the light as you would place the dish when developing; place a penny on it and leave it for five minutes. Then develop the film far away from the light, and, if the film is fogged except where the penny protected it, you may be sure your light is not safe. Many professional photographers have been surprised to find their dark-room lamp unsafe for rapid plates or films.

It is easy to think you are not over-exposing, but very easy to do so. Prove this for yourself: Make three exposures with rapid films on the same well-lighted subject at three greatly differing exposures, say  $\frac{1}{2}$ ,  $\frac{1}{4}$ , and  $\frac{1}{8}$  of a second, and you will probably find that the exposure that was much shorter than you would have dared to have given under ordinary circumstances will be best.

Do not use acid hypo for films; it does not suit some brands.

Wash your films in an ordinary plate rack in pairs, back to back.

Dry your films by hanging them to a board with their faces outwards. Ordinary tie clips will be found useful for this purpose, or dark-room pins will answer as well.

If the latter are used, cut the burr off the negatives before packing them together, or they will get scratched.

Print your films in frames containing a piece of glass. Take care the glass is free from flaws or scratches.

Store your film negatives in albums containing transparent envelopes. You can then easily select any negative by transmitted light without interfering with the others.

Films by any good maker will keep as well as plates. I have some good negatives made on films kept six years before exposure.

Small tins sealed with surgeon's plaster make a convenient method of packing for abroad.

Finally, do not condemn films because your experience long ago was bad, or because your one experience was unsatisfactory. Things disliked at first sometimes become our pet choice.

F. O. BYNOE.

#### THE PREPARATION OF PLATINUM PAPER.

THE organic salts of sesquioxide of iron are reduced by light to protoxide salts. If paper be coated with a solution of such a salt, and exposed under a negative, a faint positive is obtained which can be turned into a serviceable print by treating it with a substance that will react with the reduced iron salt to form an insoluble coloured deposit, and will not react with the unchanged ferric salt. Three such substances in common use are red prussiate of potash, a solution of silver, and one of platinum, which form, with the reduced iron salt, Turnbull's blue, metallic silver, and metallic platinum, the resulting prints being known as the blue print, the kallitype, and the platinum print.

The iron salt used in the platinum process is the oxalate. The ferrous oxalate formed by the action of the light must be brought into a soluble condition before it will reduce platinum. It is insoluble in water, but soluble in solutions of several of the alkali salts, one of which, therefore (usually oxalate of potash), together with the iron oxalate and the platinum salt, form the three essential constituents in the platinum process.

There are three methods of preparing the print. The paper may be coated with the iron solution, printed and developed with a mixture of platinum and oxalate of potash; it may be coated with the iron and platinum, and developed with the oxalate of potash; or it may be coated with all three, and printed as a printing-out paper. These three methods do not give equal results. Each has its advantages and disadvantages, and, on the whole, it can be said that in the order above given the convenience in manipulation increases and the quality of the print decreases. The printing-out paper is still manufactured, and on the market, usually under the name of Pizzighelli paper. It gives good results where soft prints are desired from dense, contrastful negatives, otherwise it is inferior to the more popular paper with platinum and iron, which is easy to manipulate, and which gives better results in the majority of cases. The paper containing iron only, to be developed with platinum and oxalate of potash, is no longer on the market. It has been pushed out by the ordinary paper, probably because the developing was more expensive and more difficult, and the quality of the result very much the same.

The method in common use by those who prepare their own paper is also that with iron and platinum in the paper. With this method it is not difficult to obtain satisfactory results; these results are, however, only exceptionally equal to those obtained with ready-made paper, or with self-prepared paper with platinum in the developer. A good platinum paper should, when made for soft effects, give a print that is free from fog, with pure whites and good deep blue-black tones in the shadows, and at the same time soft. When made for brilliant effects, the whites should be pure, the deep shadows should be intensely blue-black, not easily solarised, and clear, and the deep half-tones should stand out from the shadows. A good ready-made paper, such as that of the Platinotype Company, possesses these qualities almost as far as is possible with a paper of a single degree of brilliancy. Self-prepared paper, with platinum in the sensitising solution, is uneven in its results. At times, under conditions which it is not easy to control, it is very satisfactory. Again, it shows a tendency to give hazy, foggy prints when made for soft effects, which can only be prevented by the addition of substances that make the print too brilliant. In the more brilliant paper the shadows, which examined alone appear to have a very satisfactory deep blue-black tone, grow faded and brown when compared with a print on ready-made paper, or on paper with platinum in the developer.

The latter method has two disadvantages. The platinum is deposited more upon the surface of the paper, and is consequently more apt to float off into the developing fluid, and the latter must be very carefully and evenly brushed over the print to avoid streaks. These are not serious evils, as they may be prevented with a little care. In every other respect the method is better than the other. It requires less platinum, it offers a wider range from softness to brilliancy, the print solarises less readily and is more visible, and therefore more easily controlled in printing, it gives with more certainty deeper and bluer blacks, with more detail in the shadows, and the prepared paper keeps better, especially in hot weather.

The following directions for the preparation of prints by this method are based on those given by von Hübl in his book, *Der Platinruck*, with a few changes and additions:—

The character of the paper plays an important rôle because the print lies directly on its surface. Small prints depend for their effect upon details and require smooth paper. Large prints, especially when the subject is in part out of focus, gain in artistic effect when made upon rougher paper. For small negatives, up to quarter-plate or 4 × 5, two

Excellent papers are the ordinary Rives smooth 19 kilo normal platinum paper, and the fine grain pyramidinkorn paper made by Schaeuffelen in Heilbrunn in Germany. The latter paper has a file-like surface, fine enough to preserve the details, which by preventing reflection increases the depth of tone in the shadows, and which gives an agreeable effect otherwise. This paper is made in at least two thicknesses, and with two or more grains. The heavier is excellent for making post cards, the lighter coarse grain is suitable for medium-sized portraits. For half-plates and larger sizes two good papers are the 21 kilo rough and 32 kilo rough Rives' paper.

These papers should be first coated with a thin gelatine solution, prepared by heating 2 grammes of gelatine in 250 c. c. of water until it dissolves, adding  $\frac{1}{2}$  to 1 gramme of alum, and straining through a handkerchief. The paper should be tacked to a clean surface, painted with the warm solution and laid over a chair, or hung up, to dry. The pyramidinkorn paper requires a more careful treatment. When the moisture begins to disappear, the excess of the gelatine solution should be removed with a sponge squeezed as dry as possible, or it should be spread evenly over the surface with a wide soft brush. If this is not done, the gelatine will settle in the hollows and form shiny scales. The object of this preliminary sizing is to prevent the sensitising solution sinking into the pores of the paper. The paper takes a more even coating, and the tone of the print is bettered. The papers above mentioned are well sized and need only a weak coating. More porous papers require a more vigorous treatment. The sizing should be repeated, or the gelatine solution made stronger, or the paper should be soaked in a large dish of the warm solution. A too heavy sizing causes the platinum to be reduced by the iron after the latter has been dissolved off the paper. In the beginning it is better to buy the paper ready prepared with gelatine. Hand-made water-colour paper is sized with animal glue, which seriously hinders the reduction of platinum.

The iron solution, which should be prepared by artificial light, is made by adding all at once to 100 c. c. of water, 25 grammes of ferric oxalate in scales, 2 grammes of oxalic acid, and 1 gramme of lead oxalate. The mixture should be shaken for a quarter to half an hour, and filtered into a brown glass bottle. The lead oxalate is not very soluble, and may not wholly dissolve. The greater part should, however, and if it does not it is because the iron oxalate contains sulphate, in which case the solution should be filtered and a second gramme of lead added. The oxalic acid prevents rusty brown tones; the lead oxalate, according to Von Hübl, causes the platinum to be more thoroughly and quickly reduced.

Two platinum solutions are required: a solution of 1 gramme (15 grains) of chloro-platinite of potassium in 6 c. c. of water, and of 1 gramme of sodium platonic chloride in 6 c. c. of water.

The addition of a small amount of quicksilver or of platinum to the iron solution is necessary. The latter is supposed to more effectually prevent the floating off of the reduced platinum in developing, and by varying the proportion of the two platinum salts the brilliancy of the paper is easily and exactly controlled. For soft effects, 1 part of the potassium platinum solution should be added to 10 parts of the iron solution. For extremely brilliant effects, 1 part of the sodium platinum salt should be substituted for the other. Between these extremes all grades of brilliancy can be obtained by substituting for a part of the one an equal volume of the other. In the majority of cases the correct proportion will lie between 0.8 parts potassium platinous chloride to 0.2 parts sodium platonic chloride and equal parts of each. The two platinum salts should be added separately to the iron; mixed alone, they precipitate potassium platonic chloride.

It is advisable to prepare the paper on a small scale, especially at first. The iron solution is conveniently measured in a 10 c. c. measuring glass, and the two platinum solutions by drops, with the assumption that twenty drops make a cubic centimetre. The two proportions given above then become, for instance, iron solution, 2  $\frac{1}{2}$  c. c.; potassium platinum solution, 4 drops; sodium platinum solution, 1 drop; and iron solution, 3 c. c.; and 3 drops each of the platinum solutions.

The solution, poured into a teacup, should be painted evenly over the paper with a brush, and the paper allowed to dry at the room temperature for twenty minutes to half an hour. The drying should then be finished by artificial heat at not too high a temperature. The rate at which the paper dries is an important factor in this method with platinum in the developer. If the paper remains moist for an hour or two the iron will lose in sensitiveness, and the resulting prints will have a faded brown tone. If, on the other hand, the paper be dried too quickly, the entire picture will swim off the surface of the paper when the print is developed. It has already been said that a too heavy sizing has the same effect, and

these are the two principal causes of this, the most serious disadvantage of the method. Two others are a too concentrated iron solution and a too vigorous application of the developer. The same volume of sensitising solution will cover a larger surface of smooth firm paper than of coarse porous paper. With the latter more iron will be reduced than can be replaced by metallic platinum, and the latter will be reduced in the developer and may deposit on the high lights. The iron solution should, therefore, be diluted for such papers, according to Von Hübl, with 3 to 6 c. c. of water for every 5 c. c. of sensitising solution. For the smooth Rives paper the solution need not be diluted. For the other papers mentioned above, 1.5 to 2.5 c. c. of water may be added. The degree of dilution depends on the temperature and dryness of the paper, and on the nature of the preliminary sizing as well as on the paper itself, and it must be determined by each for himself. Excessive dilution gives a paper which solarises easily, and on which the print is only faintly visible during the printing. It also gives prints with heavy shadows without detail.

The developer consists of 1 part of the chloro-platinite of potassium solution and 10 parts of a solution of—

Potassium oxalate .....	100 grammes,
Potassium phosphate .....	50     "
Water .....	1000 c. c.,

or of—

Potassium oxalate .....	160 grammes,
Potassium phosphate .....	8     "
Potassium sulphate .....	1 gramme,
Water .....	480 c. c.

or of the ordinary developer used with ready-made platinum paper. With ordinary platinum paper the developer may be applied very carelessly. When platinum is added to it, more care is necessary. One should not use a pig's-bristle brush, but a soft flat camel's-hair brush, at least 1  $\frac{1}{2}$  inches wide for small, and 2 or 2  $\frac{1}{2}$  inches for larger prints. It should be drawn lightly and steadily across the print and dipped into the developer after each stroke, to avoid streaky results. After the print has been thus quickly and evenly wet, it should be left undisturbed for a few seconds. One should not be disturbed by an apparent utter collapse of the picture, for a presentable print may still be obtained. At the same time if the developing fluid grows very black with suspended platinum after two or three prints have been developed with it, one should seek to prevent this by reducing the strength of the gelatine sizing solution, by diluting the sensitising solution or by drying the paper more slowly. A slight turbidity does not matter. Unexposed prints improve slightly by being kept wet with the developer for five or ten minutes.

The prints should be washed in two or three changes of acidulated water, containing 1 part of hydrochloric acid in 50 to 80 parts of water, and finally in running water.

In place of the sodium platonic chloride, a second iron solution, containing 0.5 gramme of chlorate of potash in 100 c. c., may be substituted.

For soft prints one then proceeds as before directed, and replaces with successive parts of the first iron solution for an equal volume of the (so-called) chlorate iron solution, using in every case one volume of chloro-platinite of potassium to ten volumes of the mixed iron solutions.

The ordinary platinum paper with platinum in the sensitising solution may be prepared according to the two methods given above by raising the proportion of platinum solution to iron solution from 1 to 10 up to 1 to 1  $\frac{1}{2}$ . For soft effects, for instance, 1  $\frac{1}{2}$  c. c. of iron to 1 c. c. of chloro-platinite of potassium should be diluted as above directed with water, and the paper dried at once by artificial heat. For increase in brilliancy either the iron solution should be in part, or in extreme cases entirely replaced by an equal volume of the chlorate iron solution, or the potassium platinum solution be replaced in a similar way by the sodium platinum solution. A soft-working paper can be made to give more contrast by over-printing it and developing with the oxalate-phosphate-sulphate solution diluted with 5 parts of water.

The papers mentioned here can be had either "raw" or "foreprepared" with gelatine, as the Germans say, from Dr. Jacoby, 52, Thurmstrasse, Berlin, N.W., who manufactures platinum paper and the materials for its preparation. The cost of packing and forwarding by parcels post is about 2s. 6d. for 11 pounds. From him one can obtain the two iron solutions and the two platinum salts, lead, oxalate, measuring glasses, &c. Dr. Jacoby's iron solutions give good results, although, for the method with platinum in the developer, the grain of lead oxalate should be added. If one prefers to make one's own iron

solution, which is to be recommended, the iron oxalate of Dr. Schuchardt, manufacturing chemist, in Görlitz, Germany, will be found to give good results.

The exact measuring of the small quantities of platinum solution required for preparing paper on a small scale is most conveniently made in drops. Ordinary dropping bottles are inconvenient for strong solutions. One can drop from ordinary cork-stopper bottles with perfect security if the neck and lip be first wet with the solution. The size of the drops varies, however, from 8 or 9 to a c. c. up to 20, according to the rate at which they fall and whether they drop from the lip or from the neck of the bottle. The sodium platinum chloride solution has a very marked effect even in small quantities, and a more reliable arrangement for measuring it is desirable. A fountain-pen filler inserted in the cork is convenient, and, if one is skilful enough, a 3 to 5 c. c. pipette, divided into  $\frac{1}{2}$  c. c., is still more so; or one may use a conical minim glass of the smallest size.

For converting the weights and measures here given into those of the English system, it is sufficient to remember that a c. c. of water weighs a gramme; that a fluid ounce of water weighs an ounce avoirdupois; that a gramme equals 15 grains, a c. c. equals 17 minims, and that a fluid ounce equals 28.4 c. c., and therefore an avoirdupois ounce equals 28.4 grammes.

Snap-shot negatives and bits from larger negatives give, with either method, very attractive prints on post cards made from pyramidinkorn paper; the space to be printed in should be outlined in pencil, and washed in, with sensitising solution, by means of an ordinary water-colour quill brush, the edges being left somewhat ragged. If the print be developed without platinum, a faint image will be obtained, which may be written upon or coloured with water-colour paints.

The self-preparation of the platinum print is such a charming and agreeable process that no article upon it is complete that does not—and in fact almost all do—hold forth its merits, and the fact that it is not in such common use as it should be. It requires a harmonious and fully exposed negative. Harsh lights, with broad shadows without details, do not give satisfactory results, nor does a commonplace negative. The bromide print, with its poorly concealed film of gelatine, is an altogether inferior thing, the use of which is inexcusable, except for enlargements or when good sunlight cannot be had. A total of half a grain of platinum will cover a sheet 20 x 26 inches, which will make three dozen  $\frac{1}{4}$ -plate prints. The other materials being cheap, it is therefore not more expensive than other photographic papers, and has the advantage over the ready-made platinum paper, in that one always has it fresh and can select the paper and preparation most suited to the negative.

It should therefore be added for the benefit of those who, not having tried it, are not taken with the idea of painting paper with a platinum solution at five or six shillings an ounce, with nine chances in ten that the picture will float off or be otherwise valueless, that the process is, in fact, easily mastered, and is exceedingly fascinating. There are no expensive toning baths, no hypo to wash out, no stains, no surface to scratch and peel off. When one feels the inclination to make a print, the room is darkened, the bottles and a roll of paper are produced. A few drops of each solution in a teacup, and the paper is coated, dried, and is ready for use. It prints very quickly in good light. After printing, there is only a dash of a brushful of developer, a plunge into an acid bath, ditto into another, a wash under the tap, and the thing is done—clean, quick, satisfactory, and permanent.

W. S. DAVENPORT.

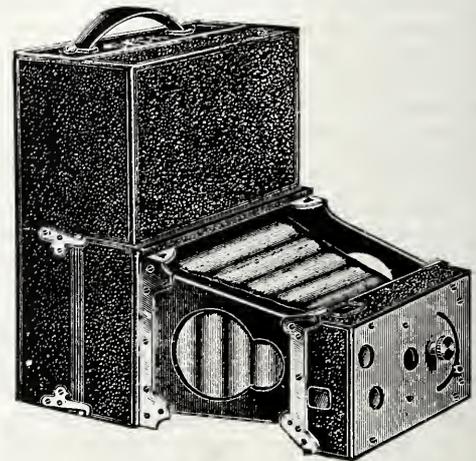

### THE FUTURE OF CHEMISTRY.

In the "mysteries of chemical energy" photographers are more or less directly interested. Our contemporary, *The Scientific American*, in a short article on the subject, points out that our modern system of mechanics begins practically with the invention of means for measuring force and for calculating its effect upon matter. Mechanics have not alone profited by the labours of Helmholtz and Maxwell, Robert Mayer, and Joule; the achievements of these physicists were also the means of elevating chemistry to the rank of an exact science. Chemists were compelled to retrace their steps, to re-explore fields which they thought had been thoroughly investigated, and to study old processes in the light of the new discoveries. The laboratory investigator was no longer content to measure only the matter at his disposal, he found it necessary to know how great was the force released or rendered latent by chemical processes. Thus it was that thermo-chemistry originated; and thus the

prophecy made by Richter one hundred years ago, that chemistry was but "a branch of applied mathematics," was fulfilled. The gap that once separated physics from chemistry is now bridged. Our study of the phenomena of dissociation and of dissolution carries us directly into the province of molecular physics. But, great as the strides have been which chemistry has made within the last half-century, proceeds our contemporary, there still remains many a weary path to be pursued. Although physicists have done much to clarify the chemist's conception of matter and force, they have not told him all. Those seventy elements which are daily used in the laboratory, surely they are but the variant forms of a single matter. We have but one force; and why should there be seventy matters? That wonderful periodical law, with its puzzling numbers, seems to contain within it the means of discovering the primeval matter for which chemists have long been seeking. The old alchemist with his theory of the transmutation of elements again lives; but he is now a chemical physicist, who endeavours not to convert a base metal into gold, but to prove the existence of one form of matter. The mysteries of chemical energy are also still to be unfathomed. The forces which we have learned to observe and to measure are phenomena of a secondary nature. The chemical energy whose transformations give rise to these forces is still a puzzle to chemists. Instruments of measurement can reveal only the sum total of this energy, but not the nature of the intramolecular changes which occur. For this reason we have no clear conception or numerical expression for the relation of chemical energy to other forces; in other words, we have no chemical equivalent of work. We know that chemical energy is converted not only into heat, but also into light and electricity. That a chemical work can be directly transformed into motion seems also probable. It cannot be for a moment doubted that the problem of chemical energy and matter will eventually be solved. When adequate laws shall have been formulated by the twentieth-century investigator, we may possibly speak of a "mechanical" or "kinetic" chemistry, which will be added to the list of exact sciences.

### A NEW FRENA CAMERA FOR GLASS PLATES OR FILMS.

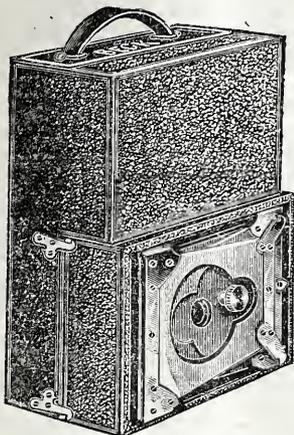

WE are indebted to Messrs. Beck for the following details of the new Frena: It is much smaller and more compact than the box form of Frena, and has the further advantage that glass plates in plate-holders may be employed if desired. The first size, which is now ready and called the No. 6 Frena, takes quarter-plate pictures. It has an achromatic single lens with a "fixed focus," whose range of focus includes any object between twenty feet from the camera and the horizon. The same system of magnifiers is used for focussing near objects as is employed in all the fixed-focus Frena cameras. By means of these, objects as near as nine inches can be photographed.

No. 6 Frena. Open.

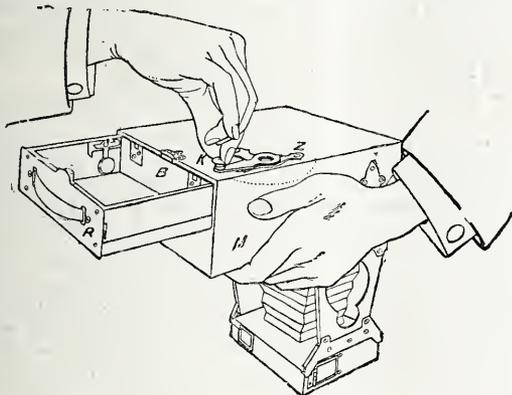

The camera is fitted with two Brilliant "stationary" finders, has diaphragms to the lens, and shutter giving exposures  $\frac{1}{2}$ ,  $\frac{1}{10}$ ,  $\frac{1}{20}$ ,  $\frac{1}{40}$ ,  $\frac{1}{80}$  of a second and time exposures. The film-changing device is on the Frena system, in which the films are dropped into a receiving chamber one by one as exposed. The construction of the film-changing portion is, however, different, the magazine holding the film being drawn out by a slide till it is opposite the receiver, the revolution of a handle then drops the exposed film into this chamber. An automatic indicator records the number of films thus dropped into the receiver.

By means of this new arrangement of the film-holder Messrs. Beck have been enabled to construct the Folding Frena so that the lens,

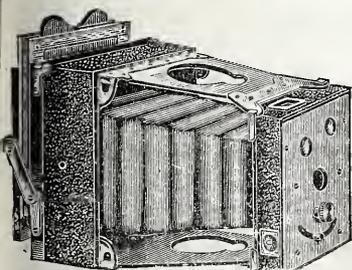

No. 6 Frena. Closed.

latter, and camera can be detached from the magazine and film-changing portion. In this manner the camera, with the addition of a

ground-glass attachment and double plate-holder, can be used as an ordinary plate camera if desired.

No. 6 Folding Frena, with glass plate attachment.

The camera is of a convenient shape to be slung over the shoulder, and can be easily used whilst still so slung.

## Our Editorial Table.

### THE "BERTHA" TRANSPARENT COLOURS.

Made by the Vanguard Manufacturing Company, Maidenhead.

The latest introduction of the Vanguard Company, who are constantly adding to their list of convenient preparations for photographic use is a series of seven concentrated transparent colours in powder for tinting photographs on glass and paper. They should be found of very great service. We quote the excellent instructions given for the use of these colours:—

Add a very small proportion of colour to a little clean water, and work with a brush until dissolved. In this condition the colours are ready for painting transparencies, lantern slides, &c. For tinting prints on platinotype, P.O.P., &c., the colours may be used in the same way; but better results will be obtained by adding a trace of gum water, and one drop of

glycerine to each ounce of water. A very good medium for use in tinting P.O.P. is the following:—

Dried egg albumen .....	2 parts by weight.
Water .....	100     "     "
Ammonia .....	2     "     "

Dissolve the albumen in the water and then add the ammonia. Apply a wash of this medium all over the print, in order to moisten the surface, before applying the colours. Prints on P.O.P. may be burnished after tinting (of course, when quite dry), and will be much improved thereby.

*Blending.*—It is not advisable to try to get special tints by directly mixing the colours. The correct way is to apply a wash of one colour

and then follow it with a wash of another. Thus, to get various shades of green, apply a wash of blue-green, and follow it with washes of yellow as required. The same remark applies to purple: first apply blue and then follow it with red, &c. There are cases, however, in which various colours may be mixed together with good effect; these will soon be apparent after a few trials.

*Complexions.*—Apply a *very weak* wash of brown, and follow with very weak washes of red where colour is most desired.

*Colouring Transparencies.*—The best plan is to first thoroughly moisten the gelatine surface and then blot off the surplus water. The colours can then be safely applied without fear of forming harsh outlines.

### FLEXIBLE PLATE BACKINGS.

Prepared and sold by C. C. Vevers, Grand Arcade, Briggate, Leeds.

We have received from Mr. Vevers a sample of his flexible plate backing. This consists of a fabric coated with a tacky or ever-moist substance which allows of its being placed in perfect optical contact with the back of the glass plate, a necessary condition of the successful use of anti-halatives. We have many times used flexible plate backings of the nature of that now sent us by Mr. Vevers, and have found them effective in practice. They are convenient, cleanly, and cheap.

MR. WALTER D. WELFORD, of Warwick Lodge, 166, Romford-road, London, E., sends us sample prints of a new series of patriotic border negatives which he has just introduced. They are made by the carbon process, and are issued on film in all sizes. Mr. Welford points out that at the present time they should prove attractive to professionals and amateurs in a patriotic frame of mind. The prices are: half-plate, 1s. 6d.;  $8\frac{1}{2} \times 6\frac{1}{2}$ , 2s. 6d. According to the prints sent the national flag and other emblems form the subjects of the negatives.

### TRAITÉ PRATIQUE DE PHOTOGRAVURE.

LÉON VIDAL. Gauthier-Villars, Quai des Grands-Augustins, 55, Paris.

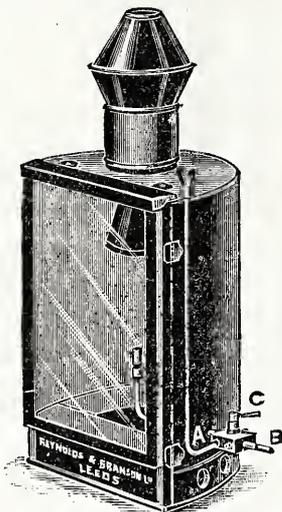

In the present volume Monsieur Léon Vidal gives a practical account of photo-engraving in all its various branches, including line and process work. The subject is not treated from the historical point of view, as the work is intended for instruction. The author correctly states that success very often depends upon dexterity of manipulation, which the professional cannot be expected to make known freely, but the volume contains a description of all the essentials of such process, and with practice the intelligent worker will, doubtless, be able to solve any difficulties which present themselves. The author is Professor at the Ecole Nationale des Arts Décoratifs.

### THE "KRYSTOS" No. 3 DARK-ROOM LAMP.

Manufactured and sold by Reynolds & Branson, Ltd., 14, Commercial-street, Leeds.

MUCH experience in the use of dark-room lamps of varied orders of design and construction led us to direct particular scrutiny to the

Krystos, which Messrs. Reynolds & Branson have kindly brought under our notice. Of one of its features we can speak with especial praise, for very often in the course of an evening's work we find ourselves called upon to develop negatives and expose bromide prints and binocular transparencies. This lamp answers for all three purposes. As the makers point out, the special tap and arrangement of burners enables the operator to use either the jet inside the lantern for non-actinic light or instantly to alter this to an invisible light, and, by the same action, turn on to full the outside jet, which is then available for lighting the dark room, or for printing transparencies or bromide prints. By turning the tap to B, both jets are at once reduced to a by-pass light; at A, white

light is obtained; and at C, non-actinic illumination. It is, therefore, easy to ensure instantly either actinic illumination, non-actinic light, or both jets turned to non-luminous lights. In order to ensure the latter, an adjusting screw is fitted to the tap, to enable the outside jet to be adjusted to invisibility for any pressure of gas. Another feature is the cone for keeping the body of the lamp cool, the hot combustion products being carried away in three separate channels. The lamp is japanned black outside and white within. It is neatly and strongly made, and decidedly convenient to use. Of course, special glazing may be had to suit individual requirements. At a cost of 10s. 6d. the Krystos lamp is a dark-room convenience well worth having.

#### "OUR BRITISH GENERALS."

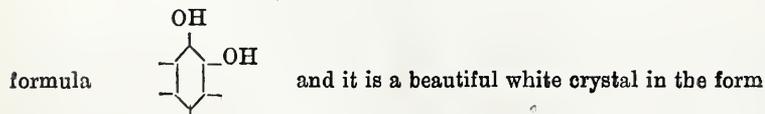

Published by William Tylar, 41, High-street, Aston, Birmingham.

TAKING advantage of the well-merited applause of which the leading British generals in South Africa have been made the objects, Mr. Tylar is issuing a series of collotype portraits of those gallant soldiers. The prints are on sheets 25 x 19 inches, with tinted margins. Portraits of the following are now ready: Lord Roberts, Lord Kitchener, Sir Redvers Buller, Sir George White, General French, General Macdonald, Major-General Baden Powell. The last-named doughty warrior forms the subject of the specimen print that has been sent to us. It is from the well-used negative of Messrs. Elliott & Fry. One shilling each is charged for these portraits, which are excellent of their kind; or a sample is sent post free to any address for 1s. 2d.

#### PYROCATECHIN "MERCK."

Manufactured and sold by E. Merck, Darmstadt, Germany, and 16, Jewry-street, London, E.C.

PYROCATECHIN (or brencatechin), first suggested as a reducing agent some twenty or more years ago, is a di-oxybenzole, having the

of prismatic needles. It is, of course, extremely soluble in water. Some months ago Mr. J. T. Sandell, the inventor of Cristoid, submitted to us a number of exceedingly brilliant negatives made on those films. They were developed with Merck's pyrocatechin, the formula being as follows:—

Pyrocatechin .....	1 ounce or 30 grammes.
Potassium bromide .....	30 grains or 2 "
Sodium sulphite .....	4 ounces or 120 "
Caustic soda .....	½ ounce or 15 "
Boiled or distilled water .....	1 pint or 600 c. c.

One part of this stock solution is diluted with 7 parts of water.

Used according to this formula, pyrocatechin is an energetic developer, and gives greyish-black negatives free from stain.

Merck's chemicals for photography are very pure and carefully prepared products. Some months ago we developed several dozen negatives with pyro-Merck, and were greatly pleased with its behaviour as a reducing agent. Indeed, of all the samples of pyrogalcol that we have used, we have handled none better. The sample of pyrocatechin sent us appears to be in all respects excellent.

## Studio Gossip.

"SE NON È VERO," &C.—A halfpenny morning paper states that to be "photographed as Kruger" is the latest idea of a suburban artist. By means of a false nose, flowing beard, and tall hat, with a Bible and pipe accessories, he is "making up" his patrons as the Transvaal ex-President. Many ladies are among his clients, and the originator of this new phase of fancy photography is reaping a rich harvest.

THE Berlin correspondent of the *Daily Telegraph* writes: "It is not generally known that the German Empress is a very skilful amateur photographer. Whenever there are any festivities at Court—and nobody can say that this is seldom at Berlin—her Majesty always manages to select some scenes which she can add to her already large collection. After the Potsdam parade was over, when her eldest son, the Crown Prince, first appeared with his regiment as full officer, the Kaiserin took a number of groups of her sons with the other young lieutenants who had passed their examinations with the Crown Prince. What interested the public most was to watch her Majesty as she turned her lens on to various groups amongst the crowds of bystanders, and it is needless to add that the persons so honoured did their best to stand well for the Royal and Imperial artist. One of the negatives that promised to turn out well represented the pupils of the large Military Orphanage at Potsdam, wearing their new 'Scotch caps' with cockades."

A PALACE OF LIGHT AT PARIS.—The Exhibition Commissioners have surprise in store for visitors to the World's Fair. This is to be a sort of fantastic palace of light, and is described as the crowning marvel of the Exhibition. The wonders of the place have been prepared in the deepest secrecy, and the mystery has been well kept. But they will shortly be ready to be displayed to an admiring public, and some idea of what they will consist of has now been allowed to leak out. The Palace of Light is hidden away between the Château d'Eau and the Salle des Fêtes, in the Galerie des Machines. It will be reached by dark and mysterious galleries. Following these, the visitor will suddenly be brought into a dazzling blaze of light. All around he will see halls brilliantly illuminated with every colour of the rainbow, stretching apparently to an infinite distance, while everywhere designs in luminous arabesques will sparkle in changing hues. This palace of wonders, as the officials who have been at work upon it in secret for months past talk, is like an Arabian Night's tale, but consists, in reality, of an hexagonal hall, each of the six sides of which are lined with mirrors. Thus the designs in electric light on the ceiling and on the walls are reflected *ad infinitum*, the changing hues being easily produced by various sets of coloured globes.

## News and Notes.

INSTRUCTIONS have been given to enlist photographers for service with the Royal Engineers in South Africa.

ROYAL PHOTOGRAPHIC SOCIETY.—The Exhibition of photographs by Dr. P. H. Emerson, at 86, Russell-square, may be viewed on presentation of visiting-card, between the hours of ten and four, Wednesdays ten to eight.

THE *Publishers' Circular* states that Professor Vivian B. Lewes's forthcoming work on acetylene gas will contain over 250 illustrations, and comprise a history of acetylene, its preparation, properties, and chemical reactions, together with a complete list of legal enactments in full concerning its use and manufacture, patents, and other important data. Messrs. Archibald Constable & Co. are to be the publishers.

WE have received the annual report of the Stonyhurst College Observatory. The volume details the results of meteorological and magnetical observations, with report and notes of the Director, Rev. W. Sidgreaves, S.J., F.R.A.S., for the year 1899. The following are two interesting extracts from the report:—"Considerable preparations were made for the possible Leonid-meteor shower. Five cameras were mounted for the meteor streaks, and one was attached to the eye-end of the Perry Memorial telescope, with the hope of obtaining a photograph of the meteor swarm as a cluster or comet outside our atmosphere. This was the chief hope of the watch on the morning of the 16th November, for which Dr. Johnstone Stoney had kindly provided the position of the sight-line tangent to the meteor orbit. Unfortunately, the sky, though clear enough for eye observations of meteors to the third magnitude, was too hazy for the feeble light from the distant swarm. Only a few Leonids were seen on this morning, and the preceding nights, from the 10th to the 14th inclusive, were cloudy throughout. The stellar spectrophotograph has been employed on all available nights, to continue the series of photographs intended for investigation of possible changes in the spectra of selected stars. But the work of measuring and mapping these has been interrupted by a corresponding work on the solar drawings of the last nineteen years."

COLOUR VALUES IN PHOTOGRAPHY.—In a paper recently read before the Edinburgh Photographic Society Mr. Cameron Todd remarked: "Happy is the one who is not colour-blind, and I hope none of us photographers are,

otherwise we would not be able to look on nature or the works in colour of famous artists, and see with our eyes the true sense of their beauty. To make ourselves acquainted with nature we must wander by the brook, by the side of the marsh, in the wood, high up the mountain-side, or by the seashore. Let us study the varied colours we come across, the shades of green, which are many, from the dark green of the rhododendron and our old Scotch fir to the olive tints of warmer climes, and we shall see their beauty. In the northern sphere we have a change of aspect much more so than those of southern countries, yet they have beauties of their own. We in this part of the world have for the photographer studies in winter where others would grumble at the cold. Look at him with his camera, hieing away to take some snow scenes, a mist effect, the curler on the ice, or the traceries on the window after a hard night's frost. Again, spring brings you to the budding and bursting to life of dormant nature, which then puts on its mantle so green. The fields are covered with the daisy and buttercup, and, as time speeds on, our gardens are ablaze with flowers of many hues. They are not lasting, for autumn comes, and reveals to us, by its beautiful foliage tints, that coming winter is nigh."

## Commercial Intelligence.

MESSRS. TAYLOR & BRAWN, chemists, Bedford, have opened a photographic dark room for the use of photographers.

THE Secco Film Company's premises at Molesey are, we are informed, rapidly approaching completion. Machinery of the most modern kind for coating paper has been erected, and it is anticipated that besides negative paper the company will also be in a position to supply gelatino-chloride and other positive printing surfaces.

THE Comptroller-General of Patents notifies that purchasers of Patent Office publications will in future be allowed to open deposit accounts at the sale branch of the Patent Office, the minimum deposit being 2/. The money may be paid in cash, or forwarded by post office or postal order or by cheque, payable to the Comptroller-General.

CATALOGUES have been received from the following: Walter D. Welford, Warwick Lodge, 166, Romford-road, London, E.; the Photographic Department of the Army and Navy Auxiliary Stores, Limited, Westminster, a volume of about 180 pages; H. F. Purser, 33, Hatton-garden, E.C. (agent for the Busch lenses and the Tribes cameras).

AN excellent and comprehensive catalogue of photographic apparatus extending to 104 pages, reaches us from Mr. F. V. A. Lloyd, of 15, Lord-street, Liverpool. We note that Mr. Lloyd prints a table of weights and measures by the Imperial and metric systems; but in the catalogue itself only the Imperial weights are listed. If weights and measures graduated on the metric system were listed in all dealers' catalogues, the use of the system would gradually extend.

PHOTOGRAPHS BY THE MILLION.—Most people, remarks the *Daily Chronicle*, have either seen or possessed one or more of the excellent little photographs which accompany packets of So-and-So's cigarettes; but few have any idea of the immense number of these which are annually turned out. One firm, which has a factory near London, supplies no fewer than 3,000,000 every year to one customer alone, to say nothing of others. In the case of the British officers who are now so popular, the fee for permission to reproduce is 10/. an officer.

PATENTS IN JAPAN.—According to the annual report of the Comptroller-General of Patents, a number of new Acts have been passed in Japan to amend the Law of Patents, Designs, and Trade Marks. Under these Acts the duration of a patent is fixed at fifteen years, and the copyright of a design ten years, subject to the payment of annual fees. The term of protection obtained by registration of a trade mark is fixed at twenty years, except in the case of trade marks previously registered abroad, where the term is the same as that for which the original registration is valid.

THE METRIC SYSTEM IN RUSSIA.—It is probable that the metric system will be introduced before long in Russia; and the Bill which has been prepared to this effect by the Minister of Finance has received the approbation of the State Council, with the understanding that the University and the various scientific societies will give their assistance in the verification of the weights and measures necessary for commercial use. The details have been nearly all decided upon, and will be submitted to the Council in the near future. Since 1896 the metric system has been used by the medical service of the army in the compounding of formulae, this having been made obligatory.

A WORLD-WIDE CATALOGUE OF SCIENCE.—In order to inaugurate an international conference on the subject of a universal catalogue of scientific literature, an "At Home" was given by the Royal Society at Burlington House on Monday last. The conference formally opened on Tuesday, and amongst the foreign delegates that have arrived in London are Professors Einosuke Yamaguchi (Japan), Masini (Padua), Ciamician (Bologna), August Heller (Budapest), B. Schwalbe (Berlin), and Dr. Klein (Göttingen). The guests were received by the President (Lord Lister) and the members of the Council. The scheme for an international science catalogue was originated in 1894 by the Royal Society, and the present is the third, and it is hoped the final, conference.

## Patent News.

THE following applications for Patents were made between May 28 and June 2, 1900:—

PRODUCTION OF PHOTOGRAPHS.—No. 9900. "Improvements in the Production of Photographs." J. A. JOHNSTON.

NATURAL-COLOUR PHOTOGRAPHY.—No. 9936. "Improvements in Photographic Cameras for Producing and Viewing Images in Natural Colours." Complete specification. E. T. BUTLER.  
 NATURAL-COLOUR PHOTOGRAPHY.—No. 10,000. "Improvements in the Means for and Method of Projecting or Viewing Photographic Pictures with Natural Colours." Complete specification. R. KRAYN.  
 CINEMATOGRAPHY.—No. 10,050. "Improvements in Apparatus for Projecting Animated Pictures." Complete specification. T. ARMAT.  
 NATURAL-COLOUR PHOTOGRAPHY.—No. 10,003. "Improvements in the Method of and Means for the Production of Photographic Pictures which may be Viewed with the Natural Colours of their Subjects." Complete specification. R. KRAYN.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
17.....	South London .....	{ Excursion: Otford and Eynsford. Leader, C. Churchill.
18.....	South London .....	{ Intensification. Mr. McIntosh.

### ROYAL PHOTOGRAPHIC SOCIETY.

JUNE 12.—Ordinary Meeting.—Mr. T. R. Dallmeyer, F.R.A.S. (President), in the chair.

#### NEW MEMBERS, &c.

Three new members were elected, and nine candidates were nominated. The PRESIDENT announced that the Bury St. Edmund's Camera Club and the Redhill and District Camera Club had been admitted to affiliation.

#### THE CONSTRUCTION OF PHOTOGRAPHIC OBJECTIVES.

Mr. H. L. ALDIS, B.A. (Cantab), read a very valuable and interesting paper on "The Construction of Photographic Objectives: Mathematical Investigation." The paper was not of such a nature as to admit of condensation. It began with a short account of Petzval's theory of the spherical aberrations of an optical system, enumerated as (1) spherical aberration; (2) coma; (3) astigmatism; (4) curvature of field; and (5) distortion; and geometrical illustrations were given of the manner in which these arise in the refraction at a spherical surface. In the second part of the discourse an analogy was drawn between the spherical aberrations and a system of parallel forces in equilibrium, and it was shown by diagrams and equations that, if an optical system is to be free from spherical aberration and coma, at least three surfaces are necessary, and that to be also free from astigmatism there must be at least four refracting surfaces. Mr. Aldis concluded by discussing the possibilities of improving photographic lenses in the directions of increased simplicity of construction and greater usefulness, the simplest form of complete lens that is theoretically possible, and the simplest forms of combination lenses that can theoretically be constructed. With regard to simplicity of construction, he thought we were still far from the theoretical limits, since it appeared to be possible to construct a perfect lens having only four refracting surfaces, such as a system composed of only two thick lenses. While it was quite possible that this limit would never be reached unless glass-makers succeeded in the future in producing glasses of altogether abnormal qualities, still systems with even five refracting surfaces, such as a cemented lens and a single lens, would be a considerable improvement on anything at present made. With respect to the question of increased usefulness, the subject of combination lenses naturally occurred. If each of the single combination of a doublet lens was to be corrected for spherical aberration, coma, and astigmatism, each combination could not have less than four refracting surfaces, either three lenses cemented together, or two lenses separated by an air space. The minimum number of refracting surfaces in such a doublet lens would therefore be eight, and consequently it could not be made very simple in construction. As a matter of fact, the only doublet lens of this nature at present constructed is the Zeiss-Satz Anastigmat, in which there are altogether five refracting surfaces in each lens, so that it appeared that an improvement in the direction of simplicity was still possible in the case of such lenses, and that there was no reason why lenses like the Goerz and the Voigtlander Collinear should not be perfected for each single component.

The PRESIDENT, in the course of a few remarks expressive of his high appreciation of the paper, said he thought the point as to the analogy between the spherical aberrations and the equilibrium of parallel forces was a particularly beautiful one.

The Rev. F. C. LAMBERT endorsed this view, and added that mathematical opticians would, no doubt, acknowledge that they were greatly indebted to Mr. Aldis for the manner in which he had brought forward this subject.

Mr. CHAPMAN JONES said it was encouraging to hear that there was a possibility of obtaining perfect lenses of simpler construction than those now available, for this would presumably bring with it a corresponding decrease in the present frightful cost of photographic objectives.

Mr. T. BOLAS referred to the researches of Goethe in connexion with optics, and to his suggestions as to the use of liquids instead of glass in the manufacture of lenses. Considering the very wide range of optical properties which could be secured by the use of liquids and mixtures, Mr. Bolas thought it might be worth while to follow up some of Goethe's suggestions in this direction.

Mr. W. P. DANDO asked whether there was such a thing as "effective aperture" of a lens, which would be greater than the  $f$  value of the stop employed.

Mr. ALDIS said the effective aperture was always greater than the absolute aperture as measured, except when the stop was placed in front of the entire combination of the lens. The purchaser must take the maker's word as to the effective aperture, or take the lens to some competent person for measurement, which was an operation beyond the powers of an amateur.

#### COMING EVENTS.

At the Technical Meeting, on June 26, Mr. J. H. Agar Baugh will read a paper entitled "The Selection of Lenses with regard to Photographic Perspective;" and the Rev. F. C. Lambert, M.A., will read a note on "How to Ascertain the Conjugates of a Lens without Calculation."

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 7.—Mr. H. C. Rapson in the chair.

Mr. PHILIP EVERITT brought up one of the Beck-Steinheil convertible orthostigmat lenses for examination. The focal length of the lens was  $5\frac{1}{8}$  inches, and it worked at  $f/3$ , being intended for a  $6 \times 4$  plate. Mr. Everitt showed it attached to a  $7\frac{1}{2} \times 5$  camera, and invited an examination of its capabilities at full aperture, which he thought were quite satisfactory. Stopped down, it would cover a circle of about eleven inches. Speaking of its construction, he said each half was composed of a central positive meniscus lens, enclosed between a double convex in front and a double concave behind. The combinations can be used singly as perfectly corrected landscape lenses of about double the focal length and half the rapidity of the original. Commenting upon a remark about the curious method of marking the apertures which was thought to add to the weight of the lens, Mr. Everitt said that on the other hand the method of mounting the lens effected economy in the metal. It did not weigh more, in all, than the orthostigmat of Steinheil's own make; in other words, the size of the mount had been reduced without affecting the size of the lenses. The lenses were of particularly hard glass, and were very little affected by atmospheric conditions and changes. In another very popular lens the outside lenses were most liable to atmospheric changes, but in this the reverse was the case.

Mr. A. MACKIE had seen some first-rate lenses terribly rubbed, especially those of landscape photographers doing a considerable amount of business. From a selling point of view they were practically valueless.

Mr. T. E. FRESHWATER believed it was a fact that the internal surfaces of the combinations of lenses generally deteriorated quicker than the outer ones, perhaps owing to the fact that the outer surfaces were more frequently wiped than the inner surfaces.

Mr. EVERITT said that particular interest attached to this lens, inasmuch as Adolf Steinheil, the father of Rudolf Steinheil, was the man to whom the credit for first applying anastigmatic correction to lenses was due. The old antipianet was corrected for astigmatism, as far as it could be with the old glass, on the same principles, one might say, as the anastigmat of Zeiss. He believed that the present lens was thought out in its construction by Adolf Steinheil, who turned over the details to his son to work out, and the first lens that he patented was of the Goerz type; but Goerz anticipated him by a few weeks, and his claim was opposed. Mr. Everitt ran through the record of Steinheil's achievements with the periscop, the rectilinear, and other lenses. The periscop lens was still largely used in Germany for hand-camera work, and especially so for fixed-focus apparatus.

Mr. MACKIE criticised the method of numbering the apertures of the iris diaphragms of this and most lenses. In a dark interior, for instance, one wanted a match in order to read the numbers. If they could be fitted with a clicking device, they would be better; but he thought a good deal more of the wheel stop, for convenience, than the iris system.

Mr. W. D. WELFORD passed round a straight-edge vignette, for obtaining a graduated result in printing a negative without other shading devices. He also showed a carbon cloud negative in conjunction therewith, and a combination printing frame with movements for placing the negative at varying distances from the vignetting card, in order to secure different qualities of shading.

Mr. EVERITT showed photographs of the front and back of a violin varnished with red varnish. The detail of the wood, he pointed out, was visible right through the varnish to a marked degree. It received an hour's exposure at  $f/14$  on a chromatic plate, without a screen, in an ordinary sitting-room.

Mr. MACKIE passed round a photograph of a phase of the recent solar eclipse, taken in a hand camera.

A discussion took place regarding the value of green glass for dark-room illumination.

The CHAIRMAN said that, not liking ruby light for orthochromatic work, he tried ruby and green, which, while perfectly safe, stopped practically all the illumination. He now used yellow light turned down until he could just see by it, but so little light was there, that if the diffusing yellow medium were removed he could see barely at all.

Mr. MACKIE said that Mr. Debenham's light was a canary medium or yellow-tinted paper, with a piece of what was known as "cathedral" green. The object of the green was not to make the light safer, but to approximate the light nearer to white light.

#### Gospel Oak Photographic Society.—June 5.—A demonstration on THE OPTICAL LANTERN

was given by the HON. TREASURER (Mr. J. E. Rayner), and it was again made manifest to the members that Mr. Rayner (as is his wont) had spared no time or effort in making the evening such a success as it was. The lecturer first dealt with the origin of the magic lantern, and then the use and abuse of the different optical parts. One strong point he emphasised was the use of suitable condensers for objectives of different foci, and also of using objectives with back lenses of large diameter to ensure flatness of field. The different illuminants were then dwelt with, beginning with the old-fashioned Argand lamp, which led up to the ordinary Refulgent and Stocks' lamp. The lecturer then demonstrated with the incandescent gas-burner, but he stated that the light as seen on the screen was much less than one would expect owing to the fact that so many of the rays of light were lost; he considered, however, that the acetylene gas was a great improvement on the latter, and for small discs gave a beautiful light. Through the kindness of Mr. Tylar, 41, High-street, Aston, Birmingham, he was enabled to show them one of his Dreadnought generators, which was a very compact apparatus. The more powerful lights the lecturer then dealt with, beginning with the ordinary blow-through oxygen-hydrogen jet, showing the correct way of connecting up to the cylinder, and also the incorrect, which was demonstrated by the blowing off of the tubing. He now came to the more powerful light still of the mixed jets, which was produced by having both gases under pressure or by substituting the hydrogen cylinder for an ether saturator, and through the courtesy of Messrs. Willway & Sons, Bristol, he very successfully demonstrated the working of one of their No. 2 Gwyer jets with one of their Pendent saturators, and the light that was obtained was most searching and powerful.

#### FORTHCOMING EXHIBITIONS.

- 1900.
- July 9-14 ..... Photographic Convention of the United Kingdom (Newcastle-on-Tyne Meeting). Hon. Secretary and Treasurer, F. A. Bridge, East Lodge, Dalston-lane, London, N.E.
- August 21..... Royal Cornwall Polytechnic Society. W. Brooks, Laurel Villa, Wray Park, Reigate.
- October 1-Nov. 3 ... Royal Photographic Society, New Gallery, Regent-street. The Hon. Secretary, '66, Russell-square, W.C.
- November 12-17 ..... Ashton-under-Lyne.
- " 21-23 ..... Hackney Photographic Society.
- 1901.
- January 14-19 ..... Blairgowrie and District Photographic Association. The Hon. Secretaries, Blairgowrie, N.B.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### STEREOSCOPIC PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—You will greatly oblige if you can give me some information on stereoscopic photography. Having been an ardent amateur for twenty years, I have lately taken up this most interesting branch. I have an old stereoscope by Mayall, but fail to get the images from transparencies good unless the centres are under  $2\frac{3}{8}$  inches. Now, I notice in the modern prints anything from 3 inches up to  $3\frac{1}{2}$  inches seems to stand out perfectly viewed through the cheap stereoscopes of, say, 2s. 6d. to 6d. each. I am trying to buy an old box stereoscope as the best form. As I may say, I have read all the fine articles in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, but, unfortunately the reading makes me feel sick, as it is now quite impossible to buy the fine stereoscopes named therein, more especially the one, I think, by Sir H. Grubb, which was arranged by means of prisms reflected on to a mirror.

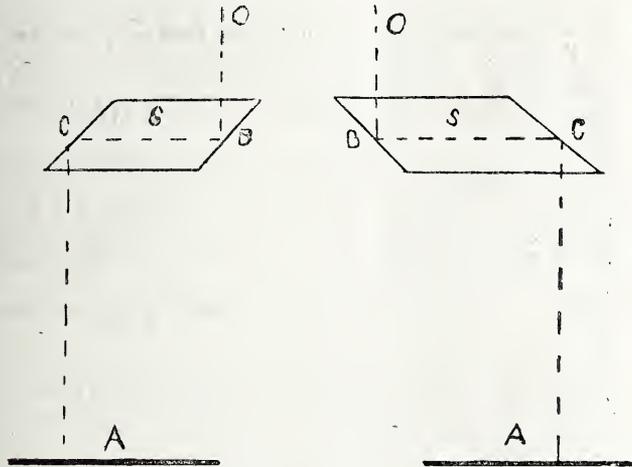

The point I am anxious to know is this: I am using an  $8 \times 5$  camera, a pair of Ross's  $5 \times 4$  R.R. lenses. If I take negatives at, say,  $3\frac{1}{2}$  centres,

on putting them into the reducing camera the correct way the centres will then be, say,  $4\frac{1}{2}$  to  $4\frac{1}{2}$ . Now, to reduce  $8 \times 5$  to, say,  $3\frac{1}{2} \times 6\frac{1}{2}$ , I can get centres of  $2\frac{3}{4}$  or more, according to the reduction, and how much of the original negative I wish to take in. The main points I wish to trouble you about are for a box stereoscope I purpose getting (when I can come across one are: (1) What centres should I make the transparencies? (2) Is this the best class of stereoscope to get? (3) Is it possible to obtain the other form I mention? I have seen your answer some months back to an inquirer, that this form is not made now. (4) Is there any means of viewing transparencies on  $8 \times 5$  plates? I ask this latter question because all the old books say  $2\frac{3}{4}$  centres, yet in the modern prints I notice the centres are far exceeded, and yet the picture stands out, to me, far better.

If you are not very much troubled with this long letter, I will be very much obliged for a reply in your very valuable paper. I am, yours, &c.,  
E. L. JOHNSON, JUN.

23, Bergholt-crescent, Stamford Hill, N.

[In reply: Box form stereoscopes—by which we presume our correspondent means the kind of instrument introduced by the late Sir David Brewster—are not uncommon. Recently we saw some of modern make at Messrs. Watson & Sons', 313, High Holborn, W.C. As regards the questions: (1) Let the foreground centres be under 3 inches, say  $2\frac{3}{4}$  or  $2\frac{7}{8}$  inches. (2) Personally we prefer the Chadwick stereoscope described in the article mentioned. (3) We are sorry to say not. (4) Perhaps our correspondent's eyes have an abnormal width of separation. Binocular transparencies on  $8 \times 5$  plates or at a "greater distance of separation" may be viewed in the following manner: Look at the pictures through reflecting prisms as shown in the drawing, in which *o* and *o* are the eyes of the observer,

situated two and a half inches apart. *a a* are the large pictures mounted side by side on a card, *s s* are oblong square blocks of glass, polished on top and bottom, and having the ends, *b* and *c*, ground to an angle of forty-five degrees. The length of each glass block, or, in other words, the distance between the reflecting surfaces, *b* and *c*, determines the distance between the centres of the pair of large pictures. As *b* and *c* are merely reflectors, four small mirrors mounted at the same angle will serve instead of the more expensive and more difficult-to-be-obtained mirrors. Apertures are cut in each tube, one above to enable the eye to see the reflector nearest to it, and the others below to permit of the transmission of the light from the picture not to be interfered with. The construction of this piece of apparatus is so simple as to be within the scope of every one, even if he were devoid of all mechanical skill. Sir Howard Grubb is the inventor of this application of prisms for practically widening the distance between the eyes.—EDS.]

ORTOL IN INDIA.

To the EDITORS.

GENTLEMEN,—The gentleman who thought I was "trying to be funny" seems to have been himself guilty of posing as an authority on the strength of a mere guess. A nice, cheap way of obtaining renown—when it comes off! It is a dangerous thing to attempt with persons who were, perhaps, making their own early dry plates when you were in the cradle. It struck me as decidedly curious if a developer, alleged to be excellent in two solutions, should be incapable of being made in one solution. I am not accustomed to find so much self-will and obstinacy among my chemicals. To set aside all doubts as to the accuracy of the reason alleged by my instructor, I have tried the two-solution formula with potash given in the ALMANAC, and find very similar results. The reason given and underlined by my excellent mentor is thus shown to be credit-

able to his imagination. As a matter of fact, unless I buy a dozen bottles at a dozen different shops, I have no means of knowing whether the ortol sold to me is good or bad. I suspect the latter. It certainly smells of dead animals, and it certainly is of a slate colour. Nevertheless, I can make good negatives with it. It gives more density and hardness than metal, and there its superiority (if superiority it be) comes, in my opinion, to an end.  
TIPPOO.

A LOST COOKE LENS.

To the EDITORS.

GENTLEMEN,—On April 3 last a lens which was being sent to us from London was apparently stolen in the post. It was a Cooke lens, Series III., of about five inches equivalent focus, and was numbered 5058. May we ask your kind assistance in making this loss known to your readers, with the view of our recovering the lens, if possible? It was not an ordinary lens, and we would give a reward of 5*l.* for such information as may lead to its recovery.—We are, yours, &c.,

TAYLOR, TAYLOR, & HOBSON.  
Stoughton-street Works, Leicester, June 7, 1900.

TELLA CAMERA DEMONSTRATIONS.

To the EDITORS.

GENTLEMEN,—We should esteem it a favour if you would allow us to notify the secretaries of photographic societies that we are ready to fill up dates for lectures and demonstrations on the Tella Camera.

The lecture will be made as interesting as possible with the help of glass models of the various parts of the camera, and also by lantern slides.

Early application is requested, as many dates are already filled.—We are, yours, &c.,

THE TELLA CAMERA COMPANY, LIMITED.  
WM. E. DUNMORE, Secretary.  
110, Shaftesbury-avenue, W., June 8, 1900.

THE NEWCASTLE CONVENTION.

To the EDITORS.

GENTLEMEN,—When I left England, seven months ago, I quite expected I should be back in time to attend the Convention. There is now no chance of this, and, though the war is evidently in the last stage, it is quite impossible to say when the troops will commence to leave the country. Those belonging to my branch of the service will certainly not be amongst the first to get home, as after the campaign there will be a good deal of financial work to be dealt with. I was looking forward to the meeting at Newcastle, which, under your presidency, is bound to be a big success.

I came here shortly after the occupation, and it is possible I may move on to Pretoria, but I have no orders as yet. Of photography I have done very little. My department is rather short-handed, consequently there is no time for play.

I have not got Mr. Bridge's address by me, so will you kindly hand him my subscription, which I enclose. I am, yours, &c.,  
Bloemfontein, May 18, 1900. J. D. LYSAGHT.

[Although addressed to us in a private capacity, we have printed Colonel Lysaght's letter because we are sure that his many photographic friends in all parts of the country will be delighted to have good news of him from the seat of war. Though absent from the Convention at Newcastle, he is not likely to be forgotten there.—EDS.]

PHOTOGRAPHING AT THE PARIS EXHIBITION.

To the EDITORS.

GENTLEMEN,—In answer to Mr. A. L. Henderson in your last number of THE BRITISH JOURNAL OF PHOTOGRAPHY I would say that I do not think many amateur photographers have fared as bad as he has. This does not mean to say that all is perfect in regard to permission as to photographing at the Exhibition of Paris. Prices are much too high not only for one day, but also for the whole season, and even with a permit you are continually bothered by officials in uniform as well as in plain dress, asking for your permit. One thing I must however, add to your information, and that is that one day's permits are now good from 8 a.m. to 6 p.m., except on Sundays and holidays when they are only good till 1 p.m., and of course provided always you do not interfere with the circulation. This new rule dates from the 6th inst.

Asnières (Seine), June 10, 1900. ALBERT LÉVY.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPH REGISTERED:—

W. West, 74, Oxford-road, Windsor.—Photograph of drummers of 1st Grenadiers.

**KINOS.**—The use of the substance for the purpose named has been patented. We offer no opinion as to the validity of the patent.

**ADDRESS WANTED.**—W. W. asks for the address of the makers of the Aptus Magazine Hand Camera.—In reply: Messrs. Sharp & Hitchmough, Dale-street, Liverpool.

**FRENCH PHOTOGRAPHIC PAPERS.**—NEMRAC writes: "Could you give me the names of one or two French photographic papers of widest circulation?"—In reply: *Bulletin de la Société Française de Photographie*, and *Moniteur de la Photographie*, published at 55, Quai des Grands Augustins, Paris.

**PAINT FOR STUDIO.**—B. ROLLS. What is the best colour with which to paint the inside of the studio?—Any light tint, according to taste, will do, but the colour should not be very pronounced. A neutral tint, or a French grey, is very suitable. If the walls are papered, use a light paper with a nice quiet pattern upon it.

**EMULSION WASHING.**—BROMIDE asks: "How long will it take to wash bromide emulsion, squeezing once through this canvas (sample sent)?"—It must, of course, depend upon the amount of emulsion to be washed, and the quantity of water in which it is washed, as well as the attention it receives while washing. No definite time can be given.

**POISONS ACT.**—& Co. say: "We are supplying an intensifier that contains bichloride of mercury. We are not labelling the bottles 'poison' at present. Is it necessary to do so to comply with the Poisons Act?"—Yes, it is. If you are not pharmaceutical chemists, you are not qualified to sell bichloride of mercury at all, whether labelled "poison" or not.

**A PHOTOGRAPHERS' TRADE UNION.**—E. F. SANDERS writes: "Will you please let me have the address of the Secretary of the Photographers' Trade Union, so I may know it for future reference?"—In reply: No such Union is in existence. There is the Photographic Copyright Union, of which the Secretary and offices are Henry Gower, London Chamber of Commerce, Botolph House, Eastcheap, London, E.C.

**FIRE INSURANCE.**—CHARLES STUART writes: "Some little time ago you mentioned in your columns one or two very reasonable insurance companies for photographers to insure their goods and apparatus at small premiums. I should be greatly obliged if you would be good enough to inform me, through your columns, a company you could advise."—In reply: The Westminster Fire Office, King-street, Covent Garden, W.C.

**STUDIO ROOFS.**—J. W. writes: "I shall be glad if you will kindly inform me what is best to use on glass of studio to keep rays of sun out. I have found white tissue-paper turn yellow after a short time, and am afraid white paint could not be removed in winter."—Make up some thin starch or flour paste, and then mix with it some ordinary whiting. Stipple that on the glass to be obscured. It can easily be washed off as the winter approaches. It is easily applied and easily removed.

**ECLIPSE PHOTOGRAPHS.**—ASTRO sends us six photographs of the late eclipse of the sun, taken with the front lens of a R.R. of eighteen inches focus, equal to a lens of about thirty-six inches focus, and asks why the image appears in the negative transparent instead of opaque. He says that the plates were the Imperial, and backed with the backing given in the ALMANAC.—The reason is that the action of the light has been reversed by great over-exposure. We have received several examples due to the same cause.

**PAYMENT FOR BANK HOLIDAY.**—ASSISTANT writes: "Our employer tells us that he shall deduct our wages for the Bank Holiday, though the place was not open. Can he legally do so, or could we not recover the day's pay to be deducted in the County Court?—Whit Monday being a legal Bank Holiday, we imagine you could; but it may be a question of policy on your part as to whether it would be wise to invoke the law, as your employer can discharge you at a week's notice if he likes. Any how, it is very mean on his part to attempt to make the deduction, and, what is more, it is very discreditable to him to do so.

**TWENTY-EIGHT PICTURES ON ONE PLATE.**—REPEATING BACK writes: "I have a repeating back for camera in use of American make, for taking twenty-eight midgets on half-plate, and I see by the way the photographs are printed it repeats down or up, not long way, as usual. If you could give me any information, or how I could obtain one, I should consider it a great favour. Of course there is only one lens used and twenty-eight different exposures."—In reply: Our correspondent's question was evidently suggested by a reproduced photograph recently published in an illustrated magazine. We have looked through our American exchanges, but can find no reference to such a repeating back. Perhaps, if our correspondent communicates with his dealer, the latter may be able to obtain it of one of the American stock houses.

**COLD VARNISH.**—R. PALMER asks: "Can you tell me how to make a varnish that can be applied cold, such as I have seen used for glass positives?"—Make a tolerably thick solution of dammar resin in benzole; then, when settled, decant and thin with benzole to the fluidity desired.

**ECLIPSE PHOTOGRAPHY.**—OBSERVER writes: "I am enclosing you four photographs I took of the eclipse. 1 and 2 in the ordinary way; No. 2, having trifle longer exposure, does not appear sharp on account of halation, as in negative double image is clear. No. 3, on same make plate, but taken through an ordinary piece of yellow glass, same exposure as 1, 2. No. 4 without yellow glass, and mainly taken to show clouds. I send these principally to ask how it is the sun appears black in 1 and 2, but white in 3 and 4. though 1, 3, and 4 are the same exposures, and on same plates."—Nos. 1 and 2 are very much over-exposed, hence there is a reversed action of light. In No. 3 the yellow glass has cut off a great deal of the actinic light, and so the image is normal. In No. 4 the exposure has been shorter, and the sun was partially obscured by clouds, and so the sun, as in No. 3, appears normal.

**BUBBLES ON BROMIDE PRINTS.**—PHANTOM writes: "I have toned a bromide print to sepia in the hot hypo alum bath and the tone is perfect. Upon washing, however, the whole surface became covered with minute bubbles—millions of them everywhere. Thinking that cold water caused them, I toned another and rinsed with water same temperature as bath, but the same result. I have now made another, but am afraid to wash it, as, by testing a corner, I find it is prepared to act in the same way. Can you tell me what is the cause, and what I am to do? I have followed the instructions carefully, and have never had such a case before?"—The only suggestion we can offer is, that there is something in the water that causes the bubbles—probably a carbonate of lime. However, if the bubbles are removed by a flat camel's hair brush immediately the prints are put into the water, no evil will result, we imagine.

**CHOICE OF STUDIO, &c.**—THE MAJOR writes: "Kindly let me know your opinion on the sketches of studio, which you think is the most suitable for all-round work, light only obtainable from east. The first is Mr. H. P. Robinson's idea, second Mr. Inglis's (American), third Mr. Duchois's (French, I believe). Each of above studios is considered (by the writers of the instruction books) to be the best. Also, please let me know if over-printed P.O.P. is quite permanent if slightly reduced with ferrocyanide of potassium and hypo, the same as used for negative reduction."—There is really no best. All are good, and it is a mere matter of fancy of the individual worker. More depends upon him than the form of the studio or its aspect. With regard to the permanence of reduced prints, we can, from experience, scarcely hazard an opinion, for, in our own practice, when we have any over-printed prints, we destroy them and make others, as we find it less trouble. However, we do not see why reduced prints, by this process, should be less permanent.

**LENS QUERIES.**—SHUTTER writes: "Please enlighten me in the following:—1. If on a half-plate I use an eight-inch focus R.R. lens covering well the  $6\frac{1}{2} \times 4\frac{3}{4}$  at full aperture  $f/8$ , and immediately after use on the same sized camera a nine-inch focus R.R. of equal quality covering well a  $7\frac{1}{2} \times 5$  at full aperture  $f/8$ , ought I not, when employing the longer focus R.R., to allow for the greater light it admits at  $f/8$ , and so make the exposure calculations as though its largest aperture were  $f/7$ , if working at full aperture? 2. Should you consider that to use a good nine-inch focus R.R. covering well at  $f/8$  a  $7\frac{1}{2} \times 5$  plate would, if used on a half-plate camera, enable me to do instantaneous work under practically any atmospheric conditions; or when a stigmatic lens, working at  $f/6$ , is not available, would you recommend for general work (not interiors) for a half-plate the R.R. to be of longer focus than nine inches, and cover well a  $8 \times 5$  plate at its full aperture  $f/8$ ? 3. Is the roller-blind type of shutter or the one working between the combinations the better, and why?"—1. No. If both lenses have an aperture of  $f/8$ , the one will be no quicker than the other. 2. All things being equal, the longer-focus lenses will cover the plate the better with a given size aperture. The shorter the focus of the lens the smaller the stop required to cover the plate to its edges. 3. In practice the one is as good as the other.

**A BEGINNER'S QUERIES.**—H. A. H. writes: "I see by your ALMANAC (which I have found useful) that you are pleased to answer questions on photography. Would you be so kind as to answer me the following? 1. What photographic apparatus do you recommend for cycling? I want one light, good, and not expensive; I should think one that could be carried across the back would be a nice place. 2. Do you recommend plates or films? It seems to me the latter are lighter and more convenient for two or three weeks' cycle touring. What are the pros and cons concerning plates and films? I carry my luggage on cycle when touring, so have not much room for, say, twenty plates. 3. How much more in cost would films be over plates, and are they much more trouble? 4. Could I have an apparatus so as to use either, say, plates at home, films while cycling? 5. Do you recommend a quarter or half-plate? A quarter would be lighter, but I understand that half makes the best pictures, giving more detail (*sic*), and that, when I got into photography, I should want a half-plate. 6. Could I have an apparatus to use half-plates and quarter films? 7. Do you recommend a rectigraph lens, or what lens? I want a good one."—In reply: 1. If our correspondent will glance through the advertisement pages of the ALMANAC which he possesses, he will find innumerable cameras described which are suitable for cycling. 2. Both yield equally good results, but films save a great deal of weight. 3. See the makers' advertisements for prices; films are really no more trouble than plates. 4. Yes; slides and sheaths are made to take both. 5. For your purpose a quarter-plate. Size is a matter of personal predilection. 6. Yes; half-plate carriers to take quarter-plate films would have to be specially made. 7. The lens mentioned should answer your purpose.

## EX CATHEDRÁ.

MR. R. W. CRAIGIE, the courteous Honorary Secretary of the Photographic Salon, gently reminds us that "summer is fleet" by sending us a proof of the entry form and prospectus of next autumn's Exhibition of the Salon—the eighth of the series. As usual, the Dudley Gallery of the Egyptian Hall, Piccadilly, will be the scene of the Exhibition, which will be open from September 21 to November 3. A comparison of dates shows that the Salon will be opened more than a week earlier than the Royal Exhibition at the New Gallery. Both, however, close on the same date, November 3. The prospectus does not appear to have made any change in the conditions of entry previously adopted. The receiving day is Monday, September 10, from 10 a.m. to 6 p.m., on which day all pictures for exhibition must be delivered at the gallery. We note that sixty-five names are included in the list of the General Committee, but many of the gentlemen have done nothing in exhibition work for years, and the names of others are not so familiar in photography as they might be. A little "new blood" on the General

Committee would give the list of names a less mysterious aspect. We mention this matter in the interest of would-be exhibitors, who, no doubt, would prefer to submit their work for selection at the hands of a body of photographers in touch with modern movements. At least twenty-two of the General Committee are foreigners, or live abroad; and, to our knowledge, seven or eight of the remainder have practically given up "pictorial photography" altogether. Roughly, one-half the General Committee has only a nominal connexion with photography. We are drawing attention to this matter because, as a general appeal is made to outside exhibitors, the latter have a right to know not only the composition of the General Committee, but their qualifications to sit in judgment on modern pictorial work. Assuredly absenteeism or indifference on the part of thirty or forty out of a Committee of sixty-five is a qualification of a very negative kind indeed.

\* \* \*

THE Illinois College of Photography, of which we wrote last week, is in process of enlargement. The corner-stone of a new wing has been laid, and that mighty organ of the Press, the *Effingham Democrat*, tells us that five thousand people from home and abroad assembled to "witness the beautiful ceremony and to hear the splendid oration. The intelligence and beauty of the country gave an unprecedented charm to a deserving occasion. Had it not been for the heavy rain of the forenoon and the threatening weather of the afternoon, the attendance would have been 10,000. It was great, however, any way. The Illinois College of Photography is the pride of Effingham." The reporter adds that "the Kodak fiend was on hand, and reaped a rich harvest. Innumerable views of the parade and of the scenes at the grounds were taken. The parade was one of the finest ever witnessed in the city." After various ceremonies the corner-stone was laid, its contents including boxes of various brands of American dry plates; Velox, platinum, carbon, gelatino-chloride, and other prints; copies of local newspapers and copies of twenty-seven American photographic publications. A learned Judge then delivered a very long oration on nothing in particular, and a characteristically American ceremony came to an end. It is the first photographic foundation-stone-laying that we remember to have

read of. In future ages the condition of those boxed sensitive plates and the prints will be interesting to see. We take leave of the Illinois College with the remark that if, after all these ceremonies and extensions, it does not turn out large numbers of the most competent photographers, we shall be disappointed in it.

\* \* \*

WE are asked to give publicity to a special offer to the photographers of the United Kingdom, which is made by the Ohio-Michigan Photographers' Association in connexion with its first Annual Convention, to be held August 21-23, at the Hotel Victory, Put in Bay, Ohio. In the prospectus that has been sent us we perceive that a special prize, open to the world, has been scheduled. For this competition two pictures, with no restrictions as to size, must be sent, and, as the prospectus says nothing on that point, it is to be supposed that the subjects of the pictures may be either portraiture or landscape at the discretion of the exhibitor, although the former might, we suggest, be given the preference. The prizes are: first, fifty dollars in gold; second, gold medal; third, silver medal. Mr. A. L. Bowersox, the Secretary, whose address is Dayton, Ohio, writes that his Association desires to extend to the photographers of the United Kingdom the privilege of competing free of charge. Exhibits must be delivered to him not later than August 15, carriage paid. A copy of the rules has been sent to us, and we append those which are applicable to the cases of those photographers who may care to compete for the prizes offered. All pictures, whether in competition or not, are eligible to the salon. Those chosen for the same will be suitably framed at the expense of the Association. Exhibits for prizes will be judged by consultation and comparison by non-competing photographers of known ability. Pictures for the salon will be selected by art judges.

\* \* \*

OUR contemporary and neighbour, the *King*, whose reproductions of Mr. H. C. Shelley's war photographs have been so much appreciated by the public during the past six months, announces that arrangements have been made by which copies of the photographs taken during the war by Mr. Shelley may be secured at a price to cover the mere cost of material and labour. For any of Mr. Shelley's photographs, as published in the *King*, except for those specified below, 1s. per print (unmounted) and 1s. 6d. per print (mounted) will be charged. The average size of the prints is whole-plate. The now celebrated photograph of *Lord Roberts in Khaki*, with autograph attached, which was reproduced as a supplement in the issue of April 28, will be supplied, mounted only (size 19½ × 11½ inches), for 2s. 6d. For the picture of *Lord Roberts and his Staff*, which appeared in the issue of April 28, the following prices will be charged: Unmounted prints (size 8½ × 6½ inches), each 2s.; mounted prints (size 13 × 11 inches), each 2s. 6d. For the photograph entitled, *Lord Herbert Scott Hoisting the Flag at Bloemfontein*, as published in the issue of April 21, the following prices will be charged: Unmounted prints (size 12 × 10 inches), each 2s.; mounted prints (17 × 15 inches), each 2s. 6d.; postage, 3d. All communications relating to these photographs must be addressed to the Manager, Print Department, the *King* offices, 7, Catharine-street, Strand, W.C., London. These photographs will one day possess a very high historical value, and we have great pleasure in giving publicity to the fact that copies of them are obtainable.

## ABOUT PHOTOGRAPHIC PATENTS.

ON two or three occasions lately we have called attention to some proposed reforms at the Patent Office. One of these is that the Office should control or limit the issue of patents for inventions that are "obviously old," and which have been previously patented in this country. It would seem, however, according to the instructions issued to the Committee of Inquiry on the subject, that it is to be restricted to the records of previous patents, and will not extend to what has been published outside the Patent Office. Hence patentees will still have to rely upon themselves as to whether their inventions have been anticipated or not unless they happen to have previously formed the subject of patents. This will be their business as heretofore.

Many photographic inventions in late years have formed the subject of patents that were fully published and used decades previously, as may be seen by reference to the early volumes of this JOURNAL, yet they have proved profitable to their inventors, though they were obviously invalid. For example, in the late Victorian Exhibition at the Crystal Palace was a turntable in the baseboard of a camera that was made and used in 1854, but it did not then form the subject of a patent. Here is another. One of the first roller slides was that of Captain Barr, and it was used with daylight spools. The sensitive paper—"wax paper"—was fixed to black calico longer than the paper itself, so that several layers of it covered the paper at each end, thus enabling the spools to be changed in full daylight. This invention, like the one just referred to, was not patented, but it was fully described in *Notes and Queries* early in 1855. Of course, the Patent Office reforms would not apply in such cases as these and many other instances of prior publication.

At times a patentee does instruct his patent agent to make a search as to the originality or otherwise of his invention, but then the search rarely extends beyond the records of the Patent Office. Sometimes, however, the agent goes further, and consults an expert in photography, if the subject be a photographic one, as to what has been done or published before, so as to ensure his client a valid patent, or avoid getting him an invalid one, though that is not often done.

Here is an important point in connexion with photographic patents that does not seem to occur to many inventors, who, directly they make an invention, or an improvement, or even an alteration upon an old one, forthwith obtain a patent for it without even considering whether it has any commercial value. Every inventor is entitled to profit by his invention if he can, but innumerable patents have been and are being taken out in connexion with photography that never have brought, or never will bring, back the cost of the patents. There is obviously no use whatever in going to the expense of a patent for any process or appliance which is not required or ever likely to be adopted, yet this is continually being done by sanguine inventors. It is interesting to note the proportion of the photographic patents that are kept up after the fourth year by the payment of the renewal fees. It is a very small proportion indeed, and that shows conclusively that they have not proved remunerative, or they would not have been allowed to lapse.

There is another point in connexion with the taking out of a patent that may often render it invalid, if it were contested. It is this: Many photographic patentees take out their own patents, and make claims in them that cannot be sustained in a case of infringement, by reason of anticipation, though others

may be perfectly good, or the claims may be wrongly expressed. According to the present patent law, if one single claim out of several is bad, the whole patent becomes void. If the specifications were drawn out by an experienced patent agent, although part of the invention might be old, a valid patent might be secured. In such a case the agent will make reference to what has been done before, and not make any claim for that portion of the invention, but only for those parts which are actually novel. A patent agent, in the interest of his client, always reduces the claims in an English patent to the smallest possible number, but takes care that they cover all the important features of the invention; whereas the layman will often insert a large number of claims of no importance, which may weaken or void the patent if it ever have to be litigated. An old aphorism says, "The man who acts as his own lawyer usually has a fool for a client." This often applies to a patentee who acts as his own patent agent when he has a really valuable invention to protect.

In a case of infringement some patentees go at once to their solicitor. Now, as a matter of fact, the ordinary solicitor knows as much about patent-law practice as the man in the street. It is far better to consult a respectable patent agent who has the patent laws at his finger ends, and can give really practical advice in the matter offhand.

A useful hint might be borne in mind as to the advisability of taking patents for improvements in photography. In some instances it would pay the inventor better to deal with his invention as a "secret process," inasmuch as he may never be able to prove an infringement if a patent for it were infringed. Although he may see the results, and practically know they were produced by his patented process, he may yet be unable to prove that they were actually done by it to the satisfaction of a court of law.

#### Star Photography with an Ordinary Camera.—

Under this title there will be found, in the *English Mechanic* for the 8th inst., a copiously illustrated article of the greatest interest. The writer, Mr. Barker North, A.R.C.Sc., F.C.S., details his experience and illustrates it with explanatory photographs and star maps. The only apparatus used was an ordinary half-plate camera fitted with an eight-and-a-half-inch focus rectilinear lens. Every one is familiar with the fact that the sun appears to go round the earth, and that the stars apparently are subject to a somewhat similar revolution, although, to those unfamiliar with astronomical facts, it does not seem to be generally understood why, if the sun at any given time—say noon—is always nearly due south, the stars are subject to no such rule. We need not pause to explain that simple phenomenon, but will point out that the whole starry vault revolves (in appearance), the centre, or axis, of revolution being almost exactly the pole star, high overhead. This star therefore appears stationary, and never sets; the stars near it revolve in small circles, and the further away the larger the circle, till a point is reached where the circles cut into the horizon, and thus disappear for a time and rise and set. It follows therefore that, if a camera be pointed at the pole star, and several hours' exposure given, it would come out as a point or dot on the plate, but the stars removed from it, as they would be moving, would leave parts of circles of light; with exposures of a few minutes only, the portions of circles of the circumpolar stars would be so small as still to be almost points, while those more distant from the pole would have travelled sufficiently to impress themselves as a visible line—in other words, as a star trail. Of course, a camera could not embrace the whole heavens at once, so that, when a particular constellation was to be taken, the camera should be directed to it, making its centre the centre of the plate. The whole constellation would then be reproduced, and would be

capable of being used as a lantern slide of most instructive character. Mr. North points out that, for the particular purpose in question, a short-focus lens is better than a long one, as the "trail" would be shorter, and so a faint star would have a better chance of impressing itself. He would, indeed, recommend a four-inch in preference to an eight, and we would point out that one of the modern flat-field, non-astigmatic lenses would be decidedly preferable to a rectilinear, with its curved field and want of sharpness at the edge of an extended field. Another point is that plates of great sensitiveness should be employed. Mr. North reminds us that the tripod should be firmly fixed, as for some stars the camera would have to be tilted very considerably, and would thus be liable to be upset or readily moved unless the tripod legs were well pushed into the ground. "Amateurs," he says, "should receive encouragement to take up this branch of photography from the discovery of Dr. Thomas Anderson, of Edinburgh," who with the simplest apparatus made the discovery of a new star, and communicated with the Astronomer Royal of Scotland, who verified the discovery, and particulars of it were soon flashed to observatories all over the world. "Amateurs may therefore dispose of the idea that only those possessing a telescope and driving clock have the means of securing star photographs which are of any value, as it will be seen that much can be done with very ordinary apparatus; and, once the worker has secured fairly successful results, he will find a peculiar fascination, which is not easily discarded, in this branch of photography."

**Radio-activity of Uranium.**—Continuing our description of Sir W. Crookes' experiments on this subject, we may say he finally, by his method of repeated precipitation and fractionation of "pure" nitrate of uranium, separated a body to which he gives the provisional designation of UrX, which is capable of acting upon plates after five minutes' exposure, and giving as much density as twenty-four hours' exposure to the original uranium salt, this action being capable of passing through glass, celluloid, and aluminium. He sums up his views on the possibility of these new elements of the Curies as follows: "In the present state of our knowledge of these radio-active bodies it is safest to retain an open, or even a slightly sceptical, mind. We recognise them mainly by the electrical and the photographic tests—reactions which are so sensitive that they give strong results even when the body is present in too small a quantity to be detected by its spectrum. . . . Considering my most active UrX does not contain sufficient of the real material to show in the spectrograph, yet is powerful enough to give a good impression on a photographic plate in five minutes, what must be its dilution in components which require an hour, a day, or a week, to give an action?"

#### JOTTINGS.

So many photographers "skip" the optical parts of photographic periodicals, that I need not apologise for directing attention to the report of an important paper on the construction of photographic objectives, which is printed at page 381 of the *JOURNAL* for last week. The author, Mr. H. L. Aldis, B.A., is one of the few—the very few—English mathematical opticians of the first rank, and his remarks point to the probability of something like a revolution in lens construction. Modern photographic objectives often consist of four, five, six, eight, and ten glasses with a proportionate number of refracting surfaces, but Mr. Aldis holds out the hope that much greater simplicity of construction is possible. It must surprise and interest non-mathematical photographers, who have thought or believed that the limits of lens correction and construction had been reached, to be assured that given glasses of refractive and dispersive powers such as are not to be found in the Jena catalogue, a perfect lens system composed of only two thick glasses—four refracting surfaces—is possible, and that even without glasses, which would conduce to the achievement of such an optical *tour de force*, a perfectly corrected lens with only five refracting surfaces, a single glass and a

cemented lens, is, as Mr. Aldis hints, quite feasible. The major portion of the paper, as may be inferred, appeals to the mathematical optician but lens-makers will, no doubt, greatly appreciate that part of it which gives hope that the niceties of production and adjustment which many modern anastigmats necessitate will one day be greatly simplified, while photographers will surely look forward to the time when first-class lenses are less costly than they are at present. Other parts of Mr. Aldis's valuable paper will bear careful consideration by photographers using "modern" lenses.

I HAD no idea of the extent to which racecourse photography is practised until the day of the Gold Cup, at Ascot, last week. The Royal, and other enclosures, thronged with elegant ladies brightly dressed and looking just as pretty as flower gardens; the roaring crowds of horse-worshippers; the scurrying quadrupeds, urged on by pale-faced mannikins in parti-coloured coats; the mellow beauties of the Royal Heath itself—these things are annually described with mechanical regularity in the daily newspapers, and can have no interest for seriously minded people, such as the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY very properly are. Lest any of them should be inclined to raise their eyebrows at my confession of having passed a June afternoon contemplating half a dozen horse races, which are satirically alleged to be held for the purpose of improving the British thoroughbred, I may explain that curiosity as to what Royal Ascot was like as a spectacle was the principal inducement for me to go there. In the second place, Ascot lies within cannon-shot distance of my humble abode, and, as early-closing enthusiasm breaks out once a week in our village, I am forced occasionally to participate in it. Fourteen years have passed since the holiday fever directed—or misdirected, if you will—my footsteps towards a racecourse, Newmarket, to wit; and I shall be quite satisfied if an even longer period elapses before I again take part in these Isthmian games. Human nature reveals some of its worst aspects at race meetings, and no thoughtful man can see what goes on there without having his peace and happiness of mind rudely struck at.

BUT to photography. I counted scores of hand-cameras on Ascot Heath, and two or three stand photographers were busily engaged in exposing on the crowds; the aristocratic enclosures; the finishes of the races; and the incidental life and character of the motley horde of racecourse *habitués*. What struck me as worthy of note was that the hilarious turf-goers took the little army of photographers quite as a matter of course. They did not object to be snap-shotted, and you heard no ribald references to "infernal machines," "just as you are for ninepence," and so on, such as a few years ago were extremely common. The photographer nowadays appears to be recognised as a man and a brother, no matter where he goes. I was much interested at seeing the working of the "starting gate" at Ascot. The horses are marshalled behind a rope stretching across the course, and when they are in line the starter pulls a lever, up goes the rope, and the wild flight for the winning post begins. But horses are like women, "sweetly alike and yet unlike"—you can't drill them, or make them work together in harness. I fancy that, if each time Mr. Arthur Coventry, the official starter of the Jockey Club, pulls the lever of his starting gate he made a photograph of the start, he would realise that the instances whereby the animals all got off together were very few—especially in two year-old races. I dare say the delightful horses of which Dean Swift wrote, could have toed the mark had they been set the task, but racing colts and fillies are not endowed with the philosophic calmness of the animals so charmingly described in *Gulliver*. A photographer, or anybody else, awaiting the start of a two year-old race, need be a very patient individual indeed.

POOR "Warren of Leeds," as we had grown to call him, passed away with shocking suddenness last week. It is only a month since we accidentally met in London, and our last words were on the subject of the Newcastle Convention, at which he intended being present. I first saw him on the occasion of the Leeds Exhibition five years ago. He was a many-sided man, whose future place in

the army of workers it was too early to prophesy about at the time of his lamentably early death. Clever, thorough, and sometimes brilliant as he was in his photographic efforts, it never struck me that, as the years went on, he would be content to move in a circle, as those who take up pictorial photography necessarily must. His restless spirit craved for the opportunity of doing greater work than this, and of all his gifts that of the pen seemed to me to be one which would one day bring him the satisfaction of success which every brain worker craves for. His writings were graceful, witty, and fanciful. He was a hard worker and had crowded a great deal into his all too short life. One of his last letters to me was about the beauties of the upper Thames in June, within sight of which I am writing these lines. In offering his widow and the members of his family my sincere sympathy in their loss, I am conscious of being one of a very wide circle indeed of poor Warren's friends and acquaintances.

IT was noticeable that, so soon as Mafeking was relieved, the purse-strings of the patriotic and the charitable were tightened, and contributions to the various War Funds became fewer and smaller than in the dark days before the surrender of Mr. Cronje. Again, ever since Lord Roberts occupied Johannesburg most people have looked upon the war as being virtually over. These and other circumstances will explain why the War Fund started by this JOURNAL did not reach a larger sum than 1840 shillings. Besides, photographers all over the country have helped to increase locally raised funds; and in these hard times one has to be circumspect even in almsgiving. From a recent copy of the *Edinburgh Scotsman* I notice that on the occasion of the passage of a celebratory procession through the incomparable Princes-street of the entrancing city which the railway has not succeeded in spoiling, Mr. W. Croke raised the goodly sum of 50*l.* by letting seats in his windows to sightseers. Well done! At ordinary times the view from Mr. Croke's window towards Edinburgh Castle is impressive; but, with a procession in the foreground, those who paid for seats had double their money's worth. There are several "war carnivals" about to be held in and about London; perhaps this note will induce the photographers on the lines of route to follow Mr. Croke's excellent example, and let their windows for the benefit of the Fund.

SOME of the American photographic publications supply funny reading matter just now. It is all over pictorial photography. A few ladies and gentlemen in New York are industriously booming themselves and their work, which may best be described as of that kind which a professional photographer would consign to his wastebasket, whilst the public and the common-sense critics would not have it at any price. These self-deluded, if well-meaning, people claim the leadership of pictorial photography in America, on the grounds of the unrecognisable smudginess of their work and the slobbery stuff, styled "appreciations," that is written about it. But Boston warmly disputes the claim of New York to take the lead in pictorial photography, and Chicago is equally emphatic on the same subject. There are already some half-dozen rival "Salons" in the United States, and at Pittsburg, recently, a show of photographs was divided off into a "Salon" and a mere "Exhibition of photographs!" Probably not one British photographer in a thousand sees the American publications or the photography of the very newest pictorial kind which they largely illustrate. It is best described as closely resembling the inscrutable nebulosities of landscape and portrait work which were shown here some five or six years ago. In the States it is called "freak" photography. Of course, the disease in this country wrought its own cure, and we have long since passed the stage when the visitor to a photographic exhibition only too frequently found himself in a condition of despairing doubt as to what some of the productions on the walls were supposed to be, photographs or not. We know now where we are in these matters, and, when some of our American brethren begin to realise that a pictorial photograph is not necessarily an exceedingly bad one in every single respect in which camera work should excel, there will be a return to a saner state of things. Many of the recent illustrations in *Camera Notes*, the *Photo-Era*, the *Chicago Photo-Beacons*

Salon number, and the Pittsburg Catalogue, clearly show that the originals must be painfully poor things indeed, judged from any critical standpoint, artistic or photographic.

A WORD of reference to the third edition of *Naturalistic Photography* will not be out of place whilst the author's exhibition of photographs is on view at Russell-square. At the Paris Exhibition of 1889 Dr. Emerson studied the paintings that were exhibited there, and in his book he singles out the following men for favourable mention:—France: Cazin (for atmosphere), p. 120; Dagnan-Bouveret (for figures), p. 120; Roll (the work of a strong impressionist), p. 121. Holland: Israels, pp. 106-7. Scandinavia: Zorn, p. 108; Vroyer, p. 108. America: Whistler, pp. 98-100; Sargent, pp. 98-100. Belgium: Stuyts, p. 86. A fortnight ago the list of the awards made by the Jury for the 1900 Exhibition was published, and the nine artists above mentioned received medals. Upon this piece of intelligent appreciation of "coming-on" men in art Dr. Emerson is to be congratulated.

COSMOS.

### TRICHROMATIC PHOTOGRAPHY BY HOFMANN'S PROCESS.

SOME few months back it was announced in one of our German exchanges that Herr Albert Hofmann, of the *Photo-chemische Industrie* of Köln-Nippes, was about to introduce a new system of three-colour photography, but it afterwards turned out to be the now well-known one founded on the three-colour sensation, and the only novelty is apparently in placing on the market a complete outfit whereby three-colour prints and superimposed transparencies can be easily produced. This has now been fully described in a new work, *Die Praxis der Farbenphotographie nach dem Dreifarbenprozess*, just published by Otto Nemnich, of Wiesbaden.

Hofmann uses three light filters—orange, green, and violet—the first passing only the red and yellow rays, absorbing the blue, and thus providing the blue-printing negative; the second, the green filter, allows the yellow and blue rays to pass, absorbing the red, and thus gives the red-printing negative; whilst the third, which gives the yellow-printing negative, allows only the blue and red rays to pass.

A special repeating back is used, in which is fitted a focussing screen and the three light filters, the plates being carried in small metal dark slides.

To estimate the exposure Decoudun's exposure meter is recommended, and the number on the scale of this, when multiplied by two for the violet, six for the green, and twelve for the orange filter respectively, will give the correct exposure.

The essential novelty of the process is, however, the introduction of pigment tissue in blue, yellow, and red, which is sensitised in the ordinary way, with a from 2 to 4 per cent. bichromate bath, using either the potassium or ammonium bichromate, and suiting the strength of the bath to the time of the year; thus, 2 per cent. in summer, 3 per cent. in spring and autumn, and 4 per cent. in winter. The blue pigmented paper should be sensitised in a 2 per cent. bath of potassium bichromate to which 1.5 per cent. of ammonia has been added, whilst the red and yellow tissue should be sensitised in a 2 per cent. bath to which 0.1 per cent. of alum has been added. The paper is to be first soaked in water for ten seconds, then immersed in the chromate for ten seconds, and then squeegeed to a sheet of waxed glass so as to thoroughly free it from excess of solution, and then stripped and hung up to dry.

Printing is effected in the usual way, a safe edge being given to the negative, and a photometer, a special one being recommended, is used in the ordinary way. The pictures are soaked in water, and then squeegeed to waxed glass, allowed to remain under pressure for from ten to fifteen minutes, and then developed, commencing first with water at about 20° to 25° C. till the paper can be stripped off, and then using water at 30°, 40°, or even 55° C.

The yellow picture is now squeegeed to the ordinary double transfer paper and allowed to dry, and on this the blue picture laid and accurately superimposed after they have been soaked in a special

gelatine solution and then dried, and on the green picture thus formed the red picture transferred. If the result is to be a transparency, then the yellow is squeegeed on to the blue picture, the two stripped from the glass, and this green film picture squeegeed on to the red print, but in this case a special transparency tissue must also be used.

A special instrument, called the photo-chromometer can be obtained, by means of which the three pictures may be experimentally and temporarily superimposed, to see whether the colour rendering is correct or not.

Further advance is promised in the shape of a film camera with rollable films, with which forty-eight triple negatives can be made without recharging. The necessary light filters and all papers, &c., are now, however, on the market.

### REFLECTOR HAND CAMERAS IN INDIA.

THE June number of our Calcutta contemporary, *St. Veronica*, reaches us in an unfamiliar coloured cover. Green replaces khaki (everything brownish is called khaki in Great Britain to-day), and there is a representation of *St. Veronica* with the imprinted handkerchief. By way of frontispiece a portrait of Mr. George Ewing, the editor, is given. We at once add this picture of our *confrère* to our collection, for Mr. Ewing's vigorous and skilful conduct of his paper have long marked him out to us as a man of singular ability and breadth of view. In our pages, a few months ago, the subject of reflector hand-camera needs formed the subject of discussion. We take from *St. Veronica* a letter by Major Phillott, who has some aspirations on the same theme. According to this gentleman, what is wanted by Indian amateurs is a reflector camera, quarter-plate or less, that fulfils the following conditions:—

1. The reflector, when set, must form a light-tight compartment behind.
2. The shutter (focal plane) must be capable of being wound, and its speed altered from the *outside*. This would, of course, necessitate a projection in the camera, a minor disadvantage.
3. The dark slide, whether a double-back or changing box, must be manipulated from the *outside*. For preference it should be capable of being totally withdrawn.
4. A T-level must be attached to the full-sized finder, so that the operator, while focussing, can also accurately level the camera.
5. The extension must be great to permit of lenses of long and varying foci to be used.
6. The press-button, or release, must either be flush with the camera side or protected by a projection (as in the older pattern keyless watches), or else fitted with a safety bolt (as in a rifle) to prevent its being "fired" accidentally when carried by a coolie or a mounted orderly.

The above are *necessities*; the following are merely *conveniences*:—

- (a) The iris diaphragm might be fitted with a clicking arrangement as in the N. & G. cameras; the worker then knows what stop he is using without having to turn the camera round to look.
- (b) The focal-plane shutter might be constructed to give longer exposures than  $\frac{1}{20}$  of a second—say  $\frac{1}{10}$  or  $\frac{1}{5}$ .
- (c) The lens might be fitted with a self-capping device; or, if, instead, the front of the camera be protected by folding doors, they should be light-tight and dust-proof.
- (d) The lens mount and its flange might be made with an interrupted screw.
- (e) The focussing pinion might be flush with the camera.
- (f) A scale for focussing by distance might be added.

As this camera would essentially be a hand camera, it would be of minor importance whether it were capable of being used on a stand or not. If required for use on a stand, it should be fitted with the N. & G. tripod screw and bush, as well as with a second shutter giving pneumatic exposures up to half a second or even more. Whether the advantage of being able to take vertical as well as horizontal pictures would be a sufficient compensation for the necessary increase in the size of the camera, or whether it would not, is doubtful.

### THE AMATEUR PHOTOGRAPHER AS KNOWN FROM BEHIND A PHOTOGRAPHIC COUNTER.

[A paper read before the London and Provincial Photographic Association.]

WHEN our Secretary asked me to give a paper before the London and Provincial Association, I had no idea of what subject to treat. We have

had papers so often here on hand cameras, toning, developers, and other scientific subjects that I decided not to touch any of these; to go out on the beaten track, and give you some of my experiences of the photographic amateur as known from behind the photographic retail counter.

The amateur photographer (the beginner, of course, I chiefly refer to) is a rather peculiar person. He expects you to be a regular walking encyclopædia. After buying a pound of hypo he will ply you with a dozen or more questions, all of which have to be answered in their proper order.

"What are the best plates to use now?"

"Will So-and-So's S.R. plates be fast enough to take an express train?"—they always take an express train, going at about 100 miles an hour, with stop *f*-32, in a good light—and "at what speed should the shutter work?"

"Is the toning and fixing bath permanent?" A friend of his told him it was not.

He has also a lot of old negatives at home of no further use to him. "Could we take them back and get them redeveloped for further use?"

When he is politely told that we cannot entertain this latter request, he seems rather disappointed, and departs, apologising for taking up so much of your time.

Meanwhile another customer has been waiting to see you about a hand camera he bought about a week back. He explains that he has exposed several plates, but has failed to get an image on any one of them. You examine the camera carefully and find it in perfect order. You therefore suggest to him that perhaps he forgot to release the shutter, or used *f*-44 stop by mistake. No. He was very careful about these items. Eventually you find out that he had forgotten to remove the dust cover in front of the lens before exposing the plate. This, of course, explains the mystery, and he goes away perfectly happy.

One of the most peculiar and laughable incidents I ever had was when a customer came to me and wanted to know what was the matter with some unexposed plates which he had in his hand camera with him. He went on to explain that the plates had been in the camera for some little time, the camera being kept in his bedroom. Meanwhile they had a case of scarlet fever in the house, the patient being in the same bedroom, this room afterwards being fumigated by the doctor's orders. A day or two afterwards he had occasion to use his camera, and when examining his plates he found them all covered with red rust on the back, which he could not understand. He could only put it down to the fever having some action on the plates. Needless to say, I could not offer any explanation, and so took the camera down to the dark room to unravel the mystery. This mystery turned out to be that the plates had not caught the fever, but were *backed plates*.

Talking of backed plates, I fancy that there must be many amateurs who do not know what backed plates are. I am often asked the meaning of backed plates, what they are for, &c. Some time ago I sold a box of backed plates to a customer, who came back a day or two afterwards, and wanted to know what I meant by selling him plates on which he could get no image. I told him I was not aware I had done so, and asked him if he had got them with him. "Yes," he had. These I tested, and found them perfect. I found out afterwards that he had been exposing on the backed side instead of the film side.

Of all the questions you get asked oftenest is the one, "What plates to use?" A customer is going to the seaside: "What plates shall he take?" "How shall he take the sea? Would it be best to stand up on the sands or sit down?" I thought of suggesting that he should stand on his head for a change.

Some amateurs always will have special rapid plates—the fastest they can buy. They somehow think they will not get a result if they don't have the fastest plate procurable, and this is one of the chief reasons of their troubles. Such an amateur does not know how to treat them. In nine cases out of ten they are grossly over-exposed; of course, he blames the plate.

A beginner had purchased an outfit which included a Dallmeyer lens. After explaining to him the way in which to work the apparatus, he went on his way to try his luck. A day or two afterwards a letter came through, saying that, after a great deal of difficulty, he had managed to fix the camera up, but he found that the glasses of the lens had been put in wrong, as the view was upside-down. He thought it strange that a firm like Dallmeyer should make such a mistake.

Another beginner brought in some of his negatives to me, saying they were out of focus round the edges. I explained to him that by using a smaller stop he would obtain sharper negatives. His answer was that he had been told that he would strain the lens if it was stopped down too much.

Only last week an old gentleman came in and wished to see "Lancaster" camera, which was shown him. The first thing he did was to unscrew the lens and examine it. He asked if it was a Lancaster lens, and was told it was. He said he did not think it was, as he was told that the maker's name would be printed on the glass.

Hydroquinone, ready-made, is the amateur's favourite developer. I want something simple and clean. It is in development where I makes his first mistake. Some under-develop, so that the negative is mere ghost, while others grossly over-develop, some negatives I have examined being so dense that you could not see the strongest daylight through them; indeed, they would take several days to print even in the sun.

The chemical side of photography such an amateur has a very hazy knowledge of. One customer asked for a bottle of Eau-de-Cologne developer, by which I found out he wanted hydroquinone. Hypo has several different terms, such as hypophosphite of soda, hyposolite or soda, &c.

Spots on his negatives are another great trouble with the beginner, the cause of which is generally put down to the lens. The other day an amateur brought me some plates, and complained he got a single spot on all his negatives exactly in the same place on every plate he used, and he thought there must be a spot on his lens. I examined the lens, but failed to find the said spot; so, to convince him, I exposed a plate in the camera, and developed it, but I could not obtain a spot on the plate. These complaints are all mysteries, and they remain mysteries to the end, as he always asserts that he never does this or that when suggesting the probable cause.

The questions put by ladies are sometimes rather embarrassing to the assistant. I remember a lady coming in and asking the assistant to show her his legs, meaning tripods, of course.

The hand camera is the amateur's favourite instrument, and a hand camera he will have. But I often think too much is expected from the hand camera, and the uses it is put to often result in utter failure. I frequently have negatives brought in to me with the complaint that the lens is out of focus, but when I come to examine the negative it shows a distinct double image, and upon further inquiries I find he has been making a time exposure of about two or three seconds with the camera held in the hand, resulting in a blurred image, of course. One great difficulty we have behind the counter is to convince the amateur that he is wrong in the manipulation of his work, and that the failure is due to his procedure of working, but I will say that occasionally we get one who admits his faults, and then you feel quite pleased with yourself. I trust that you will not think I put down the amateur as a duffer in this paper. I have merely given you my experiences of the beginner in general as found from behind the retail counter during an experience of some years.

E. T. WRIGHT.

#### PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

At a meeting of the Council of the Photographic Convention of the United Kingdom, held at Anderton's Hotel, Fleet-street, June 13, 1900, the following gentlemen were nominated to serve on the Council, to be elected at the Annual General Meeting at Newcastle-on-Tyne, July 11, 1900:—

Harold Baker, London.	Percy Lund, Bradford.
C. A. Barkas, Newcastle-on-Tyne.	J. L. Lyell, London.
W. Barry, Hull.	Colonel Lysaght, Pretoria, S.A.
James Baty, Newcastle-on-Tyne.	A. F. Mowl, Liverpool.
Godfrey Bingley, Leeds.	Rev. T. Perkins, Blandford.
Walter S. Corder, Newcastle-on-Tyne.	J. Porritt, Leicester.
Alexander Cowan, London.	Ralph Robinson, Redhill.
W. E. Cowan, Newcastle-on-Tyne.	J. A. C. Ruthven, Dublin.
T. R. Dallmeyer, London.	A. Seaman, Chesterfield.
W. E. Dunmore, London.	H. Sturmey, Coventry.
Dr. P. H. Emerson, Christchurch.	Alexander Tate, Belfast.
S. H. Fry, London.	W. Taylor, Leicester.
F. Gandy, Derby.	J. J. Vezey, London.
J. Pattison Gibson, Hexham.	J. H. Walker, Leeds.
H. M. Hastings, London.	E. J. Wall, London.
E. J. Humphery, London.	H. Snowden Ward, London.
H. Vivian Hyde, London.	S. B. Webber, London.
Sydney Keith, Hounslow.	G. Watmough Webster, Chester.
J. J. Kirkwood, Tynemouth.	J. B. B. Wellington, Elstree.
C. Phipps Lucas, London.	A. Werner, Dublin.

Vice-Presidents are, by Rule X., members of Council *ex-officio*. Forty members of Council are to be elected, exclusive of *ex-officio* members. Members are at liberty to add the names of any other gentlemen to the list, should they desire it, but the total number of those voted for must not exceed forty. This voting list is to be delivered to the President at the Annual General Meeting at Newcastle-on-Tyne, July 11, 1900.

ON THE FADING OF GELATINE NEGATIVES.

The following paper, for which we are indebted to our contemporary, *Anthony's Bulletin*, was suggested by the recently published experiences of Dr. Isaac Roberts, F.R.S., relating to the fading of images of stars in gelatine negatives.]

SEVERAL years ago pointed out in photographic publications the probable fading of the negative images made on gelatine films on account of the impossibility of eliminating all the traces of hyposulphite by washing and of the instability of the silver hyposulphite formed during the fixing, which decomposes almost instantaneously, and from which originates, more or less, the sulphuration of the silver forming the photographic image. We all know that the positives made on gelatine paper fade more rapidly than those made on paper prepared with another vehicle, though not all of the latter stand the test of time, and this owing to the manner they are fixed, which is similar in every process. The case in point, however, is only the second that has come to my knowledge of the fading of the negatives made on gelatine as a medium. In my long practice I have never observed that the collodion negatives are apt to fade, and never have I seen it mentioned in photographic publications.

I have before me, when writing this article, a series of collodion negatives made by Mr. Lewis M. Rutherford to photograph the solar spectrum. The range of practical sensitiveness shown on one of those plates extends from  $\kappa$  to beyond  $\epsilon$  at 272, the maximum of intensity being near  $\epsilon$ . On both sides the impressions decrease in opacity, and become almost invisible beyond  $r$  and  $\kappa \pm \frac{1}{2} L$ , still the faintest impressions are as distinct now April 1900 as they were when the negative was made, April 9, 1866. There is no trace of fading, although, except varnishing, no extra care has been taken to preserve them from the atmospheric and other influences. The colour sensitiveness and the intensities vary considerably with the composition of the collodion, the exposure time, silver bath and developer being the same. But here is not the place to describe the process employed to obtain the results above mentioned, which were considered the best; it suffices to say, that out of the seven negatives not one has in the least faded.

If we except the extreme sensitiveness of the silver-bromide emulsion in gelatine, and the possibility of increasing its colour sensitiveness towards the red by ripening, which is of so great a value in orthochromography, we must acknowledge that by the wet-collodion process excellent results are obtained surely and without difficulty by simple and rapid operations, entirely under the control of the operator. But on account of its want of sensitiveness, which is about thirty times less than that of the ripened gelatine silver bromide, the latter is, so to say, a *sine qua non* in astronomical photography, and still it requires an exposure of many hours to obtain an impression from the faint stars. Of course, the ordinary negative images on gelatine plates—portraits, landscapes, &c.—if they fade, it is only in the delicate details, and, consequently, they remain serviceable; but in the case now in question everything originally photographed should remain, else they become without value for recording the changes occurring in the heavens during the course of time. Hence we must find out the causes of fading, and how it can be avoided.

The causes of fading in photographs are well known by reason of the researches of T. F. Hardwich, and especially those of Davanne and Girard, made in 1859-60-61. They necessarily apply to negatives, although very few cases of deterioration have been recorded; but, besides the nature of the silver deposit forming the image, the process was quite different from that now generally employed.\*

Fading cannot arise from the development. This needs no comment. The causes originate from the manner of fixing, the chemical actions resulting therefrom, and from the subsequent operation, *i.e.*, the washing to eliminate the hyposulphite compound, which the gelatine retains quite strongly, owing to its absorptive nature when swelled. In fact, it is doubtful whether it can be entirely eliminated from that matter except by chemical means, and this is not without objection.

Let us see how the fixing is done in the process now under consideration.

\* We have a negative on albumen plate, made in 1852, which has turned a little yellow, and a positive on plain paper, made by development with silver nitrate, which has also turned yellow and faded, but only in the delicate details in the lights. It was made in 1850.

After the development the plate is rinsed, then immersed in the sodium hyposulphite bath until the silver bromide is dissolved. When the bath is new, and therefore not in a state of decomposition, the only occurring chemical action is the formation of the soluble double silver and sodium hyposulphite. Hence, before washing, there are in the film the sodium hyposulphite and double salt dissolved therein. If the compound were wholly eliminated, the image would be permanent; if not, the silver hyposulphite, being unstable, will, in a certain period, produce the sulphuration of the silver, hence a strong cause of fading.

By this manner of operation it sometimes happens that the negative comes out from the fixing bath with a yellow fog, so called, due to the alkaline developer retained in the film. To avoid it the plate is immersed for a moment in acidified water, then rinsed, then fixed. The result is obvious, since the hyposulphite is decomposed in presence of an acid, no matter how diluted.

The images are now generally fixed in an acid clearing bath, which was introduced in 1890, to obtain negatives free from yellow, greenish or dichroic fog, according to the developer employed. This bath is compounded with sodium hyposulphite, sodium sulphite, chrome alum, and sulphuric acid. In such a bath sulphuration is inevitable, since the bath is in a state of permanent decomposition, giving rise to sulphur dioxide and unstable polythionic salts, sulphur being also deposited. The results are again obvious. Hence, whatever be the manner of operating with sodium hyposulphite as a fixing agent, a cause of fading exists, and, for such weak impressions as those formed by the faint stars, the writer believes that it should be discarded for a fixing agent having no action on metallic silver.

It has been said in the beginning of this article that negative images on collodion film have stood the test of time for about forty years without any visible alteration, and very likely they will remain without change for a good deal longer period. They were fixed by potassium cyanide. Why not use that salt for the fixing of gelatine negatives? There is no serious objection in doing it. However, except with the pure salt, it cannot be employed in the same way as in the collodion process, for the commercial article, containing a great proportion of potassium carbonate, gives a strongly alkaline solution which softens the gelatine film, partly dissolves it,\* and, as a consequence, produces blisters, reticulation, and alters the dimension of the image. But, when alcohol is added to the solution, and the gelatine is previously hardened by alum, this action is nullified, as it was years ago demonstrated by the savant photographer of Bellevue Hospital, Mr. O. G. Mason.

Another and more serious objection to the use of potassium cyanide is its dissolving action on metallic silver, if allowed to act for a certain period, depending upon the strength of the solution. In fact it was employed to reduce the intensity in the collodion processes. In our practice we never found that any of the details of the image were injured when the plate was washed immediately after the silver haloids had been dissolved, which requires a few seconds. Perhaps, however, the very weak impressions of some of the stars might be impaired; it is an experiment to be made.

The negatives can also be fixed by ammonium sulphocyanate, as proposed by Mr. Meynier in 1863.† This salt is not poisonous, and has very little action on metallic silver, but it dissolves gelatine rapidly, which, however, is prevented by the addition of alum. Mr. P. Mercier, who made a study of fixing by the sulphocyanates, recommends that the operation be preceded or followed by treating the gelatine film with a five per cent. bath of alum. The fixing solution may be compounded thus:—

Ammonium sulphocyanate .....	10 parts.
Alum .....	5 "
Water .....	100 "

In these conditions the gelatine film somewhat increases in volume, but the image suffers no modification.

The sulphocyanate, much less dangerous than the cyanide, has many advantages over hyposulphite. It is not altered under the influence of traces of acids, and, like the cyanide, it does not leave in the gelatine film any agent of fading after washing as usual in water several times renewed. While fixing, it is recommended to use two baths; the second to ensure a complete elimination of the silver sulphocyanate formed. The potassium salt can be employed instead of the ammonium, but it dissolves a less quantity of the silver haloids.

P. C. DUCHOCHOIS.

\* According to M. Vidal, it does not dissolve gelatine, but only swells it considerably. See *Bulletin de la Société Française de Photographie*, vol. xxix.  
† *Bulletin de la Société Française de Photographie*, vol. ix.; *Humphrey's Journal*, vol. xiv.

## FOREIGN NEWS AND NOTES.

**A New Intensifier.**—Mangin suggests, in *Photographische Chronik*, the following mixture instead of the usual mercuric intensifier:—

A.	
Old hydroquinone developer.....	50 parts.
Ten per cent. solution of citric acid.....	10 "

B.	
Potassium ferricyanide.....	1 part.
Distilled water.....	50 parts.

Solution B is added to A as soon as the latter has become clear, and the mixture is then well shaken and filtered and the negative immersed in it.

**Cyanine Sensitising.**—According to the *Photographische Chronik*, cyanine is still the best sensitiser that we have for red, but it is, unfortunately, rather difficult to use, as it is soon decomposed by the carbonic acid of the air. As a preventive of this the following bath is recommended:—

Alcoholic cyanine solution (1:1000).....	6 c. c.
Alcoholic codeine solution (1:1000).....	34 "
Pure aniline.....	5 drops.
Distilled water.....	960 c. c.

Plates should be bathed in this solution, freshly prepared, for two minutes, then rinsed with dilute alcohol (1:30) and dried.

**Restoring Yellow P.O.P.**—Professor Namias, in *Il Progresso Fotografico*, points out that gelatino or collodio-chloride paper which has become yellow by improper keeping can be restored to its pristine whiteness by immersion for some minutes in a two per cent. solution of ammonium persulphate rendered slightly alkaline with ammonia. When dried, the paper thus treated will yield excellent prints, which, however, are not quite so intense as those made on fresh paper; but this loss of intensity may be got over by the addition of a small quantity of silver nitrate to the persulphate solution, and that then it is difficult to detect any difference between such prints and those on freshly prepared paper.

**A Sulphocyanide of Lead and Gold Bath.**—Professor Lainer communicates a note on this subject to the *Photographische Correspondenz*, and points out that most of the sulphocyanide baths contain far too much of this salt. A bath which contains twenty-four parts of sulphocyanide to the thousand attacks the delicate half-tones of the print, causes pit markings in the gelatine, and softens the skin of the fingers, and frequently gives double tones, and it does not tone well. He has decreased the proportion of sulphocyanide to 2.5 parts per 1000; this generally gives brown tones, though blue-violet tones are those most generally desired. By the addition of lead nitrate this is attained, but the lead salt must not be added hap-hazard, for, if lead nitrate be added to sulphocyanide of ammonium solution, a precipitate of sulphocyanide of lead is formed, but, if it be added to a solution of sulphocyanide of gold, there is no precipitate, and there is formed an excellent toning bath which gives excellent tones in from twenty to twenty-five minutes. The following stock solutions should be prepared:—

A. Ammonium sulphocyanide	100 grains,	water	1000	c. c.
B. Potassio-chloride of gold	1 grain	"	100	"
C. Lead nitrate.....	200 grains	"	1000	"

For use mix:

Water.....	1000	c. c.
Solution A.....	25	"
" B.....	50	"
" C.....	30-50	"

The above quantity of bath is sufficient for from forty to fifty prints 13×18 cm. The prints should be washed before toning in four or five changes of water, and fixed in a ten per cent. solution of hypo.

**A One-solution Hydro-metol Developer.**—Guilleminot strongly commends the following developer: Boil 900 parts of water, and whilst still hot dissolve in order the following ingredients, taking care that one is completely dissolved before the next is added:—

Sodium sulphite.....	150 parts.
Hydroquinone.....	5 "
Metol.....	5 "
Potassium carbonate.....	30 "

For use, 1 part of this solution is mixed with 3 parts of water.

**A New Calcium-carbide Process.**—Herr Paul Wolff, Berlin, has just patented a new process for the manufacture of calcium-carbide which does away with the electric furnace which has hitherto been used. To the mixture of lime and coke powder aluminium is added, and the whole fired by a fuse or similar device. The aluminium combines with the oxygen of the lime and produces such a high temperature that the lime melts, is reduced, and the calcium combines with the carbon. If this statement be true, the price of carbide should suffer a fall.

**Zenker's Lehrbuch der Photochromie.**—To all those who are interested in heliochromy, the republication of this work which is but little known, but which set forth in 1868 the distinguished author's researches and views in that particular branch of photography in natural colours now so indissolubly connected with the name of Professor Lippmann will be welcome. This new edition, which is published by Vieweg & Sohn, of Brunswick, is edited by Professor Dr. Schwalbe, who was Zenker's fellow-professor at the Kaiser Wilhelm Realgymnasium in Berlin. Professor Kreckel has written an account of Zenker's life. The editor has practically given us the original work, with merely some matter descriptive of now well-known instruments omitted, and Herr Tonn brings, in a brief, concise manner, our knowledge of the subject up to the present date, and, to those who have been unable to obtain a copy of the original—and this is by no means easy to get—the new edition should be highly appreciated.

## REDUCING OVER-PRINTED PAPER BROMIDES.

In a recent leaderette of THE BRITISH JOURNAL OF PHOTOGRAPHY, March 30, the question is asked, "If the reduction of over-printed pictures is worth the time and trouble expended upon them?" and the verdict pronounced by the writer is, "No, the game is not worth the candle." The article goes on to say that it takes less time to make a fresh print than to vamp up an ill-timed or over-exposed one. If by ill-timed is meant under-timed, then I fully agree; but on the phrase "over-exposed" I venture to think that the best way to produce a perfect enlargement or a perfectly printed bromide is to slightly over-expose and slightly over-develop and this applies equally to all descriptions of bromide developing-out paper; which will, for shortness, be described as D.O.P., in the same way that printing-out paper is known as P.O.P. I wish to say here that a perfect D.O.P., be it from a negative by contact or by enlargement, must, like a good lantern slide, be both over-exposed and over-developed, and, like the lantern slide, be reduced afterwards.

The exact amount of over-exposure and over-development must be determined (a) by the make of paper, (b) by the developer used; for some papers, like some dry plates, have but little latitude.

With bromide paper for enlargements, I find the treatment required is much about the same with all papers, whether Morgan & Kidd's, Eastman's, Marion's, Barnett, Cadett's, Ilford, or Lumière's. These are all extra-rapid papers for enlarging, and cannot well be used for contact work, especially if the exposure is made out of doors; but, even with gas-light, the action is so rapid that a slower paper is preferable, and of these there is even a greater variety, and the results vary very considerably. Personally, I like a paper that allows about ten seconds' exposure at five feet within an open doorway facing north; the frame is stood on end, and so looks out upon the horizon—i.e., the trees and houses facing—and not to the clear open sky—the time of year March, and the locality London.

As the summer advances, doubtless albumenised paper will again be adopted by many who have had recourse to the D.O.P. during the slow light of winter. Ready-sensitised albumenised paper is only about half the cost of the D.O.P., and I have started by ordering five quires of paper.

The other statement of the writer is, "that it is the practice of professional printers, when a print is over or under-printed, to throw it amongst the waste; and that is also the custom with professional enlargers as a matter of economy."

Regarding printing, I can only say that, as there are so many kinds of prints, papers, and surfaces, some papers being coated with gelatine, others with albumen, and these all having a regular gamut as to bromide, chloride, tartrate, or some other salt of silver, the makers giving their paper fancy names—as Eagle, Venus, Dekko, &c., I cannot spare space to treat upon anything else except paper coated with gelatine. Referring especially to prints produced by the developing-out process, if printers and enlargers really do throw away their over-printed or over-exposed prints, I can only remark that, if these prints are on gelatino-silver paper like the paper for enlargements, they have been (1) needlessly filling the waste-paper basket, (2) needlessly emptying their own pockets—a reckless proceeding and one not in accordance with human nature.

Those who have previously been so ill-advised as to throw away their best pictures (and by that I wish to describe the over-exposed or over-

developed, D.O.P. print or the bromide enlargement) need not do so any longer, and, as previously stated, I really do consider the best way to make perfect prints and perfect enlargements is to overdo them a trifle and reduce them afterwards, either locally or all over by means of a bath.

A piece of 15 x 12 bromide paper costs 7½d., plus the time in arranging the enlargement and the development of the same. The profit on the finished article is necessarily diminished by the waste. But reducing over-printed or over-exposed bromides is the text, and to do so without alteration of colour and without affecting the permanence are the two important considerations.

Recently I came across the statement that one gentleman advocated over-developing lantern slides until they looked quite opaque (by transmitted light) before fixing in the hypo bath, and that he reduced them to the proper clearness and brightness by using the well-known Howard Farmer reducer of ferri-prussiate potash with hyposulphite soda; now, this cannot be used satisfactorily with paper, as it stains the fibres.

The only reducer that I have come across for bromide papers and also for the blue prints (those produced upon ferro-prussiate potash paper) is our old friend and poison, potassium cyanide; this will remove any slight deposit of colour in the high lights of a picture or take down the deepest depth of darkness in an enlargement of a print; in fact, you can clear the image right off, leaving the paper perfectly white.

In using potassium cyanide there are two things to observe: (a) that used must not be returned to the bottle; (b) the pure white cyanide sold as containing sixty to seventy per cent., and costing from 1s. 6d. to 2s. a pound should be used.

The sort I like best is cut or broken into lumps, and looks very much like cube sugar without the sparkle.

I am aware of various reducers, such as citric acid and alum, &c., and the value of thio-carbamid and citric acid, as per maker's formula, is not to be despised; its action is slow and sure. A dozen 12 x 10 or 15 x 12, immersed in it, are brightened and cleared immensely. The first print is ready to take out as the last is placed in it, and it will remove the pink colour that sometimes is given to paper developed with ortol. Many prefer this colour to remain, and consider it an improvement; so, if you desire to retain it, use cyanide to clear with instead of thio-carbamid. As an ounce of thio-carbamid costs about the same as a pound of cyanide it is too expensive for commercial work.

Potassium cyanide is awkward stuff to weigh in small quantities, and I find that the lumps are very much of a size, and weigh from 100 to 120 grains each, so, I just throw two lumps into a ten-ounce wide-mouthed bottle, and fill with water. If any deposit after it has dissolved, decant into a ten-ounce graduate, and throw away the bottoms or else filter. So the formula would read thus:—

Potassium cyanide (white) ... 2 pieces, or about ½ ounce.  
Tap water .....to make up 10 ounces.

In using there is one advantage, the same washing water will remove the hypo and the cyanide.

To use, take the prints from the hypo, and either throw into a dish of water, or place them on a piece of glass to drain off the surplus hypo solution, and then into the water. Now you have to decide what the prints require. Is it a good general clearing, or will some of them require local treatment? Any how, clear first. To those whose skin will allow of dipping their fingers in cyanide I advise a weak bath of, say:—

Stock solution cyanide ..... 1 ounce.  
Tap water ..... 20 ounces.

If required to be of greater strength, it is better to use ebonite pliers.

The above will be sufficient for a dozen large pictures, 12 x 10 or 15 x 12. Take them one at a time, slightly drain, and immerse. Now add one or two more, remove the first one, throw it on to a piece of glass, and you can then judge the result. If you have a rose tap, well sprinkle and wash each print upon removal from the cyanide, and do not forget the action continues after removal, and a good washing is really needed at once and sharp. This is the only caution I need give.

Try first on a waste print or a very dark one of the day's batch.

For local reduction the print is best wet; use a brush or a piece of cotton-wool. The best brush on the market is the one used for process work, as it will stand anything. It is sold by Penrose & Co., Lloyd-square, W.C., 1s. 4d. each, post free, and is described in their catalogue as the Atzpinsel Continental etching brush. If a hole be bored, or a piece of string attached, and the brush hung up after a rinse or so, it will really last a long time. Of course, any common camel's-hair will do, or, as before stated, a tuft of cotton-wool for tough fingers. To use the brush, pour out, say, a quarter or half an ounce in a graduate of stock solution cyanide, and add half an ounce of water or so. You require it strong enough to do the work in thirty to forty seconds, especially if you have a number to treat. Dip the brush in the graduate, and pass over the damp print previously placed on a sheet of glass, of course touching those parts that are darkest first. Keep the brush moving, and in a few seconds you will notice a general lightening. Work the brush well about to prevent lines or markings, but only over that part or parts you desire to reduce, as the general clearing up of the whole of the print should have been performed before attempting local work.

Reducing by cyanide is like developing with the best of all developers, ortol. In both the action is continuous, so that you need to turn on the

tap before the final result is attained; in fact, it is better to turn on the water and wash, doing this several times, cyanide and wash, see the result, and cyanide again, wash again; it is easy enough. In fifteen seconds, under the tap, the action is stopped, and in doing all this you have the satisfaction of knowing you are also washing out the hypo. When sufficiently reduced, place the print in your washing tank, and let a good flow of water pass through at first. See the prints do not stick together, or there may be marks. Label the bottle, "Poison—Cyanide," and put it away in a safe place. For under-exposed prints—if this applies to printing-out paper, albumen, or gelatine—the remedy is, not to remove from the frame until sufficiently printed; but, if it refers to developed-out prints, I find a great deal can be done by removing the print from the developer *directly* it is discovered it is under-exposed. Place upon a piece of glass, having previously poured out some of the alkali solution generally known as No. 2, and brush it on the print; rub it well in, dip the print into the developing solution, remove and brush again, using plenty of the alkali, but keep the prints moving, or stains will occur.

ARCHER CLARKE.

PANORAMIC CAMERAS: STONE'S SYSTEM.

[Patent No. 6235 of 1900.]

As much interest attaches at the present time to this subject, we give Mr. M. T. Stone's specification in full. "The chief feature of my improvement is a flexible, or, more properly, an elastic adjustable holder for the sensitised film and the ground film upon which the image is focussed, whereby the image thrown on the film by the lens may be rendered sharp at every point. Such holder is employed and particularly useful with a lens which is adapted for adjustment of focus corresponding to the distance of the camera from the object to be photographed.

"The body or box, 1, of the camera has the form of a truncated sector. A flexible bellows like tube, 2, composed of leather or some other suitable material, is secured to such truncated end, and to the front plate or board, 3, in which lens-holder, 4, is arranged. The plate, 3, is provided with vertical journals, 5 5', at its ends, by which it is held rotatably in the front ends of parallel rack bars, 6, that serve as means for adjusting the focus of the lens. Said bars, 6, slide endwise in suitable guides or keepers secured to the top and bottom of the body, 1, of the camera, as shown. The means for adjusting said rack bars, 6, are two horizontal shafts, 7 (fig. 4), whose spur pinions, 8, engage them and a vertical shaft, 9 (fig. 4), having bevelled gears 10, that engage similar ones, 11, on the shaft, 7. The vertical shaft, 9, projects through the top of the camera, 1, and has a milled head for use in rotating it.

It is thus apparent that the lens may be readily adjusted by the shaft and gear mechanism toward or from the curved back of the camera where the sensitised film is located for the purpose of focussing the image on the latter, and that the panoramic effect is attained by rotating the lens mount, 3, through the arc of a circle required to sweep over the length of the greater arc described by the films at the back of the camera. It is apparent that the flexible tube permits both these movements to be made. The rotation of the lens mount is effected by a lever arm, 12, fixed horizontally on upper journal, 5, of the plate, 3.

"The light rays are directed from the lens through a tube, 13, which is fixed to and rotates with the plate, 3. Said tube is narrow horizontally (see fig. 2), but enlarged and flared vertically (fig. 3), as required to properly direct the light rays upon the film.

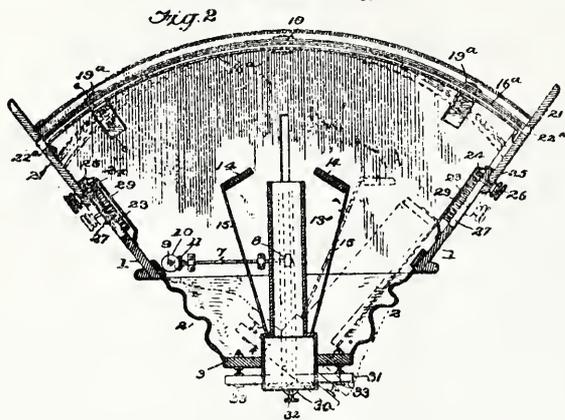

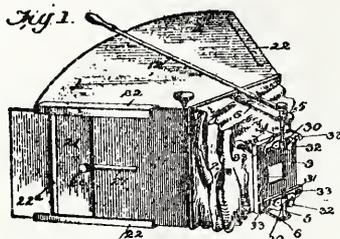

"Light screens, 14, are supported upon the free end of plate springs, 15, attached to the lens, mount, or plates, 3, and projecting horizontally therefrom. Said screens are thin, flat, and oblong wooden plates, covered with dark fabric, preferably black velvet.

"When the tube, 13, is swung laterally either way, a screen, 14, will come in contact with the side of the camera box, 1, and the springs, 15, which are yielding, the screen will be forced over the end of the light tube, 13, and thus exclude light, so that none can fall upon the film. The latter can then be removed. When the lever, 12, is again removed, that is to say, in the opposite direction to make another exposure, the springs, 15, will obviously remove the attached screen, 14, from the tube, 13.

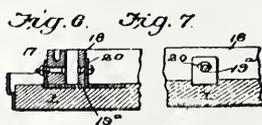

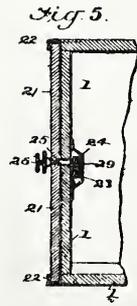

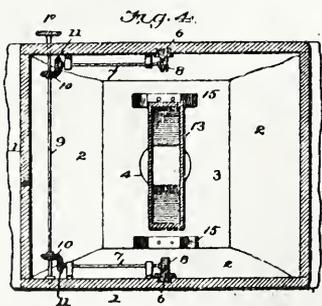

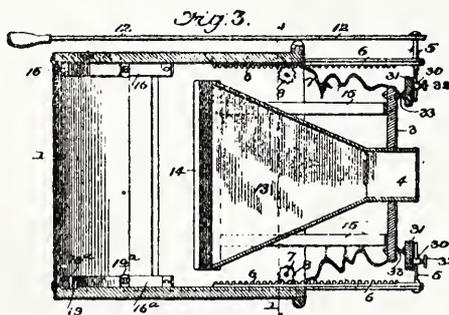

"It has been usual heretofore to arrange and hold the sensitised film and the ground film for focussing in a fixed position. Consequently the focus could not be changed without throwing either the centre or ends of the film out of focus, since, when lens is moved, the radius of the circle must be adjusted correspondingly, otherwise the distance from the lens to all parts of the circle will not be the same. It is therefore impossible to obtain a sharp image on all portions of the film. I have devised a flexible adjustable holder for both the sensitised film and ground or focussing film, and thereby converted a panoramic camera into a practical instrument, which can be perfectly focussed for different distances so as to obtain a perfectly sharp image on all portions of the film.

"My film-holder is composed of two like parts or sections, 16, 16<sup>a</sup>, one, 16, being arranged at the top, and the other, 16<sup>a</sup>, at the bottom of the camera body, 1, adjacent to the rear curved end of the same. Steel, celluloid, or any other suitable elastic material, may be employed in constructing the holder. Each part or section has two grooves (see fig. 6), one being formed in the rib, 17, and the other and larger

groove between such rib, 17, and a thinner rib, 18. Both ribs, 17 and 18, are connected and held equidistant by means of approximately U shaped bars, 19 and 19<sup>a</sup> (figs. 2 and 6), which are riveted to them as shown. The central bar, 19, is fixed, but the other, 19<sup>a</sup>, is adapted to slide. The bars, 19, may have a slot, 20, where the rivets pass through (see fig. 7), to allow movement of the latter when the film-holder is adjusted. The ends of the sections, 16 and 16<sup>a</sup>, are attached to doors, 21,

which are held slidably in guides, 22, formed by flanges attached to the top and bottom angles of the camera body 1. Said doors, 21, have vertical slot, 22<sup>a</sup> (figs. 1 and 2), to receive the film-holder proper, and the doors, 21, are adjusted as required by means of rack bars, 23, and pinions, 24. Each rack bar, 23, is fixed inside the camera box, 1, and, the pinions, 24, are mounted on short shafts, 25, having milled knobs, 26,

and held rotatably in the doors, 21, but adapted to slide in slots, 27, in the sides of the box. A box guard, 29, is arranged to cover the rack and slot on the inner side, so as to prevent entrance of light. A jam nut is applied to shafts, 25, to lock the latter, and thereby the doors, 21, in any adjustment.

"It is apparent that by rotating the knobs, 26, the pinions 24, will

travel on the racks, 23, and carry the doors, 21, with them, and, the doors being connected with the ends of the film-holder, 16, 16<sup>a</sup>, the latter will also be adjusted to describe a curve of greater or less radius. One such adjustment is indicated by dotted lines in fig 2, this adjustment being made corresponding to that of the lens focus. The image on the screen and film will be sharp at every point.

"The doors, 21, extend beyond the rear end of the box, 1, so that, when adjusted forward, the entrance of light will be prevented by the door overlapping the entrance. A vertically adjustable front is a necessary adjunct of the camera. This I provide, by adapting the plate or board, 3, to slide up or down on the shaft, 5, 5<sup>1</sup>. The inner adjacent ends of the latter are flattened on the front side and pass through keepers, 30, which are secured to cross pieces, 31, affixed to the plate, 3, adjacent to its upper and lower edges. Clamp screws, 32, work through the keepers, 30, and bear upon flattened portions of the shafts, 5, 5<sup>1</sup>. It is obvious that this combination of parts enables the plate or lens to be adjusted vertically as may be required, yet it turns with the said shafts, 5, when rotated by the lever, 12, as before described.

"The aforesaid cross pieces, 31, are adjustably attached to plate, 3, by screw-threaded rods, 33 (see figs. 2 and 3) to which nuts are applied, to hold the plate fixed in any adjustment. The object of the adjustment thus provided for is to enable the optical focus or centre of the lens to be centered where the rays of light cross directly under the centre of the pivot or plate, 3, otherwise the picture would show double lines. This feature of my camera allows different lenses to be used at will.

"I do not show the ground film on which focussing is effected preliminary to exposing the sensitised or photographic film, nor the dark slide, which forms a necessary adjunct of such film. The film-carrier or holder will be a sliding elastic frame adapted to slide into the space or groove between the ribs, 17 and 18. It may be made of celluloid, thin steel, or any other suitable material.

"It is apparent the lever arm, 12, may be detached, and the bellows part, 2, pushed back into the camera, when it is desired to pack or store the camera in the least space.

"I do not restrict myself to the described means for adjusting the film-holder, 16, 16<sup>a</sup>, and also the lens. The sliding rack bar, 6, may be arranged on the outer side of the top and bottom of the camera body."

### ARTIFICIAL LIGHT PHOTOGRAPHY: SPURR AND McQUAID'S SYSTEM.

[Patent No. 25,369 of 1899.]

THE system consists of a transparent reservoir, or receiver, in which an inflammable gas is stored. This gas is confined in the reservoir until it is desired to create an artificial light, when the gas in the reservoir is ignited, and the illuminating gas then creates an artificial light within the reservoir, which radiates through the transparent sides of the reservoir, and thus establishes an area of light within which the sensitive photographic plate is exposed.

The transparent reservoir, or receiver, A, is made of glass or other suitable material, and is in the form of a jar. In this reservoir, A, an inflammable and illuminating gas is stored, and, as it is desirable to produce a light rich in actinic rays, the patentees prefer to use nitric oxide gas rendered inflammable by carbon bisulphide, although we do not limit ourselves to such a gas. When this gas is ignited, a light is generated, the rays of which radiate through the transparent sides of the reservoir. Within the area of light so generated the photographic plate is exposed.

It is desirable to provide means whereby the shutter may be operated concurrently with the production of the artificial light, or the exposure effected at the same time, or slightly in advance, of the production of light. To accomplish this result, the patentees provide the arrangement shown in fig. 1. The camera, B, has its shutter connected, in the usual manner, with the pneumatic operating device comprising the flexible tube, D, and the compression bulb, D<sup>2</sup>. This bulb is also connected with the light-producing apparatus by means of the tube, D<sup>3</sup>, in a manner to be described, and, as this apparatus is adapted to operate automatically to ignite the gas in the reservoir, A, when the bulb is compressed, the shutter is operated to expose the plate as the gas is ignited.

The means for automatically opening the gas reservoir, A, and igniting the gas therein, comprises a lid or cover, E, pivoted or hinged at E<sup>2</sup> upon the reservoir, and acted upon by a spring, E<sup>3</sup>, which tends to open the cover or lid on its hinge, and thus afford access to the interior of the reservoir. Removably secured upon the upper portion of the reservoir by means of the lug, a, engaged in the sleeve, b, is the ignition device, which consists of a wick-carrier rod, H, within the sleeve, H<sup>2</sup>, a spring normally tending to press the wick-carrier rod toward the reservoir. One end of the wick, H<sup>4</sup>, is within the reservoir, H<sup>5</sup>, containing alcohol, or other suitable inflammable liquid, and the other, or ignition end, is adjacent to the gas reservoir.

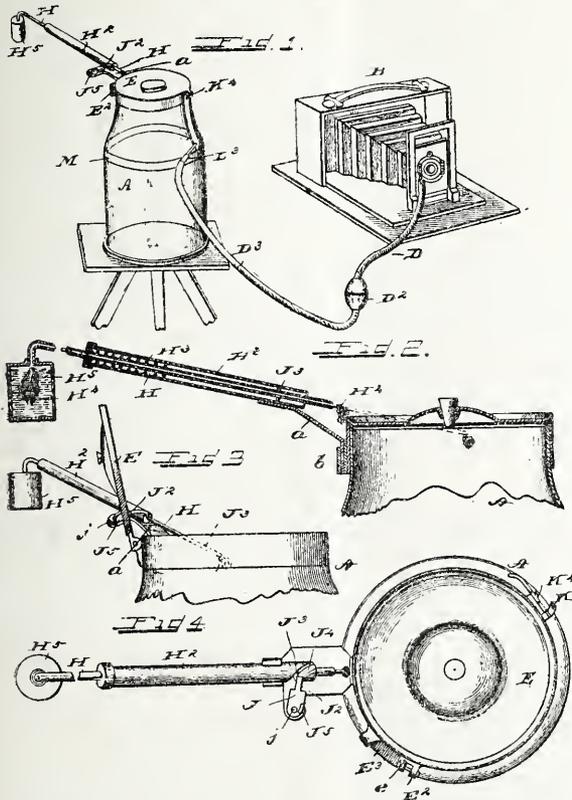

The wick-carrier rod, H, is held retracted against the pressure of the spring, H<sup>3</sup>, by means of the triggering device (fig. 6), consisting of a trigger, J, having a tongue, J<sup>2</sup>, which engages a projection, J<sup>3</sup>, on the

wick-carrier rod, this tongue extending into an oblique slot,  $J^4$ , in the sleeve,  $H^2$ , and as the tongue is engaged against one side of the slot, and engages the projection of the wick-carrier rod, this rod is held in a retracted position. The trigger,  $J$ , is loosely pivoted at  $j$ , and has an upwardly extending arm or abutment,  $J^5$ , adapted to be engaged by the lid or cover of the reservoir when it is forcibly thrown back into an open position.

The lid or cover,  $E$ , is held shut also by means of a triggering device comprising a trigger lever,  $K$ , pivoted at  $K^2$  to the latching head,  $K^3$ , engaging a lug,  $K^4$ , projected from the lid or cover. If it is desired to hold the lid permanently closed, the button,  $K^5$ , may be brought into engagement with the lug,  $K^4$ , as shown by the dotted lines in fig. 9.

The pneumatically operated connexion for triggering the lid or cover is shown in fig. 7, and it consists of a piston rod,  $L$ , and piston head,  $L^2$ , movable within the cylinder,  $L^3$ , the piston rod being connected to the trigger lever,  $K$ . A spring,  $L^5$ , bearing on the piston head,  $L^2$ , normally tends to preserve the latch connexion between the trigger lever,  $K$ , and the lid or cover lug,  $K^4$ . As one end of the cylinder,  $L^3$ , is connected to and communicates into the tube,  $D^3$ , when the bulb,  $D^2$ , is compressed, the air pressure acts upon the piston head,  $L^2$ , overcomes the opposed spring pressure, and thrusts the piston in a direction which unlatches the trigger lever, and releases the lid or cover, which latter is then violently thrown backward on its pivot by the spring,  $E^3$ .

In the backward movement of the lid or cover it strikes violently

against the trigger lever arm,  $J^5$ , which releases the wick-carrier rod,  $H^2$ , and, as the end of the wick,  $H^4$ , is now lighted, an igniting flame is quickly advanced into the now open end of the gas reservoir, thus igniting the gas in the reservoir and establishing an area of light and also concurrently exposing the sensitive plate in the camera, as the pressure generated by the compression of the bulb also operates the shutter.

The pneumatic triggering piston and cylinder are held upon the side of the reservoir by a band,  $M$ .

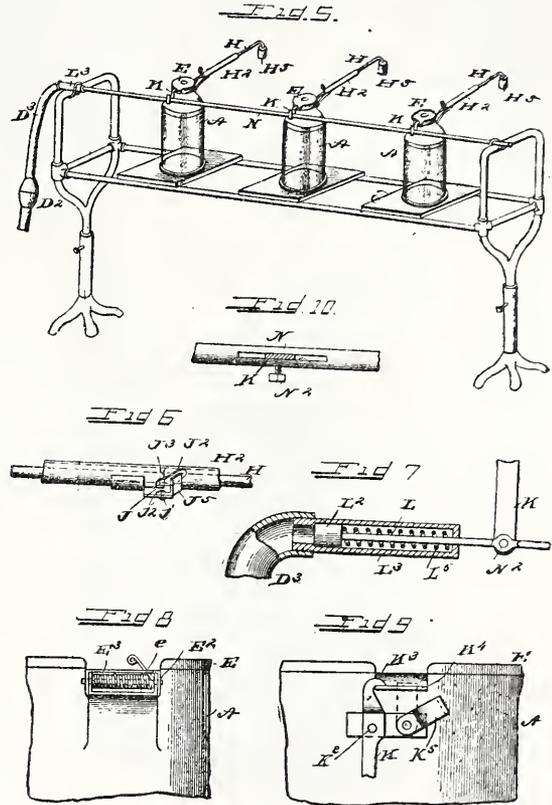

A yielding pressure device, consisting of the coiled spring,  $E^3$ , for opening the lid or cover, is connected at one of its ends in an engaging notch,  $e$ , and, upon releasing this end from such engagement, the spring is disconnected from the cover, so that the latter may be readily manipulated.

By means of the arrangement now described the patentees provide means for automatically establishing an area of artificial light within which the sensitive plate is exposed and controls the generation of the light from the same point of operation for control of the shutter.

By providing a transparent reservoir containing a gas capable of ignition to produce artificial light they are able to obtain photographs under conditions prohibited when the ordinary flash light is produced by igniting a chemical compound in a powdered state. Thus the photographing of expensive and delicate draperies in the night-time is frequently prohibited because of injury to the draperies from the smoke and gas of the flash light. The loud detonating report is also a source of annoyance. All this is avoided by this invention, as the cover or lid of the reservoir

may be immediately closed to prevent the escape of the gas, is smokeless and noiseless when ignited, and is largely confined within the reservoirs, the generated light therein radiating through its transparent sides. Again, the reservoirs are capable of being stored or charged with the gas and are in readiness for instant use. Further, a gas may be, and preferably is, used which is rich in actinic rays.

As the gas is stored in these transparent reservoirs, a battery of reservoirs may be employed, as shown in fig. 5. Under such conditions a plurality of reservoirs,  $A$ , are assembled and mounted upon a suitable table or supporting frame and connected together, in whole or part, by an operating rod,  $N$ , which is laterally thrust or moved by a pneumatic device

similar to that employed to trigger the lid or cover of the reservoir. When the bulb,  $D^2$ , is compressed, the piston,  $L$ , connected to the rod,  $N$ , imparts a lateral movement to the rod, and as the trigger,  $K$ , holding the lids or covers of the reservoirs, is secured to this rod, its lateral thrust is operated to release the several lids or covers, each of which opens and triggers its respective ignition device to produce the artificial light.

If it is desired to ignite the contents of only one reservoir, or of a pair of reservoirs for instance, of the battery, the connexion between the operating rod,  $N$ , and the reservoir or reservoirs to be cut out is removed by loosening the set screw,  $N^2$ , which removably connects the trigger to the rod.

## Our Editorial Table.

THE "UBIQUE" CAMERA.

Manufactured and sold by Perken, Son, & Co., Limited, 99, Hatton-garden, E.C.

THE well-known Optimus house sends us a book of instructions for the Ubuque camera, a clever little hand-and-stand instrument which we reviewed in our columns some time ago. Many of these cameras are in use, and the descriptive pamphlet can be obtained free by post on application.

It may be added that the special features of the Ubuque camera are that, in addition to being essentially a hand camera, and capable of taking snap-shots at any moment by merely pressing a knob, it can also be used on a tripod for all general photographic purposes, and is absolutely self-contained.

Campbell's *Photographic Exposure Note Book* is the title of a neat and conveniently arranged little book for recording particulars of exposures made. It is prefaced by thirty-six pages of formulæ, and space is provided for memoranda. It is published by Messrs. Duncan Campbell & Son, of 96, St. Vincent-street, Glasgow.

## THE "RAYMENT" SELF-LIGHTING LAMP.

Supplied by A. Rayment, 125 Farnham-grove, Forest Gate, E.

THIS ingenious little contrivance is a combination of a bichromate bottle battery with a lamp. The heat generated by the electric current in the former is utilised to incandescence a spiral platinum wire placed over the wick of a volatile essence lamp, which is lighted up at any moment by the simple pressure of a lever arranged to complete an electric circuit. On discontinuing the pressure after the lamp has lighted itself, a spring comes into action which automatically breaks the circuit and so economises the battery, which will last for months and may be recharged for two or three pence. A charge of bichromate salts is sent out with each lamp, as well as explicit instructions. Two-pennyworth of mineral essence from the nearest chemist will be sufficient to feed the light for thirty hours, and is all that is required to complete the outfit. This lamp is capable of being made an extremely useful one to the photographer, whether amateur or professional, for many purposes; for instance, when in the dark room the ruby lamp, prior to development, is often found to give insufficient light to enable the operator to fix his bottles, or to pour into

the measure the exact quantities necessary for each. Then, by pressing a lever on the "Self-lighting Lamp" a light equal to a good candle is immediately obtained, thus enabling the labels on the bottles to be read. Extinguishing the light requires but a strong puff of air from the lips. After development, whilst the plate is in the fixing bath, covered by an inverted tray to exclude light, another pressure on the lever will again ignite the lamp and facilitate preparations for the next plate, and allow the examination of the negative. After work is finished the tiny lamp may be transported to the smoking-room, and the lever pressed to light the cigar or pipe. Later on, when the weary one rests his head upon his pillow, should his slumbers be disturbed, he has but to stretch forth his hand to the lamp, which he previously placed within reach on the table, press the lever and his apartment is at once illuminated.

The price, 7s. 6d., being small, should place the lamp within general reach. It is so simply manipulated, and its uses are so manifold that we have pleasure in recommending it to those photographers who wisely surround themselves with every convenience and comfort in their work.

## FALLOWFIELD'S PHOTOGRAPHIC ANNUAL FOR 1900-1901.

Published by J. Fallowfield, 146, Charing Cross-road, W.C.

As thick as leaves in June are the pages of this very useful annual, for they reach the great total of 888. What the book does not describe and illustrate in the way of photographers' requirements is not worth having. In some prefatory Forewords—the photographic associations of Charing Cross-road are peculiarly conducive to the use of that very modern term—Mr. Fallowfield very properly says of his annual that, in comparison with the book issued ten years ago, it gives a clear and definite idea of the extraordinary advance photography has made, the one issued in 1888 being but 153 pages, whereas the present amounts to over 880—an advance of 727 pages in all. He also points out that the new additions to his stock are cinematograph and X-ray apparatus, and that there is a general elimination of all obsolete articles that have appeared in previous lists. In the mount, chemical, and lantern sections many novelties will be found. *Fallowfield's Annual* is one of the most valuable publications of its kind.

## Studio Gossip.

THE non-return of photographs sent in answer to advertisements is a subject that seems to be causing some trouble amongst actors and actresses. The *Stage* of last week said: "Letters have reached me this week regarding the unbusinesslike conduct of certain managers, who fail to return expensive photographs sent by applicants for engagements. I wish I could advise my correspondents in the matter. Thousands of letters containing photographs pass through the office of this paper each week, and, when the enormous traffic is considered, I must say that the 'forgetful' managers do not seem a large body. Of course, it is a serious matter for a young artist to send out expensive photographs, right and left, with the chance of securing an engagement, and find that there is no engagement as a result, and that the photographs have been annexed. Perhaps some reader could suggest a remedy."

READY FOR THE EMERGENCY.—A morning contemporary tells us that the Sunday after the Ascot Meeting is generally regarded as marking the zenith of the river season. But last Sunday innkeepers were contemplating untouched chickens, boat-hirers sorrowed over unlet boats, and lock-keepers had leisure to recall other Ascot Sundays when you could not drop a pin into the water of the lock for the press of boats. But the clouds of morning gave way to brilliant afternoon sunshine, and those who ventured on the Thames had their reward. Among those who did venture, in a Canadian canoe, was a well-known American writer, whose navigation of an unfamiliar craft was watched by a party of friends. With them was a pretty actress from the Gaiety, with a snap-shot camera. Suddenly the man of letters capsized his craft, and disappeared in the Thames. In a moment he emerged. "Stay right there! Don't move!" cried the excited actress. "I must take your likeness!"

AN AUTOMATIC PHOTOGRAPHER.—At the Southwark Police Court, before Mr. Paul Taylor, a young man, who described himself as an automatic photographer at the seaside, made an application for a summons against his employer, the owner of the machine, for a fortnight's wages. The Magistrate: What kind of work do you do? The Applicant: I stand by the side of the machine and pull the string, and then I pack up the photographs in lead paper. The Magistrate: What sort of a machine is it? The Applicant: It is a machine eight feet high. It takes the pictures, and I do them up. The Magistrate: So that the machine does most of the work? The Applicant: Yes; but I have to look after it, and pull the string. The Magistrate: I suppose no skill is required for your share of the work? The Applicant: Oh, yes, there is. The Magistrate: Then I cannot assist you. My jurisdiction is limited to unskilled labour. You will have to go to the County Court. The Applicant, who looked very much crestfallen, then retired.

THE MERITS OF PHOTOGRAPHY.—Writing of the Berlin Photographic Company's work on Burne-Jones, a well-known art critic remarks that it is too late in the day to point out either the merits of photography for the reproduction of pictures, or the perfection to which the Berlin firm have carried that process. Etchings and engravings are but translations or interpretations, and it is only in the prints of distinguished artists like Mr. Hall and Mr. Frank Short that the personality of the artist does not obtrude itself. But photography is a mechanical process, and no other artist comes between the painter and the reproduction. The Hermitage, the Prado, and the National Gallery collections have proved how admirably the Berlin Photographic Company can reproduce or suggest even the colour, the quality, the richness of the old masters, and the plates after Burne-Jones show no falling off. There are about ninety of these plates, including the well-known portrait of the painter by Mr. Watts, and another by Sir Philip Burne-Jones. The selection is admirable, almost all periods have been borrowed from. Examples are included of the early water colours, of the most sumptuous of all his pictures, such as the *Laus Veneris* and *Le Chant d'Amour*; of the several decorative series, the *St. George and the Dragon*, the *Briar Rose*, and the *Perseus*; of the later works, of the portraits; in fact, the series could not be more representative. It is published both in volume and portfolio form, and Mr. Walter Crane has drawn for the cover the simplest and most effective design he has yet produced. Of the fine edition, published at 100 guineas, there will be but 200 copies, each signed by Sir Philip Burne-Jones; the ordinary edition, published at 50 guineas, will also be limited in number. The royalties are to go to the Burne-Jones Memorial Fund.

## News and Notes.

THE annual visitation of the Royal Observatory at Greenwich will be held on Tuesday, June 26.

MR. E. J. HUMPHERY, of the Platinotype Company, is at present cruising in his steam yacht in the North of Scotland.

THE "DAILY TELEGRAPH" WAR FUND.—On behalf of this Fund we have received 2s. 6d. from Mr. R. J. Dubbin, of Ballycastle, county Antrim.

THE death is announced, at Paris, of M. Dagron, who, during the siege, produced many thousands of micro-photographs for transmission by pigeon service.

THE Alpine Club has an exhibition of photographs, consisting of views taken by Signor V. Sella and Mr. E. Garwood during the tour of Kanchingga, organized last year by Mr. Douglas Freshfield.

THE NEWCASTLE CONVENTION.—In addition to the papers already announced to be read at the Newcastle Convention, there will be one on the subject of "Desiccated Dry Plates," by Mr. E. Howard Farmer.

**LONDON AND PROVINCIAL ASSOCIATION.**—On the 28th inst. the Annual general Meeting will be held for the election of officers and general business. Visitors are always welcome at the White Swan, Tudor-street, E.C.

**PHOTOGRAPHIC SCHOOL AT MUNICH.**—The Bavarian Government has co-operated with the municipal authorities to found a school for the study of photography at Munich. The course commences in October next, and the instructor is Herr G. H. Emmerich, of whom all particulars may be obtained.

**LONDON VISITORS TO THE CONVENTION.**—Mr. Welford asks us to remind those who are thinking of making the journey by sea that the steamer leaves London at seven p.m. on July 7, and that, in order to make special arrangements, he must know definitely by the end of this month. His address is Warwick Lodge, 166, Romford-road, London, E.

**THE LATEST APPLICATION OF ANIMATED PHOTOGRAPHY.**—A contemporary states that it is proposed to utilise the cinematograph for representing machinery in motion. It is expected that in this way it will become a valuable auxiliary to trade in machinery, as buyers will be able to judge of the working of a machine from the microscope without seeing the thing itself.

The Council of the Society of Arts have awarded the Society's silver medal the following readers of papers during the session 1899-1900:—To Professor W. Wood, for his paper on "The Diffraction Process of Colour Photography;" to Mr. Edwin Bale, R.L., for his paper on "Artistic Copyright;" and to Professor W. M. Flinders Petrie, D.C.L., for his paper on "A National Depository of Science and Art."

**ROYAL PHOTOGRAPHIC SOCIETY.**—Technical Meeting, Tuesday, June 26, at 8, Russell-square, at eight p.m., "The Selection of Lenses with regard to photographic Perspective," by Mr. J. H. Agar Baugh. The Rev. F. C. Lambert, M.A., will read a note on "How to Ascertain the Conjugates of a Lens without Calculation." The Exhibition of Photographs by Dr. P. H. Emerson will close on Saturday, June 30. The Exhibition can be viewed on presentation of visiting card from ten to four, Wednesdays ten to eight.

**COMMERCIAL CHLORIDE OF GOLD.**—At a recent meeting of the Photographic and Microscopic Section of the Franklin Institute Mr. Lyman F. Kebler gave an account of a series of examinations he had made of commercial samples of gold chloride, in which he had discovered a considerable difference in the quality of the various brands on the market. He said that, taking an estimated quantity of 100 ounces, the difference in actual value between the best and the worst would amount to over 150 dollars, and that between these two there were all grades of value.

The Beverley Photographic and Sketching Society's Seventh Annual Exhibition of Photographs, Paintings, and Drawings will be held at Newbegin, Beverley, on Thursday, July 12, 1900. Several silver and bronze medals and certificates will be awarded as prizes. The following are the photographic classes:—Section A (open): 1, Landscape and Seascape; 2, Architecture; 3, Portraiture; 4, Figure Studies. Section B. (Members only): 1, Any subject. The Judges are Messrs. A. Keighley, F.R.P.S. and P. Sheard, Official Judges of the Yorkshire Union of Photographic Societies. All entries and other communications to be addressed to the Hon. Secretary, Mr. T. J. Torley, Toll Gavel, Beverley.

A BRILLIANT company assembled at the rooms of the Royal Institute of British Architects, in Conduit-street, on Monday evening, on the occasion of the opening meeting of the Society's Congress, when Mr. William Emerson presented Her Majesty's gold medal to Commendatore Rodolfo Lanciani, of the University of Rome. Owing to the unavoidable absence of Professor Lanciani, the medal was received on his behalf by Count Carrobio, Secretary to the Italian Embassy, who thanked the Society, not only for the award, but for the high compliment to his country. After the presentation a series of photographs, taken in Greece by the late Mr. Ernest George Spiers, were shown upon a screen, a full and graphic description of each being furnished by Mr. F. C. Penrose, F.R.S.

**THE LATE SOLAR ECLIPSE.**—A special joint meeting of the Royal Society and Royal Astronomical Society will be held at the apartments of the former in Burlington House, on Thursday, June 28, at 4.30 p.m., in order to receive preliminary accounts of the recent eclipse of the sun. Reports of the results achieved may be expected from the Astronomer Royal, Sir Norman Lockyer, Professor H. H. Turner, and others. The Académie des Sciences, Paris, has received and published preliminary reports of the eclipse a good deal in advance of the English Joint Committee. Most of these were furnished to the Academy at its sitting of June 5, and included one by the well-known lady astronomer, Mdlle. D. Klumpke, who observed the phenomenon from a balloon in the environs of Paris.

**KRUGER AND KHARI.**—At St. George's Hall last week Mr. Frederic Villiers, the well-known war artist and correspondent, gave an account of his experiences during the campaign in South Africa. Among the many excellent lectures, some 200 in number, thrown upon the screen, was one of the special correspondent of the *Daily Telegraph*, the Hon. S. R. Horsley-Beresford, who was the first to enter Ladysmith, Mr. Villiers, who arrived shortly afterwards, thoughtfully bringing with him some mutton for the famished defenders. A stirring account was given by the lecturer of the incidents that led up to the surrender of Cronjé with 4000 Boers, and excellent pictures were shown of the cunningly devised trenches and the entrances to the various underground tunnels in which the enemy took shelter.

The Photographic Section of the Great Eastern Railway Mechanics Institution brought its winter session to a close on Wednesday, May 30, and at the conclusion of the lecture a clock and illuminated address, subscribed for by the members, were presented to Mr. H. W. Bennett, F.R.P.S., a mark of the high esteem in which he is held by them, and as a token of the value they set upon his services in the capacity of Instructor to the section. During the time Mr. Bennett has instructed, the membership has increased some seventy-five per cent., and this is undoubtedly due, to a very large extent, to the manner in which he has delivered his lectures, as he has even knowledge gained from his own vast experience, and that not in a grudging

way, but keeping nothing back, and is always anxious to make the matter under consideration as plain and clear as possible. The Section has now a lecture-room set apart for their use once a week, and a dark room, always open for the use of members and those of affiliated societies.

The South London Photographic Society's Fourth Continental Excursion to the Rhine Valley and Ahrgau is on August 18 to August 27, 1900, under the leadership of Mr. William F. Slater, F.R.P.S. The following is the preliminary programme: Saturday, August 18, leave London 8.30 p.m. Sunday, August 19, arrive Remagen (headquarters), travelling *via* Hook of Holland and Cologne. Monday, August 20, Bingen by train, returning by boat, a ride of sixty miles through the finest Rhine scenery. Tuesday, August 21, Cologne by train. Wednesday, August 22, Drachenfels by boat. Thursday, August 23, Ahrweiler by train; walk seven and a half miles through the incomparable scenery of the Ahrgau to Altenahr; return by train. Friday, August 24, Bonn by boat. Saturday, August 25, off day. Sunday, August 26, start for home in afternoon. Monday, August 27, arrive in London 8 a.m. Estimated total cost, 5*l.* 5*s.*, which includes fares, hotel, and gratuities. Programme and full particulars may be obtained from the leader, Mr. William F. Slater, 5, First-parade, High-road, Lee, S.E.

**THE SPECTACLE-MAKERS' COMPANY AND THE REGISTRATION OF OPTICIANS.**—It may be remembered that the Worshipful Company of Spectacle-makers, of which the Master is Sir Reginald Hanson, Bart. (the senior member for the City of London), recently inaugurated a scheme for the examination and certification of opticians, with a view to assuring to members of the public an adequate degree of scientific knowledge and skill on the part of those who make a business of fitting spectacles. The examiners are Professor Silvanus P. Thompson, B.A., D.Sc., F.R.S.; George Lindsay Johnson, M.A., M.D., F.R.C.S., W. H. E. Thornthwaite, F.R.A.S.; and the Rev. J. Henry Smith, B.A. The following is a list of those who passed the fifth examination of the Company, held on the 28th, 29th, and 30th ult.:—F. Anderson, Elgin; H. B. De Brent, Beckenham; W. J. Bunt, London; R. A. Chadwick, Streatham; A. Charsley, London; J. R. Clarke, Newcastle; W. D. Eglinton, Lewisham; A. E. Esdaile, Liverpool; F. Fearnley, Leeds; J. J. Forbes, Stirling; S. H. Holroyd, Hull; E. W. Hovenden, Dulwich; H. A. Hughes, London; H. G. Husbands, Bristol; A. E. Ive, Worthing; J. W. Jones, Criccieth; R. P. Layfield, Liverpool; G. W. Lloyd, Sheffield; D. McFarlane, Manchester; C. Palmer, Gloucester; R. J. Scott, Waltham; W. Shelton, Stockport; G. Vogt, Kendal; J. B. Williams, Putney; W. Wood, Melbourne; A. V. Woodward, Derby. The total number of certified opticians is thus brought up to 296.

## Commercial Intelligence.

**REMOVAL.**—Mr. Wilfred Emery gives notice of removal from 8, Dyne-road, Brondesbury, to new works at Anson-parade, Cricklewood, London, N.W.

The old-established house of Moiley & Cooper, 70, Upper-street, Islington, N., has just issued a new illustrated catalogue of cameras, lenses, and accessories.

The Ozotype Company, of 1, Weedington-road, London, N.W., inform us that the materials for working the Ozotype process of carbon printing will be ready for the market on July 1 next.

**KLAY'S MULTIPLYING PLATE-HOLDER.**—Mr. George Jobson, of Adin-villas, Boston-road, Horncastle, writes us that he is sole British agent for this multiplying back, referred to in our Answers to Correspondents column last week.

**THE AUSTIN EDWARDS MONTHLY FILM-NEGATIVE COMPETITION.**—The prize camera for the current month has been awarded to Mr. Charles Wilcockson, 184, Horton-grange-road, Bradford, for his negative, *Gill Beck Waterfall, Keighley*.

**KODAK (LIMITED).**—The Directors have declared an interim dividend on the Company's preference issue for the quarter ending June 30, 1900, at the rate of six per cent. per annum, and on the ordinary shares at the rate of ten per cent. per annum for the same period, which dividends will be payable on or after the 30th inst. They have further resolved that the transfer books be closed from the 20th to the 30th inst., both days inclusive.

**THE WARWICK COMPETITIONS.**—The following is the list of awards of the Warwick Competition for the current month:—1*0*l.** prize, H. C. Leat, 2, Richmond-street, Totterdown, Bristol, *Playing Time*; 5*l.* prize, A. Waterall, Brighton-grove, Flixton, Manchester, *The Lullaby*; 1*l.* prizes, E. S. Baker, Photographer, 154, Bristol-street, Birmingham, *A Portrait*; W. Bell, 18, Nelson-street, Manchester, *The Road to the Sea*; Graystone Bird, Photographer, Milson-street, Bath, *Innocence*; Philip Bulmer, 37, The Avenue, Sunderland, *Langdale Pikes*; E. W. Burch, Buckingham Palace-road, London, S.W., *Watering Horses*; A. Clarkson, Waveney-terrace, Ballymena, *Leaping Horses*; P. J. Coggin, 1, Carlyle-square, Chelsea, *"Bravo! Baden-Powell!"*; W. E. Daw, Church-street, King's Lynn, *Eclipse of the Sun*; J. Day, 3, Denbigh-place, London, S.W., *A Sussex Mill*; Lewis Deacon, Manor Park, Lee, S.E., *Thatcher Rock, Torquay*; Michael Dillon, Ernest-street, Crewe, *Moreton Hall Courtyard*; L. J. Glendening, Pemberton-road, Harringay, London, *A Rest by the Way*; W. M. Graham, Holly-lodge, Stevingage, *Apple-tree in Blossom*; C. H. Heaton, Framlingham College, Framlingham, *Prejects, Framlingham College*; R. T. Marsland, Park-parade, Ashton-under-Lyne, *Outdoor Portraiture*; Colonel Orchard, Avenue-road, Stratford-on-Avon, *Girl Resting on Stile*; E. Simnett, Radnor-drive, Liscard, Cheshire, *Spring Flowers*; F. M. Steele, Custom House, Dublin, *Paris Exhibition, 1900*; W. E. Topping, 3, Albert-square, Belfast, *Horse Jumping*; H. V. Towell, Stony Stanton-road, Coventry, *The Mill Ford*.

THE Warwick Trading Company, of 4 and 5, Warwick-court, High Holborn, send us the following list of new war films photographed by their war staff now at the front in South Africa:—The Coldstream Guards leaving Bloemfontein: Showing this detachment of General French's column, both infantry and cavalry, on the march to Kroonstad; one of the prominent troopers passing before the camera is Mr. Burnham, the American scout. The C.I.V.'s March on Johannesburg: Showing this gallant regiment (which has cut a most prominent figure in the capture of Johannesburg) leaving Kroonstad for the march across the Veldt. The Coldstream Guards Cleaning their Rifles in Camp: Having just reached their camp at Bloemfontein after an engagement, these troops are seen busily engaged cleaning the dust and smoke from their guns. An Interrupted Game of Nap in Camp: Another one of the series of side lights of our troops in South Africa, showing a group of players seated on the ground in front of a tent, evidently reaching a most exciting period of the game, when they are interrupted by the appearance of an officer who commands them to stop the game and disperse the crowd of onlookers. Naval Gun Crossing the Vet River Drift: One of the of the most interesting of all the South African war series, showing a 4.7-inch naval gun and transport being drawn across the drift by ox teams, which splash through the water and tug at the heavy gun in crossing; as the gun descends the steep embankment of the river, it is held back by ropes in the hands of scores of troops. A Siege Gun and Transport: This subject shows a 5-inch howitzer siege gun and transport (which played such havoc with Cronjé's army) being drawn up a hill by ox teams, which are urged on by the dexterous handling of the long whips in the hands of native drivers. Boer Prisoners under Escort: The prisoners shown in this subject were captured by Lord Roberts's army during their march on Kroonstad; they are seen leaving the camp, being conducted by a mounted escort on their way to Bloemfontein; the two prisoners in the carts are field cornets; as they all pass closely by the camera, every face is recognisable, all of them wearing a most dejected look.

## Patent News.

THE following applications for Patents were made between June 5 and June 9, 1900:—

- EXPOSURE MACHINES FOR ROTARY NEGATIVES.—No. 10,282. "Improvements in Exposure Machines with Rotary Negatives." Complete specification. H. LOESCHER.
- OPTICAL PROJECTION.—No. 10,364. "Apparatus for Projecting Theatrical Performances on a Screen." Communicated by C. Assi. O. IMRAY.
- ANIMATED PHOTOGRAPHY.—No. 10,412. "An Improvement for Moving the Film on a Lifeograph or Animated Picture Machine." W. F. HURNDALL.
- ANIMATED PHOTOGRAPHY.—No. 10,428. "Improvements in Apparatus for Taking and Displaying Photographs of Moving Objects." P. A. THOMAS.
- TRIMMING PRINTS.—No. 10,468. "Improvements in Patterns for Trimming Photographic Prints." F. O. JUNGE.
- CAMERA.—No. 10,586. "A New or Improved Camera, more particularly intended for use in connexion with Architectural Photography, for Measuring Angles." Complete specification. E. MILNER.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
25.....	Southampton .....	Combination Printing. Max Mills, jun.
26.....	Birmingham Photo. Society ...	Composition. C. T. Cox.
26.....	Hackney .....	Skiagraphy. Dr. Burton.
26.....	Royal Photographic Society ...	{ The Selection of Lenses with regard to Photographic Perspective. J. H. Agar Baugh.—How to Ascertain the Conjugates of a Lens without Calcula- tion. Rev. F. C. Lambert, M.A.
27.....	Southsea .....	{ Paper: Methods of Control in Photo- graphic Printing.
28.....	London and Provincial .....	Annual General Meeting.
30.....	Ashton-under-Lyne.....	{ Excursion: Lincoln. Leader, Dr. Alex. Hamilton.
30.....	Borough Polytechnic .....	{ Excursion: Round Lingfield (Walker Miles). Leader, E. S. Taylor.

30.....	Croydon Microscopical .....	{ Excursion: Reigate. Leader, Mr. Baldock.
30.....	Liverpool Amateur .....	{ Excursion: Moreton Old Hall, Congle- ton, and Dane Valley. Leader, Dr. J. W. Ellis.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 14.—Mr. J. E. Hodd in the chair.

Mr. W. T. WILKINSON passed round some photo-micrographs of a collotype plate showing the grain magnified about 150 diameters. The normal and other grains were shown in this way for comparison, and it was stated that an extension of camera of about eleven inches, with a one-inch power, was used.

Mr. T. E. FRESHWATER thought the examples were very interesting, as

giving so clear an idea of the nature of the collotype grain and its beautiful regularity. Personally he had not seen photographs of this subject before, and he was glad to have had the opportunity.

Mr. E. T. WRIGHT (Hon. Librarian) read an amusing paper based upon his experiences of the photographic amateur from behind the photographic counter. It appeared that in his initial form the amateur photographer was a peculiarly unreasonable person, one who expected the dealer to be as rich in explanations and as capable as an Encyclopædia. He was always asking questions and propounding impossible problems, the commonest perhaps being, What is the best developer? What are the best plates? One imaginative camera man came forward with an offer of heaps of old negatives, which he thought might be re-coated, and was surprised to meet with a rebuff. There is a class of amateur which is continually going wrong, and coming up with tales reflecting upon the inefficiency of apparatus and materials. Of these Mr. Wright had several anecdotes to relate; one fired off a dozen plates and got no results, it being ultimately found that the dust cover of the lens had not been removed. In another case the amateur had been startled to find some red stuff on the backs of his plates, until, remembering that there had been a recent case of scarlet fever in the house, he deduced therefrom an idea that the epidemic had in some way affected the plates, which, needless to say, had been backed to prevent halation. Others have no idea of what a backed plate is, or what it may be for. An instance, vouched for by the reader of the paper, where backed plates had been exposed back to front, was related. Of course, no image was found to develop; but these and many other trifling things constantly form obstacles in the path of the amateur, and he as often brings them up to the dealer for explanation. The inverted image given by a lens on the ground glass was attributed by one customer to carelessness in mounting, and he thought that Dallmeyer, the maker, should have been more careful to see that lenses mounted upside down were not sent out. Possibly it was the same man who thought that it would strain a lens to stop it down too much. The chemical side of the question is sometimes very funny. Eau-de-Cologne developer has been asked for in place of hydroquinone, and similar distortions of names daily occur. Everything taken into consideration, however, the lady amateur gives as much trouble and embarrassment as any of the genus amateur photographer.

In the discussion which followed many other cases were quoted, amongst them that of the man who brought back a registering printing frame with a complaint that, after being out in the sun with a negative and paper for a whole day, the indicator had not moved a hair's breadth.

### PHOTOGRAPHIC CLUB.

JUNE 13.—Mr. H. M. Hastings in the chair.

The evening was devoted, according to custom, to the display of the slides sent in for exhibition at the Convention meetings. A large number of slides were passed through, and a special committee sat in judgment upon them, and performed the duties of selection. The average quality was very good, and it was considered that visitors to the Newcastle Convention would have presented to them an interesting miscellaneous series.

### FORTHCOMING EXHIBITIONS.

- 1900.
- July 9-14 ..... Photographic Convention of the United Kingdom (Newcastle-on-Tyne Meeting). Hon. Secretary and Treasurer, F. A. Bridge, East Lodge, Dalston-lane, London, N.E.
- August 21..... Royal Cornwall Polytechnic Society. W. Brooks, Laurel Villa, Wray Park, Reigate.
- October 1-Nov. 3 ... Royal Photographic Society, New Gallery, Regent-street. The Hon. Secretary, 66, Russell-square, W.C.
- November 12-17 ..... Ashton-under-Lyne.
- „ 21-23 ..... Hackney Photographic Society.
- 1901.
- January 14-19 ..... Blairgowrie and District Photographic Association. The Hon. Secretaries, Blairgowrie, N.B.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE SOLAR ECLIPSE.

To the EDITORS.

GENTLEMEN,—I send you a few prints of the above, taken recently, which may prove interesting, not from a strictly scientific point of view, but simply as showing what can be done, with an every-day outfit, as a remembrance of an interesting event. The prints show the photographs

is actually taken, and also enlargements from the negatives obtained. These latter are only about seven times the diameter of the others, and yet required the easel to be placed 7 feet 4 inches from the nine-inch enlarging lens. The only apparatus used was a quarter-plate camera on stand, a 5 x 4 lens divided, giving about eleven inches focus, Imperial ordinary plates, and a Thornton-Pickard time and instantaneous shutter. The shutter was set for its fastest, i.e., one-ninety second, and remained so all the time; the stop was *f*.64 to start with, going to *f*.22 at maximum, and back to *f*.64 as the moon cleared off. Owing to clouds, the first exposure could not be made till 3.23; indeed, most of the exposures, except towards the end, had to be made not systematically, but as break in the clouds permitted, and some very beautiful combinations of eclipse and cloud effects were obtained. I made ten exposures altogether, but one plate, owing to some mistake, did not get exposed; but, to compensate for this, I got two results on the next plate, as the enclosed print shows. This, also, was unintentional, but it proves one thing, i.e., that several results can be got on the same plate, the interval between the two sent being three minutes, the shadow of the moon having perceptibly moved during that time. The temperature decidedly fell as the eclipse progressed, and the clouds formed in about corresponding ratio, dispersing rapidly towards the end.—I am, yours, &c.,  
Croydon. J. H. BALDOCK.

[We are much obliged to Mr. Baldock for his letter and the accompanying photographs, which, as he points out, are of interest as showing how useful ordinary photographic apparatus may be made in obtaining interesting records of celestial phenomena. One of our leaderettes this week is devoted to the subject of star photography with an ordinary camera.—Eds.]

THE ACTINIC POWER OF THE LIGHT ABROAD.

To the EDITORS.

GENTLEMEN,—As a traveller who is also fond of his camera, I observed with some interest in your ALMANAC for 1899 (p. 1082) a reprint of what is styled "Colonel Stuart Wortley's Exposure Table," professing to give the results of "some careful tests of the different qualities of light in various places." Twelve items are formulated from observations chiefly made on the Pacific Ocean, and in adjacent lands thereto, all being compared to "the light of a very fine English day," rated (arbitrarily, I suppose) at 750 points.

If the quality of light really varies intrinsically in various places, such a table, properly constructed, would be very valuable to the photographic wanderer; but, unfortunately, in this table we are left in the dark as to the season of year, local weather conditions, and the time of day under which the observations must necessarily have been made, and we can hardly take it that Colonel Stuart Wortley has by some means or other eliminated all these disturbing factors, since he specifically says, in regard to Tahiti, "in early morning," and his English standard lacks absoluteness.

I have personally photographed in eleven out of the thirteen places he names, and have consequently gone through his list with rather more than usual attention. The conclusion I have come to is that this exposure table does not record "careful tests of the different quality of the light in various places," but rather the intensity of the sunlight at various places at various seasons of the year, the procession of the seasons being, in a sense, modified by Colonel Wortley's own movements.

To arrive at this result I have thrown out of this list five items, retaining only those which refer to the Pacific Ocean at sea level.

I will not trouble you with the full diagram upon which I base my conclusions, but the main data, outside Colonel Stuart Wortley's own figures, I give briefly in a footnote.

It seems highly probable that, after making an observation in its harbour, Colonel Wortley left San Francisco on a mail steamer early one December. At, or near, Honolulu (seven days out) he made a second observation, showing the power of the light there to be somewhat stronger than at San Francisco. His next observation was made at sea in latitude 16° S., probably near Samoa, the result obtained indicating, when considered in relation to the other figures that the sun was at that time about a fortnight from its summer solstice (Southern hemisphere).

Arrived at Auckland (twenty days out), the traveller would seem to have visited Tahiti, taking on his way his maximum recorded observation in 28° S. lat., as well as one on the island itself, the latter apparently about the middle of January. Later on he would seem to have made an observation in Sydney, probably during the March following.

In writing this I am, of course, assuming that Colonel Wortley made his observations under similar conditions, so far as time of day, aspect, state of weather, &c., are concerned.

You will, I trust, see, gentlemen, from these few remarks that more valuable figures than these of Colonel Wortley might have been obtained by a resident in San Francisco (or, for the matter of that, indeed, in Great Britain) who was willing to let the sun do the travelling.

Reliable and fully recorded observations at sea level in various parts of the world would, however, be highly desirable if there is any doubt as to

the intrinsic power of the sunlight (apart from season, &c.) in "various places," and, since a Frenchman on this boat lent me your ALMANAC, yours might well be the cosmopolitan influence to set such a scheme afoot.—I am, yours, &c.,

W. A. BOORD.  
Ss. Polynésien, lat. 43° S., approaching Albany.

ORTOL.

To the EDITORS.

GENTLEMEN,—Your correspondent, "Tippoo," who writes from India in your issue of to-day, has evidently fallen on the same trouble which I had with ortol. My difficulty and the cure were related at page 639 of your volume for 1898, and I have no doubt that a similar procedure would be satisfactory, if it be possible. But I did not find any great advantage from ortol, and the fact that it does affect the hands in many cases is against its use—I reverted to the old pyro. Now adurol seems to offer a considerable gain, and my present experience with Schering's form is that it will give me a developer as good as pyro, while free from its troubles.—I am, yours, &c.,  
J. F. T.

June 15, 1900.

DARK-ROOM LIGHTS.

To the EDITORS.

GENTLEMEN,—I see in your issue of Friday last that at the London and Provincial Society the Chairman expressed himself as dissatisfied with the ruby light, and appeared not to have met with a satisfactory substitute. Like him, I too cannot work with any comfort with a ruby light, but I have adopted what is, I believe, known as double flashed orange, and find it perfectly answer for very rapid plates. I have used it for Imperial flashlight plates (H. & D. 350) without any fog while I have abundance of light for work; my side light too is a single flashed orange.

Examination with a spectroscope shows that, while the orange glass passes a little green light, it seems to cut off entirely the blue which is transmitted by ruby glass; moreover, owing to the colour of the light, one can work with the lamp lower than with ruby, and still have clearer vision of what is going on.—I am, yours, &c.,  
J. F. T.

June 18, 1900.

Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED :—

J. E. Vatey, Wadebridge, Cornwall.—Photograph of the Commercial Hotel, Wadebridge.

J. Whyte, 37, Jamaica-street, Glasgow.—Photograph of Samuel Chisholm, Esq. Photograph of Rev. W. Ross Taylor, D.D.

W. R. Jones, 36, Cowbridge-road, Canton, Cardiff.—Photograph of boy with "Echo" placard, "Mafeking Relieved, Official Message."

J. A. N.—Address Mr. J. C. Stevens, King-street, Covent Garden, who would probably undertake the commission.

W. TULLY.—The large print is apparently a collotype, the small ones bromides. Messrs. Morgan & Kidd, Richmond, London, S.W., and other firms undertake the work.

TESTING MOUNTS.—A. C. COURVY. We do not undertake the testing of mounts for our readers. If we did, we should not have much time to spare for anything else. You can easily test them for yourself by any of the simple methods that have recently been given in our columns.

SPOTS ON PRINTS.—T. BIGNOLD. The spots are clearly due to particles of pernicious matter, and, from the data you give, we should say from the water coming through rusty iron pipes. The only remedy is to filter the water before using it. We should recommend you to get a Birkenfeld filter. That filters rapidly, and can be attached to the water pipe. Possibly the water company have been putting down new mains in your district. When that is done, the water is often charged with iron rust for a time.

- LIEUT.-COLONEL GUBBINS**—1. The only suggestions we can offer are either that the balsaming medium is very much discoloured, or that some slight displacement of the combinations has taken place. 2. We have seen some very good work produced with No. 1. If you write the agent, he would probably let you have one on approbation.
- MAKING OWN PLATES.**—B. says: "I do a large cheap business, and have to cut things very fine. I sometimes use several gross of plates a week. Do you think, under these circumstances, that it would pay me to make my own plates?"—We should say, taking all things into consideration, that it would not, and that it will be much more profitable for you to continue to purchase them as hitherto.
- DETERIORATION OF PAPER.**—T. BOWER. If all the packets of paper are like the piece sent, it is worthless. It has become spoilt through long keeping. If you only bought it a week ago, you should return it to the dealer from whom you had it. Evidently it is old stock, and must have been on the dealer's hands for a long time. It is no use expecting to get good prints on such paper by any treatment.
- REMOVING BACKING FROM GLASS POSITIVE.**—C. & J. say: "We have a glass positive to copy, and the black varnish at the back is cracked all over. We have tried to clean it off with benzole, as we have done before, but it will not dissolve. The picture has been hanging for many years on a wall?"—Evidently the bitumen (base of the varnish) has become insoluble, and you will have to scrape it off with a knife. You will find that it can easily be removed in that way.
- STUDIO LIGHT.**—THOMAS DAY writes: "I have bought a studio 19×11 feet, span roof. There is about seventy square feet of glass upon each side of roof, and about sixty square feet down one side. A friend of mine informs me that I have too much light in the studio. If this be so, please say how much glass I am to board up. The side light is facing north-east."—Cover up about four feet six inches at either end, top and sides, permanently, and fit blinds or curtains to the other portions.
- A QUESTION OF REPAIRS.**—S. R. J. says: "I rent my place on a repairing lease. During the heavy thunderstorm we had on Monday the hailstones broke several large squares of glass in the roof. Who must make them good? The landlord says it has nothing to do with him, and I say that damage done by hail is not fair wear and tear, and therefore he is liable."—You will have to repair the damage, as it is no concern of the landlord's whether the glass is put in or not, and you have covenanted to keep the premises in repair. It is unfortunate for you.
- LENS FOR CAMERA; CHARGES FOR WORK.**—E. W. writes: "Have bought 22×18 enlarging camera, kindly say what would be the most suitable lens to use. 2. Have taken up landscape and architectural photography professionally, what should I charge for first-class work, whole-plate and half-plate?"—1. Any lens that will cover the largest-size negative that has to be enlarged from. The size of the camera makes no difference in this respect. 2. Prices vary so considerably with different people that we can offer no advice. Much depends upon the character of the work and its artistic merits.
- OVER-EXPOSED NEGATIVES.**—W. C. JONES writes: "During my Whitsun holidays I exposed about five dozen plates. I have developed about a dozen of them with the ordinary pyro-ammonia developer. They came out quickly, and soon got dense-looking, but when they were fixed they were very thin and apparently fogged. Can you tell me how to get better density in the others? The plates are —'s most rapid."—The plate sent is very much over-exposed. In the development of the others increase the proportion of bromide and pyro, and decrease that of the ammonia. You may then get better results. See leaderette on the subject last week.
- SENSITISING CARBON TISSUE.**—CARBONENSIS asks: "Can you help me in this matter: I sensitise my own carbon tissue, using one ounce of bichromate to the pint of water, and give three minutes' immersion. When it has been in that time, I find the surface cannot be touched with the fingers without the coating coming off. I have never had this trouble before, but this is a new lot of tissue?"—This is a hot-weather trouble. The sensitising solution is too warm, so that the gelatine becomes much softened. Place a little broken-up ice in the solution, and handle the tissue as little as possible. By the way, a five per cent. solution is a little strong for this hot weather. A three and a half per cent. one would be better.
- STUDIO BLINDS.**—G. Y. writes: "1. Kindly advise me what sort of blinds to use in a new studio with north-east light, also best way to put them up. The studio is 22×12 with 15 feet glass top side. 2. Also, is there anything that will remove liquid ammonia, 880 off the brasswork off a 10×8 R.R. lens?"—1. Light green, or dark blue, would be a suitable colour for blinds in a studio of this aspect. Fix the blinds on rollers for the roof. Spring rollers are the most convenient. For the sides we should have curtains of the same material, running on rods. 2. We are not quite sure we understand this query. Do you mean that the ammonia has removed some of the lacquer from the mount? If so, the only thing is to apply fresh lacquer.
- DISCOLOURED NEGATIVES.**—PUZZLED writes: "Can you inform me why negatives turn very yellow and sometimes orange colour during development? Several that I have developed lately have done so, and others have kept quite clear from it, although developed at same time and formula, viz., pyro and soda. Can you give me any clue to the cause of it, and also what will remove the yellowness? If so, I shall be glad."—As some negatives are yellow and others not, it is clear that the stain is due to the manipulations. Possibly the stained plates were kept a long time out of the developer while examining them. Insufficient washing after development and before fixing is proved to cause staining of the film. Try the clearing solutions given on p. 1085 of the ALMANAC; either of them will possibly remove the yellowness.

**STAINED PRINT.**—OPERATOR writes: "The enclosed is a badly stained print on paper, worked according to formula with every care taken in the various manipulations, washing, fixing, &c.; they seem all right until put on the enamel glasses, then spots begin to appear and continue to come up gradually same as enclosed print. I may state the collodion backing and gelatine have been tested and found all right."—The spots are due to something in the manipulations, and not to either the gelatine or the collodion. The only opinion we can hazard is that the print was imperfectly fixed, but there may be other causes.

**CHARGE FOR PORTERAGE.**—OPERATOR asks: "Will you please tell me what is the custom of the trade under the following circumstances? My employer sent me to take some 12×10 groups. When I got to the station, I found the place was three miles away. I paid a man three shillings to help me carry the heavy camera, with three double slides with the six plates, three lenses, &c., there and back. He refuses to refund the three shillings, saying that, if I did not choose to carry the apparatus myself, it was no business of his. You know the heat of last Monday."—We know of no rule in the matter, but such out-of-pocket expenses are usually paid by the employer without demur. Yours must be a very mean employer indeed.

**COPYRIGHT.**—H. N. RAINBOW writes: "A friend of mine had his photograph taken by a professional, and then went out to South Africa. He could only afford to distribute a few copies over a wide circle of friends who wanted them. I (an amateur) am willing to make small reproductions of it and give them round to our friends. I can also rely on my absent friend's willingness for me to copy it, but, on writing to the original photographers for permission, they refused. What I would ask is, Should I incur any liabilities by copying it under the above circumstances?"—In reply: Not if your friend paid the photographer for the photographs and you have permission to make the copies. If the photographs were not paid for, then the photographer can proceed against you for infringement.

**COCKLED FILMS, &c.**—S. A. C. writes: "I should be much obliged if you could give me a remedy for cockled films, sample which I enclose is by no means the worst of a dozen which I dried up by spirit (methyl)? I have tried the glycerine bath, also prolonged soaking in spirit, but cannot get the unevenness out, and, as they are, it is difficult to get contact in printing. Am anxious to get them flat again. (2) I should be glad to know the reason of them cockling, as I've never had it happen before? I gave them a short soaking in methyl spirit, and then laid them on blotting-paper to dry. (3) I notice in the News and Notes of your valuable JOURNAL that 'photographers are being enlisted for service in South Africa;' could you give me further particulars, or address where I could get them?"—1. Treat the films according to the instructions issued with them and then they will not cockle. 2. The reason of the cockling is that the soaking in the spirit has caused the gelatine to contract abnormally. Soak the films for an hour or two in water to which a trace of glycerine has been added, and, when they become flat, allow them to dry spontaneously. 3. Apply to the Recruiting Department. Any of the recruiting sergeants, who stand about the east end of the National Gallery will give you the desired information.

**EXHIBITING SPECIMENS.**—A. SURL writes: "Will you kindly inform me if legal proceedings can be taken to prevent me exhibiting an enlargement in any part of my shop? I have already removed it from the shop door window to oblige the father of the girl's whose photograph it is, although I had special permission from the girl and her mother at the time of sitting, and took an extra negative at the time for that purpose, with full explanations as to the size of the enlargement and where I should want to put it for show. Now, after going to the trouble and expense of making a picture measuring 45×35, I have been demanded by the father of the girl to take it from the shop; and, to save any unpleasantness between husband and wife, I took it out of the door window at five minutes' notice, and, instead of thanking me, the man threatened what he would have done had I not removed it when I did (namely, put his fist through it). Am I obliged to further remove it from the shop? This I don't want to do, I have given him the option of buying it at a reasonable price, as he hinted something about purchasing it. I should be glad of advice on the subject."—Certainly, legal proceedings can be taken and damages recovered for exhibiting the picture against the wish of the father. As its exhibition is objected to, you should remove it at once, or you may find yourself involved in costly proceedings.

**STUDIO-BUILDING.**—STUDIO writes: "I am about erecting a studio in my yard, but, unfortunately, it faces south, being shut in all sides by high buildings, near this position. 1. Can good work be done with such light and sun shining? 2. If so, would the sample of material I enclose be suitable with opaque blinds as marked on plan? 3. Would this be sufficient when sun was shining? 4. Or would it be better to have an extra set of thin white blinds, to diffuse the sunlight instead of leaving clear glass where light was wanted, of course stopping the bulk of the light with the green blinds where not wanted? 5. If this system of blinds is not suitable, what would you suggest? 6. Is the width about in proportion to the length (25 feet is all I can get)? 7. Is the height about right (12 feet back and 7 from eaves)? 8. Are the opaque blinds about in proportion? 9. If you have answered any queries before re south light, should be glad if you would give me dates. I have about three years' BRITISH JOURNALS. I have a number of books on studio-building, but all recommend and give instruction for north light."—In reply: 1. Yes, though requiring more skill than in a studio with any other aspect. 2. The colour is good, but we should recommend a thicker material. 3. With a thicker material, yes. 4. We should advise you to have ground glass in the roof of the studio; that will diffuse the light. 5. The system will do very well. 6. Yes. 7. Yes, but perhaps six inches or a foot higher would be better, considering the aspect. 8. Yes. 9. We suggest that you get Bolas's book on the subject, published by Marion & Co.

## EX CATHEDRÁ.

ALTHOUGH it was published just seven months ago, the article in our ALMANAC for 1900 on "Stereoscopic Photography" continues to bring us letters from readers who are interested in that fascinating branch of work. This week two correspondents send us communications which enclose some interesting stereographs. The first of these comes from Mr. C. H. Crosby, of Chicago, who kindly remits some slides commercially produced by Mr. H. H. Bennett, of Kilbourn City, Wisconsin, U.S.A. The peculiarity of these productions is that the models are little dolls posed against natural backgrounds. In one some nymphs are bathing, and a darkey boy is intruding upon the sacred spot; in another a doll figure has dropped *her* doll into the water, and is made to look distressed; in a third the legend of Peeping Tom of Coventry is illustrated with variations, and so forth. This idea, which, so far as we know, is original, can obviously be utilised to produce most effective and amusing stereographic studies. Doll models do not move, and can be easily posed in a variety of ways; while, if their

facial gestures are not excessively expressive, there is consolation in the reflection that this is a drawback not wholly absent from pictures of living models.

\* \* \*

THE second letter is from a very old stereoscopic worker, who writes: "It is a long time since I had this pleasure. I think at that time I sent you some winter scenes, of which you gave a favourable notice in the JOURNAL. I now ask you to accept a few naturalistic subjects, and I may say that amongst all my extensive collections (thousands) of slides none seem to give such pleasure to old and young as these birds' nests, &c. There are many difficulties in this branch of photography. The young birds (and the old) won't 'sit quite still and look pleasant for a moment,' and the wind too, by blowing leaves and foliage about, all helps to make the waste-glass heap grow, and often to get at the nests is very difficult. Wading for moorhens, and climbing trees for rooks and other birds, and wandering through miles of woods, is not always easy work, but the results obtained, great pleasure is given to friends, and on looking over the series I think there is full payment for the labour. Your article on stereoscopic work in the ALMANAC is much appreciated. I can now see slides stereoscopically without the scope. *But, oh!* the pain to my eyes if I look over many slides. I note by letters in the JOURNAL that I am not the only one who has the pain."

\* \* \*

WITH regard to the pain caused by the examination of a number of slides without the stereoscope, we can only suggest that it is induced by the excessive width of separation given to foreground objects. If this were always kept appreciably under three inches, then we do not think any inconvenience would be experienced. The twenty-three stereographs which our esteemed correspondent is good enough to send are a tribute to his ability as a photographer and his acumen in turning stereoscopic photography to such very good account. They illustrate birds' nests in trees and hedges, bushes, grass, &c., and in securing the negatives a very great amount of skill and patience must have been expended. It need hardly be said that seen stereographically these slides are very beautiful to look at, the foreground objects in most cases being only a few

inches from the lenses. We thank both our correspondents for the opportunity they have given us of once more reminding our readers of the many wholly unique results which stereography enables the photographer to obtain.

\* \* \*

A REUTER'S telegram from Christiania tells that the Russian transport *Rurik* has arrived there, and reports that the Russian expedition for taking meridian measurements in Arctic regions is in good condition after wintering in Spitzbergen, and that the scientific results of it were very satisfactory; also that in the spring photographs of the Northern Lights were taken, and spectrum analysis observations made, and that the astronomical and physical researches were carried out systematically, the observatory being constantly at work. Most of us are as familiar with the old illustrations of the Northern Lights (*aurora borealis*) as with the old pictures of lightning. It is interesting to see how photographs of lightning differ from the representation of it in pictures, even those by the best painters, including those of modern times, notwithstanding what photography should, one would have thought, have taught them. Photographs will show how pictures of the *aurora borealis* differ from the orthodox depictions of artists. While on the subject of Polar expeditions, it may be mentioned that for the English one which is to start next year for Antarctic exploration a new ship, to be named the *Discoverer*, is being constructed by the Dundee Shipping Company, at a cost of 40,000*l.* The funds for this expedition at present amount to about 90,000*l.*, towards which the Government have contributed 40,000*l.*, just the cost of the vessel. The funds will permit the *Discoverer* to remain in the Antarctic for two years, though the Committee are desirous that it should remain there for three years. This will require, it is said, another 30,000*l.*, and it is a question at the present time if this additional sum will be raised. The expedition is to consist of sixty persons all told, which include the names of Lieutenant R. F. Scott, R.N.; Lieutenant Charles Royds, R.N.; Professor Gregory, Melbourne University, as head of the Civilian Scientific Staff; Mr. T. V. Hodgson, naturalist; Dr. Reginald Keottlitz surgeon, &c. It is needless to mention that in this expedition, like the other just referred to, photography will be a feature. Indeed, no expedition nowadays would be complete without photography.

\* \* \*

BIT by bit old London is becoming a thing of the past, and all that eventually will be left to show what it was will be photographs. Too often the taking of them is left until the work is in the housebreaker's hands, and the buildings are partly, if not wholly, hidden by hoardings or scaffolding. Newgate prison and the Old Bailey will soon be demolished, and those who desire to possess photographic records of the old buildings as they are should not delay in securing them. Neither of them are by any means picturesque, but they are interesting from the fact that they have been the scenes of the trials, and executions, of some of the greatest criminals of this country. Photographs of the interiors as well as the exteriors will be exceedingly valuable a few generations hence. Of course, permission to photograph the former will be required, and, as the red-tape formalities to be gone through to obtain it will take some time, we advise those of our readers who desire to secure photographs of the buildings, while they are intact, to lose no time in applying for the necessary permit. The

design for the new buildings, selected by the City authorities, is that of Mr. E. W. Mountford. It is somewhat of the Ionic order, and will be a totally different building from the existing ones.

\* \* \*

SMOKE and smoking chimneys are often great nuisances to photographers. It is therefore satisfactory to see that photography is occasionally an avenger. A few weeks back we mentioned that the Hammersmith authorities had produced, as evidence in the Police Court, photographs of certain factory chimneys caught in the act of emitting dense volumes of black and offensive smoke, in contravention of the Smoke Act, and a conviction followed, the magistrate remarking that the evidence was indisputable. We notice, from a report in a daily contemporary last week, that the inspector at Bradford has followed the example of the one at Hammersmith, and produced before the magistrates a number of chimneys of the defendants at the time they were pouring forth dense volumes of black smoke. Such evidence is incontestable, and we shall be surprised if it is not more made use of than it has hitherto been. We have just said that such evidence is not contestable, but possibly some defendants may produce photographs showing the chimneys when they were not sending out smoke, somewhat after the manner of the Hibernian, who, after the evidence of witnesses as to seeing an assault, averred that he could call scores of witnesses who would swear they did not see it. In any case, photographers will benefit from a business point of view.

\* \* \*

A FORTNIGHT back, it will be remembered, we referred to the objection made by the residents in the neighbourhood of Richmond to the site selected for the National Physical Laboratory in the Old Deer Park. This objection, it seems, is more general than we at the time imagined, for we see that a very influential deputation waited on Mr. Hanbury at the Treasury, on Friday last, in reference to the matter. The deputation, which included several members of Parliament, was introduced by Lord Balcarras, M.P. One of the objections raised to the present scheme was on the ground that the buildings would seriously impair one of the most beautiful views in the neighbourhood of London, and that it would also prevent any extension of Kew Gardens which may become necessary. Amongst further objections put forward was that the value of the land given to the public when Her Majesty presented the Queen's Cottage and grounds would be greatly injured if any building were erected in its immediate vicinity. In the end, Mr. Hanbury promised to carefully consider the views of the deputation; and so the matter rests for the present.

\* \* \*

SILVER phosphate printing paper, concerning which some little stir has been made in the United States, recently formed the subject of investigation by the Technical Committee of the Photographic Society of Philadelphia. The report of the experimentalist to whom the paper was referred for trial is not favourable to this resuscitated printing method. This gentleman says: "The members of the Society will remember that, at a recent wall display, two of Mrs. Käsebier's pictures created considerable comment, favourable and otherwise. They were made (so we were told) by 'an entirely new process or emulsion'—phosphate of silver. Phosphate of silver is not by any means new as a sensitiser for printing papers. It was

used early in the fifties. The present method is new only inasmuch as it calls for the use of an organic acid (tartaric or citric) in addition to the silver salt. In a recent magazine article upon the subject it was stated that 'it was made from silver nitrate, precipitated as phosphate by di-sodium-hydrogen phosphate ( $\text{Na}_2\text{HPO}_4$ ). To this well-washed precipitate is added tartaric acid solution to form an *emulsion*. This is smeared over the paper with a tuft of cotton or sponge.' I made a number of attempts, but could obtain no *emulsion*. The silver phosphate dissolved to a clear solution. This is silver tartrate in solution, and free phosphoric acid." Equally unsatisfactory are the recorded experiences of the silver phosphate paper's behaviour in practice. The experimentalist proceeds: "When this paper is exposed under a negative we obtain a print. The paper was said to be a quick printer. It required, in bright sunlight, twenty-eight hours to make one print from a weak negative, and about a week from a dense negative. This printed all day, also all night! This paper was not sized, and the image was very much 'sunk in,' flat, and very poor. I thought sizing the paper might help, so I sized some with arrowroot, worked out a few more chemical reactions, made up some more solution, coated the paper, and obtained prints quite different from the first. They look like very poor ordinary silver prints—waste-basket prints. Some of my prints, when viewed by very bright transmitted light, are not so bad. So much for the paper coated by myself. I have some paper which I received from New York, and which acts very differently. This has been sized with albumen, which keeps the emulsion more on the surface. It prints with fair negatives in sunlight in from two to seven minutes. Some of it is unevenly coated, which accounts for the streaks in some of the prints shown. Some of the coating is on ordinary charcoal paper, which has a very nice grained surface, but is difficult to work without tearing, as it becomes very filmy when wet. Personally I cannot see any advantage in the silver phosphate paper over any of the ordinary silver papers on the market. It does not compare with carbon, gum-bichromate, or platinum. The glossy surface is objectionable."

#### SITTERS AND THE PART THEY PLAY IN PHOTOGRAPHY.

It seems surprising, considering the wide-spread interest now taken in photography, that there should still exist so much misconception on the part of sitters generally in regard to the important part they play when being photographed.

In the matter of dress, for instance, it is surprising what an amount of difficulty professional photographers have to cope with when dealing with the public generally, and they are often surprised at the ludicrous examples in taste, both as regards the colour of the garments worn, as well as the style laid before them for some particular class of photograph, such as full lengths, or busts, &c.

It would appear as if a very general opinion prevails among a large section of the public that a photographer now can make a good picture out of any material or coloured garment, and that many of the earlier strictures with regard to dealing with certain colours which did not photograph satisfactorily are no longer in force, and so, when Mrs. So-and-So happens to become the happy recipient of an elegant new gown, or other fashionable article of wearing attire, which just suits her so

nicely, of course, the first thing resolved upon is to be photographed, so as to appear to the best advantage, and then it falls to the lot of the professional photographer to produce a picture, it may be, out of a garment that, in respect of colour, is about the worst possible, or in a style of portrait that does not lend itself to the particular garment at all.

Others, again, when circumstances arise necessitating the requirement of a portrait being taken, pay but little attention to the matter of the dress that best suits them, or which is more particularly suited for the style they desire being taken in, and, just because Mrs. So-and-So had such a nice full length taken, she would like to be taken in that style also, no thought being bestowed upon the suitability of the style for the garments worn, or that one sitter may suit a particular style of picture better than another. In the choice of style gentlemen sitters are quite as often as great offenders against good taste as ladies.

Of course there are exceptions, and sitters are found who can discern between what would be a suitable class of picture for the particular costumes they are wearing, such as knock-about attire, or cycling, boating, or other special class of garments. Others, again, have the good sense to be guided by the photographer as to what would be the most correct kind of picture to adopt in such summer garments; but it is surprising how many sitters appear to have only one idea as to the style they wish to be photographed in, and, no matter what class of costume they are wearing, their one desire is a vignettéd head and bust, a photographer often being driven to his wits' end to know how to persuade such sitters to select some more suitable style of picture. Then, again, in the matter of the wearing of hats or other head gear much ignorance is displayed, and it is difficult to get some people to understand that hats do not go well in a picture without any boots, and that they are generally worn out of doors, not inside, and also with other classes of head gear, which may be said to compose part of a costume, ludicrous effects are often desired by sitters.

It is well known that clever portraitists are often at their wits' end in devising alterations in the matter of dress as worn by their sitters, and not a few make bold enough to offer suggestions that necessitate the latter wearing borrowed plumes or garments, which they keep specially as a sheet anchor to meet some particular case with which they have to cope where some unsuitable article of dress, both in regard to colour and style, is worn. An example of this sort of thing may be cited in such an article as a light feather boa. A little consideration will show a photographer how much may be done with a garment of this description in the way of improving the appearance of a lady sitter. Take, for instance, the case of a lady who presents herself and asks to be photographed in a low bodice or evening dress. At a single glance the photographer notices first of all that the colour of the material worn is unsuitable, and also that the sitter's bust and neck, in vulgar parlance, are too scraggy ever to produce a pleasing result in the style desired.

Then comes into play his cleverness at *finesse*. Of course, it would never do at the very outset to pass any uncomplimentary remarks either as regards the dress or the physical condition or appearance of his fair sitter, but he can, by cleverly displaying one or two charming stock specimens, in which the aforesaid boa is so well introduced, eventually succeed in persuading the lady just to try it on, as it were, and then, by means of a little flattery when it is artistically entwined

around the neck and shoulders, and artfully displayed to cover up the scragginess, he will certainly have gained his point in more ways than one, and accomplished much to ensure a result that will afford satisfaction. In the matter of costume pictures, again, there are numerous other accessories and artifices known to clever operators that go far to please customers. We can well remember what a clever photographer (who has long since gone to his rest) did in bringing under the notice of his Scottish sitters a very handsome Highland costume specially kept for the purpose of this particular class of customers, who insisted upon full-length portraits in the most unsuitable dresses. "I have photographed that kilt thousands of times, 'he said,' and it's paid me weel."

It is, however, in the matter of wearing unsuitable colours that the public generally err most; and when it is borne in mind that a photographer is still practically powerless to portray in their true colour-values all the various hues met with in the different articles of ladies' attire, it will soon be evident that the more a sitter studies to appear in a dress that is suitable for photography, the better are the chances of satisfaction being experienced by all concerned.

No doubt every lady has a strong partiality for one, or, at most, two particular colours. These she looks upon as "*her colours*," and wisely so, perhaps, and makes a rule to adopt it in her wearing attire, simply because they suit her best. On the other hand, they possibly may be unsuitable for photography, for, when it is remembered that yellow, salmon-pink, and fawn all yield a greyish tint in the resulting photograph, and that light greens and blues yield white, while dark green and dark blue come out almost black, it is not surprising that disappointment often is felt at the results produced.

Then again, where a combination of colours is worn in a costume, a very wide range of different tints will result; hence it is evident that some thought should be bestowed in the selection of those colours that will best harmonise or combine well. White, grey, and black are looked upon as the most suitable tints for photographic purposes. The former will combine well with black or dark blue, or red or brown, simply because all these hues yield a dark tint in photography. Grey will be found to combine best with white or black, and black will combine equally well with light blue or light green or grey, simply by reason that these colours, as previously stated, yield a light tint.

It is, however, not only in the matter of colour that attention should be given to what is best to wear. There is, also, the question of the most suitable material.

Velvet has always been recognised as perhaps the best of all photographic materials, and it will be found to combine well with linen, lace, crape, and fur.

Silk, as a rule, does not combine well with linen, but cloth will generally be found to combine well with the same materials as velvet does. Fur will be found to combine with silk and lace, and many kinds of cloths and serges go well with silk. White calico will work nicely with linen and the different cloths.

Some consideration should also be bestowed upon several other equally important matters, especially that in regard to the manner in which the hair is worn. This is a matter that concerns every sitter in a marked degree, and, although, to a certain extent, will be dependent upon fashion where ladies are concerned, it, however, ought never be per-

mitted to interfere with one's particular individuality. Of course, clever portraitists have their own ideas in this matter, and, if left to themselves, might offer suggestions which would not meet with the approval of many of the fair sex. No doubt, however, a clever operator can take advantage of the style the hair is dressed in by so posing the head as will yield the most pleasing effects.

For instance, it is well known long drooping curls are best suited to a head in profile, and a fringe of hair can be made to suit certain kinds of foreheads, which would be out of the question with others.

One of the first things a portrait photographer has to get accustomed to is "disappointment." No one need attempt to try and satisfy every sitter that comes before him; and, strange as it may appear, it frequently happens that, by reason of an outrageous taste on the part of a sitter, the most satisfactory results to a photographer will often fail to please his clients, and to such an extent will this be experienced that there will be times when an operator feels so disheartened as to be inclined to throw portraiture overboard entirely. Such fastidious people, however, seldom get pleased anywhere, and this should be kept in mind by those who suffer such disappointment.

We know of one case in a group picture quite recently taken where a most excellent result was obtained in the case of over a hundred sitters. A schoolmaster found fault because the ends of his moustache were not sufficiently curled up. Operators, however, after a time, get accustomed to these little cranks on the part of their sitters, but they prove very annoying at the beginning of a career. All considered, portraiture is not the most pleasant branch of photography, and it takes a man with a more than usual amount of tact to cope with the many silly weaknesses on the part of both male and female sitters.

On the other hand, the world is not made up entirely of cranks or those who are seldom satisfied. There are reasonable and sensible people to be found, who know that sitters have their part to play in portraiture as well as the photographer, and it is a pity there are not more of them in the world.

---

**Photography at the Royal Society's Soirée.**—At the recent *Conversazione* of the Royal Society, Mr. J. Mackenzie Davidson, M.B., exhibited a stereoscopic fluoroscope, by means of which an observer is enabled to see the shadows cast by Röntgen rays on the fluorescent screen in stereoscopic relief. With this instrument a bullet, or needle, &c., can be seen in its true position, and its anatomical relations observed, and the surgeon can easily touch the bullet, &c., with a probe or forceps, while he is looking at its shadow on the screen. The position of a Mauser bullet in a leg of mutton was distinctly found by this means. The Eclipse Committee of the British Astronomical Association showed a number of interesting drawings and photographs of the total eclipse of the sun on May 28 last. A further number of photographs and drawings of the same subject were also exhibited by the Royal Astronomical Society and the Joint Permanent Eclipse Committee of the Royal and Royal Astronomical Societies. Professor Silvanus Thompson, D.Sc., showed some experiments on the aberration called "coma." Coma is an aberration due to the several zones of the lens not having equal focal lengths, and hence, when the lens is transmitting an oblique pencil, the unequal refraction of the different parts gives rise to a singular unilateral distortion of the cones of rays traversing the various zones. The actual path of the rays was very distinctly shown by means of a smoke box, which they traversed.

**Reflective Power of Metals and Alloys.**—In our issue for May 25th last we inserted a note as to the new alloy, magnalium, of Professor Mach, in which its great reflective power was mentioned; the following note, therefore, by Herren Hagen & Rubens, in the *Zeitschrift für Instrumentenkunde*, will be interesting. It gives the results of a long series of researches and the means of numerous measurements are given for various portions of the spectrum, 50  $\mu$  apart.

- L. Mach. I. : 2 Al : 1 Mg.
- " VII. : 1 Al : 1.5 Mg.
- " XII. : 1 Al : 1.75 Mg.

**Recent Progress in the Aluminium Industry.**—

Under this title Prof. J. W. Richards, of Lehigh University, recently read a paper before the Franklin Institute, which gives an excellent *résumé* of the present state of the manufacture of this metal and its alloys. To give some idea of future possibilities, we may note that Prof. Lehigh estimates the actual cost of production as probably about twenty cents a pound, and its selling price thirty cents in the United States and twenty-five abroad. With prices so low as this, and with no probability of any increase—the reverse is more likely—it is somewhat singular that more use is not made of the metal than now is the case, especially in the construction and manufacture of photographic articles in which lightness is, in so many instances, of such prime importance. Still more striking is this when we remember that, bulk for bulk, aluminium, being so much lighter than brass or copper, actually costs less. Thus, brass and copper are set down as being fifteen and seventeen cents respectively per pound; but an equivalent bulk of aluminium—*i.e.*, one-third of a pound—costs only eleven cents. It is true that the soldering is still a difficulty with this metal, and that cutting a screw thread is far less satisfactory than with copper; but these difficulties vanish when an alloy, instead of the pure metal, is used, and it is probable that it is an alloy of one kind or another that which will have the greatest future. The amount of material required for the purpose of alloy is remarkably slight; thus, Prof. Lehigh states that five per cent.

of copper makes a strong metal as rigid as bronze, but of only one-third its weight. If zinc replaces the copper, thirty per cent. is needed. He mentions specially the alloy made by the Delaware Metal Refinery, which is "a hard, white alloy, specific gravity 3.1, melts clean, runs fluid, makes beautifully sharp and perfect castings, turns and machines like the finest brass, polishes well, and, to conclude, is fully as strong and rigid as gun metal or the best of the ordinary bronzes." It is made principally of aluminium and zinc, and sells at the same price per pound as pure aluminium. The lecturer stated that it was largely used by Philadelphia firms, who were quite enthusiastic over its possibilities. With such strong *ex cathedra* utterances before us, we may justly anticipate seeing lenses in aluminium alloy settings quoted at the same price as brass, and camera fittings, tripod tops, and a host of other minor pieces of brasswork, all replaced by a light alloy, without any increase of cost, if not, indeed, at a cheaper rate than brass. Among other important uses of aluminium is that of making plates for lithographic printing, and already it is being very largely used. It is in some respects superior to stone, and possesses the inestimable advantage of being able to be bent into a cylinder, and thus allow of fast running in printing. It is replacing silver leaf for decorating. "Silver-edged" mounts may now be made which will not turn black with keeping, and the same may be said of "silver" printing with aluminium. It is capable, after rolling into sheets  $\frac{1}{2000}$  of an inch thick, of being beaten out to  $\frac{1}{70000}$  of an inch. Finally, we may say that, alone, or mixed with magnesium, it is capable of replacing that metal for flashlight photography.

**Enamel versus Oil Paint.**—The well-advertised enamel paints are well enough known, but the extent of their durability is matter for discussion. Recently the results of series of experiments, extending over a period of years, has been made public, and they are highly satisfactory. About 300 plates of sheet steel were carefully cleaned and freed from rust and scale, and then covered with three coats of the enamel or paints to be tested. One-third of these were sunk for two years in a fresh-water lake, another third suspended from a float in sea water, and the remainder in sea water in another region. The enamel paint stood the best by far, and those that had been baked were the best of all. A number of the plates were absolutely unaffected by their long immersion. It did not seem to matter much what pigment was made use of, with the one exception of red lead, which, in the case of the oil paints, proved the best. Professor Sabin explained the difference between oil and enamel paint. Oil paint is made with raw linseed oil, to which is generally added a "drier." Such a paint will "dry" in about five days; but, as that is an inconvenient time to wait, a "drier" is used, generally "boiled oil," *i.e.* linseed oil boiled with litharge and a little manganese oxide. In enamel paints the oil is replaced by a varnish made by dissolving a resin in a mixture of oil and turpentine. Enamel paint ought to be far superior to oil for the important purpose of painting studio lights, though the simple varnish itself is said to be superior to the mixture of varnish and pigment. It is, however, a question whether, for this purpose, the best compound would not be a mixture of varnish and linseed oil in the proportion, say, of three to one. Any tendency to brittleness would be mitigated, and we should have the advantages of both kinds combined. Another use for enamel paints is indicated by the report of their durability when exposed to water, *i.e.* coating of wood vessels to make them waterproof. A large porcelain dish is costly, but a light but tight-built wood dish or trough, painted three times with enamel paint, ought to be most useful for the majority of purposes, and would be kept in perfect condition by a periodical coat of paint. Professor Sabin measured the thickness of the films made by two coats of paint, and found it to be from  $\frac{1}{250}$  to  $\frac{1}{500}$  of an inch in thickness.

**Photography of the Smallest Wave-lengths of Light Rays.**—Professor Victor Schumann, after several years' interruption, has resumed his work in this direction, and in March

last read before the Imperial Academy of Sciences in Vienna a paper describing his latest results. For these short wave-lengths it is known that glass lenses and prisms are not available through being opaque to the rays, but fluor spar and quartz, not resisting their passage, is employed in lieu of glass. He finds, however, that the photographing of the short waves becomes increasingly difficult as the waves are reduced in length. A piece of quartz  $\cdot 5$  inch thick absorbs nearly all the rays beyond  $150 \mu\mu$ , while fluor spar acts in a similar manner, but up to  $100 \mu\mu$  is much more transparent than quartz, but it weakens in a striking degree all the more refrangible rays; for example, in only  $\cdot 5$  mm. thickness it more than doubles the time of exposure. In using the Cornu quartz prisms, which are joined together by glycerine, he thought the latter might be opaque, and his investigations showed that "glycerine is not so indifferent towards the above-mentioned regions of the spectrum as it has been proved to be in the less refrangible red-violet, according to the investigations of Eder and Valenta. Two quartz plates cut perpendicular to the axis increased the time of exposure to the aluminium rays from 18 to 25, from 11.4 to 25, from  $\cdot 08$  to 25, according as the wave-lengths became shorter. The introduction of glycerine caused an increase of the time thus: the 18 to 25 became 19.5 to 25, and the  $\cdot 08$  to 25 became 17.5 to 25. It is only on the smaller of the ultra-violet rays that these obstructions were shown, with the coarser waves he was not able to observe that the glycerine  $\cdot 1$  mm. thick produced any effect. It is, however, a just deduction from the above facts that, as Professor Schumann states, "it is evident that the most refrangible rays must be carefully dealt with in order to obtain their intensity undiminished."

**Value of Pictures.**—It is interesting to note the high prices, and sometimes low ones, that the works by leading painters realise at auction sales. One day last week four pictures by Sir Joshua Reynolds, at auction, realised the goodly sum of 11,000 guineas. They were portraits, and not of any very great notabilities, and it is tolerably well known that this class of picture, even by the most eminent artists, is not of the same value in the market as figure and landscape subjects. The portraits were of Mary Arundel, wife of the seventh Baron of Arundel; the Baron; Mary Conquest, wife of the eighth Baron of Arundel; and the Baron himself. All of them were in their peer's and peeresses' robes, and, being by Sir Joshua, it is scarcely necessary to say they are very fine pictures. Still, the price paid for them strikes one as being a little high, seeing that they were portraits. It would be interesting to know if these pictures had been valued by experts, and at what sum they were assessed. A little while ago we commented upon the fact that, at the sale of the Peel heirlooms, two pictures fetched, at auction, nearly four times the sum that experts valued them at if disposed of that way. Evidently the value of anything at auction sales, even photographic apparatus, is what it will fetch, and that is not a fixed amount.

#### JOTTINGS.

WELL-WISHERS of the Photographic Salon are, no doubt, grateful to the JOURNAL for having called attention to the fact that the "General Committee of the Photographic Salon," to whom exhibitors are invited to submit their work before it secures the very great honour of being hung, is mostly composed of dummies and dead-heads. The names of some of the foreigners must be absolutely unknown to the photographic "man in the street." For example: A. Alexandre, A. Buschbek, Hector Colard, A. Hildesheimer, R. Ladevèze, L. David, Otto Scharf, J. Strakosch, Carl Ulrich. So far as can be discovered, these men have no present-day connexion with British pictorial photography, and the aspirant for the much-coveted fame of an appearance on the walls of the Dudley Gallery may well ask who they are, and how they derive a right to act as London Judges of photographs. Again, besides several more of these superfluous foreigners, such men as Bhedwar, Eickemeyer, Stieglitz, Kieley, and G. H. James, live abroad, so that their inclusion in

Piccadilly Committee is not of much use. Moreover, it would be decidedly interesting to know what practical interest is nowadays taken in pictorial photography by J. S. Bergheim, Valentine Blanchard, R. Briant, B. Gay Wilkinson, Henry Van der Weyde, William Willis, Alfred Maskell, and others who might be named. My old opponent, the first Hon. Secretary of the Salon, I am informed, has given up photography altogether, but I suppose his name is kept on the list for the sake of appearances.

My point in this matter is, that the imposing list of sixty or seventy names which make up the General Committee of the Salon only exists on paper. I should run the risk of being charged with unpleasant personalities if I carried my analysis of the Committee as far as I might and could; but it will meet the needs of the case if I say that, of these sixty or seventy Committee-men, ten or a dozen only figure amongst the active administrators of the Exhibition. The remaining forty or fifty do not participate in the work of selection, so that the presence of their names in the list of the General Committee is a sham. The Salon is the only photographic Exhibition that I know of which is advertised by means of dead-heads and dummies. Such people have their uses only in that their names look well on a prospectus. A big list possibly creates an imposing effect in the mind of the would-be exhibitor. He, perhaps, pictures the General Committee as a great international conclave of pictorial photographers, turning up, to a man, at the Dudley Gallery, and laboriously "selecting" the exhibits. In fact, he not unnaturally supposes that all these people take some interest in the Salon Exhibition, and really trouble themselves about the matter. Not a bit of it. The General Committee is very largely a myth. The work of selection is done by a *coterie* of Londoners plus an occasional countryman. This is not a matter for blame or censure, and it probably cannot be avoided; but, in the interests of the exhibiting public, I decidedly think that the real state of things should be made plain on the prospectus. A man sending in a photograph to the Dudley Gallery does so on the virtual representation that it passes before a Selecting Committee of sixty or seventy men, or a Sub-Committee chosen therefrom. Why not let him know who are to be his actual judges or selectors—as is done elsewhere—and not mislead him by parading before him a long string of unnecessary foreigners and well-named supernumeraries who have no interest whatever in the Exhibition?

THE five-hundredth anniversary of the birth of Johann Gutenberg, the inventor of printing, has just been worthily celebrated at Mayence. The German press has extolled him as the Herald of the Modern Era, the man who contributed more than any one else to knock off the fetters of mediævalism, the forerunner of reformers, the liberator and awakener of the masses, the creator of the technical instrument which has been so mighty in battle for truth, liberty, righteousness, and one of the few who has made the world happier and better by his invention. A few years ago we should have called this sort of thing Americanese; to-day we accept it as a matter of course from a country where trumpet-blowing is part of the national education. The Gutenberg celebrations have set me wondering whether the memory of Fox Talbot will be honoured in a similar way when the age of photography comes to be reckoned by centuries. How many of us will be here in 1939 to join in any movement that may be made in honour of the great Englishman? The invention of printing types was, undoubtedly, a great thing in its way, but I am inclined to think that future historians will place paper photography, as devised by Fox Talbot, on a still higher plane of merit. Talbot was the first to show how a print from a negative might be made, and one need have no difficulty in tracing to that source all the wonderful, the fairy-like developments of photography that have since followed. But experience shows that it takes a very long time before really great inventions quite grip the popular imagination, and it is therefore fairly certain that nothing less than the celebration of a centenary of photography is needed to enlighten people at large as to the vast benefits which Fox Talbot's work has conferred on humanity.

THE dissociation of Mr. John Howson's name from participation in the management of the Britannia Works Company must not be allowed to pass without recognition of the strong and prominent part which that gentleman has so long played in photography. For ten years "Howson" and "Ilford" have been names that have been inextricably linked together. The splendid energy which Mr. Howson always ungrudgingly expended in the interests of his Company has earned a rich reward, and there is no doubt that the great plate and paper-making works at Ilford are to-day one of the most solidly established concerns in the trade. I am sure that, with whatever new enterprise Mr. Howson may elect to connect his future energies and fortune, he will carry a large volume of good wishes with him. He and the Britannia Works Company practically revolutionised the plate and paper trade during the last decade; but it has been, I am firmly convinced, for the good of British industry and British photography. At the time when the Britannia Company came to the front it certainly looked as if the whole of the trade in plates and papers was likely to slip into Continental hands. Happily, such a state of things has averted, and to-day sensitive photographic preparations made in England compete in price and quality with the products of America and the European Continent. I hope it may always be so, although it is rumoured that within the next few years a determined attempt, backed up by practically unlimited capital, will be made to place the control of the English plate and paper trade in other hands.

It was Mr. Gladstone who was credited with the faculty of extracting poetry out of figures. His annual budget statement distilled with dry-looking numerals, and yet it is said that the matchless orator could so present the meaning of the vast sums he dealt with to the minds of his hearers that he held them spell-bound by the demand upon the imagination which was made by a study of what was meant by the movement of millions of money amongst the people. Some of the great advertisers have evidently taken a leaf out of Mr. Gladstone's book. A tea firm tells you, for example, that its annual output, if packed in pound boxes, would reach twice round the world; a beef-extract house proudly boasts that it sends out so many millions of comforting cups a year, and so on. The imagination is compelled to play a large part in modern trade. I wonder what some of the photographic advertisers do not take the hint, and tell us how many square miles their output of plates and papers would cover. The figures would look good in print—and advertising space is so cheap. Only the other day Mr. Wellington, of Messrs. Wellington & Ward, told me that his firm had received an order for *six miles* of bromide paper forty inches wide! What becomes of the vast area of sensitive photographic surfaces annually sent out by the manufacturers? The mind reels at contemplating the tremendous amount of photographic printing that goes on in our midst. And yet there are some croakers who will have it that photography has seen its best days! I am firmly convinced that the halcyon time has not yet been reached.

Portrait photographers, especially those who make a speciality of taking little children, might find use for the following hint: A friend of mine was recently presented by his wife with one of those little pledges of affection which create so much noise in the world in the early days of their arrival, and he was so pleased at the event that he made it public in the advertisement columns of his favourite newspaper. Then the postman became very busily engaged with the knocker and the bell at his front door. Quite an army of astute tradesmen made a note of his address and sent him samples of infants' foods, catalogues of baby-linen and perambulators, betting men's cards, loan-office literature, and other supposedly indispensable requirements of child-rearing; but, amongst the assorted collection of touting circulars, my friend tells me that no photographer thought it worth while to be represented. He seemed to think that having the baby photographed is looked upon in most families as an event of such importance that photographers miss many chances by not studying the birth announcements in the newspapers and, at a discreet interval, sending the parents a prettily got-up invitation to have the little one's "likeness" taken. There may or may not be

something in the idea; but here it is for those most concerned to adopt it or not as they may think fit.

STAGNATION governs most branches of industry just now. The cry is that the war is hindering trade, and a common topic of conversation is that matters will not mend until the Chinese and African wars have been followed by a General Election. There appears to be a strong feeling that an appeal to the constituencies will be made during the present summer and coming autumn. Five years ago, when the last election took place, many photographers profited by the opportunity to dispose of portraits of candidates, &c. The work of the camera is very considerably availed of in modern electioneering, and the photographer who during these dull times casts about him to see in what way he can turn things to account when a dissolution is decided upon by the ministry will not have expended the necessary forethought in vain. The publishing trade, I learn, suffers keenly from the war fever, which detaches men's minds from subjects upon which they naturally dwell in times of peace. Were it not for the wars, it is safe to say that the coming autumn would witness the output of a great variety of books dealing with the history of the century, which closes on December 31 next, and in the production of these books photographic and phototypic illustrations would be greatly availed of. It is reasonable to suppose, however, that a branch of photography—optical lantern work—which last winter was virtually wiped out, will, during the season of 1900-1901, regain its temporarily lost popularity. In this respect there is much ground to be made up. "When Johnny comes marching home" in his tens of thousands, he should give a much-needed stimulus to trade in general and the photographic branches of it in particular. Meanwhile, photographers will be well advised to keep an eye on the General Election, and the chances it may offer of increasing their businesses.

ONE or two extracts from a little article on business suggestions may be of interest to many professionals who are not too proud to learn and study the causes of other people's success. The writer, an American, advises his readers to "make it a point never to throw cold water on a customer's expectations by telling him that you really cannot give a definite promise as to when work can be finished, as though your inability to do this was proof of the popularity of your work, for no matter how good a thing is the public will soon cease to take any interest in it if it is not forthcoming when wanted. Explain the uncertainty of the weather if you are not using a developing paper, but tell definitely when the retouching will be completed, and convey the impression that your business is alive and that results will be forthcoming promptly." This advice, boiled down, means, in the jargon of the time, "Don't give yourself away to your sitter." The writer also relates how a photographer of his acquaintance obtained a splendid advertisement amongst his sitters by holding an invitation exhibition of his best work. The studio was thoroughly renovated and rearranged, so that to even old patrons it had a changed appearance. Abundant floral decorations enlivened the effect, and a small orchestra supplied appropriate music. The pictures, which were the centre of attraction, were arranged to the best possible advantage and grouped in accordance with their characteristic features. The proprietor, assisted by his chief operator, devoted himself to explaining how the various effects in lighting, posing, and printing were obtained, calling attention to the various styles of finish, mount, and framing, with a view of familiarising the public to as great an extent as possible with the possibilities of artistic photography, not only in the direction of cabinet pictures, which has come to be the standard and almost the limit of the public's appreciation of a photographer, but rather of life-size portraits, demonstrating the possibility of obtaining portraits which rival the effects of the painter at a price which seems extremely moderate when compared with the cost of an oil painting. In fact, the photographer held a kind of musical at-home, at which he constituted himself art-critic-in-chief of his own photographs! An astute notion, at any rate, and one that probably brought its own reward.

COSMOS.

## LIGHT SCREENS.

A CURSORY examination of most opticians' catalogues which are now issued will at once show that almost every lens is advertised to cover with a small stop a much larger plate than it will with its full aperture; in fact, this is advanced as one of the great advantages of the newer forms of lenses which are now constructed. That this property is by no means confined to these new lenses is, of course, a well-known fact, but they have at least the advantage of covering a larger plate at a larger aperture than the old rapid rectilinear.

Whilst the word "covering" is used most generally, we think it would be far better to find some other term, which should express briefly what is meant, which is, of course, that the lens will define sharply over a given sized plate.

To the man who uses many different-sized cameras a lens of this character, which can be used indiscriminately as a narrow, a medium, and a wide-angle lens at will, is, of course, a great convenience, but it is an open question how many times a lens is thus used. The amateur worker is usually content with one camera; if he has two, he is frequently extravagant enough to have practically two sets of lenses. The professional, on the other hand, may thus use a lens because a complete battery of lenses for each camera means a locking up of capital which, possibly, the advantage in results does not warrant.

Let us assume, however, that a lens of this character is used, and we will take a specific instance. A six-inch anastigmat was purchased for a quarter-plate hand camera, and this was advertised to "cover" that sized plate with full aperture, a  $5 \times 4$  with  $f-11$ , and a half-plate with  $f-16$ , statements which were sufficiently borne out on testing to need no special comment; but it was found that, when the lens was raised above the centre of the plate by three-quarters of an inch, there was considerable falling off of definition in the margins of the lower half of the plate, necessitating the insertion of a stop. This has been mentioned incidentally, as it is not the particular point to which attention is to be directed.

On placing the lens on a large camera, and stopping down to  $f-45$ , the circle of sharp definition was found to have a diameter of 9.5 inches, that is to say, the area of the circle of light was approximately 71 inches, and, as the lens was to be used on a quarter-plate, or on a circle the area of which would be approximately 22 inches, it is obvious that there is a great deal of light which is not only useless, but may be prejudicial, for, although the interior of the camera bellows is always black, the black is by no means that of lampblack, which, under the most favourable conditions, will reflect from 3.5 to 6 per cent. of the incident white light. It may be said, of course, that the corrugations of the bellows will stop the greater part of the light, and, whilst this is true, it is only necessary to project a strong parallel beam of light on to one side of the bellows to see how much light is visually reflected; and, as the dry plate is far more sensitive to faint lights than the retina, one can readily understand how this superfluous light may cause a general superficial fog. It may, of course, be advanced that this general fog can only be of such a slight nature as to in no wise affect the image, or, in fact, that it may be actually advantageous as assisting to overcome the initial inertia of the silver haloid, and thus give a more fully exposed negative, just as it is said an unbacked plate does. For those who believe in this statement their obvious course is to use unbacked plates and their cameras as now built, or, to carry the argument to its logical conclusion, to actually line their cameras with a stronger reflective material than that at present employed.

The destruction of this reflection by either the absorption of the whole of the light, which is an extremely difficult thing to do, or its prevention by the exclusion of the superfluous light, is possibly worth the attention of those who like clean negatives which only bear the image as formed by the lens. Whilst all our plates are rectangular, the light transmitted by the lens is always a circle, so that it would seem but reasonable to suggest that the use of rectangular "light screens" should be adopted. The idea of such screens is by no means new, it having been broached at least by Furnell (*THE BRITISH JOURNAL OF PHOTOGRAPHY* for 1881, p. 322) who suggested an arrangement of this kind within the camera.

It may possibly be permissible to interpolate here, as a sarcas commentary upon the article, "About Photographic Patents," p. 38 of June 22, that a similar arrangement was patented in 1893 (Ap 12, No. 7481), twelve years later.

The exact position of these light screens as regards the lens is no moment, that is to say, they may be placed in front of or behind the lens, the latter being more convenient if the bellows rise when the lens is raised, otherwise before the lens should be chosen. It is of considerable importance, however, to determine their position: they have a fixed aperture, or to determine their aperture if they have a fixed position. When the light screen is placed inside the camera, which can easily be effected by cutting it of stout celluloid, ebonite, or millboard, and wedging it in the folds of the bellows, its aperture may be determined by drawing a straight line equal to the diagonal of the plate and joining the two ends with those of a straight line equal to the diameter of the diaphragm, thus forming a truncated cone, and one has only to determine at what distance from the diaphragm the light screen is to be placed to have at once the side of a square which shall effectively cut off most of the superfluous light. As, however, we never use square plates, the sides of the light-screen aperture should bear the same ratio as the sides of the plate, and to find this out a very simple procedure is required.

Let us assume that we are to use a lens of 6 inches focus and full aperture of  $f-6$  (in this case, for convenience, the actual, and not the effective, aperture is taken; to be strictly correct, the latter should be calculated), and the plate is to be  $4\frac{1}{4} \times 3\frac{1}{4}$ , and the light screen is to be fixed 2 inches from the diaphragm; then, if we call the light screen  $l$  and the plate  $p$ —

$$l : p \text{ as } 2 : 6.$$

Therefore for the longer side we have—

$$\frac{2 \times 4\frac{1}{4}}{6} = 1\frac{5}{12} \text{ for the longer side,}$$

and

$$\frac{2 \times 3\frac{1}{4}}{6} = 1\frac{1}{12} \text{ for the shorter side.}$$

Now, the sides of a rectangle inscribed in a circle of 1 inch diameter, that of the diaphragm, will be as  $\frac{1}{2}\sqrt{2}$ ,  $\frac{1}{2}\sqrt{2}$ , so that for the final size of the light screen we get for the longer side—

$$1\frac{5}{12} + \frac{1}{2}\sqrt{2} = 1\frac{9}{8} \text{ inches (= 2 inches approx.),}$$

and for the shorter—

$$1\frac{1}{12} + \frac{1}{2}\sqrt{2} = 1\frac{4}{8} \text{ inches (= } 1\frac{1}{2} \text{ inches approx.).}$$

Actually a light screen should be calculated for each diaphragm, but one will generally be found an improvement. Whatever material be used, its anterior surface—that is, the one facing the lens—should be covered with black velvet, and, if matt celluloid be used for this, there is not the slightest difficulty in cementing it down by using sheet celluloid dissolved in amyl acetate, or even moistening the surface with the acetate or acetone and pressing into contact. If wooden frames be used, a rabbet can be fitted, and it can then be used for carrying an isochromatic screen.

## MERCURY-URANIUM TONING OF PLATINUM PRINTS.

[The following paper, which was read at a meeting of the Photographic Society of Philadelphia earlier in the year, has been in type for some time, but has had to be held over for several weeks through pressure on our space.—Eds.]

THE fact that black undeveloped platinotype paper can be toned sepia by simple development is probably well known to many workers of this paper. One of the advantages of the carbon process is the fact that any coloured tissue may be used with the same facility. Still, in the platinotype process, many, in fact about all, the colours we desire may be obtained by toning. It would make this article too long to take up every possible colour, and I have therefore considered only those that will be of general use. These are various shades of sepia, brown, and red.

The sepia tone is produced by developing in the bath for the black paper, to which mercuric chloride has been added. The two solutions needed are, first, the usual platinotype developing salt, dissolved in fifty ounces water; and, second, a solution of one part bichloride of mercury in twenty-five parts water. On account of the varying solubility of this reagent, it is very inadvisable to use a saturated solution. This is mentioned, as some formulæ have been published, giving a saturated solution

of this salt; but, as it is soluble in 3 parts of boiling water and in 16 to 19 parts of cold water, you will see that a saturated solution is rather an unknown quantity. It is so with all salts, unless the temperature is given.

One part of this mercury solution is mixed with eight parts of the developer, and the bath is ready. The print is floated and developed in the regular way, and then placed in a hydrochloric acid bath, made by diluting the usual bath (1 part acid, sp. g. 1.16, to 60 parts of water) with 4 parts water, making a bath of one to 300. On testing the wash waters it was found that, after three washings in this strength of acid, all the iron had been removed. Should you wish to test for iron, the ferrocyanide of potassium should be used, for, while it is true that light reduces some of the iron to a ferrous salt, yet I found most of it in the ferric state, and the ferrocyanide and not the ferricyanide is the reagent. Should an acid bath of the usual strength be taken, it will cause the tone to rapidly fade out. One of the experiments with this toning is shown, the five prints, all printed to the same depth and mounted with the actinometer proof, being on one card.

The first is developed without mercury; the second with 1 part of the mercury solution to 32 parts platinum developer; third, 1 part to 18; fourth, 1 part to 12; and fifth, 1 part to 8, this latter being the correct amount.

This experiment is shown, not only for the tones produced, but it indicates how a rather flatly made print, whether over-printed or from other causes, can be made to look well, as the process seems to counteract flatness. This, in itself, is a good point, without regard to the colour of the print. You will note that the first weak additions of the mercury produce a muddy appearance in the prints, but when the proportions are correct this clears up entirely.

The question has been asked, "Is this colour permanent?" I think it is. I have one print that has been subjected to daylight for a long time. It was framed and hung near a window for three years, and, although the wall paper around the frame showed signs of fading, no difference could be seen in the tone of the print.

The question may also be asked, "Why not use sepia platinotype paper, and not tone?" The effects produced by the two processes are not alike, and we are able to produce any shade, with much less effort, by the toning method; and also, if the sepia is not entirely satisfactory, the toning can be continued into a deeper sepia, brown or red, by uranium. Before taking up local toning with mercury we will consider the uranium bath.

This bath is generally used in connexion with the mercury toning just described. However, a black print can be toned to a sepia brown or red by simply immersing it in the uranium bath, but the toning is very slow. The prints we have were so toned, and were in the bath about one hour. They had been black platinotypes, developed some months before the toning took place.

The best way to use this bath is to develop the exposed print in the oxalate developer, to which is added only half the strength of mercury that is used for sepia toning. By this development it acquires a faint sepia, being then well washed in the weak acid bath, and later in water. It is then toned in the following bath:—

Ten per cent. solution uranium nitrate .....	2 drachms.
"    "    ferricyanide of potassium    2    "	
Acetic acid .....	1 drachm.
Water .....	10 ounces.

The tone will go into a deeper sepia and various shades of brown and red. Almost any shade desired can be obtained, this toning being fairly rapid.

I would urge that no one put the hands in these toning solutions. This applies to both the mercury and the uranium baths, for they are both extremely poisonous and attack the skin. I found that one hand protected with rubber finger stalls was ample protection, and there is no necessity for these solutions touching the hands.

We now come to local toning. The local toning in itself is very easily accomplished, but, when one tries to combine two colours harmoniously, it will require, first, that the negative be of such a character as lends itself to two colours—and you will find very careful selection is necessary, for not many do this. This is really the most important point in local toning.

Second, the graduation of the two colours must be well balanced, so they merge one into the other. Try to paint a water colour in but two colours, and you will appreciate the difficulty encountered in this work. If the two colours do not harmonise, and good taste is not exercised, the result is entirely without artistic value. But this toning has a future for those who will work at it from an artistic standpoint.

One method is as follows: The undeveloped print is covered over entirely with a thin coating of glycerine, well rubbed in, and the surplus removed by a blotter. When the coating of glycerine is perfectly even, a brush is dipped in a mixture of equal parts glycerine and the mercury developer. Almost all of this must be removed from the brush, leaving only sufficient to work with, as there is no way of doing good work with a surplus on the brush. The portions to be toned are brushed carefully until the image appears, at which point it is quickly plunged into the black developer, and all portions, except the brush work, will come up in black. It is well to go over the surface with a wad of cotton, while in the bath, to ensure even toning. It is then washed in a weak acid bath, and finally in water. Another method of brush development is to cover over with glycerine all the parts of the print which are to remain black, leaving those parts which are to be toned sepia entirely free from glycerine. The uncovered parts are then filled in with the same mixture as above, the rest of the process being same as before stated. This tends towards less liability of making errors in the location of the sepia tone, and by having a blotter constantly at hand one can easily prevent the tone extending where not wanted.

Now, it is not necessary that this local application of the mercury developer should produce the correct tone. It is only necessary that it be applied where the tone is needed. Should the tone not be what is wanted, or should it fade in a too strong acid bath, the correct tone can be readily obtained by using the uranium bath. This will not only give the mercury sepia colour, but it will also give any deeper shade required. Some of the prints here were left in the acid bath until of an even black all over, but they immediately took the sepia locally when placed in the uranium bath.

The brush used for this mercury toning must not be used when black tones are required.

To produce the local uranium tone, after completing the above work, the print is immersed in the uranium bath, and the portions covered with mercury will soon tone to the colour desired. Should it be too deep, a weak solution of sodium carbonate will reduce the colour, but a little acetic acid should be added to the wash water if soda is used. In fact, as the water is usually alkaline, it is a very good idea to always use a little acetic acid in the washing, for an alkaline water will soon wash out the colour.

There is also another way, which, however, can only be used with certain prints; but where it can be used I think it is one of the most satisfactory means of producing local toning. It refers mostly to portrait work, and might be called selective toning. The negative should have almost clear glass for the blacks; that is, in portrait work, the background and drapery should be black.

When a print made from such a negative is immersed in the mercury developer, the deep blacks develop black, while the face and any light colour appear sepia, thus giving the effect of two colours on one print. The result is really usually more harmonious than that obtained by the glycerine method. Some prints are shown, developed in this manner, both by mercury and by mercury and uranium. The latter tone is obtained by simply placing the mercury-toned print in the uranium bath.

You will note that the methods of control differ in the mercury and in the uranium baths. In the former the colour is decided by the amount of mercury added, and not by the time of development. In the uranium bath, however, the print remains in the solution until it has acquired the proper tone. I would call attention to the fact that this uranium toning is really an intensification of the print, and produces a stronger effect than the original black tone. Where the print is too weak, this is a decided advantage.

Should you wish the mercury tone reduced, a strong hydrochloric acid bath will do it; and to remove the uranium tone, a weak solution of sodium carbonate is used. Some effects in local toning can be obtained by this latter method.

A word about the effect of reduction on the platinum image may not be out of place. A pure black platinotype, without mercury, can be reduced and intensified repeatedly, in the uranium bath, without producing any effect on the reduced platinum in the image. Nitro-muriatic acid is probably the only reagent that will effect the platinum image, and it destroys the paper at the same time. But when we combine the mercury with the platinum, and intensify with uranium, the ferricyanide in the bath is converted to ferrocyanide, and it combines with the mercury, uranium, and platinum to form ferrocyanides of these bases, wherefore the whole image can be removed in a strong alkali. I have cleared off the platinum image entirely by this means and this is the reason a weak alkali is recommended above.

I feel no diffidence in advocating a process that can be of such use to

platinotype workers. Its advantages may be summed up as follows: first, we can change the colour of our platinotype to the shade that seems most in keeping with the qualities of the picture. Second, if the colour we obtain is not what we wished for, it can be reduced or intensified at our pleasure. Third, we can take a print from a flat negative and develop it to a much stronger-looking print than would be obtained in the black; and, lastly, we can tone the same print to many shades by purely chemical means, thus placing a power in our hands not available in the one-colour print.

PRESCOTT ADAMSON.

### POLONIUM AND RADIUM.

[Translated from the *Camera Obscura*.]

In my communication upon this subject, published in the first number of this periodical, I expressed the hope that treatment of large quantities of uranium ore for the extraction of both these radio-active substances, which M. and Mde. Curie and I had undertaken, might lead to elucidation in various ways of the phenomena of the invisible rays.

This hope has been fulfilled in the most gratifying manner. Whilst at the time of the said communication the Becquerel rays were *terra incognita* even to the scientific world, at present this spontaneously radiating substance has become generally known, and a large number of learned people are eagerly studying the question.

As will hereafter be shown, radium is the more important of these two radio-active substances. Through the kindness of the Austrian Government M. and Mde. Curie were provided with 2 kilos of active barium chloride obtained from Joachimthal pitchblende. The firm of de Häen, of Hanover, also undertook most obligingly to prepare for me about 1 kilo of active barium bromide from about 1000 kilos of residue from their manufacture of uranium, and they also placed at my disposal the raw material from the same, for recovery of the polonium, but this has scarcely yielded me a gramme of the polonium preparation.

By repeated fractional crystallisation of the whole of the barium bromide I have raised its activity to such an extent that the remaining 15 to 20 grammes enabled me to exhibit the experiments for the first time before a large audience at the Munich Convention of Naturalists. This 15 grammes has now been further condensed to about 1 gramme, and it exhibits a corresponding accession of activity.

But the increase in the activity of the preparation does not even yet appear to have attained finality. It seems probable that it may be raised still more, until all the barium is removed and radium alone remains, provided sufficient substance be left. I find this already a serious difficulty in the way of further experiment. M. and Mde. Curie are rather more favourably placed, and they are strenuously endeavouring to isolate the radium by this method. The prospects are very promising now that Demarçay has shown by spectroscopic investigation that there is little doubt of the presence of a second unknown element in the active baryta salt.

Demarçay first discovered, with the Curies' intermediate preparations four new lines, and this has also been confirmed by Professor Runge, of Hanover, who has examined the preparations I had then made. Demarçay ultimately received a few milligrammes of a barium chloride which not only exhibited these four stronger spectrum lines, but also about a dozen more, which were of equal intensity with the barium lines. In this way it was possible to estimate the presence of from thirty to fifty per cent. of radium in the specimen of barium chloride. But there is a further reason for the presence of radium in the active salt.

Mde. Curie has determined the quantity of chlorine in the active barium chloride, and has found that it is much less than combines with normal barium chloride, and the deficiency increases with the activity of the salt. This is easily explained if we assume that the barium is associated with another element of higher atomic weight. Radium would thus belong to the elements of high atomic weight. Whether the property of radiation depends upon this is at present mere supposition, although the radio-activity of uranium and thorium, which are of the highest atomic weight, points in that direction. Meanwhile we are still uncertain whether this is a property of uranium and thorium, or of accompanying impurities.

The evidence for the existence of polonium, on the other hand, is quite unreliable. In regard to this both Demarçay and Runge have been unable to discover anything beyond the bismuth lines.

The activity of polonium, moreover, soon declines to such an extent, according to my experience with the preparations I have made, that it would appear to be merely a case of the so-called "introduced activity" discovered by Curie. The Curies exposed metals, fluor spar, &c., to intense radiations of radium for some time, and these substances thereupon

became active. The active bismuth (polonium) obtained from uranium ore had previously been in contact with radium, and had thus had the opportunity of acquiring activity. Perhaps it also behaves similarly with the third radio-active substance, titan, discovered by Debierne in uranium ore. We should do well to distinguish between radium and polonium, both as regards their chemical and physical properties, before we give a definite answer to these questions.

It should be remembered also that I have shown, in regard to radium, that the salts lose their activity almost completely when they are changed from the solid to the fluid state by dissolving them in water, and that the crystals obtained from the solution at first exhibit very little activity. But this condition is only transitory. The activity of the crystals increases day by day, until in the course of a few weeks a maximum is attained, which remains constant. Elster and Geitel have also observed that heating the crystals *in vacuo* for a considerable time has the same effect as solution, but in this case complete recovery also takes place in course of time.

On the other hand, when the polonium preparations lost their activity, they never returned to the original state.

The rays emitted by the preparations of radium and polonium were very different in their behaviour. Whilst the former excited slight phosphorescence upon the screen after traversing plates of lead fifteen or more millimetres thick, the latter were completely cut off by relatively thin plates of metal or even wood. In consequence of this, the rays of polonium exhibit a skiagraph of greater contrast (for instance, of the hand) upon the screen than those of radium. But, even with the aid of photography, no differentiation between the bones and the soft parts could be obtained with any of the preparations. The rays of radium filtered through a sheet of lead failed to produce a skiagraph of the hand, as they had too great power of penetration, and further sheets of the same metal offered very little more obstruction. This forces us to the conclusion that the rays of radium are not homogeneous, but of different absorbability. This want of homogeneity of the rays of radium is clearly shown by their different behaviour in the magnetic field.

Before we go into this question it is desirable first to review the other properties of the more intense Becquerel rays. These may be divided into four groups, viz., (1) their electrical action; (2) their phosphorescent action; (3) their chemical action; (4) their magnetic action.

1. The discharging property of the Becquerel rays as a consequence of the change in the conductivity of the air for electricity produced by ionisation was discussed in the first communication. According to Curie, in the case of very active preparations, the formation of ozone occurs with this ionisation.

Under suitable conditions the crackling discharge of sparks from an electrical machine is transformed to a scarcely audible buzzing discharge under the influence of radium radiation. The path of the sparks of an induction apparatus is influenced in the same way as by violet light.

Quite recently the Curies have shown that the rays themselves possess and transmit negative electricity, exactly the same as cathode rays, and the substance should therefore be capable of a very strong positive charge if it could be sufficiently isolated. As it has only been possible hitherto to generate electrical charges with substances possessing weight, it may be inferred that radium is the seat of a constant emission of negatively charged particles of matter. The preparation should therefore gradually lose weight. The Curies have, however, calculated that this loss is so infinitesimal that after many years it could scarcely be detected.

2. The phosphorescent action of the new preparations is very remarkable, and, besides the substances formerly referred to, fluor spar, glass, cinchonine bisulphate, rock salt, and many other substances become luminous.

Phosphorescent sulphide of zinc becomes intensely luminous for some time. Fluor spar becomes slightly phosphorescent for weeks if exposed to the radiations for some time after having been deprived of its thermoluminosity by heating to redness. When heated, it again radiates very intensely. The phosphorescence of the radium salts themselves is, as I have shown, most marked in the case of anhydrous barium bromide hermetically sealed in a glass tube. Such a preparation has now been diffusing its comparatively bright, blue light nearly a year, regularly and without intermission and quite independent of any source of light. The phosphorescence suffers by the action of heat, but is restored by cold. Becquerel radiations remain unaffected under the same conditions.

I prepared some barium platino-cyanide from active baryta salts. As might be expected, it was strongly phosphorescent. The phosphorescence (not the radiation), however, declined rapidly, and at the same time the green salt changed to yellow, then orange, and finally brown.

The same change in colour of the ordinary platino-cyanide of barium is known as an effect of the prolonged action of intense Röntgen rays, and the phosphorescent action is simultaneously impaired.

If the discoloured, brown, radio-active platino-cyanide of barium be dissolved in water, it may be recrystallised in the primary state.

I have ascertained that the brown colour of the salt is due to a phenomenon of polarisation, similar to that of the tourmaline, and consequently only occurs when the crystals cross, whilst a single crystal does not appear to be of different colour when examined by transmitted light.

The manifestation of light, discovered by me, when a radium preparation is brought near the closed eyes or the temporal bone, is, doubtless, due to phosphorescent action.

3. The chemical action is not confined to the photographic plate, but printing papers are also darkened if the action is sufficiently prolonged. A whole series of chemical changes brought about by the rays, and characterised by discolouration, have been published.

Curie found that a glass, in which a preparation had been kept, had been stained deep violet. Sometimes the colour was brown, and this was due to the composition of the glass. Röntgen tubes become similarly discoloured at those parts upon which the cathode rays impinge. Rock salt, bromide of potassium, chloride of potassium, &c., and colourless fluor spar become similarly discoloured when they are exposed for some time to the rays of radium, which in this respect act analogously to cathode rays. If the view be correct that we have a fixed solution of alkaline metal in these coloured salts, as seems probable from my former experiments (I obtained the same colourations by heating the salts in fumes of sodium and potassium), this would be an instance of very energetic chemical action by Becquerel rays.

The colouration of strongly radio-active barium chloride, or bromide, which may be observed after keeping the salts for some time in the dark, is attributable to the same cause. These colourations, excepting in the case of glass, are all destroyed by the action of light.

4. The divergence of the rays of polonium and radium in the magnetic field, which does not take place with Röntgen rays, was discovered by me in October of last year, and demonstrated photographically.

The densest part of the image was, of course, at that part of the plate where the polonium preparation was placed in a paper capsule. This was separated from the plate by black paper. The whole arrangement was then placed horizontally upon the pole of an electro-magnet. In one instance it was so arranged that the substance was situate on one side exterior to the rectangular pole, whilst in the other instance it was exactly within the circular pole.

Whilst the impression upon the plate would only be produced under the capsule when the magnet was not excited, the image was spread out laterally in the direction determined by the polarity of the electro-magnet, when the magnet was inserted in the circuit.

Curie and Becquerel have followed the matter further with their preparations, and Stefan Meyer and Schweidler likewise by measurements from mine. Doubtless the Becquerel rays in this case behave the same as cathode rays, and this forces us to the opinion, that the radio-active substances throw off negatively charged particles with enormous speed derived therefrom. As I have already mentioned, Curie has been successful in demonstrating this.

According to Curie, the rays of radium may be divided into those which are, and those which are not, deviable (like cathode rays), and this confirms their want of homogeneity. The Paris preparations of polonium, however, differ from mine by showing mostly rays which are not deviable. But I think that this dissimilarity does not depend upon any difference in the substance, but rather upon its age.

The experiments as to the presumptive nature of the waves of these rays have been without result, even with diffuse reflexion, but none have yet been made with the most recent preparations.

There yet remains the high sensitiveness of the test for the radio-active substances by means of their radiations, to which attention should be drawn. Upon the evidence of the spectrum observations to which we have referred, it is possible to detect in the 1000 kilos of residue from which the material I used was obtained the presence of only a few milligrammes of radium. Consequently, only one-millionth per cent. could be most distinctly detected, but this was also possible by means of an ordinary electroscope. Much more minute quantities might be discovered by means of long exposure of a photographic plate. Barium bromide becomes luminous when it contains but one-thousandth per cent. A piece as small as a pin's head vapourised in a Bunsen burner would suffice to render the air of a large hall more conductible for some time, as Elster and Geitel have shown, and thus prove the fact at a great distance.

Only by this extremely delicate proof could the discovery and preparation of the radio-active substances be made. Although this work is only half finished, it has disclosed so much that is peculiar and new that the main question of the source of the energy of these rays seems, for the present, driven into the background. If further interesting discoveries should result, it would not be matter for regret that the satisfactory explanation of the phenomena still appears far off, whilst our conjectures assume more definite form.

DR. F. GIESEL.

#### NOTES ON TELE-PHOTOGRAPHY.

At the April meeting of the Photographic Society of Philadelphia the Rev. F. S. Dobbins, who read a paper on this subject, pointed out "that there is a very simple rule for finding the approximate length of bellows required by the tele-photo attachment. The negative lens is usually one-half the focal length of the positives. Multiply the focal length of the negative lens by one less than the number of magnifications desired, and the result is the bellows length required approximately. Thus seven times  $3\frac{1}{2}$  inches gives  $24\frac{1}{2}$  inches bellows length needed with positives of 7 inches and a negative of  $3\frac{1}{2}$  inches for an eightfold magnification. On the baseboard of my camera," proceeds Mr. Dobbins, "I have marked off the points to indicate the varying bellows length required for the different magnifications—eightfold, sevenfold, &c. 'Magnification' means *linear* magnification, so many diameters greater than the original image made with the positives of the combination only.

"As to the comparative size of the tele-photo arrangement and a camera with positives only, Dallmeyer's rule, confirmed by calculations made for me by the Bausch & Lomb Company, shows this rather remarkable state of things. This little box of mine, with this tiny tele-photo attachment (the attachments cost from 16 to 24 dollars), gives precisely the same results for an eightfold magnification that would be accomplished had I a camera 56 inches in bellows length, with a pair of lenses 9 inches in diameter, mounted in a barrel (or keg, literally) 12 inches long. The rule to find the equivalent of any magnification is simply to multiply the focal length of the positives of the combination by the number of magnifications: thus, 8 times 7 gives 56. If I make simply a sixfold magnification with a bellows length of about 17 inches, it is the equivalent of an ordinary lens of 42 inches focal length.

"I may remark, in passing, that I have hitherto yielded to the desire to see what the tele-photo lens will do, and so have almost always strained the lens to its utmost. This is like a novice, but unwise. One ought to be content with a sixfold magnification, for the results are better in every way and the exposure is so much lessened. I shall mend my ways in this respect. Some of the illustrations I bring you this evening would have been much better had I but had the good sense to exercise some restraint in this direction before. Moreover, nine times out of ten the  $4 \times 5$  plate is preferable to a large one, for certain reasons.

"I put my  $4 \times 5$  camera, the box addition, the tele-photo attachment, the shutter, lenses, focussing cloth, focussing glass, six double holders with a dozen plates, all into a case. The whole measures  $18 \times 8 \times 7$  inches, and weighs just thirteen and a half pounds. So it is not bulky or weighty. I use a good, substantial tripod. When possible I get behind a tree or a building, out of the breeze; the wind's vibrations must be guarded against. In setting the camera I rack out the bellows to the point of the magnification desired, and then focus with the tele-photo adjusting screw.

"I use isochromatic plates almost altogether. I notice that Dallmeyer, Spitta, Marriage, and others who have written on tele-photo work, all use isochromatic plates. A colour screen is almost necessary for distance work, to cut out haze, and the consequent exposure is so very much less with the isochromatic plates than with others that one finds after a little that he must depend on these almost always.

"As to exposure. This is the one great problem which plagued me. I have worked away at it and with some results which I give to you in printed form. Let me say that the tables are tentative merely. I expect with larger experience to revise them. Yet they represent the results of my experimenting up to this time. The rule usually given is that the exposure should be the normal exposure with the ordinary lens multiplied by the square of the magnification.

"I have found this to be the maximum exposure.

#### "SUGGESTED TABLES OF RATIOS OF EXPOSURES.

"For use with tele-photo combinations (positive and negative lenses): Multiply the normal exposure with ordinary photographic lens for an object in the shadows by the figure given. (Usually one determines the normal exposure with a Wynne exposure meter by holding it in the shadow of the body.)

"1. For objects 1000 feet distant or less, using no colour-screen:—

Magnification.	8	7	6	5
Dark objects in shadow .....	64	49	36	25
Dark objects in good light } .....	48	36	27	18
Bright objects in shadow } .....	32	24	18	12
Bright objects in intense light .....	16	12	10	8

"2. For objects more than 1000 feet distant, using a colour screen and isochromatic plates (if no screen is used, the exposure will be, of course, but one-fourth the length of time when the screen is used):—

Magnification.	8	7	6	5
Dark objects in shadow .....	64	49	36	25
Dark objects in good light } .....	50	38	28	20
Bright objects in shadow } .....	35	28	21	15
Bright objects in intense light .....	20	18	14	10

"The variations are not so great as they seem, being equal to that from one second to three-fourths of a second, to one-half of a second, or to one-quarter of a second.

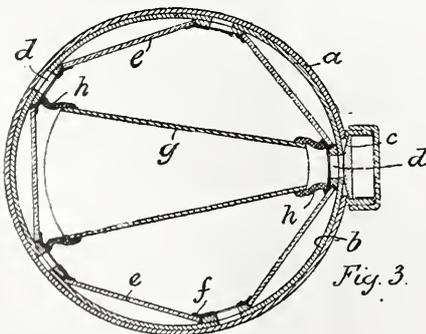

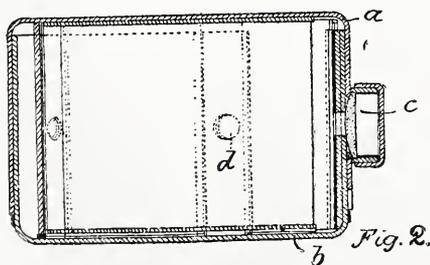

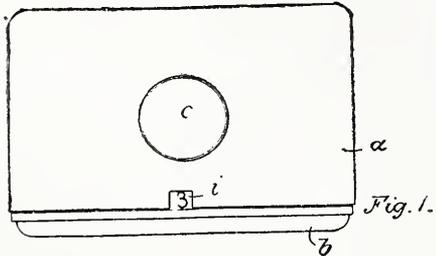

"As to the development of plates exposed, in connexion with the telephoto attachment, I notice that it must be carried much farther than with ordinary exposures. I notice, also, that the development proceeds much more slowly. I do not know the reason of this."

THIEMANN'S IMPROVEMENTS IN CAMERAS.

[Patent No. 7722 of 1900.]

A SYSTEM of construction, whereby the plates are mounted in a drum, with which they rotate, so as to be consecutively exposed on coming opposite a lens located in a second, outer drum, in the interior of which the first-mentioned drum is contained.

*a* is the outer cylindrical case or drum, of pasteboard or other suitable material and of any convenient size. At the front of this drum is located

the lens, *c*, the centre point of which coincides with the centres of a series of apertures, *d*, in the wall of an inner drum, *b*. This latter may be made of the same material as the containing drum, and is of such size as to fit closely within the latter, with capability of rotation. Between each two apertures, *d*, a photographic plate, *e*, is arranged in guides or

grooves, *f*, vertical to the base of the camera. There should be an uneven number of plates, so arranged corresponding to an uneven number of apertures.

If now the drum, *b*, is rotated relatively to the containing drum, *a*, so that the lens coincides with one of the apertures, *d*, the plate, *e*, which lies opposite the latter, will be exposed. In order to ensure the exposure of only a single plate at a time, a conical light shaft, *g*, is arranged on the top of the drum, *a*, the joints being rendered air-tight by strips, *h*, of felt or like material.

After the exposure has been completed, the drum, *b*, is rotated further until the next plate is brought into position ready for exposure. A series of numbers corresponding to the plates may be provided on the inner drum, *b*, and a slot cut in the outer drum, the appearance of a number thus indicating that a plate has come into position for exposure.

Instead of plates, films can be employed, the drum, *b*, in such case being provided with rollers to receive the film.

For taking stereoscopic pictures two such cameras may be united by suitable sliding devices.

PERAUT'S IMPROVED CHANGING BOX.

[Patent No. 4306 of 1899.]

THE apparatus consists of a box, *a*, divided into two compartments by a partition, *b*, and of two sliding shutters, *c d*.

On each side of the box is jointed, at *e*, a lever, *f*, the ends of which enter slots, *g h*, formed in the slides. The two levers, *f*, are connected together by a frame, *i*, which is kept upright by means of a spring, *j*, fixed to the upper wall of the box in which the apparatus is placed. This

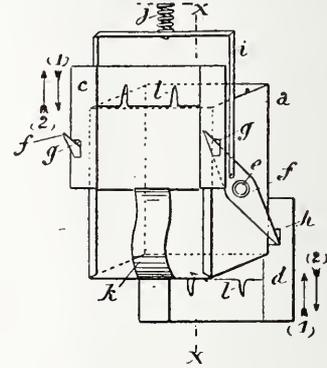

FIG. 1.

box is not shown in the drawing. *k* are springs pressing forward the images contained in their respective compartments. A button placed outside the box which contains the apparatus, when pressed downwards, presses upon the frame, *i*, and lowers it; this frame, on being lowered, acts upon the two arms, which oscillate, drawing the two slides with them in the directions indicated by the arrows, 1, 1. Each slide in its movement draws within it a plate by means of tongues, *l*, and causes it to take the last place in its respective compartment.

When the button is released, the spring draws the slides back into place.

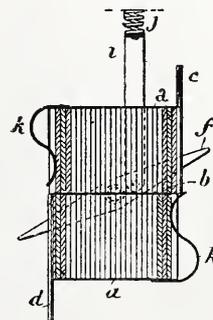

FIG. 2.

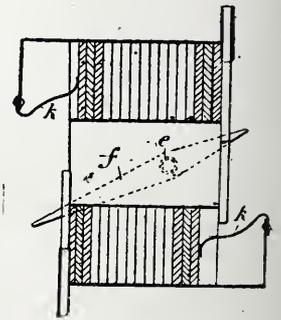

FIG. 3.

in the direction indicated by the arrows, 2 2, by means of the arms and the frame; the slides uncover the image so that it can be seen. The operation may be repeated indefinitely.

In fig. 3 is shown a modification that may be applied to the apparatus in order to allow glass negatives to be placed therein, and to be able to see the images upon a negative isolated from the others in order not to be incommoded by super-position.

For this object it is necessary to have three compartments, as shown in the drawing, and to alter the respective lengths of the arms, *f*, of the levers in the ratio of 1 to 2.

## Our Editorial Table.

### SCHERING'S CHEMICALS FOR PHOTOGRAPHY.

Wholesale Agents: A. & M. Zimmermann, 9 and 10, St. Mary-at-Hill, E.C.

WE understand that the celebrated house of Schering, of Berlin, to whom, for many years past, photographers have been indebted for the supply of exceedingly pure chemicals for developing and other purposes, intends placing pyrogallol on the market in the form of concentrated crystals, thus very greatly diminishing the bulk occupied by the ordinary sublimed or flocculent form. Of this latter substance a sample bottle has kindly been sent us by Messrs. Zimmermann. It is a great many years since we first used Schering's pyro, and we well recollect the favourable reception accorded to it on its introduction. It remains to-day what it was then, an ideally pure product yielding images which, for perfect density, gradation, and cleanliness of deposit, leave nothing to be desired. Schering's pyro is a standard photographic chemical which deservedly enjoys world-wide use. In these days of a rapidly accumulating list of reducing compounds for photographic development, it is of interest to point out that we still have in present use a brand of "pyro" which was originally brought to the notice of photographers something like a score of years ago. Messrs. Zimmermann have also sent us samples of Schering's formalin and adurol. The former, it may be noted, is a patented product which, when employed in a diluted form, has many uses in the hardening of gelatine films on glass, paper, &c. Adurol, a modified form of hydroquinone, is also one of the Schering products that has been sent us. The characteristic property of this substance may be best and most briefly indicated by the remark that it possesses the virtues of a combined hydroquinone-metol developer without the drawbacks of either. It keeps well in solution, does not stain, and is suitable alike for negative and positive work. We have much pleasure in recommending the chemical products of the house of Schering to photographers. They are always pure and carefully prepared, and their properties are not overstated. Messrs. Zimmermann will send a complete list on application.

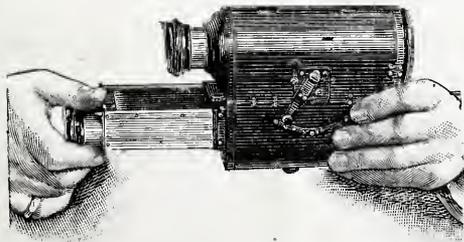

MR. COURTNEY S. JONES, of High-street, Woodford Green, Essex, sends us samples of his Mimosa midget mounts and photo seals. The latter are backed with an adhesive, and at the present time, when tiny photographs of celebrities are very greatly in vogue, they should be popular amongst the large class that appreciates the opportunity of adorning their stationary with photographic seals. The Mimosa midget mounts are fanciful in design and colour, and add to the effect of small photographs.

THE "Perfect Retouching Medium" is the name given to a preparation sent out by Mr. F. W. Slater, photographer, of Central Mostyn-street, Llandudno. The experience of a professional photographer should stand him in good service when putting up a retouching medium. Mr. Slater says that after careful and repeated trials he has at last placed a medium on the market which he hopes will meet with success by its users, and gain a fair share of patronage. Some of the advantages claimed for the medium are, that it offers a splendid tooth; that work will not shift when varnished; and that only the best materials are used in its manufacture, being perfectly pure and clear. The report we have received of the "Perfect" medium supports these claims. The medium is sent out for 1s. post free.

### THE STEREOSCOPIC "BINOCULAR" CAMERA.

Manufactured and sold by W. Watson & Sons, 313, High Holborn, W.C.

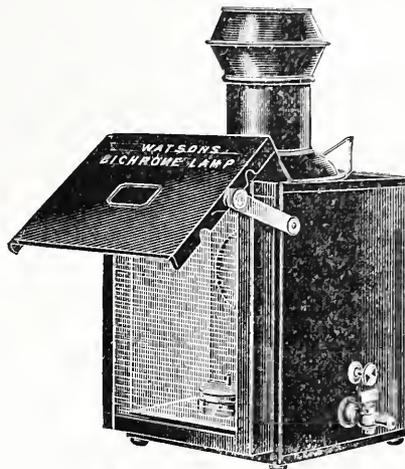

HITHERTO the ingenious little stereoscopic binocular camera which Messrs. Watson introduced a few months ago has depended for its changing method upon the bag system, the exposed plate being drawn into a bag attached to the instrument. But, by a recent improvement, a sliding magazine has been substituted for the bag, so that the changing

has been much simplified, and the convenience of the instrument enhanced. The illustration shows the extremely simple manner in which changing is now effected. To do this, the camera, it is pointed out, must be held in a horizontal position, with the lenses showing upwards. Then the lower eyepiece, which carries with it the magazine, must be drawn out by the flange provided for the purpose. When fully drawn out, the exposed plate falls to the bottom, and the magazine must then be returned to its original position, the act of returning it recording the number of the exposure. When it is required to refill the magazine, two

clamping screws at one side of the camera must be loosened, when the magazine can be entirely withdrawn; then, by removing a stop from one end of the magazine, the sheaths can be drawn or dropped out through the aperture that is provided. The mechanism by which these movements are effected is exceedingly simple, and the action is perfectly easy and certain. We are pleased to learn from the makers that the "stereoscopic binocular" is meeting with great favour. As our readers know, anything which promotes this favourite branch of work has our support.

THE use of a solution of bichromate of potash as an "illuminating medium" for dark-room purposes has given Messrs. Watson the opportunity of providing two lamps, to which a tank of the mixture may be

applied as the "light filter," if we may use the term in this connexion. The illustrations show a lamp of the ordinary construction, and an incandescent electric bulb, both of which have been adapted to take the coloured solution.

### THE ROTOGRAPH BROMIDE PAPERS.

Manufactured by the Rotary Photographic Company, Limited, 23, Moorfields, London, E.C., and West Drayton.

VISITORS to the Exhibition at the Crystal Palace two years ago may remember a strip of printed bromide paper, which stretched up to the roof of the building. This was the production of the Rotary Company, which, since that date, has been engaged in the production of bromide prints, large and small, for commercial purposes, such as the adornment of cigarette boxes, advertisement cards, Christmas cards, and many other purposes to which this method of printing renders itself so easily adaptable. By far the greater part of the paper which this Company prepares is used at the West Drayton works for making these prints, but it has recently been decided to supply photographers and others with the paper, and accordingly we have been favoured with samples of it. There are something like half a dozen kinds of the paper available, viz., thick and thin glossy, thin smooth, thick smooth, thin rough, and post-card paper. The papers appear to be prepared with great care, and to have the capability of yielding the very best quality of developed image in silver. We wish the Rotary Company success in their enterprise. The market and demand for bromide printing papers appear to have no limit. The facilities for automatic printing which the process furnishes, the cheapness of production, and the unquestioned excellence which the results may be made to possess single out this system of photographic positive work as one of the most popular of the present time. The Rotary Photographic Company enter the market at an opportune moment, and the quality of their productions should secure them a large share of public patronage.

### KURZ GEFASSTES CHEMISCHES WÖRTERBUCH.—DR. CARL ROTHE.

Verlag der Deutschen Photographen Zeitung, Weimar.

THE compiler of this dictionary of chemical terms has rendered a service to German photographers which we hope will meet with the recognition it deserves. By condensation, and the elimination of every superfluous word, not far short of four thousand references are given in an octavo volume of 192 pages. The work has been written especially for the use of photographers, and the price places it within the reach of a large number of persons for whom a Standard Chemical Dictionary would be too costly and elaborate. The following extract, with translation, will give an idea of the information contained in the volume, and the method of condensation:

S. kaliumbromid, bromkalium, kalium bromatum (Ph.)=K.Br.; fbl. Würfel; D. 2.41; l. i. 1.62 k. W., l. i. 1. h. W., l. i. 750 alk. Kg. 4.10.

Injurious or poisonous in the general sense. Potassium bromide, bromide of potassium, kalium bromatum (Pharmacy)=K. br.; colourless, cubical; specific gravity 2.41; soluble in 1.62 parts of cold water, soluble in 1 part of hot water, soluble in 750 parts of alcohol. Price, M. 4.10 per kilo.

## Studio Gossip.

**ADDRESS WANTED.**—Mr. T. Everitt Innes, of 108, Wellington-road, Heaton Chapel, writes; "I should be greatly obliged if you could inform me of the address of any one in Belfast who will undertake to teach a young lady to colour small photographs." Some Belfast reader may be able to supply Mr. Innes with the desired information.

**THE NON-RETURN OF PHOTOGRAPHS.**—Mr. J. Browning writes: "With reference to the non-return of photographs sent in answer to advertisements, a very simple and effective plan is to cut the photographs in two from corner to corner. They are just as good, and prevent unscrupulous photographers from making use of them. I have no doubt this would answer equally as well with the stage."

**AN EFFECTIVE WINDOW DISPLAY.**—Messrs. J. Bulbeck & Co., 166-168, Strand, London, W.C., are utilising the large window at the entrance to their premises for the display of a number of fine specimens of architectural photography. The pictures, which are in carbon and platinum, are of very high technical quality, and have deservedly attracted the close attention of many thousands of Strand wayfarers.

## News and Notes.

**THE Röntgen Society's Annual General Meeting** will be held on Thursday, July 5, at 20, Hanover-square. The presidential address will be delivered by Mr. Wilson Noble.

**AMONG the congresses to be held in Paris this summer** there will be one to consider "Les Arts du Dessin," which might be translated the arts of illustration, so conspicuous are they on the circular, were it not that painters and sculptors are also expected to take part. Two subjects on the programme will be all the better for serious discussion—the advantage of other than mechanical methods of reproduction, and the question of copyright in all its relations. The Congress will be held at the Ecole des Beaux-Arts from July 9 to 12.

**THE LATE G. J. SYMONS.**—A meeting was recently held at the Meteorological Society to consider the question of a memorial of the late Mr. G. J. Symons, F.R.S. It was resolved that the memorial should take the form of a gold medal, to be awarded from time to time by the Council of the Royal Meteorological Society for distinguished work in connexion with meteorological science. An executive committee was appointed to take the necessary steps to raise a fund for this purpose. Contributions will be received by the Assistant Secretary, Mr. W. Marriott.

**AFFILIATION OF PHOTOGRAPHIC SOCIETIES.**—At a meeting of the Executive Committee, Wednesday, June 20, 1900, Mr. H. Snowden Ward in the chair, the Secretary reported that the following had signified their intention of upholding the rule adopted by the Conference of Judges, in addition to those whose names are published in the "Red Book": Messrs. Valentine Blanchard, W. Thomas, Frederic Hollyer, Henry Sturmev, Harold Baker, and Mrs. Catharine Weed Ward. The total number of signatories now stands at thirty-two. General business and the consideration of arrangements for new lectures and the revision of old lectures occupied the meeting, which was adjourned on Wednesday, June 27.

**THE Aintree Photographic Society's Seventh Annual Exhibition** will be held November 13 to November 17, 1900. The classes for open competition are as follows: Class I., Landscape or Seascape; Class II., Architecture; Class III., Enlargement; Class IV., Figure Studies and Portraiture (amateurs only); Class V., Figure Studies and Portraiture (professionals only); Class VI., Hand Camera; Class VII., Lantern Slides. Lecture Class.—Lectures may be on any subject, and to be illustrated with fifteen to twenty-five slides, and occupy not more than twenty minutes in delivery. The awards will be gold medal for best picture in the Exhibition; silver medal, bronze medal, certificate in each class. The Hon. Secretary is Mr. Theodore Wood, 12, Highfield-road, Walton, Liverpool.

**PROTECTING ANCIENT BUILDINGS.**—Good evidence of the valuable work carried on by the Society for the Protection of Ancient Buildings is contained in their annual report, which was presented at a meeting held last week at the rooms of the Society of Antiquaries. In the case of London, the report regretfully notes the destruction of Tudor House, at Bromley, by the London County Council, and also hints that there is some danger lest the house in Fleet-street, known as Henry VIII.'s palace, which has been preserved by that body, may still be injured by the more insidious process of restoration. The Society is also interesting itself in the preservation of the handsome old houses in Lincoln's Inn-fields, attributed to Inigo Jones, which are likely to suffer through the construction of the new street between Holborn and the Strand.

**AUTOMOBILE CLUB 1000 MILES TRIAL.**—Mr. Henry Edmunds, a member of the Committee of the Automobile Club, has placed at the disposal of the Committee three prizes of 5*l.* 5*s.*, 2*l.* 2*s.*, and 1*l.* 1*s.* for the best set of twelve mounted photographs taken on the occasion of the 1000 miles trial of the Automobile Club. The competition is open to the public, whether they be professional photographers or not. The photographs should be addressed to the Secretary of the Automobile Club, 4, Whitehall-court, London, S.W. The Judges are Messrs. Henry Edmunds, Edward Kennard, Henry Sturmev, Charles Cordingley, and the Secretary of the Club. Photographs submitted for competition may, if desirable, be retained by the Judges, whether they are awarded a prize or not. Photographs for competition must be submitted not later than Saturday, July 14.

**THE BORCHGREVINK EXPEDITION.**—Mr. C. E. Borchgrevink read a paper on Monday night before the Royal Geographical Society on "The Results of the Sir George Newnes Antarctic Expedition." The lecturer pointed out that the great difference between Arctic and Antarctic expeditions was that in the latter

case there was absolutely no meat to be had, unless seals could be regarded as such. The reason was due to the tremendous gales of sleet and snow which raged in the Antarctic regions, and rendered it impossible for animals to exist. The expedition which he had had the honour to conduct by means of the "Southern Cross" had got further south than any previous expedition. The southernmost point was reached on February 16 of this year. In addition to discovering the approximate position of the South Pole, they had discovered the Duke of York Island and Cape Constance, a name he gave in honour of his wife. He had made careful observations of the sun and currents, and had secured specimens of the few forms of life found there, chiefly bird and fish. Lieutenant Colbeck had prepared an important map from the "Southern Cross" of a part of the coastline of Victoria Land, which contained a good deal of new information. Mr. Borchgrevink exhibited by means of the lantern a large number of photographs he had taken on the expedition.

**PROFESSOR OLIVER LODGE.**—Dr. Oliver Joseph Lodge, Professor of Experimental Physics in University College, Liverpool, who has been appointed by Her Majesty first Principal of the new University of Birmingham, is forty-nine years of age, and a native of Staffordshire. Educated at the Newport, Shropshire, Grammar School, he commenced business with his father, Mr. Oliver Lodge, who was in failing health, at the Potteries, at the age of fourteen. He continued in business till the age of twenty-one, in the mean time visiting London, and attending a course of lectures by Professor Tyndall. He passed the London Matriculation examination in 1871. He became a D.Sc. in 1877, and the same year was appointed Assistant Professor of Physics and Mathematics at the University College, Liverpool. In 1880 he was appointed to the post which he now quits, that of Professor of Physics at the University College, Liverpool. From 1884 to 1886 he was scientific adviser to the Electrical Power Storage Company. He is the President of the Physical Society of London, has been a Fellow of the Royal Society since 1887, he is a honorary LL.D. of St. Andrews, and has written largely in the scientific journals on mechanics and electricity. His works comprise *Modern Views of Electricity*, a collection of his contributions to the scientific press, *Lightning Conductors and Lightning Guards*, *Pioneers of Science*, a popular illustrated work on astronomical biography and discoveries, and *The Work of Hertz and his Successors*.

**PRESERVING OLD LONDON.**—The fourth report of the Committee for the Survey of the Memorials of Greater London has been issued. The object of the Committee is to examine certain areas in London, and in them to register whatever may be deemed to be of historic or æsthetic interest. The work is not confined to buildings only, any valuable open space, any remnant of an old village green, any beautiful tree, any object of local life or custom, or interesting piece of handiwork, comes within the Committee's survey. They first of all draw attention to these things, and, if they are under the control of a public authority, try to secure their maintenance as national trusts. Some 2000 drawings, photographs, and sketches have been made. But the most important part of the Committee's work is the compilation of the Register or Survey of London Buildings, which is carried on under the auspices of the County Council. The first volume, which is already printed, deals with the parish of Bromley, and the second with that of Bow. It is proposed in the third to deal with the parish of Chelsea, and a series of drawings has already been commenced. The report concludes by stating that the great need of the Committee is for more members, both active and subscribing. Mr. Leonard Courtney, M.P., presided at the annual meeting of the Committee, which was held last week. The Bishop of London having been elected President of the Committee, Mr. C. R. Ashbee read a paper which is to serve as an introduction to the L.C.C. Survey. After describing the origin of the Committee's work, he remarked that its great aim was to stimulate the historic and social conscience of the country, with a view to preventing the destruction of the historic and beautiful landmarks of the city. How necessary such a rousing of the public conscience could best be realised by the fact that in Bromley six out of the sixteen old buildings registered in 1894 had already been destroyed, while during the last six years historic relics in all parts of London had been swept away without mercy. Mr. Courtney, in acknowledging a vote of thanks, said that he felt he was in the presence of the standing conflict between the present and the past. Fortunately they could not destroy the love of the past. Ten years ago, when the London County Council was created, it was thought there could be no more prosaic body. Yet it had defied prophecy, for it had become the patron of this Committee, and was going to print its works.

## Commercial Intelligence.

**MR. H. ROBINS**, Market-place, Wantage, has fitted up a photographic dark room for the use of customers.

**THE Warwick Dry Plate Company** announce that they have established a London depôt for Warwick plates at 14, Dowgate-hill, E.C. Orders may now be sent to London or Warwick, as may be most convenient.

**THE LUXIA PLATINUM PAPERS.**—Owing to the unexpectedly large number of orders received, and the process of preparing platinum paper being necessarily a comparatively slow one, Messrs. Berger & Co. much regret that some delay has occurred in the execution of orders for their new Luxia platinum papers. They are, however, making all possible arrangements for obviating any such delay in the future, and hope within the next few days to be able to execute all orders promptly in the usual way.

**THE NEW YORK SKY-SCRAPERS.**—The Fairbanks Company, of 16 Great Eastern-street, E.C., send us a specimen copy of their Album, illustrating most of the prominent buildings of New York City. They will be pleased to send a copy of this book post free to any of the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY if they will forward their name and address to the Company, who remark that, as there is some discussion at the present time in relation to the desirability of tall buildings, the illustrations might prove interesting.

**THE BRITANNIA WORKS COMPANY.**—Mr. E. B. Knobel, Managing Director of the Britannia Works Company, Limited, Ilford, writes us that he is requested by the Board of his Company to inform us that the agreement with Mr. Howson as Commercial Manager of the Britannia Works Company has been terminated. Mr. Howson has, however, offered to continue his duties until a suitable successor is appointed. Consequent upon this arrangement, Mr. Howson has tendered his resignation of his seat at the Board, which has been accepted with an expression of the Board's sense of his past zealous services.

**MR. GEORGE EASTMAN.**—According to the *Rochester Post Express*, Mr. George Eastman was born in Waterville, Oneida County, on July 12, 1854. He was the son of George W. Eastman and Maria Eastman, and received his education in the public schools of Rochester. His father was the proprietor of the old Eastman Commercial College, having removed with his family to Rochester in 1860, when George Eastman was in his sixth year. In 1861, when the family were living in the old Strong house in Washington-street, which has since become the property of the Mechanics' Institute, the elder Eastman died, and Mrs. Eastman, with her two children, removed to a house in Livingstone Park. They removed later to Elizabeth-street, then to Jones-avenue, then to Ambrose-street, and, still later, to Arnold Park. It was not until 1895 that the family took possession of the Soule House, at 400, East-avenue, which is now the family home. When George Eastman was between thirteen and fourteen years of age, he entered the employ of Cornelius Waydell, who was in the insurance business. Later he was with Buell & Brewster, and then with Buell & Hayden, both firms being in the insurance business in the Reynolds-arcade. In 1877 he entered the Rochester Savings Bank as clerk, and was successively assistant bookkeeper and bookkeeper. He left this position in 1880. It was in 1878 that Mr. Eastman began experimenting in photography with the idea of making a dry plate. He experimented in his own house at first, and began making the plates for sale while he was still in his own house. He began selling dry plates in 1880, and he was so successful with them that he formed a copartnership with Henry A. Strong, who is now President of the Eastman Kodak Company, and under the firm name of Strong & Eastman they continued the manufacture of these plates. He is now the Treasurer of the Eastman Kodak Company, the largest establishment of its kind in the world.

## Patent News.

The following applications for Patents were made between June 11 and June 16, 1900:—

**DEVELOPING AND FIXING APPARATUS.**—No. 10,866. "Improvements in Apparatus suitable for Developing and Fixing Photographic Films and the like." S. QUINCEY.

**PHOTO-PRINTING APPARATUS.**—No. 10,860. "Improved Means Applicable for use in Fastening Canvas or like Aprons employed in certain descriptions of Photo-printing Apparatus." J. HALDEN.

**CINEMATOGRAPH.**—No. 10,896. "Cinematograph Machine." W. CARTER.

**CAMERA.**—No. 10,908. "Improvements in or relating to Photographic Cameras." THE TELLA CAMERA COMPANY, LTD., and A. L. ADAMS.

**COLOUR PROJECTION.**—No. 10,923. "Improved Apparatus for the Projection and Superposition of the Images of several Diapositives by aid of a Single Objective applicable for Colour Photography. Complete specification." A. SAUVE.

**CINEMATOGRAPHY.**—No. 10,992. "A New or Improved Process and Apparatus for Handling Cinematograph and other Rolled Films." H. BREHM.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
2.....	South London .....	Demonstration: <i>Secco Films</i> . C. Binns.
3.....	Gospel Oak .....	Flashlight Demonstration under the Direction of Committee.
5.....	Röntgen Society .....	Annual General Meeting.
7.....	Croydon Camera Club .....	Excursion: Old Malden and Chesham.
7.....	Darwen .....	Excursion: Leader, W. H. Rogers.
7.....	Darwen .....	Excursion: Wilpshire for Ribchester.
7.....	South London .....	Excursion: Staines. Leader, F. Goddard.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

**JUNE 21.**—Mr. A. L. Henderson in the chair. The CHAIRMAN referred to a difficulty often to be contended with abroad, and one which he had only recently experienced whilst staying at Nice. He passed round a negative suffering from a multiplicity of little blisters about the size of a pin's head. He was convinced that the defect was not inherent in the plate, which was not at all prone to blister. It had a substratum, but this was not the cause of the defect. He was sure of this, because the plate was one that could be developed in solutions having a temperature of 80° or 90°, without frilling, and it stood changes of temperature equally well. The blister-like spots came up principally in the washing. He found the cause of the mischief in the fact that the water service was at so high a pressure that it came out milky white, owing to the quantity of air held in suspension. The plate was kept as free as possible from the air bells, which thickly gathered on it, by continual friction with the hand, but there was no doubt that the blisters were the outcome of the condition of the water.

Mr. A. HADDON, in the course of some remarks, said that it was well known that water under considerable pressure took up more air into solution than it would if under the ordinary pressure of the atmosphere. Consequently, if the water, as in Mr. Henderson's case, be delivered at high pressure, it would have dissolved in it a large quantity of air. If, now, we put a negative to such water to wash, wherever there may be any nucleus in the film, of silver or foreign matter, there is at once a tendency for the air to separate from the water at those points. We know that the film is saturated with the air-laden water, so that it follows that, wherever the separation referred to arises, there we have formed a little blister in the film. Something of the same sort may be seen by taking a plate out of water for a time and then replacing it in the water, air bells at once begin to form. The suggestion that the water impinging on the plate, whilst charged with the air, caused the blisters directly was not a correct explanation.

Mr. J. E. HODD had noticed an effect similar to that alluded to by the Chairman when using the water coming through a fine spray, but only in the summer months. The water was served at a fairly high pressure.

The CHAIRMAN said that he had got over the difficulty by allowing the water to stand until the excess of air went off, leaving a normal amount corresponding to the pressure.

Mr. A. MACKIE had at times been unable to wash prints, so full was the water of air bells, which coated the whole of the prints. He had seen no blisters, however.

The nomination of officers for the ensuing year was then proceeded with. The following is the list of nominees, who will be balloted for at the next meeting:—*Trustees*: Messrs. A. Haddon and J. B. B. Wellington.—*Committee*: Messrs. R. Child Bayley, R. Beckett, R. P. Drage, T. E. Freshwater, S. H. Fry, J. E. Hodd, J. W. Hodges, E. Human, H. Vivian Hyde, F. C. Kellow, A. Mackie, H. C. Rapson, and J. S. Teape.—*Curator*: Mr. S. Heskins.—*Recorder*: Mr. J. W. Hodges and Mr. Featherstone.—*Librarian*: Mr. E. T. Wright.—*Hon. Secretary and Treasurer*: Mr. Walter D. Welford.

### PHOTOGRAPHIC CLUB.

**JUNE 20.**—Mr. F. A. Bridge in the chair.

Mr. E. W. FOXLEE brought forward several samples of papers used for photographic purposes. They included a piece of Rives' paper marked B.F.K. 74, such as was used for albumenising. It cost at the time it was made 2s. 10d. per pound. Why did not English makers produce a similar paper, he inquired? He also showed another piece of Rives' paper made by the opposition concern. There was a split some years ago, the Renage people starting in opposition. Eventually the original firm bought up the new concern and combined. Some papers of the Steinbach make of various thicknesses and quality were referred to, and a piece of surfaced paper, such as was used for emulsions, was passed round.

Mr. H. SNOWDEN WARD referred to the O.W. paper, which was produced by a combine of artists belonging to the old Water Colour Society, from whence came the name. They complained that they could not get the quality of paper obtainable in olden days, and, failing to induce paper-makers to go into the question for the sake of water-colourists, a number of them, including many of the greatest names of the time, formed a company and produced the O.W. paper. Specialising as they did in this direction, he thought it likely that they might favourably entertain a suggestion to make photographic papers. He believed they made long rolls.

Mr. J. R. GOTZ said he had failed to get any paper from them when he had wanted to. Mr. Foxlee passed round a piece of Lichtdruck or collotype paper made in Germany, which, if a little tougher, should do for emulsion work, the basis of the paper being of less importance than for albumenising. The back could be seen to be very common.

Mr. SNOWDEN WARD said that a firm of Massachusetts paper-makers had been experimenting for years on the photographic problem, but, so far, they had only been able satisfactorily to make the coated papers. They had the same trouble about the iron specks. Theoretically it could be overcome, but in practice not.

Mr. FOXLEE spoke to the effect that the little iron present in our water here should have very little effect. It would not combine with the cellulose, and there was very little water left, after washing, to dry, as it was pressed out.

### FORTHCOMING EXHIBITIONS.

1900.	Exhibition.
July 9-14 .....	Photographic Convention of the United Kingdom (Newcastle-on-Tyne Meeting). Hon. Secretary and Treasurer, F. A. Bridge, East Lodge, Dalston-lane, London, N.E.
„ 12 .....	Beverley. Hon. Secretary, T. J. Morley, Toll Gavel, Beverley.
August 21.....	Royal Cornwall Polytechnic Society. W. Brooks; Laurel Villa, Wray Park, Reigate.
Sept. 21-Nov. 3 .....	Photographic Salon, Dudley Gallery, Piccadilly. Hon. Secretary, R. W. Craigie, Camera Club, Charing Cross-road, W.C.
October 1-Nov. 3 .....	Royal Photographic Society, New Gallery, Regent-street. The Hon. Secretary, 66, Russell-square, W.C.
November 12-17 .....	Ashton-under-Lyne.
„ 21-23 .....	Hackney Photographic Society.
1901.	
January 14-19 .....	Blairgowrie and District Photographic Association. The Hon. Secretaries, Blairgowrie, N.B.

Those who desire to send photographs to the above Exhibitions

should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE BRITANNIA WORKS COMPANY.

To the EDITORS.

GENTLEMEN,—I beg to inform you that my engagement with the Britannia Works Company, Limited, has been terminated, but I have agreed to remain at my post until my successor is appointed.

You will receive an official notice of this from the Company, but I feel that it is only fitting to you and the photographic public, from whom I have always received so much courtesy, that I should personally advise you and them of the change. I would conclude by expressing sincerely, and with confidence, the hope that the Company, with which I have been connected for over eleven years, may be as successful in the future as it has been in the past.—I am, yours, &c.,

JOHN HOWSON.

Brookenhurst, Coventry-road, Ilford, June 25, 1900.

## Answers to Correspondents.

\* \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street Strand, London, W.C. Inattention to this ensures delay.

\* \* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPH REGISTERED:—

J. Hamer, 64, Walmersley-road, Bury, Lancashire.—*Photograph of Father Kelly.*

G. SMITH.—Moisture acting on the wood might disengage some organic substance, which would certainly induce fog.

YELLOW STAINS.—A. SIMMONDS. The yellow stains on the print are not caused by imperfect washing, as you surmise, but to imperfect fixation. Either the print was not allowed long enough in the fixing bath or the solution was too weak.

HYPH-ELIMINATORS.—W. RICHES. The best hypo-eliminator is water, and plenty of it; but the negatives must be perfectly fixed in the first instance. The hypo is then easily washed out by water, leaving nothing injurious behind.

MOUNTANT.—S. WATTS. There is nothing better than freshly made starch paste as an all-round mountant, as it has no injurious action on the prints. "Office gums," though convenient, should be avoided, as they often contain matters that would act deleteriously on silver prints.

METAL SPOTS.—R. E. SILCOX. The spots on the print forwarded are due to metallic particles in the paper. All drawing-papers, though excellent for the purposes for which they are made, are not suited for photography. The sample you have is a case in point. There are other makes with a similar surface that will answer. Try some of Whatman's make.

PATENT QUERY.—INQUIRER says: "A year or so ago a patent was applied for in connexion with an invention in which I take an interest. The patent was not completed. How can I learn what was in it?"—If the patent was not completed, the specification is not published, and the only way you can ascertain what was in it is to apply to the applicant for the patent.

STUDIO.—S. S. S. asks "whether there would be any advantage in having a dark passage at the end of a studio eighteen feet long in which to run the camera when required. The length of the studio, with glass, cannot be made longer than the eighteen feet."—Yes, decidedly. The dark passage will be equivalent to extending the studio by the length of the passage. Eighteen feet of glass is ample for all purposes.

DRY PLATES AT THE CUSTOMS.—TOURIST. If you have the packages labelled, "Photographic plates, must not be exposed to light," and explain the matter when the luggage is examined on the German frontier, you will have no difficulty. Better register the luggage through to your destination in Germany when you take your ticket in London, then you will not be troubled at the Belgian or Dutch customs whichever route you take.

CHEMICAL FOCUS.—H. BEDFORD. It does not follow that because the portrait lens does not work to focus that it is a bad instrument. Most of the first Petzval lenses had a chemical focus, but many of them were excellent instruments when the necessary correction was made after the image was focussed. The chief thing against them is the inconvenience.

A. C. STRUTT.—1. Theoretically such a mixture sets free a sulphur compound which attacks the image and possibly endangers its stability. 2. You probably develop too long—hence the discolouration. With regard to Ortol, you might try one on the formulæ given in our ALMANAC for 1900, but we have had no practical experience of it for the purpose. We have obtained the purest blacks by using the developer recommended by the makers.

HOLIDAY.—OPERATOR writes: "Will you please tell me the rule with regard to holidays? I have been here a year at a salary of two pounds a week. What is the length of holiday I am entitled to?"—You are not entitled to any unless your employer likes to give you one, that is supposing you did not stipulate for a holiday when you made the engagement. Some, most, employers give their operators a holiday, but many do not. There is no rule in the matter.

MOTTLED PRINTS.—ALBUMEN writes: "Can you kindly tell me the cause of the mottled appearance of the enclosed prints? They show some mottliness while they are printing, but much more when they are toned. The paper is —'s, and we sensitise it ourselves. It is only lately we have been troubled in this way."—The cause is obvious. The paper is sensitised on much too weak a bath. Add more silver to the solution and all will go well, of that we are sure.

VEILED LANTERN SLIDES.—W. HYDE says: "I cannot get my lantern slides clear, they are all veiled like the two sent. Occasionally I get one or two as clear as could be wished, but they are rare exceptions. Can you suggest the cause?"—The two slides sent clearly show that the plates are "light-struck," that is, they have been exposed to an actinic light either before exposure or before development. It may be, however, that they are developed in too strong a light, and so become fogged. Anyhow, they are fogged by light.

SALE OF BUSINESS. W. says: "Six months ago I bought this business, the returns of which I was given to understand were 300% a year. I now find they are not a quarter of that, in fact there is really no business at all. Can I compel the party to take the concern back and return the money I paid him?"—We fear not, unless you can prove there was a fraudulent misrepresentation as to the returns, and that is rather a difficult thing to do. Better consult a solicitor on the subject, that is, if the vendor has the means to refund the money.

RESTORING DAGUERREOTYPES.—F. W. TASSELL writes: "I often see in your Answers to Correspondents about advising them to place a Daguerreotype in the hands of an expert to be restored. I have one to do, and would be glad if you would kindly give the address of an expert in this business."—In reply: Some time ago, we believe, Mr. C. B. Barnes, of Alloa-street, Deptford, S.E., offered to undertake the work, but whether he is still prepared to do so we cannot say; perhaps the publication of this question will bring our correspondent the necessary information.

STAINED PRINTS.—I. CONACHER writes: "Having been annoyed for some time with stained prints, I enclose a few, in the hope that perhaps you could explain what has puzzled us for some time. They take two forms, red and blue being one, the other yellow."—We regret we cannot enlighten you. If you had furnished us with some details of your method of working, such as the paper, toning bath used, strength of fixing bath, and your mode of procedure, &c., we might possibly have helped you; but of course, by simply looking at the prints, we cannot. All we can say is that the stains are due to the manipulations.

ENAMELLED DISHES.—PLATINOTYPE writes: "We have used an enamelled dish for fixing platinotypes for some time now; but of late the enamel has become porous, and round the sides has begun to peel off. Where the iron is exposed to the acid there is a continual effervescing. I believe the combined action makes hydrogen gas, but am not certain. Is this in any way detrimental to the keeping qualities of plates, or would they turn yellow sooner?"—Certainly it is. The acid is exerting its action on the iron of the dish instead of the iron in the prints. Iron vessels denuded of the enamel should never be used for fixing platinum prints. Use porcelain dishes for the purpose if you wish the prints to remain white.

VERBAL AGREEMENT.—O. P. writes: "In March I was engaged here by Mr. — for a year certain. At the time I agreed not to enter the service of any other photographer within three miles of here until I had left the place for a year, under a penalty of fifty pounds. Last week Mr. — gave me a month's notice, when I told him that that would release me from the agreement. He replied, Oh, no, it did not, and, if I engaged with any one in the neighbourhood, he would commence an action for the fifty pounds. Can he do so? The agreement was only verbal between ourselves?"—No he cannot recover anything. As the agreement was not in writing, or duly stamped, there is no agreement at all. The threatened action is simply "bluff."

H. (H. (Paddington).—1. With regard to half-tone a book on the subject by Julius Verfassner, published by Percy Lund & Co., Bradford, will give you some very useful information. This we recommend you to supplement by addressing Messrs. Penrose & Co., Upper Baker-street, 1, Lloyd-square, E.C., who are most competent to advise you on the subject. Between the two you will learn sufficient to enable you to decide whether, it is worth your while to take up the process commercially. Here the business is "cut" badly; in Australia the scope, we imagine, is limited. 2. We have had no practical experience of it; if you intend adopting the process commercially, a small plant would not involve a very great outlay.

### EX CATHEDRÁ.

ONE of the most striking features in the west of Scotland at the present moment is undoubtedly the return by many leading professionals to what may be termed an "old fashion" in the style of finishing their productions, and this is noticeable in nearly every stage of the work, from the selection of a background to the shape and colour of the mount upon which the finished photograph remains. Not many years ago scenic backgrounds in portraiture, for instance, were voted quite out of fashion, and any one would have looked in vain for a photographer outside a third or fourth-rate position who was bold enough to continue in their use. Yet what do we see at the present moment? Why, many of the very best firms employing them whenever they can find an opportunity. In fact, plain backgrounds, with quite a number of professionals, at the moment may be said to be discarded. That several causes have contributed to bring about this change of fashion is, no doubt, apparent to any one bestowing a little thought upon the subject, and it can be clearly demonstrated to a person

walking along some of the chief thoroughfares and carefully studying the show-cases of the different leading portraitists.

\* \* \*

IN Sauchiehall-street, Glasgow, for instance, which has within recent years become the fashionable ladies' promenade, there are located perhaps as many, if not more, studios and photographic show-cases than in any other thoroughfare in the kingdom. And what do we find on examination of these high-class productions? Why, the striking fact that one of the undoubtedly best portraitists of the day has been bold enough to return to much that many of the "sickly devotees of the greenery yallery school" would term old-fashioned and inartistic—old-fashioned by reason, no doubt, of the taste displayed in the selection of accessories, and inartistic on the score of their productions being printed on a highly glazed sample of gelatine or collodio-chloride paper. And yet what is the result of this fresh departure? Why, large crowds are continually sun-gazing at the show pictures, and evidently admiring, beyond measure, the skill of the photographic firm displaying them.

\* \* \*

NOT many years ago the same firm was seen making a striking feature of platinotype, and now any one would have to look in vain among the productions shown in the streets by the best firms in Glasgow for a single show picture produced on this undoubtedly permanent printing medium. That platinotype has hitherto been a most popular printing process with many workers, no one will deny, but still the public has never entirely taken to it for portraiture; and even with several of the best amateur workers we now see this excellent printing process being more or less discarded for good old carbon, as was strongly evidenced at the recent exhibitions. On the other hand, autotypes or carbon prints are much in evidence in the show-cases of the leading professionals—a striking proof of the great beauty of the prints produced by this delightful process.

\* \* \*

ANOTHER striking feature in the various specimens at present being publicly displayed is the "individuality" shown by different professionals. This is seen in the selection by

different workers of one or other of the more modern printing papers, such as Gravura and others of the same class, while there are not wanting those bold enough to resort to good old albumen in the printing of their specimens. The one chief feature, however, would appear to be the discarding of the colder tones for the rich, warm browns and sepia in carbon and gelatino-chloride, &c. It is not only, however, in the return to much that is old-fashioned in the way of backgrounds that the present style is tending. There is also a striking innovation, not only in the shape of the mounts, but likewise in their colour. In no single instance, from among the large number of professionals who have recently exhibited their spring show-cases do we find a single specimen of the old style of cabinet mount, carrying the picture well up to the edges of the card. The present fashionable mounts would appear to be those having an embossed *circular* centre. Think of it, ye would-be "Dictators in Art," the present most fashionable shape is actually a circle, while, as to colour, the clean, white margin has actually displaced the brown-paper imitations of recent times, and even kahki is somewhat stale.

\* \* \*

ANOTHER very striking and sensible fashion, which may in a sense be termed an "individuality" on the part of one of Glasgow's portraitists lies in the production of large carbon prints having a wide white-paper margin. These are very high-class productions, and range in size from 12 x 10 to 15 x 12 inches, and carry all round a margin of about four inches of *white* paper. These high-class photographs are neither framed nor mounted in any way, but are displayed just like an unframed engraving, and in this respect they prove a striking feature, contrasting favourably with the sombre carbon prints framed without any margin in ridiculously common stained wooden frames, which a few of our boasted exclusive modern school deem so artistic.

\* \* \*

DURING recent years not a few writers have thought fit to air their opinions pretty freely both as to the shape as well as the most artistic manner of printing and finishing a photograph, and this sort of thing has entered largely into almost every branch of photography, lantern slides and their masking being no exception, circles in every instance being tabooed and deemed inartistic, and not nearly so "tony" as certain other shapes; and now we see that there are those who can, like Mr. Fred York, see some reason and even beauty in employing and exhibiting a lantern slide or silver print in a circle mask or circular form of mount. The truth is, in photography, like so many other departments of social life, there enters what must be called a strong fashion for the time being, and as yet there is no actual focus or centre from which these fresh departures in style emanate. One year we see a sickly running after a spurious style of would-be art, the next we see a return to a more sensible state of things, which was good enough for our grandfathers in bygone days, and then, again, we see the traces of would-be art being kicked over by some leading firm bold enough to adopt a style simply because the public like it and will have it. As yet the general public is certainly not educated up to much that many of the more "secluded set" deem "art in photography," and so long as common sense animates a buyer, and he buys and orders on the strength of his own taste, and not that of others, so long will there be found those bold enough to produce that which is pleasing to the public, simply by reason of the fact "that he who pays the fiddler chooses the tune."

THERE are those, no doubt, who will deplore that so much of this sort of thing is to be found, and who allege that no actual progress in photography can take place until photographers recognise that their productions must conform to certain narrow lines which they deem artistic, such as the abolition of all highly glazed printing papers, as well as an out-of-focus fuzzy effect in their prints, and the production of pictures the chief feature of which lies in false lighting and striving after so-called "pictorial effects." On the other hand, there are those bold enough, and who recognise that one of the cardinal points in photography is "truthfulness," and that photography in its proper sphere is not, nor ever can be, elevated to the lofty pinnacle of so-called art, but that it is a household necessity! Of this there can be no doubt, and, so long as the public desire a glazed print and absolutely sharp productions in commercial as well as other pictures, so long will there be found photographers willing and sensible enough to cater for their taste in a purely business-like manner.

\* \* \*

BUT what about permanency is the question that naturally follows the adoption of some of the modern printing mediums? No doubt, in former times, when only single albumenised printing papers were employed, a much greater degree of permanency was obtained in the photographs supplied to the public, but this was, to a certain extent, attributable to the treatment those prints received at the photographer's hands. At that time it was well recognised that, by subjecting all prints to a suitable "salt bath," and printing to a depth that permitted of the print being thoroughly fixed before any injurious effects to the image was contracted, those photographs were practically permanent, and it is still claimed that this mode of treatment is quite as efficacious with modern printing papers as was then the case with single albumenised samples. The truth is, much depends on the treatment the photographer bestows upon his prints, and this is clearly seen in scrutinising the productions of photographs taken years ago. In several instances, alas! the fading is only too apparent in the productions of certain workers; while, on the other hand, the productions of other houses are strikingly free of deterioration after a lapse of nearly twenty years. And here have we not something to reflect upon? That one leading photographer in the West of Scotland always insisted upon the salt bath being used between the operations of toning and fixing is well known to old workers in the district, and now we can point to the fact that, in every case, the prints that passed through his hands are practically permanent. Permanency, no doubt, is of paramount importance, and many conscientious photographers are found discarding any process liable to give out in this respect. To say, however, that all highly glazed samples of paper are lacking in permanency is going too far, and the public realise this well enough.

#### THE AVOIDANCE OF GRANULARITY IN COPYING.

IN copying a photograph or other picture on paper in which the grain or texture of the paper is distinctly visible there are certain well-recognised methods whereby the grain or other rugosities may be made to disappear in the copy when this is produced by means of photography, even the very coarsest samples of drawing or water-colour papers being amenable to certain conditions of working.

Any one who for the first time attempts to copy subjects of

this kind may very possibly fail to produce a result that does not show more or less strong resemblances to the texture of the paper picture he has copied, and this notwithstanding that he has followed closely the instructions given by practical workers as how best to avoid this granularity in a finished print, and, as a natural consequence, the writers are blamed for misleading novices in this particular branch of work. But why should such failures occur? This question is easily answered. As a rule these failures do not arise from any actual error on the part of the operator in his *modus operandi* of copying, or from his having followed out erroneous instructions, but more frequently from the simple fact that mistakes are made in differentiating between what is actually the grain or texture of the paper and that of a surface that is in a damaged condition. A simple example may be cited in explanation of the difference between two such cases. Take, for instance, the case where a photographer is called upon to make an enlargement from, say, a *carte-de-visite* size of photograph, executed probably thirty years ago (and this is by no means an uncommon case). Such pictures will almost certainly be found printed on a sample of albumenised paper known at that distant date as "single albumenised," and, according to the chance treatment the photograph may have received all down the long term of years since it was produced, will be handed to the photographer in a greater or less degree of imperfection by reason of the amount of carelessness displayed by the owner of it not protecting it from damage. This deterioration will be apparent in more ways than one. In the first case, a distinct want of brilliancy in the surface of the paper is almost sure to be noticeable, and very probably also the photograph may be more or less discoloured through the lapse of years since it was taken.

To an ordinary observer these two defects may appear all that is wrong with the picture; but to a practical worker, who has learned much from having to deal with the copying of subjects of this description, there is a third, and more serious, defect in the photograph, more serious in so far as it affects the operation of copying in a marked degree. This defect assumes the form of having the skin or surface of the sample of single albumenised paper more or less abraded, a condition which makes it very difficult to deal with in copying by means of photography. Nor is this to be wondered at when it is considered what an amount of attrition a paper photograph receives at the hands of people during its lifetime. Very probably every time it has been taken in the hand for examination a finger will have been passed over its surface by thoughtless people, who never for a moment dream of the damage they are doing a picture; and this continual attrition or rubbing of the surface of a photograph soon becomes apparent to the practised eye of a clever operator, who can detect in a moment what others never think of as a defect or deterioration, and hence, when these pictures reach the hands of a photographer for the purpose of copying and enlarging, we hear such remarks made as "That's a bad one."

Pictures, and photographs especially that have suffered by reason of attrition, are not easy to copy by means of photography, and it is just such examples as these that give rise to much disappointment and at the same time discontent, on the part of those who feel they have followed closely the instructions given from time to time in the columns of the photographic press by writers of experience.

It does not require much consideration on the part of a

thoughtful student in photography to see at once that there is a marked difference between copying a subject in which the surface presents an appearance, and is composed in reality of nothing but ordinary texture like a sheet of paper and that of a case or subject totally different, and which, in reality, is not, in a proper sense, texture at all, but consists of very minute and distinct contrasts composed of a partially intact amount of the original photographic image and a proportion of surface where no such original image longer exists, and which has been removed by friction. Such defects are not properly termed granularity, or, at least, if so, only in a very secondary degree. They are more properly classed as contrasts in colour, and cannot be dealt with by means of photography on the same lines as when treating an ordinary case of granularity.

In contrast to this, let another case be noted, and this time, say, an operator is called upon to photograph a wash drawing, or other similar subject, contained in a sample of the roughest possible drawing-paper. Here we have a case where there can be no possible doubt about the amount of texture present, and it is just about ten to one, were the novice asked which of the two subjects would copy best by means of photography without any grain being visible in the finished print, the answer would be, "The *carte-de-visite* subject, certainly." To a practical worker, however, it is all the other way about, simply because he knows that, by following out certain well-known methods of procedure, texture can be easily dealt with; but not so subjects in which the apparent texture is not grain in reality, but rather a series of contrasts in colour between that of the paper surface and the remaining photographic image.

The first consideration, therefore, when work of this description has to be undertaken, is to determine whether the original photographic image is intact, or whether it has suffered by friction, so that part of the image has been rubbed away, leaving the most minute portions of paper only. A fruitful source of damage to silver prints in this way arises from the careless dusting of a sitting-room in which photographs are lying on tables, &c., as articles of ornament.

From time to time several methods have been advocated for avoiding the appearance of grain when copying photographs or paper surfaces. Among the earliest may be mentioned what for a time was looked upon as a trade secret (for old collodion-workers kept it well up their sleeves). This method consisted in copying such subjects in varying planes of focal lengths by means of a lens through the camera, which was capable of being altered in focus by racking in and out the sensitive plate at the rear. First of all the picture was placed *in situ* in daylight, and most carefully focussed on the ground glass of the camera; an exposure of about half the necessary amount was accorded to the sensitive plate at this plane. The rack and pinion of the camera were then, after capping the lens, made to withdraw the sensitive plate to a distance very slightly beyond the true plane for the sharpest focus; at this point a brief exposure was also given to the plate, the lens capped, and the camera racked inwards to a corresponding distance in front of the plane of true focus, and a brief exposure given at this point also.

On development a perfect result will be found, providing proper attention has been bestowed upon the lighting of the picture. One thing, however, must be noted, *v z*, when this method of copying is resorted to, the alterations of focal

planes must be effected by means of a camera, whose rack and pinion is operated upon *in the rear*. The distance between the lens and the subject must not be tampered with in the slightest degree, and in this we have another proof of the deficiency in modern apparatus. Cameras are now made in thousands where utility is sacrificed entirely to portability. This we see in the new form of camera, in which focussing is done by altering the distance of the lens from the subject, instead of providing for its being possible both in front and rear.

Another method adopted by workers many years ago was that of interposing a thin, transparent film between the partially printed proof and the negative after the latter was in the printing frame. This method, however, was not so easily accomplished by reason of the difficulty of correctly registering the prints. Such manipulation, however, can be accomplished, provided a few simple precautions are taken when inserting the negative in the printing frame and the placing of the sensitive paper in contact with it.

In copying pictures having paper supports there is no doubt the chief item lies in properly lighting them. It is quite surprising the difference in results obtainable by varying the disposition of the picture in regard to the source of light. This any one can prove by a few simple experiments. A strong side light will, of course, be the most unsuitable whenever it is desired to suppress grain in a photograph. The best results are certainly obtained by placing the picture *in situ* in front of the full light of a north window. A very good test object for an experiment will be found in a sheet of coarse drawing-paper. Let this be photographed with a dead side light, and then with a full front light. On comparison very striking differences will be apparent.

A photographer, however, is frequently called upon to execute work in which the greatest amount of surface rugosities is required, such as when an imitation in paper of such articles as morocco leather or crocodile skins is required. In such cases a front light would be fatal to success, and only a concentrated side light of narrow dimensions should be employed in photographing such subjects.

Exposure also forms a very important item in suppressing grain. This should be full, or verging on what may be termed over-exposure. Where the utmost amount of rugosity is desired, it should be just right, if anything erring on the side of under-exposure.

Long-focus lenses should be employed in all operations of copying, the reason for this being, that reflections are not so liable to reach the sensitive plate when they are employed as is the case with short-focus objectives.

With highly glazed gelatino-chloride papers there is no difficulty as regards grain, but sometimes trouble arises from reflections. Such samples are best dealt with a side light, seeing there is no grain and long-focus objectives will permit of any reflected light passing outside the angle of view of the lens, provided the lighting is properly looked after.

Some workers advocate the placing of scrap photographs in optical contact with the glass as a preventive of grain in copying. No doubt, holding the photographs *in situ* in this temporary manner whilst they are damp is often very convenient, and this simple plan has much to commend it, especially where the photographs have been kept in rolls. The damping keeps them nice and flat, but it is questionable if the method reduces the grain, which, after all, is only overcome by correctly lighting the subject.

**The Royal Observatory.**—The annual inspection by the Board of Visitors of the Greenwich Observatory, which is usually made on the first Saturday in June, took place on Tuesday last week. The postponement of the visit was due to the recent eclipse of the sun disturbing the usual routine of the astronomical world. Each annual inspection reveals the fact that photography is being more and more extensively utilised in connexion with astronomy. One very interesting exhibit was the photographs of the solar corona and those of the solar spectra taken at Ovar, Portugal, during the late eclipse. These, though not showing, perhaps, quite so much detail as the corona taken in India in 1898, yet still form a valuable contribution to solar science. In another room there were on view some excellent photographs of nebulae and double stars taken with the large equatorial telescope which Sir Henry Thompson presented to the Observatory, and, also, specimens of the astrographic chart which Greenwich is making in conjunction with the other observatories.

By the way, it is to be hoped that every precaution will be taken in the production and preservation of these negatives, which are gelatine ones, in face of the statement that, in some of the negatives taken only a few years ago, many of the fainter stars have disappeared. Would it not be well to reproduce the negatives by the collodion process, or, at least, make transparencies from them by that process? The collodion process is unquestionably a permanent one when only ordinary care is exercised in its work. Our suggestion, of course, applies to all observatories that are expending years of labour in charting the heavens. If that were done, we should advise that cyanide of potassium be employed as the fixing agent, and not "hypo."

WHILE on the subject of astronomical photography it may be mentioned that, at the meeting of the British Astronomical Association and the joint meeting of the Royal Society and the Royal Astronomical Society last week, a large number of reports had been received from the observers who went to Spain, Portugal, Algiers, &c., all of which were of a very satisfactory character, several fresh phenomena being observed. It is very doubtful if any previous eclipse has been favoured by such excellent weather at all stations as this one was.

**Air in Water.**—At a recent meeting of one of the London photographic societies this topic cropped up. It is tolerably well known that water, at high pressure, often contains a considerable amount of air which is liberated when the pressure is reduced—often to cause trouble in photographic operations—possibly in nothing so much as in the carbon process. If the tissue, after exposure, be mounted on the support with such, water blisters are very likely to arise by its expansion when the picture is developed in the warm water. We have seen water drawn from high-pressure mains, particularly after repairs had been made in the pipes, that had the appearance almost of whitewash, but, after standing for a few minutes, it became perfectly clear and bright. Indeed, it might be compared to a bottle of ale, highly charged with carbonic acid, when first opened, which, though cloudy at first, quickly becomes bright and clear as the gas liberates itself. It is only when the water is drawn directly from the mains that the air it may contain is likely to cause trouble in photography. That will not be the case when the water is drawn from the cistern, as there, the pressure being taken off, the air soon escapes.

**Hertford House and the Wallace Collection.**—The art collections at Hertford House, the munificent gift of Lady Wallace, is now open to the public. Probably this is the richest gift the nation has ever received from a single individual, for not only are the art treasures given, but also the magnificent building that contains them, in Manchester-square. The art treasures consist of furniture, china, armour of different dates, paintings, &c. It is the latter that will, no doubt, interest the majority of our readers most, for in this collection every school is represented by some of the finest work in this country. Amongst these are paintings by

tubens, Van Dyke, Gainsborough, Rembrandt, Sir Joshua Reynolds, Turner, Greuze, Cuyt, Metsu, Jan Steen, &c. From the pictures and art works here shown, photographers who study art—real art, and not that affected by some pseudo "artists," by means of bad photography—may learn much, as indeed they may from any fine paintings. The collection is open to the public free on Mondays from two till six; Wednesdays, Thursdays, and Saturdays between ten and six; and on Tuesdays and Fridays between the hours of eleven and five, on payment of sixpence. The collection will also be open free on Sundays up to the last Sunday in October, between two and six, or two and five, according to the season. Thus *employés* and others who cannot get time on week days will have the opportunity of visiting the Wallace Collection on their only leisure day.

**Forgery and Photography.**—We read that a large number of forged Bank of England and Irish notes of 5*l.* and 1*l.* respectively are in circulation in Ostend and other Belgian towns, as well as in Holland. Now that the tourist season is on, it is probably the time such forged notes are most likely to be put into circulation, and accepted by the unsuspecting. Unfortunately for their credit, photography or photographic methods have been the basis of the greater majority of the forgeries of later years, alike of British and foreign bank notes, though it was more or less successful even in the earliest days of the art. It is easy to understand that on the Continent, where English bank notes are generally looked upon as being "as good as gold," many may be passed on the unsuspecting; but it does not follow that the forgeries were made in this country; more probably they are produced abroad, if not, indeed, in the country in which they are passed off. Anyhow, English tourists are scarcely likely to be victimised by them, because, when they visit a bureau-de-change, it is to get gold for notes, and not notes for gold. Furthermore, an Englishman is not likely to be deceived by these spurious notes, which, we learn, are clumsy imitations of the well-known Bank of England paper.

#### PARIS EXHIBITION NOTES.

##### I.

THE man or woman who sees the whole of the Universal Exhibition with which France—or, shall we say, Paris, the glittering Shrine of Pleasure?—closes the most turbulent century of her history, will have accomplished a very great feat. We are inclined to think that, when next autumn the housebreaker has knocked down the miles of graceful palaces on both banks of the Seine; the last visitor has taken his last look at the figure of the Parisienne, who, from the summit of the main entrance on the Place de la Concorde, stands inviting with all her heart the world to come and see the wonderful show which the genius of French administrative ability, undaunted by the threatening political outlooks at home and abroad, has got together; that when the turnstiles have ceased revolving, and all the remaining interest of France in her Exhibition is centered in the final arithmetic of the speculation, then, even with the amount of exaggeration that is permissible in the language of retrospect, few will dare claim to have "done" the whole of the Exhibition. It is probably the largest thing of the kind the world has yet seen, and, from the point of view of the visitor, the worst arranged. The patriotic Briton, for instance, who wishes to glance at the productions of his beloved homeland, must be prepared to undertake a considerable amount of pedestrian exercise in the quest. A photographer would naturally wish to look at the English photographs and the English paintings. At a rough guess, something like a mile separates the two sets of exhibits!

This idea runs throughout the entire Exhibition, which has been arranged on a decentralising plan. Each country is represented by its own pavilion in the Street of Nations, but its exhibits are scattered in various parts of the Exhibition. This system precludes the subdivision of the Exhibition into classes, and the result is that a wish on the part of a visitor to study the world's productions in one particular branch of industry can only be gratified at the expenditure of a great amount of time and trouble.

Paris within the last few days has been crowded with German and American visitors. Of the many scores of cameras that we saw in the grounds of the Exhibition, very few indeed were carried by

English photographers. The holiday months of July, August, and September will probably provide the majority of English photographers who intend visiting the Exhibition with their opportunity of doing so. Let us give a few hints for those who may wish to do work at the Exhibition. In the first place, the visitor must be prepared to enter a world of magnificent distances and lofty buildings. The intelligent photographer will have no difficulty in realising what this means. He must go provided with a series of lenses increasing in length of foci from three or four inches. At one time he may find himself working at very close quarters, as, for example, in the splendid Rue des Nations, where the gorgeous international palaces stand all together, and it is impossible to place the camera at more than a few yards' distance from any one of them. So, too, in the Oriental villages that cluster about the Trocadero, this exceedingly picturesque "food for the camera" will also necessitate the use of short-focus lenses. The river intersects the Exhibition, and from either bank fine views of the bridges and palaces are to be seen. Then there are the wide vistas of the Invalides, the Champ de Mars, and the incomparable panorama that is seen from the Trocadero, where the whole glory of an architectural paradise stretches itself out at your feet. To get photographs of these subjects at all satisfactory in size, lenses of considerable focal length are obviously essential.

The charge of a pound a day for the use of stand cameras in the Exposition appears, so far as we could judge, to confine large work, say, 12×10 and upwards, to local professional hands. From a business point of view, one pound a day or forty pounds for six months is a considerable risk to run unless the photographer has a commission to execute at prices which will allow of this very heavy tax being added to the cost of producing the negatives without diminishing the profits. We cannot imagine any professional photographer parting with his daily pound purely as a speculation.

It can easily be supposed that hundreds of thousands of hand cameras have been and are used at the Exhibition. At the time of our visit they stared us in the face at every turn, but the excellent friend who accompanied us, and who had been doing photographic work in the Exhibition since its opening in April, assured us that in May and June there were a great many more cameras to be seen.

Photographs of this vast place, taken in small hand cameras with lenses of four or five inches focus, have a disappointing and dwarfing effect. We saw many stand cameras held in the hand, in size from half to whole-plate, and this hint we would recommend the English visitor to bear in mind. The Exhibition is on such a scale of grandeur that only large direct work can do justice to it. The hand-camera man who confines himself to small negatives with a view to subsequent enlargement may be wise in doing so, but he sacrifices the panorama-like effect which only large direct work can properly give, and which constitutes, in our opinion, one of the chief features of this wonderful Exhibition, that it should be the aim of photography to suggest.

After ten o'clock in the morning the opportunities of taking photographs in which figures do not show are few, for the human flies swarm over the place in hourly increasing thousands. The Exhibition opens at eight in the morning, and between that hour and ten the photographer will find his best chances of securing views in the grounds. Later in the day photography, except from the bridges, becomes a matter of great difficulty if it be desired to exclude figures. These hints are penned for the benefit of the serious worker who wishes to secure good photographic mementoes of an Exhibition which it would be difficult to excel in point of interest, and the like of which human eyes may not look upon again.

Of course, the "snap-shotter" will find himself in his element, but we would caution the English visitor against indiscriminate photography amongst the people in the grounds—men and women of all nationalities are there, and there is a bewildering variety of Oriental costumes. The foreign photographers appear less prone to indulge in the gentle practice of photographing one another than are their British *confrères*. In Paris just now it is impossible to escape the fact, unpleasant though it may be to have to recognise it, that English people are not the favourites of their hosts. The reasons for this disagreeable state of things are not the natural subject matter of a discussion in these pages, and we make the reference

only for the purpose of advising British photographers who may be using their cameras at the Exhibition or in Paris to be wary in not giving possible causes of offence to strangers by taking photographs of them in a furtive manner.

The bad odour in which most things English are held in Paris at this time is no doubt deepened by the very poor support which the Exposition has received from this country. In this respect Great Britain comes out very indifferently. She is represented in the industrial section by, we believe, under four hundred exhibitors. Germany has sent the grand total of 7000 to take part in the Paris show. Indeed, it may be said that the Fatherland and the United States divide between them the chief honours of the Exhibition.

And, as if this paucity of British exhibits were not enough to humiliate the visitor from this country, he is further reminded of the poor figure cut by the United Kingdom at the Exhibition by the apparent lack of any effort on the part of our Royal Commission to secure some decorative effect in the display of those exhibits which permit of it. Everything has been left to individual effort, which has seldom soared above the friendly help of Drew & Cadman. Things are vastly different in other countries. Government co-operation has been freely bestowed. The pavilions are tasteful in design and execution. Each exhibit is part of a general scheme of colour and structure. Little Switzerland, for example, shows her photographic productions in a beautifully designed pavilion, which would not look out of place in a fairy scene, it is so graceful and airy. But poor British photography! It is placed upstairs, and is displayed on wooden screens, whose severity of design and colour might be appropriate enough in the British Museum, but which look inexpressibly shabby and dingy amidst surroundings so beautiful as those in the building on the Champ de Mars. Why, the *tout ensemble* of a Pall Mall Exhibition is an æsthetic dream in comparison with the paltry style in which British photography is shown at Paris.

The fault of all this may not rest with those responsible for the management of the British section at Paris; although there is some reason to fear that the high and dry officialism with which the name of South Kensington is so unhappily associated in this country is at the bottom of it. Look at the charming system of administration adopted in the case of the English House in the Rue des Nations! This latter is one of the most popular features in the Exhibition. It is a street of gorgeous national palaces open to free inspection, with one exception—that of the English house, of course! To this building, which, if the truth must be told, is about the poorest and tiniest of the series—an old English house is all very well in its way set against an English landscape, but it looks very mean when surrounded by the stately and ornate palaces which Italy, Germany, Belgium, and many other countries have raised—the British visitor naturally makes his way at some time or another, and, of course, numerous foreigners want to have a look at the inside. But to an inspection of this English House, officialism ingeniously places obstacles which would do honour to the wooden-headedness and perversity of a Somerset House clerk or a high-salaried *employé* of the Circumlocution Office. The English house is not open till two in the afternoon, it is closed on certain days in the week, and you are only admitted on presentation of a ticket obtained in a part of Paris a mile or two away! This is what you learn after having travelled perhaps two or three miles from your hotel along the noisy streets, and covered, may-be, a mile in the Exhibition grounds. Could anything be more exasperating? Nearly all the other palaces are open to you; freedom to wander among the priceless treasures of the main buildings of the Exhibition is yours; you can put your eyes as near as they are to this page of print to diamonds valued at a quarter of a million golden English sovereigns—revel, in fact, in close proximity to a great blaze of gems fit for a dozen queens and empresses; the pictures, the tapestry, the sculpture, the magnificent china are yours to look at all day; but you mustn't go into the paltry little English house with its by no means exceptionally attractive furniture and pictures, until half your day has gone and then only by ticket obtainable miles away. It is just for all the world as if a man ran down to Hampton Court Palace only to find that he had to trapeze back to Richmond for a ticket!

#### ON THINGS IN GENERAL.

I RECOMMEND those of my readers who have not already taken notice of it to carefully read Mr. Archer Clarke's paper on "Reducing Over-printed Paper-Bromides," in the June 22 number of this JOURNAL. It was founded on a reply of the Editors to the effect that it was best to do another instead of troubling over the matter. I think I myself once suggested that the furnace for waste silver paper was the best treatment. I still think so. The Editor referred to *over-printing*, which term is usually applied to printing out, Mr. Archer Clarke to *over-exposing* a bromide. This is by the way, and, whatever the text, the writer gave a capital sermon full of useful hints. He does not refer specifically to either portrait or landscape work. I am inclined to think the former was in his mind for a slight removal of the more delicate tones in such prints if it took place (and I am inclined to think it would occur) would be less likely to be observed than if a portrait print were operated upon. There is one point in Mr. Clarke's paper which points to an experience opposite in character to my own. He says, referring to a recommendation to use "the well-known Howard Farmer reducer of ferriprussiate potash with hyposulphite of soda," "Now, this cannot be used satisfactorily with paper, as it stains the whites." Now, I have used this reducer for bromide prints on very many occasions without ever observing the ill effects referred to. Old wet-collodion workers know all about the dangers of cyanide; but, as they nowadays form a very small minority of the genus photographer, it may be well to emphasise the fact that it is a very deadly poison; the stock solution described would be about as deadly as prussic acid. Further, the fingers should never be permitted to be in contact with the solution if there be the slightest cut or abrasion. Its absorption under such conditions might be rapid and highly dangerous.

An inquirer, "Platinotype," has been writing to the Editors, asking about an enamelled iron dish which had its coating chipped away, and the iron gave off an effervescence when the acid touched it. He wanted to know if the dish would do any harm to "plates" (presumably a slip for prints). Really, it is extraordinary what questions some people will put. How any reasonably intelligent man could care to use a dish under such conditions is a problem beyond my power to solve. I may take this opportunity of saying that enamelled iron dishes should never be used for acids. There are, no doubt, many makes of these dishes, but in all my experience I have never yet met with one which would not be acted upon by hydrochloric acid. These operations in platinotype work should always be carried on in an earthenware (so-called "porcelain") dish.

It is an actual pleasure to read of some one wanting information about albumenised paper, that beautiful process about which so few modern photographers know anything whatever, and still fewer as to how to sensitise it themselves. The Editors have hit upon the cause of an inquirer's difficulties: a dozen or more sheets of paper floated in succession, the first good, the last two or three bad. The floating of the paper takes up a portion of the silver, and leaves the surface portion of the liquid that much poorer in silver. This goes on till at last it is too weak altogether. The inquirer is directed to stir up the bath so as to equalise the strength. As a matter of fact, the dish should be gently waved to and fro several times between the floating of each sheet. A solution of silver nitrate has a considerable specific gravity, and it is quite a singular phenomenon to observe how two solutions, or plain water and a solution of silver may be placed in one vessel and remain unmixed. I have seen a winchester of silver bath made by first dissolving, to the extent of 20 grains to the ounce, in a bottle nearly full of distilled water, and then made up to 35 grains by adding about 10 or 12 ounces of very strong solution. I have then seen the winchester turned upside down twice over to mix the solutions of differing density, then put aside for a week or two, and finally seen half the bath poured into a glass bath, and prove so weak as to be useless. The strong solution was so heavy that most of it sank to the bottom, notwithstanding the double upturning, and remained weeks, and would have remained months, without equalising itself. This may appear incredible, but I repeat I have seen it.

In Our Editorial Table in these columns there was recently mentioned what I take to be an exceedingly useful work—"A Profit and Loss Chart" for the use of works managers. The editors say, Works managers should find the book of the greatest use," and I could think they are quite right; but, if the publishers, Messrs. Percy Lund, Humphries, & Co., would only get some one to compile such a book for managers on a smaller scale, to wit, owners of a photographic studio, they would confer a distinct benefit on a worthy class of professionals. How many photographers are there who, perhaps, may be capable of keeping, a businesslike profit-and-loss account? The result of such lack of business knowledge is seen too often in the commercial lists which spell disaster, and are always such a reading, showing blighted hopes and wrecked ventures. The profits to be made from running a photographic studio are sadly below what is popularly ascribed to them, and are only discovered usually when a man, say of undoubted ability and taste, starts a studio on a small capital. He runs it for a year, does a fair amount of business, draws what he thinks a moderate sum for his profits, and finds at the end of a short time that he is virtually bankrupt. Such a book that referred to, simply arranged, would show where the expenses and the leakages came in, what the probabilities of profit were, and whether the former could be curtailed sufficiently to leave a margin worth living or working for. The lamentable failures that many earnest and good workers have made in their business essays is an object-lesson that should add double force to the recommendation to employ some such system. Cognate to this question of the business aspects of photography is one referred to also in recent Answers to Correspondents. The inquirer had made a year's engagement verbally, and an agreement not to take employment in the district under a penalty of fifty pounds. To the employed I would say, attend to the advice so often given in the column I refer to, and remember that any engagement for a specified period is virtually worthless unless written, duly signed, and, preferably, "witnessed" and stamped with a sixpenny stamp. Further, to employer and employer I would say that any clause in an agreement whereby a penalty is to be paid or a forfeit made if certain conditions are infringed is, even if written, signed, witnessed, and duly stamped, absolutely worthless and incapable of being enforced unless drawn out in a particular way, or with certain additions which I will not particularise, as any such document ought to be made out by a solicitor unless the parties to it are expert business men.

The question of "Is photography a fine art?" has, by tacit consent, been laid aside for a long time, and I am not purposing to reopen it; but what might be termed a side view of the question came up recently in a very amusing manner. The attendant at an automatic photographic machine applied to a magistrate for a summons against his employer for a fortnight's wages. This man clearly thought himself an "artist." His work consisted in pulling the string and wrapping up the portraits, but he was very indignant at the magistrate's suggestion that no skill was needed. The soul of the artist was at once aflame. "Oh, yes, but there is," he replied. "Alas, poor artist! That sealed the matter. If he had only looked upon himself as a mere labourer, he would have had his summons or nothing; but, as a skilled workman, he must apply to the County Court for his summons, and pay the usual fees."

I find I am rather tangled up with artist ideas, and can't free myself of all references (my readers need not be afraid, I am not going to start the old controversy), for I noted an extract given a short time ago from a well-known art critic's remarks. From the paragraph I re-extract the following: "Photogravure is a mechanical process, and no artist comes in between the painter and the reproduction." Doesn't he? Engravers are allowed to be artists, and I should like to see the photogravure in which no such artist, at any stage of its production, has had a hand in the matter in his own particular line.

I was much obliged to Mr. Frank Bishop for his drawing attention to what he justly terms a funny error of mine *in re* Copyright

Acts. The real truth is, most of that lucubration was written while I lay ill in bed. I have unfortunately been a martyr to repeated attacks of "flu" of late, and have had to employ an amanuensis at times, who, on the occasion in question, beautifully mixed up my past and present memoranda on the subject dealt with.

FREE LANCE.

## THE PHOTOGRAPHER'S YEAR.

JULY.

JULY, spite of the longest day being in the possession of June, is the hottest month of the year. In the heat and languor of the town thoughts turn more readily in this month to the cool, loose idleness of a holiday than at any other time. The touch of fickleness that the weather shows in June has also passed away, and the continuance of a spell of fine weather becomes more assured, an important consideration in its bearing upon the enjoyment of a holiday. Photographs in the month should be holiday pictures. They should also turn out the best of the year, for, in addition to wealth of novel material, there is fulness of leisure rarely possible at other times to a busy man. The photographer has a very great advantage as a holiday-maker in the possession of his hobby, light or earnest as he chooses to make it. In all anticipations of a holiday, wherever it is to be spent, one essential is idleness, if not of both body and mind, at least of mind. It is the natural reaction from over-much or long-continued work. The doctor, engineer, and shop-keeper, tired out with bustling about for ten or twelve hours out of the twenty-four, think of rest as the leading feature of enjoyment. Thoughts wander to cool seaside rocks, hammocks swinging under shady trees to the murmur of softly running streams, and elastic couches in scented heather. There will be no patients to see, no night bell to answer, no job requiring personal supervision, no exacting customer to attend to.

Where the ordinary work is sedentary, and bodily tiredness not so much felt, as in the case of a lawyer, banker, or insurance agent, the holiday may take the form of a cycling tour, sailing cruise, canoe trip, or fishing expedition; but, if there be physical labour in it, there will be no mental work. The intricacies of law, money, and life tables are to be thrown completely out of the mind for the time being, and the luxury of no books, or only those in the lightest vein, indulged in. Fine anticipations and resolutions, but how do they turn out in practice? As a rule, unsatisfactorily. The busy man finds his holiday, after the first two or three days, palling upon him. He cannot lay himself in soak in idleness. The novel is trashy, the newspaper he has been accustomed to skim over in a few minutes cannot suddenly be made to last out two or three hours' reading, the time between meals seems very long, and the evenings are dull. Accustomed, during fifty weeks of the year, to a certain groove, he cannot, in the odd two, travel with comfort and pleasure in a totally new one. A sneaking longing for the flesh-pots of the city steals over his soul, becoming more and more pronounced as his absence from them lengthens. When free to return, he does so with a higher opinion of Adam as the originator of work, and the conviction that it is a blessed institution, after all. It may not go to this length with all, but, with few exceptions, holiday-makers would be much the happier for something to think over and do. A diluted continuance of ordinary work is out of the question. It must be change of work of not too severe a type, readily and agreeably taken to. Photography fills the want most admirably. Photography, that is, to one who has some natural artistic inclinations, and who can crystallise out a vague feeling of pleasure at his surroundings into the selection of a definite object that acts most suggestively as its central essential.

To take an instance to prove this point: One has elected, say, to spend his holiday at the seaside. There are certain to be some regularly recurring incidents in the life of the place that appeal more particularly to his fancy and liking, which he finds himself on the look-out for, and making something of an effort not to miss. It may be the return of the night fishers to the beach in the morning, or of the day fishers to the harbour in the evening, the caulking of a boat, tanning nets, the coast guardsman on his round, or what not. These are the things which, suddenly presenting themselves by some association of ideas to the memory later on in the year, recall most vividly the air of the place, and serve to give point to the pleasures of recollection. Every sensible man, wishing to get as much out of life in the way of pleasure as he possibly can, will do well to encourage the easy remembrance of such past pleasures. And the quiet pleasures that have had the time and opportunity during a holiday to incorporate themselves insensibly with the nature of their recipient have this marked advantage of one more keenly felt at

the time, that they are recalled more readily and with greater satisfaction. The indefinite recalling, indeed, is often felt to be a greater enjoyment than the original one, and even make a pleasure of what we were hardly conscious of as such at the time. It has the charm of distant music heard over still water. Time, like the water, has absorbed the harsher or discordant notes. Nature does her best to help out in this. A whiff of boiling pitch, during road-mending operations in the Strand will bring up the caulker's pot on the Cornish coast, a waft of burning wood or weed in a suburban garden present to the mind's eye Scotch moors and peat reek. The day's work or evening's leisure must necessarily be unconsciously lightened and subdued by such mental pictures and remembrances.

Photography does the same quite as effectively and reliably. More so, for the Strand, by some strange chance, may not be up, or the tar and burning squitch be too strong for a mere suggestion, and regarded rather as a nuisance. Selecting the best pictures from a suggestive point of view, and thinking out the best way of doing the work will serve well as the agreeable change of work referred to. Without the thinking it is very possible to take a camera along with one, and find, looking at results, that it has been more of a hindrance and an encumbrance than a source of pleasure. The usual pictures of the parade, pier pavilion, beach, Saint Somebody's church, and the something drive, or head, and far better ones than he can take, can be got with no trouble and at little cost at any of the local fancy shops. But if the visitor have any individuality, and succeed in impressing it in a pleasing picture, it will be worth a great deal to him. The personal element, too, is a factor to be considered.

A picture of any child playing a holiday part in the beach world is very pleasing, but, when that child is one's own, its value is immeasurably heightened. Holiday pastime, scraps of sailing, fishing, and camping out have a breezy air about them at all times, but there is an added air of closer interest when the one at the tiller, making the cast, or seated at the tent door, is the *fidus Achates* with whom the holiday was spent. The chief reason for the lack of sustained interest in very many pictures is that the subjects were not chosen as ones particularly appealing to the taste of the one who took them. This should be an essential factor. A man visits a certain place noted for a particular object—church, bridge, castle, ruined abbey, glen, or waterfall—and, as tribute, conscious or unconscious, to the orthodox, feels it incumbent upon himself to have a shot at the well-known subject, whether he cares for it or not. It is a mistake. However important towards success a subscribing to the orthodox may be in the ordinary concerns and walks of life, during the holiday it should be thrown reasonably over. A man should then at least take his soul, as he does his body, out of its frock coat and stiff collar, and give one, as well as the other, a less trammelled chance of benefit in the freedom and lightness of flannel. Photographing the stately church front merely because it happens to be the most important feature of the town has little suggestion of a soul in flannel about it. Taking the boat repairing behind the wooden jetty, or the copper pan in which the harvest beer is boiling, has, provided they appeal strongly to personal liking. The resulting picture will be part and parcel of one, as it were, an expression of individuality, and not merely the leading subject of a guide-book, and the stock one of local professionals.

Here, as a matter of practice, comes the question as to what kind of camera to use, whether a stand or a hand one. Much could be, and has been said both, in favour of, and to the detriment of, both. The question rises, in reality, much higher than one of mechanical merit and demerit. It is a psychological one for the user. The camera ranks among the "fruits" by which a man may be known. He of the stand camera has qualities and traits wanting, or present in a much lesser degree in him of the hand camera, and *vice versa*. Take the extra publicity of object, for instance, given in carrying the former. One man may not object to it in the least—may like it, indeed; whereas another would as soon lead an ostrich by a chain through a town as carry and pitch tripod and camera in a public place. Both are estimable men, but they differ in degree of sensitiveness. The one can be seen and heard on public platforms explaining and asserting political and civil rights; the other is fonder of his garden and books. The extra weight of the stand camera would betoken firmer purpose in the attainment of a special object, the added care and work necessary in using it, a careful and deliberate man. He is likely to be one engaged in an occupation with much detail in it, due attention to which he has learnt the value of, generally in the school of experience. He is the kind of man we are not surprised to hear quoting a proverb.

The hand-camera user is more off-handed in his nature, is inclined rather to ignore detail, but keen at seeing and seizing a salient point. His artistic taste is as high as his fellows', possibly higher, but he gratifies it more satisfactorily by a scrappy suggestion than a full picture. One would expect him to be rather indifferent to politics and a Broad Churchman. With differences so deeply rooted, what is the use of recommending that which one likes to the other? Let each consult his own special constitution first, and then the dealer's catalogue. If there be no marked individuality and plenty of money, and they generally go together, both kinds of camera can be used. The majority, taking all into consideration, will probably elect for a hand camera folding into a small compass to take with them for a holiday. What desirable occupation and pleasure it can give, any intelligent man can realise for himself by thinking for a moment of the great number of charming little spots and incidents of life outside his ordinary groove he has missed in the past from not having such a one with him.

The broad suggestion for July work, then, is quiet, thoughtful selection of personally pleasing and suggestive holiday subjects taken with the easiest-working camera.

### THE CHEMICAL NATURE OF RADIO-ACTIVE SUBSTANCES.

[Translated from the *Deutsche Photographen-Zeitung*.]

THE "photography of the invisible" has made considerable progress in recent years. It is well known that Becquerel discovered the radiating property of uranium. Not long afterwards G. C. Schmidt discovered that similar radiations were emitted by compounds of thorium. Lastly, M. and Mde. Curie obtained from pitchblende a radio-active substance which is photo-chemically four hundred times more active than uranium. It was surmised by the Curies that this very radio-active substance contained a new element strikingly similar to bismuth, and named it polonium.\* Mde. Sklodowska Curie is a Pole by birth. Shortly after this discovery, the Curies, in conjunction with G. Beinont, found a second substance, of much greater radio-activity, in pitchblende, and again thought this was a new element, radium.† Lastly, Debierne also obtained from pitchblende a new substance likewise characterised by very considerable radio activity.‡

We thus know of radio-active substances obtained from five different sources, viz., compounds of uranium, thorium, polonium, radium, and Debierne's substance. Of these five, the chemical properties of the first two, uranium and thorium, have been known for years, and exactly defined. Both are elements, and consequently cannot be further decomposed chemically with the means at our disposal.

But it is quite different with the last three substances mentioned, which are merely hypothetical, and only accepted as supposititious elements. Polonium agrees completely with bismuth in all its chemical properties, and it is impossible to separate or isolate it.

Radium strikingly resembles barium, and cannot be separated from it any more than polonium from bismuth. It is therefore correctly described as radio-active barium.

Professor F. Giesel, of the Technical High School, Brunswick, has made important contributions to our knowledge concerning both these substances.§ Although he used a quite different method from the Curies, he has also obtained radio-active barium from pitchblende. From 1000 kilos of crude pitchblende he obtained 15 grammes of radio-active barium preparation. Giesel has also found polonium associated with lead.

The substance discovered by Debierne behaves, chemically, exactly the same as titan, and hitherto it has been impossible to separate it from the latter.

These three hypothetical elements are all obtained from the same material, and have the striking peculiarity of being mistakably like other well-known chemical elements, with which they are always found in association, and from which it is impossible to separate them. The only difference is their radio-activity. These facts forcibly suggest that the three hypothetical substances are not to be regarded as elements, which opinion is confirmed by the examination of the properties hitherto known of the three substances. However, such a discussion is of a purely theoretical chemical nature, and, as it would be of no interest to the readers of this periodical, we must leave it without examining the point more critically.

\* *Comptes Rendus*, vol. cxxvii. p. 175.

† *Ibid.*, vol. cxxvii. p. 1215.

‡ *Ibid.*, vol. cxxix. p. 197.

§ *Archiv für Wissenschaftliche Photographie*, vol. i. p. 297.

A definite answer to the question, whether the radio-active substances contain really new elements or not, can only be given after they have been subjected to experimental chemical examination. Two well-known ways are open, the analytical and the synthetical methods. The first reduces the substance under examination to its components, and the second forms the substance artificially from the chemical elements. Hitherto all the radio-active substances in which a new element is supposed to exist have been obtained from pitchblende by analytical methods. If a radio-active substance could be obtained artificially from one that is radio-inactive by use of the synthetical method, we should have incontrovertible experimental proof that the radio-active substances are not new chemical elements.

Considerations such as these induced Professor Béla v. Lengyel, of the II Chemical Laboratory of Buda-Pesth University, to attempt to prepare the radio-active substances synthetically. According to the treatise which he has just published, *he has actually succeeded in converting ordinary barium to radio-active barium, or, in other words, he has prepared radium synthetically.* He has, in fact, prepared three radio-active compounds—barium sulphate, and from it the chloride and carbonate. The radio-activity increased after the lapse of several days, and was proved with photographic dry plates (Schleusener's). The photographic action was shown not only with the substance by itself, but also after interposition of a copper coin between it and the plate, and the developed image increased in density with the thinness of the coin, and was most intense where the rays had fallen upon the plate unprotected by the coin. Moreover, the radiations of Lengyel's preparations illuminated the fluorescent platino-cyanide of barium screen, in the same manner as the radiations of radium. Lastly, the radiations from the artificial preparation rendered the air highly conductive of electricity, which is also the case with the radium rays.

These facts call in question the elementary nature of radium, but further work of the most discriminating kind is necessary before a final answer can be given, whether the radio-active substances are new elements or not. We have to thank Professor von Lengyel for the first contributions to the solution of this interesting question. These were experimental, and therefore beyond doubt. He is now occupied in preparing the necessary material for a decisive examination. For those who are interested in the subject we give the method of preparing the radio-active barium sulphate adopted by Von Lengyel. Uranyl nitrate is fused with two to three per cent. of barium nitrate, kept at a red heat to eliminate the nitric acid, and the oxides which are left are fused in an electric arc light. The fused mass is then dissolved in nitric acid, and by evaporation most of the barium nitrate is crystallised out. The hot solution is poured off the crystals, and, when clear, diluted with three to four times the quantity of distilled water. Sulphuric acid is then added. Radio-active barium sulphate is thus precipitated as a fine white precipitate. Wash well with hot distilled water, dry, and raise to red heat. The radio-active barium sulphate obtained in this way is a fine white powder, with a yellowish tinge, due, probably, to the presence of a trace of uranium. The yield is not very large. From twenty grammes of barium nitrate three to five grammes of radio-active barium sulphate are obtained, and this is, doubtless, contaminated with ordinary barium sulphate, which is not radio-active. DR. F.

### THE NEWCASTLE CONVENTION.

The following is a synopsis of next week's proceedings:  
MONDAY, JULY 9.

*Excursion in and around Newcastle.*—Parties will be conducted from the Assembly Rooms to the old Castle, Black Gate Museum, Cathedral, Tyneside, &c., as may be desired.

*Proceedings.*—At the Grand Assembly Rooms, at 7.30 p.m., official opening of the Convention by the Mayor, after which the new President will deliver his Presidential Address; followed by an Exhibition of specially selected lantern slides and a collection of slides illustrative of places to be visited during the excursions.

TUESDAY, JULY 10.

*Excursion to Hexham, the Roman Wall, &c.*—Train leaves Central Station at 9.50 a.m.; luncheon at the Town Hall at 1.30 p.m.; brakes leave Town Hall at 2.30; trains from Hexham at 8.3 and 8.53; arriving at Newcastle at 8.58 and 9.35.

There will be no meeting at the Assembly Rooms on Tuesday evening.

WEDNESDAY, JULY 11.

*Excursion to Jesmond Dene.*—Reception by G. P. Bainbridge, Esq., J.P. (President of the Newcastle and Northern Counties Photo-

graphic Association), in the Banqueting Hall at 2 p.m.; the Official Convention Group will be taken at the Old Mill (top end of the Dene) at 3; refreshments in the Banqueting Hall at 4.30.

*Proceedings.*—At the Grand Assembly Rooms, at 10 a.m., the Annual General Meeting, election of Council for the ensuing year, &c.; meeting of the new Council at 11; Annual Dinner and Smoking Concert at 7 p.m.

THURSDAY, JULY 12.

*Excursion to Durham.*—Train leaves Central Station at 9.30 a.m.; arriving at Durham at 9.50; luncheon in the Banqueting Hall, Durham Castle, at 1.30 p.m.; train leaves Durham at 6.5; arriving at Newcastle at 6.50.

*Proceedings.*—At the Grand Assembly Rooms, at 8 p.m., a paper by Sir J. Benjamin Stone, M.P., on "National Photographic Records;" a paper by Mr. J. Bridges Lee, M.A., on "Photogrametric Methods as applied to Record and Survey Work;" followed by an Exhibition of specially selected lantern slides.

FRIDAY, JULY 13.

*Excursion to Alnwick, Hulne Abbey, &c.*—Train leaves Central Station at 9.30 a.m.; arriving at Alnwick at 10.39; brakes will be awaiting the arrival of the train at Alnwick; luncheon at the White Swan Hotel at 1.30 p.m.; after luncheon visit Castle, churches, &c.; train leaves Alnwick at 4.10; arriving at Newcastle at 6.30.

*Proceedings.*—At the Grand Assembly Rooms, at 8 p.m., a paper by Dr. P. H. Emerson, M.A., entitled "Bubbles;" a paper by Mr. S. B. Webber on "Some Residues, and what to do with them;" a paper by Mr. E. Howard Farmer on "Desiccated Dry Plates;" followed by an Exhibition of specially selected lantern slides.

SATURDAY, JULY 14.

Various short excursions to places in and around Newcastle will be arranged as may be required. Members will oblige by signifying their wishes to the Hon. Secretaries as early as possible, in order that satisfactory arrangements may be made for the desired excursions, and particulars duly posted on the notice-boards.

### THE HOME AND HAUNTS OF CHARLES DICKENS.

ON Saturday, the 23rd ult., a whole day's excursion, which was arranged by the President (Mr. Hector Maclean, F.R.P.S.), was participated in by a number of the more prominent and expert members of the Club to Rochester.

Leaving East Croydon about 8.30, and proceeding *via* London Bridge, Rochester was reached soon after ten o'clock. The slopes of the railway cuttings for several miles from Strood were remarkable for the sheets and clumps of the brilliant-hued crimson flowers of the spurred valerian.

At Rochester, a three-horse brake, in which the party took their seats, galloped down the renowned High-street, over the bridge, and climbed one of the steep, long hills which encircle the Pickwickian town. Passing by the quaint house known as "Mock Beggar," a distant view of "Joe Gargary's" forge was obtained. Proceeding into the hundred of Hoo, our cicerone, the Rev. C. H. Fielding, reminds us that a cutting of the new railway, not long since made in this primitive corner of England, passed right through a huge whale, whose remains the line bisected almost at right angles. Just over twenty years ago, when curate of Higham, Mr. Fielding had to do duty at St. Mary's, Hoo, and, driving over by the high road, he was surprised to find that at one point it had been ploughed up for several hundred feet. If this is done to the main road, what must happen to byways? Cooling Church was next visited on account of its connexion with *Great Expectations* (remember the scene between "Pip" and the escaped convict). But what the photographers enjoyed most was the fine old fourteenth-century moated castle. This yielded a large number of exposures. All too soon the drive was resumed back to Rochester. Here, at the never-to-be-forgotten Bull Inn, the party lunched, in the very same coffee-room in which the members of the Pickwick Club enjoyed their convivialities. The assembly room, where "Jingle" and "Dr. Slammer" had high words, and other notable rooms, nooks, &c., were duly inspected. After luncheon, the party took open or skirmishing order, and individually visited and photographed Eastgate House (associated with "Rosebud"), the Seven Poor Travellers (Watts' Charity), the Castle, Cathedral, Guildhall, and other notable spots. At three sharp away we drove to the Sir John Falstaff, hard by, where Prince Henry relieved the knavish knight of his ill-gotten gains. Our chief objective was, of course, Gad's Hill House, where the great novelist lived his last years. We could easily dwell upon the manifold

beauties and their suggestions of this place of pilgrimage, describe the grand cedars and cypresses which face the house, the delightful roary, the restful and graceful garden at the rear, the cricket field, which was the scene of so many free-and-easy cricket matches, the sham books with their humorous catch titles, the very spot where the greatest of English novelists passed away, the table by the study window where he wrote a great part of his last novel. But time forbids; besides, truth to tell, most of his novel-writing was in late years done at odd moments—anywhere but at home. Thus many still living hereabouts can remember how Charles Dickens was wont to walk over to Higham Station, sit down in the waiting-room, and scribble away at *Edwin Drood* almost by the hour, and then perhaps get into a train and continue to write on his journey.

Gad's Hill has too often been the scene of robbery and murder, as many a well-authenticated record shows. Thus a highwayman, who one morning killed his victim just here, galloped to Gravesend, crossed to Tilbury by the ferry, and rode into York within the day. Soon after arriving he spoke to the Mayor, of whom he asked the time. A few days afterwards, being arrested, he pleaded that no man could have done the crime at Gad's Hill in Kent, and within a day's span ridden to York. This fact is what suggested to Harrison Ainsworth Dick Turpin's fictional ride. Driving through the delightful Shorne Woods, just now ablaze with rhododendrons, Cobham Hall, that magnificent mansion belonging to Lord Darnley, was reached.

By the special influence of Mr. Fielding, the party were permitted to enter the noble State apartments, amongst those seen being the gilt hall, the picture gallery, the portrait gallery, the Queen's bedroom, &c. Passing through the delightful park, with its large herds of deer, and noticing the long dark avenue of lime trees, never used but for the funeral of the master of the house to take its mournful way, tea was enjoyed at "The Leather Bottle," which, as every one who knows his *Pickwick* will remember, was the inn to which Mr. Tupman fled when deserted by his Rachel, and hard by which the immortal discovery of the prehistoric stone was made, the first portion of the inscription on which ran as follows: " + BILST. VM.," &c.

After tea, some time was spent around Cobham Church and the quaint almshouses, then through the cornfields and hop gardens to Sole-street, Croydon being finally reached at 9.45. It may be safely said that those who went for this memorable trip will have a lifelong pleasure in the reminiscences of the many scenes and suggestions stored up in their minds, to say nothing of the photographs. Those others who missed their chance must try and obtain consolation by forming a resolution to do better for themselves next time.

An unusually pleasant afternoon's outing has been arranged by the Hon. Secretary, Mr. W. H. Rogers, for Saturday, July 7, when a party of members and friends will drive over to the delightful but little known district of Chessington. The brake or brakes will start from the Club at two p.m. Those wishing to accompany the party should notify Mr. Rogers by Wednesday next.

## GELATINO-CHLORIDE EMULSION.

### I.

DESPITE the numerous published formulæ for the manufacture of gelatino-chloride emulsion, the writer has not yet found a thoroughly exhaustive treatise upon the subject, *i.e.*, one which explains the *rationale* of the process, and the why and wherefore of using the different ingredients; in fact, most formulæ seem to agree with W. S. Gilbert in *H. M. S. Pinafore*, and "never mind the why and wherefore." This may answer all right for superficial experimenters, but for scientific workers, and more especially for commercial purposes, it is useless. These introductory remarks explain the perpetration of the following article.

A gelatino-chloride emulsion is made by forming chloride of silver in a very fine state of division in a solution of gelatine, the viscosity of the gelatine holding the fine particles of silver in suspension. It is not possible to form an emulsion without using a colloid, as, in the absence of the latter, only a precipitate is formed.

The usual ingredients in a gelatino-chloride emulsion are gelatine, nitrate of silver, an alkaline chloride, and one or more organic salts. Several formulæ give, as the only ingredients, gelatine, silver nitrate, and an alkaline chloride. Certainly this will give an emulsion, but one that is useless if kept more than a few days.

In the published formulæ for gelatino-chloride emulsion a great diversity of opinion seems to exist in regard to whether an emulsion should be washed or not. The advocates of the washed emulsion say (in several cases) that it is imperative, while the advocates of the unwashed ignore washing. The writer unhesitatingly declares for the unwashed, on the following grounds: first and foremost being that it is

totally unnecessary, therefore a waste of time and material, as the paper should be thoroughly washed before it is toned, and disregard of this washing is one of the chief reasons why so many people fail in working the commercial gelatino-chloride paper; secondly, the salts left in the film help to absorb the chlorine, consequently print quicker and avoid bleaching the image. The only advantage which the writer can see obtained by washing the emulsion is, that it is not so likely to absorb moisture when washed as it is when left unwashed, for nearly all nitrates are deliquescent; but, as it is not a difficult matter to keep the paper free from damp, this is not a great argument in favour of washing. The writer is of opinion that a much more vigorous image is obtained with an unwashed, than with a washed emulsion. If free silver is desired in the film of a washed emulsion, it must be added after the washing, as the uncombined nitrate of silver is washed away.

The question of free silver in the film is another point upon which difference of opinion prevails, some maintaining that an emulsion containing free silver will not keep any length of time, which is slightly erroneous, as the writer has kept paper containing free silver for nearly six months, with only very slight deterioration of colour, though, undoubtedly, the more free silver contained in the film, the more likely it is to discolour. Many maintain that free silver is necessary to absorb the chlorine, but the writer is hardly inclined to agree with this view, as he believes that the citrates and tartrates form the sensitising agents, for chlorine has a very much stronger affinity for silver than either citric or tartaric acids; but, after all, so long as an emulsion is obtained which prints, tones, and keeps well, besides being satisfactory in other ways, the free-silver controversy may be dismissed. Undoubtedly, most of the commercial papers contain little, if any, free silver.

Another debatable ground is on the quantity of nitrate of silver required in an emulsion. Among the published formulæ which the writer has tried, this diversity ranges from 7 grains per ounce of emulsion to 22½ grains per ounce. The first quantity the writer considers ridiculously inadequate, while the latter is exactly the reverse, and the writer considers that the most suitable quantity will be found to be midway between these two extremes, about 15 grains per ounce of emulsion being ample to get a good image, while in quantities this may be reduced, as the waste in large quantities is little, if any, more than the waste in small, and merely the amount necessary to give a good image is required. Recrystallised nitrate of silver should be used, as the ordinary kind is usually of too acid a nature to be good for emulsion work.

The question of filtering has been carried almost to absurdity in many formulæ, some writers saying that chamois leather, or several thicknesses of swansdown, are necessary to filter through. The writer cannot agree with this, as, if the emulsion is properly made, with practically no grain, filtering through an ordinary jelly-bag, or, better still, one of the filters obtainable commercially seamless is quite sufficient; while, if the emulsion is not properly made, a very high temperature is necessary to filter through such dense materials, and very frequently even then they clog, and the emulsion refuses to percolate. In filtering gelatino-chloride emulsion it is necessary to wash the filter in hot water and wring it out before commencing filtration, or great difficulty will be experienced.

One of the most necessary articles to study in gelatino-chloride emulsions is the gelatine, and, for the sake of English commerce and enterprise, the writer is sorry to say that he is unable to recommend a single English gelatine among the large quantity manufactured. Messrs. Nelson manufacture two which are eminently suitable in every way except one, but, unfortunately, that one is fatal, being a strongly pronounced yellowness, otherwise Nelson's D 1 and No. 2 Photographic are excellent, being hard, not too absorbent, giving a good glossy film, with perfect freedom from grease, which, as the writer explained in a previous article, entitled, "Gelatine for Emulsion Work," which appeared in *THE BRITISH JOURNAL OF PHOTOGRAPHY* on September 23, 1898, are, with absence of yellowness, absolutely essential in a satisfactory emulsion gelatine.

The reader may think that with the very thin film required upon gelatino-chloride paper the slight colour of the gelatine would not be noticed, but, to prove that such is not the case, a piece of the thin skin used by goldbeaters should be placed upon *white* paper, when, although the skin is very thin indeed, the colour is plainly discernible. The writer has only found two of the Continental gelatines quite satisfactory, some which in all other respects are admirable being spoilt by the large amount of grease which they contain, and therefore the only gelatines which the writer can confidently recommend, as suitable for gelatino-chloride emulsions, are the Winterthur Swiss gelatine, and a German gelatine manufactured by Fischer & Schmitt; both of these are excellent in all respects. The quality of the gelatine and the method by which it is manufactured largely affect the resulting emulsion, a point which seems to have escaped the notice of most writers upon this subject, for upon the gelatine to a large extent depends the colour which the film gives, which makes it all the more regrettable that English gelatines are not suitable, for Nelson's No. 2 Photographic gives a light red tint, which is easy to tone, and does not reduce much in working. Winterthur gives a reddish-blue print, while that of Fischer & Schmitt gives a violet of great vigour and beauty, but rather more difficult to tone; fortunately this can be somewhat overcome by a variation in the different chlorides and salts. As water is the solvent of gelatine, the question of choosing

a chloride becomes an easy matter, as all the suitable chlorides are soluble in water, and consequently it is only a question of selecting the most convenient. The chlorides most generally used for emulsions are ammonium, calcium, lithium, strontium, and sodium, the colours of the images given by them being ammonium, violet, calcium, dark blue, lithium, medium red, strontium, and sodium, light red. Those most generally used for gelatino-chloride emulsions are ammonium and sodium, principally because they seem most suitable, are cheapest, easily obtainable, can be procured in a fairly pure state commercially, have a high combining power, and possibly because ammonium is obtained more pure than sodium as a rule, and has a slightly higher combining power than the latter, it is generally preferred—personally the writer favours sodium, as the light red tone which it gives is much more easy to manipulate afterwards, and sodium nitrate, which is one of the salts left in the film, is not so deliquescent as ammonium nitrate, thus the paper is not so likely to absorb moisture. Should there be any difficulty in procuring sodium chloride in a pure state, it may very easily be manufactured by adding carbonate of soda to hydrochloric acid until it is neutral to litmus paper, and, on evaporating the water, a hard cake of perfectly pure sodium chloride is left; this is a very good way, even if it is not difficult to obtain what is usually sold as pure sodium chloride, and which is often of a very hygroscopic nature, showing that it contains other salts (probably magnesium) besides sodium, the latter of which should not easily absorb moisture from the atmosphere.

The next items to consider are the organic salts, to preserve the paper so that it will keep its colour well for some length of time, besides helping to give greater vigour to the image. The salts which answer this purpose are citrates, tartrates, and oxalates, but it is found in practice that the two former are most suitable, and the most generally used of these are citric and tartaric acids, potassium and sodium citrates, Rochelle salts (potassio-sodio-tartrate), and cream of tartar. Salicylic acid is sometimes used as a preservative, but it must be carefully used in gelatino-chloride emulsions, as it is not very soluble in cold water, though more so in hot, one grain of the acid requiring about two ounces of cold water to dissolve it; therefore, if a greater quantity is used than a quantity of cold water equal to the emulsion would dissolve, the acid will crystallize out. Citrates are generally found to give darker images than tartrates; in practice the best results are obtained by combining the two. Citric acid and citrates seem to give the best keeping properties; tartaric acid and tartrates, brilliancy; and Rochelle salts, depth and vigour. The writer, therefore, combines all three.

The aim in a gelatino-chloride emulsion is to obtain one which does not reduce much in toning and fixing. This is secured by a printed image of a light red colour, which is very much easier to tone than one of a dark colour, gives a greater range of tone, with nothing like the reduction that a dark-coloured print gives, the latter of which apparently, but not really sooner reaches the requisite tone, and then largely disappears. This disadvantage may be obviated to a large extent by printing the image deeper; but, at best, this is a misleading way, and getting an emulsion which only reduces slightly, is very much better, and, for commercial purposes, is absolutely essential to success.

In making gelatine emulsions the temperature must be carefully studied. In some of the published formulæ a temperature of from 140° to 180° F. is advised. The writer believes that he has tried all the hardest gelatines made, and he has not found one which is not fluid at 100° F., and, as Messrs. Nelson say in a little card of directions which they issue, gelatine should never be heated to a higher temperature than 120° F. This the writer cordially endorses, except for bromide emulsions, and it is a fact which should be especially borne in mind when making gelatino-chloride emulsions, as a high temperature discolours gelatine and destroys its setting power, both very bad things for printing-out emulsions. The writer advises melting the gelatine at a temperature of 100° F., and keeping at this point while mixing, raising it to not more than 120° F. just before filtering. Gelatine should not be kept too long in a dilute state, or decomposition may set in.

Many formulæ give alum as one of the ingredients in a gelatino-chloride emulsion, and some points in its favour are that it has an antiseptic, hardening, and clarifying effect upon gelatine, and, as no gelatine has yet been produced which is quite colourless, the latter is an important advantage. Some of its advocates contend that it gives detail of the emulsion, this may be so, although the writer does not hold that view, and does not quite agree with using alum in an emulsion, but he gives a very good formula containing alum for those who care to use it.

This is the formula which the writer recommends:—

FORMULA I.

No. 1.

Silver nitrate recrystallised .....	150 grains.
Citric acid .....	40 "
Distilled water .....	1½ fluid ounces.

No. 2.

Tartaric acid .....	20 grains.
Sodium bicarbonate .....	10 "
Water .....	1½ fluid ounces.

No. 3.

Hard gelatine .....	480 to 500 grains.
Sodium chloride .....	20 "
Rochelle salts .....	20 "
Water .....	7½ fluid ounces.

Distilled water *must* be used to dissolve the silver, or probably the latter will be reduced, but ordinary tap water is good enough for No. 2 and No. 3.

The silver should be weighed out and dissolved in the water, then warm, and shortly before using, add the citric acid, and allow to dissolve also; it is advisable to form the citrate of silver before adding to the gelatine, so that as little free silver as possible may be added direct to the fomer. It is better to warm the silver solution before adding the citric acid; otherwise, when the silver citrate is formed, it is very liable to be precipitated, owing to the fact that silver citrate is not very soluble in cold water.

Place tartaric acid in the water, and, when quite dissolved, add sodium bicarbonate; effervescence will ensue, which must be allowed to subside. This will be found more reliable and economical than using commercial sodium tartrate. A discretionary margin has been allowed for the gelatine, as gelatines differ very much in their viscosity, and, where 480 grains are ample with one kind, 500 are necessary with another. The sodium chloride, Rochelle salts, and gelatine should be placed in the given quantity of cold water, and left until the gelatine is quite soft and swollen; place the jar in a water bath and gently raise the gelatine solution to *not more* than 100° F., when the hardest gelatine will be found liquid, and this is the temperature at which mixing should take place.

C. T. SUTTON.

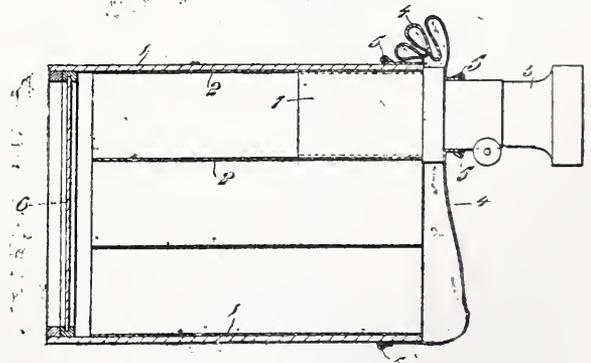

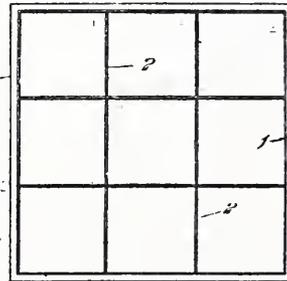

IMPROVEMENTS IN CAMERAS.

[Willis & Mence's Patent No. 12,623 of 1899.]

THE invention relates more particularly to that class of camera by which the different parts of a sensitised plate may be exposed consecutively.

The patentees state that they are aware that cameras have been made to utilise one portion of a sensitised plate for one position of an object, and another portion for another position, or that one view has been produced on one portion of a plate and another view on another portion, and that, when the plate has been fully utilised, all the views contained thereon have been developed at one operation, and prints of all the views taken from the negative plate at one time.

According to the invention the apparatus is simplified, the operation

of taking the photograph rendered facile, and the possibility of taking the different views in rapid succession is assured.

They prefer to use an ordinary square-shaped camera, though other kinds may be adapted for their purpose, and they divide the interior vertically and horizontally or otherwise, so that longitudinal tubes are formed which extend from the front to the back of the camera or a part of such distance. The ordinary focussing-screen plate-holder and lens are employed, or films may be used, but they mount the lens on a short length of tubing which will fit freely into the tubes of the camera. The interior of this short length of tubing and of the longitudinal tubes are

coated with lampblack or other ordinary material. Around the end of the camera, and covering the front of the same, they fix a loose bag so that it is light-proof, and they make the same of any suitable textile material which is impervious to light. A hole is cut near the centre of this cloth, and the front of the lens passed through the same and so fastened as to be light-proof.

The tubes may be made telescopic and capable of sliding in other tubes in order to obtain a correct focal distance between the lens and the glass screen as required for different views or subjects.

In taking photographs the lens is applied to one of the tubes and an exposure effected by removing the cap or operating a shutter in the ordinary way. The cap or shutter is replaced and the lens applied to another of the tubes for a second exposure, the operation being thus repeated until the lens has been applied to all the tubes.

By removing the tubes the camera can be used as an ordinary camera, and a photograph taken which will cover the whole plate.

1 is a camera with its front removed and shown on the drawing square-shaped; 2 are the tubes, which may be made of tinplate, light wood, vulcanite or other suitable material coated with lampblack; 3 is the tube containing the lens; 4, the extensible covers made light-proof upon the camera and the tube, 2, by elastic rings, 5, or by other suitable means; 6 is the focussing screen.

The lens tube, 3, is mounted upon a short length of tubing, 7, which is made to fit the tubes, 2, and may be readily removed from one tube, 2, to another.

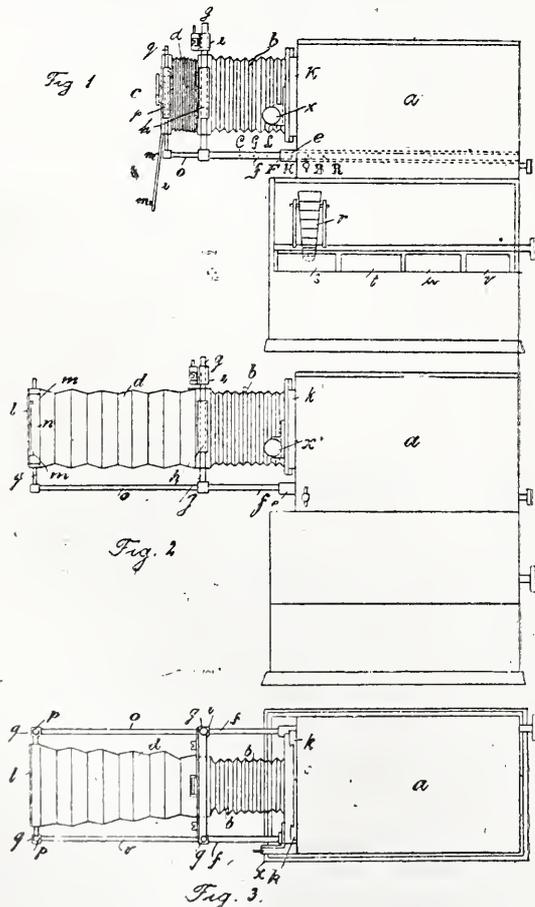

An exposure is effected with the tube, 7, in any of the tubes, 2; the said tube, 7, is then moved into another tube, 2, for a fresh exposure, and so on until the whole divided interior has been exposed. The cover, 4, excludes the light during the removal of the said tube, 7.

POSITIVES IN THE CAMERA.

[Foersterling's Patent No. 19,474 of 1899.]

AN apparatus for photographing the negatives previously obtained in the same apparatus instead of converting the negatives into positives, as hitherto, by printing or chemical action, on black backgrounds. This apparatus may be vertically or horizontally arranged, and the operation effected automatically or by hand.

Figs. 1 and 2 are side views of the photographic apparatus. Fig. 3 is a plan. The bellows, *b*, with the objective, *c*, serves for taking the nega-

tive. The finished negative is placed from inside on the front, *l*, so that, when the bellows, *d*, is drawn out, it stands opposite to the objective, *c*, and, upon being "taken" again, furnishes the desired positive. The top of the bellows, *d*, is made of some material through which the light can penetrate, gauze for example.

The apparatus here represented is composed of a case, *a*, for receiving and changing the plates of the bellows, *b*, with the objective, *c*, and the bellows, *d*. In the chamber, *a*, are two parallel tubes, *e*, in which tubes, *f*, are telescopically adjustable. The tubes, *f*, support the vertical tubes, *g*, on which the objective frame can be raised or lowered and adjusted by means of sleeves, *h*. The back frame of the bellows, *b*, is adjustable in a prismatic guide, *k*.

This apparatus has no matt or focussing screen, but the focussing is effected in accordance with a graduated scale placed on the tube, *f*, and experimentally fixed according to the distance of the object. For determining the distance, a measuring band, *x*, arranged at the side of the apparatus, is employed. The chief points in the graduated scale, placed on the two tubes, are indicated in fig. 1 with *c*, copy; *g*, group; *l*, landscape; *r*, full figure; *κ*, three-quarter figure; *b*, bust; *r*, bicyclist. The number of points may be as preferred.

By means of this apparatus the plates are exposed, the finished negative, *n*, placed between the guides, *m*, of the closing plate or shutter, *l*. The bellows, *d*, is adjustable by means of tubes, *o*, guided in the tubes, *f*. The tubes, *o*, also may be furnished with an experimentally determined graduated scale, for the purpose of adjusting the bellows, *d*. By means of the sleeves, *h* and *i*, the bellows, *d*, can be adjusted higher or lower on the tubes, *g* and *g*. For the purpose of developing the positive taken from the negative the negative is brought into the carrier, *r*, and the carrier successively immersed in the developing baths, *s*, *t*, *u*, *v*.

PHOTO-MECHANICAL PRINTING SURFACES.

[Vogel's Patent No. 8038 of 1900.]

AN impression on a translucent medium, such as paper, gelatine, celluloid, or the like, is first made from a printing block (woodcut, line etching, autotype, or the like).

The positive thus obtained is copied by means of light upon a plate of copper, brass, zinc, or other suitable metal, or on to stone, and developed in the same way as is usually employed for relief or cameo etchings, and in this process the same substances, sensitive to light, such as asphalt, chrome albumen, chrome gum, chrome gelatine, or chrome glue, or even mixtures of these separate substances, are employed.

A negative copy is thus obtained, that is to say, the metal or stone is blank at those places which correspond with the black parts of the positive, whilst it is covered at the places which correspond with the transparent parts of the positive, owing to the layer of asphalt, chrome albumen, chrome gum, chrome gelatine, chrome glue, or the like, rendered insoluble at these places by the action of the light, and therefore permanently retained when developed.

Instead of copying the positive directly on metal or stone, it may be copied on photo-lithographic transfer or pigment paper, and then the copy transferred in the usual way to metal or stone, and subsequently developed.

If the metal plate or stone be placed in an etching substance, that is to say, a solution which dissolves the metal employed, such as an acid, perchloride of iron, or the like, this solution can only attack the metal or stone at the uncovered places, as at the other places the etching liquid is kept off by the coating which covers the metal or stone.

A relief is thus obtained in which, as opposed to an ordinary printing block, the parts corresponding to the dark parts of the positive are countersunk or in intaglio, whilst the parts corresponding to the white portions of the positive are raised or in relief.

The relief is deeper the longer the etching substance is allowed to act on the plate. From the deeply impressed plate thus obtained impressions or prints may then be taken, which are applicable for use in a printing press. For instance, as in the case of the Woodbury prints, impressions may be taken therefrom, melted gelatine being poured over the plate, and then a sheet of paper or other flexible medium laid over it, and the whole placed in a press. After the gelatine has set, the sheet of paper may be drawn off the plate and dried. Celluloid papier mâché, indiarubber, guttapercha, or other suitable material, may be employed in place of gelatine for forming the relief, whilst the penetration of the material into the etched (intaglio) parts of the printing plate may be assisted, if necessary, by the application of heat.

Studio Gossip.

RESTORING DAGUERRETYPES.—Mr. J. Adams, of New Marston, Oxford, writes: "If your correspondent, F. W. Tassell, will let me know the condition of the Daguerreotype, I will tell him if any good can be done. I am one of the very few old Daguerreotypists left, dating back to 1848, and was an exhibitor at the Exhibition of 1851."

PATENTS IN JAPAN.—A number of new Acts have been passed in Japan to amend the Law of Patents, Designs, and Trade Marks. Under these Acts the duration of a patent is fixed at fifteen years, and of a copyright of a design ten years, subject to the payment of annual fees. The term of protection obtained by registration of a trade mark is fixed at twenty years, except in the case of trade marks previously registered abroad, where the term is the same as that for which the original registration is valid.

**ECLIPSE PHOTOGRAPHY WITH AN ORDINARY LENS.**—Mr. E. Williams, of Wokhurst, sends us a print from a negative which he made of the eclipse, following our suggestion of using the half of a lens to obtain a long focus. It was made with the half of a 16-inch Dallmeyer rectilinear with a specially made stop about  $\frac{1}{4}$ -inch aperture, thus giving about  $f/250$ . The exposure was made with a Kershaw shutter, probably about  $\frac{1}{10}$  of a second, on a backed "Bee" plate, time four p.m. The result is excellent.

**THE THREE-COLOUR PROCESS.**—The art critic of the *Daily Chronicle* notes that Mr. Hentschel still perseveres in his "three-colour" experiments. It is suggested that he should try to reproduce a Japanese colour print, with flat tones and simple scheme. He has followed the advice, and just omitted the result. It is certainly more satisfactory than the reproduction of the same process of elaborate paintings; but, except where the colour is red, as with the positive blues and greens and reds, it has a tendency to oddness. Surely the brown in the road and the house roofs was very different in the original print. However, it is distinctly one of the best things Mr. Hentschel has done, and a new process that can already accomplish much may reasonably be expected to accomplish more in the future, though the chances are, always within rather narrow limits.

**THE LIGHT TREATMENT AT A LONDON HOSPITAL.**—A department has been opened at the London Hospital for the treatment of lupus and some other diseases of the skin by Professor Sinsen's method of phototherapy, or "light treatment." This work is being carried on in connexion with the department of diseases of the skin, and is superintended by the physicians in charge and under the immediate care of the special dermatological clinical assistant. The introduction of this method of treatment at the London Hospital, the first in Great Britain to adopt it, is due to the Princess of Wales, who has taken great interest in it since she saw it carried out in Copenhagen. Her Royal Highness presented the necessary and expensive apparatus required, being anxious that its benefits should be extended to the poor of London. The treatment consists in the application of the chemical rays of light either by sunlight or by electric light by means of carefully arranged appliances. The arrangement has now been in operation for several weeks. Four patients only have been treated free of expense in the mornings, but it is intended to devote the evenings to the treatment of those who can afford to pay. Nurses have been specially trained for the work at Copenhagen.

## News and Notes.

**MR. E. CECIL HERTSLET, F.R.P.S.,** Her Majesty's Consul General at Havre, has been appointed by the Royal Commission for the Paris Exhibition to be a Juror on the International Jury in Class 12, Photography, in the place of Sir William Abney, K.C.B. resigned.

**THE NEWCASTLE CONVENTION.**—Messrs. Marion's representative, Mr. T. E. Tether, will be in Newcastle during Convention week, and will have an extensive show of their latest introductions, &c., at the Central Exchange Hotel (nearest hotel to the Grand Assembly Rooms).

**THE *Picture Post Card*** is the name of a new monthly publication which made its appearance on July 2. As its sub-title explains, it is "a magazine of travel, philately, and art," and is intended primarily for those interested in holiday travel, illustrated post cards, and stamp, coin, crest, and curio collecting, but it will at the same time give prominence to cognate subjects.

**NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.**—At a Council meeting held at 66, Russell-square, 225 prints were received, including 100 from Sir J. Benjamin Stone of Windsor Castle, from Messrs. Malby, Harold and Oliver Carter, Diveri, Mr. and Mrs. Snowden Ward, Mr. E. Scamell, the Hon. Secretary, &c., and a series of reproductions from the Editor of the *London News*, and it was announced that 253 prints had been forwarded to the British Museum.

**THE South London Photographic Society's Fourth Continental Excursion** to the Valley and Ahrgau, will take place from August 18 to 27. The leader is Mr. William F. Slater, F.R.P.S. The estimated total cost is 5*l.* 5*s.*, which includes fares on railways, second class between London and Cologne, third class on daily excursions, and saloon on all boats, hotel accommodation, meals per programme, and all gratuities. The headquarters are at the Hotel Toriaberger, Remagen. A detailed programme has been issued. Those desiring to join this excursion must remit to William F. Slater, 5, Firsade, High-road, Lee, S.E., not later than Saturday, July 28, the sum of 10*s.* towards travelling expenses. Any further information can be obtained from Mr. Slater.

**THE Redhill and District Camera Club's excursion** on Saturday, July 14, to Chilworth Pools, St. Martha's (the Pilgrim's Church), Newland's Corner, and the Silent Pool. The following itinerary has been issued to members:—Starting: Redhill Station at 1.50 p.m. Book to Gomshall (return); train at 2.15 p.m. (Reigate 2.5). Conductor, Mr. Ralph W. Robinson. Route: Drive, or walk to Chilworth Pools, thence to St. Martha's. Walk by path (one way) or drive round by road to Newland's Corner. At 6 p.m. drive to the Silent Pool for tea (6*d.*). At 7.30 drive to Gomshall for return train at 8.15 p.m., Redhill 8.40. Charge for conveyances, 1*s.* 9*d.* each. Scenery: The route is through the most beautiful scenery in Surrey, and the view from Newland's Corner is, perhaps, the finest in S.E. England.

**THE ANDRÉE EXPEDITION ONCE MORE.**—When, one is inclined to wonder, will we receive the last reports and rumours about this ill-fated expedition? The *Standard* of Thursday, last week, contains a telegram from its Berlin correspondent, saying that a Copenhagen paper has received a telegram from Stockholm, containing only the two words, in Finnish, "Andrée rescued," adding significantly that no confirmation of the report has been received. In an issue of the same day we read that a bottle has been found on the

Irish coast containing a post card, stating that it had been thrown into the sea by the Swedish Polar expedition in 1898 to test the ocean currents. The card is said to be addressed to Captain Ernest Andrée in Sweden, and the finder was requested to post it on to him. One may well ask what next?

**THE PARIS EXPOSITION.**—The University of Paris has an exhibit in the Palace of Letters, Science, and Art, containing a number of reproductions of photographs of the moon and of the heavens, covering a wall space of eighteen metres long by four high. The large photographs of the moon are presented to the public for the first time. They have been taken by Messrs. Loewy and Puiseux with the large telescope of the observatory; the photographs are shown in small size in order to appreciate the fineness of detail obtained by the instrument, then a series of bromide enlargements is shown by which they are more clearly seen. One of the photographs is that obtained by taking two plates of the moon at ten and at twenty days after new moon; these have been enlarged sixty times the surface, and placed side by side, the result being an image of the whole hemisphere of the moon with a direction of light which brings out the relief and shows the details of the craters and mountainous region.

At the Frome Police Court, on June 27, John Stuart, *alias* Watts, Banks, and Lane, was charged with having, on March 25 last, at Kilmerston, obtained by means of false pretences 9*s.* from Louisa Cox, and various other sums from a number of people. The evidence was to the effect that prisoner represented himself as an agent for the London Stereoscopic Company, on whose behalf he requested to be allowed to take photographs of farmhouses, the pictures being required for magic-lantern slides, railway carriages, and panoramic views. The prisoner told the various farmers that he would forward them pictures according to the payment made, but he failed to do so. The camera used by the prisoner was an empty box, on an ordinary stand. There was no lens, and it was quite impossible for the prisoner to take photographs. Edward Simpson, Secretary to the London Stereoscopic Company, said the prisoner had not been in the employ of the Company, but during the last four or five years they had received complaints from all parts of the country of similar frauds being perpetrated in their name. Further evidence was given to show the prisoner had a receipt book in his possession, in which receipts had been entered for 4*l.* 3*s.* 3*d.* The prisoner was formerly in the 12th Foot, and was in receipt of a pension. He was committed for trial at the Quarter Sessions.

## Commercial Intelligence.

WE are informed that the Directors of J. H. Dallmeyer, Limited, have declared and paid an interim dividend on the Company's Deferred Stock, for the six months ending June 30, at the rate of twelve per cent. per annum.

**CHANGE OF ADDRESS.**—Mr. Wilfred Emery, of 15, Anson-parade, Cricklewood, N.W., writes: "I have fitted up a dark room for amateurs at the above address, and as it is on the much-frequented main road to Edgware, near the Crown, Cricklewood, it should prove useful to many cyclist photographers. I can also supply them with plates, films, &c. I shall be glad if you will mention, as many customers are still unfamiliar with the change of address."

**THE Thornton-Pickard Manufacturing Company, of Altrincham, send us a copy of the new edition of their German catalogue, which has just been published. The Company add: "Should any of your readers desire to possess a copy either for themselves or their friends who may reside in Germany or in other countries where the German language is spoken, we shall be happy to send one or more on application. You will be pleased to hear, we are sure, that our shutters continue to have a largely increasing sale in Germany, our sales for last year showing a very satisfactory increase over the previous year. The German photographic public, like the English, appreciate a reliable article." We congratulate the Company on the continued success of their celebrated shutters.**

**TRADE SECRETS.**—According to a contemporary, a trade secret decision has recently been handed down in one of the German courts, which possesses considerable interest. The foreman of a factory invented a substance which was used by his employer in finishing rustling velvet. The foreman imparted the composition of this substance to other makers, and was sued by his employer, and in the lower court was found guilty. The defence was that the foreman had only parted with his own invention, which was his intellectual property. The case was appealed, and was dismissed on the ground that the foreman was employed by the firm, and his invention was only a part of the service which he owed to his employer, and only an *employé* would be trusted with experiments which would lead to such an invention. On account of the facilities which his position offered, he was enabled to make an invention which an outsider would not have made, and that he made it in consequence of his employment, for which he was duly paid. The Court held that, when he imparted his secret to strangers, he violated the German law for "the suppression of base competition."

**"FORMALIN."**—In the Chancery Division, on Tuesday, June 26, Mr. Justice Farwell had before him an application by the Formalin Hygienic Company, Limited, to register the word "Formalin" as a trade mark. The matter came before the Court on an appeal from the Comptroller, who had already refused the application. The applicant's case was that a forty per cent. solution of formaldehyde, manufactured by the Chemische Fabrik auf Aktien vormals E. Schering, of Berlin, was first placed on the English market by Messrs. A. and M. Zimmermann as sole agents for Messrs. Schering, in 1882, under the name "Formalin," which name was registered in Germany as a trade mark. It was then sold for the purposes of disinfection and general antiseptics. The applicant company was formed in 1897, and acquired all the rights of sole agency from Messrs. Schering for the sale of their manufacture of "Formalin." The applicants applied the word "Formalin" to various other articles besides the forty per cent. solution, such as "Dry Formalin," or Paraform; "Normal

Formalin," a weak solution for domestic use; "Formalin Powder," "Formalin Gelatine," and "Formalin Soap." There was also a lamp, in which paraform is burnt for disinfecting purposes, called the "Formalin Lamp." Drs. Rideal and Passmore and Mr. Bevan deposed that the word "Formalin" *per se* conveyed no meaning to the chemist upon his hearing it for the first time. Mr. Hughes, Q.C., and Mr. Ward Coldridge appeared in support of the application; the Attorney-General (Sir Robert Finlay, Q.C., M.P.) and Mr. Ingle Joyce appeared for the Comptroller. Mr. Justice Farwell, in dismissing the application, held that it was a fatal objection to it that it was not made by the proprietors of the article in question. He was convinced on the evidence that the word "Formalin" had never in England represented to the trade at large or to the public any manufacture of any particular individual. He held that there had not, as a fact, ever been acquired in England any such association of the name "Formalin" with the manufacture of the German company or of Schering as would entitle either of them to say that it connoted their manufacture and nothing else. The application failed, and would be dismissed with costs.

## Patent News.

THE following applications for Patents were made between June 18 and June 23, 1900:—

- COLOUR PHOTOGRAPHY.—No. 11, 213. "Improved Apparatus for Viewing the Superimposed Images of Multiple Diapositives with Colour Screens." Complete specification. A. SAUVE.
- CAMERAS.—No. 11,277. "Improvements in Photographic Cameras." H. ERNEMANN.
- PLATES.—No. 11,290. "An Improvement in Photographic Plates." F. C. SHARDLOW.
- SHUTTERS.—No. 11,320. "Improvements in or relating to Photographic Shutters." J. HARRINGTON.
- FINDER.—No. 11,333. "An Improved Photographic Finder." J. C. CARSON and A. J. JONES.
- OPTICAL ILLUSIONS.—No. 11,393. "Optical Illusion Apparatus." J. LOCKIE.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
9.....	Southampton .....	Print Competition: <i>Animal Studies</i> .
10.....	Birmingham Photo. Society ...	{ Presentation of Prizes Awarded at the Annual Exhibition
10.....	Hackney .....	Demonstration: <i>Venus Paper</i> .
13.....	Birmingham Photo. Society ...	{ Complimentary Dinner to Mr. Harold Baker.
14.....	Bootle .....	Excursion: Altcar. Leader, R. C. Bond.
14.....	Borough Polytechnic .....	{ Excursion: Southfleet. Leader, W. Page.
14.....	Brentford .....	{ Excursion: The Chalfonts and the Jordans. Leader, F. Turner.
14.....	Oroydon Camera Club .....	Excursion: Aldershot.
14.....	Redhill and District .....	{ Excursion: Chilworth Pools, St. Martha's (the Pilgrim's Church), Newland's Corner, and the Silent Pool. Leader, Ralph W. Robinson.

### ROYAL PHOTOGRAPHIC SOCIETY.

JUNE 26,—Technical Meeting,—Major-General J. W. Waterhouse, I.S.C. (Vice-President), in the chair.

#### A BIG ENLARGEMENT.

Mr. EAST, of Kingston, sent for exhibition a bromide enlargement, 40 inches by 70 inches, from a negative about 1 inch by 1½ inches. The original—a portrait of a lion—was taken with a Zeiss-Satz Anastigmat of 9 inches focus and an aperture of *f*-12.5, and the enlargement was of an exceedingly satisfactory character.

#### NEW LENSES AND A NEW ALLOY.

Mr. J. H. AGAR BAUGH showed a new lens by Messrs. Voigtlander, with a focal length of 3 inches and working at *f*-2.3, and said that a similar lens, working at *f*-1.8, had been made exclusively for astro-photography, for which purpose it had been used with much success at the Yerkes Observatory and other places. He also showed a lens mounted in magnalium, an alloy of pure magnesium and pure aluminium, and possessing some remarkable properties. Magnalium is silver-white in appearance, without the greyness of aluminium. Its specific gravity is 2.2, and it is therefore lighter than aluminium, the specific gravity of which is 2.7. It will not oxidise in air, but is affected by alkalis. As regards its use, it is very much harder than aluminium, can be filed as easily as brass, and screws can be cut in it as fine as 100 threads to the inch for instruments of precision. It is not yet on the market, but will not be expensive, and Messrs. Voigtlander propose to supply lenses of certain sizes mounted in magnalium at the same price as for those with brass mounts.

#### A CHAT ABOUT LENSES.

Mr. J. H. AGAR BAUGH had announced to read a paper on "The Selection of Lenses with regard to Photographic Perspective," but the address which he delivered dealt with many points in connexion with lenses. He began by expressing the opinion that the Society's standard method of measuring or numbering stop apertures was rather out of date, and suggested the advisability of adopting the method in general use by Continental opticians namely,

to ascertain the efficient aperture by focussing the sun on the ground glass, then substituting for the latter a piece of ferrotype plate with a pinhole, putting a light behind the pinhole, and measuring the circle of light on the front lens. He showed four lenses of the same focus, working at apertures respectively of *f*-2.3, *f*-5.4, *f*-7.7, and *f*-11.3, and said he preferred the last-mentioned because he appeared to get sharper images with it than when stopping down the others to the same extent. He thought this was due to the thinness of the lens, there being no room for the light to go backwards and forwards, and to the fact that when using it there was less stray light in the camera. He thought that for prints on paper no photograph should be taken with a lens of less than 10 inches focus; if, in the case of quarter or half-plate pictures, a lens of shorter focus must be used, the image could only be correctly seen by viewing it through the lens with which the negative was taken, or by enlarging it at least two diameters. When the rising front of the camera was brought into operation, the picture could not be correctly seen unless it were held at a suitable angle, and he suggested that the hanging committees of photographic exhibitions should take care that pictures taken with a rising front should be hung in such a manner as to produce the proper idea of perspective. He strongly objected to photographs taken with wide-angle lenses. If one was standing near a church tower, one could only see the whole of it by shifting the position of the eyes, and he therefore suggested that such subjects should be photographed in sections, at different angles, and the prints joined together, and even then they must be enlarged if the proper effect was to be produced.

Mr. W. E. DEBENHAM said the title of the paper was misleading, and that it tended to perpetuate the fallacy that the selection of lenses had anything to do with perspective. Whatever lens was employed the perspective was identical, for it was solely dependent upon the station point and the plane of the picture.

Mr. H. W. BENNETT, referring to the use of wide-angle lenses, thought the ultimate result of the picture should be considered rather than any arbitrary rule as to the angle included. There was a general objection to the use of wide-angle lenses unless they were absolutely necessary, but it frequently happened that the only way to make a thoroughly satisfactory composition was by including a rather wide angle.

The Rev. F. C. LAMBERT said there was a good deal of truth in the contention that, for a picture to be seen at its best, it must be hung or held in a definite position in relation to the eye. He instanced the case of a photograph taken down a well, which represented nothing at all when hanging on a wall, and could only be understood when placed upon the floor and looked down upon.

The conversation was continued by the President, and Messrs. Bolas, Hodges, Brown, and others, and Mr. Baugh replied.

#### LENSES CONJUGATES.

The Rev. F. C. LAMBERT read a note upon "How to Ascertain the Conjugates of a Lens without Calculation," and showed how the information referred to might be found with no more apparatus than a sheet of cartridge paper, a paper measure, a broomstick, and a few pins.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 28,—Annual Meeting,—Mr. A. Haddon in the chair.

Mr. A. L. HENDERSON brought up and passed round a number of lantern slides from photographs taken in Paris during his recent stay there. He promised early in the autumn to give a show of his Bordighera and Paris slides.

Mr. T. E. FRESHWATER showed some old large-size stereoscopic prints of Niagara, made in 1875, also of a Daguerreotype of a gardener amongst his plants, in an excellent state of preservation and tinted in the colours of nature.

The HON. SECRETARY read the following report upon the past year's work, and presented the balance-sheet, duly audited:—

Although not, perhaps, so eventful a year as some previous ones, I think the Association is to be congratulated upon a steady year of progress and a satisfactory record.

To turn first to some of the dry but usual items of an annual report, it is with pleasure that I am able to say our membership has increased during the year. We have elected more members than we have lost, so that we are in on this deal. We have, however, lost this year a member whose death was equally a loss to the photographic world at large. I refer to Mr. W. K. Burton, of Japan, who has long been an honorary member of our Association, and a respected one.

As regards attendances, we have also kept up to the standard. The average for the year, with its fifty meetings, is certainly satisfactory. Even during the dead season as some call it, or holiday months as others term it, June, July, and August, the average was good.

We have had some very good evenings indeed, but for a characterial definition I should call 1899-1900 the year of the younger member. To commence with, three of our valued workers, Messrs. Heskins, Hodges, and Wright, as Lanternist, Recorder, and Librarian respectively, have been most assiduous, and, if the Librarian has not been worked to death by would-be borrowers of the solid volumes of fact and fancy that we possess, that is not his fault. Then, again, we have been favoured with about six papers from them, and, moreover, the end of the table to the left of the Chairman has not been nearly so silent during the year.

Our Open Nights, an institution that is essentially a feature of the London and Provincial Photographic Association, have been on the whole a great success, and we can readily forget the one or two failures. With very little trouble members can make an open night of the greatest interest. It only requires a few objects brought for inspection, or a judicious and well-timed question that will tread upon some one's favourite corn, either as to toning, developing, lens construction, &c.

We have not used the blackboard much this year. We have missed the A being equal to B, with C a bad third and D did not bad. But I do not think we have missed aught else.

I do not think our Lantern Nights have been up to the mark, and now that the summer months are here, or coming, I hope members will make a few hundred slides each, ready for the autumn evenings. During the year we have added a new lens to the lantern, and the front has been altered and renovated. It took a good while to settle about that lens, but we have got it now, and a few hundred slides more or less will not "strain" it. Amongst the lantern nights, I may mention the following:—"Lowestoft and Neighbourhood," Mr. H. Vivian Hyde; Gloucester Convention Slides; "Photomicrographs," Mr. T. E. Freshwater.
