### EX CATHEDRÀ.

THE number of the Royal Photographic Society's Journal just issued contains the nomination form for the election of officers and Council, 1900. This form must be returned to the Secretary not later than January 19. It is understood that the Earl of Crawford will not stand for re-election as President. In October 1898, his Lordship only yielded to considerable pressure in accepting nomination to the office for the year 1899-1900, and on that occasion he said he was strongly of opinion that the Presidency should not be held for more than two years in succession by the same person. The members of the Society will therefore have to choose a successor to the gifted and amiable nobleman who for the last three years has filled the Presidential chair of the Royal Photographic Society with such remarkable success. Lord Crawford's term of office covers a notable period in the Society's history. The Incorporation; the Crystal Palace Exhibition; the removal to a permanent home in Russell-square are the three chief events that occurred during a presidency which has conferred very great benefits, indeed, on the Society and upon photography at large. Lord Crawford's disappearance as the official head of the chief photo-

graphic society in the world will be much regretted, but the recollection of his untiring and splendid devotion to its interests will, we are sure, long be held in grateful recollection by the members.

\* \* \*

PRIVATE letters that we have received from him also inform us that Major-General Waterhouse does not propose accepting re-election as Honorary Secretary of the Society next month. Bronchial troubles are, we believe, the immediate cause of a decision which, in the interests of the Society, we hope General Waterhouse will find himself in a position to alter by the time the Council, a few weeks hence, takes in hand the matter of selecting an Honorary Secretary. Coupled with Lord Crawford's disappearance from the Presidency, General Waterhouse's relinquishment of the chief active control of the affairs of the Society at this moment would be very much regretted by those who are conscious that, in such distinguished hands, the Honorary Secretaryship of the Society has a dignity quite in accordance with the best traditions of the office. It is no secret that various occurrences connected with the last Exhibition temporarily rendered General Waterhouse's position a somewhat troublesome one; but these things are not likely to suffer repetition, and we are firmly of opinion that, if General Waterhouse will consent to accept re-election as Honorary Secretary, he will secure the entire support of the members, who will heartily co-operate with him in making next autumn's first Exhibition at the New Gallery a very great success.

\* \* \*

THE work of Vandyck is that which specially appeals to portrait photographers, inasmuch as it is mostly confined to portraiture and figure pictures. Unfortunately, however, our public art collections are by no means overstocked with examples of this great master's works. The majority of his best work is only to be found in private collections, which are not accessible to the general public. The Queen has between thirty and forty examples at Windsor, and others at Buckingham Palace. With these and others in various private collections, the photographic reproductions of some Continental firms, such as those of Hanfstaengl, Braun, and others, have made us somewhat familiar. Just now, at Burlington House, there is on view one

of the finest collections, obtained from various private galleries, including those of Her Majesty, of Vandyck's works that has ever been shown in this country. Those of our readers who desire to see the pictures should avail themselves of the opportunity, as a similar one may not occur again. It will also be an excellent opportunity of comparing the photographic reproductions, by the best houses, with the originals, and of seeing how the various colours are rendered in them.

\* \* \*

A PARAGRAPH has been going the round which might almost be headed "spirit photography," and possibly will be so construed by some who are believers in it. The paragraph is to this effect: Lieut. Long, who was unfortunately killed in Lord Methuen's second battle, was some time before showing and explaining to a sister a new weapon, when it accidentally went off, killing her. After his departure for the seat of war, Lieut. Long wrote to another sister, presumably an amateur photographer, to take a photograph of the deceased's grave and send it out to him. When the negative was developed, it showed the grave with Lieut. Long standing beside it in uniform. The paragraph, to its credit, says that the explanation is that Miss Long took the photograph of the grave on an undeveloped plate, which had been previously used to photograph her brother himself. It also adds: "None the less, the coincidence is a remarkable one." The writer of the paragraph attributes the appearance of the secondary image to its true cause. Had he not done [so, probably those who believe in spiritualism and spirit photography would have assigned it to a totally different one, and some might have made capital out of it. Previously exposed plates are a stock in trade with charlatans in spirit photography, though little suspected by their dupes.

\* \* \*

SOME little while ago the *Photo Chronik*, a German contemporary, published a process credited to Benham, and this has been reproduced here in abstract, and, in one of our contemporaries, described as a copper-sulphate process without any reference to its being our old friend the "chromatype" process of Hunt of half a century ago. Slightly modified, this further emphasises what we have frequently said before, namely, that it would be well for experimentalists and would-be inventors to overhaul many of the ancient processes, with our modern knowledge of photography and chemistry. The chromatype process of Hunt is this: The paper is brushed over with a solution of sulphate of copper and bichromate of potash, and dried. When printed, the image, which is brown, is further developed with a solution of nitrate of silver. In the "new" process the brown image is further developed in a strong solution of pyrogallol acid, the paper being sensitised exactly according to Hunt's method.

\* \* \*

THE chromatype process of Hunt is an interesting one. Here is a quotation from his *Manual of Photography* (1854): "When exposed to sunshine, the first change is to a dull brown, and, if checked at this stage of the process, we get a negative picture; but, if the action of light is continued, the browning gives way, and we have a positive yellow picture on a white ground. In either case, if the paper, when removed from the sunshine, is washed over with a solution of nitrate of silver, a very beautiful positive picture results."

"To fix these pictures it is necessary to remove the nitrate of silver, which is done by washing in pure water; if the water contains any muriates, the picture suffers, and long soaking in such water obliterates it; or, if a few grains of common salt are added to the water, the apparent destruction is very rapid. The picture is, however, capable of restoration, all that is necessary being to expose it to sunshine for a quarter of an hour, when it revives; but, instead of being of a red colour, it becomes lilac." Mr. Bingham, at the time, found that, with the substitution of sulphate of nickel for the copper salt, the paper was more sensitive and the picture was clearer. These pictures can also be developed with nitrate of mercury. This process, as given in Hunt's *Manual*, is highly interesting in other ways, but space will not allow of further quotation here. Only a few weeks ago we alluded to a process that had recently been patented in America, which was identical with that published in Hunt's *Researches on Light* in 1854, and now we have another of these old and obsolete methods, with slight modification, reinvented.

\* \* \*

WE congratulate Captain Abney on his promotion in the Order of the Bath, which was one of the New Year's Day honours gazetted on Monday last. He becomes K.C.B., and we are sure that photographers all the world over will join in felicitating the most distinguished of their number on the well-deserved honour that has been conferred upon him. *Apropos* of Sir W. de W. Abney's recent assumption of the principal directorate of science at South Kensington "F.R.A.S.," the learned and vigorous writer in the *English Mechanic* has the following eulogistic remarks: "Most happily for the nation, and for the dignity and purity of science generally—Sir John Donnelly is succeeded by as honourable and high-minded an English gentleman as himself. I mean, of course, Captain Abney, who may be most thoroughly trusted not to connive at the low arts and wiles of some of those whom he has been appointed to supervise."

\* \* \*

A FINAL glance through the very great number of Christmas and New-year's cards that have reached us during the last ten days persuades us that the pretty custom of photographers making their own camera productions the principal features of those cards is, if anything, on the increase. To give our readers some idea of the variety of photographic Christmas and New-year's cards that we have received we select half a score for mention. One gentleman chooses a half-plate gelatino-chloride view of the French village in which he lives; another sends us capital quarter-plate photogravures from two of his own landscape negatives.

\* \* \*

MR. GEORGE DAVISON pleasantly jogs our recollection of the '98 Salon Exhibition by sending us a picture on satin of his well-known study of a group of horses; and from Mr. Walter Barnett comes a costume portrait of a lady looking uncommonly like Mrs. Brown Potter. Amusing pictures of kittens were sent us by Mr. W. J. Croall, and a view of Dunbar by Mr. W. Crooke. The veteran Mr. James Alexander Forrest, who has not ceased to take a kindly interest in the *JOURNAL* and its conductors for the last forty-five years, is represented in our collection by a portrait of himself; and in the silhouette "photogram" of Mr. John Stuart, of Helensburgh, we recognise a perfect likeness of the genial President

of the Glasgow Convention. Mr. Vivian Hyde's card bore a print of one of his charming landscapes, and Mr. W. Thomas, faithful to his old love, the river, sends us a beautiful print of craft, *Waiting for the Wind*. Truly an agreeable and welcome collection of good photographs. We hope that the custom of exchanging photographic Christmas cards will spread amongst all classes of photographers; its capacity for causing pleasure to one's friends at the festive season has, we are convinced, not yet been fully appreciated.

---

### OURSELVES.

THE controversy that is being carried on around the question as to whether the year that has just opened commences or ends a century does not invite our intervention; but, in either case, it supplies us with an opportunity for addressing to our readers a few words on the subject of our future relations towards them, and the many interests confided to our charge.

Those words shall be few and brief. Throughout its long and unchequered career, it has always been the aim of THE BRITISH JOURNAL OF PHOTOGRAPHY, by the aid of the experience and knowledge that has been continuously placed at its disposal, to discuss all phases of the science and practice of photography in a manner best calculated to be of advantage to its wide circle of readers and supporters. The fact that a vast number of the latter consists of professional men, whose business it is to furnish photographs to the general public, has ever been steadily kept in view, and will explain why many passing fads and crazes obviously incompatible with the everyday exigencies of practical work have received little encouragement in our pages. To the great interests of professional photography we shall continue to devote ourselves with the same thoroughness as in the past.

But THE BRITISH JOURNAL OF PHOTOGRAPHY is happy in addressing week by week many other sections of photographers besides the one just referred to. We have a world-wide amateur *clientèle*, as our subscription list and correspondence testify. There are classes specially interested in the optics and chemistry of photography; classes separately interested in the many scientific and industrial subdivisions of the main subject; in short, almost every single branch of photographic work constitutes a more or less distinct public of itself, into whose hands each issue of this JOURNAL regularly falls. The consciousness of the wide and varied public it is our happiness of constantly addressing will remain with us in the future as in the past, and it will be our endeavour to make our pages themselves the witness of the great pride and responsibility we feel in representing the best and most permanent interests of the photographic world.

When, in due course, the Jubilee of THE BRITISH JOURNAL OF PHOTOGRAPHY (which traces its date of origin back to the year 1854) comes to be written, it will be found that its history is very largely the history of photography itself for the last half-century. Leaving this task to the future, we will, however, allow ourselves to cast a glance back over the last decade or so, which is contemporaneous with our own intimate editorial connexion with the JOURNAL, and cull a few facts to support us in saying that, even beyond the immediate interests of its readers and supporters, the policy of THE BRITISH JOURNAL OF PHOTOGRAPHY has been directed towards promoting the advancement of the photographic world at large.

Founded by a former editor of the JOURNAL in 1886, that

pleasant and profitable annual gathering of photographers known as "The Convention," has always been steadily supported in these pages. In 1891-92 the early gelatine emulsion experiments of Dr. R. L. Maddox were brought prominently to notice in our pages, and on our initiative a sum of between 600*l.* and 700*l.* was raised and presented to him in recognition of the value of his discovery. The work of Messrs. Hurter & Driffield, long neglected or misunderstood by photographers, formed the subject of special study on our part some years ago, and we take pleasure in reflecting that it was to our efforts that the Progress Medal of the Royal Photographic Society was awarded to two of the most original workers and thinkers photography has so far produced.

Ever since the Photographic Copyright Union was formed we have done our best, in order to assist photographers in protecting their copyright interests, to forward the work of the Union. The part played by the JOURNAL in suggesting and supporting the great Crystal Palace Exhibition stands on our record. The work and writings of the founder and chief exponent of modern pictorial photography, Dr. P. H. Emerson, have been frequently brought to our notice, and the efforts of the JOURNAL have long been expended in securing recognition of one of the greatest intellects in photography.

The establishment of the Traill Taylor Memorial must be put to the credit of the JOURNAL and its supporters, and in more recent times we have interested ourselves in the attempt to persuade photographers to take up the use of metric weights and measures. Such institutions as the Benevolent Fund (now, alas, in process of extinction, through the apathy of those on whose behalf it was established) have ever received our sympathetic help.

We might extend the recital of the active part which the JOURNAL has always taken in stimulating photographic progress and activity; but sufficient has perhaps been said to assure its readers that the position which it admittedly occupies in the world's photographic journalism to-day is the result of the breadth of policy which has always directed it. That policy will animate us in the future, and the sphere of usefulness filled by the JOURNAL will, we hope, widen rather than diminish. To all sections of its supporters we address the assurance that no effort on our part will be relaxed to maintain THE BRITISH JOURNAL OF PHOTOGRAPHY in the proud position it has so long occupied.

---

**Incandescent Lamps without Gas.**—Many dwellers in the country who are debarred the luxury of gas will hail with pleasure the advent of a new lamp, capable of rivalling the incandescent gas burner but without the need for gas. Such a lamp has been devised by M. Denayrouze, and was recently exhibited before the French Society of Civil Engineers. The light of an ordinary fishtail burner is due to the incandescence of particles of carbon reduced from the coal gas by the act of combustion, and rendered white hot by the heat thereby evolved. According to Saint-Claire Deville, there is only about from three to six per cent. of carbon in coal gas, the surplus hydrogen being able to raise to white heat a far larger proportion than this if it were present. This fact is made use of in the Welsbach burner, which from a given amount of gas, produces about five times more illumination than if burnt in an ordinary fishtail or bat's-wing, or even an Argand burner. Many burners have been devised to cause an incandescent illumination from alcohol or petroleum, &c., as the combustible; but, so far, with little practical success. M. Denayrouze has hit upon a combination of the two systems. He uses alcohol to which a hydrocarbon has been added; in heating the mantle carbon is deposited

upon it, and along with the mantle itself is rendered incandescent, and thus a double source of light is provided. The lamp was a success, but the inventor kept to himself all details as to what form of carburetted agent was supplied. Still, it is probable that an invention of such value will be taken up by the manufacturers and placed upon the market, if in its present shape it is a really practical lamp.

**An Electrical Lighter for Flash Lights.**—The *Scientific American* describes a new method of igniting magnesium or other powders by means of electricity in the form of a simple apparatus manufactured by Messrs. Himmer & Potter, of New York. The motive idea is, from a double cell dry battery to provide a simple circuit passing through the flash powder, the current at that point passing through a small length of thin platinum wire. This, forming, when the current flows, a resistance, develops sufficient heat to become white hot, when, of course, the powder ignites. A simple means of making or breaking the current forms part of the apparatus, which, if well made, should be a very useful contrivance, as dry batteries easily rival the well-known Leclanché in their constant readiness for use.

**Direct Photographs of the Moon over a Quarter of a Yard in Diameter.**—Referring to the new long-focus telescope of the Harvard College Observatory, which is expected to be in actual use in a very short time, a small calculation will give some idea of its power. The object-glass will be a foot in diameter, with a focus of over a hundred feet. Taking the moon as, roundly, half a degree in diameter, we have 0.0039 (the sine of half a degree) multiplied by 100, equals 0.89 of a foot, *i.e.*, about ten inches as the size of the image on a negative without any previous amplification. It will be understood that this telescope is constructed specially for photo-astronomy.

**A Marvellous Radiometer.**—The anticipations once felt as to the probable use of the radiometer for photographic purposes were shown to be illusory, as it is the part of the spectrum which manifests heat rather than light which mainly actuates the vanes of the instrument. As proving this, there may be mentioned a marvellous little radiometer recently successfully tested at the Yerkes Observatory, for testing the heat radiated by stars. Obscure heat rays, as is well known, are entirely obstructed by glass, so that an ordinary radiometer placed at the focus of a refractor pointed to a star would not act simply because its walls are of glass, and the objective of the telescope of the same material, a double obstacle being thus interposed. The latter difficulty is surmounted by using a reflector (24 in. in diameter) to collect the rays, and the second by constructing the radiometer with a window of fluor spar let in, this substance being transparent to the least refrangible rays of the spectrum.

**Sham X-ray Instrument.**—In Boston there is being manufactured and sold an "X-ray camera" which is nothing but a fraud. The "camera," with pneumatic ball, is placed in position before a sitter in front of whose body is placed a sheet, apparently of white paper, without a mark upon it. Behind the body is placed a lamp. The exposure is made by pressing the ball. Gradually the paper loses its whiteness, the various organs of the body quickly depict themselves, first in faint colour, then almost immediately in brilliant reds for the lungs, a duller red for the heart, green for the stomach and intestines, and blue for the veins, other parts in black. This result, however, is only a trick. The white sheet of paper has previously been painted over with strong and diluted sulphocyanide solution, ferrocyanide solution, weak and strong, and finally with tannin, the details being supplied by an anatomical drawing, over which the thin paper is placed while the organs are being painted by the various solutions named. The squeezing of the bulb does not, as imagined, open the lens, it simply ejects an invisible spray of solution of ferric chloride from a concealed source upon the paper, the well-known reaction of this salt with the chemicals named producing these various colours. So long as it is understood to be a trick, the idea is

ingenious and amusing—so ingenious, indeed, that we shall be rather surprised if some unscrupulous inventor does not appropriate it to his own nefarious ends and bring out a new scheme for "photography in colours," the process being such as would lend itself admirably to the fraud.

## THE PHOTOGRAPHER'S YEAR.

JANUARY.

THERE is no particular reason why the year should commence in January more than in February or March, nor that the good resolutions of various sorts generally made on the first of January should be made on that day more than on any other. There is no difference, beyond a slight astronomical one of length, which can have little to do with a successful holding to determined-upon changes for the better, between December 31 and January 1. But, as there must be a definite point to begin the year with somewhere, we may as well accept the present one without seeking any particular reason for its institution. The good resolutions, too, being in the main but expressions of the dismal reaction after the gaieties of Christmas, need not be worried much over, as they will so soon be broken. And wisely so probably, for, if a man held on to highflown plans often made at the beginning of the year, in the saving of money, reading more, eating less, not drinking at all, keeping a diary, and so on, he would soon become too perfect altogether for earth. Whipt off to adorn a higher sphere, his virtues on a tombstone would be all left to us. Still, in moderation, a good resolution is a very desirable thing. The beginning of the year, too, is a reasonable point of time at which to make it, and as such offers perhaps something of adventitious aid in its keeping. The fault of most new-year resolutions of amendment is that they are too drastic. This is the direct cause of the majority being so short-lived. Those most likely to be kept are the ones that do not necessitate any awkward or marked departure from the ordinary course of living. Commonplace continuous efforts are far more likely to bring a reward than more spasmodic, though higher, ones. Lack of continuity means lack of sustained interest, and failure. To the furthering of continuity a plan is essential; not too rigid a one that the spirit would have the frequent opportunity of humanly rebelling against, but one that like a good wife would find its truest strength in a little elastic give at need.

Applying the foregoing general truths to the particular case of photography and the great mass of its non-professional followers, it will have to be admitted that one great source of the weakness of work lies in its scrappy nature. Excepting a very small minority of earnest workers in special directions in which they have excelled, a look through most stocks of negatives will readily prove the point. Not only does this scrappiness detract from the value of result, but also in its aimlessness from the pleasure of accomplishment. The remedy lies in working to a broad, reasonably definite plan. Individual temperaments varying so markedly, it is difficult to suggest one that would have a chance of acceptance by the majority. The suggestion is, however, made that this time framework of the year is one sufficiently elastic to be taken to fill up photographically. It will not be filled up alike by two workers, that is immaterial; but common to all who may elect to take it up will be the fact that photographs will be taken in every month to illustrate something in a continuous way to the forming of an organic whole. An album of such prints would be interesting at the end of a single year, valuable at the end of three or four, invaluable at the end of twenty. It would form a pictorial account of one's life for its term, truer, more easily consulted, and infinitely more interesting than a diary. Or, as a record of mood, imagine a diary supplemented by such an album! But this is rising to heights of grandeur inaccessible to ordinary minds, with which as forming one we are most in sympathy.

But what can one do photographically in many portions of the year? may be asked. What is there worth photographing, for instance, in this and the next two months? More than one would think until he comes to look more closely at things. And not the least of the advantages of acting upon the suggestion would be the noting of a vast amount of hitherto unnoticed and unsuspected features peculiar to each month, and the differences between those of one month and the other. We do not mean to say that January is so rich in photographic possibilities as June. The pictures of the former need not be so numerous as those of the latter, and even thus in a mere matter of numbers our comparative appreciation of the two be shown. But working to the filling in of a plan can do much more. The best part of human pleasure lies in its anticipation, or in looking back upon it when it has passed. The re-

membrances of summer scenes and out-of door enjoyments are extremely pleasant when looked back upon, or forward to again at the winter fireside; those of winter equally so when tired with excess of heat and sunshine, as was the case markedly enough during this last summer. Our photographer has the added zest and emphasis given by turning over his year-book of pictures.

As there are wheels within wheels in the making of a piece of mechanism of high value, so, within the loose binding of this plan based upon time and season, there may be a more definite one making for a special purpose. A square of carpet looks better and is more serviceable than scraps of rug thrown here and there upon the floor of a room; but the square of carpet is in turn much heightened in estimation and beauty by having a suitable pattern woven into it. So, with the photographic worker, a particular object within the year's bounds will make his work more valuable. What form it may take depends upon his individual tastes and leanings. It may be that of picturing a year's sport, the appearance of a favourite walk, the garden or farmstead for a year. Dwellers on the seashore are specially blessed in having the infinite variety of the sea, and those finding a living in and upon it, to picture throughout a year's moods. To the interested eye, soon becoming an acutely discerning one, there is a wealth of material both landward and seaward in our beautiful England, with its so frequently changing weather conditions.

Presuming that enough has been said in broad, general support of the idea, a few suggestions each month as to satisfactory methods of carrying it out may prove interesting. The town-dweller will have very different aspects presented to him in January to the country one. With respect to the characteristic one of snow, it looks very different in the country to the town—at least, after the first day or two. A country road, with its sparing traffic, and the clear indications of its kind and purpose in wheel and footmarks, tracks leading off along a side lane or towards a solitary cottage, bordering burdened trees and hedges, are very different features to those of the town street with its slush, and the corporation carts and men hard at work clearing it away. Both are pictures worth catching; both would be prized six months hence, when the thought of snow will be so much out of the current order of things; or, if the town-dweller be of too delicate an artistic fibre to see much worth preserving as a record in a sloppy street, in all towns there are delightful little bits of quaint roofs and gables that can be caught when the snow is fresh. In many towns the luxury of rich tracery of church or cathedral walls, windows, spires, turrets, are improved yet further in beauty by a dusting of white—such pictures are ones generally enjoyed more in the abstract, though, for, although desired in a vaguely artistic way, the conditions under which they must be taken are not the best photographically more than the pleasantest physically. The same cold that brings the snow makes the warmth and comfort of the fireside so much the more acceptable and attractive. Carrying a camera about and fingering screws on a frosty morning are not generally looked upon as pleasures; but the result is well worth the trouble, and appreciated all the more highly from the difficulties and unpleasantness in obtaining it.

There are too, in January, peculiar effects of sunlight breaking through dominating grey clouds that are not to be seen at any other time of the year. Golden light we are apt to associate exclusively with later summer and autumn, and correctly so in its mellowness; but there is often a rich, clear gold, especially when thrown upon distant water, in January, that we fail to see at any other time. This is certainly exceptional, and it might, perhaps, be better upon the whole to take characteristic features. Grey, bare dulness is the dominant note of the month, to be caught as such if a true picture is what is aimed for—not so easy a matter as it looks, for the standards to judge by, both on the artistic and technical sides, are so different in every way to the orthodox ones we have unconsciously formed under the usual conditions of summer work.

What objects or scenes are to be taken under the prevailing dense light or coating of snow rests with the individual taste. There is no lack of choice; it is the same earth, under different conditions, as the summer one. Snow scenes, bare stretches of country roads, gaunt tree forms, naked copses, skating and hunting scenes, cosy interiors, and so on, offer an ample and a varied field from which at least half a dozen pictures can be picked to be placed in the first section of the year's work.

#### BRITISH PHOTOGRAPHY FROM THE AMERICAN POINT OF VIEW.

By the last batch of our Transatlantic exchanges we observe that British photography, especially the "pictorial" section of it, has recently attracted the close critical attention of some of our photo-

graphic brethren on the other side. Thus, Mr. F. Dundas Todd (formerly of Edinburgh and now editor of the *Photo-Beacon*, Chicago) delivers himself of the following emphatically unfavourable opinions. We take the extract from a review of *Photograms of the Year*, and it will be observed that the writer is no more complimentary to the New York amateur than he is to the British professional:—

There are one or two rather amusing features in the book, however, especially with reference to American work. The writer of the article on "The American School" is a New Yorker and an amateur photographer, therefore there is a whole lot he does not know, and he is not aware of the extent of his ignorance. He deplures, first, that there is no strictly American school of photographic art, and, in the second place, sees a little hint of the dawn coming, and gives credit for that little ray of hope to a photographic publication issued to a select few once a quarter. We live in Chicago, in the "Wild and Woolly West," where men's minds are given up to the making of pork and the handling of grain, therefore there is no art in this benighted spot. So thinks our Eastern friend, who believes he sees it all because, forsooth, he lives in New York. May we tell him that there is an American school of photographic art, distinctly its own in style, and that—horror of horrors!—it is to be found in professional photography? We have gone carefully through the *Photograms of 1899*, examined every portrait therein, and have no hesitation in saying there is not one really good specimen of portraiture in the whole book, according to the American ideals of the last three years. Nay, more, but yesterday we had a call from a photographer in a small town in the Middle States, a man who but five years ago was a farmer, and we placed in his hand some portraits made by one who is in every one's mouth in Britain as an artistic professional photographer. He looked through them, and passed them back with the remark, "Who made that ordinary stuff? He must have been asleep for a few years." Long before *Camera Notes* was ever dreamed of, James Inglis and the writer were stirring things up considerably, and to-day these two men can walk into any photographic convention, claim a part interest in practically every picture hung on the walls, and, what is more, have it accorded them with a smile. So this new American school is a Western product, not an Eastern; is distinctly American by birth, and not European. The American to-day is an originator, not a copier, and the sooner the folk who live at the jumping-on place look across the prairie and turn their back on the sea the more chance there will be for them to see something.

At the recent Exhibition of the Philadelphia Photographic Salon, British pictorial photography was largely represented. In the pages of the *Photo Era*, Mr. Joseph Prince Loud, who is President of the Boston Camera Club, makes the following comparisons between American and English work:—

English photographers have for so many years been recognised as leaders in their art that it is now most gratifying to find that the average American work here exhibited can be compared most favourably, while in individual cases it is equal, if not superior, to theirs.

The English pictures are all more distinctly exhibition works, and, having greater carrying capacity, are therefore more impressive to the casual observer.

There is, however, a greater monotony of style than in the American pictures; which effect is further increased by the similarity of framing, due to the rule of foreign exhibitions, which prohibits the use of mats in the requirement of close frames.

In a degree the same national characteristics of style are apparent which exist in the two distinct schools of painting. The English work, while more finished, often has the effect of being over-studied; while the American work is generally broader and more imaginative in style, or, to use a painter's phrase, more sketchy in treatment.

The English pictures almost invariably impress one with their wealth of detail, which, in a measure, may be due to a desire to truthfully portray their more picturesque surroundings. In comparison the American pictures have a far greater individuality. The compositions are usually more simple, and are more dependent upon their tone and colour values, in which there is often a tendency to go to the other extreme of barrenness in detail, in order to gain effect by strong contrasts of light and shade.

The American simplicity of taste is strongly shown in the method of framing, which, when mats are not used, have generally the plainest of broad, flat mouldings. In contrast, the English pictures, with few exceptions, have rather heavy frames, with inside gilt edgings, and are moulded with cuttings often so deep and complicated that one with difficulty forgets the frame long enough to enjoy the picture within.

Among the exceptions to be noted are the pictures of J. Craig Annan and Ralph W. Robinson, which are framed with as good taste as their compositions are simple and effective.

Of the English exhibitors, the work of the two artists above mentioned is the most individual in treatment, and their pictures undoubtedly rank among the best in the entire Exhibition. Mr. Annan's work is always original. His portraits of James Guthrie, Esq., and Miss Ellen Terry are exceptionally fine, as is also his *Lombardy Ploughing Team*, which is treated in a charming decorative style. Mr. Robinson's landscapes are of his best work, and are exceedingly strong pictures. His portrait, the *Head of a Girl*, is also particularly fine.

The work of A. Horsley Hinton is, perhaps, as familiar to Americans as that of any foreign artist, through its frequent reproductions in our photographic publications. His seven landscapes exhibited are characteristic, and are wonderful pictures, especially *The Headland*. His work shows less variety than that of almost any other artist, which is particularly noticeable here, where in each case the composition is divided horizontally in the middle by the sky line. The prominent features of his pictures are the foregrounds, which are selected with great care, the sharply defined middle distance, and the strong skies, which are never subordinated. His clouds are generally heavy, yet truthful, and thrust themselves into the landscape as only the English atmosphere can. That he is a keen student of nature is apparent in all his work.

Landscape photography seems to be the strongest forte of the greater number of English artists, among whom W. Smedley Aston, Karl Greger, and W. Thomas show some very excellent examples.

In portraiture, most of the English work is rather conventional in style, the pictures of Harold Baker, H. Walter Barnett, and Frederick H. Evans being of chief interest. William Crooke also shows some clever portraits, but the extent to which he has undertaken in some of his work to imitate old engravings, even in the framing and quaint margin lettering, is certainly questionable photographic art. The resemblance is so perfect that the results appear simply as photographic copies.

Collectively, the French photographs have more of the characteristics of the American rather than the English work in their greater individuality and broader treatment.

A second criticism of the Philadelphia Salon appears in the *American Amateur*. It is by Mr. C. R. Pancoast, who says that, in portraiture, William Crooke, of Edinburgh, stands alone. "It is simply a triumph of photographic art, and his pictures are by all odds the finest portraits in the Salon."

Mr. J. Craig Annan's seven pictures are all up to his high standard. It is seldom that one meets a more satisfactory photograph than his *Lombardy Plowing Team* (No. 14). A Rosa Bonheur could do no better. Among other works of note may be mentioned *Grey Avons Peace* (No. 25), by Harold Baker; *Reedy Wastes* (No. 18), by W. Smedley Aston; *Dreamy Marshland* (No. 146) and *Evening Before the Day of Rest* (No. 149), by Karl Greger. *The Storm Lifting* (No. 167), by Charles F. Inston, is one of those superb effects where everything combines to make a wonderful result. The effect of the light on the water, the lugger under reefed canvas against a background of storm clouds, completes a happy combination rarely met with. Will Cadby is guilty of perpetrating a fake in his *There Came a Big Spider* (No. 73). The idea of a nude female figure sitting on a stone wall in close proximity to a *toy spider* of mammoth proportions is, to say the least, ludicrous. That the talent of the father has descended to the son is marked in the work of Mr. Ralph W. Robinson. His *Becalmed* (No. 251) is a gem. The broad expanse of water, the idle sails, all tell the story. The exhibit of Mr. Robert Demachy, of Paris, is especially interesting and very beautiful, as showing the great capabilities of the gum-bichromate process, of which he is evidently a master. His pictures do not bear reproduction, and one must see the originals to appreciate the subtle effects he strives for. *A Group of Cattle* (No. 56), by Maurice Bucquet (Paris), is a wonderful piece of photography, as showing the effect of motion without the rigidity so often seen in effects of this kind, where the exposure has been too brief. His *Open Sea* (No. 57) is a clever marine.

#### P.O.P. MANIPULATION.

GELATINO-CHLORIDE printing-out-paper, or, as it is technically called, P.O.P., is probably at the present time the most popular and most generally used of the printing-out papers, which makes it more difficult to understand why such a number of people are still unable to work it properly, or to get anything like the best results from it; about ninety per

cent. of this is the fault of the operators themselves, the other ten per cent. we may perhaps put down to the paper, although this is rather a liberal estimate.

We hear complaints of yellow prints, marks in the prints, double tones, tackiness, &c. Taking the minority first, i.e., faults from bad paper, what do we find? Seldom that it is the fault of the manufacturer, but rather that of the dealer, or perhaps, more properly, the fault of the dealer not having a sufficiently quick sale for the paper. This is a matter which is very difficult to overcome, as the dealer has to cater for a casual as well as a regular trade, and, if he has not a sufficient stock of paper in hand when his customers want it, they go elsewhere, and very often this loss is not merely temporary, but permanent, so he always stocks more than he expects to sell; consequently, although P.O.P., if properly prepared, is by far the best keeping of all the printing-out-papers, it deteriorates and becomes discoloured, and, no matter how carefully worked, the best results can never be obtained upon it. Unless a dealer's business is carelessly worked, paper should never be kept so long a time that this deterioration becomes serious, as P.O.P. ought to keep in good condition for six months at least, although, of course, the very best results can only be obtained when the paper is fresh. In buying from a dealer there are two chances of the paper being old, as it may have been some little time in stock at the factory besides the time the dealer has it. Most professionals who study their business order direct from the manufacturers; this, undoubtedly, is the best way, despite the fact that in small quantities it is slightly more trouble and expense at starting, though often this is compensated for by the saving of time in working. I believe the manufacturers do not now supply paper quite freshly coated, as, being more sensitive, it is more likely to spoil in the hands of careless workers, who, unfortunately, seem to predominate. To the average amateur the dealer is almost indispensable, as often their orders do not extend to more than one packet, and the trouble and expense of getting this from the manufacturers greatly discount the advantages gained; besides, the amateur is only able to print in spare time; consequently, should he not get the paper just when he wants it, possibly he may have no use for it until some time afterwards, thus losing any advantage gained.

Long-kept paper will account for some yellow prints, but very often carelessness in toning and fixing accounts for a lot more. Unless the combined bath is used, and no photographer who wants good and permanent prints should ever use it, the paper *must be well washed before toning*. The importance of this washing does not seem to be generally understood. P.O.P. contains a lot of salts which are not required in the finished print, and, unless these are washed away, they get into the toning bath and spoil it, therefore the prints do not get properly toned. Some of these salts are very soluble in cold water; thus the preliminary washing eradicates them, and saves further trouble.

Several of the manufacturers say in their instructions that, after taking the prints from the printing frame, they may be placed in a weak solution of common salt (chloride of sodium) and water, but also say this bath may be omitted if desired, which is very vague, and many photographers do not understand the reason for this bath, which is really a very important one. The chloride of sodium converts the organic salts (usually citrates and tartrates) contained in the film into chloride of silver, and in turn forms citrates and tartrates of sodium. This makes the washing before toning more simple and thorough, as silver citrate and tartrate are not very soluble in cold water, while sodium citrate and tartrate are very soluble, consequently the washing easily removes them. In addition to this, the salt bath gives the prints a redder tinge, and a greater range of tone, with very much better results, can then be obtained. A five per cent. solution should be used. The prints must be well washed after the salt bath.

Most manufacturers say that any toning bath may be used to tone P.O.P. This is quite correct up to a certain point, but, if the best tones are required, only the sulphocyanide bath should be used, for, as explained in an article entitled "Toning Troubles," which appeared in *THE BRITISH JOURNAL OF PHOTOGRAPHY* of July 21, 1899, under many circumstances gold, like silver, combines with gelatine and robs the toning bath. The sulphocyanide obviates this, therefore better tones can be obtained. Sulphocyanide also has a bleaching effect upon P.O.P., tending to give purer whites, and it also has a slight fixing action.

Many complaints are made that P.O.P. uses a very large quantity of gold in toning, more than either collodio-chloride or albumen; but this is remedied by using the sulphocyanide bath, for, although gold chloride does combine with gelatine, gold sulphocyanide does not, thereby accounting for the superiority of the sulphocyanide bath; consequently, if photographers will insist on using other baths, they must be prepared to allow an extra quantity of gold, besides risking uncertain and double toning.

An interesting experiment in toning is to place one or two P.O.P. prints in the same toning bath with some collodio-chloride, when it will be found that the P.O.P. prints will tone until all the gold is exhausted, while the collodio-chloride prints will hardly tone at all. This is probably accounted for by reason of the great affinity which gelatine has for gold.

Double toning, which seems to be one of the principal, if not the principal, troubles that many photographers have with P.O.P., is sometimes caused by a toning bath too strong in gold, which then deposits

unevenly. The writer believes that the following toning bath will be found quite strong enough for any P.O.P. :—

Ammonium sulphocyanide .....	15 grains,‡
Gold chloride .....	1½ ”
Distilled water .....	8 fluid ounces,

and, if used at this strength, little trouble should be found with double toning. Certainly it will not tone so quickly as a stronger bath, nor will it give such violet-blue tones as these can only be obtained by a bath which deposits gold quickly, but few prints should be spoiled by the above. This bath is easily and quickly made if stock solutions of the gold and sulphocyanide are kept. The gold is generally bought in tubes containing 15 grains, and, if the contents of this tube are dissolved in 1½ fluid ounces of distilled water, each drachm of the solution contains 1½ grains of gold, and, if to every 180 grains of ammonium sulphocyanide 1½ ounces of distilled water are added, each drachm of this solution contains 15 grains of sulphocyanide; so, by taking 1 drachm of each stock solution and adding to 8 fluid ounces of distilled water, the bath is made at a cost of very little time and trouble. The writer strongly advises photographers to use nothing but distilled water for making up stock toning solutions and toning baths, as time, trouble, and money are thereby saved. Add the sulphocyanide to the water first, and pour the gold into it. *On no account reverse this order.* On first adding the gold, a red colouration is imparted to the solution, which, however, quickly disappears. Ammonium sulphocyanide should always be dissolved directly it is purchased, as it is very deliquescent, the same remark applying to gold chloride, the tube containing which should be broken into the water. In toning with the sulphocyanide bath, on first immersing the prints they lose density to a very large extent, and turn a peculiar yellow colour, which should then steadily change to the proper tone if the bath is in good working order. The writer has known amateurs to think their prints spoil at this first loss of density.

It is often desired to harden the surface of P.O.P., and many prefer to do this before toning and fixing, especially if the weather be very hot. Still, even in the hottest weather, unless the toning room is much exposed to the sun's rays and gets very hot, it should not affect the toning and fixing baths sufficiently to make trouble with the film. In exceptional cases, where the heat of the sun brings the temperature of the toning room up to 80° F., and the baths have been standing in the room some time, and nearly, if not quite, reached the same temperature, trouble is sure to be experienced; but this may be averted by standing the dishes in a cold-water bath. Ordinary tap water seldom reaches a higher temperature than 65° F., even in the hottest weather, and any P.O.P. should be safely worked at this temperature. In fact, it is about the best at which it can be worked; so, if the toning and fixing baths stand in another dish of water at this temperature, all trouble should be avoided without hardening the film, which the writer believes is a bad practice before toning and fixing. Should it be decided to harden the film, a solution of either chrome alum, potash alum, or formalin, may be used. Chrome alum is a very good agent as far as the actual hardening goes, but it is liable to give a greenish tinge to the prints, besides which it is a compound of sulphur, as its formula,  $Al_2Cr_2SO_4 + 24H_2O$ , shows. The latter is also a fault in common or potash alum, which is probably the most generally used of all the hardening agents where the  $Cr_2$  is replaced by  $K_2$ . The alums are generally used in a five per cent. solution, and, if thoroughly washed away afterwards, probably no harm results, as the writer is of opinion that the Al and Cr are the principal factors in hardening. Still, he believes that a good deal of the yellowness complained of in P.O.P. prints could be largely traced to an improper use of alum. The writer prefers to use a four per cent. solution of formalin for hardening the film, as it has none of the disadvantages of the alums. Formalin is usually obtained commercially as a forty per cent. solution. Hardening done after toning and fixing is an advantage, as all the three hardening agents mentioned above act as antiseptics to gelatine, and thus tend to preserve it, but, being used before the prints are finished, helps to lock up the silver salts in the film, and it is doubtful if the proper effect of toning and fixing is produced.

In several of the manufacturers' instructions it is stated that P.O.P. may be worked the same as albumen, and in many respects this is true; but it should be remembered that each variety of printing-out paper, whether collodion, gelatine, or albumen, has its own peculiar properties and characteristics, and upon no other paper can the rich velvety tones be obtained such as are produced upon P.O.P.

An item requiring attention is the washing between toning and fixing. A good deal of the chloride of gold obtained commercially is strongly acid, sufficiently so to make solutions prepared with it also acid, and, although it does not seem to affect the toning of P.O.P. in the same way that the toning of collodio-chloride is affected, taking P.O.P. prints straight from an acid toning bath and immersing them in hypo causes a deposition of sulphur upon them, and, although there are some photographers willing and ready to try and prove, with an ingenuity worthy of a better cause, that sulphur toning is permanent, it has been well established for many years that the exact opposite is the case, added to which is the fact that some of the yellow prints may be traced to this cause.

There is often a very false economy practised in fixing. Some photo-

graphers, both amateur and professional, seem to try and make a "record" of how many prints it is possible to fix (not necessarily properly and permanently) in one pound of hypo. At the present time hypo is remarkably cheap, and such a niggardly use of it is neither necessary nor wise, as hypo forms two compounds with silver, one soluble, the other insoluble. The soluble one is formed with a strong solution of hypo, while the insoluble one is formed by a weak solution; therefore, if fixing is started with a weak solution, as each print is fixed the solution gets weaker still, until at last it merely forms an insoluble compound with the silver in the paper, and no amount of washing will remove this, consequently the print fades and discolours, and the blame is thrown upon the P.O.P., which is immediately pronounced no good. The fixing bath is safest when used at a strength of

Hyposulphite of sodium .....	3 ounces,
Water .....	1 pint.

This leaves a fair margin of hypo over what is absolutely necessary, ensuring the safety of the prints. Enough should be used to just cover the prints well. The immersion should last about fifteen minutes, when the hypo should be discarded.

One of the greatest advantages about P.O.P. is the ease with which almost any surface is obtained upon it. Taking the ordinary glossy paper after it is toned and fixed, we can either take it straight from the final washing water, and mount it as it is, or, if a glazed surface is required, merely *thoroughly* clean, and either French chalk or wax a polished glass or ferrotype plate. Take the print from the wash water, and squeegee into *close* contact, making sure that no air bubbles are in between the glass plate and the print, or dull spots will be left where each air bubble is. Should a matt surface be desired, substitute a ground-glass plate for the polished one, and proceed as before, when a very effective matt surface is obtained, combining many of the advantages of a glazed surface without the loss of detail and depth which often occurs with commercial matt paper.

No difficulty whatever need be experienced in getting the print away from the plate if the latter is clean, a careful raising of one corner with a knife blade usually effecting this if the print is dry, but no amount of care will get the latter away without injury if the plate is not properly clean. The print should leave the plate directly the corner is raised. If it does not do so, allow a further time for drying, and when again tried, and the print still refuses to come away, immerse plate and print bodily in water until they separate, clean the glass, squeegee again, and no difficulty should afterwards be experienced. Although this is the easiest way to glaze P.O.P., undoubtedly the best and most permanent method is to coat a glass plate with collodion. Immerse P.O.P. print in a weak and not too hot solution of gelatine, and then squeegee on to collodionised plate, when the collodion film may be easily stripped from the glass if clean; and, as collodion is not affected by moisture, the gloss is permanent. When these methods are adopted, it is advisable to put a backing to the print while on the plate, or in the former case the surface may be spoiled.

The question of a mountant is a very important one with P. O. P., as unless carefully used, any mountant where water is the solvent is likely to cause trouble; stiff starch paste is as good as anything if carefully applied, but perhaps the safest kinds are the alcoholic mountants, as these scarcely affect the gelatine, which, of course, is easily acted upon by mountants containing water. Very good mountants can be made by a saturated solution of shellac or any of the gum resins, such as copal, mastic, elemi, &c., in alcohol.

Sufficient care is not always displayed in storing P.O.P., which should never be kept near the ceiling in a room where gas is burnt, as the fumes will spoil it, as will the fumes from chemicals; the safest plan is to store it in a box by itself, where no fumes of any kind can penetrate. A good deal of trouble was caused recently where P. O. P. had been stored in a cupboard, and, a large quantity of hypo used and kept close to the outside of one wall, the hypo gradually penetrated the wall and spoiled the paper. In handling P. O. P., remember that the film is delicate, and finger nails will scratch it, while dirty chemical-stained hands are fatal to good prints, leaving them covered with red marks and lines. There should be no more difficulty in working P. O. P. than in working albumen if proper care is taken, but, if (as sometimes happens) the prints are shot into the toning baths like rubbish into a hole, it is small matter for wonder when many prints are spoiled, and P. O. P. gets blamed for the carelessness of the operator.

C. T. SUTTON.

#### A PHOTOGRAPHER'S CHRISTMAS ENTERTAINMENT.

By invitation of Mr. and Mrs. Albert Young, a most enjoyable Christmas entertainment was given on the 28th ult. to the staffs of Messrs. Fradelle & Young's Studios and Works.

Unfortunately, some were prevented by prior engagements from being present, but nearly thirty members met at the chief studio, at 283, Regent-street, and spent such a merry time that it was long in the small hours of the morning before the party broke up.

The gathering was also a "send-off" to Mr. A. Wheeler, who was leaving on the following morning to represent the firm on a journey to

N. Africa, Palestine, and Egypt. Mr. Wheeler is a favourite with all, and had a fine reception for his songs.

Mr. Delaney, who had only recently returned from a long journey through Norway, on behalf of Messrs. Fradelle & Young, was also present and gave a song with a rousing chorus, whilst suitable words, expressing the pleasure of being present, were spoken by Misses K. & M. Young, Miss Harrington, Miss Pearce, Miss Winter, Miss Hammond, Mrs. Webb, Misses G. & E. Webb, Miss Elizabeth Hogger, and the lads Rouse, Thone, and Michaels.

Miss Shipman amused the company with some very funny recitations; Mr. Groves gave a soldier's song; Mr. Constable not only entertained every one with his cornet, but gave a most excellent vocal rendering of "The Absent-minded Beggar;" Mr. Frank Santiero astonished all by proving himself the possessor of a most melodious voice, whilst Mr. Hutchins gave evidence of his powers as a most excellent reciter (with suitable action) of long and difficult pieces, and Gerald Morrison also cleverly recited.

The "Edison-Bell" Phonograph, which Mr. Young daily uses for the dictation of his correspondence, was pressed into the service, for this night, as a recorder of every item of the programme, and, after an interval for the display of some remarkably fine animated photographs, great amusement was caused by the repetition the phonograph gave of all the earlier portion of the evening's entertainment.

Mr. Eckhardt and Mr. Bacon came as the representatives of past members of the staff, and gave much pleasure by whistling and vocal solos. They were accompanied by their wives, who most kindly assisted in many ways to the pleasure of the company.

Many other members contributed to the mutual enjoyment, and before leaving all were presented with suitably framed portraits of Mr. and Mrs. Young.

This most enjoyable meeting was brought to a close by the health of Mr. and Mrs. Young, and little baby Franklin Young, being most enthusiastically drunk, and the expressions of hearty goodwill.

## ON THE ACTION OF LIGHT ON THE SALTS OF COBALT.

### PART VII.—EXPERIMENTS WITH COBALTIC HYPHOSPHITE.

This compound was prepared by double decomposition, a mixed sensitising solution of cobaltic oxalate and potassium hypophosphite being employed for the purpose. Paper having been sensitised and dried as usual, several strips thereof were successively exposed to the action of the solar spectrum.

In the first of these experiments an exposure of forty hours was given. On removing the strip for examination no image was perceptible, and it was accordingly transferred to the usual neutral ferricyanide bath. The progress of development was extremely slow, and at first no change in the appearance of the strip could be detected. Ultimately, however, a very feeble rose-pink image was obtained, consisting only of an extremely faint band in the region of the yellow rays, and a second and feebler band in that of the indigo rays—this latter being, however, so excessively feeble as to raise a doubt whether it were fairly entitled to be regarded as a portion of the image. The next strip was exposed to light in the spectrum slide for 100 hours. No change of appearance could be

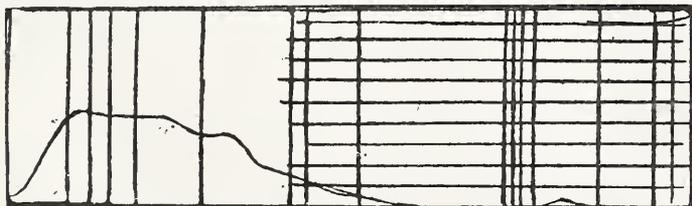

Fig. 23.—COBALTIC HYPHOSPHITE.

detected on examination after exposure. On attempting to develop it in the ferricyanide bath, it persistently retained its original greenish-white colour, and, although many minutes were suffered to elapse before the print was removed from the developer, no indications of an image could be traced at any stage of the operations. Here, evidently, was a fresh instance of that phenomenon characteristic of so many of the cobaltic salts, viz., the bleaching of the primary image under the influence of light. In addition to this, however, the experiment served to demonstrate what hitherto had not been clearly established, namely, the fact that the bleaching action, called into operation where there is a visible image to attack, is capable of manifesting itself under other and different conditions, i.e., in the presence of the latent image, and, as before, of undoing the work performed in the initial stages of the exposure to light.

A third strip of the sensitised paper, which also had been exposed in the spectrum slide for 100 hours, was developed in a bath containing a very weak aqueous solution of argentic nitrate.

Owing to the slowness of the action of the developer, upwards of an hour's immersion in this bath was found necessary to produce a print of a density sufficient to represent with accuracy the action of the rays operative in producing the image. Notwithstanding the care bestowed

on the print, the black deposit of metallic silver representing the image was somewhat feeble in regard to depth and vigour, even at the less refrangible end, where the action of the light had been most intense; whilst at the violet end it was represented by a mere tint, scarcely perceptible to the eye.

It was, however, found possible to assign approximate numerical values to the several groups of rays represented in the print; and in fig. 23, accompanying this article, an attempt has been made to reproduce its leading features.

The remarkable fact will be noticed that the action is due, not to the more, but to the less refrangible rays, it being almost wholly attributable to the red rays and those lying in their immediate neighbourhood. The maximum point is situated in the red, but both the orange and the yellow rays exercise a pretty strong influence. The falling-off in intensity in the region of the green is very marked, and beyond, if we except the inappreciable and doubtful band in the indigo, there is no further chemical action.

### EXPERIMENTS WITH COBALTIC CARBONATE.

This salt, so far as can be judged from the somewhat limited data cited below, does not appear to be readily affected by exposure to light.

The earlier experiments of the series were made on paper which had been sensitised with a solution of cobaltic citrate, dried, and resensitised with a strong solution of sodium carbonate.

A number of pieces of this paper were exposed in succession under a negative in bright sunshine, the exposures ranging from one hour to two hours in duration. Four different developing solutions were employed, namely, (1) an ammoniacal solution of disodic orthophosphate; (2) an alcoholic solution of gallic acid; (3) an aqueous solution of tannic acid; (4) a very weak aqueous solution of potassium permanganate. An exposed strip was immersed in each bath, with the following results:—

(1.) The phosphate bath failed to produce any change that could be identified as an image.

(2.) The gallic acid bath stained the paper violet, the coloured deposit being, however, of a perfectly uniform character.

(3.) The tannic acid bath produced an equally uniform deposit of a reddish-brown colour.

(4.) The permanganate bath stained the paper a sepia brown, the deposit exhibiting certain slight variations in intensity which might be due to development, but which, with a greater measure of probability, were attributed to the presence of inequalities in the texture of the paper.

On developing a second strip in the gallic acid bath, it was thought that similar doubtful traces of an image in violet could be discerned, but in all likelihood these were also due to a physical rather than to a chemical cause.

The presence of the citrate along with the carbonate in the sensitised paper being considered undesirable, an attempt was made to prepare a solution of the carbonate by other means. For this purpose freshly precipitated zinc carbonate was dissolved in a concentrated aqueous solution of ammonium carbonate, any insoluble residue being carefully filtered off.

A solution of cobaltic oxalate was then added in the proportions necessary to effect the precipitation of the zinc in the state of oxalate. The mixed solutions having been allowed to stand until all the insoluble oxalate was deposited, the pale, bluish-green liquid was decanted off, and applied to the surface of the paper to be sensitised. This, when dry, was exposed to the light of the spectrum for forty-five hours. No image was, however, obtained, and the exposed strip was accordingly transferred to the usual ferricyanide bath. With the exception of an extremely doubtful indication of a band in the blue, no change ensued in the appearance of the paper during development, nor, on extending the period of immersion in the bath, was any more conclusive evidence of spectral action forthcoming.

### EXPERIMENTS WITH COBALTIC ANTIMONIATE.

Paper was sensitised with a concentrated solution containing a mixture of cobaltic oxalate and potassium antimoniato, the latter salt being in excess. When dry, it was exposed to light beneath a negative, but

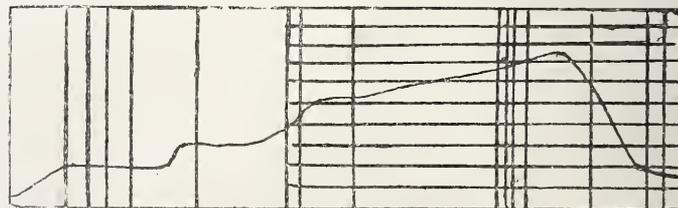

Fig. 24.—COBALTIC ANTIMONIATE.

without perceptible result, an exposure of 100 hours in diffused light effecting no alteration.

A strip of the prepared paper was then exposed to the action of the spectrum for a like period. As before, no image was produced. That a latent image had nevertheless been formed was proved on immersing the

exposed paper in the ferricyanide bath. When thus treated, it instantly assumed a rich purple colour, especially intense towards the more refrangible end of the spectrum, where evidently the chief action had taken place. In fig. 24 a reproduction is given of the print in question. The actinic action, as here exhibited, is strong in the blue, and attains a maximum in the indigo. The violet rays, however, it is curious to note, produce very little effect, in this respect resembling the red and the orange, these three sets of rays representing the minima in the diagram. The influence exercised by the green rays, on the other hand, is only a little inferior to that of the blue. Lastly, the yellow rays occupy a place, in regard to intensity, intermediate between the green and the less refrangible portion of the orange.

EXPERIMENTS WITH COBALTIC METANTIMONATE.

A concentrated solution of potassium metantimonate having been substituted for the antimonate in the mixed bath of the preceding experiments, paper was again sensitised and dried in darkness.

Two pieces were successively exposed to light for 100 hours, the first under a negative and the second in the spectrum slide. In neither case did any image result. On developing the second strip in the ferricyanide bath, in the course of about ten minutes a dark band appeared, due to

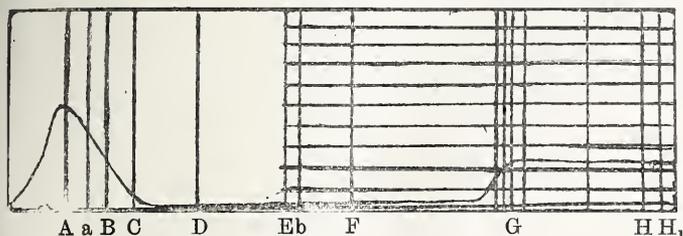

Fig. 25.—COBALTIC METANTIMONATE.

the action of the red rays. As a confirmatory test, a third sheet was exposed and developed under similar conditions. This time a print was obtained exhibiting three bands, situated respectively in the red, the indigo, and the violet. The two latter were, however, excessively faint, a circumstance which served to account for their being overlooked in the former experiment. The band in the red, it should be added, though perfectly distinct, was somewhat weaker than before. In fig. 25 a representation is given of this metantimonate image.

EXPERIMENTS WITH COBALTIC SULPHANTIMONATE.

A slightly acid solution of cobaltic tartrate was agitated with one of potassium sulphantimonate and allowed to stand for a few hours. The clear solution was then decanted off from the precipitated acid tartrate and employed as a sensitiser in the usual way. A sheet of the sensitised and dried paper was exposed to the action of the spectrum. In the course of from forty to fifty hours an extremely faint band was noticed lying in the blue rays. A further exposure of thirty hours effected no appreciable alteration in the appearance of this band. The print was then removed to the ferricyanide bath. After several minutes had elapsed it acquired a fairly uniform plum colour all over, the band in the blue being destroyed, or at all events lost to sight. There were no indications of bands in any other quarter.

A second strip was next exposed in the spectrum slide for seventy-five hours, and transferred to a bath containing a very weak aqueous solution of argentic nitrate. The chemical action displayed was of a more energetic character than had been anticipated, and, owing to the granularity of the black coating deposited on the exposed surface, it was found impossible to decide whether or not an image by development had been formed.

EXPERIMENTS WITH COBALTIC THIOSULPHATE.

A solution of sodium thiosulphate was made alkaline with ammonia, and added in slight excess to one of cobaltic oxalate, and paper was sensitised with the mixture. After drying in the dark, a sheet was exposed in sunshine beneath a negative for two hours, but no perceptible image was produced. A second sheet was exposed for three hours in the

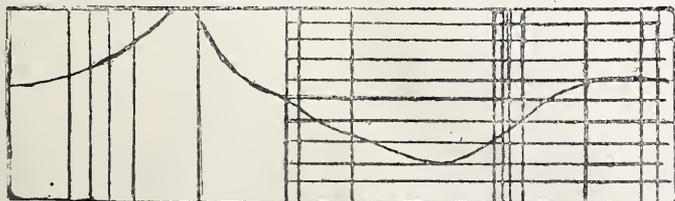

Fig. 26.—COBALTIC THIOSULPHATE.

spectrum slide. On development in the ferricyanide bath, there appeared, after long soaking, two very delicate bands of an olive colour, situated respectively under the orange and the yellow rays.

It was also noted that beneath the indigo and the more refrangible portion of the blue the paper was bleached a pure white, a circumstance

clearly attributable to the action of the developer. In the next experiment, a sheet of the sensitised paper was exposed to the rays of the spectrum for a period of forty hours. On examination, it was found that it had assumed a faint sea-green colour under the red and the orange rays. The sheet was divided lengthwise into three pieces, and one of these was then treated in the ferricyanide bath. Beyond an alteration in the colour of the bands, which now became pale pink, no change ensued, the paper at the more refrangible end remaining white as before.

The second strip was developed in an aqueous solution of mercurous nitrate. It instantly assumed an intense black colour, the depth of which was such as effectually to conceal the suppositious image. The remaining strip was transferred to a weak developer, made by adding to the mercurous nitrate bath a very dilute aqueous solution of nitrate of lead. The action was again almost instantaneous, but the black deposit, though still considerably stronger than was desired, was scarcely so vigorous as before. On removing the print from the bath, and subjecting it to pressure under a leaf of dry paper in order to remove the superfluous precipitate, indications of a negative image were presently perceptible.

Where the action of light had been strongest, viz., under the red and orange rays, the black deposit had almost entirely detached itself from the paper, leaving only a faint impression.

Where, on the contrary, the light had exercised least influence—as, for instance, under the blue, and to a less degree under the green rays—the colour was very intense, the precipitate having resisted removal with unexpected tenacity.

An attempt has been made to reproduce this instructive negative image in a positive form, the relative intensities throughout being carefully preserved. Fig. 26 represents the result.

The experiments above described suffice to show that cobaltic thiosulphate is very little sensitive to light, and also that its decomposition is probably due to the action of the red, the orange, and the yellow rays.

EXPERIMENTS WITH COBALTIC BORATE.

Cobaltic oxide is apparently quite insoluble in a cold solution of boric acid. On prolonged boiling, a very pale pink solution is obtained, but it seems doubtful whether this is a cobaltic or a cobaltous compound. For photographic purposes, therefore, it is better to prepare the borate by double decomposition. The paper employed in the following experiments was one which had been sensitised with cobaltic oxalate, and resensitised with a concentrated solution of borax. Two sheets thus prepared were exposed in sunshine beneath a negative, the one for two, the other for three, hours. In neither case were any signs of an image produced. They were then treated to a long soaking in the ferricyanide bath, but this did not effect the desired development. A third sheet was then exposed, this time to the action of the solar spectrum. When forty hours had elapsed, it was removed from the spectrum slide for examination.

Not the least indication of a picture was visible. The sheet was divided into three parts, each of which was developed in turn.

The first strip was treated in a bath containing a solution of mercurous nitrate. As no change manifested itself, the strip was removed, rinsed in water, and immersed in a very weak aqueous solution of potassium dichromate. It speedily assumed a yellow tint, but the character of the deposit was too uniform to suggest the idea of an image. The second strip was transferred to a mixed solution of the nitrates of lead and mercury. The result was equally unsatisfactory, nothing resembling an image being obtained. The last portion of the print was developed in the ferricyanide bath. In the course of a few minutes an exceedingly curious and interesting phenomenon, probably of the nature of interference, made itself apparent. A print of excessive delicacy was produced in colours bearing a tolerably close resemblance to those of the spectrum. Under the red, the orange, and the violet rays, a pink was produced; under the yellow rays, a yellow; under the green, a bluish-green; and beneath the blue and the indigo a blue, so faint as to be almost imperceptible. These colours were still more evident when the strip was removed from the bath and the surface gently wiped free from superfluous moisture.

The heliochromatic effect was, unfortunately, very evanescent. On replacing the print in the bath, with the object of intensifying the colours, the bands soon disappeared from sight, and the strip assumed a dirty white colour.

The pink due to the action of the red rays alone survived, and that only in an attenuated form. This, the only permanent band, seemed, therefore, to represent the true latent image, a circumstance that would seem to warrant our assigning a low place to the borate in the scale of sensitiveness.

EXPERIMENTS WITH COBALTIC CHROMATE.

Some experiments made with a chromate in the presence of a cobaltic salt were described in the second of these articles. It may be remembered that, in the cases therein alluded to, the colour of the image obtained was blue, a fact which seemed to point to the absence of chromium trioxide in the newly-formed compound. The experiments with the citrate now to be described yielded results differing so much from the foregoing in character as to raise a doubt whether they could be attributed to the

same source. It was thought well, therefore, to defer mention of them till the present stage was reached.

The classification now adopted, it should, however, be stated, is purely one of convenience. Strictly speaking, the term, cobaltic chromate, should be applied rather to the salt formed by dissolving cobaltic hydrate in chromic acid rather than to the somewhat dubious compound which may be supposed to result from double decomposition.

Paper was coated with a strong aqueous solution of potassium dichromate, dried in darkness, and treated with two washes of a solution of cobaltic citrate. When dry, three sheets were exposed in succession to light under the same negative, the exposures given being respectively ten, twenty, and thirty hours.

In the first case, the result was a greenish-grey image, somewhat lacking in vigour, but remarkably distinct and full of detail. Treated in a bath containing an alcoholic solution of gallic acid to which one-third of its volume of a strong aqueous solution of acetate of soda had been added, the picture was speedily blurred beyond recognition, nor were there subsequently any signs indicative of the formation of a new image by development.

When the second of the exposed sheets was removed from the printing frame, the faint outlines of an image were just barely perceptible. The bleaching process had evidently made considerable progress, for even in those portions of the paper least exposed to light the original yellow colour due to the dichromate was almost wholly discharged. The sheet was transferred for intensification to a bath containing an aqueous solu-

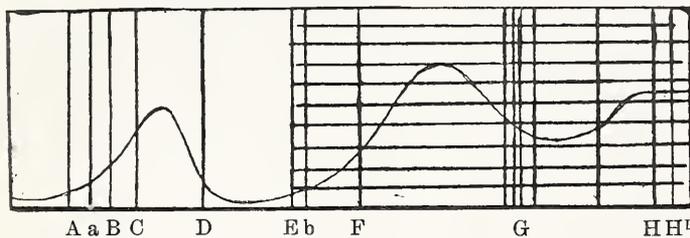

Fig. 27.—COBALDIC CHROMATE.

tion of potassium nitrite rendered slightly alkaline by the addition of a little ammonia. An alteration in the appearance of the print was speedily effected. The outlines of the image, formerly so feeble, became very distinct, the increase in density being due to the deposition, in considerable quantity, of potassio-cobaltic nitrite ( $K_2Co_2(NO_2)_2$ ), more commonly known by the name of aurolein or cobalt yellow.

A peculiar significance attaches to the experiment just described. The intensifying process, as has been said, resulted in the formation of a cobaltic salt. Now, at first sight it would seem difficult to account for the presence in the exposed sheet of a cobaltic compound capable of reacting with the nitrite of the bath, for, as we know, cobaltic compounds are reduced to the cobaltous state by the action of light. On the other hand, the fact that the yellow double nitrite was so formed furnishes the strongest possible evidence for our affirming the existence of such a compound.

The only way, apparently, in which we can seek to reconcile these conflicting data is by inquiring whether some vital circumstance has not been overlooked. Let us, then, step by step, review the facts with which experiment has provided us. In the first place there is the main fact that an image is formed. To state it in a different way, by the solar action the salts of the higher oxide of cobalt present in the sensitive medium have been reduced to the state of the lower. In the second place we note, as the result of further exposure, a phenomenon of quite a contrary character. Contrary to what might be expected, the intensity of the image diminishes in proportion as the exposure is increased. Bleaching ensues, and the work originally performed is gradually undone. What chemical explanation, we ask, can be given for this remarkable change? The answer—and it is satisfactory to find that experiment supports what analogy suggests—is that the deoxidised cobalt compounds when exposed to light again take up oxygen and reassume the cobaltic state. According to Chastang, a similar behaviour characterises the salts of ferrous oxide when exposed to rays of a low degree of refrangibility. The reaction in the case of the cobaltic salts is probably of a somewhat complicated character as regards the rays operative in producing the change. It was shown in an earlier article that the picture formed when the citrate and dichromate are exposed together to light bleaches most readily under the blue rays. See the diagrams in the number of this JOURNAL for August 19, 1898. At the time of writing the said article, however, as may be seen from the concluding paragraph, no evidence had yet been obtained to show that the bleaching action was due to oxidation.

The third sheet (*i.e.*, that exposed for thirty hours) exhibited no image when removed from the printing frame. On transferring it to the gallic acid bath, and adding from time to time a little ammonia to facilitate the operations, an orange-brown picture was gradually developed which, on drying, became excessively feeble, only the bare outlines of the image remaining.

The remaining experiments were made with the pure chromate.

Cobaltic hydrate having been dissolved by the aid of a gentle heat in chromic acid, paper was sensitised with the yellow solution and dried. Two strips of this were then exposed to the light of the spectrum, the one for thirty-five, the other for sixty hours. No change was apparent in either case. On developing the former in the usual ferricyanide bath, it assumed a faint reddish colour, which was, unfortunately, too slight to afford a clue to the nature of the change effected by exposure. The second strip, on being treated in the same way, yielded, after a considerable expenditure of time and pains, a very faint purple image, the details of which are represented with an approximate fidelity in fig. 27.

The point of maximum action lies in the blue. The influence of the violet rays is somewhat marked, that of the indigo a little less so, while, at the opposite end, the orange rays play a prominent part, and rank equal with the violet as regards intensity.

### THE NEW GOERZ DOUBLE ANASTIGMAT LENS.

HERR KLEPP gives the following comparative notes of his examination of one of the new Series IIa double anastigmats, composed of ten lenses, and one of the old double anastigmats (Series III.,  $f-7.7$ ). The apertures are calculated on Stolze's system, which takes as its unit  $\frac{1}{\sqrt{10}}$ , and the full aperture of the lens was  $f-5.428$ , the catalogue aperture being  $f-5.5$ . The spherical aberration was as follows for the various angles:—

	0°	5°	10°	15°	20°	25°	30°	35°
New Double Anastigmat (Series IIa). Full aperture, $f-5.5$ .	—	+0.0	-0.2	-0.3	-0.5	-0.4	+0.0	Meridional +1.0, sagittal +1.8.
Old Double Anastigmat (Series III). Full aperture, $f-7.7$ .	—	-0.2	-0.5	-0.8	-0.5	-0.1	+0.1	—

All measurements in millimetres.

### THE CADETT LIGHT FILTERS.

MESSRS. CADETT AND NEALL, of Ashted, are issuing the following revised particulars of their light filters:—

1. The "Absolutus." The "Absolutus" light filters are adjusted for the lightning spectrum plates, and will render all colour luminosities correctly, with a small margin of error. Each light filter is carefully tested with the latest form of Captain Abney's colour sensitometer. These filters are of no use for any other orthochromatic plate than the lightning spectrum plates. The best and most easily arranged position for the filter is immediately behind the lens in the camera, care being taken to exclude all reflected light between the filter and the lens. The filter can, however, be placed in any suitable position. Exposures, when using the "Absolute" filter, are increased twenty times under glass or in well-lighted studios, and about forty times out of doors.

2. The "Gilvus." The "Gilvus" filters are also adjusted for the lightning spectrum plates, and will render the violet, blue, and green luminosities correctly, leaving the red luminosities uncorrected. The "Gilvus" filter is a compromise for use where rapid exposures are necessary, and they give great improvement in landscape and portrait work. The exposure is only increased from three to four times. Care should be taken to avoid leaving these filters in direct sunshine or long-continued daylight; when not in use, they should be kept in the case. The surfaces being optically worked, the filters should be treated as a lens, and every care taken to avoid scratches.

### EXHIBITION OF THE BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.

THE Borough Polytechnic Photographic Society held its Fifth Annual Exhibition of photographs at the Borough Polytechnic Institute, Borough-road, S.E., on December 27, 28, 29, and 30.

There are probably few photographic societies that can lay claim to a career of greater usefulness than that which forms a section of the Borough Polytechnic Institute. We must confess to some feeling of surprise on perusing the syllabus of the present session. That the Society was an active one we have always understood, but we were not prepared to find anything like the organization that exists. The Society holds two meetings in each week. One is conducted on the ordinary

lines of a photographic society's meeting, and needs no comment except that the programme gives an admirable list of lectures and demonstrations. The second meeting in the week is purely educational, and includes, during the session, twenty-three lectures of a more or less elementary nature upon the practical points of photography. In addition to that of attending all these meetings, the members have the privilege of using the dark room and the apparatus and accessories belonging to the Society, and all for quite a nominal subscription. The elementary lectures on the practice of photography constitute a feature particularly worthy of commendation. There is a perennial complaint of the rule-of-thumb methods and the absence of knowledge of the simplest scientific facts connected with the business on the part of photographic operators and assistants, and, as the opportunities afforded for obtaining more exact knowledge are quite insufficient, every systematic attempt to supply the deficiency deserves all encouragement.

The Exhibition, though not a very large one, was of a fairly high level of excellence. There were about the same number of frames in the members' classes as in the open classes, and, on the whole, the members made the better show. The classes on the members' side were the usual subject ones, and, in addition, a class for instantaneous and hand-camera work. The last-mentioned class, the smallest in the Exhibition, had its awards withheld. The exhibitors evidently took the sensible course of exhibiting their hand-camera work in the subject classes. The Judges appointed were Messrs. J. A. Hodges, F.R.P.S., E. J. Wall, F.R.P.S., and the Rev. F. C. Lambert. The two last-named did not materialise, leaving Mr. Hodges to act alone; and, judging by the awards, he seems to have performed his duties somewhat hurriedly.

The Landscape and Seascape Class was noticeable for the prevalence of what, we suppose, must be looked upon as the fashionable subject of the day—woodland scenery with or without sheep, much of it very good work, that would have been thought a great deal of a few years ago, when swamps and mud-flats were all the rage, but somewhat tiresome now in its monotony. The Architecture was not so satisfactory. Many of the pictures, enlargements on bromide paper, suffered either from a general flatness and want of differentiation of planes, or an offensive wiry sharpness, which, though it frequently occurs, may easily be avoided. The three prizes were awarded to Mr. A. Bedding, whose work was all excellent, but the Judge must either have omitted to see Mr. R. R. Rawkins' *Canal Lock*, or must have misunderstood it.

The animals had evidently strayed from the class for Flower and Animal Studies, and were to be found grazing elsewhere but there was a wonderfully good show of flowers and fruit. E. W. Burch fully deserved his two medals for groups of fruit, and many of the flower studies by himself and others were capital; one felt, however, a tendency to look at most of the flower studies as nicely arranged botanical specimens rather than as pictures.

In the Portraiture Class W. H. Andrew received a medal for a very commonplace piece of work entitled *A Puzzler*. It is a puzzler to us why his infinitely better attempt, *Weary, Worn, and Sad*, in the Novices' Class, was passed over. We can only suppose the Judge did not see it. The members' lantern slides were very good indeed, and as a whole better than those in the open classes.

The Champion Class in the open classes was as usual a weak one, but it should be noted that F. W. Bannister, a member of the Society, gained the award. The General Class contained a good deal of interesting work, the most noteworthy exhibitors being G. B. Cowen, Mrs. A. M. Dumas, E. B. Eldridge, A. R. Read, jun., H. C. Leat, Graystone Bird, J. L. Shawcross, J. Kearney, jun., J. C. Ashton, W. J. Byrne, S. R. Brewerton, T. P. Cooley, J. K. Ayling, W. Illingworth, F. W. Bannister, and R. R. Rawkins. In addition to the ordinary attractions of the Exhibition there were lantern displays each evening and various other entertainments.

LIST OF AWARDS.

Members' Classes.

Class A (Landscape and Seascape).—Silver medal, F. W. Bannister; bronze, H. Heath and R. R. Rawkins.

Class B (Architecture).—Silver medal, A. Bedding; bronze medals (two), A. Bedding.

Class C (Flower and Animal Studies).—Silver medal, E. W. Burch; bronze, E. W. Burch.

Class D (Instantaneous and Hand-camera Work).—Awards withheld.

Class E (Figure Studies and Portraits).—Bronze medals, W. H. Andrews and E. W. Burch.

Novices' Class.

Class F.—Bronze medal, W. W. Brewer.

Class G (Lantern Slides).—Silver medal, H. J. Blane; bronze, E. J. Hoare and A. Bedding.

Mr. Harris's silver medal for Best Print in members' classes, F. W. Bannister.

Open Classes.

Class H (Prints previously Medalled).—Gold medal, J. Kearney, jun.; silver, F. W. Bannister.

Class I (Prints not Medalled previous to December 9, 1899).—Silver medal, Mrs. A. M. Dumas; bronze, Eve'yn Boden, F.R.P.S., and R. Jones.

Class K (Lantern Slides previously Medalled).—Gold medallion, A. E. Smith; silver medal, J. Kearney, jun.

Class L (Lantern Slides not Medalled previously to December 9, 1899).—Bronze medal, F. Judge, John Beeby, and R. R. Rawkins.

THE R.P.S. COUNCIL ELECTION.

THE "TWENTIETH CENTURY" PHOTOGRAPHIC EXHIBITION.

NOVEL COMPETITIONS, AND COMPETITIONS FOR PROFESSIONALS AND EMPLOYEES.

The prospectus of the above, which forms a section of the Twentieth Century Engineering and General Trades Exhibition, Bingley Hall, Birmingham, March 1900, is now before us, and we note with some pleasure a slight return to the days of old, with special classes for professional workers. Mr. Walter D. Welford, 19 Southampton-buildings, Chancery-lane, W.C., is manager again, and these competitions give evidence of some desire to cater for the professional photographer, and for the hard-working army of *employés*, for whom that gentleman still has a warm corner in his heart, evidently. Referring first to these special classes, the following are the details:—

Class J (Combination Printing).—A series of half-plate negatives of the same figure subject are obtainable from the Manager, price 2s. 6d. each, post free. The competitor must, by combination printing, produce a picture containing this figure, with his own background. Print may be by any process and any size. The usual entry fee per framed print must be paid, and the competitor may send more than one result. Silver medal, bronze medal, diploma.

Class K (Negative Working Up).—A series of half-plate negatives of one subject, absolutely alike, containing certain marked defects, are obtainable from the Manager, price 2s. 6d. each, post free. The competitor must so work up, retouch, or spot the negative to obtain the best print (any process) which in turn may be worked up. The frame must contain two prints, one from the negative in its original state, and the other the finished result. The entry fee for this class will be 1s. for the frame, but, if the prints are framed separately, the fee will be 2s. Confined to *employés* of professional photographers. Silver-gilt medal and diploma, bronze medal and diploma.

Class L (Trade Work).—Photographs of Machinery, Samples, Tools, &c., made for trade, advertising, or catalogue purposes. For professional photographers only. Silver gilt medal and diploma, bronze medal and diploma.

Although, perhaps, the award (in Class K, say) would not be of value

to that issued by some Examination Board, yet it must be remembered that at present the *employé* has no opportunity of obtaining anything of the kind, so a diploma gained against other workers for skill in retouching and working up of a negative ought to be a little assistance to him with employers. We hope to see Mr. Welford's enterprise well supported by professional photographers.

Turning now to the competitions generally, there are twelve classes altogether, for which are offered (counting the Champion medals) one gold, eleven silver gilt, four silver, and twelve bronze medals, and fourteen diplomas, with the following extra and special prizes, two silver medals, hand camera value 2l. 10s., "Tella" cash prize 2l. 2s., and a prize value 1l. 1s. The majority of the classes are open alike to amateur and professional, and there is no restriction as to previously medalled work (except in one class), but pictures exhibited at Birmingham in 1899 are debarred. Mr. Welford will be pleased to send prospectuses upon receipt of stamp.

#### THE BIRMINGHAM PHOTOGRAPHIC SOCIETY'S EXHIBITION.

The Fifteenth Annual Exhibition of the Birmingham Photographic Society will be held at the Royal Society of Artists, New-street, from February 24 to March 3, 1900.

The Exhibition will be inaugurated on Saturday evening, February 24, by a private view and *conversazione*, and will remain open from 10 a.m. to 10 p.m. from Monday, February 26, to Saturday, March 3. The rooms are excellently lighted from the top (artificially by electricity), and admirably arranged for the display of artistic work to the best advantage. The Judges will be Messrs. William Crooke, W. J. Wainwright, A.R.W.S., and J. B. B. Wellington.

In addition to the competitive sections there will be a loan collection of photographs contributed by a selection of the leading pictorial and artistic workers of the country, also a series of exhibits by eminent professional photographers in Birmingham. There will also be an exhibition of apparatus. Cinematograph and lantern entertainments, vocal and instrumental music will be given each evening.

The Hon. Secretary of the Exhibition Committee is Mr. L. Lloyd, The Hollies, Church-road, Moseley, Birmingham.

#### THE LATE W. J. BELTON.

We are sorry to learn of the death of Mr. W. J. Belton, the well-known photographer, which took place at his residence, Aberdeen, on the 20th ult. Mr. Belton, who was about fifty-three years of age, had been ill for some weeks with rheumatism, died very suddenly, and leaves a widow and a large family.

The deceased gentleman will be recollected in recent years as the very able demonstrator of the Velox specialities for Messrs. Griffin. Prior to this, he was for some time connected with the well-known house of G. W. Wilson & Co., of Aberdeen; but his photographic experiences went back nearly forty years. His father before him was a well-known trade printer and general photographer, and the son followed the same profession for something like a quarter of a century. He was a man of great photographic ability and experience, and of a most genial disposition.

We are sure that very many of our readers will learn of Mr. Belton's early death with sincere sorrow, and will sympathise with the widow and family in their loss. For ourselves, we lament the loss of a personal friend of nearly twenty years' standing.

Messrs. J. J. Griffin & Sons send us the following sympathetic references to our late friend:—Mr. W. John Belton has followed photography from his youth, being associated with his father (26 St. Paul's-crescent, N.W.), for twenty years, carrying on a prosperous business in printing and enlarging. An opening presenting itself at Messrs. Wilson & Co.'s, of Aberdeen, he accepted a position as manager, acting for them in that capacity for a considerable time. He will best be remembered, however, in connexion with his many able demonstrations of Velox paper during its first introduction to the British public in the years 1898-99. The members of photographic societies all over the country will miss his cheery and interesting lectures and painstaking demonstrations. The solicitude he showed for explaining every difficulty, and answering as fully as possible the frequently harassing questions put to him, made him much sought after at these gatherings, and in consequence his loss will be keenly felt.

#### THE PHOTOGRAPHIC SOCIETY OF IRELAND'S FORTH-COMING EXHIBITION.

The following are the classes and rules for competition at the Annual Exhibition, to be held in the large hall of the Photographic Society of Ireland, 35, Dawson-street, Dublin, from March 26 to 31, 1900. For members only—Silver and bronze medals in each class, each entry to

consist of one picture: 1. Landscape and Marine; 2. Landscape and Marine, taken with camera held in the hand; 3. Pictures with objects in motion; 4. Figure and Animal Studies, and Portraits, if not taken in professional studio; 5. Historical, Architectural, and Archaeological; 6. Still Life, including Fruit and Flowers; 7. Lantern slides, (a) landscape or marine, (b) other subjects, sets of four; 8. Enlargements For members who have never won a medal in any society—Bronze medals: 9. Prints, any subject; 10. Lantern Slides, sets of four, any subject. There is no entrance fee for the foregoing. The "Werner" special medal will be awarded to the member of the P.S.I. whose picture will be judged the best in artistic merit. The "Strangeways" special medal will be awarded for best set of four stereoscopic pictures shown by a member of the P.S.I. The Open Class, for all comers, in which gold silver, and bronze medals will be awarded, is as follows: 11. For best picture, any subject or size, produced by any process. The gold medal will not be awarded unless there are at least 100 entries. The entry fee is one shilling for each picture sent in. All exhibits must be delivered at the Society's premises before March 10, and be removed within a week after close of Exhibition. Exhibits from a distance will be packed and returned to carriers; carriage must be paid both ways by exhibitors and, while every care will be exercised, no responsibility will be accepted by the Society. The Council invite pictures for exhibition only. All further particulars can be obtained of the Hon. Secretary, Mr. W. F. Cooper, 35, Dawson-street, Dublin.

## Our Editorial Table.

#### THE GLOUCESTER DIARY FOR 1900.

By the courtesy of the Gloucester Wagon Company we have received a copy of their conveniently arranged Diary for 1900. The special features of the book include a "Directors' Calendar" on pages 70 and 71, and a note on each day throughout the Diary to enable the periodic recurrence of fixed engagements to be recorded, such as Board or Council Meetings fixed to be held, for example, on the second Tuesday in each month. Among the notes for visitors to Gloucester on pages 65 to 69 particular are given respecting many features of interest, including the Severn "Bore," the Gloucester "Mop," and the "Festival of the Three Choirs," which is perhaps the oldest and most important annual musical meeting held in Great Britain (the Welsh Eisteddfod alone excepted.) This Festival occurs in Hereford in September 1900.

#### LIESEGANG'S PHOTOGRAPHISCHER ALMANACH, 1900.

Ed. Liesegang, Düsseldorf.

This annual appears for the twentieth time, and the present volume deserves the hearty support of German photographers. It contains a series of very interesting articles by leading German writers, among whom we notice Professor Valenta, Dr. R. Abegg, Dr. von Rohr, C. A. Angerer, J. Gaedicke, S. Jaffe, and E. Obernetter. There is also a collection of recently published formulæ.

#### PHOTOGRAPHISCHE PHYSIC.

By R. ED. LIESEGANG. Ed. Liesegang, Düsseldorf.

We are glad to see that Dr. R. E. Liesegang has published, in this small volume, some account of the studies he has made, during the last few years, of the physics of photography. He justly remarks in the preface that, in addition to the purely chemical, there is a series of physical processes involved in photography, and that they have hitherto received very little attention. We recently published a translation of a chapter from this book (see THE BRITISH JOURNAL OF PHOTOGRAPHY, August 26, 1899), which Dr. Liesegang kindly sent us in advance, and those of our readers who are interested in the science of photography will find the volume of great interest.

#### THE CADETT BROMIDE PAPERS.

Manufactured by Cadett & Neall, Ashtead.

To their list of well-known and justly appreciated photographic preparations Messrs. Cadett & Neall have just added a happily named "Platinum-black" bromide paper, issued with both rough and smooth surfaces. The manufacturers state that they have received some valuable reports on the quality of the papers, which are prepared to give brilliant prints from delicate negatives such as are made in portrait studios. In the instructions for development the following useful hints are given:

As a rule users of bromide papers prefer to soak the paper in water before development, in order that the paper may lie flat on the dish; we do not, however, recommend this to be done if it can be possibly avoided, development being much more even by pouring the developer rapidly over the surface of the dry paper; there is also much less danger of

veloping bubbles. Our advice is to use plenty of developer, drain the dish carefully and the paper will generally be found flat enough to use dry, and will lie flat if the corners be pressed down on the slightly wet dish. No time should, however, be lost in pouring on the developer before any moisture from the dish can soak through the paper. Should making be thought desirable, it should be done for at least two minutes.

FORMULÆ.

No. 1.

Metol .....	100 grains.
Hydroquinone .....	50 "
Sodium sulphite (cryst. and fresh) .....	2 ounces av.
Water to make altogether .....	40 ounces fl.

No. 2

Sodium carb. (cryst. washing soda, select translucent pieces) .....	1 ounce avd.
Potassium bromide .....	60 grains.
Water to make altogether .....	40 ounces fl.

Equal parts of Nos. 1 and 2 to make developer. No clearing solution required.

Fixing.

Water .....	20 ounces fl.
Hyposulphite of soda .....	½ lb.

This developer works slowly, but gives very brilliant prints. The bromide of potassium may be halved if thought desirable. In cases where dense negatives are used or soft prints required, the following developer will be found more suitable:—

METOL DEVELOPER (one solution only).

Distilled or soft water .....	80 ounces fl.
Metol .....	1 ounce avd.
Sodium sulphite (pure recryst.) .....	5 ounces.
Sodium carbonate (cryst. washing soda, select translucent pieces) .....	6¾ ounces.
Or, instead, anhydrous sodium carbonate ...	2½ ounces.

These must be completely dissolved in the order named, the water not being colder than 60° F. Take 1 part of the above one-solution developer and dilute it with 3 parts of water. This developer works with great rapidity. Variations may be made in the brilliancy of the prints by altering exposure, time of development, and by diluting the developer with water. Should the prints be too brilliant, increase exposure and dilute the developer. Remember that prints appear more brilliant when wet than when dry.

Fixing Solution.

Hypo .....	½ pound.
Water .....	1 quart.

The developer keeps fairly well in stoppered bottles.

FERROUS-OXALATE DEVELOPER.

A.

Protosulphate of iron .....	2½ ounces avd.
Sulphuric acid .....	15 minims.
Or citric acid .....	20 grains.
Distilled water to make altogether .....	10 ounces fl.

B.

Neutral potassium oxalate .....	10 ounces avd.
Potassium bromide .....	10 to 20 grains.
Distilled water to make altogether .....	40 ounces fl.

For use take 1 part of A to 4 parts of B. A clearing bath should be used with this developer to get rid of the oxalate of lime formed in ordinary washing water:—

Water .....	80 ounces.
Glacial acetic acid or hydrochloric acid.....	½ ounce fl.

We prefer to use this bath after fixing and well washing. If used before fixing, wash the prints well before fixing, or the hypo will be decomposed in the film and the prints may fade. The clearing bath should act for ten minutes, then wash well.

Fixing Bath.

Hypo .....	½ pound.
Water .....	1 quart.

ORTOL DEVELOPER.

A.

Potassium metabisulphite .....	200 grains.
Ortol .....	400 "
Distilled water .....	40 ounces fl.

B.

Potassium carbonate (anhydrous) .....	900 grains.
Sodium sulphite .....	6 ounces avd.
Distilled water .....	40 " fl.
Potassium bromide .....	10 to 20 grains.

Take equal parts of A and B, and then dilute with an equal part or more of distilled or boiled water. The bromide of potassium may be omitted if desired.

Fixing Bath.

Hypo .....	½ pound.
Water.....	1 quart.

The popularity of the bromide process increases with its age. Fourteen or fifteen years ago, when the paper then available gave dull, heavy blacks and little or no gradation, it was thought that the process was not destined to survive; but, as improvement after improvement was introduced, and it became possible to produce a bromide print giving transparency in the shadows and rendering the most delicate gradations, the popularity of this method of printing advanced in an equal degree. There is no doubt that Messrs. Cadett & Neall have chosen wisely in entering this branch of manufacture, and that their very high reputation for excellence of sensitive preparations will stand them in good stead in catering for a demand which is practically unlimited.

CAMERA NOTES FOR JANUARY 1900.

Published by the Camera Club of New York, 3-7 W. 29th-street, New York.

In another part of this week's JOURNAL we print several American criticisms of English photographs that have recently been exhibited in the United States, and we wish we had the space to make a long extract from the thirty-page notice of the late Exhibition of the Philadelphia Photographic Salon, contributed to the number of *Camera Notes* now lying before us, by Mr. J. T. Keiley. It is one of the ablest and best-balanced pieces of critical writing about a photographic exhibition that we have read for a long time—appreciative, discriminative, and founded upon an intimate study of the pictorial possibilities of photography.

We must congratulate the editor (Mr. Stieglitz, we believe) upon this number of *Camera Notes*. It occupies over eighty well-printed pages, and there are many photogravure and half-tone reproductions of notable photographs. Its one fault is a superabundance of unilluminating twaddle on pictorial photography (we are here excepting Mr. Keiley's tersely cast criticisms), which simply resolves itself into a defence of photo-faking—the sort of thing with which photographers here have been deluged *ad nauseam* for the last ten years, and which we do not anticipate our sensible American brethren will long tolerate. Decidedly *Camera Notes* is a charming publication, and we regard it as the best thing of its kind issued in connexion with photography.

“P.P.P.” (PLEASANT PRINTING PAPER).

Manufactured by J. D. Mucklow, 2, Turle-road, Tollington-park, N.

THE pleasant printing paper of Mr. Mucklow, who has long been very favourably known for the excellence of his printing surfaces, is an albumen paper which we find to give results fully comparable to the best produced by this old-fashioned system of printing, which, in these days of a multiplicity of processes, has much to recommend it. Any ordinary toning bath used for albumen prints will suit “P.P.P.,” and the Paget combined bath for P.O.P. also answers well with it. We can thoroughly recommend Mr. Mucklow's “P.P.P.” to lovers of albumen printing.

RECENTLY ELECTED OFFICERS OF SOCIETIES.

(Received too late for the ALMANAC.)

ATTERCLIFFE (SHEFFIELD) PHOTOGRAPHIC SOCIETY.—Meetings held at the Friends' Adult School, Leeds-road, on the second Monday in the month. *President*: Mr. J. Ashurst.—*Vice-Presidents*: Messrs. A. W. Cotterell, V. J. Roberts, and L. Havenhand.—*Council*: Messrs. Ellis, Mills, Armitage, Moxon, Driver, Walton, Blythe, Gosling, and Rogers.—*Treasurer*: Mr. S. Hughes.—*Hon. Secretary*: Mr. A. Birtles, 51, Cresswell-road, Darnall, Sheffield.

HAWKE'S BAY CAMERA CLUB.—Established April 19, 1895. Meetings held at the Club Room. *President*: Dr. J. H. E. Jarvis.—*Vice-President*: Mr. A. A. Kennedy.—*Committee*: Dr. A. Milne Thomson, Messrs. H. A. Banner, R. J. Duncan, S. E. Cooper, J. K. Newton, and C. Saunders.—*Secretary and Treasurer*: Mr. W. Beswick, Post Office.

KINGSTON-ON-THAMES AND DISTRICT PHOTOGRAPHIC SOCIETY.—Established 1893. Meetings held at the Sun Hotel, Kingston-on-Thames. *President*: Mr. Rev. G. I. Swinnerton, M.A.—*Vice-Presidents*: Dr. Finny, Rev. F. C. Lambert, M.A., Dr. Luscombe, Dr. Munyard, Messrs. W. E. Price, A.M.I.C.E., W. Montagu Robertson, and George Sanders, J.P. *Committee*: Messrs. Albert Hill, W. F. J. Hodgson, H. M. C. Sprunt, A. Vandendriesche, and T. W. Wilson.—*Treasurer*: Mr. W. Montagu Robertson.—*Secretaries*: Messrs. John F. East, Uxbridge House, Kingston-on-Thames, and A. Evelyn Smith, 6, Beaufort-villas, Beaufort-road, Kingston-on-Thames.

**NELSON CAMERA CLUB.**—Established 1888. Meetings are held at the Club Rooms, Hardy-street, Nelson, N.Z. *President:* Mr. C. Y. Fell.—*Committee:* Messrs. H. Brusewitz, H. V. Gully, and F. W. Hamilton.—*Treasurer:* Mr. F. Washbourne.—*Secretary:* Mr. A. H. Patterson, Nelson, N.Z.

**NORTHERN TASMANIAN CAMERA CLUB.**—Established 1889. Meetings held at the Albert Hall, Launceston, Tasmania. *President:* Mr. F. C. Birchall.—*Vice-Presidents:* Messrs. William Gibson, W. H. Twelvetees, and J. Sparrow.—*Committee:* Messrs. H. B. Brownrigg, C. Hart, and A. H. Masters.—*Secretary and Treasurer:* Mr. F. Styant Browne, 112, Brisbane-street, Launceston, Tasmania.

**NOTTINGHAM CAMERA CLUB.**—Meetings held at the Mechanics' Institution. *President:* His Grace the Duke of Newcastle.—*Vice-Presidents:* Messrs. A. Pyatt, W. J. Abel, B.A., C. B. Wright, and F. N. Ellis, J.P.—*Committee:* Messrs. A. W. Flowerdew (Acting Chairman), Thomas Wright, A. R. Hartley, R. Chapman, T. K. Gordon, J. Anderson, W. R. Anderson, and Rev. W. H. Kynaston, M.A.—*Secretary and Treasurer:* Mr. Willis Ward, 14, Stratford-terrace, Nottingham.

**NYMEEGSCHE AMATEUR FOTOGRAFEN VEREENIGING "M. C.," NIJMEGEN, HOLLAND.**—Established December 23, 1893. Meetings are held at the Café Suisse. *President:* Jacq. Kneppers.—*Treasurer:* Van de Graaff.—*Secretary:* Baron van Hemert.

**PHOTOGRAPHIC SOCIETY OF NEW SOUTH WALES.**—Established 1894. Meetings held at the School of Arts, Pitt-street. *Patron:* His Excellency Earl Beauchamp.—*President:* His Honour Judge Docker.—*Vice-Presidents:* Sir J. P. Abbott, K.C.M.G., Hon. F. T. Humphery, Messrs. C. G. Alford, R. W. Kirk, and E. T. Davis.—*Committee:* Messrs. H. T. Blake, F. H. Copeland, J. Hiron, M. V. Murphy, and L. Roeber.—*Treasurer:* Mr. J. M. Jago.—*Secretary:* Mr. James S. Stening, Box 829, G.P.O., Sydney, New South Wales.

**SHASHIN-KIOKAI (THE PHOTOGRAPHIC SOCIETY OF JAPAN).**—Established 1888. Meetings held at 1, Ichome Uchiyamashitacho, Tokyo. *President:* Prince M. Nijo.—*Vice-President:* Vice-Count M. Nagaoka.—*Committee:* Count U. Toda, Vice-Count Gnomoto, Baron Y. Hanabusa, Captain S. Toya, Dr. T. Kato, M. Nakajima, Count S. Omura, Vice-Count N. Okabe, Prof. Dr. D. Kikuchi, K. Ogawa, I. Tanaka, Dr. B. Marumo, R. Konishi, H. Shigyo, and S. Kiga.—*Treasurers:* S. Ohashi and K. Ikeda.—*Secretaries:* Prof. I. Ishikawa, Nandomachi, Tokyo, and K. Ogura, Minamiyokimachi, Tokyo.

**SOUTHAMPTON CAMERA CLUB.**—Established 1896. Meetings held at the Kell Memorial Hall, Bellevue. *President:* Rev. E. C. Bennett.—*Council:* Messrs. W. Jarvis, E. J. Evans, F. Winzar, J. Stone, and F. Walter.—*Lanternist:* Mr. E. J. Evans.—*Treasurer:* Mr. W. H. Trigg.—*Secretary:* Mr. S. G. Kimber, Oakdene, Highfield, Southampton.

**SOUTH AUSTRALIAN PHOTOGRAPHIC SOCIETY.**—Established 1885. Meetings held at the Chamber of Manufactures, Adelaide. *President:* Mr. Andrew Scott, B.A.—*Vice-Presidents:* Messrs. R. F. Griffiths and F. A. Joyner.—*Committee:* The Executive Officers, and Messrs. C. L. Whitham, A. H. Kingsborough, and A. W. Marshall.—*Treasurer:* Mr. S. P. Bond.—*Secretary:* Mr. J. Gazard, 111, King William-street, Adelaide.—*Assistant Secretary and Librarian:* Mr. R. B. Adamson.

**ST. MICHAEL'S PHOTOGRAPHIC SOCIETY.**—Established 1896. Meetings held at the Church Institute. *President:* Rev. H. Gresford Jones, M.A.—*Secretary:* Mr. R. R. J. Lutas, Church Institute, St. Michael's-in-the-Hamlet, Liverpool.

**WANGANUI CAMERA CLUB.**—Established June, 1894. Meetings held at the Wanganui Museum Buildings. *President:* Mr. A. Elliott.—*Vice-Presidents:* Messrs. Babbage and S. Griffiths.—*Committee:* Messrs. Anderson, Drew, Allison, and Kersley, President, Vice-Presidents, and Secretary.—*Hon. Secretary and Treasurer:* D. Meldrum, Wanganui.

**WORKING MEN'S COLLEGE PHOTOGRAPHIC CLUB.**—Established 1891. Meetings held at Latrobe-street, Melbourne, Victoria. *Patron:* His Excellency Lord Brassey.—*President:* Prof. Kernot, M.A., M.E.—*Vice-Presidents:* Messrs. F. A. Campbell, C.E., T. C. Camm, and A. J. Campbell.—*Committee:* Messrs. H. P. Bennett, T. J. Eastham, J. Cathie, H. Vanheems, T. Gray, J. Glover, H. Hampson, A. B. Sturtevant, and L. Hart, F.R.M.S.—*Treasurer:* Mr. E. C. Moore.—*Secretary:* Mr. Arthur J. Relph, Government Printing Office, Melbourne.

## News and Notes.

**ROYAL PHOTOGRAPHIC SOCIETY.**—Ordinary Meeting, January 9, at 66, Russell-square, W.C., at eight p.m. "Toning and Intensification with the Salts of Copper," by W. B. Ferguson, M.A. (Oxon).

**PHOTOGRAPHIC CLUB.**—Wednesday evening, January 10, at eight o'clock. Mr. Charles R. Rowe will deliver a lecture on "Fair Devon," illustrated by slides. All interested in the county will be cordially welcomed at the meeting.

THE Duke of Portland states that he has received the following telegram from his brother, who is an officer in South Africa with the 10th Hussars: "Please send good telescope." His Grace thinks the publication of this message may be useful as a hint to officers proceeding to South Africa.

THE Waterworks Committee of the Rochdale Corporation have received and considered an application from the Rochdale and District Photographic Society with respect to the charge for water used for photographic purposes by amateur photographers. The Committee have resolved that the present scale of charges for photographic purposes shall henceforth apply only to water used for photography for business purposes.

**SOUTHSEA AMATEUR PHOTOGRAPHIC SOCIETY'S EXHIBITION.**—The Judges at the Twelfth Annual Exhibition to be held at the end of January will be

Messrs. H. Snowden Ward, H. Symonds, and G. West. Both the latter gentlemen are well-known marine photographers. There are five open classes, and the Exhibition promises to be a big show. All further information and entry forms can be obtained from the Hon. Secretary, 5, Pembroke-road, Portsmouth.

## Patent News.

THE following applications for Patents were made between December 18 and December 23, 1899:—

**STEREOSCOPIC PHOTOGRAPHY.**—No. 25,110. "Improvement in relation to Stereoscopic Photography." J. E. THORNTON.

**DIPPER.**—No. 25,201. "An Improved Dipper for Photographic Bath or Bath for Metals." F. L. ORWIN.

**DEVELOPING APPLIANCE.**—No. 25,270. "Improvements relating to the Means for Applying Photographic Developer Solution or other Liquids to Prepared Surfaces." Communicated by C. W. Earle. J. WETTER.

### ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 2,—Lantern Meeting,—Mr. J. J. Vezey in the chair.

#### AN ALPINE EVENING.

Mr. HENRY SPEYER gave a lecture entitled, "Round about the Matterhorn and the Aletsch Glacier," which he illustrated by 130 lantern slides from his own negatives. Mr. Speyer's alpine photographs are exceptionally fine, and the Committee who have the arrangement of the lantern meetings of the Society were well advised when they invited him to show a series of his views of the neighbourhood of the Matterhorn, a locality with which he is, apparently, quite as well or better acquainted as with the squares of Bloomsbury. An intrepid and enthusiastic mountaineer, and also a very painstaking photographer, Mr. Speyer is remarkably successful in securing adequate representations of the subtle and delicate gradations of light and shade which abound among the mountains and glaciers of the Alps, and all who have had the pleasure of seeing his slides are loud in their appreciation of the wonderful manner in which he is able to represent the transparency of great walls of ice, the awful grandeur of lofty snow-clad peaks, the shimmering whiteness of the snow-fields, and the glaciers, and seracs, and cornices, and other elements of danger which are so dear to the true climber. The slides exhibited on this occasion dealt first with the scenery in the neighbourhood of the Schwartzee Hotel, above Zermatt, in which there were in-

aded views of the Matterhorn, Gabelhorn, the Mischabel group, the Breithorn, the Theodule Pass, the Dent Blanche, and these were followed by photographs taken from the Riffel Hotel as a centre. Ascents of Castor and Pollux, the Dent Blanche, the Lyskamm, the Matterhorn, and other mountains, were very fully described and illustrated, together with an exploration of the great Gletsch glacier from the Eggshorn Hotel, the long succession of beautiful pictures being received with the greatest interest by a crowded audience, who were evidently delighted at the "show." Mr. Speyer said that nearly all of the negatives were taken with a stand camera on thickly coated slow cut films and developed with pyro ammonia, the slides being made on gelatine plates, which he preferred to collodion.

COMING EVENTS.

January 9, Ordinary Meeting, "Toning and Intensification with Salts of Copper," by Mr. W. B. Ferguson, M.A. (Oxon). February 6, Lantern Meeting, subject to be announced.

Southsea Amateur Photographic Society.—At the last meeting the HON. SECRETARY read a lecture on

HOW A LENS IS MADE.

In introducing his subject, the lecturer invited his audience to accompany him on an imaginary journey through the lens factory of C. P. Goerz, and follow the various manufacturing stages, commencing with the raw blocks of glass and ending with the testing of the finished lens. The Goerz Works were founded in the year 1883, when three men only were employed, and their rapid progress since is one of the most remarkable stories of commerce. At present the works at Berlin are the largest of their kind in the world, and, when the extensions now in progress are completed, will accommodate 1200 workmen. Each block of glass when received at the lens factory is carefully examined, and a sample prism made from which the refractive power of the material is determined. Mathematicians then calculate the exact curves of the lens surfaces. Each lens is made from calculations and drawings made for that one lens only, and it is this purely scientific work which to a great extent accounts for the apparently high prices of the objectives. After the lens has been in this manner theoretically designed, its actual construction commences. The glass is roughly shaped and reduced to the form of a disc somewhat higher than the future lens. The flat face of the disc is then roughly ground to the proper curves upon grinders fed with wet sand, the progress of this operation being carefully estimated by gauges and callipers. The blocks of glass are now rendered smooth and clear by fine grinding and polishing, special machinery being used for these operations. No known mechanical instrument is capable of taking the measurements necessary for accuracy in the fine grinding, and recourse must be had to a physical method—to Newton's coloured rings, where advantage is taken of the known wave-lengths of light, some of which are but  $\frac{1}{10000}$  millimetre. During the process of fine grinding the lens is also constantly examined with test glasses and the spherometer. The second stage of manufacture is now entered upon, the fitting together of the various parts, for each modern anastigmat consists of six, eight, and even more glasses cemented into combinations. The lens is centered and its units cemented together, delicate instruments being employed to judge of correct centering. The finished combinations are now subjected to exact optical tests, and when these are completed are taken to the mechanical department to be fitted into their metal mountings, and in this stage machinery quite as complicated as in the previous is used. The mounted lens is once again thoroughly tested, and the diaphragm scale, &c., engraved upon the mount. The effects of the various stops are also examined. The care taken in manufacturing and the repeated tests ensure that the buyer of a Goerz objective receives a lens which is equal to every purpose to which a lens can be applied, and that no objective sold is inferior to other makes of the same design and construction. The lecturer then threw upon the screen a few of the other specialities of the firm: the Trieder binocular, a very compact field glass of high power, giving remarkably large field with clear definition; the Anschütz camera and shutter, with speeds varying from  $\frac{1}{25}$  to  $\frac{1}{1000}$  second; and its latest production, a wonderful and effective combination of field glass, opera glass, twin lens and stereoscopic cameras. A number of views taken with the Anschütz and Kodak cameras fitted with the Goerz lens were thrown upon the screen, and gave ample proof that the care taken in the manufacture had indeed produced perfect lenses. The lecturer concluded by exhibiting a striking series of instantaneous photographs. Horses leaping over hurdles and some daring feats of horsemanship performed at the riding school of the Italian cavalry, together with pictures of accidents—of horses rolling over their riders—followed one another upon the screen in quick succession. Instantaneous photographs of this kind, many of which had an exposure of  $\frac{1}{1000}$  second, can only be taken with such a shutter as that fitted to the Anschütz camera.

FORTHCOMING EXHIBITIONS.

1900.		
January	.....	Huddersfield (Invitation). W. A. Beever. Cloth Hall-street, Huddersfield.
"	29-31.....	Southsea Amateur Photographic Society. F. J. Mortimer, 10, Ordnance-row, Portsea.
February	10-24 .....	Edinburgh Photographic Society. J. S. McCulloch, 10A, George-street, Edinburgh.
"	24-March 3	Birmingham Photographic Society. Lewis Lloyd, The Hollies, Church-road, Moseley.
March	.....	South London Photographic Society.
April	3-7 .....	Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* We do not undertake responsibility for the opinions expressed by our correspondents.

DR. VON ROHR'S THEORY AND HISTORY OF LENSES.

To the EDITORS.

GENTLEMEN,—My object has been accomplished by the publication of my "Protest" in your issue of December 15.

An important work like that of Dr. von Rohr is not likely to escape the notice of any future historian, and I may expect, too, that my letter will arrest his attention.

Dr. von Rohr is quite entitled to his own opinion, not only of the merits of the late J. H. Dallmeyer as an original thinker in optical matters, but also on matters concerning "good taste." My knowledge of the German language is amply sufficient to find myself in entire disagreement with him here; hence the protest.

I should not have protested if Dr. von Rohr had artlessly recorded the fact that "Mr. J. H. Dallmeyer was a very kind employer," although I should have thought the statement out of place in such a work as his. At best he could only have been told it; it would not have been found in the "sources of information" referred to in the last paragraph of his letter. It is the personalities in his work I do object to most strongly.—I am, yours, &c.

WILLIAM CURRY.

195, Great Portland-street, W.

A PROFESSIONAL'S TROUBLES.

To the EDITORS.

GENTLEMEN,—I read with much interest the many and varied letters which appear from time to time in your much-valued paper, THE BRITISH JOURNAL OF PHOTOGRAPHY, and thought I should like to send you a little of my experience and opinions, which may not prove uninteresting to some of your readers.

Rightly or wrongly, I am often interested and amused at the difficulties some photographers appear to experience in the quick drying of negatives.

I can, and do, dry any negative when necessary within five or eight minutes after taking same from the water. I simply wipe both sides dry as I can with a clean soft duster, and then hold them within about a foot or so of a moderate fire, film away from the fire. I have dried hundreds like this, and have never yet injured one.

In the middle of the summer, when the sun has been very hot, I have placed them in the sun, and by this means have dried them in a few minutes.

I find frequently there is great difficulty in pleasing some of my customers, especially the ladies, for they never require a portrait that bears any resemblance to themselves, but I can produce a portrait that is about a thousand times better-looking than they are, and every wrinkle and pimple removed, crooked noses made straight, projecting teeth removed, big mouths reduced to about two-thirds their size, and every possible defect removed; then they will tell me it is exactly like them, and only one in five hundred will confess that it is too good-looking.

There is a prominent photographer in a town not far away; his work is so retouched that it is only by a very careful study that one can at last determine who they are intended for. Only last week a young lady brought me one of herself taken by him. She was delighted with it, but I was obliged to confess to her that I could discover no resemblance to her whatever. In order to give satisfaction, I am obliged to retouch every bit of the face—nose, mouth, chin, and every other conceivable part, and I expect this is the experience of thousands of other professional photographers.

I tell my customers that the great art in photography is to produce portraits as unlike as possible the persons they are intended for. I photographed an old (and exceptionally plain) lady a short time since. Her age was about seventy. I sent her two proofs, one made to look about sixty years of age, and the other retouched beyond all resemblance—nearly as smooth as a billiard ball. Needless to say, she had a dozen of the latter.

I must not fill up any more of your valuable space; so, with intimating that portraits are mostly frauds, I am, yours, &c.,

A PROFESSIONAL PHOTOGRAPHER.

## "FREAK" PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—In your issue of December 29 you mention a contributor to the *Revue Suisse de Photographie* who states that he has produced a photograph in which a door behind the sitter is seen through him. You say that you are not surprised that the Editors of the journal add that the publication is made "sous toutes réserves." I enclose a print in which exactly the same phenomenon appears. The sitter donned the postman's coat and cap while the postman held the pneumatic ball, the cap being off, of course. I do not think the blind of the shutter leaks; if it does, of course that is sufficient explanation, it may also explain the phenomenon in the case above mentioned. If it is not this, there must be some new X rays to account for it. I may add that the plate was under-exposed, and the development forced as much as possible.—I am, yours, &c.,  
J. M. J.

[In the photograph sent the fence shows through the pseudo-postman. We possess many photographs illustrating this phenomenon.—EDS.]

## PHOTOGRAPHY AND THE WAR.

To the EDITORS.

GENTLEMEN,—Some interesting letters have appeared in the *Pall Mall Gazette* on the question of the use of the camera as an aid to effective scouting, it being suggested that cameras fitted with the tele-photo lens would be serviceable. Is it not a fact that some of the European armies make use of the camera considerably for this purpose? There would be occasions, of course, when the use of the camera would be dangerous to the operator, but an infested country does not necessarily mean that the enemy is everywhere. A photographer could make a dozen exposures whilst a draughtsman is making one rough sketch, although some allowance would have to be made for photographic perspective, which is not a reliable quantity. Some remarkable photographs have been published from time to time, showing the accomplishments of the tele-photo lens.

Modern warfare is a fine art, and, if anything can be utilised to avoid blunders and to bring hostilities to a speedy conclusion, it surely should be made use of.

Perhaps some of the readers of this JOURNAL who may be intimately acquainted with the possibilities of the tele-photo lens will give their opinions, as the matter is surely of considerable importance.—I am, yours, &c.,  
J. A. REID.

"Kinraig," Cutcliffe-grove, Bedford, January 1, 1900.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

## PHOTOGRAPHS REGISTERED:—

A. J. Ashbolt, 10, Exmoor-road, Southampton.—Photograph of Group of the Southampton Football Club.

A. B. Legard, Sunningdale, Bexley, Kent.—Photograph of Sir Redvers Buller when Lieutenant in the 60th Royal Rifles.

ERNEST OETZMANN.—We reciprocate your good wishes, and thank you for the charming little photogravures.

FILMS.—H. W. Neither of the two new films named is yet fairly on the market; but we have little doubt that the makers of them will let you have some to experiment with.

CRACKED CONDENSER.—J. R. B. asks the cheapest way to get a fresh lens to replace one that is cracked in the condenser.—Any optician will refit the condenser with a new glass. The cheapest way, probably, will be to get it done by those who supplied the lantern.

REMOVING PAINT FROM STUDIO ROOF.—W. P. asks: "The best way to remove paint from the glass of his studio, which is at present painted all over."—Apply to the paint a strong solution of pearlshes, or, better still, American potash. In a little time the paint will be sufficiently softened to be scraped, or washed, off. Care should be taken not to get the solution on to the skin of the hands.

SITUATION IN PARIS.—E. T. 1 and 2. So far as we are able to form an opinion, the demand for English operators in Paris is extremely limited. Your chances of success are small. 3. *Moniteur de Photographie*, 55, Quai des Grandes Augustins, Paris. 4. Unable to say, probably in early spring. 5. The lady's chances are exceedingly remote; at present we strongly advise you and her to give up the idea.

COLLOTYPE PORTRAIT.—J. CASSIE asks: "Can you tell me by what process the portrait enclosed herewith is produced? I say it is an albumen print of the ordinary kind, but I am told it was done by some mechanical process, which I cannot believe."—The print is a collytype, glazed so as to resemble a silver picture. It is, however, better than the majority of collytype portraits produced in this country.

LACK OF WHITES IN BROMIDE PRINTS.—W. CHARLES asks: "What is the cause of all my bromides having no pure whites in them? I use —'s extra-sensitive paper, and have more bromide of potassium in the developer than that given in the formula."—The cause is that too strong a light is used in the development, or, maybe, the paper has been fogged by exposure to light. Extra-sensitive paper wants more careful protection from light than slower ones.

SPOTS ON NEGATIVES.—W. BENN asks: "Will you please tell me the probable cause of the small black spots on this negative? I have been much troubled with them of late, and they do not show when the negative is first finished. They seem to make their appearance only when it is dry."—The spots are due to particles of dust settling on the negatives while they are wet. Many of them can be removed by a little friction, leaving the negative intact. Remedy: Shield the negatives from dust while they are drying.

STAINED NEGATIVES.—D. BARKER says: "Kindly let me know the cause of stains on all the negatives that I intensify with mercury. They all go like the one herewith. I am told that they are caused by the hypo not being washed out; but I know that is not the case, because I always wash the negatives for two hours in running water."—The stains, no doubt, arise from the negatives not being sufficiently fixed in the first instance. Unless that is done, no amount of washing will remove the hypo salts, and then stains will result.

STUDIO BUILDING.—J. T. says: "My intended studio is only sixteen feet in length; but still I should like, if possible, to use a long-focus lens. I have thought of overcoming the difficulty by having a door in the centre of the end of studio, so that I could get as far away from sitter as I wished; it being on the ground floor, and on my own premises, I could, of course, do this. Could as good results be obtained in this way as in a large studio?"—Yes; but it will be advisable to shield the camera and lens with an overhead screen, to stop off some of the intervening light.

BLACKING INSIDE OF CAMERA.—N. COOPER says: "I have just bought a box camera (an old one) to use for enlarging with. Will you please tell me the best way to reblack the inside, as the old blacking seems to have disappeared almost entirely?"—Take some lamp black, or, better still, "drop black," and mix it with French polish diluted with methylated spirit, and apply with a brush. The more polish that is used, the less dead will be the surface. A few trials will show the best proportions to use. If French polish is not at hand, ordinary negative varnish may be used instead.

CRACKED ALBUMEN PRINTS.—S. R. OSMAN sends some prints on highly albumenised paper, and asks the cause of the fine scratches on them, saying that every care was taken that the paper was not scratched during the manipulations, and neither did the scratches show until the prints were dried and ready for mounting."—The so-called scratches are really cracks in the albumen. They are caused by the prints being allowed to curl up while drying, and then uncurling them in the dry state. They may be avoided by drying the prints between blotting-paper, so that they are kept flat. Another way is to mount the prints while they are wet.

COPYRIGHT IN FOREIGN PHOTOGRAPHS.—A. R. T. writes: "There are a large number of photographs of the paintings in the Continental galleries, taken by two or three German houses, on sale here. Is there anything to prevent me from copying them, for sale, as transparencies for the lantern? I cannot find that they have been made copyright at Stationers' Hall, but searching there seems very much like hunting for a needle in a haystack."—If the pictures are copyright in Germany—and there is little doubt that they are—they are also copyright here, without their being registered at Stationers' Hall.

COMPOSITION OF FORMULA.—INVESTIGATOR says: "I have to make up of a formula worded as follow: Water, 150 c.c.; bichrom. potass. 6½ grammes; brom. potass. 1½ grammes; citric acid, 25 drops. Will you kindly inform me as to the probable strength of the citric acid solution, or, in other words, how many grains will 25 drops be the equivalent of in pure solid citric acid?"—We have no idea, as the strength of the citric acid solution is not given. Probably the original formula, as written, gives the strength of the solution; if it does not, we are sorry we cannot help, as it may mean anything from a saturated solution to a very dilute one.

VARNISH.—MAGNESIUM POWDER.—VARNISH says: "1. I enclose a small bottle of varnish, I should be much obliged if you could tell me what it is made of. It is generally known as 'lac,' or stopping-out varnish, and is used by etchers on copper. 2. Do you know of any flashlight formula that avoids the white dust after the explosion? I have used magnesium powder and chlorate of potash on gun-cotton. 3. Is this very dangerous?"—1. We do not know the formula by which the varnish sent is compounded. It is probably a solution of shellac in spirit—with, perhaps, other resins—tinted with a black pigment. 2. No; but, by substituting aluminium for the magnesium, there will be less smoke. 3. Yes, unless used with the greatest care. See Leaderette on another page.

\* \* Several answers to correspondents, Editorial Table, and other matter unavoidably held over.

### EX CATHEDRA.

IT is announced that the Annual Exhibition of the Royal Amateur Society (President, Her Royal Highness the Princess of Wales) will take place towards the end of March. Half the proceeds will be given to Lady Lansdowne's Officers' Families Fund. The Loan Annexe, under the management of the Dowager Lady Newton, will comprise old miniatures on ivory of all countries, with a few specimens of pinchbeck and a collection of photographs by members of the Photographic Salon.

\* \* \*

THE daily papers state that the retiring President of the Royal Photographic Society (the Earl of Crawford) is to receive from the Wigan Corporation the freedom of the borough in celebration of the twenty-first anniversary of the opening of the Free Library (of which he is Chairman), and in recognition of his Lordship's services as scientist and bibliophile and his many valuable gifts to the Library.

\* \* \*

The King, the newest of Messrs. George Newnes' many periodicals, relies for its illustrations upon photography to a

greater extent, if it be possible, than any other of the weekly illustrated papers. A feature is made of the war photographs sent home from South Africa by the King's special correspondent at the front, Mr. H. C. Shelley, who is well known to many Glasgow and London photographers. Mr. Shelley is an excellent type of the photographer-journalist, who appears to be meeting with great success in his profession, which, just at the present time, is perhaps somewhat hazardous.

\* \* \*

By the death of Mr. Henry Tracey Coxwell, who lately expired at Seaford in his eightieth year, one of the famous balloonists of the century has passed away. He made hundreds of ascents, some of which have become classical. On September 5, 1862, he and Mr. James Glaisher, F.R.S., the still living past-President of the Photographic Society of Great Britain, created a record by rising to a height of seven miles. After a time, the valve line having become entangled owing to the rotatory motion of the balloon, Mr. Coxwell had to leave the car and mount to the ring; but there was hoar frost all round the neck of the aerostat, and the moment his hands touched the metal they were frost-bitten and rendered useless, so that he had to put his arms on the ring, and in this way drop back into the car. In the mean time Mr. Glaisher, who had observed that they had attained a height of 29,000 feet, found his sight affected, and soon afterwards his arms fell powerless; then he seemed to have no limbs at all, his back and neck lost all muscular power, and he became unconscious. This was the condition in which Mr. Coxwell, on reaching the car again, his own hands powerless, found him. Happily Mr. Coxwell was able to seize the valve cord with his teeth, and some vigorous pulls speedily brought them into a warmer temperature, when Mr. Glaisher recovered and was himself able to attend to his colleague.

\* \* \*

AMONGST the gentlemen whom Her Majesty has been pleased to approve, on the recommendation of the Lord Chancellor, for the appointment to the rank of Queen's Counsel is Mr. W. B. Ferguson. Well known as an active member of the Royal Photographic Society, the new Q.C. further demonstrated his interest in photography by reading at the Society's meeting, on

Tuesday evening last, a paper on "Toning and Intensification with the Salts of Copper," a report of which we print elsewhere.

\* \* \*

SOME of our American contemporaries and several correspondents of our own have adversely criticised the printing paper "combine" known in the States as the General Aristo Company, which has control of the whole output of photographic printing papers on the other side. It has been suggested that the concentration of all the manufacturers' interests has operated disadvantageously both to dealers and consumers; but Mr. F. J. Ibbetson, of Messrs. J. J. Griffin & Sons, who has just returned from a business visit to the States, puts a different complexion on the state of affairs. The combine, he tells us, has stopped cutting in the trade, and has not raised prices to the consumer. He is of opinion that it is working very well for all concerned. This impartial view of the matter should reassure those who have feared that the combine in question was a tyrannous monopoly.

\* \* \*

INTO the illustrated notice of the Tella camera, which appears at pp. 898-900 of our ALMANAC for 1900, a strange block, by one of those accidents which will occur in the best regulated of printing works, unfortunately found its way. The immediate result was a considerable number of inquiries addressed to the Tella Company within a few hours of the publication of the ALMANAC, as to whether the construction of their highly popular hand camera had undergone some alteration as regards its external appearance. We have to express our regrets to the Company, as well as to our readers, for the intrusion of this misleading block, which, at least, has had the compensating effect of endorsing the popularity of the Tella hand camera, and of proving with what attention and closeness the pages of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC are perused by its readers.

#### A POINT IN CONNEXION WITH THE RIGHT TO THE NEGATIVE.

SINCE the article on the right to the negative appeared in our issue for November 17, and the reserved judgment in the case then before the Yarmouth County Court has been given, we have been asked questions on one or two points in connexion with the photographer's right to the negative when taken under other conditions. One correspondent says, in effect, that although there is no question that a portrait negative taken in the studio, in the ordinary course of business, is the property of the photographer, it may not be the case when groups and the like are taken at customers' own houses, or when, for instance, the photographer goes a distance to take a building, or photograph a ceremony, and charges his travelling expenses in addition to those for taking the photograph.

One correspondent writes as follows: "Some time back I was engaged to take photographs of a wedding party some miles from my place of business. I charged so much for attending and taking the picture, and so much for travelling expenses. When I sent in the proofs and the bill, the party would not pay unless I gave up the negatives. They said, as I had charged them for taking the pictures, and also charged them with my travelling expenses to do the work, the negatives were their property, and, unless I gave them up, they would

not pay the account. As I could not get the money, and did not wish to try the matter in the County Court, I gave up the negatives, and they paid. The negatives were then sent to another photographer to print from at a less price than I charge." Our correspondent now asks if he did wrong in giving up the negatives, and if a similar case had been decided in Court.

Here the photographer did wrong in handing over the negatives, as they were his property. A very similar case to his was decided some years ago (in 1884) in the Swansea County Court. This case was briefly referred to in the previous article. It was this: the claim was for something over 10*l*., about half of which was for "photographing" a vessel with officers and men on board, the other half being for duplicates supplied. The latter claim was paid into Court, and the former contested because the negatives were not given up to the defendant. His advocate contended, with some ability, that, as a definite charge was made for "photographing" the vessel, &c., the negatives became the property of the customer. But this argument did not avail, for the Judge was evidently aware of the custom of the trade in photography, and found for the plaintiff with costs. During the arguments in the case the Judge remarked that the negative should be looked upon as one of the photographer's instruments of trade, adding that "a negative may be a secret in his trade, and he does not part with it unless there is a contract to that effect." Leave to appeal was asked for and granted, though at the same time the Judge said, "I think it will be useless to appeal." The appeal was not, however, proceeded with.

The case detailed by our correspondent is one precisely on all fours with that just quoted, but we are not at all sure that every County Court Judge would take the same view of the case as did the one at Swansea, hence the present article.

Litigation in all cases is best avoided if possible. In the case recently tried in the Yarmouth County Court, for example, the Judge at the first hearing said that he was of opinion that the negatives were clearly the property of the customer, adding that "it was just the same when one had a plate engraved for cards;" though, after he had seen previously decided cases, possibly those we had quoted, he found himself in error, as he gave a verdict for the photographer.

What we should advise, with the view to avoiding litigation in any way, is in all instances to make no definite charge in any shape whatever for taking the negative, or for photographing, but merely charging for what is actually supplied. When the work is done away from home, the invoice should be made out in some such form as this: To so many photographs of groups, or whatever it may be, so much; travelling expenses, so much; so many duplicates, so much. Then the charges are made for only what is actually supplied to the customer, and for nothing more. We are quite aware that many photographers, like solicitors, make out long wordy accounts, with the view to make the work done appear as large as possible; but, in the case of photography, this may prove a mistake, as it may lead to unpleasant misunderstandings, and perhaps something more with litigiously inclined customers.

Our object here is to impress upon our professional readers, as we have done on more than one previous occasion, that in making out their charges they should charge only for what is actually supplied, with, of course, travelling and similar out-of-pocket expenses, without any allusion whatever to anything else. Any reference to taking negatives, photographing, or

he like, should be studiously avoided, for, notwithstanding the decision in the Swansea case, as we have just intimated, disputes or litigations may arise, and they, in any form, even if they are successfully contested, are best avoided.

**The Solar Eclipse.**—Preparations are going on apace with regard to the observing of the eclipse on May 28 next, and, as the distance to be travelled in order to be in a suitable position is very small in comparison with the requirements of the last eclipse, it is probable that large numbers of astronomers will take advantage of this opportunity. The British Astronomical Association have made such arrangements that, if the requisite number of observers give in their names, the Royal Mail steamer *Tagus* will be chartered. It is then to start from Southampton on May 18 at 6 p.m., and is to call en route at Cadiz and Alicante, and arrive at Algiers 6 a.m. on Thursday, May 24. The plan of operations is for the observers to form three groups to carry on operations: (1) in the interior of Spain, (2) at Alicante or its neighbourhood, (3) in Algeria. Those who elect to observe in the latter region will have the advantage of being able, if they wish, to use the ship as an hotel.

**Photographs of the New Moon.**—Many of our readers will be familiar with the phenomenon of the "old moon in the young one's arms," as the effect of the slight visibility of the so-called non-illuminated major portion of the satellite's surface embraced as it were by the luminous portion, apparently part of a space of larger area, is termed. On some occasions the dark part becomes extremely clearly discernible to the eye, and recently some excellent photographs have been taken of the whole surface. In the *Bulletin* of the French Astronomical Society for last month an article is devoted to this subject, and is illustrated by an excellent photograph, thus showing that the visibility is a true objective phenomenon, and not an optical illusion. We may note that the real cause of this visibility of the dark part was for a long while unknown. The eminent astronomer, Tycho Brahe, thought that it was produced by what might be termed Venus shine, but Leonardo da Vinci, that marvellous genius, as eminent in architecture as painting, and in astronomy as in architecture, clearly pointed out the cause as being earth shine, *i.e.*, sunlight reflected from the earth on to the moon, just as the moon reflects the light received from the sun on to the earth. The French term the effect *la lumière cendrée*.

**Celestial Photography.**—This branch of astronomy has, says the *English Mechanic* in its annual review, advanced "at a surprising rate, and the sensitised plate is taking the place of the human eye in numerous directions. The astrographic chart and catalogue proceed apace, and the sun is photographed whenever he is visible at Greenwich. Dr. Roberts's superb photographs continue to be taken with undeviating regularity, and we hear that a second of the invaluable volumes issued from the Crowborough Observatory is to appear immediately. Perhaps there is no more curious story in reference to the photography of the sky than that of the Crossley reflector now at Lick Observatory. Purchased originally from Dr. Common by Mr. Crossley, the three-feet reflector never did any good in its new possessor's hands; not even after he had had it refigured by one of our most eminent opticians were its capabilities to any extent developed. Now at Lick it seems to have found its *métier*, and, in the hands of Professor Keeley, to have produced results of the highest value."

**Preserving of Brasswork from Corrosion.**—The writer in the above journal, whose letters appear over the signature of "Glatton," makes some very suggestive remarks upon this subject. He points out that, in a paper published by the Society of Arts, the lecturer called attention to the fact that the varnish used by the old masters was absolutely damp-proof, but that the kind used by the

moderns was not absolutely so. He concluded that damp was the cause of faded pictures, and he endeavoured to find a damp-proof varnish. As he found that such a varnish was not commercially obtainable, he set to work to discover the best way to make one himself. He found that the damp penetrated through minute pores or holes in the varnish, and the problem that presented itself was how to prevent these pores forming. His method of testing was to dehydrate some cupric sulphate, which then lost its blue colour and became white; this he mixed with the varnish to be tested and then painted a glass slip with the compound. If water gained access through the varnish, it was absorbed by the copper salt, which again became blue; but, if it retained its whiteness, it was non-porous. A large number of varnishes were tried, but none answered the test till he added Venice turpentine. Then the secret was discovered. A very small quantity of this substance added to the varnish conferred the property of impenetrability to moisture. The writer suggests that, if added to lacquer, it might still further add to its value and render it damp-proof. It is well known that, although a lens mounting, for instance, will keep intact under ordinary conditions, the time comes when, if it be exposed to damp, or more especially to chemical fumes, the varnish or lacquer is penetrated, and the instrument becomes rusty-looking and pitted through corrosion of the brass. Again, if the addition answered in one case, it ought to do so in another; and the one fault of shellac varnish, its easy penetrability to water which has obtained accidental access to it, might be removed.

It must, however, be pointed out that care should be taken that the genuine Venice turpentine be used, for a very large quantity of that purchasable at the chemists' shops is merely a solution of common residue in turpentine.

#### JOTTINGS.

WITH poor Belton, who died so suddenly the other day, I had many a pleasant hour—many a useful talk on photography—in past years. As far back as 1882 some of his New Forest landscapes were hung at the Photographic Society's Exhibition in Pall Mall. Printed and framed according to the most modern ideas these sylvan studies would bear comparison with much good work of to-day. I believe Belton was the first to photograph the sea of faces in Fleet-street on a Derby afternoon anxiously gazing towards the windows of the sporting newspaper offices for the result of the greatest horse race in the world. The photograph caused a mild sensation at the time. He belonged to the school of photographers which was formed in the early sixties, and, though he was less fortunate in the bitter battle of life than many neither so deserving nor so competent, he will be long remembered for many excellent personal qualities, and by nobody more kindly than the writer of this paragraph.

THE widespread anxiety of the nation to help the sufferers by the stern war in South Africa hardly appears to have reached photographers as a class. One society—the Southsea—has raised 45*l.* as the result of a lantern lecture, but that is all. I believe that, if the scores of societies who hold lantern evenings in the winter would follow the lead of their Hampshire brethren, a very respectable sum would be raised and added to the war funds. It is not too late for something to be done. The war has only just commenced, and we have not yet reached mid-winter. My friend, the admirable Mr. W. E. Dunmore, of Tella Camera celebrity, has lived in South Africa, and he (and doubtless other photographers similarly experienced) might be disposed to help with local information at any lantern lectures which took the district of the battlefields as a subject for illustration.

"ANASTIGMAT *versus* Rectilinear Lenses" is the title of a paper read one night this week before the Borough Polytechnic Photographic Society by Mr. Harris. But at what points do anastigmatism and rectilinearity antagonise? In no class of camera work

is either of these valuable optical properties a disadvantage, so that to pit the one against the other serves no purpose that I can discover. I imagine, however, that the author of the paper intended to discuss the relative merits of lenses giving round and flat fields respectively. That is a horse of another colour. Lenses having an appreciable amount of curvature will always be useful for such subjects as interiors, street views, &c., offering a field concave to the lens, while for transmitting a plane image of a plane surface a flat field lens is essential. Lying between these two propositions there may be some ground for discussion, but not so, my dear Mr. Harris, with regard to anastigmatism and rectilinearity. Curvature, though an optical fault, may in most cases be no practical drawback, but a lens which either distorts or will not focus for the oblique rays must be a very poor thing indeed nowadays.

I HAVE been asked for the address of a maker of stereoscopic slides from professionals' or amateurs' negatives, but I know of no trade photographer who undertakes such work. I mention the fact, because possibly there might be an opening for a photographer who would lay himself out to make a speciality of preparing binocular slides and transparencies. There is so much stereoscopic photography done nowadays in a quiet way that the hint I am giving is certainly worth attention. It is not always a thankful task pointing out where demand awaits supply. Some years ago, in this column, I advised photographers to take up the preparation, or, at any rate, the furnishing to their clients, of note-headings, cards, and so forth, with half-tone views or portraits printed on them. A contemporary writer jeered at the idea, but to-day the production of half-tone illustrated stationery has reached the dimensions of a respectable industry. In the picturesque village where I live the stationer advertises and sells the little local half-tone views, and the photographer's window is barren of them. By rights, of course, it should be the other way about.

NEXT to the virtual impossibility of having stereo slides made commercially lies the difficulty of getting the prints themselves properly mounted and transposed. Not half-a-dozen trade printers in the country would be equal to the task, I am sure. Quite recently I hurriedly wanted something like a hundred binocular prints cut, trimmed, transposed, and mounted. It was a little job which, from past experience, I knew I could not get through under several evenings; but it was perfectly done for me in twenty-four hours by Messrs. E. Fox & Co., of 12, Little Britain, E.C. For print-mounting of all sorts, probably no firm is so cleanly and so expeditious as Messrs. Fox. It is many years since I first handled any of their work, so that, in the words of the sporting writers, I am putting my readers "on to a good thing" if they will intrust the mounting of their photographs to Messrs. Fox.

CONCERNING the mounting of prints, photographers might, in many cases, borrow a hint from some of the publications which give photographic pictures as frontispieces or illustrations. No less than five of these periodicals simply mount the prints by the edges, so that there is virtually no contact with the support, and thus between the latter, the mountant and the silver image, no chemical action takes place. Such a plan may reasonably be supposed to conduce to the permanency of the image. At least one well-known London photographer attaches his prints to the mounts in this way. It is, perhaps, not practicable for *carte-de-visite* surface prints and other small work, but has a very great deal to recommend it for the better class of larger-sized platinum and carbon portraiture, &c.

THE arm chair generals and strategists, who have been writing to the daily newspapers about the misconduct of the war and the shortcomings of those who are directing it, may at least be thanked for paving the way to an increase of optical and photographic knowledge on the part of the general public. We were told the other day that the Boer officers were furnished with prismatic binoculars of a power and field not made, and this original misstatement has been the means of informing the public precisely what a prismatic

binocular is, and its uses in spying out the land in military operations. Again, some nonsensical suggestions that "snap-shot hand cameras" (*sic*) with lenses of five or six inches focal length would be of use in photographing an enemy's intrenchments at a distance of several miles have led to the publication of some authoritative information about the only system that would be of use in such a case, viz., tele-photography.

A PERUSAL of some of the letters to which I have referred might, however, lead the public to suppose that the military authorities were not alive to the value of photography in warfare. At this time of national trial it is satisfactory to know that this is not the case. For many years past there has been a photographic branch attached to the School of Military Engineering at Chatham, which has done good work in imparting a knowledge of photography to officers and others. But, indeed, throughout the service balloon photography, tele-photography, and all the minor processes are thoroughly well understood and practised, and the number of officers who are intimately acquainted with the possibilities and limitations of photography in warfare must be exceedingly large. If some of the armchair commanders were a little better informed on the subject, the volume of ignorant criticism just now being directed against the sorely harassed War Office would be appreciably smaller.

COSMOS.

#### BRITISH PHOTOGRAPHY FROM THE AMERICAN POINT OF VIEW.

[SECOND ARTICLE.]

LAST week we reproduced some interesting, if contradictory, American criticisms on the British photographs lately exhibited in Philadelphia, and in our review columns we referred approvingly to a lengthy notice of these photographs which appears in *Camera Notes* (New York) over the signature of J. T. Keiley. Mr. Keiley's photographic writings, which we have long followed with interest, stamp him as a sincere and well-informed critic. In the belief that his opinions of the British photographs shown at Philadelphia will carry weight with those interested, we here reproduce the essential portions of his admirably written notice:—

Of Mr. J. Craig Annan's seven pictures, *A Lombardy Ploughing Team*, No. 14, alone was pre-eminently great, and worthy of its eminent reputation. This picture is too well known to need any description, and too perfect a thing of its kind to call for any criticism. Not so, however, *The Church or the World* (No. 13), which was the sheerest travesty. It presented to us three damsels, two apparently in hooded mackintoshes, presumably intended for *religieuses*, and representing the Church, leading through a forest or garden a little pony, on which the third was seated arrayed in spring attire. Just which one of these two latter was intended to represent the world was not apparent. A fair observer, with a *bonbonnière* in her hand, who paused before the picture as I was examining it, made the only kind criticism to which the picture was open. She looked at it a moment, and exclaimed ecstatically, "Isn't he just too 'cute for anything, that little pony?" *A Lady in White* (No. 12) was simply a Davis & Sanford of a girl, a shawl, a table, and some ornaments, framed very handsomely in black and gold. I failed to see anything remarkable in Mr. Annan's picture of Miss Ellen Terry (No. 9), but one day, while standing near it, I was enlightened as to one of its charms by a dapper little gentleman, nattily dressed, and distinguished from the common crowd by a flower in his buttonhole, dove-coloured spats, pointed beard and curved moustaches, and silk-ribboned eye-glasses, who, designating the picture by a graceful and comprehensive hand and arm movement, exclaimed to his friend, "Isn't she sweet? I bought that;" and thereupon the two fell to discussing the legitimacy of some of Mrs. Käsebier's work. No. 10 was the picture of a woolly palette with a man alongside of it.

Pictures by Karl Greger: (No. 144) *Afterglow*, (No. 145) *Suffolk Meadows*, (No. 146) *Dreamy Marshland*, (No. 147) *A Woodland Pond*, (No. 149) *Evening Before the Day of Rest*, were little better than space-fillers. No. 148, however, *The Playground of Wind and Waves*, showed rather nice-feeling, although the tone was rather leaden; this, however, may have been due to the glass. The sea in this picture is too solidly rendered. I should remark of picture No. 146, a picture of sheep with heavy storm clouds darkening the sky, that the sheep threw strong sun shadows.

*My Lady's Garden* (No. 188) was, without doubt, the best of the five pictures shown by Alexander Keighley. The picture was distinctly English in its type, and the sky portions and overhanging trees that break and shut out part of the sky were classically rendered. The idea conveyed to the observer in the contrasted forms of the grim old sun-dial on the one hand, and on the other the peacock and handsome flower-picker, both with their backs to the dial, is a very poetic one. While there were certain things that I did not like about the picture, I think that, on the whole, its composition was good, and that it had the merit of being a successful, a pleasing picture, if not a great one. In *Father ye Roses while ye may, Old Time is still a-flying* (No. 192) Mr. Keighley also displayed much poetic feeling. His other pictures (No. 89), a railroad photograph; (No. 190), a picture of rays of light that skip dark places; and No. 191, are a different class of work, and only passably interesting.

As a member of the bar I could not fail to entertain a certain professional admiration for Mr. Crooke's pictures of *Lord Kinnear* (No. 86), *Alexander Carle, Esq.* (No. 87), and *Sheriff Comrie Thompson, Q.C.* (No. 88), they so entirely resembled modern reproductions of the old tinted prints of barristers, solicitors, queen's counsellors, and lords chief-justice that we lawyers are so fond of ripping out of old books, framing in the stiffest manner possible for dignity's sake and hanging in our offices for the purpose of spurring us on to perpetuate ourselves in like manner, and incidentally to excite a proper sense of awe and respect in the breasts of our clients by impressing them with the fact that we attorneys belong to a superior and gifted class of the community—its intellectual and linguistic aristocracy, so to speak. Those pictures were all of that professional dignity and superiority that the lawyer so loves, and if there be any among my readers who, having seen Mr. Crooke's photographs, are inclined to question the truthfulness of their portrayal of those characteristics, let them call to mind if they know him, and if not let them seek out our own esteemed fellow-citizen and international celebrity, for I understand that he has of late purchased a castle and estate in Ireland, the Honorable Barrister Nolan, of the New York bar, when all doubt will vanish into thin air. But we all have it in greater or less degree, we lawyers, down to the merest little popinjay of a hystery, whose knowledge of law would scarcely fill a thimble. Indeed, I have long since come to believe that it is this divine characteristic of personal and intellectual superiority (in judging of this we, of course, act as our own judge and jury), which inclines us to the study of the law. To medicine, of course, we could never take, for, eminently respectable as it is to-day, we cannot forget that in its pristine simplicity its profession was part of the repertoire of that loquacious and menial member of the community, the barber, and that originally the medico's coat of arms consisted of three pills rampant on a soup plate pendant with a semi-circular fragment chipped out of its upper edge. Mr. Crooke's pictures were, from a technical point of view, beautiful pieces of work. The background consisted in most cases of a heavily draped window, and the view out of the window was cleverly varied in the different pictures by the use in the aperture of the window of a series of out-door views that just filled with precision the space to be covered.

Mr. Job's picture, *Snow and Sunshine* (No. 170), was disturbing because of its sky, whose clouds were unpleasantly like puffs of cigar smoke.

*Farmstead* (No. 19), W. S. Ashton, was spoiled by too much foreground. Otherwise the picture was well spaced and its general effect pleasing.

*The Quay Side* (No. 169), Job, is a subject very similar to a picture by Mr. Russell shown in the same Exhibition. The latter picture was handled with a delightful appreciation of the picturesque possibilities of the subject, and, while by no means a masterpiece, was certainly a very decorative bit, full of refinement and feeling. Such was not the case, however, with print No. 169, which was neither vague enough to excite the imagination, hard enough to shock, nor picturesque enough to attract—in a word, it was simply a good photograph.

Of Mr. Mummy's two pictures, that entitled *Unveiled her peerless Light*, and *O'er the Dark her Silver Mantle threw*, No. 231 alone seemed to call for special notice. It was so framed and matted that its really great charm almost escaped me. Executed in soft blacks and luminous greys that had all the quality of charcoal, this little night scene is truly nocturnal in its feeling, and it certainly stood in a class by itself. Some who looked at it objected to the brightness of the rising moon. For my own part, I found nothing to object to in this or in anything else in the picture except the artist's printed name on the lower corner of the print, which, besides not being in the best of taste, was most injurious to the picture because of the rigidity and heaviness of the letters.

In *Afternoon* (No. 217), Viscount Maitland; *On the Way* (No. 218),

Maitland; and *Suffolk Lowlands* (No. 227), L. Morgan; *An Outcast on the Essex Saltings*, No. 228 (L. Morgan), the sky portions of the pictures seemed to clash with their other parts, and this is a fatal defect, as harmony of parts is one of the essential elements of a perfect picture. This clashing was especially noticeable in No. 218. When we behold such a sky as this in nature, the foreground, with all of the details, is taken in by the eye only as an incident, and appears as a massing of shadowy lines and forms against the sky beyond. In this picture, however, the foreground has been rendered with painful exactness. The resulting effect is extremely disturbing and unpicturesque. No. 228 hardly tells its own story.

Of the seven pictures shown by A. Horsley Hinton, *Sylvan Solitude* (No. 162) appealed to me the most strongly. Indeed it has left a more permanent impression than any other picture by him that I have yet seen, and has caused me to regret that I am but indifferently familiar with his work. If I am not greatly mistaken, it is a picture that one could live with, and grow fonder of, with more intimate knowledge of it, which, after all, is the crucial test of the depth of a picture—and which cannot be said of the majority of the few pictures of Mr. Hinton which I know. The picture presents to us a forest hillside, well wooded with ancient trees that outline their majestic forms against a sky that hints of advancing night or coming storm. The sloping hillside is carpeted with soft grey moss that has all the appearance of never having been disturbed by the foot of man. One cannot look upon this picture without feeling the peace of such solitudes as this, where no sound is heard save, perhaps, the snapping of a dry twig under foot, the song of some forest warbler, or the music of plashing brook, where, far removed from the hardening influence of the tumultuous passions and ceaseless strife of inhabited places, man communes again with mother earth, and through the refreshing and inspiring influence of her sublime beauty feels the nobility of his manhood within his soul, and awakens to the paltry meanness of most of the ambitions of the world.

Of the other pictures shown by Mr. Hinton, *The Headland* (No. 158) was perhaps the most striking—yet neither this nor the remaining pictures gave me more than a passing pleasure. They lack something that is essential to a picture's immortality. Whether it be that they are false in their renderings I am not prepared to say.

There were certain qualities in Italian, French, and English paintings that I never understood till I had visited those countries, though I doubt not that previously I had more than once presumed to comment upon them; and since then, realising how very silly some of my early comments must have been, I have made it a rule never to pass judgment upon that concerning which I am indifferently informed. It is to be hoped that in time certain English and American critics will learn the same lesson.

*After the Storm* (No. 206), George Lamley, was a satisfactory marine bit, very suggestive of Harrison's paintings of the sea.

J. A. Sinclair's picture (No. 266), entitled *Twilight*, raised a doubt in my mind as to whether my own conception of twilight was the correct one.

Paul Martin's two pictures, *A Frosty Night* (No. 219) and *A Winter's Night on the Embankment* (No. 220), were most interesting, not only from a picturesque but from an historical point of view, as Mr. Martin was one of the first Englishmen to undertake night photography, making his experiments in England at the same time that Mr. Stieglitz was making the initial experiments in this country, each working without any knowledge that the other was labouring along the same lines. Mr. Martin's pictures seemed to me somewhat hard and unatmospheric, otherwise they were quite perfect in their way.

*My Nephew* (No. 79), Archibald Cochrane, while not as large as his picture of last year, was well worthy of study.

None the less interesting because of its small size was F. A. Bolton's *Shades of Evening* (No. 98). It was a narrow river or canal scene, the stream flowing outwards, so that both banks were visible, and was well treated and showed much imagination and feeling, its pictorial value being pronounced.

Mr. J. P. Croft sent one of his delightfully poetic pictures entitled *On the Hillside* (No. 84), that was full of a vague dreaminess that appealed to the imagination. Like most of Mr. Croft's pictures, it possessed a quiet charm and refined originality that was truly admirable.

Of the two pictures shown by W. T. Greatbach (No. 142), *Sunshine and Shadow*, a woodland bit that displayed no little appreciation of the charm of leaf-filtered light, was by far the best.

J. C. Warburg's *At the Spring* (No. 322) cannot be passed over unnoticed, for it certainly possessed a distinct charm and fascination. Its studied irregularity, its vagueness, its odd side strip, all challenged

attention. Most of those who saw it denounced it at first, but I noticed that later on they went back to it, and that the oftener that they saw it the milder was their condemnation.

*Head of a Girl* (No. 252), by R. W. Robinson, has certain pleasing qualities of light and line; but, unhappily for the picture, it is sufficiently like, in general effect, to a well-known picture of the fascinating Lady Hamilton, of Nelson fame, to invite comparison to the injury of the photograph. The lower portion of the arm is treated in such a way as to spoil its symmetry and to give it an unpleasant heaviness.

*On the Hither Side of Night* (No. 253), R. W. Robinson, impressed me as hard, badly handled, and scarcely interesting, and certainly not in keeping with Mr. Robinson's reputation, while *Becalmed* (No. 251) and *The Golden Close of Evening* (No. 254) impressed me as being simply conventional.

Mr. Calland's *Barley Mowers* (No. 74) had in it the making of a very fine picture of country life, but, owing to certain defects of composition, the picture is very badly out of balance; but *In the Row, London* (No. 75), can scarcely be improved upon. The subject is not one that appeals to my personal liking, but, for what it is, it is the best thing of the kind that I know. It is full of character and action, and is treated in a masterly manner that places Mr. Calland in the front rank of serious photographic workers.

*Rose Trail* (No. 69) and *Vine Leaves* (No. 70), by Carine Cadby, were interesting as delicate colour studies of trailing leaves, and much in advance of most of the painted things of the kind with which I am familiar.

The pictures of H. W. Barnett (Nos. 33 to 39), while somewhat conventional, were executed with great taste and refinement, and evidenced an intimate familiarity with the style of some of England's best portrait painters of the past, both in their style and composition. Several of these pictures were faulty in composition, and one was so trimmed (it was cut in circular form) as to exaggerate the unsymmetrical lines of the composition of the subject, crowding the figure, seemingly, into a very awkward attitude. Of these pictures *Memories* (No. 34), *The Princess* (No. 35), and *Agnes Romney* (No. 36) were much the most attractive. In the case of the picture of the violin-player, the picture was rather unfortunately cut in two by the violin, and most disturbing in its composition in consequence.

*Tears* (No. 71), Will Cadby, was the photograph of a child partly draped in what appeared to be a portion of a lace shawl or curtain, and supposed to be weeping, from the fact that it had its knuckles screwed into its eyes; while *Blossoms* (No. 72) was a Bergeesque production à la *Magdalene*, which lacked both force and purpose. *There came a Big Spider* (No. 73) can only be described in jingle:—

"A wall with a fall,  
A spider dried,  
Nude child beside,  
Wraps and leaves,  
Frame from eaves."

*Apropos* of the frame, some one referred to the English frames as umber-yards, and I must confess that the characterisation was most apt, for, with some notable exceptions, they were ungainly, massive affairs, made seemingly from the same sort of moulding from which the eaves of old frame houses were constructed.

Mr. Craigie's portrait, *George Batten* (No. 91) was one of the best examples of forceful portrait work shown in the Salon. The head was strong, well poised and lighted, and full of character, without being unpleasantly sharp. The neckcloth and collar seemed to me a trifle brilliant for the subdued tones of the balance of the picture. The framing of the picture was atrocious.

*Dr. John Todhunter* (No. 126), *G. A. Story, Esq., R.A.* (No. 127), and portrait study, *A Jewess* (No. 128), three pictures by F. H. Evans, were so wretchedly spaced and horribly framed that the observer was tempted to pass them without looking at them twice. A careful examination showed rather good modelling and an evident effort to convey something of the character of the sitter, but, when it comes to giving Dr. Todhunter a complexion as jaundiced as the bindings of some of his illustrious namesake's mathematical works, I think that some one should call a halt. I have since seen this picture reproduced in black and white, and thus rendered and freed from the damning influence of its frame, which was not in evidence in the reproduction, the picture looked vastly better. Picture No. 127 was anemic in tone, while No. 128 was as chalky as some of England's own cliffs. As fragmentary studies these prints were interesting, as finished pictures they were not.

*An Evening Sky* (No. 129), also by Evans, suggested possibilities only

to show how far they had been missed; while *In Surrey Wood* (No. 130) is a puzzle picture, which, till closely examined, strikingly resembled a posterior view of a line of ostriches with their heads buried in the ground raising a cloud of dust. The picture is tastelessly matted and framed. In No. 131, *Gloucester Cathedral, in the North Transept*, Mr. Evans was seen at his best. This was really a fine bit of architectural work and worthy of careful study. It is in this work that Mr. Evans is most happy and successful.

As I stood before No. 68, *Le Monde c'est ce qui m'amuse*, A. Burchett, I heard a dainty little lady say, "Nice dress, nice gloves, nice parasol, but her hat! it's shockingly out of style, and I guess she must know it too, she looks so distressed." This, one of the largest pictures shown, was certainly not an example of high art, and the little lady above referred to classed it well; it was little better than a clever fashion plate. Its most distinguished feature was its French title. No. 67, *Caller Herrin'*, A. Burchett, was evidently intended for a character or type study. The motive that prompted the attempt is all that I can commend, for the picture itself was false, posey, and wanting in atmosphere. The girl's eyes were not the eyes of a simple fish-vendor, but of a charming little Miss, who was entirely conscious that she was having her picture taken. Her soft and faultlessly clean hands never carried a fish basket about nor handled fish, and the basket itself is a marvel of cleanliness, bearing never a stain. The spacing of the picture is rather well managed, but the picture, as a picture, is insincere. No. 64, *Winter*, Arthur Burchett; such a title is too comprehensive to be bestowed on a picture like this, which shows merely a snow-covered landscape, in which the snow was badly rendered, the composition poor, and the subject very commonplace. It neither presented nor suggests to the imagination anything of the bleakness of winter, with its whistling winds, its driving storms, its icy whisperings of weird, frozen mysteries, or its prefigurations of death.

The title of a picture will invariably betray how much or how little its maker is in sympathy with his work. It is amusing to note the misfit qualities of many titles; it is depressing and significant also, for such, though it may be pleasing, is never deep, and often not sincere, and it rarely happens that its author ever goes beyond it into higher and nobler fields of intellectual and artistic activity.

*Apropos* of titles, I quite clearly recall the explanation given by a gentleman well known in the photographic world of the title of one of his exhibits that had caused much speculation among those who had noted it. "After I had concluded to arrange this exhibit thus," he said, "my friend and I got together to select a name for it, and we decided upon this name because we concluded that it would give people something to think about." "Then your title and arrangement was merely an afterthought?" I asked. "Precisely," was the reply. This reminded me of an experience I once had with an Italian who turned plaster into gold by selling casts and plaster reproductions of well-known masterpieces. I had ordered from him a mask of Cicero and another of Demosthenes. When the masks reached me, I had no trouble in recognising the features of the eloquent citizen of Rome, but that of Demosthenes filled me with consternation, for he had lost his beard and grown quite stout. Yet with much eloquence my Italian friend assured me that it was Demosthenes. Despite this fact, however, it has always been my private opinion that the vendor of casts, having discovered that he did not have Demosthenes in stock, had made a plaster cast of the face of his father-in-law, and called it after the Greek. And, after all, as one of the defenders of this method of naming pictures put it, "parents don't name their children till after they are born, especially in America, where to call a boy *Marie* would mean juvenile persecution on the part of his future schoolfellows, and lifelong impertinence from all the *funny* people he chanced to know.

To No. 63, also called *Winter*, Arthur Burchett, the same objection applies. As a mere study of trees, the texture was very well portrayed, but the trees themselves were entirely too black and individually too assertive, each demanding separate attention.

*Reedy Wastes* (No. 18), W. Smedley Aston, was a landscape that reminded me somewhat of certain of Hinton's pictures. The manner of the treatment of the subject and the naming of the picture displays no real feeling for its artistic qualities, for, while the sky possessed some little charm, the distance was not well rendered, and the reeds in the foreground were peculiarly aggressive, but not sufficiently impressive to suggest the picture's title, the interest actually centering in the sky.

I found the frames of Nos. 295 and 297, W. Thomas, quite original. The former contained a clever photograph of a dog, and was called in the catalogue *Cats*; the latter, a salt sprinkled landscape, entitled *Winter*. No. 298 was a picture of a number of sheep. The catalogued title is

sturbed. Its effect on the observer was disturbing. It had all the appearance of a plain or hillside that has been hit underneath either by earthquake or the hammer of Thor, and set vibrating in a most remarkable manner. While I was observing the picture a gentleman on the side of me, who had been examining an adjoining picture, turned his eyes upon this one. Instantly he grasped the distance-bar in front of me, and exclaimed, in shaky tones, "Great heavens, look at that Dizzy-ope!"

Pictures (No. 296) *Autumn*, (299) *Woodland Graces*, (302) *In a Kentish Wood*, other examples of Mr. Thomas' work, were broad expanses of mosses, ferns, and frames. No. 301, *Sunset in the Pool*, was perhaps the most pleasing of all his pictures, because the least visible—thanks to its modest dimness—while No. 300, *A Summer Evening*, possessed certain merit because of the manner in which the water was indicated.

Mr. Harold Baker displayed ten pictures, Nos. 23-32. No. 26, *Miss Emily Hanbury*, was chiefly remarkable for the jewellery worn by the subject. It was pretty jewellery. No. 31, *Stratford-on-Avon in February*, was simply a waste of space; No. 29, *Portrait in Costume*, was of a costume with a man in it; No. 25, *Grey Avon's Peace*, appeared somewhat better than No. 31, while No. 28, *A. Horsley Hinton, Esq.*, was an example of Mr. Horsley Hinton's great forbearance. I heard more than one person say, as they looked at this picture, that never again could they like Mr. Hinton's pictures as well as they did before having seen his portrait of him. No. 30, *The Countess of Warwick*, the picture of a very charming woman, was rather well posed, and rendered flesh and structural values with a considerable degree of truth; No. 27, *Edward R. Taylor, Esq.*, was an example of the horrible possibilities of photography. The general impression created by *A Pleasant Story* (No. 24) was that the lady must have been indulging in very light literature from the way in which the book floats in air, supported at one end by the tip of a tapering finger touched to the leaves, and at the other by a downy pillow; No. 23 was the portrait of a rather charming child, while No. 32, *Room in which Shakespeare was Born*, seemed somewhat untrue in line.

### THE COMBINATION OF COLOURS.

[Translated from the *Archiv für Wissenschaftliche Photographie*.]

It is well known that the law of the combination of colour rays is applicable to the material admixture of colours, and the example which is often given, that ultramarine and vermilion yield a brown mixture, whilst blue and red light combined form violet, illustrates very clearly the difference between a mixture of pigments and a combination of rays of light. The effects of the admixture of pigments are frequently said to be irrational, but there cannot be any doubt of some connexion between both sets of phenomena, and it is not only of theoretical, but also of practical, importance to elucidate this.

The colour of a substance depends upon its capacity to absorb rays of definite wave-length, or to abstract them from the incident white light. The residual reflected rays unite according to the laws of colour combination, and cause a simple sensation, which we call the colour of the object. The nature and quantity of the absorbed rays are determined by the spectrum of absorption, and if we add up the elements of the band of absorption, with due regard to their intensity, according to the laws of colour combination, the colour thus obtained must be complementary to that of the substance.

If another pigment be added to the first, the second pigment absorbs part of the rays reflected by the first, and the mixed colour thus produced corresponds to the sum of the residual reflected rays. The same result may be obtained by taking the sum of the bands of absorption and subtracting it from white light, or, in other words, by finding the complementary to the absorption colour.

The colour obtained by the combination of various rays of coloured light corresponds to the sum of those rays, and the colour obtained by the admixture of pigments is determined by the sum of the rays which are absorbed. But, as the same laws apply to both cases, there appears to be no reason at present why the result obtained by adding up the sum of the rays should not also apply to the admixture of pigments. Red light combined with blue gives violet; a red pigment absorbs the green rays, and a blue pigment the yellow. A mixture of both would therefore absorb yellow-green, and the complementary to this is also violet.

It must be remembered, of course, that in combining rays of light the intensity is increased, and that, at the same time, more or less white light is produced, according to the colours which are combined. On the

other hand, in mixing pigments, degradation ensues, and a certain amount of black is formed.

Experience teaches us, in fact, that the admixture of pigments corresponds in tone to that of their colour rays, and instances are frequently cited as deviations from the law of the combination of colours, which should certainly not be so described. For example, there is a rather widespread opinion that blue and yellow pigments always form green, whilst blue and yellow rays of light in combination produce a sensation of white. But this is only an apparent difference caused by want of precision in the definition of "blue" and "yellow." Pure blue and yellow, as shades of colour corresponding approximately with the colours of the spectrum, of wave-lengths 578 and 475, always form a colourless combination. These colours give white in combination, and pigments of the same tone, such as ultramarine and chrome yellow, form grey or black when mixed. On the other hand, a greenish-blue mixed with yellow forms green; but rays of light yield a whitish tone, whilst pigments, such as Paris blue and chrome yellow, yield a blackish tone.

But there is no doubt that all pigments do not conform to the laws of the combination of light rays, as shown by the instance given at the outset. Further consideration teaches us, however, that deviation from the rules of combination can only occur if the absorption bands of both colours partially overlap, because the increase of absorption at every part of the spectrum can only make itself apparent within certain limits, and any further intensification has no influence upon the colour. For instance, if certain rays are absent from the light reflected from a pigment, they cannot be absorbed by a second pigment, and their agreement with the law of combination will be disturbed.

Vermilion, for example, reflects only spectral red and orange from incident light, and, if it is mixed with pure blue, the yellow and the adjacent spectrum colours will be absorbed. The absorption which occurs in the yellow will no longer be operative, and the mixture will appear to be blackish-red, consequently brown; but, if double absorption become apparent in the yellow, it would produce the complementary colour, blue, and the mixture would appear violet.

If a red pigment be used, whose bands of absorption lie only in the green and blue-green, we find its mixture with a blue pigment will actually appear violet, as both bands of absorption do not clash.

The knowledge of this fact leads up to the general proposition: If the bands of absorption do not clash when two pigments are mixed, the resultant tone will agree with the law of colour combination. The form and extent of the bands of absorption are of no consequence, neither is the circumstance whether they comprise one or more divisions.

The shade of the mixed pigment will always be the same as that obtained from the combination of similar-coloured rays of light, and, by constant alteration of the quantity of a pigment, the colour of the mixture will also be altered.

If this condition be true, the law governing the combination of coloured

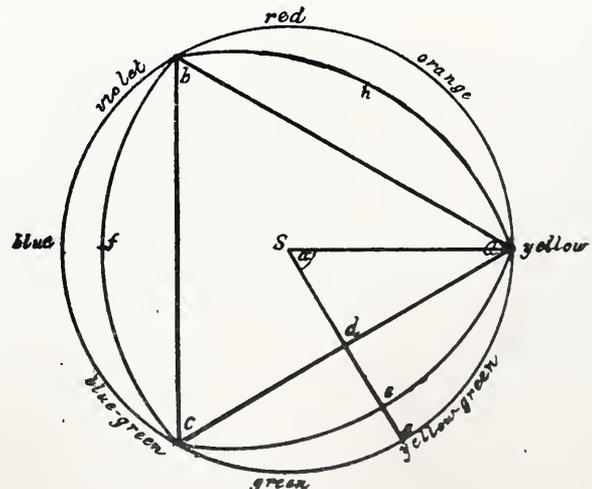

Fig. 1.

rays will also hold good for pigments: "Constituents of similar appearance will produce mixtures of similar appearance."

From these considerations the author has applied the geometrical representation of the law of combination of coloured light to pigments. Upon the circumference of a circle Hering's four primary colours are spread—red, yellow, green, and blue (fig. 1). These are supposed to

be of equal purity and intensity, and situate at  $90^\circ$  from each other. The centre of the circles, *s*, is black, and each radius represents the quantity of black mixed with each corresponding colour at the circumference.

For this colour chart to be of universal application, there should be no clashing of the bands of absorption when any two or more colours are combined, be they taken from the circumference or the surface of the disc. This condition will only be fulfilled if each pigment at the circumference give a single-absorption band in the form of a stripe, lying, of course, in that part of the spectrum representing the complementary colour.

Such pigments are found almost exclusively in the group of tar colours, but they must be used only in moderate intensity, as the band of absorption otherwise grows rapidly in breadth.

Only in the selection of the yellow-green and the pure green pigments do we encounter insurmountable difficulty, as there is not, even amongst the tar colours, any pigment of this colour with only a narrow band of absorption. This should lie in the purple, and rays of this colour are absolutely wanting in white light, because the eye is incapable of perceiving rays of light of this wave-length. The elements of white light, therefore, do not comprise the whole circle of our colour sensations, and this circumstance is the cause of deviations from the regular law in the case of certain mixed colours.

As the violet also is so slightly represented in the spectrum that it plays no part in the colour of pigments, we find that all green pigments show a double band of red and blue in the spectrum, instead of absorption in the purple. In consequence of this we find that moderate additions of yellow or blue pigments scarcely affect their appearance. The double absorption to which we have referred comes about in this way, and it has scarcely any influence upon the colour of the mixture.

But another consequence of the spectrum peculiarity of all green pigments is much more remarkable. It concerns the purity of their mixed colours, and, as these conditions have not been taken into consideration yet, they demand a more thorough investigation.

We have already mentioned that, in addition to the new shade of colour, a certain amount of black is also formed when pigments are mixed, and its quantity is equal to that of the white light formed when colour rays are combined under similar conditions. This conclusion is easily arrived at if we watch the course of both sets of phenomena. The greater the distance separating the colours upon the colour disc, the greater will their visual difference be, and the blacker their resultant tone. The quantity of black simultaneously formed may be taken from the colour chart. If pigments with broad bands of absorption are used, a larger quantity of black will be formed, and this is more especially the case if the new band of absorption affects complementary parts of the spectrum. Precisely the same thing is observed when we combine coloured rays of light. The colour of the combined light is whiter than that of simple rays, and the quantity of white is especially large when complementary colours are included in the combination.

On this account it is impossible to produce yellow by mixing green and orange pigments, since a substance must reflect spectral red and green in addition to yellow in order to appear yellow. The latter is, however, excluded from any mixture containing a green pigment, for the reasons we have stated. The band of absorption of the mixture is situate in the complementary colours, red and blue-green, and so much black is therefore produced that the yellow, which is formed, is scarcely perceptible.

The same phenomenon is also observed when green and blue pigments are mixed. Owing to the preponderating blackness of the mixture, the sensation of "blue-green" is almost destroyed in this case also.

Pure blue-green is a colour seldom met with. The splendour of the peacock's feather may be ascribed to it, and the peculiar delight we feel in looking at a clear mountain stream or a crevasse is in no small measure due to its peculiarity of colour. This blue-green can never be mistaken for a mixed blue-green, and is as far removed from it as a pure yellow is from a mixed yellowish-brown formed from orange and yellow-green.

Pure blue-green is only seen when the object reflects, in addition to these rays, all the blue and all the green, but this cannot be the case when a green pigment enters into the mixture.

The inability of the eye to see pure purple rays is due to the fact that there is no green pigment from which yellow and blue-green may be compounded, and the correctness of the colour chart ceases as soon as green enters into a mixed colour.

For all other parts of the coloured disc pigments may be found which will yield that quantity of black when they are mixed that the law of the colour chart expresses; but a peculiar phenomenon may be observed,

which appears to call in question the correctness of the geometrical representation.

For example, if we mix equal parts of the pigments at *a* and *c*, which are separated from each other by  $120^\circ$ , the result is blackish-green lying at *d*, which is also obtained by combining the pure colour, *g*, of the circumference with black. As the angle  $\alpha = 60^\circ$ , the mixed colour, *d*, consists of 0.485 parts of pure green, *g*, and 0.515 parts of black.

This deduction from the theory is not, however, confirmed by experience, as it is possible to produce a very pure green by mixing blue-green and yellow. We thus meet with a contradiction between theory and experience, but this may be explained by the circumstance that the addition of black to a pure pigment does not have a visual effect proportional to the ratio of the admixture.

The effect may be observed by mixing white with black. If we add 10 to 20 per cent. of black, we scarcely perceive any marked degradation unless we compare it with some pure white object. Equal parts of white and black rotated upon a Newton's disc have the appearance of light grey, and the shade does not by any means appear to be midway between black and white. Not until we mix about twenty parts of white with eighty parts of black do we obtain a colour which may be called "medium" grey.

A white surface, covered with fine lines or a dotted network, gives an entirely different impression. Such a surface has a brightness determined by the relative quantities of white and black, and gives the impression of "medium" grey when the black lines occupy the same amount of space as the intervening white.

There is evidently a difference between objective brightness and subjective sensation. In looking at the ruled or dotted surface, a portion of the retina is deprived of its sensation of white by the black lines, and consequently the feeling corresponds to the quantity of white actually present, whilst the differences in brightness of homogeneous colour surfaces are not proportional to the white which may be present.

It will be remembered that Fechner has elucidated the interdependence of objective brightness and subjective sensation as a law. By comparing the tints of ruled surfaces with homogeneous mixed greys upon a rotated Newton's disc, the correctness of Fechner's law could be immediately confirmed.

For this purpose a scale of five different degrees of brightness was made by drawing upon paper black lines of various breadth, ranging from 0.05 mm. to 0.40 mm., and by measurement of their breadth and that of the intervening spaces the brightness of the screens could be determined. With the aid of two discs of white and black paper fixed upon a whirler, the tint of these lines was imitated. The angle of the white sector was measured, and the brightness of the homogeneous grey calculated from it.

The tones of the ruled screens were observed at such a distance that the lines were still perfectly distinguishable. The surface did not appear homogeneous, but, with a little practice and frequent repetition of the experiment, the comparison could be made without much difficulty. The objective brightness of the grey formed upon the rotating disc was determined by its components, and, by means of the ruled screen of corresponding brightness, the subjective sensation was ascertained.

The following table gives the mean values obtained from a number of experiments:—

Grey formed on the disc, composed of		Objective brightness of the surface of the disc.	Ruled screen of same brightness in proportional parts.		Objective and subjective brightness of the ruled surface.
White.	Black.		White.	Black.	
$35^\circ$	$325^\circ$	0.10	10	20	0.33
$60^\circ$	$300^\circ$	0.17	14	14	0.50
$90^\circ$	$270^\circ$	0.25	18	10	0.64
$135^\circ$	$225^\circ$	0.37	22	6	0.78
$230^\circ$	$130^\circ$	0.64	30	2	0.94

As may be seen, the homogeneous grey always appears to be much brighter than it actually is, according to the amount of black in its composition.

These proportions are more clearly seen if the results of the experiments are expressed graphically. In fig. 2 the abscissæ are the objective brightness of the mixtures on the rotating disc, and the ordinates the corresponding subjective sensations. If the subjective and objective brightness were equal, the degree of their composition would be deter-

mined by  $oa$ , in which case the brightness, 0.5, of the rotating disc would correspond to a screen tone composed of equal parts of black and white.

The curve shown in the diagram has the appearance of a logarithmic line of the universal form:—  
 $y = C_1 \log x + C_2$ ,

and, by calculation, the coefficients,  $C_1 = 0.79$  and  $C_2 = 1.11$ , were determined.

However, it appears that the value of these coefficients may be partly dependent upon the individuality of the observer, which might also be explained by the fact that a certain amount of consideration is necessary in comparing the surface of the screen with the homogeneous grey.

The subjective sensation of brightness therefore increases in logarithmic progression with the objective brightness, as required by

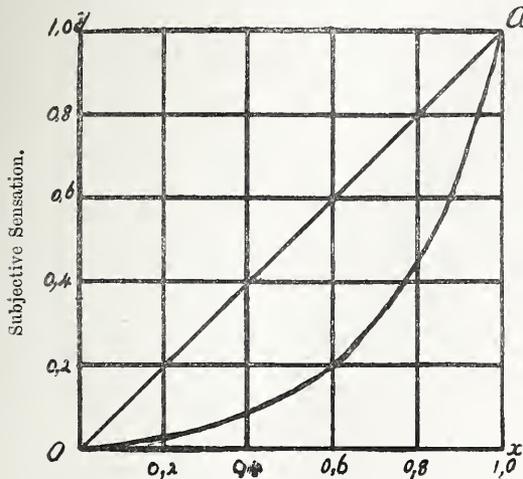

Fig. 2.—Objective Brightness.

Fechner's psycho-physical law. A grey composed of 3.5 parts of white and 7.5 parts of black, for instance, appears twice as bright as it should be, and we only see one-fourth of the black in a mixture composed of equal parts of black and white.

It may be inferred that, in mixing black with other pigments, similar phenomena occur, in which case it would be necessary to determine how far the law is influenced by the brightness of the colour.

In any case these conditions are of the highest importance in the mixture of pigments, as only a portion of the black entering into their composition is perceived, and they consequently seem purer than they are in fact.

Green obtained by mixing equal parts of Paris blue and chrome yellow contains, according to the law of colour composition, about 75 per cent. of black, a quantity which is justified, if we consider that both pigments are separated from each other by 150°. If our sensations followed the law of composition, only a greenish-grey would be obtained from the union of these pigments; but, since the addition of 75 per cent. of black only produces a subjective brightness of 0.64, the sensation of black is so much reduced that the mixed green appears to be sufficiently pure.

The conditions are more favourable still for two colours separated from each other upon the colour disc by 120°. The quantity of black contained by the intermediate mixed colour, as shown above, is 52 per cent., and it should really excite a sensation midway between that colour and black. But this is by no means the case, for a mixture of 52 per cent. of black excites a subjective brightness of nearly 0.9, and it therefore appears as though it were only degraded with 10 per cent. of black. We consequently obtain a green shade, which does not correspond in appearance with point  $d$  of the colour chart, but rather with  $e$ , which is much further removed from black.

If we determine similarly the subjective purity of all the colours situate upon the line of mixture,  $ac$ , we obtain the curve,  $ace$ , according to which they should be classified by their appearance.

From this examination of the behaviour of pigments when mixed, a number of important deductions of various kinds may be made for technical purposes.

Pigments which are to be mixed should not be selected by appearance only, but their spectroscopic peculiarities should be considered, and it is not permissible to modify their tone by indiscriminately adding other pigments.

Yellow and peacock-blue cannot be formed by mixture, and they should

consequently be regarded as primary colours, technically. If the largest possible number of mixed colours has to be produced from a small number of pigments, the primary colours should be selected at equal distances on the colour disc, as the purity of the mixed shades will then be secured equally in all directions.

The mixed colours appear to be much purer than they are by the law of their composition, and, but for this peculiarity of our sensations, the art of the painter and the process of chromo-lithography would be impossible.

For these reasons, three sufficiently pure pigments are enough to reproduce every shade of colour required in practice. They must be selected at distances of 120° upon the colour disc, and, as yellow and peacock-blue are at this distance from each other, it follows that purple is a primary colour. From these three pigments, situate at  $a$ ,  $b$ , and  $c$  (fig. 1), not only all the colours enclosed by the triangle  $abc$ , but also all the tones comprised within the curves,  $e$ ,  $f$ , and  $h$ , may be obtained by mixture.

This fact is of the highest importance for three-colour printing by photography. It is well known that by this process three monochrome pictures may be made in the primary colours, which, by superposition, will combine and form a perfect colour picture.

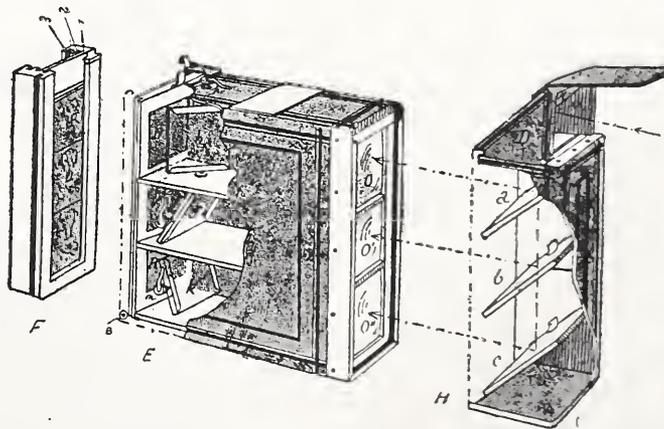

The three monochrome pictures are obtained by photography. The optical image is formed upon three photographic plates, each of which is only sensitive to a definite region of the spectrum, and from the negatives thus obtained the monochrome pictures are produced. The coloured rays reflected by the pigments are reduced to three by decomposition, and the colour sensation excited by each is represented by a pigment. It is evident that the process is only possible if the decomposition and combination of coloured rays of light are governed by the same laws as those of pigments. As pigments can be found, in the manner we have shown above, which behave in the same way as coloured light, a three-colour printing process, perfect in all respects, is a possibility.

BARON ARTHUR VON HÜBL.

THE MELANO-CHROMOSCOPE.

We have already recorded the introduction of this instrument, which has been devised by M. Louis Ducos du Hauron for three-colour work. We extract the following description and illustrations from *Les Nouvelles Scientifiques et Photographiques*, which explains its construction.

The Melano-chromoscope is composed of three distinct parts:  $E$ , the body, which is a kind of camera, carrying the lenses,  $o$ ,  $o'$ ,  $o''$ ; the glaces, which reverse the images,  $h$ ,  $j$ ,  $k$ ; and the frame carrying the colour filters,  $B$  (blue),  $V$  (green), and  $R$  (red), and it is divided into three compartments, as shown where partly in section. The front portion,  $H$

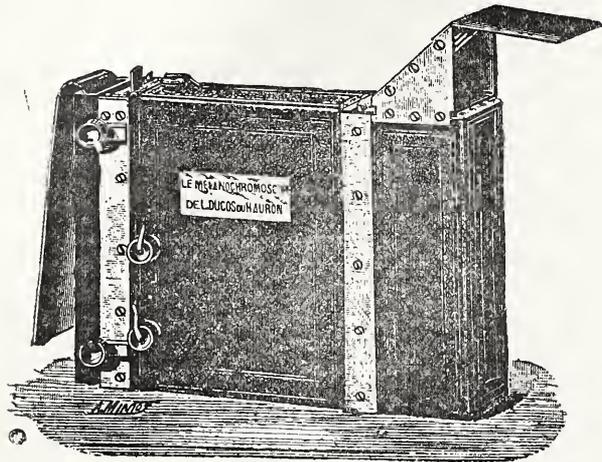

fits on to the camera,  $E$ , by means of grooves, and this carries two plain glasses,  $a$ ,  $b$ , inclined at 45°, and a mirror,  $c$ , also inclined to the same angle; on top is the hood,  $D$ , surmounted by a sky shade, and furnished with a mirror,  $M$ , at an angle of 45°, which is used to reverse the images for the negative-taking.

The back portion,  $F$ , is a frame with three grooves, 1, 2, 3; the first is for the positive, the second for a grey glass to reduce the red image, the third for a ground glass to diffuse the light.

In order to take the negative, a panchromatic plate is placed in a dark slide at the back of the camera, against the colour screens. An actinometer is issued with the instrument to enable one to gauge the exposure, but with a yellow screen this is in sunlight about 120 seconds.

The rays proceeding from the object, after reflection from the mirror, *m*, in the hood, *d*, traverse a circular aperture, not shown in the diagram, and fall on the glass, *a*, and are thence partially reflected and traverse the objective, *o*, and form the blue negative, the remainder of the rays passing through this glass on to the second, *b*, and there undergo the same phenomenon, and the reflected part forms the green negative, and finally the remainder of the rays, after having traversed the two glasses, are entirely reflected by the mirror, *c*, through the objective, *o'*, to form the red negative.

The plate is, of course, developed as usual, a positive made by contact

therefrom, and this is placed in the groove, *l*, of the frame, *F*, which is attached to the body. The hood, *d*, is removed, and an eyepiece put in its place, which can be focussed on the frame, *F*. If the red image is too brilliant, a grey glass is placed behind it in the second groove. To ensure the absolute coincidence of the three images, the three glasses, *h*, *j*, *k*, which turn on their axes, are placed in the back of the body, *E*, and are actuated by the three screws outside, *m*, *n*, *h*.

The firm of M. L. Lesueur & Ducos du Hauron, of 22 Rue Rambuteau, Paris, are placing this on the market.

### PHOSPHORESCENCE.

ON Wednesday evening, the 3rd inst., Mr. Herbert Jackson delivered the first lecture of his course, addressed to a juvenile audience, at the Society of Arts, the subject being "The Phenomena of Phosphorescence."

The lecturer commenced by a reference to the natural sources of phosphorescence, as seen in the sea and in some cases of animal decay, &c. Phosphorescence and fluorescence might be treated as identical terms. They were illustrated by the exhibition of a phosphorescent jet of steam from a vessel containing water and phosphorus, and of the effect produced by sprinkling fluor spar on a heated plate. He then proceeded to show how there were certain substances which showed light, generally of a yellowish or greenish colour, when exposed to the more refrangible rays—the rays at the violet end of the spectrum—and showed how the visible spectrum was apparently extended in length when the violet and ultra-violet rays fell on a surface prepared with such materials as sulphate of quinine or thallene. On passing a slab of uranium glass along the spectrum, it was made manifest that no effect was produced on the glass by the red end, whereas, as soon as it was placed in the violet rays, it glowed with its characteristic greenish-yellow colour. The phosphorescence of quinine and of fluoresceine, when the solution was dropped into a tall jar of water, was also shown, and further illustrated by burning sulphur in oxygen in a jar immersed within a larger jar filled with the phosphorescent solution. The phosphorescence of such materials only lasted while the exciting cause was present, but there were other materials which continued to emit light after the exciting light had been withdrawn. Of these, possibly the best known was Balmain's luminous paint. A card coated with this was exhibited, and it was shown how the brightness of the phosphorescence was temporarily increased by heat and diminished by cold. It was, however, possible to make other similar substances which acted in the same way, but showed light of different colours; and Mr. Jackson exhibited a fine series of phosphorescent bodies, principally lime salts, which, when excited by the brilliant discharge from a large induction coil, glowed for a certain time

with various tints, blue, yellowish-green, and pinkish-red. Phosphorescence could be produced in a block of lime, such as that used for the limelight, but it was of very short duration. If, however, such a block were rapidly rotated in the close neighbourhood of the induction discharge, the phosphorescence produced by the discharge lasted long enough to be perceived on the side of the lime turned away from the spark as it rotated. After this the lecturer passed to the phosphorescent effects produced by the electrical discharge in vacuous tubes, and showed the very beautiful results in a long tube, in which a spark from an induction coil was passed, as the air and the various gases with which the tube was filled were gradually exhausted.

### THE THREE-COLOUR PROCESS IN THE MAGAZINES.

THE writer of the weekly notes on "Arts and Artists" in the *Daily Chronicle* is not favourably impressed with the three-colour process for purposes of artistic illustration. The colour prints, he says, is the fashion of the moment in illustration. This month, he adds, both the *Magazine of Art* and the *Studio* make a special feature of it. By way of showing its possibilities, the *Studio* reproduces first a pastel by Sisley, and then a water colour by Mr. Charles Robinson. The *Magazine of Art* experiments in a different direction, and gives a reproduction of a wood block in colour by Mr. Edward Detmold. The other illustrated monthlies are using colour more and more, even for the drawings printed in the text, which means an additional expense we are afraid the casual reader does not appreciate. Lately, the American magazines—the *Century*, *Harper's*, *Scribner's*—have been full of colour prints. The critic proceeds: "We believe in experimenting. Without experiment process or mechanical engraving, which was despised at the start, could never have been developed to its present perfection. But we think the colour print experiments have begun at the wrong end. Publishers and editors, as a rule, are trying to do too much, before even very little can be done well. As yet, the results of the three-colour processes are rarely successful, that is, from the artist's standpoint, wonderful as they may be scientifically. Colour is muddy, subtleties are lost, delicate tone vanishes. There are certain ways in which colour can be introduced satisfactorily. Take a chalk drawing on tinted paper, like Mr. Waterhouse's 'Study of a Head' in the *Studio*. The effect could not have been rendered so truly without the blue tint. This is excellent, in every respect better than the more ambitious attempts, but so simple, it is not called a colour print at all. The *Century* has been trying something of the kind by using a yellow tint, but with slightly more elaboration, the whites being cut out—a method that would answer very well for chalk or pencil drawings, heightened with white on tinted paper. It may be said that this is nothing new—it is only borrowing a hint, borrowed before, from the lithographer of thirty or forty years ago—and novelty is what is wanted. But there are still a few people left who want a thing to be good, whether it is new or old. When you come to colour carried a little or a great deal further, the trouble usually is that often the drawing or painting has not been made specially for reproduction, and it is as necessary to work for colour process as for ordinary process. This really is where the chief mistake is made. We do not mean to say that the artist should work down to the engraver and the printer. Not a bit of it. He should always keep a little in advance of them, so as to force them constantly to new effort and improvement; but he should know what they can do and what they cannot, and not ask them to accomplish the impossible, which is, after all, what happens when a pastel or a water colour, made without thought of reproduction, is handed over to the engraver. The colour print in illustration may have a great future before it, but we must confess that, up to the present, we should rather have a good reproduction of a good drawing, printed in good black ink on white paper, than all the colour the various processes have so far succeeded in giving.

### NEW EXPERIMENTS WITH LIPPMANN'S PROCESS.\*

WORKING with gelatine plates during this last summer was extraordinarily successful, and it proved that, if the approved formula† be followed, failure can hardly occur.

Our experiments were directed, in the first place, to simplify the preparation of the plates. The washing of the emulsion after the coating of the plates is by no means so simple when a large number (two dozen or

\* Continued from p. 822 (1899).

† Dr. R. Neubauss, *Die Farbenphotographie nach Lippmann's Verfahren*. Published by Wilhelm Knapp, Halle a/S., 1898. Price 3 marks.

more) of plates are to be prepared. The unwashed emulsion ripens very quickly. The coating of the plates must be done with the greatest speed, and there is always the danger that the plates first coated will be already dry on the marble slab, and that the films will be spoilt by the crystallising out of the excess of the salts before the whole of the plates have been coated. Moreover, especially in the cool of the year, the drying of the washed plates is accompanied by many inconveniences. Even when well whirled there will be formed on the washed plates, during drying, figures like the cells of the honey bee, by the remains of the liquids, which, by altering the sensitiveness of the gelatine film underneath, are unpleasantly noticeable on the developed plate. By using distilled water as the last washing water, and by the use of artificial heat in drying the plates, this fault can be partially, but not completely, obviated.

All this is avoided if the emulsion is washed, as in the preparation of very sensitive ordinary plates, before coating; but this method cannot be used with plates for Lippmann's process, as any ripening of the emulsion during a long washing has to be avoided. In his book, *Photographie in natürlichen Farben* (published by Wm. Knapp, Halle a/S., 1894), Valenta advises the precipitation of the emulsion by alcohol; that it should be broken up finely, washed, and again bringing it up to its original volume with water, and then, after the addition of the necessary dyes, coating the plate. Exclusive of the fact that this process is very costly in consequence of the large quantity of alcohol that must be used, we could never obtain satisfactory results with it. After several failures, another method gave us the best results: The mixed emulsion, with the dyes added, is made to set as quickly as possible by means of ice water, and is broken up by pressing through fine-meshed muslin. The breaking up must be much finer than with ordinary ripened emulsions, so that the washing may be done as quickly as possible. The broken-up emulsion should be placed in an emulsion filter, such as supplied by Braun (Berlin, Königgrätzer-strasse, 31). The larger mouth of this filter should be covered with muslin and one layer of fine white mull. Washing is effected as follows: The flask is quickly plunged in a pail filled with water, so that the larger mouth of the filter is underneath. Whilst the air escapes from the small opening, the water penetrates through the larger opening of the materials, with some force, into the filter, and stirs up the broken-up emulsion. As soon as the filter is full, it should be quickly raised from the pail so that the water runs out, and, in order to avoid the blocking up of the pores of the stuff by the gelatine, the filter should be vigorously shaken.

This process should be repeated for fifteen minutes and the emulsion is completely washed with safety. A trial showed that even after five minutes washing scarcely any noticeable trace of the excess salts was present in the emulsion. Finally half a litre of distilled water is poured through the smaller opening of the filter, and it should then be allowed to drain for two hours at least, in order to remove as much as possible the excess of water which is sucked by the emulsion as by a sponge. The last traces of water are driven out by a gentle pressure of air obtained by an indiarubber ball. After melting at about 35° C. the emulsion is ready for coating.]

Obviously, by washing, a portion of the dye is removed, but this also occurs when washing the coated plates. It would obviously therefore be more convenient to add the dye after washing; we never obtained satisfactory results, however, with such experiments. It appears as though certain constituents of the dyes must be washed out.

An emulsion thus prepared will keep from two to three weeks in a cool room. The most satisfactory point is that the washed emulsion does not subsequently ripen in a cool temperature; unwashed emulsion ripens even in the cold, so that even after two or three days it is quite useless for Lippmann's process. Washed emulsion, by which the preparation of plates in large quantities is rendered much easier, can be heated to 45° C. without its usefulness suffering, only at 50° does it become cloudy by ripening.

In the *Bulletin de la Société Française* (1890, No. 4), Professor Lippmann published his present method of emulsion preparation, which shows certain variations from the usual methods. Lippmann uses for sensitising a surprisingly large quantity of dye, especially cyanine. Whilst according to Valenta's formula 1:2 c. c. of cyanine solution (1:500) should be used for 100 c. c. of emulsion, Lippmann takes 6 c. c. of cyanine solution to the same quantity of emulsion, besides 3 c. c. of an alcoholic solution of chinoline red (1:500) for the green sensitising. Now, it obviously depends upon the duration and the vigour of the subsequent washing how much dye remains in the emulsion. It should be specially noted, too, that Lippmann uses an alcohol bath before washing.

By testing the quantities of dyes prescribed by Lippmann we could not determine that there was any improvement in the rendering of the

red by the copious addition of the cyanine. On the other hand, we gained the impression that the red sensitiveness suffered because the screening action of the dye came into play. However, the various preparations of cyanine behave very differently and, this ought to explain the variations in the results.

With regard to the quantity of silver nitrate and potassium bromide, Lippmann's formula does not sensibly differ from other formulæ, one is confined here to narrow limits. The author has determined that even with double the usual quantity of silver bromide useless plates were obtained.

Very peculiar is the method by which Lippmann adds the silver nitrate to the bromised gelatine solution. Whilst, according to the earlier formulæ, the potassium bromide and silver nitrate were dissolved in separate portions of gelatine solution, and then, with constant stirring, the gelatine solution added drop by drop to the bromised gelatine, Lippmann shakes the finely powdered and dry silver nitrate into the bromised gelatine. The author has proved that both processes give exactly the same results. We now use, however, Lippmann's process entirely, as it simplifies the preparation of the emulsion. Only one pot of gelatine is now necessary, whilst previously two were required.

The correct colour reproduction depends essentially on the correct sensitising of the plates by suitable dyes. For red sensitiveness cyanine alone comes into consideration, although it would be highly desirable to replace this uncertain dye, that keeps so badly, by a better one. Obviously have also other dyes been recommended for red sensitising; still, they are far behind cyanine in their action. We made especial experiments with the continually vaunted nigrosine B. (Beyer), and both with bathed and plates coloured with the emulsion; the red sensitiveness thus obtained was extremely poor. Its behaviour was least unfavourable when 6 c. c. of an alcoholic solution of nigrosin (1:500) were added to 100 c. c. of emulsion. With increased addition of dye, the red action was still worse.

The author's trial of adding the cyanine by bathing the finished plates was not satisfactory. The solution recommended by Hübl (*Photo. Rundschau*, 1899, Heft 6, p. 170) was used as follows:—

Aqueous dextrine solution, ten per cent. ....	400 c. c.
Alcohol .....	150 "
Borax solution (cold saturated) .....	20 "
Cyanine solution (1:500) .....	3 "

The results were still worse when the gelatine plates, like the albumen plates, were bathed in 2 c. c. of cyanine solution to 400 c. c. of water. There remains therefore nothing to do for the red sensitiveness but to add the cyanine to the emulsion. We use 3 c. c. cyanine solution (1:500) to 100 c. c. of emulsion.

For green sensitising the author had previously used erythrosine. Still, this dye is very unsuitable, because it only sensitises for yellow-green, whilst blue-green is neglected. This is particularly noticeable in taking compound colours by the preponderance of the yellow green. Considerably better results are obtained by the use of chinoline red, as used by Lippmann. The most excellent results, however, were obtained by glycinrot, to be obtained from Kinzelberger, of Prague, and which has been lately recommended by Valenta.\*

Valenta took 12 to 14 c. c. of a solution of glycinrot (1:500) to every 100 c. c. of emulsion. It is not here stated whether alcoholic or aqueous solutions were used. Previously alcoholic solutions have been used, but glycinrot will not dissolve in alcohol to a strength of 1:500, whilst its solubility in water is great.

The author instituted a long series of experiments with various additions of glycinrot, and always found excellent blue-green sensitising. With compound colours, however, yellow-green always remained deficient. Finally, a combination of cyanine, erythrosine, and glycinrot (this in saturated alcoholic solution), proved to be the best for the preparation of an actually panchromatic plate. To every 100 c. c. of emulsion was used—

Alcoholic cyanine solution (1:500) .....	3 c. c.
„ erythrosine solution (1:500) .....	2 "
„ glycinrot (saturated) .....	10 "

With emulsions thus coloured, under normal light conditions, with spectra and compound colours, the different colours from red to violet are rendered absolutely equal.

Whether this combination of dyes would give equally satisfactory results, as regards panchromatism, with highly sensitive emulsion, we have not yet worked out. Naturally must the quantity of dyes be altered,

\* *Photo. Corresp.*, 1899 Heft 9, p. 150.

since with Lippmann's emulsions, on account of the subsequent washing, large quantities of dye have to be taken.

The large addition of alcohol (15 c. c. to 100 c. c. emulsion) appears doubtful. Experience teaches, however, that it is not only harmless, but, on the contrary, is very advantageous, since in this way extremely fine-grained and clear emulsions are obtained. A striking phenomenon is observed in the preparation of the emulsion: if the cold alcoholic dye solutions are poured into the warm emulsion, there will be an increase in temperature of at least 1.5° C. If, therefore, in the preparation of the emulsion the temperature of 40° C is not to be overstepped, the temperature of the emulsion before the addition of the dye solutions should not be more than 38° C.

(To be continued.)

## DIRECT POSITIVES IN THE CAMERA.

Messrs. J. E. Thornton and C. F. S. Rothwell have patented a process to enable positive pictures to be produced direct, by developing, fixing, whitening, and washing the colloid sensitised surface that has been exposed in the camera, thus dispensing with all subsequent processes, such as printing, toning, and washing of a positive prepared from a negative.

They add: "A positive picture thus obtained may at once be mounted in a frame, or on a card or other suitable mount. The process will be of great convenience to tourists, travellers, and others, as they may see the finished picture before leaving the scene of operations.

"Owing to the fact that such a positive image is required only on the surface of the film, and very much weaker for viewing by transmitted light than a negative image, which is required or used for printing, a much shorter exposure is necessary to produce a perfect picture; in fact, an exposure of half the duration necessary for the usual processes has been found sufficient by us. This reducing or shortening of the exposure is of great advantage to photographers, as it often occurs that sufficient exposure cannot be obtained under some conditions of light and subject to produce negatives with the existing rapidity of lenses and speed of gelatino-bromide emulsions. It therefore follows that a process by which results are obtained with half the exposure hitherto required will often, under adverse conditions, render good results where otherwise no results of value would have been obtainable.

"This invention consists essentially in a photographic receiving film, or plate, comprising a transparent gelatino-bromide emulsion coated on an opaque flexible backing, such as black paper, celluloid, or other similar material, which, when exposed in the camera, is developed and fixed, and afterwards treated with a whitening solution. The black or coloured base forms by its colour the dark portions of the picture, the shades and light portions being formed by the varying layers of white-coloured deposit which form the image. The sensitive coating we find may be very thin, much thinner than is usual in the ordinary process, as by our process the images do not require to be of such an intense nature when developed, as they are further reinforced during the process of whitening the image. For the same reason a shorter exposure may be given in the camera.

"In the preparation of the flexible sensitised film, or plate, it is possible to vary the process of manufacture, according to the exact requirements of the user, without departing from the principle of the invention.

"In its simplest form it is sufficient to coat the sensitive gelatino-bromide emulsion directly upon the black or coloured paper. In other cases we may use a white or non-opaque paper, and coat it with a suitable coloured substratum before applying the sensitive gelatino-bromide emulsion. Such a suitable substratum is celluloid, gelatine, or other like substance, with which is incorporated a pigment of suitable colour. An advantage of this latter method is that any suitable kind of surface may be given to the paper as a support for the sensitised emulsion.

"The surface of the flexible or paper backing may be so hard that the image, when developed, will not partially 'sink' into the pores of the paper; the surface may be very glossy, bright, and smooth, giving the picture similar characteristics; or it may have a grain which will give the picture a matt or dead appearance. It is often desirable to calender the prepared backing before coating with emulsion.

"In any case it is important that the sensitive coating shall be on the surface of the black or coloured-paper backing only, and shall not be allowed to penetrate into the pores or substance of the film base in order to prevent the image upon the exceedingly thin and fine sensitive coating from sinking as aforesaid, which would otherwise not only give the picture a rough surface, but also a dirty and indistinct appearance, with insufficient contrasts between the high lights and deepest shadows. Therefore, the black or coloured-paper backing must either be sufficiently waterproof and hard on the surface, or otherwise be rendered so with suitable resinous or other varnish, before applying the sensitive emulsion. For this reason we prefer always to apply such a varnish unless we use an opaque

backing such as black or coloured celluloid or other flexible material that already possesses a sufficiently hard or non-absorbent surface.

"A suitable positive film may be built up as follows:—

- A. Black or coloured paper backing or base.  
Sensitised gelatino-bromide layer.
- B. Paper backing or base.  
Black or coloured waterproof layer.  
Sensitised gelatino-bromide layer.

"Films made according to this invention are conveniently supplied in lengths, wound on spools for roll-holders and cameras, and, by reason of their opaque backing, can be loaded into such exposure apparatus in daylight without a dark room.

"They may also be made in sheets for use in dark slides, magazines, and similar apparatus.

"In use, the photographer who produces the picture places the sensitised positive film in the camera for exposure, and, after an exposure of very short duration, the picture is developed by means of any of the ordinary photographic developers, preference being given to those which have little or no staining action upon the film, as, for example, hydroquinone, glycin, or metol. After developing the picture until all the image is clearly seen and of sufficient density or strength, it is fixed (that is to say, the unused silver salts are removed) by placing the picture in a solution of hyposulphite of soda of a suitable strength. We find in practice a ten to twenty per cent. solution acts well, but it may be stronger or weaker than this. Any other suitable fixer, such as cyanide of potassium, for instance, may be used. The fixing solution is afterwards removed from the film by washing in the usual way.

"The film carrying the picture (which is now only just visible) is immersed in a solution composed of mercuric bichloride, with or without the addition of ammonium chloride, salt, hydrochloric acid, sulphuric acid, or potassium bromide until the picture is whitened sufficiently. We thus obtain a picture composed of a light deposit, on a ground varying in colour according to the colour of the film base used.

"Instead of using mercuric bichloride we may attain the same end by the use of bromide of copper, cupric chloride, ferric chloride, or any other chemical which, when acting upon the silver image, converts it into a white or light-coloured condition. After whitening, the picture is finally washed and then dried, which latter operation may be assisted by heat if quick drying is required."

Messrs. Thornton & Rothwell conclude: "We are aware that positive pictures have been made direct in the camera by a sensitised collodion on metal previously prepared with a black varnish, but in the present state of knowledge of the photographic art such a film is too slow for the requirements of modern instantaneous photography, and cannot be rolled up on spools, and it is only by combining a gelatino-bromide emulsion with a black or coloured backing, and by whitening the image after development, that the necessary requirements of a good, cheap, and instantaneous positive film, which may be wound on rolls or used in flat cut pieces are fulfilled. This is what our invention renders possible and actually accomplishes, and as such it constitutes a new step or advance in the art of photography."

## NOTES FROM THE WEST OF SCOTLAND.

CHRISTMAS and New-year weeks among photographers in the West of Scotland have always been looked forward to with eagerness by reason of the annual Exhibition of work by members of the Glasgow and West of Scotland Amateur Association, at which all important work executed during the previous year was generally displayed. This year, however, the Council has made a fresh departure in their annual fixture. Instead of having the Exhibition during the holiday weeks, they have decided upon postponing the Exhibition until the first week in February, a change which is expected to work in several ways more satisfactorily, especially in regard to there being a larger attendance of members and the public, many of whom, from private reasons, are called away during the Christmas holidays.

At the forthcoming Exhibition, which opens on February 2 next, the judging will be effected by the vote of the members of the Association.

A movement has been set on foot to form an optical association in Glasgow, the object being to bring the various opticians more in touch with each other, and to discuss matters more particularly of interest to the optical trade. The movement emanated, we understand, with Mr. Sam Fulton, of Messrs. Gardner & Co., and the idea is well entertained by several of our leading opticians; among others, Mr. Matthew Ballantyne, of Messrs. Lizars', strongly favouring the scheme.

There has been, so far as the season has gone, an enormous run on the cinematograph, and those firms who saw fit to cater more especially for this class of entertainment have far more orders placed before them than they can execute. No doubt, the fact that several firms who had previously catered for such with the public, but who gave the business up last season, has had much to do with the rush that has been thrown upon the few who continue to make a specialty of the cinematograph.

## Our Editorial Table.

SHARLAND'S *New Zealand Photographer*, which is published at Auckland, New Zealand, and 43, London Wall, London, E.C., begins a new series with the January issue, a copy of which is now before us. It contains many articles on practical photographic subjects, illustrations, &c. The section "Current market quotations, in New Zealand, for photographic requisites, should be found useful for reference. Quarter-plates are 1s. 3d. and 1s. 4d. per doz.; silver nitrate, 3s. 6d. per oz.; hypo, 4 lbs. for 1s.; metal, 4s. per oz.; and so forth. We welcome our *New Zealand Photographer*, and wish it a long and prosperous career.

Mr. S. H. Fry, of 12, South Villas, Camden-square, N.W., sends us his Almanack and Date Card for 1900. It is a pretty as well as a useful office adjunct, for it is embellished with a capital carbon print from a negative by Messrs. Byrne & Co., of Richmond, Surrey.

FROM Messrs. Ede & Allom, the well-known printers, we have also received a number of Date Cards for 1900. These are tasteful and effective in design, and, like all the firm's work, beautifully turned out.

ONE of the Christmas cards that we have not yet acknowledged, and that demands both special and separate recognition, was sent us by Messrs. Mayall & Newman, Limited, photographers, of 91, King's-road, Brighton. It is a beautifully framed portrait of an individual, who need not be particularly indicated here. Let it, however, be said that those most qualified to pass an opinion pronounce the likeness a remarkably faithful one, and declare the facial expression of the sitter to be happy and characteristic. In thanking Messrs. Mayall & Newman for the portrait, which is a very fine specimen of artistic photography, we may say that the interest which others, besides ourselves, take in the original will ensure it the best possible reception—namely, permanent preservation.

### THE LANCET PRINT-TRIMMERS.

Manufactured by R. & J. Beck, 68, Cornhill, E.C.

FOR sevenpence Messrs. Beck supply the photographer with a holder and a box of twelve "trimmers," resembling miniature blades, which can be used for the purposes of trimming and cutting prints. We have put the little trimmers to practical use, and perceive that the photographer should find them of great service.

By the courtesy of the Editors of our esteemed contemporary, the *Photogram*, we have been made the recipients of the bound volume of that admirable publication for 1899. With its wealth of beautiful illustrations and well-chosen articles it makes a superb gift-book for a photographer.

## News and Notes.

THE headquarters of the Bootle Photographic Society are at 168, Strand-road, Bootle, and not at the address given in our ALMANAC just published.

ROYAL PHOTOGRAPHIC SOCIETY.—Photo-mechanical Meeting, Tuesday, January 16, at 66, Russell-square, W.C., at eight p.m. "Screen Gears for Half-tone," by W. Gamble.

PHOTOGRAPHIC CLUB.—Wednesday evening, January 17, at eight o'clock, "Lantern-slide Making without a Dark Room on Kristal Plates, and a Series of Views of Venice," by B. J. Edwards & Co.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the meeting on Thursday, January 18, Mr. E. Hunt will demonstrate "Photogravure." Visitors will be cordially welcomed at the White Swan, Tudor-street, E.C.

WE are sorry to learn of the death, on the 2nd instant, of Mr. W. F. Mills, at the age of seventy-nine. Deceased passed away at his residence, Markham-square, and was cremated at Woking on Friday. Mr. Mills will be remembered as the head of the business of Messrs. Newman, artists and photographers' colourmen, Soho-square.

THE Fifth Annual Bohemian Concert of the *employés* of Mr. J. Fallowfield will be held on Friday evening, February 16 next, at the Champion Hotel, Aldersgate-street, E.C. Mr. F. W. Hindley will preside. The Hon. Secretaryship is again in the capable hands of Mr. F. J. Goode, and an enjoyable evening may therefore be anticipated.

THE HUDDERSFIELD EXHIBITION.—Mr. A. G. Lockett, the Curator of the Art Gallery, Huddersfield, writes that he has had a communication from Mr. Reginald Craigie, Secretary to the "Linked Ring," to the effect that, contrary to anticipation, very few of the "Ring" exhibits (in the second room of the Art Gallery) will be required for the Paris Exhibition, as the exhibitors are sending duplicates for exhibition there. This means that the present exhibition in the Art Gallery will remain open almost in its entirety until the end of this month. There have been up to the present twenty-three pictures sold, exclusive of two extra copies of one, and one of another.

THE *University Correspondent* has published its annual crop of amusing mistakes made by schoolboys in answers to examination questions. The following answers, selected from many similar ones, show how easy it is for pupils to receive inaccurate and confused impressions when given didactic instruction, and also how essential it is that examination questions should be explicit: "When would you expect an eclipse of the sun to take place?" "In the night." "The sun never sets on English possessions, because the sun sets in the west, and our colonies are in the north, south, and east." "The experts of Ceylon are peculiar to any other part of the world. The chief are piano steamers (sc. P. and O. steamer)." "A cubic foot of water weighs 64 lbs.; ∴ a square foot of water weighs 16 lb., and a foot of water weighs 4 lb." "The three principal parts of the eye are the pupil, the moat, and the beam." "A mariner's compass is a little poast stuck up in the sea, and, when people want to know the way, the ships go and look at it."

PHOTOGRAPHY FOR ARCHITECTS.—To the professional and practising architect photography is, if anything, of even more value than to the student, for by it he has the power of recording, at all stages, the progress of his works in course of construction, and their final effect when completed and ready to leave his hands. Most architects who have been in practice for any length of time would probably value a complete collection of photographs of their works very much indeed, and such a collection, especially if accompanied by reduced photographs of the plans, would also be very useful for showing to clients, who rarely understand geometrical drawings by themselves, and seldom gather from them a correct idea of the buildings they represent. It is also often of great convenience to be able to produce quickly and in quantity reduced copies of plans, elevations, and perspectives for purposes of publication or transmission to a distance, and this also can be done by the architect, who is his own photographer, without the drawings leaving the office, and without the errors which too often occur when any chance professional not familiar with this kind of work is called in. When rebuilding has to be done, photography is often also of use, not only for preserving a record of the original edifice and its surroundings, but also for providing evidence on legal points which may arise on such matters as ancient lights, damage to adjacent property, &c. Cracks in walls may, for instance, be carefully photographed from time to time for the purpose of seeing if they extend or widen in consequence of any alterations in progress; subsidences may be detected and recorded, and other data of much value be obtained by the use of the camera.—"D. B." in the *Builder*.

### ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 9,—Ordinary Meeting,—Mr. Chapman Jones, F.I.C., F.C.S. (Vice-President), in the chair.

#### NEW MEMBERS, &c.

Ten new members were elected, and three candidates for membership were nominated.

The CHAIRMAN announced that the following members had been admitted as

Fellows, viz., G. T. Harris, J. E. Hodd, Professor Smiley, W. T. Greatbatch, W. B. Ferguson, Q.C., and B. L. Warren; also, that the Dudley Camera Club had been admitted to affiliation.

#### SCRUTINEERS.

The following members were appointed to act as scrutineers at the forthcoming election of Council and officers, viz., Messrs. R. Beckett, J. H. Agar, H. W. Bennett, Drinkwater Butt, E. Clifton, E. Crofton, T. Sebastian Davis, J. R. Gotz, H. C. Rapson, and E. Sanger Shepherd.

#### COPPER TONING.

Mr. W. B. FERGUSON, M.A., Q.C., read a paper entitled "Toning and Intensification with Copper Salts." Having occasion, in 1895, to look over a number of lantern slides which had been toned with uranium, or intensified, after bleaching, with mercuric chloride, he found that many of them had undergone such remarkable and unlooked-for changes, that they were more like specimens of Mr. Bennetto's colour process than anything else. These colour effects, however, did not altogether meet with his approval, and, in subsequently attempting to find some more satisfactory method of toning lantern slides, he turned his attention more particularly to the salts of copper, and his paper consisted of a detailed account of his experiments—begun in 1895, and continued until quite recently—with a view of finding the best process of toning lantern slides and bromide prints with copper salts. The materials utilised were ferricyanide of potassium and cupric sulphate, the latter salt being chosen, not only because it was cheap and easily obtainable, but also because it was a stable salt without oxidising or reducing action on the other reagents employed. After recounting his experiences with an ammoniacal solution of copper ferricyanide in combination with ammonium carbonate, carbonate of potash, and nitrate of ammonium, all of which produced stains which could not be readily removed, he tried oxalate of potash, which, with the cupric ferricyanide, formed a solution in which plates and papers were toned with considerable success, as was shown by some excellent prints made in 1897. This process, however, possessed certain disadvantages. The toning solution rapidly deteriorated, and had to be used as soon as mixed; its successful use necessitated the removal from the print or plate of every trace of hypo; unless the water was pure and free from lime, the high lights were slightly stained, and prolonged treatment was required in order to secure a red tone. The author therefore sought a more suitable solvent for the ferricyanide, and, after trying phosphate of soda, acetate of soda, tartaric acid, and ammonium citrate, he found in potassic citrate a substance which apparently met all the requirements of the case. The method recommended was to make ten per cent. solution of neutral potassic citrate, sulphate of copper, and ferricyanide of potassium, a mixture of which, in the following proportions, was shown to yield, either on plates or paper, a series of beautiful tones, without stain, varying from purple-black to cherry red, according to the time of immersion:—

Neutral citrate of potash (ten per cent. solution)	.....	250 c. c.
Sulphate of copper	" "	35 "
Ferricyanide of potassium	" "	30 "
Mix in the order named.		

A number of bromide prints and lantern slides which had been toned by this process were shown, and demonstrated the many beautiful shades of colour which might be obtained by stopping the operation at different stages.

Mr. FERGUSON prepared a toning bath, and toned some prints and transparencies, the method appearing to be simple, certain, and expeditious.

Mr. J. SPILLER congratulated Mr. Ferguson upon the undoubted success which had followed his experiments, and recalled the fact that his (Mr. Spiller's) first paper, read before the Chemical Society in 1857, dealt with the remarkable solvent powers of neutral citrates.

Mr. E. MARRIAGE showed some lantern slides treated by various methods as follows: Partially toned in ten per cent. solution of copper chloride; bleached in a ten per cent. solution of copper chloride and then sunned; bleached in a weak solution of perchloride of iron and hydrochloric acid, and also in a solution of bichromate of potash and hydrochloric acid; Schlippe's salt after copper chloride; ammonium sulphide, followed by copper chloride; bleached with chloride of nickel, and then sunned or treated with Schlippe's salt; and several other methods with ferricyanide, followed by cobalt, nickel, and manganese, and Mr. Ferguson's formulae.

Mr. BOLAS, Mr. SNOWDEN WARD, and the CHAIRMAN also took part in the brief discussion.

#### COMING EVENTS.

January 16, Photo-mechanical Meeting, "Screen Gears for Half-tone Work," by Mr. W. Gamble.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 4.—Mr. A. Mackie in the chair.

Mr. J. E. HODD made some observations respecting the use of the Welsbach light for projecting purposes. The new No. 2 Welsbach burner required no chimney, which was, of course, a great advantage. He used the light for enlarging with a six-inch condenser, and found that the same light could be used for projection, a six-foot disc admirably illuminated being obtained. It was his custom to employ Novitas paper in preparing the transparency for enlarging negatives, and thought it altogether superior to the plate. One may correct anything wrong, and dodge so much better upon a printed-out image. He never toned the Novitas prints intended for use as transparencies. The dirty yellow tone which appeared after fixing a chloride image suited well. There seemed to be better gradation and half-tone detail. Of course, the print would have to be bronzed right through for transparency purposes.

The CHAIRMAN pointed out that it would, of course, be necessary to suit the negative to the scale of gradation given by Novitas, as one would with other printing-out papers. Platinotype was similar in this respect. A still better scale would be given by transmitted light with such papers than by reflected light.

Mr. J. S. TEAPE, referring to this question of scale in a negative, said that

he had through his hands some time ago a negative in which two figures dressed respectively in black and white gave such harshness that the negative, as it was, would be valueless. He made a very good negative, however, by printing upon Novitas stripping film paper, stripping the positive, and affixing to the glass side of the negative, and scraping away the parts not required in reducing the contrasts. This course was suggested some time ago by Mr. A. Haddon, who superimposed a positive Novitas paper image upon the negative, so compensating some unnecessary details which appeared in the photograph as originally taken, the detail required, of course, being left as before.

The subject of backing for plates, and whether backing did slow the speed, as asserted by Mr. Thomas Fall and others, was discussed at some length.

Mr. J. S. TEAPE thought that plates nowadays did not require backing so much as they did three or four years ago.

The discussion eventually arrived at that point at which the suggestion was made that backing should really *increase* the speed of a plate, and it was decided to invite Mr. Fall to favour the Association by attending some night and giving his experiences in the matter.

Messrs. J. E. Freshwater, E. T. Wright, and W. D. Welford were appointed a Committee to arrange for the Annual Supper.

**Borough Polytechnic Photographic Society.**—Mr. R. R. RAWKINS opened the New-year's programme of this Society on the 3rd inst, with a popular lantern lecture descriptive of farm life in Dorset. The success achieved by Mr. Rawkins as a lantern-slide maker is well known, and every one of the 120 slides shown by him were typical examples of perfect technique, combined with high artistic feeling. A pleasant break in the lecture was made the occasion of an interesting presentation by the Chairman of the Society, Mr. F. W. Bannister, of the medals gained in the Society's fifth annual Exhibition, which closed on the preceding Saturday. In addition to the Exhibition awards, the medals and certificates gained in members' competitions during the past year were also distributed.

**Croydon Camera Club.**—January 3, Mr. Hector Maclean in the chair.

#### HELPING FAULTY NEGATIVES.

The perfect negative can hardly be said to exist, the imperfect one being everywhere the rule. All that can be claimed is that some negatives are a good deal worse than others. Mr. F. T. BEESON, F.R.P.S., held the attention of a capital attendance of the members for an hour and a half while he in much detail, and with the evident knowledge of one who only preaches what he has practised, explained the various expedients useful for "the preparation of a negative for printing." As the PRESIDENT reminded the meeting, although help is mostly called for, it is seldom rendered to the negative by the ordinary amateur, in spite of the fact that most of the medal winners, especially professional, spend much care and taste in "preparing" a negative for printing. Mr. Beeson stated that it was generally impossible by purely photographic means to obtain a critically correct rendering of tones, especially when engaged in outdoor work under widely varying conditions of lighting. As Payne Jennings once said to the lecturer, "You've got a great deal to learn if you think that negatives are fit to print directly they are dry." Having carefully explained several chemical means of improving defects in negatives, Mr. Beeson went on to speak of mechanical means, in the course of which he clearly described a number of useful ways of masking (*i.e.*, stopping back of light on the glass). Amongst pigments, &c., not often heard of, the use of a mixture of putty and chrome was described. But chief reliance was placed by Mr. Beeson upon a combination of gamboge, Prussian blue, flake white, turpentine, and Megilph or siccativ applied with a brush. How this was done was demonstrated with considerable detail. Other expedients having been spoken of, a considerable amount of attention was given to the best way of working on the film side to eradicate the spots and markings which negatives are at times prone to, in the course of which Mr. Beeson, by means of a blackboard, showed members how the spotting brush and the retouching pencil should be employed for the above purposes.

**Rotherham Photographic Society.**—January 2, Mr. E. Isle Hubbard, M.S.A., presided.—The preliminary business included the adoption of a petition against the Copyright Bill, which will come before the next session of Parliament. It was decided to continue in affiliation with the Royal Photographic Society, and the President, Dr. Baldwin, and the Hon. Secretary, Mr. H. C. Hemmingway, were re-elected delegates. Mr. Harold Baker's lecture on portrait photography was read, the accompanying illustrations in the form of slides being projected on the screen, and much appreciated by the members. Mr. Darling, who is on the staff of a London technical institute, subsequently gave a demonstration of inkless printing, the invention of a photographer, Mr. Friese-Greene. The process may be described as an electro-chemical one. Mr. Darling superimposed paper chemically treated on a metal plate in connexion with one of the poles of a powerful battery. The other wire of the battery was attached to the type, and the moment it touched the paper the electric circuit was completed and there resulted a printed impression.

#### FORTHCOMING EXHIBITIONS.

1900.	
January	..... Huddersfield (Invitation). W. A. Beevers. Cloth Hall-street, Huddersfield.
"	29-31..... Southsea Amateur Photographic Society. F. J. Mortimer, 10, Ordnance-row, Portsea.
February 10-24	..... Edinburgh Photographic Society. J. S. McCulloch, 10A, George-street, Edinburgh.
"	24-March 3 Birmingham Photographic Society. Lewis Lloyd, The Hollies, Church-road, Moseley.

- March ..... South London Photographic Society.  
 " 26 ..... Twentieth Century International, Birmingham.  
 Walter D. Welford, 19, Southampton-buildings,  
 Chancery-lane, London, W. C.  
 " 26-31 ..... Photographic Society of Ireland. W. F. Cooper,  
 35, Dawson-street, Dublin.  
 April 3-7 ..... Birkenhead International. C. F. Inston, 25, South  
 John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Patent News.

THE following applications for Patents were made between December 27 and December 30, 1899:—

- SHUTTERS.—No. 25,549. "Improvements in Photographic Shutters and Cameras." J. E. THORNTON.  
 PRINTING FRAMES.—No. 25,657. "Improvements in Photographic Printing Frames." Complete specification. W. HUDSON and L. HUDSON.  
 CHANGING APPARATUS.—No. 25,696. "Improvements in Film-changing Apparatus for Photographic Cameras." E. FIELD.

## Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
 \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### DR. VON ROHR'S THEORY AND HISTORY OF LENSES.

To the EDITORS.

GENTLEMEN,—I was really much puzzled on reading Mr. W. Curry's letter.

Every reader is, of course, free to approve or disapprove of any author's opinions, and I am not silly enough to think mine an exception to this fate common to all authors. I only protested and protest against the reproach of having written anything inconsistent with the sources given.

When, finally, Mr. W. Curry finds fault with me for my mentioning Mr. J. H. Dallmeyer's kindness in my answer of December 18, 1899, I submit to all readers, if it was not Mr. W. Curry himself who first introduced this personal quality of Mr. J. H. Dallmeyer's. I am glad, however, that in this case, at any rate, Mr. W. Curry and myself agree that this point mentioned by him in his first letter has nothing whatever to do with my theory and history of lenses.—I am, yours, &c.,

Jena, January 6, 1900.

DR. VON ROHR.

[Both sides having been fully heard we here terminate this correspondence.—EDS]

### MATT PRINTING.

To the EDITORS.

GENTLEMEN,—In your issue of December 15, you copy one of my contributions on silver printing, giving it the heading of "Permanent Albumen Prints." I hope you will pardon me if I correct what to my mind is misleading. Any one reading the article carefully will see that it is intended for a simple, permanent matt-paper print; hence the immersion of the paper in the solution instead of floating it. This does not, however, prevent its being used on the glossy side, the print, however, not being so much on the surface as when the paper is merely floated. It has, however, other advantages, such as retaining more detail in the delicate half-tones than floated paper, and also being almost free from any danger of blisters, as the albumen by immersion is coagulated equally as much on the back as on the surface. The results for matt printing on the back of the paper are superior to those obtained on the usual plain salted papers, as well as for working with water colours. It is not new, the idea being the result of necessity caused by close ideas of economy.

In 1863, when a mere boy, I was employed as assistant printer by a thrifty German photographer of this city, and my sole means of silvering albumen paper (then only single albumenised) was a dish 10 x 12 inches. As two and sometimes three dozen sheets per day were consumed, the silvering was very tedious, and I asked for a dish to hold a whole sheet. This was thought preposterous, as such sizes were rare, and nitrate of silver was then \$2.40 per ounce in our paper currency. So, after adding my brains over night, it occurred to me to try, surreptitiously, immersion,

first of one sheet, then of three or four, and finally of entire batches, until I found that no difference was noted, and I then gave my employer the tip. He thought it a huge joke, and would poke any amount of fun at my constantly blackened fingers, as a result of immersing eight or ten sheets at a time instead of the cleaner method of floating. It never occurred to him that the method used up more silver by absorption in the paper, else he would not have been so complacent.

There is one other fact that has impressed itself on me which seems to have escaped general notice; that is, when papers are employed which bleach greatly in the toning and fixing process, and which lose the delicate half-tones. In strong negatives, an exposure of the paper, previous to printing, to the action of light until it is somewhat grey, will entirely prevent any loss of detail, and the bleaching action of the toning bath seems to be exhausted on the whites, so that really no degradation of high lights is noticeable in the finished print. This fact is really very valuable, when properly used, with certain classes of negatives and papers.—I am, yours, &c.,

D. BACHRACH.

Baltimore, December 26, 1899.

### DOES BACKING SLOW A PLATE?

To the EDITORS.

GENTLEMEN,—Some remarks have been made in the JOURNAL which tend to the belief that backed plates become slower in consequence of being so treated.

I have carefully backed every plate used for ten years past with great advantage in result, and I do not think it makes the slightest difference; but I fancy the idea has grown up in consequence of the greater clearness of the image resulting from backing, and from the undoubted fact that backed plates can be given much longer exposures than usual without showing the well-known results of over-exposure.

If you back only half of a plate and expose it to a test landscape, i.e., one in which halation is very likely to be present on its development, after a full (not necessarily excessive) exposure, it will show a marked difference between the backed and unbacked portions, flatness and want of crispness of the overlapping portions, and gradation of distances in the unbacked part, and brightness and well-defined edges in distances in the other, though practically identical as to detail and density.

What appears to me to take place is this: The unbacked film suffers throughout from a modified form of halation in every bit of detail where there is a variation in gradation of tone, best appreciated in gradation of distances, and, if examined under a magnifier, will be found to be blurred at every such edge, melting into each other, and causing the well-known flat and smudgy effect of over-exposure, whilst the backed film is preserved from this degrading effect and comes out clean, crisp, and true in its gradations, in fact it is saved to a large extent from the natural results of over-exposure by the backing.

Thus people see that longer exposure can be given without the fatal results of over-exposure, and they jump to the conclusion that because they see a much cleaner result (which is characteristic and correct, or even slight under-exposure), therefore the plate must be slower in speed in consequence of being backed; the true test is to place the result of backing or no backing side by side on the same plate, preferably a large one, and examine them carefully for halation, but this knowledge is a comfortable one for the operator in making an exposure, that, if he thinks he might err a little on the outside of what he believes to be absolutely correct time, he will not be punished by finding a flat and washy-looking result in his negative on development.—I am, yours, &c.,

"LUX."

### COPYRIGHT.

To the EDITORS.

GENTLEMEN,—In your Answers to Correspondents' column a week ago, I noticed that you said it is fraudulent to mark a photograph copyright which has not been registered at Stationers' Hall. I think you must have overlooked the fact that copyright is a genuine property previous to registration, and that therefore a copyright photograph may be quite rightly marked copyright, although such copyright be unregistered.

I have noticed that at least one eminent photographer publishes a notice to the effect that he reserves the copyright of all portraits taken by him.

It would be very useful for the profession generally to know whether such a notice does really secure the copyright to the photographer.

If it does, it seems to me so essentially conducive to the standing and interest of the profession that every photographer who respects his craft should print it on his price-lists, prospectuses, or similar means of communication with his clientele.

It would at once protect him from the unauthorised reproduction of his work by any other person or firm. He would be released from the loss and mortification of seeing his work reproduced at trade rates to private customers by trade enlarging firms and free-portrait swindlers; the first-rate professional would no longer have to suffer incompetent fifth-rate rivals to reproduce and enlarge his work at ridiculously low charges and in a quality of work which is a perfect horror to a man of taste.

and the illustrated press would have to treat with the photographer direct for every photograph reproduced, besides many other advantages to the professional needless to enumerate. I think there is little fear of objection to this arrangement on the part of the general public, which is usually fair, and would willingly agree to the photographer who sows reaping a full and just harvest in return for his work.

The validity of the copyright under the circumstances stated above would, no doubt, depend on the validity of the contract between photographer and client made by the notice of retention of copyright, whether that be a binding agreement, or whether a written agreement, signed by both parties, be necessary. Perhaps some of your readers learned in the law will enlighten us.

Photographers generally, even at this date, have not one-tenth the knowledge they should have of copyright matters.—I am, yours, &c.,

RALPH W. ROBINSON.

A and 6, Linkfield-corner, Redhill, Surrey, January 8, 1900.

## A LUNAR PHENOMENON.

To the EDITORS.

GENTLEMEN,—It was with no languid interest that I read, in your issue of December 29, Allan Blair's highly entertaining account of his attempt to photograph the meteors. It intensified my satisfaction at having successfully resisted the temptation to make the same venture myself. He would have my hearty sympathy for his non-success but for one thing. I would have given more than one night's sleep to witness, as he had the great good fortune to do, what may be unhesitatingly termed the most marvellous phenomenon in the history of astronomy. He may truly congratulate himself on having patiently outstayed all other watchers, and long after they had slipped away to rest had his reward in seeing that most unique event; for, as he tells us (in the twenty-third line, second column, p. 829), "the moon sank below the eastern horizon," and "in a blaze of golden glory," too.—I am, yours, &c.,

136, Calabria-road, Highbury, N.

JOHN H. GOUDEY.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

R. W. Wicks, 57, Clarence-square, Brighton.—(1) Photograph of wreckage; and (2) Engine on line at railway accident at Wivelsfield.

FINCHLEY.—Your question was answered on December 15 last.

P. O. MOUNTANT.—T. STOKOE asks for a good receipt for P.O.P. mountant.—Freshly made starch paste. Messrs. Fallowfield supply an excellent mountant for the purpose.

BLACKENING ALUMINIUM.—MANCUNIAM asks: "Will you please inform me of some method of blackening aluminium without the application of heat?"—If the metal cannot be heated, we can suggest nothing better than diluted brown, hard varnish, to which is added some "drop black." Bates's dead black varnish would probably be more convenient.

THE ROYAL BIORAMA.—F. HOPE says: "Can you inform me the address of the works of the Royal Biorama, the living pictures now appearing at Olympia?"—In reply: We have not seen the particular exhibition referred to, but we imagine that the films are obtained from the Warwick Company, Warwick-court, or Messrs. Fuerst Brothers, Philpot-lane, E.C.

-COLLOTYPE PRESS.—W. LOTZ asks what make and size of press we recommend for colotype printing to produce about 1200 pictures, 8×6 inches, the day?—To produce that number of prints per day from one plate, a colotype machine will be required. Such machines are supplied by Furnival & Co., St. Bride-street, E.C., and by Schmiere, Werner, & Stein, of Leipzig.

PHOTOGRAPHING A PRINT FROM A BOOK.—AMATEUR says: "Could you tell me how to photograph a print from a book. There is printed matter on the other side of the page, and, the papers being rather thin, the printing shows through on to the picture, both the black images of the letters and also raised impressions of them showing the picture is of a piece of scientific apparatus, and therefore must be copied in the finest detail."—If the print shows through the paper, we do not see how it can be avoided in the copy. The trouble may, however, be mitigated by backing up the picture with a piece of white paper before copying it.

SPENCE'S METAL.—H. REID asks: "What is the alloy known as Spence's Metal, its melting point, and whether it differs from ordinary fusible metal; also, where it can be obtained?"—Spence's Metal is not a metal at all, but a sulphur sulphide. Its melting point is somewhere about 250° F. We cannot say where it can be obtained, or if it is now an article of commerce.

BOOKS.—Probably the three books most suited to your requirements would be the *Science and Practice of Photography*, by Chapman Jones, published by Iiffe, St. Bride-street, E.C.; the *Studio and what to do with it*, by H. P. Robinson, published by Sampson Low & Co., Fetter-lane; and *Posing and Lighting*, by Inghis, published by Dawbarn & Ward, 6, Farringdon-avenue, E.C.

BAS-RELIEF PORTRAITS.—T. C. J. says: "I wish to make some bas-relief portraits, but I find there are several patents in connexion with them. I have found a method for producing them, that was published fifteen or twenty years ago, that will answer my purpose very well, and it is very similar to some of the recently patented ones. Shall I be getting into trouble if I use that old method?"—No. You are perfectly at liberty to work by any method that was published prior to the patents, even though any of them may be exactly the same thing.

A LIGHT QUESTION.—J. D. H. writes: "Can a neighbour block out a photographer's light? The facts are these: My studio is at the top of the house, two stories, and my next-door neighbour is going to put another story on the top of his, and, if I cannot stop him, I shall practically lose all my side light, a very serious matter to me. Cannot I prevent him from interfering with my light, which is necessary for my business?"—Yes, if you can claim "Ancient lights," but not without. If your studio has been built twenty years, you can prevent your neighbour from interfering with your "Ancient lights."

LARGE PORTRAITS DIRECT.—H. CONWAY says: "I want to take large direct portraits on 18×15 plates. The largest lens I have is a rapid rectilinear of eighteen inches focus, and, when stopped down, covers that size plate up to the edges. I have done a few, but, though perfectly sharp, they do not seem to please any one. Can you account for this, as the photographs are really good?"—Yes, easily. When they are taken with such a short-focus lens, the perspective is too violent to be pleasant to any one. To take 18×15 portraits direct, a lens of double at least the focal length of the one used should be employed. See article on the subject that appeared a few weeks back.

CLAUSE IN LEASE.—R. C. writes: "I have a house in a private road, through which there is a large traffic, on a seven years' lease, and I find I can, at a small cost, convert the two top rooms into a photographic studio. Can the landlord prevent me doing this? There is a clause in the lease that no business is to be carried on the premises. What I wish to know is whether photography can be considered, in law, a business. Is it not a profession?"—In reply: We should say that the landlord could prevent the alterations in the structure. Any how, he could compel reinstatement at the end of the tenancy. There is little question that photography would be considered a business in the eyes of the law.

COLOURS IN P.O.P.—T. C. R. says: "In using aniline colours for P.O.P., I find that the colours entirely disappear or sink through the surface when dry. I have used a two-and-a-half per cent. of albumen with the anilines, both with the colours, and brushed over surface of print, with the same result. Can you, through the pages of your valuable JOURNAL, suggest a means of keeping the colours on the surface when dry? They are all right so long as the colours are wet, but, on drying, entirely disappear, and, if again wetted by soaking in water, the colours appear again."—Possibly the colours were used too dilute, or they were not of a suitable kind. Messrs. Houghton & Sons supply special colours that would probably be just what you require. Try them.

PAYMENT OF TRAVELLING EXPENSES.—MONEY says: "About two years ago I was engaged as operator and retoucher, for a branch, and, though nothing was stated in our letters with regard to expenses incurred in the journey, they were verbally promised me when I arrived at my destination. The principal now being ill and on my pressing for payment, his representatives refuse to recognise my claim. Have I any legal standing in the matter, and can I force my claim? I have always understood that it is usual in photography to have travelling expenses paid or defrayed."—As you have been in the situation for two years, and during the time have, apparently, made no claim for the travelling expenses, we do not think you can now recover them. You should have got them at the time.

FERROTYPES.—M. P. says: "Will you tell me where I am at fault? I am going in for ferrotypes. I have made up my bath and developers as follows, but can get no image at all on the exposed plates. Bath: Nitrate of silver, Reay's, 5 ounces; distilled water, 80 fluid ounces; nitric acid, pure, 12 minims. When dissolved, add iodide of potash and filter. I have coated a glass plate with collodion, and left it in the bath for several hours. Bath was made up twenty-four hours before using. I have used the following without any success. Developers: Proto-sulphate of iron, 6 ounces; nitrate of baryta, 4 ounces; alcohol, 4 ounces; nitric acid, 2½ drachms; water, 80 ounces. Also: Ferrous sulphate, 150 grains; glacial acetic acid, ½ ounce; nitric acid, 5 minims; alcohol, ½ ounce; water, 10 ounces. Is there a good book on this business? Please give name and price."—If the plate was left in the bath for several hours, we are not at all surprised at failure. The plate should only be left in it for three or four minutes, or only sufficient for it to lose its "greasy" appearance. The bath is also rather weak; it should not be less than 30 grains to the ounce. Any of the old manuals on photography—Hughes's, for example—give full details. If we mistake not, Fallowfields have a small work on the ferrotype process.

### EX CATHEDRÂ.

THE war, which at its outbreak made professional photographers as a class somewhat busy, is at the present time having an adverse effect on many branches of trade, and photographic manufacturers and dealers are not escaping the general depression. We have heard from several firms, notably some which very largely rely on the winter trade in lantern goods, that the South African struggle has seriously interfered with their business this season. Much the same story reaches us from many other representative sources of photographic manufacture. It is to be hoped that the speedy termination of hostilities will be followed by the restoration of all departments of industry to that level of prosperity at which only a condition of peace can maintain it.

\* \* \*

AMERICAN photography, we gather from our exchanges, is likely to enjoy a larger share of representation at the Paris Exposition than photographic work produced in the British Isles. New York City will be illustrated by a relief map of the Greater City, which is reported to be now in process of

construction by the City Engineer's Department, and which is to measure 24 x 28 feet when completed. Furthermore, in connexion with this enormous map it is proposed to display a large number of photographs and drawings of the most prominent buildings at present erected and under way. It is said that \$10,000 has been appropriated for the relief map alone.

\* \* \*

THE American Government also proposes sending a complete series of photographs, representing many of the special commercial industries of the country, and views from the fifty-four agricultural experiment stations of the United States, all of which are being prepared and collected by Mr. Charles Richardson Dodge, of Washington, who represents the Secretary of Agriculture in this matter. The prints will all be mounted either singly or in groups on 22 x 28 cards, which will be arranged in classes and enclosed in portfolios, which will be classified and titled. They will illustrate, among many other things, such industries as the catching and preparing of fish for food; the meat-packing industry, showing in detail its numerous steps, from the cattle grazing "on the hoof" to the shipment of the prepared packages; bee-raising and dairy farming, fruit-canning and tobacco cultivation, and a vast number of other branches of American industrial life.

\* \* \*

AFTER having been before the world for eight or nine years, tele-photography has been discovered by one of our daily contemporaries in connexion with its possible uses in the South African War. Tele-photography, it says, is a long word, but the range of the tele-photo lens is long also; and, remembering that the camera has made more than one stride since Daguerre first experimented with iodine and copper (*sic*), one reads with surprise of English officers sniped while sketching. 'French balloonists, we believe, have achieved some remarkable results, not only by personal use of the camera, but by a system of plates automatically exposed at different heights in different directions. There seems some difficulty in ascertaining the exact use which we ourselves have made of photography during the present war; but, as has been pointed out, there is a new '(!!)' tele-photo lens which has been able to show the clearest detail at a range of forty miles, and at a range of four, say, it

might be expected to do even better. But that the pencil should still be preferred to the plate is surely an anomaly nowadays. We would not overwhelm the War Office with demands; let us call this a hint." And we say this: That it would probably pay an educated photographer to rent an office in the neighbourhood of Fleet-street, and set up as expert photographic adviser to the "great" London newspapers. A nightly glance over their proof-sheets would save them publishing no end of erroneous twaddle about photography.

\* \* \*

WE learn that a revised and enlarged edition of Captain Sir W. de W. Abney's *Instruction in Photography* will shortly be published by Messrs. Sampson Low, Marston, & Co., of Fetterlane. The work, which has been brought up to date, includes fresh chapters on Photo-lithography, Photo-engraving, and kindred processes. Probably no book on photography in the English language has passed through so many editions as the *Instruction*, or has so frequently been utilised as a basis upon which other books on the subject have been founded.

\* \* \*

SEVERAL of our contemporaries have stated that Dr. Emil Berger has constructed a binocular microscope which admits of seeing objects plastically (*i.e.*, in relief), and one of them adds: "If the news is credible, Dr. Berger's invention will prove a great boon to the hundreds of thousands whose profession forces them to use a microscope." Commenting on this discovery, "F.R.A.S.," of the *English Mechanic*, points out that as far back as 1851—forty-nine years ago—Professor Riddell, of New Orleans, devised a binocular microscope for exhibiting objects stereoscopically, or apparently solid. He was speedily followed by Mr. Wenham, in London, and by M. Nacet, in Paris. Then we had Stephenson's form, and later still the binocular eyepieces of Tolles and Abbé. The idea, he adds, of there being any novelty in the mere obtaining of stereoscopic vision by a binocular microscope is simply ridiculous.

\* \* \*

TWO of the February meetings at the Society of Arts should be of very great interest to photographers. On the 14th Professor R. W. Wood is to lecture on the "Diffraction Process of Colour Photography," which he fully described last year in the *Philosophical Magazine*, *Nature*, and other periodicals. A *résumé* of those writings appears in our ALMANAC for 1900. On February 21, Mr. Edwin Bale is to give a paper on "Artistic Copyright." We hope that Mr. Bale will have something to say regarding those provisions of the Copyright Bill that was introduced to the House of Lords last session, and which sought to substitute for the present satisfactory law of photographic copyright a grossly unjust and tyrannical series of enactments. Those interested in the subject should make a point of attending the meeting, which we commend to the special notice of the Committee of the Photographic Copyright Union.

\* \* \*

AT the [Education] Exhibition, now open at the Imperial Institute, South Kensington, a portion of the Cambridge University exhibit consists of a series of 10 × 8, 12 × 10, and 15 × 12 sepia platinotype photographs closed framed in walnut, and representing interesting bits of the University side of Cambridge. These are the work of that excellent photographer, Mr. F. H. Sanderson, the inventor of the Sanderson

camera, while his partner, Mr. Goodrich, is represented by a Royal group, taken several years ago. The firm is now busily engaged in illustrating eighteen volumes of a new history of the University.

#### PERSONAL DANGER IN PHOTOGRAPHY.

WRITING without any desire to be alarmist or to arouse attention in Accident Insurance Offices to the profession, inimical to the interests of its members, we may yet point out that the practice of photography entails personal risks absent in many other callings. It may, of course, be said that every walk of life has its own risks; literally speaking, it would be true. A man has been known to strangle himself with one of his own neckties; the patentee of a new form of a dog chain committed suicide by means of a sample of his patent; it was but a short time since that one of the largest provision dealers in the country was fined for adulterating his sugar with twenty-five per cent. of paving stones (ground to powder), and the results to any *employé* incautious enough to take a packet home to his family can be easily imagined. The tale could be increased indefinitely; but these are usual, if not trivial, accidents, and do not compare with the real risks besetting dark-room and studio work. Fire insurance companies certainly entertain an idea that there is risk from their standpoint, as they ask a premium of an unconscionably large rate, and wherever danger of fire is danger to the person exists. It used to be explained that the use of collodion was attended with danger, but, although it is little employed now, the rates are not lowered in consequence.

In referring *seriatim* to the various risks we may suitably start with collodion. First, we may treat of the acids for pyroxyline-making, which entail many dangers in their handling. In using the mineral acids there is always one point to remember, and that is to be careful (and especially is this the case when the acid is stored in carboys) that, in restoring the containing vessel to its upright position after inclining it for pouring from, it be not done with a jerk or suddenly.

This is no idle advice, for we have known instances of persons being blinded by a drop of acid spurting from the neck of the bottle into the eyes; and it is only a few years ago since we recorded a serious injury to the eyes of a society man, who was compelled to leave his party out photographing in Norway and return to England through ammonia spurting into his eye when opening a small bottle of that liquid. Similarly we recorded the death of a young man who, pouring nitric acid out of a Winchester quart, accidentally dropped the bottle on the floor, and, through inhaling some of the fumes so suddenly evolved, succumbed in a day or two to the injuries consequent to his lungs. The gun-cotton, or, more correctly speaking, the pyroxyline used as the basis of collodion, is, on the other hand, not so dangerous as usually supposed, it is not much more explosive than dry cotton-wool.

Again, speaking of danger to the eyesight, it is common knowledge that the practice of retouching involves considerable risk of its impairment, the chief precautions to be taken being to use spectacles the moment it is found that the work is more easily seen when removed a little farther from the eyes. We have also, as have most of our readers, heard many complaints of the strain to the eyesight from the reddish light of the dark room or of the dry-plate manufactory. Care should be taken not to come into the comparative glare of

broad daylight too suddenly and frequently when the eyes have only experienced the red illumination for some considerable time.

We spoke of fire risks, and before leaving the topic we might, while not forgetting the danger of spilling varnish and igniting it at the fire or flame used to heat the negative, call attention to the governing conditions, not always known or thought of, that the danger of fire in using collodion lies in the fact that the vapour of ether, being heavier than air, falls and travels along the floor, and, being explosive and inflammable, may be set on fire at some distance from the pouring bottle if in its way it meets a naked flame.

Again, it is only a week or two ago since we warned our readers against the incautious handling of flashlight powders, or mixing the constituent ingredients by any metal stirrer. As to the danger from the most popular hobby of the day—the use of acetylene—that is well known, and too many sad fatal accidents have already happened through its employment. We must, however, say that, now the curious causes of explosion have been discovered, and attention has been drawn to them, it can scarcely be put down to the account of this gas if the precautions are neglected and accident occur.

Returning to a survey of the chemicals used, it will at once be seen that there is a sufficiency of risk to every photographer. There is danger of accidental poisoning through misadventure with cyanide of potassium, bichloride of mercury, or oxalic acid—all chemicals to be found in use by the all-round photographer, while well-used hypo fixing solution is very poisonous. Another aspect of chemical risks lies in the danger to the hands through the use of such chemicals as bichromate of potassium or developing agents like metol—a very real danger of serious evil to some people, although this is a matter of idiosyncrasy.

Science has lately added another risk to the practising photographer in the use of the Röntgen rays, which, if allowed to fall for too long a time, or too frequently, upon the skin are capable of inducing acute dermatitis.

We may conclude our survey by a reference to one or two of the minor risks, such as the frequent occurrence of cut fingers through handling accidentally broken plates in a dim light, or getting nasty wounds through glass splinters entering the fingers. In another direction we may refer to the experience of a well-known professional, who tells us he always keeps suitable remedies for cut fingers at hand, as it has invariably happened that, when a new hand starts cutting prints with a glass shape, a badly cut finger seems a necessity of the initiation.

We think we have made good the just views of the title to this article, but, at the same time, we may say ordinary care would ensure the avoidance of almost every one of the risks we have tabulated.

**Another Picture Lost to England.**—We have more than once referred to the number of pictures that leave this country for the States. Many of our readers will be familiar with Sir Benjamin West's picture of the *Raising of Lazarus*, which has been a conspicuous feature of the screen of Winchester Cathedral for over a hundred years. This work has now been sold, much to the regret of the diocese generally, to an American firm for fifteen hundred pounds. A number of criticisms have been passed upon the Dean and Chapter for the sale, and Dean Stephens replies that the picture was not presented to the Cathedral, as supposed, but was purchased in 1781. Nevertheless, the picture is sold by the Dean and Chapter and goes to America, hence once more fine work is lost

to this country. The reason given for the sale is that it was, in the Cathedral, "out of keeping with all its surroundings." Be that, according to the idea of the Dean and Chapter, as it may, we should have liked the picture to have been sold to an English firm rather than an American one; then it might have been retained in the country of its production.

#### **The Three-colour Process for Artistic Illustration.**

—Last week we quoted from a daily contemporary some adverse criticisms on the three-colour process for purposes of artistic illustration. The writer, in a further note, says that Mr. Hentschel sends him a very interesting letter, in which he points out that the three-colour process is still in its infancy. But how good or bad it is cannot be told from any of the pictures he sends, rejoins the critic. Wash has got to be made in colour specially for reproduction, just as you must draw with a pen if you want to get a perfect line block. "We certainly have seen some remarkable results from his colour process. But we have one suggestion to offer him. Let him get a clever and intelligent artist to make some drawings in three colours, and have these colours put down like mosaic, side by side, and not superimposed; or let him try to reproduce a Japanese print containing three colours. He will then discover how good or bad his process is. That we are right in suggesting such a method is proved by the fact that the best reproduction he sends us is a page of illuminated manuscript, where the colours are only three or four in number and perfectly flat. But has not in this a fourth printing been added to get the gold?"

**Artists and Photographers' Photographs.**—The same writer, whose identity it is not difficult to discover, delivers himself of the following ideas on photography *apropos* of some photographs from the Leusart series by Alfred Lys Baldry and W. J. Day recently sent him. "They seem to be clear and sharp," he remarks, "as everything photographed should be; but we hardly see what they are intended for. They can scarcely be, like so many so-called artists' photographs, which are always of the most artless character, for use, to save the difficulty of drawing from a model by tracing over a print; they can scarcely be considered as decorations. These prints only seem to us to prove that, even if an artist and photographer deliberately try to make mechanical pictures, they are doomed to failure. The human form is not often divine, and the camera does not idealise it." The writer's ideas on the possibilities of three-colour and monochrome photography will, we imagine, find little endorsement at the hands of those who have given practical attention to both subjects.

**The Admiralty and X Rays.**—Severe comments have been made on the War Office departments as to the neglect by them of Röntgen's discovery, and its utility in alleviating suffering on the battlefield. It now appears that there is an apparatus in use there, and we know that the hospital ships, the *Princess of Wales* and the *Maine*, took with them very complete X-ray installations; but these were not supplied by Government. There is no question that this valuable discovery of Röntgen has been far too tardily recognised by the powers that be. It is satisfactory, however, to know that at last they have done something in that direction, as we now learn that the Admiralty has appointed a civilian expert at Plymouth to give a number of naval medical officers in the Royal Naval Hospital a course of instruction in the use of the Röntgen rays in surgical cases. When reading this, one cannot help wondering why, considering the time the rays have been in use in the hospital and their value demonstrated, the thing has not been done before; also why the Army medical staff did not receive similar instruction, and why it was not supplied with proper field equipments before it was dispatched to South Africa? Verily our Government moves slowly, and it takes it a long time to recognise any new discovery, however valuable. Red tape binds tightly!

**Acetylene again.**—In a suburban paper we read that, at Acton, there has been another serious accident with acetylene. It appears, from the report, that a lad entered an outhouse where an acetylene gas apparatus was situated, and in some way brought about an explosion, with the result that he was terribly injured about the face and head, part of the skull being fractured. It is unfortunate for the future of this illuminant that we read of so many accidents with it, though they can all be attributed to carelessness or lack of knowledge of its properties by those having to do with it. The restrictions and conditions laid down by the County Council and the insurance companies have been severely commented upon as retarding the more general adoption of the acetylene light, but these continually occurring accidents tend to show that they are fully warranted.

#### ON THINGS IN GENERAL.

THE great event of the year. No, kind reader, I am not contemplating writing a single word on the great century or no-century beginning controversy; this is a serious journal, and our Editor, I am sure, would at once put his foot down upon any attempt at that kind of frivolity. The great event of the year is, I was about to say when interrupted, THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC. I had intended to say so last week, but have been engaged most of the time since in trying to fog out the pagination. What a pity the printers did not put a key to the pages on the front page where they tell us where to find the indexes and other useful trifles hid among such a heap of good things. There is enough solid, substantial, satisfying reading in the book to last for a twelvemonth. It is a great book—1548 pages—never mind the fact that the last page says 1516, not including the covers (mine is a handsomely bound library edition). A man given to much photography hit it off in the vernacular the other day in the crusted old saying "it is as full of good stuff as an egg's full of meat." And he was right; but I will pass on from this, for, as good wine needs no bush, every photographer will ere this have found out for himself what a treasure of a shilling's-worth this cyclopaedia of photographic knowledge is. I have read many of the articles with much interest, some being worth each the whole price of the book. I cannot, however, avoid noting one article, "Time-tables on Enlargements of Bromide Paper." The writer is evidently familiar with his subject, but by some unaccountable error has misquoted Mr. Debenham's valuable instructions regarding the time of exposure needed as plates increase in size. He makes Mr. Debenham responsible for the dictum that the exposure is a function of the square of the figures obtained by adding together the measurements of the two sides of the plate. So that, according to this system, the exposures used when a negative is enlarged to 12 x 10 in. or to 16 x 6 in., say, would not differ. Obviously, Mr. Debenham's instructions, which would well repay reprinting periodically, are very different from this.

I am fearful of being accused of attempting to gild the lily, yet, taking the risk, I am about to suggest an extra department in future ALMANACS. It is all very well, and very instructive, to keep on telling us what to do; my suggestion is to have a corner telling us what not to do. Numbers of amateurs anxious to excel are naturally desirous of trying many of the clever dodges recommended in various papers by various writers; but, as I need not say, many of them need a sign-post, which my friend of the vernacular just quoted suggests should be painted with one word, "rot." He is rather vulgar, as you will see. Perhaps an example may be given of what I mean. I noted the other day the instruction given (from a high authority) to keep sulphite of soda in fifty per cent. solution; the said H. A. remarked that he always did it. The question arises, What did he put in his precious fifty per cent. concoction? Certainly neither chemically nor commercial sulphite of soda, for, to keep that salt dissolved for six months apparently quite unaltered, outside of a special heating apparatus, would need a conjuror, and a clever one at that.

One more example. A writer signing himself a "Professional Photographer" instructs us how to dry a negative quickly: Wipe it

as dry as possible, and then hold before the fire from four to eight minutes, or, failing that, to put in the sun if it be very hot. Now, really this is trusting to our confiding innocence rather too greatly. Perhaps, however, it is a joke, for such treatment would ruin any ordinary negative. The funniest picture I ever saw was treated this way by an amateur I know. The negative was nearly, but not quite, dry; he was anxious to see a print, so he put the half-dry negative in the sun—not very hot this time. In a short time the whole film became such a mass of distortion that his favourite daughter came out apparently about fifteen feet six inches high, and she really is not so tall as that. It was such a very droll thing, that he made an enlargement from it (and hung it in his drawing-room. I wanted him to exhibit it, but he was sure it would be rejected; but now he is considering whether he would not have a chance at the Salon. If it should be shown there, my readers will now know the inner history of the picture.

Whatever Mr. Bolas writes about, he generally illumines with strong common sense, and I commend his informative paper upon focometers, read at the Royal, to the attention of those who may not have seen it. I think his suggestion as to the value, as a measuring instrument, of Mr. Dallmeyer's focometer very valuable; but I think the line ought to be drawn at using it for measuring plates. Mr. Bolas makes a strong point as to the want of trustworthiness of the ordinary measuring apparatus. Let the focometer therefore, if needed, be used to verify measures, but let not every Tom, Dick, or Harry, who thinks his badly made dark slide justifies him in finding fault with his plate-maker's glass-cutting, desecrate the instrument by taking his plate to it and measuring it. I am afraid a ticket would need putting over it after the fashion of the well-known advertisement with the similar illustrations, "Won't wash clothes."

I was just writing about sulphite of soda, and I might, with advantage, make a reference to another phase of the sulphite of soda question. Messrs. Lumière & Seyewetz have added another to their long list of valuable contributions to the technique of photographic manipulations in their instructions for making a mercury intensifier, and using it so as to obtain permanent results, a desideratum hitherto not obtained. I heartily commend it to the consideration and employment of any who desire to use an easy and trustworthy intensifier. But here is the point—there is not the slightest need to use anhydrous sulphite of soda in making up the solution as recommended. It is no doubt a useful form in which to keep it, but it is not to be found in one photographic store out of a hundred, nor in our chemists', and for my own choice I prefer the crystals for all purposes. If they have gone wrong by absorption of oxygen, they will show it at a glance; but kept at all carefully—I keep them in a cask with a wooden lid—they do not readily change.

"Does backing a plate slow it?" seems to be agitating many bosoms just at present. Surely it is not difficult to settle the matter. Back one half of a plate and expose it, first the backed and then the unbacked half, to a sensitometer, say a Warnerke, and see what the results are. A little more doing and a little less saying.

All this agitation in favour of the metric system is not likely to lead to much among the older devotees of photography, or any other science. The fact is we cannot use grammes and cubic centimetres with facility unless we think in grammes and centimetres. We pass a grocer's shop, and see hundreds of handy packets of tea piled up. How much do they hold? Most of us will say, as we think, "Oh, half a pound." Our friends of the metric system would say, "Oh, just under a quarter of a kilogramme." It is all a matter of habit, and we shall have to begin with the young ones if it is to be finally adopted. I, for one, hope it won't be. For every-day life, our pound weight, our shilling pieces, our yards and feet, are infinitely preferable and much more convenient by reason of their adaptability to subdivision. Referring to tea again, it is a very simple thing to ask for an eighth of a pound as a couple of ounces, but what Englishwoman would go to her grocers and ask for 125 grammes of tea? Any one who knows anything about buying goods in France will tell us the same thing. In the very home of the metric system, the metric system, as a system, is practically non-existent, at any rate for domestic purchases.

"Wad some power the giftie gie us to see ourselves as ithers see us," and the apostrophe has been answered by the American writer quoted last week in these pages, some of his most scathing comments on the framings of our exhibition pictures not being given. It is to be hoped that his teaching may be taken to heart, for of all the pretentious, heavy, inharmonious surroundings to soulless, dead, washed-out leaden results of photographic manipulation, surely the exhibits of last year bear the palm.

FREE LANCE.

### FRAUDULENT COPYRIGHT CLAIMS.

THE letter of Mr. Ralph W. Robinson in our last issue must not be allowed to pass without comment, otherwise it might be misleading to some. It is anent an answer we gave to a correspondent a short time ago, in which we said it was illegal to mark a photograph "copyright" in which no copyright existed. Mr. Robinson, in his communication, says: "I think you must have overlooked the fact that copyright is a genuine property previous to registration, and therefore a copyright photograph may be quite rightly marked copyright, although such copyright be unregistered." Just so, if the photograph is copyright. The query that we replied to was this: "A photographer here is in the habit of marking the portraits he takes of his sitters in the ordinary course of business, and for which he has been paid, 'copyright.' . . . What I want to know is whether he can legally mark a photograph copyright when there is no copyright in it?" Our reply was, Certainly not.

The Copyright Act enacts that, when a painting or photograph is executed for a valuable consideration—i.e., the sitter, in the case of a photograph, pays for the work—the copyright in the picture does not belong to the photographer, "unless it be expressly reserved to him by agreement in writing." Therefore, the photographer, it is manifest, has no copyright in portraits which he takes in the ordinary course of business, and is paid for taking, unless he has a special agreement in writing to that effect with the sitter. Unless he has a legal copyright, acquired under these conditions, it is illegal for him to mark the photographs copyright, as we told our querist.

Mr. Robinson mentions that "I have noticed that at least one eminent photographer publishes a notice to the effect that he reserves the copyright of all portraits taken by him," adding that "it would be very useful for the profession generally to know whether such a notice does really secure the copyright to the photographer." It is a little difficult to conceive how any one can retain what he does not possess, and there is no question that a photographer does not possess a copyright of a portrait he is paid for taking unless there is a special agreement to that effect in writing between him and his sitter. We quite agree with Mr. Robinson that it is hard upon the photographer that his work is occasionally reproduced at trade rates to private customers by trade enlarging firms and free-portrait swindlers, &c. But there is another side to the question. A person pays for a thing, and consequently he has the right to do what he likes with it. In the case of a photograph, which he has paid the photographer to take of him, why should he not have the right to have it reproduced, enlarged, or what not, as he may like, and by any one he chooses, whether the result is good, bad, or indifferent? That is his business; he is doing what he likes with his own. We merely allude to these facts because they exist, though they are not what many would have them; still they exist, and, we surmise, will not be altered, so must perforce be endured.

### FOG ON PLATES—A QUESTION OF RESPONSIBILITY.

AN old correspondent of this JOURNAL, and a photographer of many years' experience, recently wrote us to the following effect: "I send you to-day, by parcel post, a negative, which, as you will see when it reaches you, has a dark rim around the four edges. It is a copy from another negative. It is an enlargement; the original is perfect. The same dark borders show on views taken direct. I made several trials, with different holders, with same results. What can be the cause if not in original plates, or manufacturer's fault? I am not a new hand at it, therefore cannot blame light in changing plates or developing; and then, why the four edges bad, only centre part perfect, free from fog or light. Camera, &c., twenty years old; holders same. Not the wood at fault,

as the grooves are, and have always been, unvarnished; and this defect only appears now, with a new lot of plates. If light, why four edges, and why also the rims, which are covered by wood, and should always be clear and not dark, as in this instance? With plates not keeping, I always found edges to be less sensitive; but here they seem to be more so. The plates are ———, which I have used for twenty years. This is the first trouble. If you can help me I would be very much obliged, as you can see, having a great many dozens on hand yet."

From a careful examination of the negative, we suggested to our correspondent that the packing strips between the plates had, perhaps, not been pure, or the plates might have been stored in boxes giving off exhalations of a nature to affect the sensitive salts. To this our friend replied:—

"I thank you very much for your good advice. This said, I must say that I believe only one part of your sayings to be correct, and that is impure packing; this is proven by markings from paper on edges to separate plates, but here of little consequence. What is more important is the edges all around and the smoky-looking plate all through. The edges may be very well darkened by contact with paper packing all around but how about the balance of plate? As this may interest you somewhat in case of another complaint asking your advice, here are in a few words my trials to find out: Exposure in holder, plates in it for several weeks. Short exposures (ten seconds), small dark edges. Long exposure (ten minutes), larger edges dark. To find out if the holder is at fault; one edge covered with paper, others in contact as usual. After one week's contact result same, all around dark. Next exposure by contact in printing-frame plate right out from original packing, edges dark, the same. At last I developed a plate right from the original package without any exposure whatever, after fixing as usual, results: edges dark and plate smoky; so the original plates are at fault and not my holders. Now, as to exhalations from boxes, &c. Since fifteen years I live in my own house and store the unopened packages in the same place and box. From this the plates go direct to the holders to expose within more or less time, but never has that edge troubled before. After exposure I develop, taking plate, from holder direct, using no intermediate box; no damp, no fire, no smell. My opinion is that the origin is in the manufacture, and most probably in the substratum used to prevent frilling, as, if you kept my plate you can see on the edges the drying marks of it darkened and a dirty-looking edge all around, such as dust specks creeping up and showing granulated all around. This is better seen with a magnifying glass. Maybe you will remember a letter I wrote in the JOURNAL a few years ago asking why nowadays plates are no more as brilliant as heretofore, but all more or less foggy-looking; no answer came. Yet it is a fact. Look at it critically, and compare a negative of to-day and one ten years old."

This appears to be a clear case of lack of fault on the part of the photographer for the fogged condition of the plates. Perhaps in bringing the fact to the notice of the various firms of plate-manufacturers, we may be instrumental in assuring an avoidance of such troubles in future.

### NEWS-PHOTOGRAPHY.

THE war between Britons and Boers in South Africa has directed a great deal of public attention to those portions of the illustrated press which are the work of the photographer-journalist; in the current saying, he has come very much to the front of late. As some interest may be felt in knowing to what extent this branch of journalism has developed in the United States, the home of journalistic enterprise, we reproduce from the *American Annual* a very readable article by Gilson Willets, which gives a vivid picture of the deft and ready manner in which the smart New York journalist uses his camera in the service of his paper:—

Not many months ago the newspapers depended, for pictures, almost entirely upon artists. The news was illustrated by sketches that sometimes resembled the real scene or person, but which usually looked like something or somebody else. All young women suicides, poisoners, and the like, were shown as the most beautiful creatures the artists could sketch. Events happening a thousand miles away were pictured "by our special artist on the spot," that is, by an imaginative disciple of the brush, sitting in the office of the newspaper that was paying for his sketches.

Now, all this slipshod, any-old-way of presenting the news in picture is abandoned—by enterprising newspapers, at least. The artist has been supplanted by the photographer. Every newspaper of importance employs a staff photographer, who has his corps of assistants. To all parts

of the city and the country—indeed, all over the world—the newspapers are sending photographers to gather the news with camera as well as with pen. These bright, active, daring men are now recognised as news-photographers, and their work is called news-photography.

News-photography is a sign language. Who runs may read it. By means of this language the busy man can learn the news at a glance. This news-photography tells news stories truthfully. None of the inaccuracies of the pen, no fiction, no exaggerating of facts, no news that is not news. A camera does not lie. It shows people as they really look, reproduces scenes with realistic exactness. No chance here for the city editor to make the ugly young woman suicide a beauty, no need of "faking" a picture of events that are happening on the other side of the world.

And it is to be noted, to the credit of the so-called yellow journals, that they were the first to adopt the camera—the truth-teller—in presenting the news. At increased expense the journals who make use of news-photography are obliged to use paper that will take hairpoints from a half-tone on a rapid press. The *New York Journal* was the first, the *World* followed, the *Herald* is now in line. So also are the leading papers of most of the large cities. Not that the newspapers were the original users of news-photography, for the weekly illustrated journals and the magazines used photographs long before newspapers printed any pictures of any kind, even sketches. And to-day the weeklies spend a great deal more money for news-photography than the newspapers.

The news-photographer's berth is no sinecure. He must get up before daylight to photograph a celebrity on an incoming ocean liner. He must travel two or three hundred miles in a single day, hiring a section on a train, or a state room on a boat, to be used as a dark room in which to develop his plates in transit. He must sit up the remainder of the night to develop, to artificially dry, and to make platinum or bromide prints of the flashlights which he has taken in the early evening—that he may deliver the photographs in the early morning. During the war with Spain, he had to go to the front and make pictures, amid every difficulty and without a single convenience, as best he could. He must go out in a blizzard and make storm scenes. He must stand all day and all night, too, in wait for the coming or going of a personage of news importance. Let him fail to get a single photograph which he went to make and, if he is on the staff, he is in danger of losing his position. Let him fail thrice and he is peremptorily dismissed.

Meantime he gets a good salary while on the staff, and excellent pay if a free-lance. One free-lance news-photographer in New York, that I know of, will not take his camera out for less than fifty dollars. Others get five dollars each for negatives, and sometimes an extra allowance for their time. When employed for a special purpose, the news-photographer's expenses are paid. If he makes pictures on speculation, he must, of course, pay his own expenses.

The best known news-photographers in this country are Joseph Byron, who is most famous for his flashlights; J. K. Hemment, of the *Journal* and *Lester's Weekly*, who made such a fine record during the war; J. Hare, of *Collier's Weekly*, who also achieved a war record and who is such a persistent traveller; Vander Veer and Vander Wyde, the celebrity expert; Hare and Hart, who make a specialty of naval news; and Bidwell, who attends to horse events. Of all these, Joseph Byron stands at the head. His work always combines the qualities of timeliness and art. These men, and many others equally worthy of mention, are constantly on the jump, earning their money by the hardest, most nerve-racking kind of labour.

In Havana I saw Hemment, and Hare, and Hart, all three working themselves to skeletons, making photographs of the wreck of the *Maine* and the stirring scenes in Havana. Vander Wyde works day and night, giving the daily papers the story of the news in surprisingly fine pictures. Byron seldom gets but a few hours' sleep o' nights, because of the necessity of developing, and having ready for delivery the next day, the flashlights of "first night" theatrical events, made during the evening.

It is obvious that the news-photographer must have a fine nose for news; must not flinch where others flee; must always look alive; give no quarter even to people who do not wish to be photographed. He is ordered to get a snap-shot of a well-known Society woman. He must follow that lady till he gets a chance to snap his camera, and he must press the button or uncap the lens at the right moment. I was with Byron one winter day, when he—and I, too—stood all day long in the bitter cold and blinding snow, at Iydhurst-on-the-Hudson, to make a picture of Helen Gould when she should drive up to the castle door, on her return from the city. One hundred dollars was offered for this pic-

ture, but the reward was failure and two bad colds. Another news-photographer was recently ordered to get a snap-shot of Mrs. O. H. P. Belmont. It was a case of dead or alive—get the lady at all hazards. We shadowed her for three days, and at last got a flashlight of the great lady at night, just as she was stepping out of her carriage to enter Delmonico's ball-room. But, alack! even then the picture was only an excellent view of the lady's back. I had even a sadder experience recently in New York, when Admiral and Mrs. Sampson arrived from Cuba. I stood at the gangway on board the ship, and, when the Admiral began descending the boarding steps, I snapped my Kodak. Then, anxious to get Mrs. Sampson also, I snapped again without having turned the film-holder. The result was a blurred photograph, showing neither of the subjects.

The news-photographer must sacrifice art for subject-matter. The subject is everything; the excellence or the demerits of the photograph count for nothing for or against the worker. The idea is, Picture the news, whether the pictures are artistic or not. A poor picture of a public personage at a crucial, newsy moment is worth its weight in gold, while the finest, most artistic photograph of the same person at an unimportant moment is not worth the paper it is printed on. There is no time for posing the subject, or for taking the scene from the best point. Get the subject in the act, get action in the scene; these are the main objects.

News-photography is news-reporting, and the chief merit of a news-photograph lies in its timeliness. To-day the picture has a princely value, to-morrow no value at all. News-photographer Bidwell once sold a certain photograph of Cornelius Vanderbilt to one of the so-called yellow journals for ten dollars; ten minutes afterwards a rival paper offered twenty, fifty, a hundred, and actually two hundred dollars for a copy of that same particular photograph.

An article of this kind should end with practical suggestions regarding which cameras are best suited to news-photography. But, as no one camera is best for all work or for all operators, I can only say that the news-photographers I know best find a six by ten the most useful and most convenient for all-round general work. An eleven by fourteen instrument, with a long-focus lens, is found best adapted for sea work and long-range pictures. Shutters of a very rapid-acting type are an essential. When the use of these larger cameras is not always possible, a four by five snap-shot will be of excellent service. Indeed, for ordinary outdoor work, the success of which depends upon making a large number of exposures in the smallest possible time, the four by five snap has been proved to be the news-photographer's best friend.

#### A GLIMPSE AT "STEVENS'S."

Who does not know Stevens's, the well-known Covent Garden auctioneer's, through whose rooms, week by week, an endless stream of photographic and general scientific apparatus makes its way from one set of possessors to another? In the current number of the *Strand Magazine*, Mr. F. Anstey, the author of that amusing book, *Vice-versa*, commences a new story, in the course of which one of the characters has to betake himself to a sale at Hammonds', the Covent Garden auctioneers. In an excellent bit of descriptive writing he gives us the following picture of the sale, which may be witnessed several mornings a week at King-street, Covent Garden: "In spite of the fact that it was the luncheon hour when Ventimore reached Hammonds' Auction Rooms, he found the big, sky-lighted gallery, where the sale of the furniture and effects of the late General Collingham was proceeding, crowded to a degree which showed that the deceased officer had some reputation as a *connoisseur*."

"The narrow green-baize tables below the auctioneers' rostrum were occupied by professional dealers, one or two of them women, who sat, paper and pencil in hand, with much the same air of apparent apathy and real vigilance that may be noticed in the Casino at Monte Carlo. Around them stood a decorous and business-like crowd, mostly dealers, of various types. On a magisterial-looking bench sat the auctioneer, conducting the sale with a judicial impartiality and dignity which forbade him, even in his most laudatory comments, the faintest accent of enthusiasm."

"The October sunshine, striking through the glazed roof, regilded the tarnished gas stars, and suffused the dusty atmosphere with palest gold; but somehow the utter absence of excitement in the crowd, the calm, methodical tone of the auctioneer, and the occasional mournful cry of 'Lot here, gentlemen!' from the porter when any article was too large to move, all served to depress Ventimore's usually mercurial spirits."

"For all Horace knew, the collection as a whole might be of little value,

at it very soon became clear that others besides Professor Futvoye had angled out such gems as there were, also that the Professor had considerably under-rated the prices they were likely to fetch.

"Ventimore made his bids with all possible discretion, but time after time he found the competition for some perforated mosque lantern, engraved ewer, or ancient porcelain tile, so great that his limit was soon reached, and his sole consolation was that the article eventually changed hands for sums which were very nearly double the Professor's estimate.

"Several dealers and brokers, despairing of a bargain that day, left, murmuring profanities; most of those who remained ceased to take a serious interest in the proceedings, and consoled themselves with cheap vituperations at every favourable occasion."

### A USEFUL FORM OF STEREOSCOPE.

A CONTRIBUTOR to the *American Annual* gives the following particulars of a stereoscope which he attributes to Dr. T. R. Robinson :

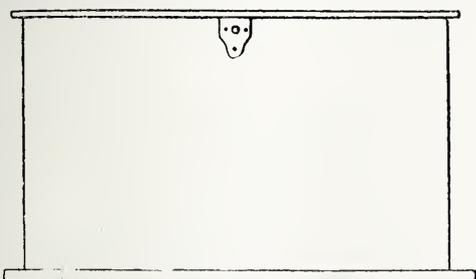

Fig. 1. The instrument when closed forms a case 13 inches long by 13 inches square (inside measure).

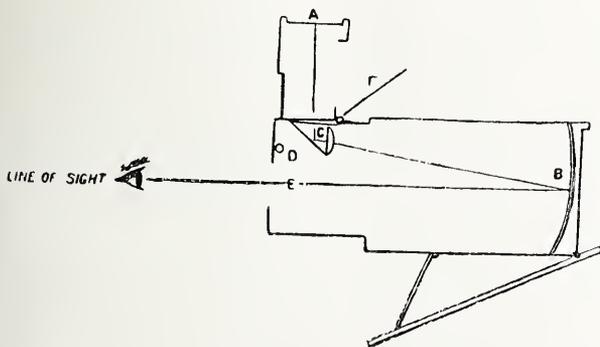

Fig. 2 shows the optical arrangement. A is where the slide faces downwards. c is a right-angled prism with two convex lenses cemented on its front face as shown, the centres of which are a little closer together than the views on the slide, and they form an inverted image on the large concave mirror, B, at the end of the case, and is viewed by the eyes through the opening, E; the top face of the prism is fixed in a line with the top of the case, and D is a milled head by which the part carrying the slide can be raised or lowered so as to adjust the instrument for distinct vision; Finally, F is a mirror for throwing the light up on to the slide.

The mirror (B) is 7 inches square and 11 inches focus. The prism (c) about 4 inches long, the sides including right angle  $1\frac{3}{4}$  inches. Focus of lenses, 5 inches and  $1\frac{3}{4}$  inches diameter.

### DIFFICULTIES IN SILVER PRINTING.

THAT much may be done to produce a good print from a faulty negative, by means of dodging in printing as well as submitting the negative to special preparation prior to its being placed out to print, is a fact well known to every photographer who is possessed of even a moderate amount of photographic experience, and it is also well known that, in the hands of an expert printer, many seemingly useless negatives can be so manipulated as to cause really serviceable prints being pulled from them.

The numerous dodges to which printers resort in dealing with faulty negatives are now and again trotted out in the different handbooks and

other photographic literature, very much of which all run in the same groove, and too often savour of an amateurish nature, for professional printers know when to keep a good thing up their sleeve quite as well as any one.

That a deal may be done to improve the printing quality of a negative by subjecting it to one or other of the common every-day dodges, such as the application of ground glass or mineral paper to certain parts of its surface, and also by reducing over-density by any of the well-known methods so generally practised, is a fact recognised by every one; but, as a rule, all our handbooks and guides to photography stop here, leaving a student to worry over an indifferent-printing negative, and which, in his hands, is never capable of being made to yield anything like the results an expert printer can produce, simply by reason of the fact that the expert printer carries his treatment of a faulty negative a long way further than many might imagine.

During recent years the production of special photographs for reproduction by means of half-tone blocks has caused the utmost attention to be devoted to this branch of photography, and it is quite surprising what is now capable of being accomplished in the way of turning out high-class results from indifferent negatives.

Take, for instance, the case of a dimly lighted interior, in which a stained-glass window forms a prominent object in the view, the details of which are required to be faithfully rendered as well as the architectural features of the building surrounding the window, and we have a by no means easy subject to photograph without special means of lighting, only practised by a few expert architectural photographers. Even with their special knowledge of how best to photograph such a subject it is quite ten to one the negative they produce will be considerably improved by after-manipulation; but it is not only in the treatment to which such a negative is subjected that much of the final success in reproduction lies, there is what may be termed an intermediate stage of dodging not only the negative during its printing, but a very clever system of treating the actual print (during the time it may be said to be printing) in such a manner as completely stops the printing of those parts that are being over-done before the denser portions gain a sufficiency of depth. To many not experienced in printing difficult negatives this may appear almost an impossibility; but, as everything is easy when you know how to do it, so such a method of treating a faulty negative gives little thought or trouble to an expert printer.

When it is impossible to produce a fairly even print by means of ordinary printing, one of the most effectual means of gaining satisfactory prints from an uneven negative will be found to consist in subjecting those parts of the surface of the silver prints that are being over-done to a blocking-out operation, performed by applying a suitable water-colour pigment where it is desired to stop any further action of light. Many young printers, although quite appreciating the *rationale* of such a method, fail to understand how it is possible to obtain possession of a silver print so as to apply to its surface such a pigment in as careful a manner as is necessary without the removal of the print from the surface of the negative, and the consequent liability of being unable to register it in exactly the proper position, so as to avoid even the slightest semblance of what is termed movement in a printing frame.

In practice, however, there is no real difficulty in accomplishing such an operation, and, once a printer has ocular demonstration of this treatment of a print, he for all time coming would never think the operation a difficult one.

To carry out this seemingly difficult printing dodge, the negatives should be printed in frames a size or two larger than that of the negative itself. This is best accomplished by attaching the negative to the centre of a thick sheet of glass by means of strips of gummed paper, binding carefully round its edges, so that it will not move during the time it is in the printing frame. This done, the negative will be found firmly attached to a sheet of glass having a margin all round its sides. This margin is of service in the way of permitting a sheet of paper being used in printing that is larger in size than the negative, and will enable the side or one end of the printing paper being gummed or otherwise firmly attached to the glass support in such a manner as will permit of the negative and its glass support being removed from the printing frame as often as may be desired during the time of printing, so that the most careful examination of all portions of the surface of the print may be made.

The printing paper being of considerably larger size than the negative permits of the print being folded over. After the negative and its support are removed from the printing frame, when folded over, it enables any water-colour pigment, such as gamboge, or ivory or lamp-black, being carefully painted over the very finest part that may require to be stopped off from further printing, and, when the pigment is dry, the print is merely folded down in contact with the surface of the negative again, with the certainty of being in perfect registration. Of course, the application of the pigment is best conducted under a good lamp light, such as a powerful paraffin table lamp would yield in a darkened room. This prevents any degradation of the paper during inspection and manipulation. The painting of an opaque pigment on the surface of a silver print will cause no evil effects to the print, for the pigment will wash off in the first washing water, and the toning operation proceed as

usual, and there is also no difficulty in tracing over the minutest outline if merely an ordinary amount of care be taken and a suitable brush employed.

By this means an expert printer is possessed of almost unlimited power in the production of single as well as even combination prints. Faulty backgrounds being blocked out in the negative will enable any portion of a picture being printed on one negative to any extent, and, this being blocked off on the surface of the print, may then be removed to another negative, and quite a different background printed in.

The secret of success lies in so attaching the print to the surface of the glass support that the entire surface of the printing paper is capable of being got at without the possibility of the image showing any movement from the surface of the negative when readjusted.

To many this method of printing a negative may be considered difficult. In practice, however, it is quite easy of accomplishment, and, once practised, can be made to yield quite a number of particularly fine prints from negatives that would by many be discarded as unprintable.

T. N. ARMSTRONG.

### COLOUR PHOTOGRAPHY: KRAYN'S SYSTEM OF VIEWING THE PICTURES.

IN Herr Krain's invention the object is to bring the development of the coloured picture before the eyes of the spectator in such a way that the latter sees at first what appears as an ordinary photograph, and not one that is affected by a colouring light filter, and thereafter part-pictures, appearing in the three ground colours, are successively brought to view, and the complete picture then appears in natural colours.

This purpose is attained by the arrangement of movable mirrors, and contingently also of movable screens in front of separate part-pictures.

In the position of rest, the two mirrors, which are employed for bringing to view two of the part-pictures into the optical axis of the ocular, are outside the range of view of the eye, and only the one part-picture is visible, that which lies directly in the optical axis of the ocular, and which, like the two others, is a glass diapositive in black and white, and is lighted by a white reflector behind. By means of a crank or clockwork, the disengaging of which can be effected by the insertion of a coin in any preferred manner, the mirrors are gradually carried into the interior of the apparatus and within the optic range of the eye, and at length attain, by means of a suitable mechanical arrangement, the

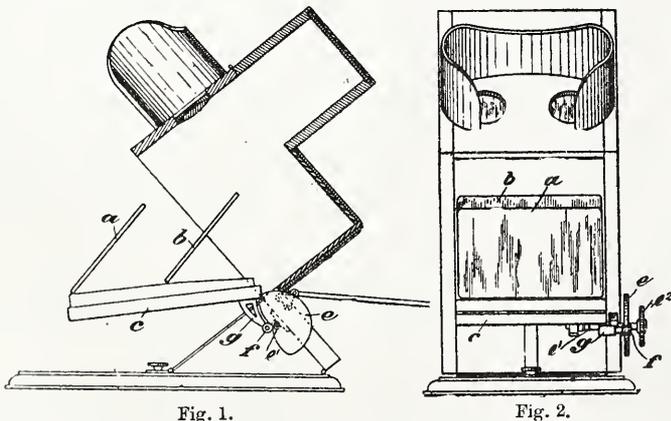

Fig. 1.

Fig. 2.

position in which the other two picture-parts, made visible by means of the mirrors, come into the optical axis of the ocular, and are covered at all points by the directly visible picture.

For automatic purposes the mechanism can be arranged in such a manner that the mirrors, after a certain time, return to the position of rest.

With the mechanism for moving the mirrors, the screens which are intended to cover the two diapositive part-pictures before the moving of the mirrors into the position for use can be so connected that they release the two diapositives successively. The white reflector also, which illuminates the directly visible picture-part, can be so moved aside when the mirrors are moved that the picture-part directly visible becomes illuminated by a yellow reflector placed below.

The movable screens, as also the white reflector, are, however, not absolutely necessary for the intended purpose, as without them the production or origination of the coloured picture will be clearly shown.

The directly visible picture is in this case illuminated by a yellow reflector, and appears in ordinary photographic tones on a bright yellow background whilst in the mirrors, which, in consequence of their position in relation to their axis of rotation, appear successively within the range of vision of the spectator's eye, the red and blue part-pictures become successively visible.

In the chromoscope, *a* and *b* are the two movable mirrors. These are supported by the plate, *c*, and move together with the latter around the axis, *d*. The motion itself is produced by means of a cam, *e*, on the circumference of which a small roller, *f*, supported by a bracket,

*g*, fixed to the plate, *c*, slides. On the shaft, *e*<sup>1</sup>, of the cam, *e*, a tooth-wheel, *e*<sup>2</sup>, for rotating the shaft, *e*<sup>1</sup>, may be provided as shown in figs. 2 and 4. The rotation may also be effected directly by hand, through the medium of a crank keyed on the shaft, *e*<sup>1</sup>.

The cam is so constructed that, when it makes a quarter turn, the mirrors are moved out of the position of rest into the working position; then, upon the execution of a further half-turn, the mirrors are left in

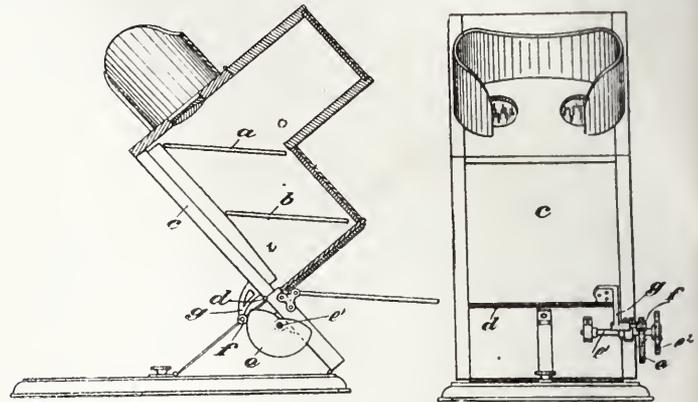

Fig. 3.

Fig. 4.

the working position, and therefore, at the last quarter-turn, the mirrors are returned again to the position of rest.

In the position of rest for the mirrors, the small roller, *f*, is in the heart-shaped incision of the cam, *e*, as shown in fig. 1. Upon the cam being rotated, no matter in which direction, the roller is brought out of the heart-shaped incision to the concentric circumference of the cam. As soon as this is effected, the mirrors take the working position indicated in fig. 3, in which the three part-pictures are superposed. The mirrors remain in their working position until the roller, *f*, leaves the concentric circumference of the cam, whereupon the mirrors move back again until the roller in the heart-shaped incision of the cam forms their immovable point of support.

### NOTES ON MOUNTING STEREOSCOPIC PRINTS.

[Specially translated from the *Revue Suisse*.]

HAVING recently had occasion to mount a number of stereoscopic photographs, the empirical—not to say inaccurate—manner in which this operation is described in the special text-books on the subject led me to study the question for myself with some degree of care; as a result, I found that it is possible to conduct this operation according to determinate principles, the explanation of which is the object of this article.

I propose considering only those prints intended for examination in a direct vision stereoscope of the usual type, passing over the theory of mounting those larger prints for which special and rarely used apparatus is required.

Of course, the method of making stereoscopic prints is well known, viz., by the most usual plan of using a camera carrying two lenses, separated about three and a half inches, thus obtaining two views the planes in which are geometrically similar but slightly differently disposed. If we mount two stereoscopic prints on a card so that the two inside margins touch on what we may call the *axis* of the card, then it is easily shown that, if the distance between two *homologous*\* points in the foreground is called *d*, the distance, *d'*, between two homologous points in the distance, will be less than *d*. In the right-hand view the foreground is displaced towards the left in relation to the distance, whilst in the case of the left-hand view the opposite is the case. These homologous points are thus drawn towards the axis of each print, and therefore their distance apart is less than those of points in the foreground.† This difference of separation is, of course, not large; with lenses of 6 inches focal length it only amounts to .12 of an inch for planes situated 15 feet from the camera, a distance within which one would rarely go. At 30 feet the difference between *d* and *d'* is only .056 of an inch, whilst at 60 feet it falls to .028. It is this difference between homologous points in the two views that is the cause of the stereoscopic effect. As it is practically and inversely proportional to the distance of the different planes from the objective, it is evident that it sinks to a minimum as those distances increase. Consequently the sensation of relief can only be given in stereoscopic pictures in which the foreground is fairly close.

Imagine our two prints mounted on card, and exactly coincident (inner edge to inner edge) with the axis of the card. Let us further suppose that their breadth is equal to the distance, *d*, between homologous points

\* I use this term to designate the points in each view corresponding to the same point in the subject.

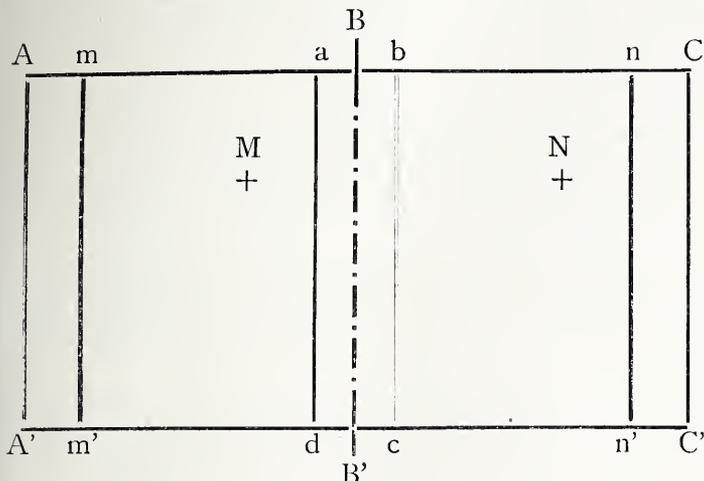

† If we call the focal length of the lenses *f*, their separation *l*, and the distance of the first plane considered, *A*, then calculation shows that

$$d' = d - f \times \frac{l}{A - f}$$

in the foreground. I will call this the *normal condition* of a stereoscopic view. This distance, approximately equal to the separation of the eyes of the observer, may vary from 2.56 to 3.35 inches without any inconvenience being felt.\*

In the normal state the foreground will be identical in each print; each point will have its homologue in the other. This method of mounting is to be recommended more particularly for paper prints.

I ought to mention here a defect frequently observable in commercial stereoscopic views. Many stereoscopic photographers, following the erroneous directions in the manuals, get into the bad habit of making each of the two views (which meet at the centre of the card) broader than the distance between two homologous points. The natural result is that the points in the portions beyond the normal width have no homologues in the other view, and so do not aid the production of relief. Besides which, it is a necessary consequence of the way in which the majority of

stereoscopes are made that the left eye can always see part of the left edge of the right-hand image, a similar thing taking place in regard to the right eye. When the prints are normal, they exactly coincide, and the eye instinctively disregards the two edges of the images which surround the relief view on either side; but, when the images spread over their outside edges—that is to say, appear there as points without homologues—it is evident that the right eye will project the right-hand edge of the right-hand print to the same point in space where the left eye is projecting the left-hand edge of the same print. The same thing occurs in the case of the outside edge of the other print, and the total result is that the stereoscopic view is bounded on right and left by an irritating appearance of non-coincident images. This is an extremely annoying defect, and greatly detracts from the pleasure of examining stereoscopic prints.

I have before me a collection of views in which the photographer has made his prints 3.3 inches, whilst the separation of homologous points is only 2.76 inches. This difference of .56 of an inch greatly diminishes the stereoscopic effect of otherwise very excellent views.

Other stereoscopes do not possess this inconvenience, and are arranged so that each eye can see only that image which it ought to see. In those cases the superfluous portions of the edges are projected on the black partitions of the apparatus, and the stereoscopic view is bounded on either side by indistinct margins consisting of the parts of each print left without homologues. It is a very simple matter to convince oneself that to retain these parts without corresponding homologous parts is not only useless, but detrimental, to the whole effect.

My advice is to trim each print up to its homologous points. If a wide print is wanted, then a similarly wide separation of the corresponding points in the foreground must be insisted upon; but this must not exceed 3.35 inches, since, beyond this limit, the eye can obtain the sensation of relief only with some strain, and soon grows fatigued. It is better to make this distance and the width of the prints from 3 to 2.55 inches. One can have even narrower views than this latter dimension so long as the distance between homologous points is kept at this figure. This would, of course, mean that the prints would not meet at the centre of the mount.

Obviously, the same rules apply to stereoscopic transparencies, and, as the ground glass of commercial stereoscopes rarely exceeds five and a half inches in length, the width of the prints should never exceed or even reach two and three-quarter inches, *i.e.*, the distance between their homologous points.

One point here must be insisted upon. Suppose we have two views in the normal state, *i.e.*, in which the width, A B, or B C, is equal to the distance, M N, between two homologous points. It is usual to mount transparencies with a mask, by which they are separated, as shown at a b c d. If the outside edges at A A' or C C' are at the normal distance,

\* Lenses are generally placed about 3½ inches apart, so as to give two views on a plate about 7 inches across. This amount of separation is a little too great for the printed views.

the views will embrace superfluous portions corresponding to the parts hidden under a b c d. The masks should be cut so that the outside border falls as shown at m m' and n n'.

It is even a good plan to bring these side masks, m m' and n n', closer to the centre so as to conceal in the right-hand image the homologous points of the line a d and in the left-hand image those of c b. The distance between the edges, a d and n n', or between m m' and b c, will be smaller than that between two homologous points, as M N', and it will therefore appear as though the mask were in front of the view; in other words, the sensation of relief will be enhanced by the suggestion that the scene is being viewed through a window. If, on the other hand, the edges of the mask fall on A A' or C C' or outside of these lines, the anachronism of the frame behind the view is produced. Perhaps I can explain better by taking an actual example. The masks of the photographic depot are sold with openings each 63 mm. (=2½ inches, very nearly), separated by a band 6 mm. (=¼-inch very nearly), giving a total length of 132 mm. (practically 5¼ inches). Taking 72 mm. (=2.84 inches) as the distance between homologous points in the foreground, this distance is greater than 36+6=69 (=2.71 inches), the distance between corresponding edges of the mask. The latter will therefore stand boldly out, which it would not do if a smaller separation than 69 mm. were taken between homologous points in each print. The height of the prints does not enter into these calculations, being regulated merely by the conventional proportions of commercial stereoscopes. As a general rule, a height of 70 to 80 mm. (=2.76 to 3.15 inches) is the best. It is, of course, absolutely essential that homologous points shall occupy practically the same vertical position in each view.

Stereoscopic relief is generally attributed to binocular vision; but, if a stereoscopic print is viewed in the stereoscope first with both eyes and then with only one, it is at once perceived that the difference is slight. With the exception of the foreground, the relief in which is much less apparent in the case of monocular examination, the image produces the same impression as when viewed with both eyes. It may be concluded—and this advice is very frequently given by authors of stereoscopic manuals—that in order to obtain stereoscopic prints showing good relief, it is necessary to select subjects possessing striking foregrounds, such as interiors, caverns, gorges, &c., distant landscapes being outside the scope of the stereo photographer.

The use of the stereoscopic relief in the foreground is to give the effect of relief to the rest of the image; it gives rise to the same effect produced in dioramas, the first planes of which are the only ones separate and real, and are skilfully combined with a background painted on canvas. Yet in the diorama the appearance of solidity is as apparent as in nature, and this despite the fact that binocular vision plays no further part in it than it does in the observation of a painting. The perspective of a picture can be appreciated much better with one eye than with two, for in this instance binocular vision, by revealing the flatness of the canvas, helps to destroy the effect aimed at by the painter, whilst the single eye permits itself to be deceived by the illusion of good perspective.

If, therefore, we discern natural objects in relief, it is because of an unconscious education of our eye; and this sensation depends exclusively on perspective—on geometrical perspective as much as on aerial perspective. Binocular vision comes into play only in the case of objects near at hand emphasising the idea of the space between them in a manner impossible to the most successful perspective. If we have the sensation of relief at distances beyond about thirty to forty yards, it is because our eyes have been specially educated, and we experience the sensation of such relief quite as intensely, even when, as in the case of a painted scene placed some yards from our eyes, it is non-existent, provided that some real objects are placed before it to suggest the idea of relief. An additional proof of this is to observe a painting through a tube by which the eye is screened from the sight of all real objects. The eye is, under these conditions, easily led away by the perspective of the picture, with the result that the relief appears as great as that of the middle distance in the stereoscope, or even as that of actual objects occupying a position some distance from the eye. Distant objects cannot be seen in relief by the eye.

J. Bois.

#### SHORT-LENGTH SPOOLS FOR CARTRIDGE KODAKS.

In the JOURNAL for December 22 last we called attention to the fact that the Eastman Kodak Company, of Rochester, N.Y., were supplying the American photographic public with daylight cartridges for Kodak work, containing rollable film for two or six exposures, and we remarked that this departure had been made to meet the requirements of the photographer who may wish to make a few exposures without using up an entire spool of a dozen exposures before resorting to development. We then anticipated that this new convenience in film photography would in due course be placed at the disposal of European photographers. Kodak Limited now inform us that these short-length spools are available on the English market, and they send us the following particulars and prices of them.

The Company state that now and then, especially in winter, the photographer wishes to take two, or, say, half a dozen pictures, but does not

care to be obliged to use up an entire spool of a dozen exposures before development. They have, in consequence, often had requests for short spools of six exposures. In response to this demand they announce the introduction of short-length spools of daylight-changing cartridge film, of six-exposure and two-exposure capacity each.

The following is the price-list:—

	Six-exposure spool	Box of two spools, two exposures each	Single spool, two exposures	Ordinary spool of twelve exposures
	s. 6.	s. d.	s. d.	s. d.

### AN OPEN LANTERN-SLIDE COMPETITION.

THE Southport Photographic Society announce a lantern-slide competition in March 1900. It is to be open to all photographers, and medals, silver and bronze, will be placed at the disposal of the Judges.

Competitors are to send in sets of six slides, for which an entrance fee of 1s. will be charged.

The following are the general regulations:—

1. No competitor shall receive more than one award.
2. All slides must be three and a quarter inches square, properly mounted and marked, and must be from negatives of original subjects, taken by the competitor. The name of the subject or title to be plainly written on the face of the slide when looked at in its correct position. Any slide not properly marked will be disqualified.
3. Sets of slides, addressed to the Hon Secretary, must be delivered free of charge at the studio, 15, Cambridge-arcade, Southport, on or before March 24, and will be returned not later than April 2, 1900.
4. Entry form and fee (1s.) to be enclosed with each set of slides.
5. All reasonable care will be taken of slides, but the Society cannot accept any responsibility for damage.

Judges (not members of the Southport Photographic Society) will be chosen by the Committee. Their adjudications shall be final.

Arrangements will be made for publicly showing the slides in Southport.

The Hon. Secretary is Mr. George Cross, 15, Cambridge-arcade, Southport.

### TWO FLOURISHING PROVINCIAL PHOTOGRAPHIC SOCIETIES.

WE have this week received the annual reports of two of the most important and progressive photographic societies in the country, the Liverpool Amateur Association and the Birmingham Photographic Society. From the record of the year's work of the former body we take the following extract:—

The membership roll at the beginning of the year contained 326 names; the number of new members elected during the year amounted to 40; resignations, lapses, and deaths, to 38; leaving 328 names in the books at the end of the year.

The Coffee Meetings, held on Wednesday afternoons from four to five, still prove an attraction to a number of members who are inclined for a social chat.

The special feature of the year has been the completion of the new enlarging room, at a cost of about 60l., the greater portion of which was defrayed by voluntary subscriptions from members. The room has been fitted up with all the latest appliances for enlarging on paper, or for making enlarged negatives by artificial light. The source of light is incandescent gas, and the lantern, by Ross, has a ten-inch condenser and the latest stigmatic lens. Altogether it is perhaps one of the finest lanterns ever made for enlarging purposes. Subject to certain necessary by-laws regulating its use, the enlarging room is at the disposal of members free. For those who still prefer to use daylight the old enlarging camera is available as before.

Upon such evidence of prosperity we heartily congratulate the old and historic Liverpool Association.

In like manner we felicitate the Birmingham Society on a year's splendid photographic work, to which the following few extracts from its voluminous report bear testimony:—

The Fourth Annual *Conversazione* was held at the Grosvenor Rooms on January 31, when 148 members and friends spent an enjoyable evening. Mr. Gregory's band again contributed the musical programme, and Mr. C. J. Fowler acted as M.C.

It is with regret that your Council records the retirement of Sir J. Benjamin Stone, M.P., from the office of President, which he held for nine years. During this long period the Society has considerably developed its resources and materially increased its reputation under the potential influence of Sir Benjamin, and every member will cordially join

in expressing hearty appreciation and thanks for his honourable association with the office.

Professor F. J. Allen, M.A., M.D., fulfilled the office of President for the greater portion of the year, but, as he left Birmingham in the autumn, it will be necessary to appoint a successor.

Mr. J. T. Middlemore, M.P., has kindly consented to act in this capacity for the ensuing year.

The list of members has been increased by thirty, thus equalling the accessions of last year, which were the most numerous recorded.

The financial position of the Society continues to be thoroughly sound. The revenue is sufficient to meet current expenditure, and, in addition to the purchase of necessary lantern appliances, drapery, &c., the profits from the Exhibition and *Conversazione* enable further increase to be made to the reserve fund.

Inquiry is frequently made as to the object in creating a large reserve fund. Your Council recognises the desirability of making provision for adverse emergencies, and is also of opinion that, amongst other objects, a portion of the amount may be serviceable for furnishing rooms when suitable premises for the requirements of the Society may be procured.

The Annual Exhibition was, by kind permission of the Royal Society of Artists, again held in their admirable Galleries in New-street.

The pronounced success of the previous Exhibition in these rooms induced your Council to make strong endeavours to still further improve the general character and to raise the standard to the highest excellence upon this occasion.

A scheme of decorative drapery for the whole of the rooms was taken in hand by a sub-Committee, who provided a subdued background of pale green, relieved by darker shades, the colours being reversed in other rooms.

For the first time all pictures sent in were subjected to the approval of a Selecting Committee, and the severity of the ordeal is indicated by the fact that over 180 prints were rejected.

While the total number of exhibits was thereby materially reduced, the quality of the work accepted was much above previous standards, and probably very few frames were hung which were undeserving of attention.

The artistic success of the experiment encourages your Council to strongly advocate the exhibition of none but high-class work.

The old order of classification was dispensed with, pictures of any subjects being accepted in the Open and Members' sections.

In addition to the competitive work, a loan collection of 113 pictures by twenty-five of the leading artistic workers was displayed, and these included the unique series produced some thirty years ago by the late O. G. Rejlander, and kindly lent by the Council of the Royal Photographic Society.

The total number of pictures exhibited was about 470, in addition to the display of professional work.

The total attendance during the Exhibition was between five and six thousand.

In June last the Curator handed over to the City Art Gallery authorities prints to the number of 385, which have been contributed to the Survey by members during the last few years. These will, as soon as sufficient space is available, be exhibited in the City Gallery for a time, and afterwards deposited with the permanent collection, which now numbers upwards of 2000, in the Reference Library.

In addition to this number the Curator received fifty-three prints, contributed by five members of the Birmingham Photographic Society, and these were entered for competition at the last Exhibition, when a silver and bronze medal and certificate of hon. mention were awarded. This is unfortunately the smallest number of prints that has been handed in for several years past, and, considering the extensive membership of the Society, a poor representation of its workers in this section. It may be as well to remind our friends that *all members* of the Birmingham Photographic Society may contribute prints to the Survey, the only stipulation being that such prints shall be printed in platinum, carbon, or bromide, and should preferably consist of a series of some object, or objects, in Warwickshire not already in the Survey collection. These can be handed to the Survey Curator at any time during the year, and those sent in good time for cataloguing and mounting will be entered by him in the members' names for competition at the next following Birmingham Photographic Society's Exhibition.

It is to be regretted that no meetings of the "Photographic Survey of Warwickshire" have been held for the last eighteen months, and therefore your representatives upon that body have had no opportunity of advancing its cause.

The journey to London for the inspection of the Autumn Photographic Exhibitions, &c., was again included, and may now be regarded as an annual event.

### THE CAMERA CLUB.

THE January number of the *Club Journal* states that it has been decided that for the future the *Journal* shall be conducted by a small committee. The gentlemen who have been elected members of the Editorial Committee are Messrs. Charles A. Cooper, Basil E. Lawrence, Henry H. P. Powles, and Horace Wilmer. By special arrangement with the Central

News, Limited, a column printing machine has been placed in the Club House, and is now in working order. It is intended to continue the house dinners during the present year. The next dinner arranged is a cycling dinner, of which due notice will be given. A member, Mr. F. M. Elliot, of Singapore, will be happy to receive any members of the Camera Club who may visit the Straits Settlements, and will place a dark room at their disposal.

To the same number Mr. Andrew Pringle contributes a memoir of the late W. K. Burton, in the course of which he says: "He and I spent many days together in my laboratory working out photographic problems, for these were the vastly interesting days of the earliest gelatine emulsion experiments. I also collaborated with him in writing a very long and exhaustive book on photography, theoretical and practical, a book which, by the way, I had to boil down to about one-eighth of its original size. He was one of the most acute observers I have ever known; no phenomenon, however apparently insignificant, escaped his notice, and he never rested till he had at least made a vigorous attempt to account for it. As an example I shall never forget the time when he noticed that certain plates, though extremely sensitive, had an emulsion almost ruby colour by transmitted light; we puzzled and worked over this for a long time before he, not I, discovered the reason, which I now know to have been the true one. Probably this faculty of observation was the key to his eminence as a scientific observer, for beyond doubt he was one of our best writers and experimenters. I have been told that he was no less a man of mark in his own professional line. He was one of the founders of the Camera Club, and took the greatest interest in its career in the good old one-horse days of Bedford-street. It will be long before we find another 'W. K. B.'"

Other contents of the number, which is a very interesting one, are papers on "Some principles of Development," by Mr. Alfred Watkins; "Continental Romanesque and Gothic Architecture," by Mr. Middleton, and "Illusion and Anomalies of Vision," by Mr. Shelford Bidwell.

## THE GLOUCESTER CONVENTION AND THE GLOUCESTER-SHIRE PHOTOGRAPHIC SOCIETY.

### PRESENTATION TO THE LOCAL HON. SECRETARY.

ON Monday evening, January 15, after the usual business in connexion with the election of officials for 1900, the retiring President (Mr. Medland) said that one of the last duties of his official year was a very pleasing one, viz., to hand Mr. Dugdale a cheque which had been subscribed for by the local members in acknowledgment of the very efficient manner in which he had discharged the duties of local Hon. Secretary to the Convention. He had heard on all sides that the arrangements made were excellent, and the members of the Convention who attended the Gloucester meeting were more than satisfied.

Mr. Dugdale, in replying, said that, when he undertook the duties, he did not look for any reward, and was pleased to find that his services met with such a handsome recognition. He had received the greatest assistance from the local Committee, and the success of the meeting was entirely due to them. He need hardly say that the cheque should be put to a good use: in purchasing photographic apparatus.

The new officials appointed for 1900 were:—President, Dr. John Campbell; Vice-President, Mr. S. Jones; Secretary, Mr. E. A. Ind; Treasurer, Mr. John Tibbetts; Committee, Dr. Oscar Clarke, Messrs. R. W. Dugdale, and H. Medland; Hon. Lanternist, Mr. A. Pitcher.

## News and Notes.

WE are sorry to learn that Mr. Alfred Seaman, of Chesterfield, has been ill with influenza. He has now recovered, and is able to attend to business.

WE also regret to hear of the death of Mr. Mitchell, photographer, of Brighton, who carried on business in the town under the style of "Mora."

THE Hon. Secretary of the Hove Camera Club asks us to state that the medals awarded at the Exhibition in December last have been posted to the successful competitors.

LIEUTENANT ALISTAIR VALENTINE, of the firm of Messrs. Valentine & Sons, Dundee, will be in command of the first battalion of Dundee Volunteers, shortly proceeding to South Africa.

THE SOUTHSEA EXHIBITION.—The Hon. Secretary asks us to state that the 22nd inst. is the latest date for receiving entries for the Twelfth Annual Exhibition of the Southsea Amateur Photographic Society.

ROYAL PHOTOGRAPHIC SOCIETY.—Technical Meeting, Tuesday, January 23, at 66, Russell-square, at eight p.m. "Note on Dr. Vogel's Method of Preparing Subhaloid Salts of Silver," by Major-General J. Waterhouse, I.S.C.

THE Bay State Photo Company, Lymm, inform us that their monthly developing competition for one guinea has been awarded to Mr. J. Massey, Ruthin-street, Pendleton, for a bromide print developed with their developer.

MR. H. H. H. CAMERON devoted the whole of the proceedings of last Monday evening's performance of *The Snow Man* at the Lyceum to the War Fund. The Lyceum was the first theatre to announce a children's entertainment on behalf of the fund.

MESSRS. FUERST BROS.' latest cinematograph films, taken at Southampton on Saturday last, the 13th inst, are as follows: Arrival of the Lord Mayor, in state, on board s.s. *Briton*; Embarkation of the City of London Volunteers on board the Union Liner *Briton*.

THREATENED STRIKE OF BELGIAN GLASS-WORKERS.—A Brussels correspondent states that an extensive strike is threatened among the glass-workers in the district of Charleroi. The dispute turns on the question of wages and the employment of non-union men.

PHOTOGRAPHIC CLUB.—Wednesday evening, January 24, at eight o'clock, Annual Ladies' Night. Tickets will be forwarded to each member, and any remaining will be distributed to those members requiring them. Early application is requested, as the supply is limited.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday next, the 25th inst., there will be a demonstration of the "Biokam Animated Photography," by Mr. Walter D. Welford. Amongst other films those taken at the Belgian excursion will be shown, and members of the Belgian party and other visitors will be welcomed at the White Swan, Tudor-street, E.C.

ACCORDING to the Paris correspondent of a contemporary, Englishmen resident in Paris have been chaffed and jibed at since the war broke out, and they have seen the British uniform hissed and howled at when it was reproduced on the films of the cinematograph, where poor "Tommy," hearing nothing and seeing nothing, could not throw off his belt and jacket and shout, "Arf a mo'" to his insulters.

THE "SPHERE."—Mr. Clement Shorter has been for some months preparing for his new paper. Such well-known black-and-white artists as Mr. Prater, Mr. Woollen, and Mr. Schonberg have been sketching in advance in South Africa for the first number, which will make its appearance at the end of this month. Lord Rosslyn has lately been commissioned to use his camera at the seat of war in the interests of the *Sphere*.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.—There will be a meeting of the Council at Anderson's Hotel, Fleet-street, London, E.C., on Thursday, January 25, 1900, at six o'clock. The following is the agenda: To discuss the proposed arrangements for the Newcastle Meeting; to elect three members of Council; to revise the rules in accordance with the alteration agreed to at the Gloucester Meeting; general business.

THE Photographic Club's forthcoming fixtures are as follows: January 24, Annual Ladies' Night; January 31, Paper by Mr. A. H. Wall, "Rejlander, his Life and Work"; February 7th, Lecture, "A Holiday in Norway," by Mr. H. J. Klosz; February 14, Members' Open Night; February 21, Exhibition of Prints and Slides of "The Belgian Photographic Excursion, 1899," arranged by Messrs. W. D. Welford and W. F. Slater.

REDHILL AND DISTRICT CAMERA CLUB.—A lantern Exhibition and lecture on "Round about the Matterhorn and Aletsch Glacier" will be given in aid of the scientific apparatus fund of the Club by Mr. Henry Speyer at the small assembly room, Market Hall, on Wednesday, January 24. The lantern will be operated by Mr. William Brooks (late of the Crystal Palace). The chair will be taken at eight o'clock by the Mayor of Reigate (Mr. F. E. Barnes, J.P., C.C.).

THE South London Photographic Society will hold their Eleventh Annual Exhibition at the Camberwell Public Baths as hitherto. It will be opened on March 3 and continued to March 10. Messrs. R. Child Bayley, F.R.P.S., Thomas Bedding, F.R.P.S., and E. J. Wall, F.R.P.S., have consented to act as Judges. Full particulars and entry forms can be obtained from the Hon. Secretary, Mr. F. Goddard, Woodlands, Vanbrugh Hill, Blackheath.

THE TWENTIETH CENTURY PHOTOGRAPHIC EXHIBITION, BIRMINGHAM.—Mr. Walter D. Welford points out that in Class K, "Negative working up," it is not intended that professional photographers should be debarred. Both employees of professional photographers and the photographers themselves are eligible, and are invited to compete. The test negatives are now ready, and may be obtained, along with conditions, from 19, Southampton-buildings, Chancery-lane, London, W.C., price 2s. 6d. each, post free.

A COMPETITOR for a prize offered by a contemporary for some verses about the century makes the following monstrously diverting reference to photography "in the brave days of old":—

"You could not buy a photo then of girls like Edna May,  
For Daguerreotypes were negatives, plain English did not pay,  
And Slater's female Sherlocks did not snap-shot night and day,  
When this old grey-headed century was young."

PHOTOGRAPHS IN A DIVORCE CASE.—In the course of a recent divorce action it transpired that, after he had commenced his suit, the petitioner received a parcel of photographs from the co-respondent, upon each of which there were words in the co-respondent's handwriting. One, entitled "The Welcome," represented the co-respondent and respondent shaking hands; a second, called "A Good-bye," showed the co-respondent on horseback, and the lady saying good-bye; a third, entitled "A Call Back," pictured the co-respondent on horseback, with the lady standing by his side, both looking towards the house; while a fourth, beneath which was the word "Yes," represented the gentleman proposing to the lady, whose answer evidently was "Yes."

THE AUSTIN-EDWARDS MONTHLY COMPETITION.—The following is the list of awards in the Austin-Edwards lantern-slide and film-negative competition for the current month: 3l. cash prize, Mr. M. Harding, Shrewsbury, *Statue of Artemis, Eaton Hall*; 2l. cash prize, Mr. J. Browning, Lowestoft, *Evening on Oulton Broad*; 1l. cash prizes, Mr. G. Bird, Bath, *Happy Childhood*; Dr. P. Sharp, Newark, *Dew-drops on Spider's Web*; Mr. E. R. Bull, Forest Hill, *The Crypt, Wells Cathedral*; Mr. W. H. Tomkinson, Liverpool, *Frost Scene*; Mr. H. O. Isaac, Bristol, *Sunset on River Avon*. The Frena camera, given each month for the best negative on an Austin-Edwards film, has been secured by Mr. W. M. Dodson, Bettws-y-Coed, for his negative, *South Aisle, Ely Cathedral*.

THE following are some of the Warwick Trading Company's new war films of the Modder River engagement, photographed by Mr. Bennett Stanford of the Company's staff, now with General Gatacre's column in South Africa: Lancers under the Earl of Airlie fording the Modder River on their return from the Enslin engagement, December 8, 1899; The Hospital Corps attending the wounded on the battlefield after the Modder River engagement; Troop train carrying the Seaforth Highlanders over the Modder River, crossing on a temporary bridge erected in place of one blown up by the Boers, showing hundreds of troops riding in open coal trucks, both ends of the train being guarded by an armoured car and engine; The ("Fighting Fifth") Northumberland Fusiliers making trenches at Orange River, South Africa. The passing of an armoured train.

**THEFT BY AN EMPLOYÉ.**—James Dalgety, twenty-seven, a warehouseman, of Leighton-road, Kentish Town, was charged at the Clerkenwell Police Court, with stealing from 43, Clerkenwell-road, a Kodak camera, value 3*l.*, the property of George Davison and others, of 43, Clerkenwell-road. The prisoner was further charged with stealing during the past six months a quantity of photographic goods, value 29*l.*, the property of the same prosecutor. Prisoner entered the service of the prosecutor as storekeeper in July 1898, and was discharged in October last. He subsequently offered for sale at premises in Cheapside the Kodak mentioned in the charge. Other property mentioned found in his possession was also identified by the prosecutor. Detective-Sergeant Urben proved arresting the prisoner at Aden-grove, Stoke Newington. At the prisoner's address the officer found some of the stolen property. He also found in Dalgety's possession a number of pawn tickets. Mr. Broc remanded the prisoner.

**BOOKS FOR THE SALVATION ARMY.**—We have received the following letter from the City Colony Headquarters of the Salvation Army, 20 and 22, White-chapel-road:—"Commissioner Cadman desires me to bring before your notice an effort we are making to provide small libraries for some of our Homes, and, considering the philanthropic object in view, it has occurred to him that probably you may have some waste or soiled copies of different books which you might feel led to donate for the purpose. Perhaps we should explain that the institutions referred to are those for the men for whom we daily find employment in our workshops and who stay in our Homes at night. You will readily see that something to read will go a long way to beguile the evening hours, and act as a strong counter attraction to the public-house outside. We are not particular for the reading matter to be of a religious strain, but anything which is interesting and at the same time elevating and instructive will be acceptable." Perhaps some of our readers may have books to spare for this deserving purpose.]

**SUDDEN DEATH OF A BOLTON PHOTOGRAPHER.**—Mr. Peter Greshalgh, photographer, of Market-street, Farnworth, and Bridge-street, Bolton, died very suddenly about eight o'clock on Thursday Jan. 11 while in his bathroom. The deceased was sixty-eight years of age, and was a native of Walshaw. He had carried on the business of a photographer and stationer, at Farnworth for more than thirty years, he and the late Mr. Kay being the first to follow the profession in the district. Although not occupying any public office, he always took the greatest interest in Farnworth affairs. He was one of the founders of the Moses Gate Wesleyan Church, leaving Holland School with other friends to labour in that locality, and in connexion with the school he has been a class leader, trustee, superintendent, and for very many years teacher of the first male class. He was very greatly interested in the temperance work, and was the Vice-President of the Farnworth P.S.A. Some time ago he was troubled with a serious heart affection, and for six or eight months he had suffered very acute attacks, although he has not been confined to bed for a long period. He was busy photographing on Wednesday.

In the course of a recent lecture at the London Institution, Dr. A. H. Fison referred to the phenomenon of the persistence of vision, explaining why the image of an object formed on the retina did not immediately disappear when the object was removed from the sight, but gradually faded away until, in about one-quarter of a second, it had completely vanished. It was for this reason, he said, that the eye could not follow very quick motions, and that a red-hot poker swung round rapidly gave the impression of a circle of fire. After illustrating this persistence of vision with several experiments, the lecturer said it was the basis of a method of mixing colours—that known as Newton's whirling disc—which he proceeded to describe. If a disc, painted in stripes with the colours of the spectrum, were rapidly rotated, no single colour was distinguishable to the eye, but the mixture of all the colours gave the sensation of white. Dr. Fison showed several examples of this mixing, and pointed out that a given tint could be matched by several different combinations of colours, though the matching might not be correct in every light. The general law of colour mixture was next set forth, and it was explained that every colour in nature could be produced by the combination of red, green, and violet, which, on that account, were termed the primary colours.

## Commercial Intelligence.

**MESSRS. ROSS, LIMITED,** of 111, New Bond-street, W., and Cockspur-street, Charing Cross, are opening a branch of their business at Paris.

THE interesting process of colour photography known as the Kromaz will, we understand, shortly be brought prominently to the notice of the public by a syndicate now in process of formation for that purpose.

FOR a considerable time past there have been rumours as to a projected combination of English plate and paper-makers. We have the highest authority for stating that such a combination is not now likely to take place.

THE Clifton Cabinet Competition at the National Trades Exhibition resulted in the gold medal diploma being awarded to Mr. Muirhead, photographer, Albany Chambers, Charing Cross, Glasgow, for a cabinet photograph of Bothwell Castle on the Clifton sensitised paper.

WE understand that Mr. Arthur Rayment, late of the firm of Messrs. Perken, Son, & Rayment, 99, Hatton-garden, E.C., will in future devote himself to the business of wholesale agent in photographic and optical goods. Mr. Rayment's wide and intimate knowledge of the business should stand him in good stead, and we are sure that he will carry with him general good wishes for his success.

WE are sorry to hear of the death, in London, recently, of Mr. D. H. Hogg, the well-known dealer, of Montreal, Canada, the result of an accident on board *ss. Majestic, en route* a business trip to Europe. We are informed that the business will be conducted on behalf of Mrs. Hogg, and that the many customers and friends of the late Mr. Hogg will be accorded the same treatment as during his useful and thoughtful life.

**MESSRS. PERKEN, SON, & CO.,** of 99, Hatton-garden, E.C., notify us that the partnership that has subsisted for some years between them and Mr. Arthur Rayment (under the style of Perken, Son, & Rayment) was determined by effluxion of time on the 31st. ult. Messrs. Edgar T. Perken and F. L. Perken will continue to carry on business at the above address under the style of Perken, Son, & Co., and, by arrangement with Mr. Rayment, will receive accounts due to and discharge all liabilities of the former partnership. We wish the well-known and respected Optimus house continued success. The business, which dates back some forty years, was formerly known as Lejeune & Perken, and is one of the oldest and most esteemed in the photographic trade.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

January.	Name of Society.	Subject.
22.....	Bradford Photo. Society .....	Secco Film Company's Demonstration.
22.....	Camera Club .....	{ A Year and a Half's Experience with a Benz Motor Car. J. H. Knight.
22.....	Kingston-on-Thames .....	{ Defects and their Remedies. E. Dockree.
23.....	Birmingham Photo. Society ...	{ The Western Shores of the Emerald Isle. Miss E. M. Finney.
23.....	Bootle .....	{ Lecture: With the South London Photographic Society in Belgium.
23.....	Camera Club .....	Club House Dinner.
23.....	Hackney .....	{ Some Recent Developments in Photography. R. Child Bayley.
23.....	Leeds Photo. Society .....	{ Con ersazione and Exhibition of Members' Work.
23.....	Royal Photographic Society ...	{ Note on Dr. Vogel's Method of Preparing Subhaloid Salts of Silver. Major-General J. Waterhouse, I.S.C.
24.....	Ashton-under-Lyne.....	{ Demonstration: Platinotype Printing and Developing. Dr. Hamilton.
24.....	Borough Polytechnic.....	Lantern Night.
24.....	Croydon Camera Club .....	Tele-photography. Ernest Marriage.
24.....	Photographic Club .....	Annual Ladies' Night.
24.....	Redhill and District .....	{ Round about the Matterhorn and Aletsch Glacier. Henry Speyer.
24.....	Southport .....	Exposure. Alfred Watkins.
25.....	Camera Club.....	The Massai. Captain Hinde.
25.....	Leigh .....	{ The Eye versus the Camera. Joseph Jones, M.B., Ch.B.
25.....	Liverpool Amateur.....	{ Evening Exhibition of Competition Prints.
25.....	London and Provincial.....	{ Demonstration: Biokam Animated Photography. Walter D. Welford.
25.....	Oldham .....	{ Plates and Papers for Pictorial Work. Reader, J. Wrigley.
26.....	Ashton-under-Lyne.....	Elementary Photography Class.

26.....	Bristol and West of England ...	Marine Photography. H. A. Hood Daniel.
26.....	Croydon Microscopical .....	{ Demonstration: Cristoid Film. J. H. Baldock, F.O.S.

### ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 16.—Photo-mechanical Meeting.—Mr. W. B. Ferguson, Q.C., in the chair.

#### PHOTOGRAVURE IN COLOURS.

MR. IGNATZ HERBST showed several examples—some of them very large—of photogravure printing in colours. He said they were produced in England, and at one operation. They were examined with much interest and were greatly admired, and, as considerable curiosity was evinced as to the method employed, Mr. Herbst kindly undertook to read a paper upon the subject at a future meeting.

#### SCREEN GEARS FOR HALF-TONE.

MR. W. GAMBLE read a paper on "Screen Gears for Half-tone," starting by defining a screen gear as any mechanism for adjusting the distance of the ruled screen relative to the fixed position of the sensitive plate when working the half-tone process. Such a screen gear might be contained in the body of the camera or in the dark slide, but the term was more generally applied to a gear contained in the rear of the camera body. It had been found that to obtain dots of a proper size on the negative there existed a definite proportion between the distance of the lens from the plate and that of the screen from the plate, and that this proportion also bore a fixed ratio to the size of the diaphragm opening and the size of the screen opening. If, therefore, it was

necessary to change the camera extension to suit different sizes of copies, to change the stops to govern exposures, and to change the screen to suit the demand for varying degrees of fineness in the ruling, it was obvious that the screen distance must also be shifted, and the object of a screen gear was to mechanically vary the distance to any desired extent. The genesis of modern half-tone was dated from 1893, and in that year Mr. Gamble's firm made the first screen gear, which included also a means of rotating a single-line screen for the purpose of securing a crossing of the lines during exposure. The paper then proceeded to describe the various stages of progress in the construction and improvement of the apparatus, and the modifications which had been made on the original idea. The author thought that the present tendency was to put more and more metal into screen gear cameras, and to make them unnecessarily complicated; but he expressed a fear that makers might go too far in the direction of making the camera a masterpiece of mechanical engineering. He showed an American screen gear which possessed a bewildering multiplicity of attachments, and which was said to be capable of everything but talking. In his opinion, all improvements in mechanism of this kind should be in the direction of greater simplicity. Every part likely to go wrong should be improved; every detail should be made so definite in direction that the operator could not possibly turn it the wrong way—in fact, every effort should be made to spare the operator from thinking, for the poor fellow had quite enough to think about to get the work out, and did not want to lose an exposure by forgetting to turn some knob or screw. The best way of setting screen distance was stated as follows: Insert the screen, pin up the copy, and focus it sharply, and of proper size; insert a suitable square stop of medium size proportional to the camera extension, putting it in the lens with its sides parallel to the sides of the camera; then take a powerful focussing eyepiece, and apply it to the clear space of the ground glass; move the screen up, and the dot effect will gradually become sharper, the dots having much the appearance that they take on the negative, but less dense and precise. The correct position is, as nearly as possible, at that point where there is a chess-board effect, the corners of the dots being distinctly square. When this effect has been secured, look again more closely, trying to see white squares, and try to shift the screen so that these white squares just touch at the corners.

Messrs. BOLAS and LAMBERT and the CHAIRMAN spoke in eulogistic terms of the value and lucidity of Mr. Gamble's paper, but there was no discussion, the members present proceeding to inspect the apparatus, comprising the most approved system of screen gear, which he had brought for exhibition.

#### COMING EVENTS.

January 23, Technical Meeting, "A Note on Dr. Otto Vogel's Method of Preparing Sub-haloid Salts of Silver," by Major-General Waterhouse, I.S.C.  
February 6, Lantern Meeting, "Shakespeare at Home," by Mrs. Catherine Weed Ward.  
February 13, Annual General Meeting.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 11,—Mr. E. T. Wright in the chair.

The question of the effect of backing upon the speed of a plate was again brought up.

Mr. R. BECKETT understood the argument to turn upon the point whether or no the backing, by absorbing light which would otherwise be reflected again into the film, reduced the amount of light action upon the plate to that extent. It was, he took it, a question of exposure, and not of actual speed of emulsion.

Mr. PHILIP EVERITT suggested that it might be that the speed of the emulsion was affected. As an example, he said, suppose one backed a plate with aurantia dissolved in collodion. The surface of the gelatine was immediately bedewed with moisture from the atmosphere, caused by the chilling influence upon the glass plate of the evaporating solvent, and some little time elapses before the film regains its former dryness. He was assuming that the plate was coated with emulsion before the backing was applied, although he did not assert that this was done commercially. Would the partial damping of the emulsion surface involved in the operation described and the following drying process affect the speed of the plate? It is not altogether a question of the difference of speed between a wetted and a dry plate, but as between a dry plate and one wetted and dried.

Mr. A. HADDON said a friend who had tried the experiment found that a plate was slower before it was dried than when dry, the difference being two numbers on Warnerke's sensitometer.

Mr. S. H. FRY considered that an emulsion was generally ripened up to its reasonable maximum before coating, and that consequently there should not be much difference between its speed wet and dry.

Mr. EVERITT said that it had been asserted by Mr. Wellington that the fact that an emulsion had set and been melted again increased its sensitiveness.

Mr. BECKETT stated the position respecting backing was this: Backing renders a plate capable of taking more exposure than it would if unbacked. There was, as a consequence, less danger of over-exposing, and a far more correct rendering was also given.

Mr. FRY said that the better rendering was given only if the exposure had been enough. A short exposure on a backed plate tended to give hardness, on account of the elimination of fog by the backing medium.

It was hoped that members would make some experiments to determine whether there was a difference in sensitiveness in consequence of wetting a plate, and the following tests were suggested: to dip half of a plate in water and then expose; and, secondly, to dry the plate before exposure.

#### PHOTOGRAPHIC CLUB.

JANUARY 10,—Mr. Hans Müller in the chair.

Mr. CHARLES R. ROWE gave an interesting lecture on

#### FAIR DEVON,

illustrated by many lantern-slide pictures taken within the county. The

United Devon Association, which he represented, was one whose aim was to smooth the paths of the tourist, and it was with a hope that he might influence many who journeyed annually to the Continent for their recreation to turn their backs thereon this season, and come to their delightful county of Devon. The views included all the principal places of note—Exeter, Teignmouth, Dartmouth, Plymouth, and neighbourhood, and others on the north coast and interior.

A vote of thanks was passed to Mr. Rowe.

**Hackney Photographic Society.**—January 9, the President (Mr. W. Fenton-Jones) in the chair. The feature of the evening was a demonstration of the

#### SANDELL CRISTOID FILM,

by Mr. J. T. SANDELL. Mr. Sandell claimed for the film all the good points of the well-known multiple-film plates, with many additional advantages. Any developer might be used, but one of pyrocatechin was recommended. In warm weather a preliminary bath of formalin was necessary. As the solutions acted on both sides of the films at once instead of on one side only, as in the case of the glass plates, the operations of developing, fixing, and washing were shortened, the average time for development being about six minutes, and that of washing after fixing not more than half an hour. After washing, the films would be found to have increased in size about twenty-five per cent., but this enlargement might be reduced if desired by immersion in methylated spirit before drying. To dry the films they must be squeezed upon glass or ferrotype plates, stood in a cool place, and allowed to dry naturally. Mr. Sandell developed at the meeting four films at the same time in one dish, giving each the same amount of developing, although the respective exposures had varied greatly, being, in fact, one second, fifteen seconds, fifty seconds, and five minutes. The one-second exposure seemed by the results to have been the correct one; but, although the last two negatives were much too dense, they were made good printing negatives by reducing in a ferricyanide bath. A large number of negatives, prints, and lantern slides were shown to illustrate the capabilities of the Sandell multiple-coated plates and films.

**North Middlesex Photographic Society.**—January 8.—At the Annual General Meeting of the above Society Mr. Mummery, to the great regret of all the members, announced that circumstances compelled him to relinquish the post of President, which he had held for the past four years. He read his annual report, which showed that the Society was as vigorous and in as good a position as ever it had been. The election of officers for the current year took place, and resulted as follows:—*President*: Mr. R. Child Bayley, F.R.P.S.—*Vice-Presidents*: Messrs. H. W. Bennett, F.R.P.S., and F. W. Cox.—*Council*: Messrs. J. J. Armitage, S. Barnard, S. H. Fry, F.R.P.S., E. W. Hickox, A. G. Lawson, J. W. Marchant, F.R.P.S., J. O. S. Mummery, F. L. Pither, R. R. Rawkins, C. R. Steele, and W. Taylor.—*Librarian*: Mr. F. A. Haylett.—*Treasurer*: Mr. H. Smith.—*Secretary*: Mr. H. Stuart, 40, Lambton-road, Hornsey-road, N.—*Assistant-Secretary and Curator*: Mr. T. Pring. Mr. Child Bayley, on his election, said he would try and follow in the footsteps of his predecessor. He recognised that it was no easy task before him, but would do his best, and asked for the hearty co-operation of the members. He would like, if it was in order, to propose a hearty vote of thanks on behalf of the Society to Mr. Mummery for his untiring efforts for its welfare. This was seconded by Mr. Marchant, and carried unanimously.

**West London Photographic Society.**—January 5.—Mr. J. BROWN (Hon. Secretary), gave a practical demonstration of the

#### CARBON PROCESS BY SINGLE TRANSFER.

He commended the process for its ease and cheapness, and for the wide choice of colour and surface which it afforded. Using a smooth thin paper for the support presented no difficulty, but, in the case of the thick and rough papers, certain precautions were necessary in order to obtain thorough adhesion between tissue and support. He always soaked such papers for fully half an hour after having first squeezed them vigorously, under water, to a glass plate or to the bottom of the dish, and in some cases it was desirable that they should be soaked in warm water. By these means air bubbles were removed, and the paper thoroughly permeated with the water. With such papers the tissue required more vigorous squeezing, and they should be kept under pressure for thirty minutes or longer. In very warm weather there was a risk of reticulation taking place in development, and as a preventive it was advisable to cool the sensitising bath and the water in which the tissue was to be soaked. It was usually regarded as a drawback to the process that development must take place the same day as the exposure on account of the well-known continuing action of light, but this could be overcome by either keeping the exposed tissue in a calcium tube or by thoroughly washing out the bichromate after exposure. Burton's actinometer was recommended as the simplest form. A number of very fine prints, showing the various colours in which the tissue is prepared, were kindly lent by the Autotype Company, and much admired by the members present.

**Leicester and Leicestershire Photographic Society.**—The Annual Meeting was held on Wednesday, January 10. Mr. J. Toone was elected President for the year, and Mr. W. Murray, 185, Melton-road, Leicester, Hon. Secretary.

**Liverpool Amateur Photographic Association.**—January 10, Mr. Paul Lange (President) occupied the chair.—Mr. F. W. SAXBY gave a demonstration on

#### HOW TO PHOTOGRAPH MICROSCOPIC OBJECTS WITH AN ORDINARY CAMERA.

Mr. Saxby dealt with his subject in a very able manner, and lucidly explained how, by the aid of improvised apparatus, such as might be possessed by any photographer, objects on microscopic slides could be photographed in enlarged dimensions. A number of beautiful slides, taken by himself, were passed through the lantern in illustration of the demonstration, and were greatly admired by those present.

**Edinburgh Photographic Society.**—January 10, Mr. James Hay (Vice-President) in the chair.—A lecture was delivered by Mr. F. P. MOFFAT on

#### PORTRAITURE AT HOME.

The lecturer said that the branch of photography which he had taken for his subject was not an easy one; in fact, it was perhaps one of the most difficult; but, at the same time, it was also one of the most fascinating. When taking photographs in an ordinary room, he thought photographers should avoid aiming at the production of what he might call studio photography, or the head-and-shoulders style, of which millions were being turned out yearly. He was not running down that style, which was perhaps the most popular of all, but he thought it was quite impossible to get any but second-rate results in a room where there were no appliances for the regulation of light and shade. Speaking of what he characterised as the most important element in home photography—lighting—he said that they must always remember that the light should come from one direction only. After giving a number of valuable hints, the lecturer discussed the question of backgrounds. He did not recommend artificial backgrounds, except for bust photographs. With regard to lens, he said the most suitable and convenient was a good rectilinear landscape lens, not too short in the focus. In conclusion, Mr. Moffat spoke against photographers striving to get what he might term professional attitudes. Let them take their friends in their own natural positions, with their usual expressions. The more unlike a photograph was to the ordinary run of photography, the better chance they would have of pleasing, as there would be less chance of unfavourable comparison. The lecture, which was illustrated by limelight views, was closely followed throughout by a large audience. After the lecture the presentation print for 1900 was distributed to the members. It is from the negative by Mr. J. B. Johnston, entitled, *In Largs Bay*, which secured in 1898 the Society's silver medal, being the highest award for landscape work.

#### FORTHCOMING EXHIBITIONS.

1900.		
January	.....	Huddersfield (Invitation). W. A. Beevers. Cloth Hall-street, Huddersfield.
„	29-31.....	Southsea Amateur Photographic Society. F. J. Mortimer, 10, Ordnance-row, Portsea.
February	10-24 .....	Edinburgh Photographic Society. J. S. McCulloch, 10A, George-street, Edinburgh.
„	24-March 3	Birmingham Photographic Society. Lewis Lloyd, The Hollies, Church-road, Moseley.
March	.....	South London Photographic Society.
„	26 .....	Twentieth Century International, Birmingham. Walter D. Welford, 19, Southampton-buildings, Chancery-lane, London, W.C.
„	26-31 .....	Photographic Society of Ireland. W. F. Cooper, 35, Dawson-street, Dublin.
April	3-7 .....	Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Patent News.

The following applications for Patents were made between January 1 and January 6, 1900:—

- PLATE-CHANGING APPARATUS.**—No. 12. "Improvements in Photographic Apparatus and in the Method of Changing Plates or Films in Photographic Cameras also applicable to Colour Photography." C. G. WARNECKE and W. H. HEATH.
- PLATE-HOLDERS.**—No. 17. "Improvements in Envelopes and Holders for Sensitive Photographic Plates." P. WALLIS and E. F. WALLIS.
- CAMERAS.**—No. 218. "Improvements in and relating to Photographic Cameras." Complete specification. J. A. PAUTASSO.
- HALF-TONE SCREENS.**—No. 249. "An Improved Method of Making Screens or Light Subdividers for Use in Making Process Blocks." E. SPITZER.
- EXPOSING APPARATUS.**—No. 294. "An Improvement in Apparatus for Taking a Number of Photographs on One Plate and at One Exposure." T. BROWN.
- PHOTOGRAPHY ON COPPER.**—No. 301. "A Method of Producing a Permanent Likeness on Copper or other known Metals or Alloys by the Aid of Photography for the Purposes of Decoration." W. H. BABINGTON.
- CAMERAS.**—No. 306. "Improvements in Photographic Cameras." I. G. SIGLER.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE DEVELOBOX.

To the EDITORS.

GENTLEMEN,—I read with most interest in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC (p. 867) the article concerning the apparatus of Mr. Donny, the Develobox, for which I am the exclusive agent in the United Kingdom, so I take the liberty to point out a slight mistake.

Instead of the "cover or cloth," mentioned in your article, "placed over the upper part of the apparatus, and over the head and shoulders of the operator," we have devised a pair of special eyepieces with plush-covered openings, through which the eyes may follow the various manipulations inside the apparatus, whilst all outside light is strictly shut out. The addition of these eyepieces is a capital improvement. The Develobox, being provided with a developing dish, in which, by means of a special leather, the plates can be perfectly protected from the light, allows the operator to move about, to leave the eyepieces or the sleeves, and even to open the door without any risk of spoiling or fogging his negatives.

Hoping you will take notice of this last improvement in the Develobox, —I am, yours, &c,  
O. LAMIRAULT.  
8, Upper Bedford place, London, W.C., January 9, 1900.

[We insert the desired correction with pleasure, but it must be pointed out that our information was obtained from the patent specification of the invention.—EDS.]

#### FREAK PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—I read in THE BRITISH JOURNAL OF PHOTOGRAPHY references to pictures showing subjects through others or the like. I think, until further proof, that they are double exposures. To illustrate this, I will give you the experience of a friend of mine using a Kodak. Some time ago he went to the Combat Naval, an exhibition now shown here in advance of the big 1900 Exhibition, and took a few views of same. Shortly afterwards, and before developing the three or four views taken (out of the twelve of the roll), he met with a small accident to his Kodak, and went to a dealer to have it repaired, mentioning the fact of the exposed films. By mistake the dealer or his clerk replaced the film in his drawer with a quantity of others for sale, and put an entirely new film in the Kodak. My friend is now without the views, but what will the party that bought the other film think when, upon developing, he finds a war ship across the lovely face of a dear friend, or, maybe, standing upon her head, or over a "bus," or across a landscape? No hole in the camera will ever explain this mystery to him. Some similar subject appeared some years ago in THE BRITISH JOURNAL OF PHOTOGRAPHY, and was answered, but I doubt if it ever was tried conclusively or in any satisfactory way. In the postman's case (THE BRITISH JOURNAL OF PHOTOGRAPHY, 1900, p. 16), are you quite sure that the postman did not press the ball accidentally while partly down postman's coat, &c., and exposed door first?—I am, yours, &c.,  
A. LÉVY.

Asnières, Seine, January 9, 1900.

#### THE PARIS EXHIBITION.

To the EDITORS.

GENTLEMEN,—I am desirous of exhibiting at the forthcoming Paris Exposition, and shall feel grateful if you could give me information on the following through your valuable paper:—

1. Where must I apply, and to whom, in France or England?
2. Do you know anything about wall space and charges?
3. What would be the most suitable subjects, portraiture or native rural scenes?
4. Large or small work, and what style of framing, all gold or otherwise, and any other suggestion that you might think useful?—I am, yours, &c.,  
Easebourne-road, Midhurst, January 11, 1900.  
F. COZE.

[The authorities of the Paris Exposition have apportioned very little space for British photography, and do not invite an exhibition of it. Mr. Craigie, of the Photographic Salon, and General Waterhouse, of the Royal Photographic Society, have been asked by the British Commission to organize a small collection of pictorial and technical work, and this we believe is being done by invitation. With this exception it may be taken that British photography is shut out of the Paris Exposition.—EDS.]

PHOTOGRAPHING A PRINT FROM A BOOK.

To the EDITORS.

GENTLEMEN,—Replying to "Amateur" in your issue of the 12th, I would recommend him to press the leaf heavily with a warm iron, placing a sheet of tin under it and thin paper over to avoid scorching or soiling, and to back up with black paper to diminish contrast, not with white, which would increase it.—I am, yours, &c., THOS. STOKOE.  
Clare, Suffolk, January 12, 1900.

COLOUR PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—I have been arguing with a gentleman concerning coloured photographs. He says photographs can be taken in colours. That is, photographs are taken on the plate in colours.—I am, yours, &c., 18, Great Church-street, Wisbech, January 12, 1900. A. E. HENSON.

[The gentleman is, in effect, correct. By the Lippmann interferential process, often described in our pages, you can obtain a picture on glass in natural colours.—EDS.]

COPYRIGHT.

To the EDITORS.

GENTLEMEN,—Mr. Ralph W. Robinson's letter on the above subject should interest all photographers. As the matter stands, the sitter who pays for his or her photographs is supposed to have the copyright thrown in into the bargain, for the "good and valuable consideration," which the framers of the Act wrote, instead of the words "payment" or the "coin of the realm." This being so, evidently the photographer will have to buy back the copyright from his sitter. Could not this be done by stating on the price-list that the photographs are supplied at a certain rate on the express condition that the sitter, at the time of sitting, signs his or her name in a book, making over the copyright to the photographer, and that any sitter who objects to do so, or who wishes to retain the copyright of his or her portrait, will be charged twice the amount stated in the price-list?

Whether the following words would be legally binding I cannot say, perhaps you can tell me?

THE COPYRIGHT in the portrait of the undersigned is the property of John Jones, photographer, of Slocum-on-Podgis, according to the price-list issued by him, dated January 1, 1900.

Date.....  
.....Sitter's Signature.  
Date.....  
.....Sitter's Signature.

Whether any benefit would revert to the photographer is doubtful, for the game of taking legal proceedings against infringements of copyright is not worth the candle to the photographer, for the pirates are men of straw. The photographer, and the photographer alone, has to pay all expenses, and, if the pirate is a man of property, he takes his revenge afterwards.

But the photographer, when he gets his copyright, can please himself whether he fights the pirates or not. If he is wise, he will get the Copyright Union to fight for him.—I am, yours, &c. FRANK M. SUTCLIFFE.  
Whitby, Yorks, January 12, 1900.

[We have some remarks on the subject of copyright in another column. In the supposititious case put by Mr. Sutcliffe it is doubtful if the document would be legally binding. A properly executed assignment, registered at Stationers' Hall, might be necessary. We shall, however, be glad to hear the opinions of any of our readers on the matter.—EDS.]

PHOTOGRAPHY IN WARFARE.

To the EDITORS.

GENTLEMEN,—You have some informing notes relative to the above in your last issue. Since sending you a letter which appeared in a recent issue, I have learnt that several military men, and more than one war correspondent now in South Africa, are equipped with cameras fitted with the tele-photo lens. Mr. Shelley has a remarkable photograph of Lord Methuen directing operations at the Battle of Magersfontein, taken at a distance of over a quarter of a mile by the aid of the tele-photo lens, in the second number of the *King*. The photograph is a notable achievement for all concerned. The proprietors of the illustrated papers, at any rate, recognise the value of the invention. Photography as a means to effective illustration is just now being taken full advantage of. It is an interesting fact that Mr. René Bull, the special correspondent of *Black and White*, supplements his drawings by means of photographs taken by himself.

Mr. Thomas R. Dallmeyer strongly believes in the value of balloon tele-photography as an aid to successful warfare. There are some striking "telephotograms" taken in this way, in his recently published book on *Tele-photography*.

You point out that the military authorities are already fully alive to the importance of the possible uses of photography in warfare. This being the case, much that has recently been written on the subject is perhaps superfluous, as you suggest. Probably I come under your castigation.—I am, yours, &c., J. A. REID.  
*Kincraig, Cutcliffe Grove, Bedford, January 13, 1900.*

[With regard to the last line of our correspondent's letter, it is right to say that Mr. Reid was not one of the persons referred to in "Jottings." He is obviously better informed on photographic matters than the ignorant people who write in the daily papers on the subject, and whom "Cosmos" had in mind. A paragraph in this week's *Ex Cathedra* may be of interest in connexion with the matter.—EDS.]

THE COMMERCIAL PRODUCTION OF STEREOSCOPIC PRINTS AND TRANSPARENCIES.

To the EDITORS.

GENTLEMEN,—I see, in "Jottings" in your last issue, a reference to making prints and transparencies from stereoscopic negatives, and quite endorse your views as to the difficulty of getting properly cut and mounted slides, many commercial ones being very faulty in this respect. As I have had twenty or thirty years' experience in this class of work and making slides on either wet or dry plates, I shall be happy to undertake any work of that class from photographers' own negatives, feeling sure that they will be satisfied with the result.—I am, yours, &c., E. H. ALLIS.

11 Grove-lane, Denmark Hill, S.E., January 13, 1900.

[Messrs. Seaman & Sons, of Chesterfield, and other correspondents write us to the same effect. We hope this department of trade-printing will receive increased encouragement at the hands of professionals and amateurs.—EDS.]

PHOTOGRAPHIC MASONIC LODGE.

To the EDITORS.

GENTLEMEN,—I should be obliged if you would kindly announce that a meeting will be held in the Masonic Temple, Anderton's Hotel, Fleet-street, E.C., on Wednesday the 24th inst, at eight p.m., to further consider the preliminary steps in connexion with the above scheme, which has already been ventilated in your columns. All those interested in the matter are invited to attend, or, if unable to do so, to write me at the address below.—I am, yours, &c., W. E. DUNMORE.

110, Shaftesbury avenue, London, W., January 15, 1900.

Answers to Correspondents.

- \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.
- \* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

J. A. Horsburgh, 4, West Maitland-street, Edinburgh.—Photograph of General Wauchope, in uniform, Black Watch. Photograph of the Right Hon. the Marquis of Lothian. Photograph of the Hon. James Horier, M.P. Photograph of the late Lieut.-Colonel Lowman.

- W. VICK (Muswell Hill).—1. In your particular case, perhaps not worth specially troubling about; some firms are, we hear, making it known that they undertake the work. 2. We could not suggest what to charge.
- BOOK ON HALF-TONE.—W. H. W. says: "Will you kindly advise me the best book I can get on half-tone negative-making and printing?"—In reply: *The Half-tone Process*, by Verfasser, published by Percy Lund & Co., Bradford.
- BROKEN CONDENSER.—P. HAIGH says: "One of the glasses in my four-inch condenser is cracked right across the middle. Can you tell me of any cement with which I can repair it so that the break does not show, as I do not want to go to the expense of a new glass if I can help it?"—No, the lens cannot be repaired. The only thing is to get a fresh one. It will not cost much.

**MOUNTING.**—C. E. says: "Will you kindly tell me if you know of a mountant for mounting P.O.P. prints in albums without wetting them? I know it can be done, but cannot find out how. When the prints are wet, I have to wait for each to dry, which takes a long time, besides which the leaves cockle."—This subject was fully dealt with on pp. 659 and 706 of our last volume, to which our correspondent is referred.

**PHOTO-LITHOGRAPHY.**—GEO. BRAY says: "I have a small 'model' printing press, and I want to try my hand at photo-lithography. I find that I can, by a slight alteration, make the press to take a thin lithographic stone. Do you think, with that alteration, I could use the press to produce photo-lithographs?"—No, we do not; because, with the press mentioned, the pressure is a flat, direct one; whereas, for photo-lithography a scraping or a rolling pressure is required, as it is applied by the lithographic press.

**CENTRIFUGAL SEPARATORS.**—CENTRIFUGAL says: "I remember seeing a description of a centrifugal machine for making silver emulsion in THE BRITISH JOURNAL OF PHOTOGRAPHY. Will you kindly give me the following information? 1. Where can I obtain it? 2. Can I make it? 3. Is it possible to separate resin from oil by the same?"—In reply: 1. Our correspondent can obtain the machine, we believe, from Messrs. Watson, Laidlaw, & Co., Glasgow. We give the address from memory. 2. It is engineers' work. 3. We should think so, but have no data on the subject.

**OXIDISING STEEL, &c.**—H. P. asks: "1. How can brass and steel be oxidised? 2. Where can aluminium be bought, and how can it be chemically blackened? 3. Where can leather be bought for covering hand cameras?"—1. We scarcely understand what is meant by oxidised in this case. Is it blackened? If so, a receipt for blacking brass is given on page 972 of the ALMANAC for last year. 2. The Aluminium Co., Goswell-road. We do not know a satisfactory method of chemically blackening it. 3. At any of the dealers' in bookbinders' material.

**COMMENCING BUSINESS.**—PICTORIAL says: "I am about to commence business as a landscape photographer, and shall feel obliged if you will kindly reply to the following questions: 1. When supplying dealers in photographs, stationers, &c., with views, is it usual to sell them the views, or to allow commission on the sale of them? 2. What is the usual discount or (if the latter is the rule) commission allowed?"—In reply: 1. It is quite a mutual arrangement between the photographer and those he supplies. Both systems are in vogue. 2. This also is quite a matter of arrangement.

**LIABILITY FOR COPYRIGHT INFRINGEMENT.**—J. A. R. says: "I sent some photographs to an illustrated paper some time ago. They were reproduced, considerably enlarged. The affairs of the paper were recently in liquidation, when I was informed that there would be no prospect of any payment being received. The paper is still in existence, but my requests for payment are ignored. What redress have I?"—In reply: None, we fear; at any rate, if the former proprietor of the paper has failed, it looks like a case of throwing good money after bad to sue.

**SPOTS ON PRINTS.**—PLATINO TONE says: "Can you tell me the cause of spots on the enclosed? I am very careful in manipulation, using separate dishes: 1, One first wash; 2, gold tone; 3, second wash; 4, platino tone, well washed; then, 5, fixing. They will appear sometimes in a few days. These were toned on December 20 last."—On the data given it is impossible to say the cause of the spots beyond that it is want of care in the manipulation, but at what stage we cannot say. The spots rather look as if particles of pernicious matter came in contact with the paper while in a moist condition.

**ARTICLING PUPIL.**—GUARDIAN writes: "I am guardian of a youth who has a great taste for photography, and has already done some fair pictures. About what should you say would be a fair sum for articling him for three years? A photographer here, in a small way of business, wants 75l. for three years, the lad to have no wages the first year, 2s. 6d. a week the second, and 5s. the third. The lad is 18 years of age."—We should say, in the circumstances, Don't pay any such sum under such terms. There is not much to learn in photography now that everything is supplied ready for use, and the remuneration now is very small.

**A. G. B.**—1. The method described should answer. 2. It is a chemical and not a mechanical mixture, and therefore a comparison cannot easily be made. 3. Let  $F$ =focus of lens,  $f$ =focus of supplementary lens, and  $d$ =distance of separation, the focus of the single combination being, we will suppose, 12 inches, and you wish to obtain a focus of 10 inches, the following formula is given  $10 = \frac{F \times f}{F + f - d}$ . The best position would be behind. Yes; biconcave for increasing, and biconvex for decreasing focal length. 4. The omission is an oversight, although the substance is referred to in Practical Notes.

**ANIMATED PHOTOGRAPHY.**—CINEMATOGRAPH asks: "1. The names and addresses for films and cinematograph apparatus for entertainments, same as used at Empire and Palace theatres, London. 2. What is about the cost of cinematograph complete (without films)? 3. What is the power used to drive films on apparatus? 4. Have seen them driven by hand. Is that the usual method? 5. What is the largest picture shown on screens, and has the sheet to be wet or damped, similar to magic-lantern and limelight views?"—In reply: 1. The pictures at the places of entertainment named are, we believe, shown by the Biograph Syndicate, of Great Windmill-street. Write them for particulars. 2. Difficult to say, but it might range between ten pounds and a hundred. 3 and 4. The pictures above referred to are, we believe, electrically driven, but they are commonly driven by hand. 5. Twenty feet square would be considered a very large size; the screen need not be damped.

**STEREOSCOPIC PHOTOGRAPHY WITH ONE LENS.**—COLONEL GUBBINS says: "I remember seeing an advertisement of an arrangement for taking stereoscopic pictures with one lens. The price was, I think, 10s. 6d. I have looked for it in vain in the ALMANACS, both this and last year. Can you tell me (1) the name of the apparatus, which was an arrangement of mirrors; (2) the maker, or where it can be bought; (3) if it is of any use?"—In reply: Apparatus of the kind can be obtained of Mr. Theodore Brown, of Salisbury, or Mr. Fallowfield, Charing Cross-road, W.C. The system is quite practicable for taking stereoscopic photographs with a single lens, but the lefts and rights of the picture are reversed.

**FACTORY ACT.**—W. says: "I have a small house away from the studio for printing, where six girls are employed. The other day a man called, who said he was a factory inspector, and that I must not employ the girls so long as I do, and that I must give them certain hours for meals, as well as a half-day holiday a week; also I must have an abstract of the Factories Act posted in the place, and a lot of other nonsense. What I want to know is, Does an ordinary photographic place come under the Factory Act?"—Yes, certainly; and you will have to conform with it in all its particulars. The Act is for the purpose of protecting employes, and for preventing them being employed too long hours. &c.

**WARPED DARK SLIDE.**—E. JOHNSON says: "One of the dark slides of my 10x8 camera was left for a couple of months in a damp attic, and, when I wanted to use it, I found that the shutters would not draw out and the glue at the joints was soft. It was put some distance from the fire to dry, and now not only are the shutters warped, but the slide itself is twisted. What can I do?"—We fear very little. We would, however, suggest that the shutters be taken out, and the whole be put in the attic again till they become as damp as before, and then be put under pressure to dry slowly in a dry place, so that they be kept flat the while. That is the best suggestion we can offer, though we are a little doubtful of the result.

**REMOVING GLASS FROM OPALINE; COPYRIGHT.**—OPALINE says: "1. Could you kindly tell me the best way to get a broken glass from the P.O.P. photograph of an opaline view? It was broken coming through the post, and I want to remount the photograph. 2. I have taken the interior of a church on my own account, and have sold several copies of the same. Now I find a block has been made from one of the prints, and is being used as a cover to a magazine without my being asked if it could be used for such a purpose. If I put the photograph into copyright, will it prevent any more prints being taken from the block without my permission?"—1. Soak the opaline in water for some hours; it can then probably be removed. 2. Yes, we think so; but the photograph should have been registered in the first instance.

**DEVELOPMENT OF UNDER-EXPOSED NEGATIVES.**—G. BARKER says: "1. I should be glad to know how far development of negative ought to be carried in case of under-exposure. I find that, when the developer is much or little diluted, the plate begins to fog at the end of twenty or thirty minutes. I have tried adding bromide—say at the end of ten or twenty minutes—but this does not prevent the veil or fog. 2. I should also be glad to know how to improve an over-exposed and fogged negative. I tried reducing, then intensifying, but the result was plate returned exactly to its original state."—1. The development should be continued as long as any detail can be obtained. You do not say what developer you employ, but there should be no fog in the time named. That may, possibly, be due to too much light while developing. 2. Only by the method you have tried. Probably you did not reduce sufficiently, or, more probably, the negative was light fogged.

**LENSES FOR FLASHLIGHT WORK.**—QUICK LENS writes: "Could you inform me the best kind of lens to use for flashlight photography? I should want a lens that would give a good depth of focus, say a dinner table with a dozen men down each side, and the room so small that it would be impossible to plant your camera anywhere but at one end, looking straight down the table. I have been using a Ross 12x10 Doublet, which, of course, is a good lens, but thought perhaps there might be a quicker lens and one with greater depth of focus, as I have to stop a Ross down, and therefore make it slow."—In reply: Most of the best flashlight work recently produced has passed under our observation, and we have found, upon inquiry, that it has been produced by the aid of lenses very much diaphragmed down. Some of the newer anastigmats might answer our correspondent's requirements at a larger aperture than his old lens, but the cheapest advice we can give him is to continue using the latter, and abbreviate his exposures by increasing the efficiency of his light.

**ENLARGING, &c.**—MERCURY STAIN writes: "1. Given an average negative, about how many times may it be enlarged and still appear about as good as the original (without any working up), many enlargements looking rather inferior because of the absence of half-tone? 2. Is it usual when applying for a situation to ask for rail fare? 3. When intensifying with mercury, unless all the hyposulphite of soda has been washed out of the film of the negative, a brown stain is caused. Is there any method of getting rid of the stain? If so, how?"—1. All depends upon the quality of the negative; and what is an "average negative?" Generally, when there is an absence of half-tone, that is due to the negative, or the quality of the enlargement, rather than the degree of amplification. 2. If at a long distance, we believe it is. 3. In intensifying with mercury, when there are brown stains, they are generally caused by imperfect fixation, i.e., the silver hyposulphite not brought into the soluble condition. It is doubtful if the stains can be entirely removed. Try rebleaching in the mercury solution.

### EX CATHEDRÀ.

SOME time ago we inserted an appeal from the Head Master of the Orange-street Board School, Southwark, for lantern slides, wherewith the children of one of the poorest quarters of London could be entertained and instructed. What measure of success attended the appeal we do not know. A day or two since, however, we received from the well-known amateur photographer, Mr. John Bushby, whose pictorial work in South-eastern Europe has brought him well-deserved distinction, a case of lantern slides, which he has authorised us to use on his behalf for a good purpose. We have sent them to Orange-street, and we are sure that, by whomsoever they are seen, the pictures will be highly appreciated. Mr. Bushby tells us that he is off to Corfu and Greece for a couple of months. More power to his (photographic) elbow, so often as it is exerted on behalf of the poor children of squalid Southwark.

\* \* \*

WE are asked to again draw attention to the International Congress of Photography, which will be held in Paris this summer. A Committee has been appointed under the presi-

dency of M. Janssen. This Committee is subdivided into five sub-commissions, which will have charge of the five sections, and will prepare the programme of the work to be carried out in the sessions of the Congress. These five sections are constituted as follows: 1. Physical Questions relating to Photography. 2. Photographic Materials. 3. Photographic Chemistry. 4. Terminology and Bibliography. 5. Legal and Professional Questions. All applications for admission to the Congress, for which the fee is fixed at ten francs, as well as all other communications, should be addressed to the General Secretary, M. S. Pector, 9, Rue Lincoln, Paris. Among the members of the Committee may be mentioned Messrs. Vidal, Lippmann, Braun, Lumière, and Molteni. We trust that the Congress will be successful in its aims, although, having regard to the results of former meetings at Brussels, Paris, &c., during the last eight or nine years, we have no faith that the outcome of the gathering will have any practical advantage for photography in these islands.

\* \* \*

LIKE their brethren in this country, American photographers are being exercised by a proposed Copyright Bill, which seeks to injuriously affect their interests. By the kindness of a friend we have received the report of a judgment recently given in a United States Circuit Court, the effect of which can scarcely be to leave the equanimity of the American photographic profession undisturbed. It appears that the Judge gave a decision that no photograph of animate or inanimate subjects can be copyrighted unless there is something strikingly original and out of the ordinary in the artist's treatment of the subject. It was an ordinary case of infringement of a coloured photograph. The Judge said: "A photograph of natural scenery is not the subject of copyright, because it is not an original conception of the artist, it is merely a skilful manipulation of the camera. Further, it is not shown there was any originality about the colouring of the photograph in question, and it was shown by the defence that the result achieved was old and in common practice."

\* \* \*

THE gist of the remainder of the Judge's opinion was that mere skill and ability to take a good photograph was not a

subject of monopoly by the copyright laws. There must essentially enter into a valid copyright originality of conception, and, where that is wanting, no copyright can be valid. It does not appear, he remarked, that the process of colouring is anything but a skilful mechanical device, producing an extremely clever imitation of nature, and about nature there is no originality. Originality might exist in the process (which might be a subject of patent), but the imitation of nature negates idea of originality. From the English standpoint this judgment is, of course, against common sense. Even the unjust Bill introduced into the House of Lords last session, which sought to whittle away photographers' interests in their own copyright productions, did not go so far as to absolutely deny legal protection to a man for his own work in photographic print-making, plain or coloured, due to the "skilful manipulation of the camera," which, according to the sapient American Judge, always does duty for "originality of conception."

\* \* \*

ELSEWHERE in this week's JOURNAL we print an announcement that the London Spiritualist Alliance have appointed a special Committee to investigate and experiment with the phenomena of psychic or spirit photography. The Committee, which includes Mr. Page Hopps, Mr. J. J. Morse, Mr. Dawson Rogers and Mr. F. W. Thurstan, invites photographers to send in accounts of experiments, with the prints of results, if any, accompanied by the negative. It is the intention of the Committee to establish in London a kind of museum for permanent reference, in which negatives, prints, reports, pamphlets, &c., will be stored. The names of the Committee are well known in the spiritualist world; but there is a marked absence of persons identified with practical photography, whose co-operation we should have thought would have been invited in experiments and investigations where considerable special knowledge of the subject is decidedly called for.

\* \* \*

It is announced that the President of the Board of Trade has appointed a Departmental Committee upon the subject of patent facilities. The official terms of the reference are "to consider various suggestions which have been made for developing the benefits afforded by the Patent Office to inventors, and to report." The Chairman of the Committee will be Mr. F. J. S. Hopwood. Other members will include Mr. Carpmael, President of the Chartered Institute of Patent Agents; Mr. C. N. Dalton, C.B., Controller-General of Patents; Mr. Kempe, Deputy Chairman of the Board of Customs; and Mr. S. E. Spring Rice, C.B., of the Treasury. Mr. Arthur Reeves, of the Board of Trade, has been appointed Secretary to the Committee.

\* \* \*

MR. J. CRAIG ANNAN will provide the first of a series of "One Man" shows, to be held at the Royal Photographic Society's house, 66, Russell-square, by the exhibition of a selection of his work. The Exhibition will be opened on Wednesday, January 31, at eight p.m., when Mr. Craig Annan will make a few introductory remarks, and it will remain open during the month of February, from ten to four. Admission on presentation of card.

\* \* \*

THE second and third numbers of the *King*, published by Messrs. Newnes, contain many interesting war photographs,

and for the first time in the history of illustrated journalism a feature is made of the power which tele-photography supplies, of taking direct enlarged views of distant scenes. Some incidents of the campaign have been photographed in this manner by Mr. H. C. Shelley, the *King's* energetic "special" (of whom we give a brief sketch in another part of this week's JOURNAL), and we gather from a note in our contemporary that it is intended for the future to place great reliance on tele-photography for its illustrations of the progress of the war. We congratulate the *King* on its enterprise; and we are pleased to learn that it is meeting with great success.

#### ARTICLING PUPILS IN PHOTOGRAPHY.

LAST week we had to reply to a correspondent as to what might be considered a fair sum for "articling" a pupil to learn the business of photography. We may mention that this is by no means the first time we have been asked such a question by parents and guardians. It is a difficult one to answer, seeing that there is really so little to learn in photography now that everything is supplied ready for use and with full directions for using them; and in face of the fact that remuneration to employees is so small, that is,—if one may judge from the salaries often offered in the advertisement columns of the JOURNAL. For example, here is one that appeared a few weeks back: "Operator and Retoucher, quick and good, abstainer, Sunday work, for branch at ———. Wages 21s." In the same issue was another: "Young man as Operator and Printer, all-round-hand, P.O.P. used, address, ———. Wages 20s. Open on Sundays." Last week we notice this: "Operator and Retoucher for branch, 25s. per week, must be quick."

Taking the first advertisement referred to, we see that twenty-one shillings for seven days' labour is three shillings a day, and, supposing that the hours are from nine till six—they are sometimes longer—this comes out at fourpence per hour. Now, the minimum wage of day labourers, such as "navvies," bricklayers' labourers, and the like is, we believe, from sixpence to sevenpence per hour; and that of carpenters, bricklayers, and similar mechanics, ninepence and upwards per hour. Of course, a photographic operator has to dress well and make some appearance, and for this and his skill he is offered fourpence an hour! The advertisement we quote stipulates that the man must be an "abstainer," and he must, perforce, we surmise, be an abstainer from more things than those indicated in the advertisement. Now comes the question, What is a fair sum, as premium, for articling a pupil to enable him to earn the munificent salary of fourpence an hour and dress well upon it?

It must not, however, be taken that the cases we have quoted at all represent the salaries that operators are usually paid, though we regret to say that they are generally very low nowadays, and for the reason that there is at the present time so very little to learn, and, as a consequence, the labour market, as the unskilled labour market always was, is over-stocked. It is a relief to know that high skill and artistic abilities are better recognised and remunerated in some quarters, for we notice an advertisement only last week of a gentleman seeking an appointment at four and a half guineas a week. Of course, to earn any such sum as this a premium is warranted; but, in many cases where a premium is obtained, it is more for the

money and services for nominal salaries than anything else that the "articling" premium is obtained.

But, though it be granted that, with modern plates and papers, cheap apparatus, and readily accessible elementary literature on photography, the difficulty of producing passable results in portrait and view work is greater than we have supposed, nothing is detracted from the fact that the articling or apprenticeship system in photography is never found to work satisfactorily. It is not easy to define a "knowledge of photography," or of the "business of photography." An honours' medallist at the City and Guilds' examination may find himself very much at sea when he comes to take his first studio portrait of a squalling infant, or attempt to persuade a lady sitter to order a 24 x 20 framed carbon enlargement from a cabinet portrait. These things are not learned in the ordinary way, and cannot be assured by articling or apprenticeship.

We begin to think that the successful photographer, like the poet, is born, not made. A good studio manner, like the good bedside manner so much prized by professors of the healing art, does more towards making a man popular with the public than a whole encyclopædia of dark-room knowledge. To paraphrase the popular saying, It is not exactly what you do, it is the way in which you do it. And again, though the grammar of lighting and posing may be acquired by constant work and observation in the studio, success in portraiture may not follow as a matter of course. In many trades and professions the service of an apprenticeship passes for competency; but, in photography, the mere fact that a young man has been bound for a time to a professional photographer is a guarantee of nothing. The sole test of ability in photography is the production of work which shall command the remunerative patronage of the public.

We come across many cases of youths anxious to learn portrait photography by working in the studio with the principal, but it is seldom that a photographer in good practice cares, even with the inducement of a premium, to prepare a possible rival. It is a very human feeling in such times of keen competition. In no other profession with which we are acquainted does the personal element count for so much as in photography, and those men who have made a position for themselves in it are scarcely to be blamed if they give scant encouragement to a system which may operate adversely to their continued success. On the other hand, the lower grades of photographers may look kindly on the articling or apprenticeship system for reasons of their own. As a rule, such men have little to teach, and their pupils, of course, have therefore no great opportunity of learning much. But, as we have already said, the articling or apprenticeship system does not work well in photography, and we are sorry that we can see no way at present in which matters can be improved.

**Miniature Painting and Photography.**—Will miniature painting ever take the place it once held in the fine arts? The Society of Miniature Painters, which was formed a few years ago, is making good progress, and several R.A.'s have become honorary members of it. The fifth Annual Exhibition of the Society is now open at the Modern Gallery, in Bond-street, and professional portraitists will do well to visit it. There is no question that photography did a great deal towards killing miniature painting, but, at the same time, many of the old miniature painters turned photography to a good account by colouring photographs; exquisite work they did, and high were the prices charged, and obtained, for the work. Three, five, and up to ten guineas was not uncommon for

a highly coloured small photograph; but then the work was really worth the money, they were like fine ivory miniatures. Where is such work to be found now? High class—that is, really *high class*—coloured photographic miniatures seem to be quite ignored by first-class photographers, who at one time made a special feature of them—but why? By the way, it may be mentioned that the late Sir Wm. Newton, who was one of our finest miniature painters, was one of the founders of the Photographic Society—now the Royal—and was for some years one of its Vice-Presidents.

**Aluminium.**—The uses to which aluminium are being put at the present time are indeed multitudinous. In connexion with photography its applications are tolerably well recognised. It is largely, by reason of its lightness, taking the place of brass for the metal fittings of amateurs' field cameras. For the same reason it is extensively employed for the mounts of lenses. Another application of the metal in connexion with photography is in flashlight compositions in place of magnesium. Its advantage over magnesium in this case is that its light is considered to be more actinic than that of magnesium, and that the product of combustion—the "soot"—is lighter and more easily got rid of out of the apartment. The latest application of aluminium that we have heard of is for the manufacture of horse-shoes. American owners of racehorses have, so we read, been using them a good deal of late. Owners of cameras with aluminium fittings that have been long in use will, no doubt, fancy that aluminium horse-shoes are better suited to the grass of the race-course than they are to macadam roads or the granite blocks of the streets of large towns.

**New Instantaneous Shutter.**—At the meeting of the Paris Academy of Sciences, held on the 8th inst., a new arrangement for the product of quick exposures mathematically measured was exhibited and described by M. Guido Sigriste. The modifications embodied in the apparatus, as set out in the *Comptes Rendus*, consist in a means of regulating the width of the slit of the shutter, keeping the edges absolutely parallel, and of moving the plane of the shutter a small determinate distance (0.1 millimetre) from the focal plane. The duration of the exposures can be varied the fortieth to five-thousandth of a second. The photographs exhibited showing the work of the new shutter (a "focal plane" type) had no fog, and no part suffered from imperfect illumination.

**Lens Formulæ.**—At a recent meeting of the Physical Society Mr. T. H. Blakesley read a paper on "Exact Formulæ for Lenses." He made use in it of his previously given definition of focal length with respect to magnifying power (referred to in the *Proceedings* of the Physical Society for November 1897). By this method, instead of as usual representing the focal length of a lens as the distance between two points, the author treats of it as a simple line. Following the lines of his paper referred to, Mr. Blakesley showed a method of determining accurately the constants of combinations of lenses, and showed how practical use could be made of it in the method of racking out telescopes for astronomical work, determining refractive indices, &c.

**Formalin as a Preservative.**—Photographers are familiar with this most useful substance as a hardener of gelatine merely, but it has functions that might be useful to them in other directions. It is one of the best preservatives known of various animal and other substances liable to putrefaction and other fermentation. Obviously the very property it possesses which renders it useful in the known direction referred to would prevent its use as a preservative of thin solutions of glue; but, without having tried it, we yet are under the impression that it should be an excellent preservative of that favourite mountant of all—starch. Then, again, with carbon prints in frames, which, under certain conditions, are liable to attacks of the mildew fungus, it would be an excellent thing, before placing the backboard of the frame in position and pasting it down, to place at the back of the print a piece of blotting-paper dipped in formalin. Its vapour would diffuse into all the air inside the frame, and effectually kill any mildew germs, which are what may be termed seeds or spores of the mildew fungus.

### Does Backing Plates Interfere with Sensibility?

—A few weeks ago we called attention to a discussion at the Photographic Club as to the allegation that backing a gelatine plate rendered it slower than it would have been if unbacked, and also mentioned that, as the assertion had been made before, it would be desirable to settle the point in a tentative way. Since then the subject has twice been discussed at the London and Provincial Association without any definite conclusion being arrived at. The general impression, however, appears from the reports to be that it really does not in reality slow the plate; but, as it prevents the reflection of light from the back of the plate on to the film, a brighter negative is obtained—one more free from veil—which might lead to the idea that it was less fully exposed. One thing, however, is quite certain, namely, that for very many subjects the backing of the plate does very materially improve the quality of the negative. Still, the question remains, Does a plate that is backed in reality necessitate a prolonged exposure? It is an interesting as well as an important one; it is also one that should be decided authoritatively.

**Photogravure in Colours.**—As will be seen from the report, some photogravures in colour were shown at the meeting of the Royal on the 16th, which were much admired, though the method of their production was not described. Prints from engraved plates in colours are not new, neither are they from photogravure plates, as they have been done systematically by the house of Goupil and that of Hanfstaengl and others for some years, but the method is somewhat tedious. It is this: The plate is inked up locally with the different colours, which are blended in the operation, and, when the inking up is completed, the impression is taken. It need not be mentioned that great skill on the part of the workman is required to obtain good results in this way, and the rate of production is necessarily very slow. Some time back we saw the method in operation in a Continental house, and we were told that it was only possible, with the large plates we saw being worked, for a man to get more than a couple or three prints off per day. They were, however, very fine when obtained. It is to be hoped that the prints shown the other night are produced by simpler means than this.

### BRITISH PHOTOGRAPHY FROM THE AMERICAN POINT OF VIEW.

[THIRD ARTICLE.]

So much interest has been aroused by the extracts we have already given from the American criticisms of British photographic work recently exhibited in the United States that we are induced to make levies upon a further batch of notices that have appeared in some of our Transatlantic contemporaries lately to hand.

In the *Photo Era*, a well-illustrated and most artistic monthly production emanating from Boston, the following very high compliment is paid to English landscape work:—

The landscapes from England show the highest artistic merit and the greatest intimacy with artistic effects. In them lies a lesson that will take long to learn. Last year the same lesson came, and as forcibly as this; but our landscape workers have not, as a general rule, profited thereby. It will be, at least, unfortunate to let another such opportunity pass. I speak, of course, only generally.

The most obvious elements of excellence in the British landscapes are these: Primarily, a broad, broken, expressive foreground, as in paintings, an unimportant middle space, and abundance of appropriate, well-defined clouds filling in the sky. Even a casual glance shows these merits to be general in the English work.

To compare our American landscapes with them, the exhibit by numerous examples shows a tendency in American work manifestly inartistic, but surely easy to overcome. The faults, to mention only three, are, first, a foreground often blank and generally inexpressive for lack of sufficient light and appropriate objects; secondly, a centralisation of objects of interest, especially in the middle distance; and, lastly, empty skies. Blank foreground, centralised objects, and plain sky—forty-eight out of sixty-five landscapes from American workers had one or more of these shortcomings, while among the English pictures only four out of thirty-three failed in a like respect, and that, too, in such a way as perhaps to be entirely excused by the nature of the subject treated.

Mr. E. Lee Fergusson, in the *Photographic Times*, which, under its new editor, is making a great feature of pictorial photography, is not very complimentary to the Linked Ring work.

It is most unfortunate, he says, that the best of the foreign exhibitors appear to consider anything good enough for Philadelphia. After being specially invited to exhibit because they are members of the Linked Ring, and because they have won other laurels, they owe it to themselves and to those who compliment them by extending the invitation to either send a representative exhibit or gracefully decline. Such names as Demachy, Craig Annan, Ralph W. Robinson, and others, look well in the catalogue, but some of the things they saw fit to send belittles them and the world-famed organization of which they are honoured members. It were better to ignore the Europeans until such time as they shall be willing to treat our efforts seriously than to pay all charges on their third-rate work.

But Mr. Fergusson's criticisms are hardly less sharp than those of the editor of the *Times* himself, who caustically points out that the English pictures present were nearly all there [*i.e.*, at the Philadelphia Salon] by invitation, an invitation which meant admittance without examination and approval by the jury. Now, this, he proceeds, is an exceedingly pretty compliment to the recipient. It tells him—or is evidently meant to—that his works are beyond criticism, and that he will do honour by the presence of his pictures. "But, when I am invited to show myself and honour others by my presence, I put not on my worst clothes, nay, not even my second-best, but don my prettiest tie and my least-worn shoes. But not so in the case of these invited guests. True, they endeavoured to show us how big they are—by the size of their pictures, giving a decorative effect, at least—but they did not show us how strong they are—in art. A half-carat diamond is more valuable than a ton of iron, but it is infinitely smaller. And there were enlargements there from the "other side" (I cannot call them pictures) which could almost be measured by the yard, and which would not have been looked at twice by the jury had they had to stand examination. And then the monotony. A scene of bracken and trees is beautiful when well composed, but why three similar scenes, all large, and all from the same author?"

The writer proceeds: The American work was certainly the best that has yet been shown in any public exhibition, and did not stand one whit behind the best English work on the walls. This speaks volumes for the great strides our photographers are making, and I predict that it will not be long before the members of the Linked Ring will send only their best work to be shown over here, and will not send it on invitation either, but will have to submit to a jury like the rank and file. Of course, there were some poor pictures present, pictures lacking in judgment, in harmony of light values, in purpose, but the general average was excellent.

### REFLECTION AS AN AID TO EXPOSURE.

THE editor of the *Photographisches Wochenblatt* gives an account of some experiments he has made to utilise the light which passes through the film during exposure without affecting it. That such is the case may readily be proved by placing one plate behind another in the dark slide: upon development an image will also be found upon the second plate. Herr Gaedicke points out that the first attempt to utilise this waste light by turning it back to the film was made by Brewster. Unfortunately, the thickness of the glass presents difficulties in applying the idea to plates, but films, being much thinner, are comparatively free from drawback. A pack of six films was exposed for 120 candle metre seconds behind a sensitometer. The following numbers appeared after simultaneous development:—

Film	1	2	3	4	5	6
Sensitometer No.	15	11	8	4	1	0

A number of experiments were then made to obtain by trial and error three negatives exactly corresponding with films Nos. 2, 3, and 4. The exposures were converted to seconds and used to express the quantity of light which each plate had received. This gave the following result:—

Film	Exposure Given.	Calculated Exposure.
Film 1	120.0 c. m. s.	—
" 2	33.3 "	33.3 = $\frac{5}{18} \cdot 120$
" 3	9.4 "	9.25 = $\frac{3.5}{4} \cdot 120 = (\frac{5}{8})^2 \cdot 120$
" 4	2.6 "	2.57 = $\frac{1.25}{5} \cdot 120 = (\frac{5}{18})^3 \cdot 120$
" 5	— "	0.71
" 6	— "	0.2

below the inertia of the plate.

It follows that each film absorbs  $\frac{1}{18}$  and transmits  $\frac{5}{18}$  light. The co-efficient of absorption is, therefore, 0.722, and of transmission 0.278. The peculiar fact was also observed that comparatively small quantities of light did not deviate in their effect upon the film, and were absorbed

and transmitted in similar degrees. Experiments were then made by exposing films backed with paper and tinfoil. The latter was, of course, the more efficient. If the transmitted light could be totally reflected, the normal exposure should be reduced to  $\frac{1}{2}$ , but, as there is some loss in reflection, it was found by experiment that  $\frac{3}{4}$  normal exposure was the correct proportion. It follows, therefore, that exposure may be reduced 25 per cent. when films backed with tinfoil are used, a consideration of some importance for instantaneous photography under unfavourable conditions. When using films backed with tinfoil, two important facts must be remembered. As the image is partly at the back of the film, the developer must be given sufficient time to bring out the full exposure. As a film saturated with developer can only be freed from it by prolonged washing, it is desirable to fix the film before exposing it to light.

#### SOME METHODS OF CONTROL IN PHOTOGRAPHIC PRINTING.

**SPEAKING** before the Borough Polytechnic Photographic Society, on the 17th inst., Mr. G. J. T. Walford said that in pictorial work the proportion of negatives that would not be improved by some control deliberately practised in printing was a very small one indeed, and he held that, for the photographic picture-maker, any device in printing was permissible by which the limitations incident to the process were successfully overcome.

He had recently had the opportunity of examining a large number of landscape negatives, and, speaking generally, he thought that, as regards skies and clouds, they might be classed under four heads, viz. :—

(a) Negatives in which suitable clouds were not only present, but in which they also printed out with the landscape, and needed no control to secure the best results. It was not often desirable, however, to obtain, by a compromise in exposure, clouds and landscape on the same plate, as such a procedure usually resulted in a very distinct loss of quality. "Sea" and "open river" subjects gave, perhaps, the most satisfactory results without recourse being had to any method of control.

(b) Negatives in which suitable cloud effects were present, but which required a longer, sometimes a very considerably longer, time than the landscape to print out. These could be remedied by the application of matt varnish on the glass side of the negative, which should be scraped away from those parts at which its assistance was not required; or the back of the negative might be covered where necessary with tissue or tracing paper and worked upon with stump or water colour, but he obtained the most satisfactory results through the medium of ground glass. A spoiled negative was cleared of all emulsion and squeezed in contact with a damp silver print made from the negative to be treated, then by means of fine emery powder a ground-glass effect was produced on those parts of the glass that coincided with the portions of the negative it was desired to control, the sky being left quite clear. The silver print was then removed, and printing performed through the partially ground glass in conjunction with the negative. A focussing screen might be substituted where difficulty was experienced in grinding the glass, and the necessary control obtained by means of blacklead or water colour.

(c) Negatives that possessed a thin sky, without clouds, but with a broken and intricate sky line, presented perhaps the most difficulties, and he thought there were probably not many photographers of the rank and file who would accomplish the task of blocking out such a sky with credit to themselves. The lecturer then went on to explain a method by which cloud forms might be suggested, the existing weak skies of this class of negative being utilised to this end. A sheet of ground glass was placed in a printing frame with an uncontrolled silver print, and fastened up together as a child's drawing plate. Finally, powdered blacklead was then worked into the ground glass with chamois leather, or other suitable material, over such places as it was desired that the high lights of the sky should come. Water reflections or other high lights could also be introduced at pleasure in a precisely similar manner.

(d) This class included negatives without clouds, but in which it was desired to introduce some by means of combination printing. If the negative was sufficiently opaque to secure a white sky after the landscape was printed, well and good, but, if not, some means must be adopted to obtain it; and this could be done by the usual methods of blocking out either by painting over the sky with Brunswick black or one of the other preparations sold for this purpose, or by vignetting.

Leaving the question of clouds, he next proceeded to deal with those negatives which exhibit excessive contrast and hardness. In such cases he advocated a judicious treatment by the method of control known as sunning or toning down. With P.O.P. this was very simple, but he

assumed that most pictorial work was executed either in platinum or carbon. With either of these processes the difficulty was that the image in the printing frame was in the one case but partially visible, and in the other not visible at all. For platinum he recommended the following mode of working: Estimate the amount of toning down required, then place the printed paper under clear glass, covering those parts needing no treatment; fix with a drawing pin near the part to be treated a small piece of P.O.P.; then allow the light to act on the selected portions of the print and also the scrap of P.O.P. together. The tinting of the P.O.P. will serve as an indication of the actinic value of the light, enabling the worker, with a little practice, to correctly gauge the amount of reduction secured. With carbon, he placed a sheet of ground glass in contact with the negative, and sketched lightly with pencil upon the ground glass the leading lines of the composition and of the parts requiring modification. If this was done, a carbon print might be controlled almost as easily as platinum and in much the same manner, the carbon print, however, being treated under the pencilled ground glass.

Such methods of control as he had described could, of course, be applied in any other ways that would readily suggest themselves to the individual worker, and results might often be considerably modified, according to the will of the worker, by the omission of some object or detail considered objectionable, as well as by the addition of some object deemed desirable.

#### FOREIGN NEWS AND NOTES.

**Starch in Emulsion.**—An interesting controversy is pending in the German law courts concerning the use of starch in emulsion. From the *Deutsche Photographen Zeitung* it appears that a photographer named Junk obtained a patent in Germany some time ago for the preparation of sensitive materials with an emulsion composed principally of boiled starch, with a small addition of gelatine, such material being especially suitable for subsequent retouching or colouring. The granting of the patent was opposed at the time by the Berlin Photographic Society, but unsuccessfully. The Dresden United Photographic Paper Company bought the patent, and an effort was then made to bring gelatino-bromide papers within its scope. The Eastman Company was attacked, and, although they were using raw instead of boiled starch, the action was successful in the Courts of First Instance. An appeal was granted, and the matter stands for a new trial at an early date. Meanwhile, the *Neue Photographische Gesellschaft* has informed the patentee that they also use starch in the preparation of gelatino-bromide paper. As the latter has declared this to be an infringement of his rights, the *Neue Photographische Gesellschaft* has instituted an action to annul the patent. We trust the action will be successful, for not only is the process devoid of originality, but there seems also to have been a want of discernment on the part of the Judges in extending the scope of the patent to the raw material.

**The Preservation of Indiarubber Goods.**—*Helios* states that, according to Fane, stearine is a very good preservative of articles made of indiarubber. The stearine should be cut into fine shreds and used as a packing. Portions of diving dresses have been kept in this manner for twenty years without becoming brittle or stiff. The hint may be of use to photographers in keeping their apparatus in good order.

**The Cinematograph and Surgery.**—We recently drew attention to the value of the cinematograph as a means of instruction in surgery. Some further remarks upon the subject, by Dr. Doyen, appear in the *Bulletin Phonographique et Cinématographique*, and they deserve the attention of our surgeons. Dr. Doyen states that many technical details, which appeared to him satisfactory, have had to receive further consideration since he has studied the cinematograph records of his own operations. The cinematograph supplies him with a true picture of what he has done, and he can thus reconsider the most minute details of the operation, with a view to their improvement in future cases. It must be self-evident that the opportunity of seeing an animated photograph of an operation from the point of view of a spectator should be of the greatest interest to the surgeon.

**Hard Negatives.**—The *Photographische Chronik* recommends that the plates should not be alumed, and that, after fixing and washing, they should be immersed in a weak solution of blue-green dye. This stain will be absorbed most in the shadows, where no reduction of silver has taken place. After drying, the negative will print with less contrast and give a better rendering of the lights and shadows.

**An Old Lens.**—In Liesegang's *Photographischer Almanach*, Dr. von Rohr asks for information concerning any types of lenses he has omitted to include in his recent work on the "History of Photographic Optics." In particular, he would be glad to receive for inspection a lens constructed by Petzval in the fifties or sixties. It was a doublet, and both combinations were composed of three cemented lenses. A specimen made by Voigtlander would be preferred.

#### A SIMPLE METHOD FOR PREPARING SALTED PAPER.

FRANZ HOFBAUER describes, in the current number of the *Camera Obscura*, the following simple method of preparing a matt-surface plain paper, which differs from most methods in that plain and not boiled arrowroot is used for the salting solution.

Strong white paper is coated by means of a badger's-hair brush with a mixture of—

Arrowroot (finely powdered) .....	10	grammes.
Salt .....	0.66	grammes.
Distilled water.....	33	c. c.
Carbolic acid (pure) .....	6	drops.

This mixture should be well shaken before use till the whole of the precipitate is suspended. The brush should be kept about half full of the mixture, and the paper brushed over in all directions, so as to obtain as even a coating as possible, and, finally, all marks evened out with the damp brush. Any streaks faintly visible after drying will not matter, as the important thing is not so much an even coating as an even damping of the paper. The paper should now be allowed to dry spontaneously, without heat, in a place protected from dust; it should be left to lie flat for twenty-four hours.

In order to sensitise this paper, the two following solutions should be prepared:—

A.		
Silver nitrate .....	5	grammes.
Distilled water .....	25	c. c.
B.		
Citric acid .....	5	grammes.
Distilled water .....	25	c. c.
Carbolic acid (pure).....	6	drops.

Mix immediately before use just enough of these solutions by pouring one part of solution B into two parts of solution A. The paper should be supported at an angle of 45°, and fastened down by the corners by sealing-wax, and the sensitising solutions painted across it from left to right without pressure, so that the streaks of the liquid shall run into one another. Metal pins must not be used, nor should the brush be fastened with metal.

The sensitising solution will gradually become cloudy from the chloride and arrowroot taken up from the surface of the paper by the brush, but this is of no moment, if the brush be not dipped too far into the liquid so as to disturb any precipitate.

Thick, rough papers as a rule require more coatings than thin smooth ones, though a good deal depends upon the kind of paper.

The sensitised paper should be allowed to dry spontaneously in a place free from dust, and, as a rule, paper sensitised at night will be ready for use the next day; it will keep longer, but better results are always obtained if it is used at once, and the freshly prepared paper is always slightly damp, which is in favour of the prints.

The finest prints are obtained from tolerably plucky negatives with the following platinum bath. The paper should not be much over-printed, and then washed for about half an hour in three changes of water and then treated with the following:—

Potassium chloro-platinite .....	1	gramme.
Distilled water .....	300	c. c.
Nitric acid (pure) .....	20	drops.

The prints will turn first reddish-brown, then violet-black, and finally black. Toning should only be carried to the violet-black stage, then washed and fixed in a ten per cent. solution of hyposulphite of soda for a quarter of an hour, and then well washed and dried. Greyish-black tones are thus obtained. If toning is carried on too long, the whites become yellow.

If, when dry, the prints do not show a fine grey and the whites are yellow, they may be toned in the following bath:—

Ammonium sulphocyanide .....	10	grammes.
Sodium phosphate .....	12	"
Distilled water .....	250	c. c.
Solution chloride of gold (one per cent.) .....	30	"

#### EXPERIMENTAL PSYCHIC PHOTOGRAPHY.

SIGNED by D. S. Hehner, J. Page Hopps, J. J. Morse, E. Pierce, E. Dawson Rogers, Lt.-Col. Le M. Taylor, and F. W. Thurstan (Hon. Sec.), the following appeared in the last issue of our contemporary, *Light*:—

The London Spiritualist Alliance, Limited, has recently delegated to us as a Committee, with power to add to our number, the task of investigating, and experimenting in, the phenomena of "Psychic" or "Spirit" Photography.

We therefore invite all persons and periodicals interested in psychic research and spiritualism to give publicity to the fact that a regularly constituted body has been formed for the above special line of investigation, and that we invite any evidence that may be sent us by correspondents from every part of the world.

The following are some of the special classes of evidence which we are anxious to collect, tabulate, and report upon:—

1. Accounts of experiments made by private or professional operators, whether with or without cameras.

2. Prints of results, good or indifferent, accompanied, if possible, by the negative.

In both cases the evidence will be considered valuable in proportion to the information sent on the following definite points:—

(a) The social and psychic character of the operator or operators who may have exposed, developed, or handled the plates or films.

(b) The same with regard to the sitters, if any.

(c) The nature of the camera, plates, or films, and developers used.

(d) The quality of light in the room at the taking of the photograph.

(e) Whether any special background was employed.

(f) Any special tests or proofs that the results submitted were not obtained by double exposure, second negatives from altered positives, fluorescent chemicals, and other well-known methods of imitating psychic results.

(g) Precautions in regard to the plates used, and whether there was any chance, in a series of experiments, that the marked plates of any particular occasion were taken away unused, tampered with in private, and then substituted at a subsequent experiment.

Besides collecting the above evidence and reporting upon it to the Alliance, and thereby to the public, we intend, so far as the small fund at our disposal will permit us, to conduct a course of experiments ourselves, and to invite and help others to do the same. To this end we invite the assistance of any one who can offer to us personally, or through a friend, the quality of psychic mediumship through which experiments in this way are likely to be successful. In the case of professional or other mediums who require some compensation for their time or travelling expenses, a small fee will be offered.

We wish it to be expressly understood that we desire psychic photographs of every description, whether obtained by camera or without one, or whether through a negative or without one.

It is our intention, if an adequate response is given to our invitation, to establish in the rooms of the Alliance a portfolio or case in which any negatives, prints, reports, books, pamphlets, magazine articles, cuttings of publications, and similar records on the subject, may be kept as a sort of museum for permanent reference. Gifts for this purpose are respectfully solicited.

There is always a special value in cumulative evidence; but, if our proposal be fully carried out, that special value would be greatly increased, as the various pieces of evidence, gathered from witnesses and operators far apart, could be compared at any time, as objects of vision, and not as matters of mere hearsay; and certainly, if evidence of the reality of spirit or psychic photography can be accumulated, an immense service will be done, and a remarkably interesting and convincing method of spirit-communion will be brought to light.

Considering the important nature of the inquiry committed to the care and conduct of this Committee, it is felt that a ready response will be made to the foregoing requests from thoughtful students of psychic phenomena all over the world.

Communications of all kinds should be sent to the Hon. Secretary of the Committee on Psychic Photography, care of London Spiritualist Alliance, 110, St. Martin's-lane, London, W.C.

#### PHOTOGRAVURE.

At the meeting of the London and Provincial Photographic Association, on January 18, Mr. E. A. Hunt gave a description of the process of photogravure. His preliminary remarks were upon the position of photogravure amongst reproduction processes for art works. If, he said, artists could now get accurate reproductions of their pictures in a far shorter time than was previously the case, the credit was due to photogravure. So, too, was the fact that large numbers of the old masters and other educational art productions were now obtainable, and at such cheap rates compared with those for the older engravings, which were beyond the means of all but a few. At the same time, if the future of line engraving now looked so dull and unpromising, the credit was still due to photogravure. Photogravure exerted an influence greater than would be supposed. Not only had it affected reproduction processes, but production processes had alike been influenced. Art publishers:

and that the cheapness of photogravure, looked at alongside the cost producing engravings by the old methods, placed them in a position to produce ten plates where previously only one could be accomplished. Opposing half of these failed commercially, the loss was nothing like so serious as it would have been under the old system of line engraving. In consequence upon this, artists were able to bring their works within reach of the pockets of an ever-increasing number of people. The orthochromatic plate and the use of light filters rendered it also possible to produce the colour values of any picture, but it would be noticed that the colours of pictures had also been affected. Notwithstanding the great perfection of methods of rendering colour values, it was well known that some sets of colours reproduced better than others. Artists, knowing this, paint their pictures, which are intended for reproduction in colours suited for the purpose, possibly different to what might otherwise have been used. It would be, perhaps, interesting to observe the essential differences between photogravure and the processes which it has so largely superseded. In the old line-engraving process a steel plate was taken, and upon it was drawn the picture to be reproduced. The lines which were necessary to make the smooth steel a printing plate had then to be cut out by hand with a special tool, with an expenditure of an immense amount of artistic ability and a great deal of time. The difference between line engraving and photogravure lay in the fact that the effects of light and shade were produced in the first by lines of varying depths and breadth, while in photogravure they are produced in half-tone. Another process of producing *intaglio* plates—the etching process—was that in which a copper plate was covered with an acid-resisting varnish. Upon this was drawn, with a needle, the picture to be reproduced, and then, by means of various etching fluids, nitric acid, for instance, the design was bitten in, the acid affecting the copper only where the needle had penetrated the coating of varnish. The mezzotint process—yet another means of producing *intaglio* plates—was entirely different to the line engraving, approaching more nearly the nature of photogravure, in that the lights and shadows are in half-tone and not in line. Very few mezzotints were produced nowadays, but an example of this process, and of the preceding methods, was passed round. A copper plate was taken, and the whole of its surface rolled over with a tool like a minute file, producing a uniform burr all over the plate. Printed in this condition, it would yield a solid black impression. The artist produces his picture by scraping down the portions more or less where the high lights and half-tones are to appear. In a sense this is a reversal of previous processes, where one started with a plate which could give a mass of high light, the shadows having to be cut in by a tool. In mezzotint one commenced with a plate giving all shadow, and produced the lights by scraping down. None of the methods so far depend upon the camera.

With reference to the examples of line engraving, etching, mezzotint, and photogravure passed round, it would be seen that there were certain marked differences. The photogravures looked like satin, while the true line engravings in the deep shadows were rough to the touch. Many so-called line engravings were turned out, which were in reality photogravure reproductions of line engravings. By remembering that the shadows of the true engraving were rough to the touch, such impostures could be detected.

To come to the production of a photogravure plate: If a painting is to be reproduced, orthochromatic plates and light filters are necessary for the truthful rendering of the colour luminosities. It is well to notice that, finally, a photogravure reproduction is at least a reproduction of a reproduction of a reproduction of another reproduction. Every reproduction tends to lose detail, so that one should choose a developer in the first place which will give the sharpest outlines possible.

Mr. Hunt saw no reason to name a developer, holding the opinion that it was the ability of the user rather than the constituents of a developer that gave a satisfactory result. Given the negative, a transparency on glass was next required, and this was made by the carbon process. The carbon process conveniently gave a reversed image, which was necessary, unless one was content to have the final print in reverse. In transferring the carbon positives on glass, the use of collodion was often stated to be necessary, but Mr. Hunt never used so much as would fill a teaspoon. The secret lay in using rolled or plate glass instead of sheet glass. The best copper is required. If not perfectly hammered out after rolling, hollow places will exist below the surface, which, directly the acid is applied, are found out and revealed. The result is disastrous, especially if the holes occur in the high lights, as they produce, of course, a black impression. The copper then should be perfectly hammered, and "round" polished. Straight polishing gives minute lines, which greatly disfigure should they cross a face, whereas those following "round" polishing are not aggressive. The copper must be scrupulously clean. American potash in solution is brushed over with vigour, a brush like a scrubbing brush, only softer, being employed. This is followed by a bath of sulphuric acid, when the plate should be reasonably clean. When dry, the plate has to be "grained" with a very fine dust. Various gums are used: in France resin is much used; in Germany, where the finest work is produced, bitumen or asphalt as fine as flour is employed. Two or three pounds are placed in what is known as a graining box. This box is capable of being revolved on an axle, causing the dust to rise in a cloud according to the nature of the grain to be applied to the plate, the box is

then allowed to stand. The coarser particles of dust soon fall, and the longer the box is left before inserting the copper plate in the bottom of the box to receive the falling dust, the finer will be the grain. If a coarse grain is wanted, one would insert the plate at once. Looked at obliquely, after dusting, the plate appears like a fawn-coloured cloth, but directly downwards there is not much change. This grain has to be fixed by heating. The grains of bitumen become first transparent, then steel blue (the proper condition), finally, if left long enough, melting and spreading over the whole plate. In such a condition the etching fluid would fail to reach the plate at all, whereas the object of the grains of bitumen is only to prevent its access to the plate in parts.

From the carbon positive previously referred to one makes a print in the Autotype photogravure tissue, a tissue very lightly pigmented. This print is transferred to the grained copper in the usual way, using the copper as one would the single transfer paper. Exceeding care is here wanted. If anything gets between the copper and the carbon transfer, it will pierce the carbon film and allow the acid improper access to the plate. Again, no collodion is necessary for transfer, the grain on the plate is sufficient to hold the film during subsequent development of the carbon print and the etching process.

The carbon print having been developed, the next thing is to etch the plate, first varnishing the same with an acid-proof varnish on the back and round the edge to the margins of the picture, to prevent undue action of the etching fluid. The etching fluid is almost universally the perchloride of iron. Seven pounds are added to five pints of water, and the mixture allowed to boil in an enamelled pan. The clear portion is poured off, and tested with a Beaumé hydrometer for heavy liquids. It may register 50°. If so, pour off a pint and bottle it up. Add more water and boil. Test, and it should be a little weaker, say 45°. Go on until one has solutions from 50° down to 30° in easy stages. It is curious that the strongest bath with which one commences only penetrates the thinnest parts of the carbon resist. The plate, it will be noticed, grows black in these thin parts, and, when it has ceased to blacken, the plate should be put in the next weaker bath, and the next thinnest parts are etched. So one goes on, using the weaker and weaker baths, until the whole of the plate is etched except the high lights. The plate is then placed under a strong stream of water, or in a solution of potash, to stop action. The carbon film removed, one may examine the work, and, however well done, it will look to the beginner very bad. The bitumen grain is next removed by making the plate hot and rubbing off with turpentine. The copper is next thoroughly cleaned, as the slightest trace of etching fluid left in the fine detail will go on acting and clog up the work. The plate may then be proved. If one has over-etched the high lights, the burnisher will correct it; or, if the shadows want strengthening, the roulette will give a little more burr, which will retain the ink and give more depth to the print.

There was considerable discussion upon Mr. Hunt's interesting remarks, and a vote of thanks was passed with acclamation.

#### A SCOTTISH PHOTOGRAPHER AT "THE FRONT."

In the ranks of the special correspondents at present with our forces in South Africa, Glasgow can lay claim not only to the *doyen* of war correspondents on the active list—Bennet Burleigh, but also to the first photographic illustrator—H. C. Shelley. It is true that in previous campaigns artists have used the camera to register the scenes on and around the battlefield, but in their case the camera was only an accessory to the pencil; in Mr. Shelley's case the camera, *plus*, of course, the man in charge, is the illustrator, and, as a good horseman can take more out of his horse than a novice, so, in the hands of the expert photographer, the camera is capable of successes in circumstances which to the *dilettante* would spell failure.

This is Mr. Shelley's first experience of war, but he is peculiarly well equipped to take the field as the pioneer of a new branch of illustration in the early days of specials, and the photographs that he has contributed to the first number of *The King*, Newnes' new weekly, show not only the stern, bare realities of war, but in several instances, notably *Difficulties of Transports*, have the added merit of artistic qualities. His *Dead* showing a dead Boer lying in the trenches, simple in the extreme, is yet one of the most telling pictures of the actual horrors of war that we have seen.

Mr. Henry Charles Shelley is a man in his prime, born in the sunny month of June, 1860; his father was a yeoman farmer and part of his early days were spent in Lincolnshire, in the vicinity of Peterborough, where the proximity of so many of the grand cathedrals of England would in all probability instil into him that love of the beautiful which has found vent through the medium of his photography. Here he learned the accomplishments of a "young man from the country," and his ability to ride a horse, and shoot straight, are the acquisitions that he will now find the benefit of, although we trust that his peaceful calling—peace in the midst of war—will not render his shooting necessary.

That he has not forgotten the country of his early days is proved by his admirable lecture on "The Broads," where his discourse, with its racy anecdote and eloquent flow of language, vied with the beautiful lantern

slides in securing for him a very high place in the esteem of his audiences.

After he came to Glasgow, he wrote a considerable number of articles for *The Glasgow Herald*, including a series on microscopic work, on which he was an authority. Photography now gained a hold on him, and his "capacity for taking pains," assisted by an inherent artistic faculty, speedily gained him a prominent place in the art-science. The method and attention to details, necessitated by his microscopic researches, proved useful and prevented the "artistic" running away with him, so that we see in none of his work that extravagance that mars the work of not a few holding high place in the photographic world.

He claims to be the originator of photographic notes in the modern lay press, by reason of the "Photographic Jottings" which he inaugurated and conducted with great success in the *Glasgow Evening Times* for many years. So great was the popularity of this feature in that paper, that it resulted in the founding on March 11, 1895, of the *Evening Times Camera Club*, a society that at one time laid claim to being in the first flight of the "large" photographic societies in the kingdom. For some years Mr. Shelley acted as Honorary Secretary of the Club, and under his tactful and enthusiastic guidance it flourished amazingly. He did not exhibit to any extent, but, on the few occasions on which he submitted his work to the criticism of the Judges, he gained several medals.

He has a thorough knowledge of photography in all its branches, and his ability with the hand camera, combined with the pen of a ready writer, make his employment as a war-correspondent illustrator an acquisition indeed to Newnes.

In April 1897, he left Glasgow for London, but his friends would not allow him to go away empty-handed, and, as a token of the high esteem in which he was held in Sanct Mungo's Town, he was presented before his departure with a handsome gold watch.

Since going to the metropolis he has contributed articles to the *Windsor* and *Ludgate* Magazines, the *Sketch*, *Black and White*, and many other important papers, including *American Illustrations*.

He has also wandered into the realms of book-making, and his *Homes and Haunts of Robert Burns* (illustrated) gained a fair share of public favour.

As a man, he had in an exceptional degree the faculty of making and retaining friends; the following tribute from a personal friend, may well conclude this meagre sketch: "He was a man, who, having once set his mind on a thing, would carry it through, and in emergencies was ever 'cool as a leek,' and will therefore make a first-rate war correspondent, as he will not scruple to face any danger to gain his ends. A kind, sympathetic, and trusty friend, and a most sociable companion, a better man never walked in shoe leather; he was ever ready to put his hand in his pocket to assist a more unfortunate brother, and his advice was always sound and helpful. I pray God that he may be spared to come back among us, when I know he will have made a name for himself."

ALLAN BLAIR.

### IS A SHOW-CASE A STRUCTURE?

At the North London Police Court, on January 17, Thompson Fisher, photographer, of Mare-street, Hackney, was summoned before Mr. Fordham for erecting a building in the forecourt of his house beyond the general line of frontage without the consent in writing of the London County Council.

Mr. Chilvers appeared for the County Council, and Mr. C. V. Young defended.

Mr. Chilvers said that the defendant had erected a show-case in his front garden for the display of his photographs without the consent of the Council as required by the London Building Act of 1894. This structure was 13 ft. long, 8 ft. high, and 3 ft. wide, and was made with wood, covered with zinc, on a brick foundation. The front was glazed, and at the back were panelled doors. It was lighted by gas. Evidence was given to show that no consent for the erection of the show-case had been given, and that it stood 8 ft. 9 in. beyond the general line of frontage.

Mr. Young contended that the London Building Act was designed for the regulation of the habitations of men, and he argued that, as this was not a habitable structure, it would be exempt from the operation of the Act. He quoted cases to show that a builder's office, which was 10 ft. high, and a wood and iron bungalow of four rooms, erected as an advertisement and for sale, had been held not to be buildings within the meaning of the Act.

Mr. Fordham: In the first case, the office was on wheels; in the second, the bungalow was never meant for habitation or use at the place where it was erected.

Mr. Young: This structure is not intended for habitation.

Mr. Fordham: It is intended for use—for the display of the defendant's photographs.

Mr. Young went on to say that the present show-case took the place of a similar one which had been there since 1891, and had never been interfered with. Moreover, the County Council had proceeded against

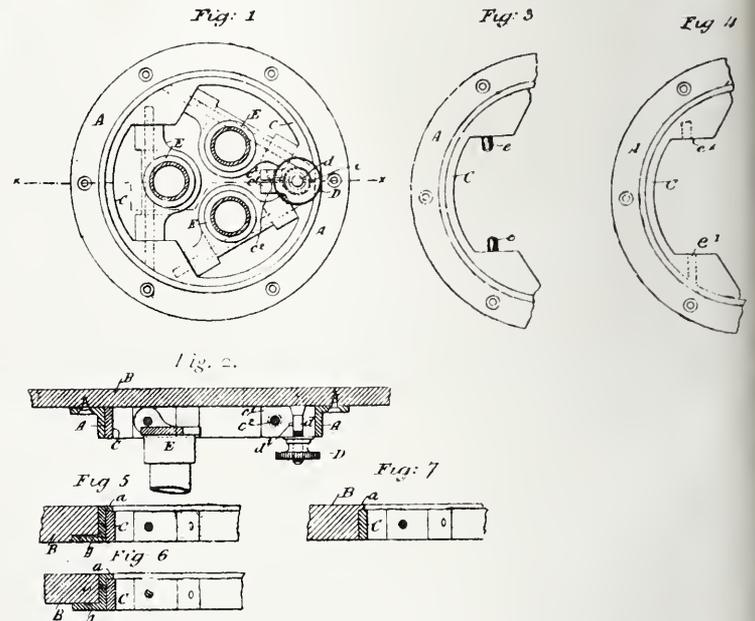

another photographer in the same street, in 1894, for erecting a similar show-case, and had failed. As they did not appeal, the defendant thought he would be quite safe in taking away his old case and renewing it.

Mr. Fordham said at present he was of opinion that this show-case was a structure, and that the consent of the Council was required for its erection; but, still, he thought it would be very hard on the defendant to pull down a structure which really did no harm to any one. He adjourned the case to consider his decision, and in the mean time he hoped the defendant would come to some arrangement with the Council.

### A NOVEL TRIPOD HEAD AND STAND.

Mr. G. W. ATKINS, of the Palmers Villa, Elstree, is an esteemed worker of many years' standing, to whose accomplishments in the mechanical branches of photography our pages in former times often bore witness. He will be remembered by many of our readers as a valued member of the London and Provincial Photographic Association, of which he was long an officer. Endowed with many abilities out of the common, Mr. Atkins is alike highly skilful in making his own cameras, shutters, brasswork, and even his own lenses. One of the best types of amateur workers, he has long been a devotee of stereoscopic photography. For some years resident in the country, he has now returned to take up his residence near London.

The latest outcome of Mr. Atkins's ingenuity takes the form of an ingenious method of attaching the camera to the stand. Quoting from the words of his patent specification, the bottom of the camera is furnished underneath with a metallic ring, permanently secured. Into this ring is inserted another ring, to which are secured the legs of the tripod. This ring is divided transversely, so as to be capable of ex-

pansion or contraction within the other ring, to make a firm bind therein or to permit of easy removal.

To proceed with the description: A is a metal ring, permanently secured to the camera base, B. When a ring is used, it may be secured by means of screws, as shown in fig. 2, or by letting the ring into the base, as shown in figs. 5 and 6.

In the cases of figs. 5 and 6, where the camera base is cut away to receive the ring, an internal flange, a, at the upper edge of the ring, is provided, and in fig. 7, where there is no ring, but merely a recess, a flange, a, is formed out of the material of the camera base.

c is also a metal ring divided transversely at c, and provided at that point with an expanding device; for instance, a conically ended screw, d, inserted between the lugs, c', c', and furnished with a thumb nut, D, for operating the cone or wedge to and fro, to expand the ring to the extent of its capacity, or allow it to contract. Its capacity for expansion is limited by a screw, c<sup>2</sup>, passed through the lugs, c', c' (see fig. 1). d<sup>1</sup> is a small pin inserted in the screw, d, to prevent its rotation when the thumb nut, D, is turned.

The ring, c, being inserted into the ring or recess, a, so that it bears up against the camera base, or against the flange, a, the thumb nut is operated to expand the said ring, c, as above explained, to bind tightly with the ring or recess, a, attached to the camera, and in this way a quick and rigid attachment is effected.

To remove the support the thumb nut is unscrewed, thereby releasing

the wedge and allowing the ring, c, to contract, when the apparatus can be readily taken apart.

Mr. Atkins has shown us one of the new tripod heads. These are made, at present, of aluminium. In use, the head is placed in the ring in the base of the camera, instantly "expanded" by means of the screw adjustment, and so firmly fixed that there is absolutely no fear of the camera becoming detached. It is one of the simplest and most effective means of attaching the camera to the tripod that we have seen, and, if placed on the market, will, no doubt, be highly popular.

#### JAMES PATRICK—AN EDINBURGH PHOTOGRAPHER.

IN the *Photo-Beacon* for January Mr. F. Dundas Todd gives the following sympathetic sketch of Mr. James Patrick, the well-known Edinburgh photographer:—

Some dozen years ago, when I was living in Scotland's capital, and "artistic" photography ran in my mind night and day, a bright idea suddenly flashed upon me, and that was to organize a club whose sole aim would be to help its members in that particular direction. I had acquaintanceship with a number of really good amateur and professional photographers, and was also fortunate enough to have the run of about half a dozen painters' studios; so I laid my little scheme before them, and ultimately we formed the "View finders" Club, which was composed in equal numbers of painters and photographers. We met once a month, and each member in his turn had to produce at least four examples of recent work for criticism by the others. I will never forget these meetings—how we sat around the poor victim, and between puffs of tobacco smoke told him very plainly what we thought of him and his work. This I will say, it was a capital training, and when I was in Edinburgh recently I met a number of the old members, and one and all referred, with bright and glowing eyes, to the good old times now gone.

One of these was "Jim" Patrick, as we all liked to call him. Although engaged in professional photography, he had never been associated in any way with a photographic society, but I had spotted the work he was doing, and willingly or unwillingly—I must frankly say modestly is his greatest failing—he had to become a member, and a splendid fellow he proved to be once his diffidence began to wear off.

Though far removed from him during the past seven years, I never lost sight of him, and with pleasure I marked his steady upward progress. Every now and then I saw his name published, with the information that he had been the winner of another gold, silver, or bronze medal, as the case might happen to be, and so, when I once more found myself in "Auld Reekie," I invaded him in his home one evening, and insisted on seeing every one of his medalled pictures. I was simply charmed with them, both from a pictorial and from a personal standpoint, for all of them were made round about Swanston, a "sleepy hollow" lying under the shadow of the Pentland Hills. It is a locality dear to lovers of the picturesque, but has other interests, for it was in this neighbourhood that Robert Louis Stevenson spent his youthful days, wandering at his sweet will among fertile fields or climbing to the higher pastoral solitudes.

Many of my readers will be tempted to exclaim, "No wonder he could make pictures! With such material, who could fail?" But one of Mr. Patrick's friends confessed to me that he had frequently visited the same region with his camera, and never yet had brought back anything that was worth comparing with the work of Mr. Patrick, and I may add he is no mean photographer; so that it is not merely a question of subject, but very much a matter of individual. Now about this individual and his method of working. Mr. Patrick first saw the light not so very many miles from where I did, but I should fancy a few years later, and I acknowledge being forty-one. His father was and is a professional photographer, having started in business as far back as 1853, and is well known as the maker of possibly the most successful portrait of Thomas Carlyle, which, by the way, was reproduced about a year ago in *Scribner's Magazine*, and was accompanied by a very interesting article by Mr. Patrick, sen., giving his reminiscences of the great author. Before entering the photographic profession our subject underwent a very thorough art training. For four years he was a student in the Royal Institution, Edinburgh, and, having then shown sufficient ability, was permitted to attend the Royal Scottish Academy Life School, which he did for four years more. During that period and since, he exhibited in the Royal Scottish Academy and many other exhibitions. So, when he turned to photography, he brought to it a training for his future work that was simply ideal.

His photographic training he received from his father, his first and only employer, and for that branch he was certainly in good hands.

Mr. Patrick's methods of working certainly spell success, but I am afraid there are but few who would care to follow them—the more's the pity. He haunted Swanston until he simply became saturated with the glamour of the place, and had every topographical feature in his mind's eye. When the idea of a picture gets into his head, he pins a large sheet of white paper on his easel, and with charcoal sketches the main features of the scene. Then the sheep, cattle, or horses, as the case may be, are sketched in, and the composition arranged down to the minutest detail. Weeks are sometimes spent in this way, and then he arranges with the shepherd, if sheep be the accessory, or grieve, should it be cattle or horses, to be on the ground at a certain day or hour—even the

particular condition of light is settled beforehand. After the camera is in position it is not unusual for hours to be spent in getting the animals into the correct position, and only when everything is just as he planned it is the exposure made. On one occasion it was only after days of patient labour that the predetermined combination was secured, but the result was a much-medalled picture.

As showing the thoroughness of Mr. Patrick's nature, I may state that, in the case of the beautiful picture of the old lady, entitled *Eventide*, in order to get sufficient light to give a little detail in the shadow side of the figure, he had a mason knock a hole in the wall, and then sent a carpenter to put in a window.

Stevenson describes Swanston as "a little hamlet of some twenty cottages in the woody fold of a green hill." Mr. Patrick says of it, "Abundance of pictorial wealth is all around. At every turn the eye is delighted, and, in whatever mood one may wander, sympathetic scenery presents itself. Nature is continually delighting the mind with its atmospheric glamour, and in every mood one sees new possibilities of picture-making. One could work here for a lifetime, and always find something new."

#### THE LATE J. A. HARRISON.

WE are sorry to learn of the death of Mr. J. A. Harrison, which took place on the 19th instant as the result of an attack of pneumonia. The deceased gentleman, who was seventy-eight years of age, only survived the death of his wife ten days.

The late Mr. Harrison will be chiefly remembered in connexion with the Pantascopic Camera, of which he and the late J. R. Johnson were the inventors over thirty years ago. Of this camera the late Mr. Traill Taylor in the *ALMANAC* of 1892 gave the following description and opinion: "Probably no camera which has ever been introduced at all approaches in mechanical ingenuity the one I shall now endeavour to describe. Although every part of it except the stand is in motion by means of clockwork during the taking of the picture, such is the perfection of both its principle of construction and its workmanship that I have frequently subjected negatives taken by one in my possession to examination under a compound microscope, the limit to the power employed being that degree of amplification at which the silver granules forming the collodion image became too pronounced.

"The pantascopic camera is composed of a small chamber capable of rotating freely on a strong pin fixed in a circular base plate. This pin is situated directly under the optical centre of the lens. The back is closed, all but a narrow slot reaching from top to bottom, and has wings fitted to it for the purpose of opening or narrowing the slot, or making it wider opposite the foreground and closer for the sky, so that, no matter how dark the one and how bright the other, the picture will be harmoniously rendered. Attached to and projecting laterally from each side of the camera is a steel rail, on which runs, on two castors, a carriage bearing the dark slide, which is covered with an endless band of opaque cloth running over two rollers at each end of the carriage, and is attached to the camera proper by means of a brass flange. The edge of the circular plate on which the camera rotates is grooved, and on this groove two strings fold, one end of each being attached to the base, the other to the carriage that carries the dark slide. The camera rotating, and the base being stationary, the strings fold and unfold respectively, giving a rectilinear motion to the carriage, which runs upon the rail at the back of the camera. The diameter of the circular plate upon which the strings fold has a definite relation to the focus of the lens, and thus the relative motion of sensitive plate and lens is obtained. The plate is therefore always tangential to the supposed cylinder upon which the image ought to be received. The camera is driven by clockwork so arranged that a perfectly uniform motion is maintained during the whole time that the camera is being rotated. The dimensions of the plate depend, of course, upon the focus of the lens and the angle of view to be obtained. If the focus of the lens be three and three quarter inches, which is that in our camera, then, if the whole horizon is to be included, the length of the plate must equal the circumference of a circle whose radius equals the focus of the lens. Our camera, however, is fitted for half-plates, and on these we secure an angle of 120° on the base line, the extreme ends being necessarily as sharp as the centre.

"When in action, the camera, carrying the carriage with the dark slide, moves round the central pivot below the optical centre of the lens. The carriage, at the same time, has a movement of translation from one end of the rail to the other, this being effected by the strings spoken of. The axial rays only of the lens are employed in forming the image, hence there is no distortion.

"Pantascopic negatives of the size above indicated have yielded enlargements 36 × 12 inches, in which there is no want of sharpness. The perspective is panoramic. This invention was originated in 1862, but it was three years later ere it was quite perfected."

Many other ingenious mechanical photographic devices of which he was the inventor were from time to time exhibited by the late Mr. Harrison at various societies, including the South London, the Photographic Club, the London and Provincial, the Royal, &c.

## DEVELOPERS, OLD AND NEW.

ON the 18th instant, Mr. C. H. Bothamley gave a lecture upon "Developers, old and new," and found awaiting him a large audience. This was, no doubt, due in the first place to the nature of the subject, for it would attract not only those who are students of photography, but the less thoughtful ones who try in turn every new developer which is placed upon the market. It must also be noted that Mr. Bothamley lectures with such charming ease, clear enunciation, and well-chosen phrases, that it is quite a pleasure to listen to him. This last consideration had, no doubt, its influence in swelling the attendance at his lecture.

Since Mr. Bothamley gave his experiences of orator to the Club, two years ago, no fewer than four others have, by the enterprise of German chemists, made their appearance. The lecturer said that each of these had a strong claim to public support, and that a consideration of their merits would form the groundwork of his lecture. Although his chosen title was "Developers, Old and New," the older compounds would be merely referred to by way of comparison. Some might say that the old developers were good enough for them, and that they did not want to bother themselves with anything new. But we can never say, in this world, that we have attained the best possible results, or, at any rate, the best under all conditions.

What has been the solid gain to photography through the introduction of these new developing agents? We may most certainly say that they have put the printing of bromide papers upon an entirely new footing. Few realise the enormous difference between the bromide printing of to-day and that of a few years back, when the operator had only one developer—ferrous-oxalate—with which to coax an image from the paper. In this important field of work we have at least gained, and we say also that in a lesser degree these new developers have helped us to produce lantern slides on bromide plates with ease and certainty. Some lantern slides, developed with the new agents about which he had to tell would be shown on the screen at a later stage of his lecture.

The first developer which he would notice, diamido-resorcin, had a close relation to amidol, which, it would be remembered, was nearly allied to phenol, or carbolic acid. At the risk of frightening those nervous souls who generally fled at the sight of a chemical or mathematical symbol, he would point out the actual difference between the composition of these bodies. [Demonstration.] Amidol and diamido-resorcin darkened to about the same extent with access to air, an action which was at once retarded by the addition of a preservative such as sodic sulphite. They still darken, but at a slower rate. Amidol crystallises in white crystals, and diamido-resorcin in small yellowish leaflets. He believed that the extent to which amidol alters in the air has been exaggerated; it seems to be largely dependent upon purity. Here was a bottle of amidol-Hauff, which he had purchased years ago, which was as good as ever. On the other hand, he had another sample, obtained from a different source, which had discoloured to an alarming extent. Diamido-resorcin alters very little in the dry state, even if left exposed to the air on a sheet of paper; it should be used with sodic sulphite, and the fact remembered that it is more soluble in a three per cent. of that salt than when the strength is raised to five per cent. He would hand round prints of bromide paper which had been developed with this new agent, and, although the two prints were of the same subject, they were very different in appearance. The difference was gained by varying the length of time under development. A short immersion in the developer gave a soft negative, or bromide print, but, if development is allowed to go on, you can get as much vigour as you like. The drawback with prolonged development is a deep orange stain, which will affect both gelatine and paper. On the whole, it may be thought that diamido-resorcin does not present any great advantage over amidol.

The next developer to come under review was a very peculiar substance indeed, and its name was hydramine. It is formed by the combination of hydroquinone with another substance, and was presented in the form of plates having a pearly lustre. Dissolved in a solution of sodic sulphite two per cent., with two per cent. of potash metabisulphite, it can be left in an open vessel for weeks without getting discoloured. One of the most curious properties of hydramine was that it would act as a developer when mixed with water alone. It was unusual and remarkable to find a substance which would do this. He only knew of two others, of which eikonogen was one. Certainly it took a couple of days to do its work, but still the fact remains that an aqueous solution of hydramine, without anything else, would develop the photographic image.

The developing power of hydramine is not much increased by the usual agents, and the best alkali to use is found to be caustic lithia, which possesses several advantages over caustic potash or soda for the purpose. The composition of the developer recommended in 1000 parts of water is as follows:—Anhydrous sodic sulphite, 16 parts; hydramine, 5 parts; and caustic lithia, 3 parts. This solution keeps well, and, even if exposed to the air in an open dish for twenty-four hours, the discolouration only amounts to a golden tint. The addition of a small quantity of bromide to this developer sets up a restraining action, and there is a very decided alteration in the gradation. (A number of plates developed with hydramine were here shown, as were also some bromide prints. The latter showed a tendency to fog, but half a grain of bromine per ounce of developer was sufficient to clear the whites, and the scale of gradation was shortened, as in the case of negatives developed with the

same agent.) Hydramine has no tendency to stain like diamido-resorcin; it is, in fact, a substance of an entirely new class, with certain points of resemblance to both metol and amidol.

The two remaining new developers to which he would call attention were first cousins to hydroquinone, and these again represent a new class of developers. A chemist would describe them as halogen substitution derivatives. These two developers were respectively known as adurol-Hauff and adurol-Schering, denoting the names of their German makers. In the first-named, and comparing its composition with that of hydroquinone, an atom of hydrogen was displaced by one of chlorine; but in the second developer—aduro-Schering—the atom of hydrogen was displaced by one of bromine. One could therefore otherwise describe the first-named as chloro-hydroquinone and the second as bromo-hydroquinone. As they all knew, hydroquinone by itself was not a developer, but each of these new bodies—the adurols—have a faint developing action. They alter very little by exposure to air; they are more soluble in water than hydroquinone, and with sodic or potassic carbonate they exert a developing power greater than that of the last-named.

As they all knew, it was next to impossible to get good results in cold weather with hydroquinone; indeed, on some occasions in winter he had failed with that agent to get the ghost of an image. This is not the case with the adurols. They are good developers for either plates, bromide paper, or lantern slides, and he would show examples of such. Mr. Bothamley's admirable lecture concluded with an exhibition of lantern slides developed by the various agents which he had described, and they evoked much applause.

A short discussion followed the reading of the paper, the trend of which can be sufficiently seen by the following brief summary of the lecturer's reply.

He said, with regard to the amount of bromide added to the developer to affect the colour of lantern slides, that, so far as his experience went, the colour of the image depended chiefly upon the time occupied in development. If this is retarded by dilution with water or hastened by heat, you get much the same results. The repeated use of the same lot of developer for many plates is a question depending upon the degree of discolouration of the liquid by the air. One of the most useful properties of these new developers is that they do not, like pyrogallol, get rapidly dirty. When they discolour, you must change the solution. All the slides he showed were developed one after the other in their respective developers, only one batch of solution being used for each lot. The influence exerted by the addition of bromide to the developer was by no means the same in every case. With hydroquinone the effect was very great and immediately apparent; with metol, on the other hand, a large quantity of bromide must be employed before one could get any marked result. If the whole of the light action is developed out, much the same result can be scored with all developers, the colour of the image being the only point of difference discernible. He believed that the adurols would be found very valuable for cold-weather development, and that they would work well with metol, but his experiments in this direction were not yet concluded.

Mr. Webber, who occupied the chair, closed the proceedings with a few well-chosen words.

## THE THORNTON "GLASSOLINE" FILM.

THE prospectus of the Thornton Film Company is in circulation, the capital being 20,000*l.*, with a present issue of 7500*l.* Two of the Directors, Messrs. J. E. Thoratton (Chairman and Managing Director) and C. F. S. Rothwell (Chief Chemist) are Directors of the Flexoid Syndicate, the promoters, who have fixed the purchase price of the patent rights at 9000*l.*

A perusal of the prospectus, which extends to eight pages, shows that the Company anticipate an immense opening for the film, the advantages of which are set forth at considerable length and in great detail. Glassoline film is described as "pure gelatine, coated with the sensitive emulsion, and having a backing of transparent paper, which can be instantly removed from the film itself when the negative is finished and dry." Between the film and the backing is a transparent material, "flexoid," which "renders the backing waterproof, thus preventing stretching, cockling, unequal expansion," &c. Other properties of flexoid and the entire film are also quoted. The "disadvantages of films hitherto produced" are set forth, and glassoline film is declared to be "the perfection of simplicity, reliability, and cheapness."

It is stated that, so soon as the parent Company shall have successfully shown the scope and value of glassoline films, a larger Company, with a capital of 100,000*l.*, will be formed. Messrs. Cunliffe, Brooks, & Co., of Altrincham, are the bankers, and no doubt they will furnish copies of the prospectus on application.

Financial criticism does not fall within our province, and we have not seen a sample of glassoline film, so that upon these two points we are not called upon to offer a remark. But we may pause to note the references of the prospectus to the "disadvantages of films hitherto produced." Roll celluloid films are declared to be a trouble to manipulate, owing to their tendency to roll, and this and other difficulties are stated to cause many photographers to discard their use, whilst novices and amateur photographers are said to find almost insurmountable difficulties in their use. Again, after stating that "all the other

materials or methods hitherto tried for film supports have been found wanting," a paragraph is devoted to pointing out the respects in which each of those systems "did not fulfil all photographic requirements."

It will thus be seen that, in claiming to succeed where all those systems are declared, in the prospectus, to have failed, glassoline film demands to be judged by very stringent tests indeed. We await its introduction with much interest. In the meanwhile, we cannot help feeling that its chances of a favourable reception at the hands of the photographic public are somewhat handicapped by the wholesale condemnation of past and present film processes in which the prospectus somewhat incautiously indulges. We are practically familiar with the history of film photography for the last twenty years. Most excellent results were produced by some of the older methods, whilst of modern systems it is sufficient to say that some of them have great possibilities, and at least one of them is in successful world-wide use.

#### THE "KRISTAL" PLATES.

At the Photographic Club, on Jan. 17, Mr. J. P. W. Goodwin demonstrated the use of B. J. Edwards & Co.'s "Kristal" plates for lantern and stereoscopic slides and transparencies by contact printing. The "Kristal" plates may be handled without the use of a dark room, in an ordinary gas-lit room, without fear of trouble. The aim has been to make a plate not only easy to work and convenient to use, but also one which should give results as nearly as possible like the old slides by the albumen process, which was the prince of processes for lantern work. No better slides have been made than the old albumen slides. "Kristal" plates had an exceedingly fine grain; only a high-power glass would reveal it. This, with pure blacks or any degree of warmth, perfectly clear high lights and detail in the shadows, were the characteristics of the plate. Consequent upon the extreme slowness of the emulsion, the plate was suited only for contact printing, and not reduction, although he had made slides with the plates by reduction, two or three hours to a whole day, being required. The plates were not intended, however, for reduction processes. In the speaker's opinion they possessed all the advantages of the ordinary plate in addition to other good points. First among these, naturally, is the fact that no dark room is essential when using the plate. Secondly, good results are to be got from negatives which with ordinary plates would be out of the question. Then there was the big range of colours, very easily obtained. Two developers are given, one for black and one for warm tones. It should not be forgotten that with some negatives it was almost impossible to get a good black. In that case he would ask—why try? It will give a good warm tone, perhaps! Mr. Goodwin preferred warm tones, and found a tone much to his liking by diluting the black tone developer and increasing the exposure. He showed what he would call an average negative, and proceeded to print from it for black tones, an inch of magnesium ribbon burnt at twenty inches distance giving just about sufficient exposure. For brown tones he would increase the magnesium to four inches, or decrease the distance, according to the tone required, and dilute the black tone developer. Several slides were produced during the evening with great precision and ease, and a number of finished slides by Mr. B. J. Edwards and Mr. Goodwin were afterwards shown upon the screen. The use of Rodinal for black tones, with any class of negative, was alluded to, and the following formula was given:—

Rodinal, 1 part in 12.

Bromide, 2 grains per ounce of mixed developer.

#### THE PHOTOGRAPHIC CLUB.

Of the Photographic Club, now in the twenty-first year of its existence, Mr. Alexander Mackie has recently written the following short but sympathetic history:—

During the summer recess of the old South London Photographic Society, in 1879, a number of the members met weekly, by invitation of Mr. A. Brittlebank, at his studio, to discuss the then absorbing topic of the gelatine process. These meetings proved so pleasant, and the informal and conversational character of the proceedings was found to bring out such a valuable fund of knowledge and experience from men who would not willingly speak at the formal meeting of a scientific society, that, at the resumption of the Society's session, it was resolved to form a separate organization to continue the "Brittlebank" meetings. Accordingly the Photographic Club was formed, and held its first meeting on November 19, 1879, and has continued to meet every Wednesday evening to the present time.

For several years no subjects were announced for discussion, but it must be remembered these were times when every photographer was of necessity an experimenter, when even the more simple processes of photography were not so thoroughly understood as they are now, and when but few of the preparations which every dealer sells now were to be had commercially. Of late years, however, it has been the custom at most of the meetings to have a lecture, demonstrator, or set subject for discussion announced, though opportunity is still afforded to members to bring forward matters of interest, or to ask for information with regard to their difficulties. The Club always extends a hearty welcome to all

interested in photography, and at lantern lectures, of which there are several during the winter session, ladies are specially made welcome.

The Club has a good photographic library, and members have the privilege of borrowing the books for home reading.

In the twenty-first year of its existence, the Club has naturally to some extent changed its methods; but it has not departed from its traditions and has not changed its nature. Its meetings are social meetings of photographers to discuss photography.

#### THE THORNTON-PICKARD COMPETITION.

THE Thornton-Pickard Manufacturing Co., of Altrincham, announce the following photographic competition for 1900. The competition will be divided into three classes as follows:—Class I.: 35l. will be given in prizes for the best sets of four instantaneous photographs of subjects of general interest taken with the Thornton-Pickard "Amber" or "Ruby" Camera and Time and Instantaneous Shutter. Class II.: 35l. will be given in prizes for the best sets of four instantaneous photographs of quickly moving objects taken with the Thornton-Pickard Focal-plane Shutter. Class III.: 35l. will be given in prizes for the best sets of four instantaneous photographs of any subjects of general interest taken with any of the Thornton-Pickard various patterns of "Time" and "Instantaneous" or "Snap-shot" Shutters. There will be five prizes in each class as follows, making a total of fifteen prizes: First prize, 15l.; second prize, 10l.; third prize, 5l.; fourth prize, 3l.; fifth prize, 2l.

The following are the principal rules:—  
All competing photographs must be sent in on or before October 1, 1900. Any received after that date will not be admissible.

The prizes are offered for sets of prints. Each set must consist of four prints from different negatives. Any number of sets may be entered in either class. They may all be different subjects, or a series of the same subject in different styles or positions, but must be instantaneous exposures of from  $\frac{1}{8}$  to  $\frac{1}{1000}$  sec.

The prints may be any size, but must be printed direct from the negatives. Enlargements not allowed.

All prints must be mounted; this may be done in any way the competitor desires, but framing is not allowed.

The pictures may be printed by any process, on any kind of paper, but transparencies are not allowed. Composite negatives or printing from two or more negatives not allowed.

Ordinary spotting of defects on the prints or negatives will be allowed, but retouching will result in disqualification.

Both prints and negatives will become the absolute property of the Thornton-Pickard Manufacturing Co., Ltd., who will have the sole right to publish, copyright, and use them for advertising and other purposes.

Successful competitors must furnish such information as may be deemed necessary, and, if desired, submit their apparatus for inspection and state when and where it was purchased.

Intending competitors in Class I. must use both the Thornton-Pickard Camera and Shutter. Either the "Ruby," "Amber," or any other pattern of their cameras, and any pattern of their Time and Instantaneous Shutters may be used.

In Class II. any make of camera (including hand cameras) may be used, but the picture must be taken with a Thornton-Pickard Focal-plane Shutter.

In Class III. any make of camera may be used providing it is fitted with any of their various patterns of "Time and Instantaneous" and "Snap-shot Shutters."

Competitors can enter in one class only.

Every print must be clearly marked in ink on the back of its mount with the following particulars:—

- (a) The name and address of competitor.
- (b) The class in which it is entered.
- (c) The exposure given, and full particulars of the circumstances under which the picture was taken.
- (d) The pattern of camera and shutter used.

The negatives must accompany the prints.

The pictures will be judged by the Directors and officers of the Thornton-Pickard Manufacturing Co., Ltd., whose decision shall be final. No Director, officer, or employee of the Thornton-Pickard Manufacturing Co., Ltd., will be allowed to compete.

The pictures in Classes I. and III. will be judged mainly from the standpoint of technical excellence, general interest, form and arrangement of subject.

Those in Class II. will be judged mainly from the standpoint of technical excellence, movement, form, and uniqueness of subject.

Entry forms will be supplied on application to the Company.

#### Our Editorial Table.

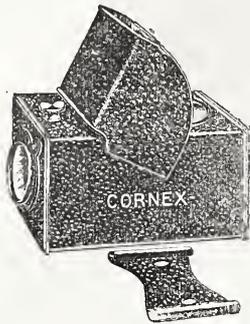

THE CORNEX FINDER.

R. & J. Beck, Limited, 68, Cornhill, E.C.

THE construction of the Cornex finder is such that the amount of view included in it is stationary, and remains so from whatever position it is observed.

The shade which is provided to prevent the reflection from the top lens folds down when not in use and protects the lens from injury.

At the back of the front lens an oblong mask has been placed, which can be revolved by turning the small knob on the top of the finder, and by this means a vertical or horizontal view is seen.

For attaching the finder to the camera two separate metal carriers are provided. It is recommended that one of these be screwed on to the top and the other on to the side of the camera, in the required position. It is then only necessary to press the finder down on to whichever carrier is to be used, and it will be held firm and in position by the springs at the sides of the carrier.

An examination of the Cornex finder shows it to possess the properties claimed for it, the image given, besides being stationary, being also extremely brilliant. It is strongly and neatly made, the outer case being of metal, retails at five shillings, and should be found of great service by hand-camera workers.

#### CATHEDRAL PICTURES BY PHOTOGRAPHY.

By Frederick H. Evans, 27, Fairford-road, Bedford Park, W.

In the sympathetic photography of cathedral architecture Mr. Evans is probably unexcelled. He has the faculty of extracting all that is pictorial and, we might add, poetical, out of his subjects, and he does it by means of pure photography. His work is always well defined; it is characterised by natural effects of light and shade, and bears throughout the impress of having been produced as a result of a thorough mastery of the tools at hand, yet, withal it satisfies the most artistic tastes. In fine, while Mr. Evans is doing perfect justice to his subjects, he is also, consciously or not, illustrating the capacity of photography for rendering pictorial architectural effects without the assistance of photo-faking or photo-patchwork.

In deciding to publish some of his well-known architectural photographs Mr. Evans is making an experiment to which we cordially wish every success. Four specimen prints are before us. They are signed proof impressions in photogravure by the Swantype Company and it is in this form that it is intended the prints shall be issued for sale. The prints are, of course, on plate-marked paper, but they are enclosed in brown cut-out mounts,  $15\frac{1}{2} \times 12\frac{1}{2}$ , being thus adapted either for the portfolio or for framing.

The following four subjects comprise the first issue:—Lincoln Cathedral: The Towers, from the castle; A Stairway, in the south-west turret; The Angel Choir, from the south choir aisle. Ely Cathedral: The Octagon, from the north choir aisle (free from the usual benches and chairs).

Mr. Evans states that, if this first issue should be taken up freely enough, he proposes following it at intervals with others from his cathedral sets, his intention being to issue nothing but what is exceptionally artistic, both in choice of subject, treatment, mode of reproduction, and issue.

We trust that the result of his experiment will justify Mr. Evans in continuing the issue of his series of cathedral photographs. Of the four examples before us we can say nothing in higher praise than that they are beautiful photogravures of beautiful photographs, well worth the half-guinea each it is proposed to charge for them. They would constitute an excellent adornment for the walls of a gentleman's house. Their delicacy, their charm, their refinement are so distinct and convincing that in years to come we shall be disappointed if we do not find that they have outlived in popular esteem most of the puffed-up and belauded "pictorial" rubbish of the day which is the outcome of photo-faking.

#### PHOTOGRAPHIC MOSAICS FOR 1900.

Edited by Edward L. Wilson. New York: E. L. Wilson. London: Dawbarn & Ward. *Mosaics* is the last of the American annuals to reach us; but, though late, it is welcome. In its 300 pages there are some sixty excellent half-tone reproductions of portraits and studies, about the same number of articles, and a lengthy summary of the experiences of 1899. It is a chatty and instructive volume, and many of the portraits are delightful representations of the fair sex. A practised hand has been at work in the compilation of *Mosaics*, which we can recommend to our professional readers as likely to supply them with many a useful wrinkle in practical work, many a pose for adoption in the studio.

#### THE "AXE" BRAND CARTRIDGES.

Fuerst Brothers, 17 Philpot-lane, E.C.

THE latest introductions of the Axe-brand preparations for photography comprises a flashlight powder which, it is stated, contains no explosive material such as chlorate or permanganate of potash or picric acid. There is no report on combustion. Each package contains a fuse paper, by means of which and a lighted match ignition is secured. The powder has been tried in our presence, and we can state that it is a safe and pleasant mixture to employ. With the Axe flashlight cartridges a small piece of fuse paper is also supplied; each cartridge contains sufficient powder to photograph a group or interior. The intensifying cartridges give a deposit of a reddish colour, which can be reduced by water, if necessary, or removed altogether by solution of ammonia. The reducing cartridges contain material for mixing a reducing solution, which may be used indefinitely.

#### CATALOGUE RECEIVED.

The Thornton-Pickard Manufacturing Company, Altrincham.

IN sending us a copy of their New Illustrated Catalogue for 1900, the Thornton-Pickard Company state, in regard to the sale of their well-known shutters, that after making them for the last twelve years, during which time the sales have gradually increased year by year, the year 1899 eclipses all previous records. The experience the Company have gained during these years enables them now to produce what is really a faultless article. Every single part of every shutter is most carefully made, and all evenly balanced, which accounts for the fact, as the Company point out, that it is so seldom one hears of a Thornton-Pickard shutter going wrong. Although of late the raw material employed in the making of every part of the shutter has gone up in value, yet the prices of all the Company's shutters remain the same as last year.

Besides shutters, the Company's other productions, as cameras—the well-known "Ruby" and "Amber" patterns—plate-holders, automatic stands, lenses, film-carriers, &c., are fully described.

There are also particulars of a new prize competition, in which cash prizes to the sum of 100 guineas are to be given for the best sets of instantaneous photographs sent in.

The Company send out these catalogues to all applicants for them who are interested in photography, gratis and post free.

The Company have just enlarged their premises, this being the second time they have done so since their factory was built a few years ago.

MESSRS. ROSS, LTD., of 111, New Bond-street, W., and 31, Cockspur-street, S.W., are issuing a series of neatly produced supplementary catalogues of their optical and photographic instruments. Prominent notice is given to their prismatic binocular glasses, which it is stated are supplied to Sir Redvers Buller and many other officers in the South African Field Force.

\* \* Owing to exceptional pressure on our space this week, we are compelled to hold over several notices of apparatus and other items for Editorial Table.

## News and Notes.

WITH a neat Calendar for 1900, Mr. R. W. Howes, of East Dereham, also sends us his latest price-list of enlargements, &c.

WE are pleased to learn that Mr. A. L. Henderson is now fully restored to health. He is shortly proceeding to Bordighera for the spring.

*Photographic Light* is the name of a new monthly magazine devoted to photography. It is issued by Messrs. J. H. Smith & Co., Chicago.

OFF TO THE WAR.—A son of Mr. E. H. Holder, of the Studio, Redhill, Surrey, is proceeding to the front with the Imperial Yeomanry. Mr. Holder, who has had considerable experience in South Africa, will carry with him the good wishes of all.

MR. ALFRED UNDERHILL, of 32, Clarendon-road, Croydon, writes: "Having seen the paragraph re name of maker of stereoscopic slides in THE BRITISH JOURNAL OF PHOTOGRAPHY of January 12, I beg to inform you that I can make and supply stereoscopic slides either on glass or as paper prints."

THE Röntgen Society's next Ordinary General Meeting will be held on Thursday, February 1, at 20, Hanover-square. A paper will be read by Dr. Hugh Walsham, "Röntgen Rays in Diseases of the Chest." Mr. A. Hastings Stewart, M.R.C.S.E., will show a small Egyptian mummy and skiagrams of the same.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the meeting on February 1 there will be a demonstration of the new Sandell film. Visitors are welcome at the White Swan, Tudor-street, E.C. It is announced that Mr. H. Vivian Hyde will see to the musical arrangements at the Annual Supper in February.

At the Ordinary Meeting of the Manchester Literary and Philosophical Society on January 9, 1900, Mr. Thomas Thorp exhibited two film gratings of a ruling designed to weaken the direct image, and to condense the illumination of the spectra of the first and second order, and thus to compete with the prism spectrum in brilliancy.

**CRIPPLEGATE INSTITUTE.**—A course of eleven practical lessons in photography, specially arranged for amateurs, will be given at the above Institute on Fridays, at seven p.m., commencing Friday, February 2, 1900. Instructor, R. C. W. Coe. Further particulars can be obtained on application to the manager, Cripplegate Institute, Golden-lane, E.C.

**LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY'S EXHIBITION,** February 27 to March 1, 1900.—Mr. W. E. Dunmore, of the Tella Camera Company, Limited, 110, Shaftesbury-avenue, London, W., has kindly consented to receive and forward London exhibits for the Loan Collection. Names may be sent to Mr. Dunmore, addressed as above until Thursday, February 22.

A DAILY contemporary says that Mr. W. L. Wyllie, A.R.A., is about to sume the position of a pavement artist, though he will, doubtless, earn more as a pavement artist's emoluments. His appearance in this capacity is due, not to necessity, but to charity, in order to help the Mayor of Rochester's and for the sufferers by the war, and will take place at a promenade concert at the Corn Exchange of the City on the Medway, which has inspired his most successful pictures.

**HOW KIPLING WAS PHOTOGRAPHED.**—Mr. Kipling left for the Cape on Saturday. On boarding the liner his chief desire was to escape the interviewers and the camera. There were two or three animated picture operators aboard, anxious to snap-shot the great man. They waited for him at casual corners. He was hopeless to think he would pose, and one of them, it is understood, succeeded in his fell purpose. Mr. Kipling was certainly photographed. He had gone upstairs to his cabin. As he came on deck he found a camera directed towards him. He turned hastily to retreat, but Sir Donald Currie, entering to the spirit of the thing, seized him by the arm and compelled him to stand on the ground. So the two were photographed side by side—the man who makes tips run and the man who makes them talk.

**"ACUTENESS OF Vision Among Savages,"** the first of three lectures on "The Uses of Primitive Man," was recently delivered at the Royal Institution by Mr. W. H. R. Rivers, F.R.C.P. According to the rough observations of travellers, he said, savage races have far more developed senses than races that are civilised. Careful and scientific investigation, however, shows that what Europeans lack is not so much acute senses, but the highly specialised knowledge which would enable them to take note of small indications. Short sight is almost unknown among primitive peoples, and there is no doubt that savages possessed the power of adjusting their eyes to darkness and distinguishing objects in a far greater degree than civilised men. Little doubt now exists that this power is due to the accumulation in the retina of "visual purple," which is found in nocturnal animals. Therefore it would be interesting to learn if some primitive peoples can see better in the dark than ourselves.

**SQUEL TO BETTING.**—At the Clerkenwell Police Court, on January 16, James Dalgety, twenty-seven, of 9, Leighton-road, Kentish Town, was charged with a remand with stealing from 43, Clerkenwell-road, photographic appliances, value 32s., the property of Kodak, Limited. Prisoner was formerly in the employment of Kodak, Limited, and subsequently entered the service of a pen-fink, Cheapside. At the latter firm he was found in the possession of a Kodak, the possession of which he could not satisfactorily account for. The property turned out to be the property of Kodak, Limited, and Dalgety was arrested. Dalgety had in his possession pawn tickets relating to a quantity of property belonging to his former employers, which he had pledged. The prisoner pleaded guilty, and exclaimed, "I must have been a fool. I started to bet, and could not get out of it." Mr. Bros said he thought the spirit of gambling was at the bottom of the prisoner's behaviour. Betting was generally associated with charges of this sort. The lightest sentence, however, he could pass on the prisoner was three months' imprisonment.

## Commercial Intelligence.

**MESSRS. A. E. STALEY & Co.,** 35, Aldermanbury, have been appointed London agents for Messrs. Krauss & Co., Paris.

**Re W. J. LE COUTEUR,** Managing Director of the Photographic Association, Limited, Brook-street, Hanover-square. The public examination of this debtor was held at the London Bankruptcy Court, on January 19, before Mr. Registrar Brougham. It appeared that the Photographic Association was formed on March 31, 1899, for the purpose of acquiring his business. The statement of affairs showed unsecured liabilities, amounting to 3,916s., and assets estimated to produce 10s. The examination was concluded.

On the 16th inst. a company was registered by Jordan & Sons, Limited, of 20, Chancery-lane, London, under the title of The Brighouse Photographic Company, Limited, to carry on the business of photographers, photographic chemists, and dealers in photographic and optical goods and apparatus. The nominal capital of the Company is 1000s., divided into 1000 shares of 1s. each. The registered office is situate at 2, Victoria-street, Brighouse, Yorks. The Memorandum of Association was subscribed by Mr. Arthur Hoyle Ormerod, Greenroyd, Brighouse (silk spinner); Mr. George Albert Farrar, Spring Villa, Brighouse (surgeon); Mr. John Wood, Ravenspring, Brighouse (silk spinner); Mr. Spence Ormerod, Boothroyde Park, Brighouse (silk spinner); Mr. John Edward Longbottom, Castle Fields, Rastrick, Brighouse (bank manager); Mr. Boglare Edward Edwards, Claremont-villas, Brighouse (surgeon); Mr. Martin Hanley, The Terrace, Brighouse (optician). The first Directors are to be appointed by the subscribers to the Memorandum and Articles of Association.

The case of Kodak, Limited, *versus* Elliott came before Mr. Justice Mathew in the Queen's Bench Division on January 16, and is of importance to dealers in photographic materials. Mr. D. M. Kerly appeared as counsel for the plaintiffs, and Mr. Spokes for the defendant. The plaintiffs are the well-known firm of photographic materials manufacturers, and owners of the Kodak

patents. The defendant is a dealer in photographic materials and a customer of the plaintiffs. It was stated by counsel that the plaintiff Company, in the interests of its dealer customers, imposed upon them individually the condition of selling its manufactures retail not below list prices. Finding that a particular firm of dealers were underselling Kodak goods, they took steps to prevent them obtaining supplies, and to this end they imposed the further condition upon all dealers not to resell wholesale to any other dealer without having previously obtained a written undertaking that the conditions of sale of Kodak, Limited, would be observed. The defendant agreed to these conditions on July 6 last, and goods supplied to him were subsequently traced to a cutting firm, by whom they were sold retail below list price. The plaintiff Company (Kodak, Limited) sought to recover damages for breach of the conditions of sale. Judgment was entered for them, with damages 50s., and costs.

## Patent News.

THE following applications for Patents were made between January 8 and January 13, 1900:—

**CAMERAS**—No. 406. "Improvements in and relating to Photographic Cameras." S. D. MCKELLEN.

**ANIMATED PHOTOGRAPHY**—No. 432. "Improved Means of Exhibiting Photographs in Rapid Succession." J. A. PRESTWICH.

**REDUCING AGENTS**—No. 476. "Reducing Agents for Photographic Negatives." Communicated by La Société Anonyme des Plaques et Papiers Photographiques A. Lumière et ses Fils, France. B. J. B. MILLS.

**CURVED PRINTING SURFACES**—No. 557. "Improvements in the Production of Curved Printing Surfaces." E. S. SHEPHERD.

**ARTIFICIAL LIGHT**—No. 611. "Intense Lighting Apparatus for Instantaneous Photography." J. F. GUIMARAES.

### ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 23,—Technical Meeting,—Mr. Chapman Jones, F.I.C., F.C.S. (Vice-President), in the chair.

#### THE HONORARY SECRETARY.

The CHAIRMAN, on behalf of the Society, expressed much pleasure at the presence of General Waterhouse, the Hon. Secretary, and congratulated him upon his recovery from his recent illness.

#### AN ENLARGING APPARATUS.

Mr. HUDSON, exhibited an electric enlarging apparatus, with which no condenser or diffusing medium was required. It consisted of a chamber for attachment to the back of an ordinary camera, carrying the reversing back, and having at each of its sides three six-volt electric glow lamps of three-candle power. The light did not reach the negative direct, but was thrown upon it by means of a pot-opal reflector. Some bromide enlargements made with the apparatus were shown, and the exposure for enlarging from half-plate to 12 x 10 was said to be from two to three and a half minutes, according to the density of the original negative.

#### PREPARATION OF SILVER SUB-HALOIDS.

Major-General J. WATERHOUSE, I.S.C., read "A Note on Dr. Otto Vogel's Method of Preparing Sub-haloid Salts of Silver." He said that, in a

paper published in the *Photographische Mittheilungen* for September 1899, of which he gave a translation in the last number of the Society's *Journal*, Dr. Vogel described what appeared to be a very simple and effective method of preparing the sub-chloride, sub-iodide, and sub-bromide of silver, substances which, he believed, had never been satisfactorily isolated, except, perhaps, by Guntz. Dr. Vogel's method was to treat the sub-haloid salts of copper with a ten per cent. solution of silver nitrate in excess, access of air being, as far as possible, avoided, and it was founded upon the copper bromide intensifier, but using cuprous bromide instead of cupric bromide. On trying this method Major-General Waterhouse found that the reaction was not so simple as he expected, the products all showing the presence of copper; but, acting on the supposition that the cuprous salts were incompletely reduced by a single treatment with the silver nitrate solution, he repeated the treatment, at the same time heating the solution to boiling point, when he found that copper came into solution. Three repetitions of this treatment with the bromide were sufficient to extract very nearly all the copper; the chloride required more boiling, but the iodide gave up its copper more readily than the bromide. After showing and describing the substances which he had obtained, the author of the paper said Dr. Vogel did not appear to be certain that these products were true sub-haloid compounds or only mixtures; but he was himself inclined to think, from their composition and behaviour, that they were true sub-haloids.

A very brief conversation, in which Professor MELDOLA, Mr. T. BOLAS, General WATERHOUSE, and the CHAIRMAN took part, followed the reading of the paper.

#### COMING EVENTS.—A "ONE-MAN" EXHIBITION.

On Wednesday, January 31, Mr. J. Craig Annau will formally open an exhibition of examples of his work. The opening will take place at the Society's house, 66, Russell-square, at eight p.m., when a few introductory remarks will be made, and the Exhibition will continue during the month of February, from ten to four o'clock daily. February 6, Lantern Meeting, "Shakespeare at Home," by Mrs. Catherine Weed Ward. February 13, Annual General Meeting.

**Croydon Camera Club.**—In spite of all temptations to go elsewhere or to stay at home, there was a goodly company in the Small Public Hall, Croydon, on Wednesday, January 17, standing room only being the order in the unreserved area, and a capital evening's display ensued. To begin with, there were many of our warrior sons to cheer, one picture by the President, of the Colonials passing along by Hounsditch, proving especially acceptable. Mr. JEFFERY also received much approval for his interesting gossip about camp life at Richmond and Aldershot, illustrated by slides made by himself. Of these particularly popular was a portrait, taken in camp, of the Commander of the City of London Yeomanry, viz., the Earl of Albemarle. Before passing on to the mixed slides, the PRESIDENT took occasion to emphasise the great value of photography and the lantern might have proved in familiarising our officers in South Africa with the physical geography of the neighbourhood, and in making clear to them the natural features of the positions held by the enemy. If at Frere, Stormberg, and the Modder, and elsewhere, such lantern lectures had been given, and full use made of the remarkable powers of the tele-photo lens, he considered many valuable lives would have been saved, a remark which the audience emphatically endorsed.

**Richmond Camera Club.**—January 8.—Ladies were invited. Slides were shown by the following members of the Club: Messrs. Davis, Etherington, Gibson, Kilbey, Richards, Richardson, and Wilson.

At the meeting on January 15, Mr. Cembrano in the chair, a paper on

#### NEGATIVE-MAKING,

by the Rev. F. C. LAMBERT, was read. Mr. Lambert dealt with the variations in the character of the negative to be obtained by modifications of the time of exposure and of the composition of the developer, and his paper was illustrated with an interesting series of negatives shown as lantern slides. It will, perhaps, not be thought hypercritical to mention that Mr. Lambert's formulae of the different developers recommended by him would have been much more easily followed if they had been given as so many grains of pyro, bromide, soda, &c., to the ounce of developer, instead of as so many drachms (or "drops" in some cases) of a solution—and that not always a ten per cent. solution—of pyro, bromide, soda, &c., to be made up with water to a certain number of ounces of developer. It was really impossible in some cases to ascertain the actual composition of a particular developer without working out an elaborate arithmetical calculation.

**West Surrey Photographic Society.**—January 17.—Mr. JOHN H. GEAR gave a lecture on

#### THE ARTISTIC SIDE OF PHOTOGRAPHY AND THE MECHANICAL SIDE ALSO

showing by lantern slides how some of his well-known and popular pictures had been absolutely made: his *Silvery Moon* and *The Receding Tide*, by cutting down, suppression, and the addition of suitable skies; his *Autumn* (shown at the Royal last year), by the combination of three negatives, which were shown separately and then as the finished picture. The lecturer gave most interesting details of his various modes of working, notably of his use of ammonium persulphate for reduction, which he presented in actual progress on the screen till the film dissolved by the heat of the lantern. Incidentally he dwelt on the use of tabloids, which enabled him to bring down to this demonstration, in a case but little larger than a cheap novel, a complete chemical outfit. There was also much advice as to the treatment of the negative, and to its possible modification and correction where necessary.

**Liverpool Amateur Photographic Association.**—January 18, Annual Meeting.—The PRESIDENT, in moving the adoption of the reports, said the Society was one of the very few able to keep out of debt without extra subscription. Mr. J. H. Welch was chosen President for the ensuing year; Dr. Morgan and Mr. E. R. Dibdin, Vice-Presidents; Mr. R. H. Phillips, Hon. Treasurer; and Mr. F. A. Schierwater, Hon. Secretary; while, to fill the vacancies in the Council, the following were elected: Messrs. Lange, Lloyd, Leby, Depree, Taylor, and T. E. C. Wilson. Mr. LANGE read the report of

the Judges at the Annual Competition, which drew attention to the decreased number of the exhibits, but gave high praise to the excellent quality of those sent in. The following were the results: Challenge Trophy, gold medal, Mr. T. E. C. Wilson. Class A (for set of three prints, any size or subject, open to any member of the Society), Dr. J. C. Saunders, Mr. J. Appleby, and Dr. Morgan. Class B (for set of three prints, open to any member who has not previously taken an award for prints in any photographic competition), Mr. F. C. Timpanv. Class C (for set of six lantern slides, open to any member of the Society), Messrs. H. J. Houghton and J. Parkinson. Class D (for sets of six lantern slides, open to members who have not previously taken an award for lantern slides at any photographic exhibition), Messrs. C. Gostenhofer and S. Cann.

**Rotherham Photographic Society.**—January 16.—Mr. GRANT, of the Sandell Films and Plate Company, Limited, gave a practical demonstration of the uses of the

#### PERFECT PLATE AND CRISTOID FILMS.

The audience included a contingent of members of the Attercliffe Photographic Society. Mr. Grant developed four of the films, which had respectively received one second, five seconds, fifty seconds, and five minutes' exposure. The one second appeared to have been rightly timed; but, of course, the others—they were all developed in one dish—showed unmistakable signs of over-exposure. By means of a ferridcyanide reducing bath the densest of the four was made into a good negative. It was claimed that the films had advantages additional to those of the multiple film plates, and that their manipulation did not present any special difficulties.

#### FORTHCOMING EXHIBITIONS.

1900.	
January .....	Huddersfield (Invitation). W. A. Beevers. Cloth Hall-street, Huddersfield.
" 29-31.....	Southsea Amateur Photographic Society. F. J. Mortimer. 10, Ordnance-row, Portsea.
February 10-24 .....	Edinburgh Photographic Society. J. S. McCulloch, 10A, George-street, Edinburgh.
" 24-March 3 .....	Birmingham Photographic Society. Lewis Lloyd, The Hollies, Church-road, Moseley.
March .....	South London Photographic Society.
" 26 .....	Twentieth Century International, Birmingham. Walter D. Welford, 19, Southampton-buildings, Chancery-lane, London, W.C.
" 26-31 .....	Photographic Society of Ireland. W. F. Cooper, 35, Dawson-street, Dublin.
April 3-7 .....	Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### LANTERN SLIDES OF THE PARIS EXPOSITION.

To the EDITORS.

GENTLEMEN,—Will you please inform me where I can obtain the best set of lantern slides of the Paris Fair of 1900? I should desire about 150 to 200 of the very choicest subjects, and slides only of the highest quality.

Is it possible to get a good set about next May? Have been looking over your BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for advertisements of slide-makers, but am unable to determine who is the very best one to order from.—I am, yours, &c.,

WALTER BARRIE.

Strathelair, Manitoba, Canada.

[Perhaps some of those firms who contemplate producing lantern slides of the Paris Exposition will communicate direct with our correspondent. It is an obvious impossibility for us to give him the information he desires so far in advance of the opening of the Exposition.—EDS.]

#### THE METRIC SYSTEM.

To the EDITORS.

GENTLEMEN,—Your correspondent, "Free Lance," is, no doubt, quite right in saying that grammes and metres will not be used with facility unless we think in them, but what can be done is to make people think in them by using them, and showing how much more convenient they are for accurate expression than the usual measures. Of course, no one expects to convince the true conservative John Bull, who considers that his education was completed in his school days, and that it is a sort of crime to

acquire knowledge afterwards. Photographers, however, are not in this position; they have all learnt their business later in life, and are well aware, most of them, that knowledge has not yet reached its limits. Some of them may be induced to try what is recommended in your JOURNAL, and even to persevere through the first difficulties till they arrive at the full advantage of thinking, as well as writing, in the metric measures.

I am glad, therefore, that you have urged on the teachers of the art of photography that they should use metric units in their schools. Depend on it that pupils who have been accustomed to use the convenient and certain formulæ of such schools would never willingly change them for others. Of course, those who work for old-fashioned employers might be obliged to comply with the customs of their masters, but it is to be hoped that the mass of the pupils of the schools do not remain all their lives in subordinate positions, and, when free, they will probably supply themselves with metric weights and measures, unless dealers put difficulties in their way and become centres of reform in practice.

Never mind the grocers; let them sell their tea by the pound while the law allows them to do so and the public want it. If the more intellectual portion of the British public habitually use metric weights and measures, the practice will increase, and there may be some hope of compulsion, instead of permissive, use of them.—I am, yours, &c.,

J. F. T.

### SIR HOWARD GRUBB'S STEREOSCOPE.

To the Editors.

GENTLEMEN,—I observe an article in the last number of your JOURNAL giving a diagram of a stereoscope which is precisely the same as that described in my paper which I sent you a short time since, and several of which were made. Not only the principle but the details are so absolutely similar to mine, that it is quite evident that whoever wrote it did so from a description of one of the instruments, or had seen one of the instruments themselves. I do not know who the Dr. T. R. Robinson can be except that it means Dr. Thomas Romney Robinson, of Armagh, the late astronomer there, and a connexion of my own, who left work behind him of extraordinary value, but who certainly had nothing to do with the stereoscope. From the way the article is worded, one would rather imagine that it was claimed by the Americans as an invention, but in any case you will see that it is in every respect exactly the same as that which I described in the paper sent to you. If I am wrong in thinking that I sent you one of these papers, I could send you one to look at, but only to look at, as I am quite out of my private copies.—I am, yours, &c.,

H. GRUBB.

*Optical and Mechanical Works, January 18, 1900.*

[We are very much obliged to Sir Howard Grubb for his letter. It was our intention this week to point out the similarity between the stereoscope attributed by the contributor to the *American Annual* to Dr. T. R. Robinson, and the instrument devised by Sir Howard himself more than twenty years ago, and described in his paper read before the Royal Dublin Society in 1878. We reprinted that paper, a copy of which was kindly sent us by Sir Howard, in the JOURNAL for June 3, 1898, and in our ALMANAC for 1900 we gave lengthy extracts from it, amongst them one descriptive of the stereoscope now attributed to Dr. T. R. Robinson.—EDS.]

### FOG ON PLATES.

To the Editors.

GENTLEMEN,—In your last issue you published remarks of a correspondent *re* fog on plates, and blame the manufacturer wholly for this. I venture to differ from your conclusion, and to blame the dealers for the mischief. Last month, on commencing to use a new gross batch of plates, I was surprised to see, on development, that they were badly under-exposed, and had a black margin round, as described by your correspondent. I at first attributed the former effect to my mistaking the quality of the light, and the latter to some defect in the slide. The same thing occurring in a different slide and an excellent light, I developed a plate straight from the box, and the margin was still there. I wrote to the makers, enclosing an under-exposed plate and the batch number.

I soon received a reply, stating that the plates were made in 1896, and saying that it was only likely they would be useless by now. They also inquired the dealer's name, who they afterwards persuaded to forward me a fresh batch. They also stated that the reason the date of manufacture was not marked on each box was because the dealers are opposed to such a course.

Now, I think that the gentleman complaining must in the same way have got hold of a stale batch. Surely the members of the Royal Photographic Society and other societies could put pressure on the manufacturers to date their products. It could not do any real damage to the dealers; as no one would refuse a plate six months old, and no dealer need stock longer than that. The present system only induces carelessness on their part. I know that using old plates this Christmas was at least 5l. out of my pocket, as several of my customers were only here on a holiday, and their negatives were useless. If your correspondent would

use the slow brands of plates, I think he would get negatives similar to those produced years ago; only, would they suit the present paper generally used?—I am, yours, &c.,

H. C.

To the Editors.

GENTLEMEN,—I WAS much interested in the article in last week's JOURNAL, entitled "Fog on Plates," having had a similar experience myself.

Like your correspondent, I am an old and careful worker, and, like him, I have used the same make of plates for many years, getting a sufficient number in the spring, direct from the makers, to last me through the year, and up to last season have always found them of excellent quality. Last April I ordered my stock as usual, and, on receipt, tested a plate of each size with perfectly satisfactory results. Having some plates left from the previous year, I had no occasion to expose more of the new batch till I started for a tour in June. When I developed the negatives on my return, I found every plate of the  $7\frac{1}{2} \times 5$  size more or less fogged round the edges, while the  $\frac{1}{4}$ -plates, used in hand camera, were all I could desire. I took a plate from an unopened box that had been left at home, exposed and developed at once, and the result was the same.

I feel sure that the boxes were responsible for the defect. Where the edges were protected by the dividing cards the fog was not so bad, the marks made by the cards plainly showing in many instances. I think it probable that the boxes were by a new maker, as they were somewhat longer than I had ever had them before, necessitating a piece of crumpled paper being placed at one end to keep the plates from moving.

As I had exposed most of the plates, and could use the negatives by trimming the prints a trifle smaller, I made no complaint to the makers, intending to mention the matter when I send my order this year.—I am, yours, &c.,

J. TILFORD.

231, Elgin-avenue, Maida Vale, W., January 22, 1900.

### PHOTOGRAPHERS IN SOUTH AFRICA—A WARNING.

To the Editors.

GENTLEMEN,—It has come to my knowledge that some photographers are contemplating leaving this country for South Africa with a view to engaging in business there.

As one who has had considerable experience of that country, I must say that no more inopportune time could be chosen than the present.

In times of peace there are very few openings for photographers, whilst at present, when most of those employed formerly in the Transvaal and Orange Free State are perforce compelled to stay in Natal or Cape Colony, there is an absolute surfeit of photographic talent there.

At the conclusion of the war there is little likelihood that any one, not previously settled in the two States (now at war with us), will be allowed to enter them for some considerable time, until law and order are restored on a substantial basis, which may be a matter of years.

Under these circumstances, I think it will be allowed that it would be most unwise to embark on such a risky venture unless supplied with unlimited resources.—I am, yours, &c.,

PHOTOGRAPHERIST.

### ADVERTISEMENTS—A SUGGESTION.

To the Editors.

GENTLEMEN,—I have a suggestion to make *re* your advertisements. When using a number, such as H 24, for instance, any one replying has not the faintest idea of where it is. Would it not be advisable to put the name of the town or county from which the advertisement emanates in brackets at the end of advertisement, in the same way as the *Bazaar* does? Personally, I have answered advertisements for operators in both Ireland and Scotland at different periods when I have no desire to go there. If this suggestion was adopted, it would avoid much trouble and expense to numerous subscribers who use your valuable paper. I should like to hear what your correspondents have to say if you will kindly insert this. Thanking you in anticipation,—I am, yours, &c.,

55, Market-street, Manchester, January 20, 1900. J. A. HOWARTH.

[There are practical difficulties in the way of a general adoption of our correspondent's suggestion, but we give it publicity in case individuals may find themselves in a position to utilise it.—EDS.]

### STEREOSCOPIC PHOTOGRAPHY WITH ONE LENS.

To the Editors.

GENTLEMEN,—In your issue of January 19, in answer to one of your correspondents, you say that, when using the apparatus (The Stereophoto-duplicon) described in your Almanac two years ago, the views are reversed. Such a statement is not correct, and, lest any of your readers may have a wrong impression as to the action of this instrument, it should be said that the Stereophoto-duplicon, now being supplied by Mr. J. Fallowfield of Charing Cross-road, transposes the two views in the camera, but does not reverse them, the result being that both views are taken in their correct position, and the negative obtained may be printed from direct. This is a very great advantage, as no mistake can possibly be made by the inexperienced stereoscopist when printing from his negatives or mounting them.—I am, yours, &c.,

THEODORE BROWN.

## DIRECT POSITIVES IN THE CAMERA.

To the EDITORS.

GENTLEMEN,—The process patented by Messrs. Thornton and Rothwell, published in your issue of January 12, for producing positives direct in the camera, appears to me to be nothing more nor less than the old and original method of taking positives direct on glass, which was the only method in use when collodion was first introduced, back in the fifties, for photographic purposes. At this time the process was entirely confined to taking positives on glass, and it was some few years later before it was discovered that, by prolonging the development with the iron developer, and afterwards intensifying with pyro and silver, the positive was converted into a negative from which positive prints could be obtained *ad libitum* by placing sensitised paper, plain or albumenised, in contact with the negative, and exposing it to sunlight. This same method of printing is continued to the present day with hardly any alteration or improvement beyond the substitution, to a large extent, of P.O.P. for albumenised paper, and, in the manufacture of plates, gelatine for collodion.

In producing positives on glass, the development was carried no further than was necessary to render visible the high lights of the picture, the half-tones and shadows were quite invisible, and no detail was apparent until after the fixing solution (cyanide of potassium) was applied, and even then the deposit was so thin that very little detail could be seen by transmitted light. But, when the plate was backed up by some dark opaque substance such as black velvet, black paper, or black opaque varnish, either of which was then used for the purpose, a brilliant positive picture with beautiful gradation of tone and all necessary detail was the result. A bleaching effect was also produced by the addition of hydrochloric or sulphuric acid to the developer, the exact formula for which I cannot at present remember. The picture was backed up sometimes on the collodion side, and sometimes on the plain glass side of the plate. If on the collodion side, the image was seen through the glass in its correct position as a positive picture, but, if on the plain glass side, it was seen as a positive picture reversed, or as a person would see himself in a mirror. The latter method was generally resorted to when the picture had to be coloured either in oil or water colour. I have seen some very pleasing effects produced by tinting on the collodion side of the picture with dry powdered colours, and in other cases by a more pronounced colouring which, seen through the picture, has an effect somewhat resembling crystoleum.

The only difference I am able to discern between the method above described and that patented by Messrs. Thornton and Rothwell is that the latter have substituted a flexible film for that of glass for taking the impressions.—I am, yours, &c.,  
THOS. MITCHELL.  
Newport, January 22, 1900.

## Answers to Correspondents.

\* \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

## PHOTOGRAPHS REGISTERED:—

Edith Weston, 23, Sandgate-road, Folkestone.—Two photographs of Colonel John Denton Pinkstone French.

RECEIVED.—W. WILKINSON; G.; BURETTE; R. T. WALL; EXCELSIOR; CINEMATOGRAPH; and others. These will be answered in our next.

H. A. WASSELL (Stourbridge).—We are sorry that we have no information to add to that already given.

FOREIGN VIEWS.—E. SEAMAN asks for a likely firm where he can obtain the following foreign views: Königswinter, Andernach, Marksberg Castle, near Braubach?—In reply: Possibly of Spooner's, Strand, London.

M. PELLECHET.—The original film is, we believe, hardened in the method of preparation, the precise details of which are not published. But, according to that method, we do not think the expansion can be obviated.

H. F.—We can only reply to you in general terms, as it is strictly against our rules to make particular recommendations of the nature suggested. All the instruments named are of high class. We suggest that you make your choice by practical trial.

Z. Y. Z.—Of our own experience we cannot give such a formula. What we suggest is that you should try one of the "gaslight" development papers that produce the colour as directed in the instructions, viz., by modification of exposure and development.

GOLD SOLUTION.—R. BAINES says: "What is the reason that, when I recently dissolved a fifteen-grain tube of chloride of gold (Johnson's) in two ounces of water, it at once changed colour, and now there is a dark sediment at the bottom of the bottle? The sulphocyanide bath made with it will not tone at all."—The reason is that either the water was impure or the solution was made in a dirty bottle, and all the gold has been precipitated.

BENZO (Cardiff).—1. The print is apparently on Nikko paper. 2. We do not now know of such a machine which is obtainable commercially. The one you indicate is obviously for a larger size than quarter-plate. Try small advertisement in our outer pages. It would probably bring you the information you desire.

ILLUMINATED ADDRESSES.—R. MEREDITH wishes to know "if there is a firm anywhere producing illuminated addresses by machinery, where sample and designs can be obtained, as he wants to lay them before a committee to choose their design and prices from."—In reply: Probably some such firm as Waterlow's, Finsbury, or Bemrose, Derby, would supply you correspondent with what he requires.

REPRODUCTION FEES.—MAGAZINE says: "I supplied two 10x8 views to a firm to put into a magazine before Christmas. Should be glad if you would give me an idea of what is the usual reproduction fee, as they say they are prepared to pay this."—In reply: The minimum fee recommended by the Photographic Copyright Union is 10s. 6d. In the case cited by our correspondent a guinea each picture might be charged.

OFF TO THE WAR.—WAR writes: "I saw in your JOURNAL of the 5th a letter on 'The Possibility of the Camera in regard to the War.' I should like to go. Do you think it would be worth while, and, if so, what would be the best means of doing so?"—In reply: The only suggestion we can make is that our correspondent should endeavour to obtain an engagement as photographer-correspondent of a newspaper—that is, if he should think it worth his while to go. We do not.

AGREEMENT.—OPERATOR writes: "I am offered an engagement for a year certain from March 1; should the agreement for the year be in writing to be binding on the employer, because I have heard of cases where an engagement for a year has been made and the operator discharged when the season is through? Your advice will be gratefully received."—To make the agreement binding it must be in writing, and see that you have it before you enter the service. The agreement must also be stamped—a sixpenny stamp.

DRY-PLATE MAKING.—W. BEAL says: "I have made some dry plates according to a formula given in one of the old ALMANACS, and they are fairly good, though slow; but the film is covered with depressions from the size of a small pin's head to a small bead. Can you suggest the cause?"—Doubtless the depressions are what are known as "pits." If so, they are due to the employment of an unsuitable kind of gelatine. Some brands of gelatine are very prone to this defect. Try Heinrich's or Simeon's photographic gelatine next time.

COLLODIO-CHLORIDE PAPER.—J. H. C. writes: "How long should collodio-chloride paper keep in good working condition? I had some of —, and it had not been in the house a fortnight before it had gone quite a light brown, more on the back than on the front. On complaining, I was told that I had not kept it properly, though it was stored in the case it was received in."—The paper would not have gone brown in so short a time, if carefully stored, unless it had been faulty in its make. This rather seems to be the case, as the back has changed more than the sensitive surface.

DETENTION OF NEGATIVES, &c.—H. H. says: "About a month ago I sent a negative and remittance to an enlarger, ordering an enlargement, and have written to him several times, but cannot get either the enlargement or negative, or any reply to my letters. Kindly let me know the best way to proceed to recover the amount sent and the return of my negative. Can I take action through the County Court?"—In reply: Your remedy, we think, would lie in the County Court. You should also communicate with the local Superintendent of Police, as people of this sort deserve to be made an example of.

RESTORING A DAGUERRETYPE.—J. CHRISTIE says: "Will you inform me if a very old Daguerreotype, taken forty-six years ago, and which has both faded considerably and become scratched and spoiled, possibly through damp, can be restored to some extent? If you can also furnish me with the name and address in London of an expert in this class of restoration, I should feel obliged."—We have never yet seen a faded Daguerreotype. They tarnish, and that can be cleaned off; but there is no means by which the scratches can be removed. Any of the old photographers who are familiar with the Daguerreotype process will do the work for you.

GETTING PLATES THROUGH THE CUSTOMS.—F. J. P. says: "Can you give me any information as to the best way to get my undeveloped plates through the Customs offices at Calais on outward journey, and at either Dover or Newhaven on return? As I am carrying rather a large number, I propose taking them in a box (into which they exactly fit) quite separately to other luggage. They will be packed in Newman & Guardia's refill boxes, on to which will be pasted the label of the plate-maker. Any suggestion you can make I shall be grateful for."—You will experience no difficulty if you explain at the Customs houses what the packets contain. If you do not speak French, it will be well to have a label on the boxes in French, that the plates will be spoilt if exposed to light. The makers of the plates will, doubtless, supply the labels.

EYE TROUBLES.—OMEGA asks: "Can you inform me of any lotion that will strengthen the eyes? I may say my eyes are somewhat weak. They are subject to water, which is very uncomfortable, especially when retouching, or, when my eyes are fixed on an object for length of time, they become weakened. My eyesight is very good. I can readily perceive an imperfection of the smallest form at a distance or close at hand. If you can give me some information, I shall be much obliged as I detest the wearing of spectacles."—You may think your eyesight is very good, but there is little question that you require suitable spectacles and our advice is to lose no time in getting them, also to have them fitted by an oculist. A dilute solution of sulphate of zinc is sometimes used as a lotion for the eyes, but we should not recommend you to use it without advice.

### EX CATHEDRA.

At the Annual Meeting of the members of the Royal Photographic Society, on Tuesday evening, February 13, Mr. T. R. Dallmeyer, F.R.A.S., will be declared President of the Society. The nomination paper does not contain the name of any other candidate for the office, and thus the election takes place as a matter of course. Mr. Dallmeyer has been a member of the Society since 1886, and a Vice-President since 1894. In 1896 he was awarded the Society's progress medal for his work in tele-photography. Besides contributing many papers on optics to the Society, he has always manifested a strong practical interest in its progress. The new President, whose election will undoubtedly be popular with the members of the Society, has our heartiest congratulations on his accession.

\* \* \*

A CORRESPONDENT sends us a print recently made on bromide paper thirteen years old. The date on the package is 1886. Except for some marks of staining round the edges, due in all probability to the method of development adopted, the print is of very good quality. We often have mention of instances in which sensitive dry plates have been found to retain their

original good qualities unimpaired for many years; but data with regard to bromide paper are not so plentiful. The case we are quoting probably constitutes a record.

\* \* \*

A MEMBERSHIP of over sixty, at the end of only a year's existence, is a fact of which a newly formed photographic society may justifiably be proud. The Redhill and District Camera Club finds itself in this happy position. It has a good balance in hand, and an excellent programme of papers and demonstrations has been arranged for future meetings. On its executive we see the names of many photographers of the highest skill and reputation. Mr. William Brooks, the new President, has had over forty years' experience in photography, which, with his fine practical knowledge of all branches of work, should be of immense service to the Club. Mr. Ralph Robinson, Mr. J. O. Grant (late of the Hackney Society), and Mr. Henry Speyer (the very able Alpine photographer) are also active members of the executive. The Club's recent lantern lecture, delivered by Mr. Speyer, was remarkably successful. The Redhill Club appears to have a prosperous future in front of it, and we wish it the utmost success in spreading a knowledge of photography in the beautiful county of Surrey.

\* \* \*

WE have already drawn attention to the fact that the war is adversely affecting most branches of photographic manufacture and production. Its evil influence, it appears, extends even so far as the Exhibition of a photographic society. We are asked to note "that the Woolwich Photographic Society has decided to postpone their annual Exhibition until the autumn, on account of the large number of members and supporters engaged in the Royal Arsenal having to work overtime, and who are therefore unable to prepare pictures or assist in any way."

\* \* \*

WE have received the first number of *British Invention*, a weekly review of patents, improvements, and developments, which is published at 55 and 56, Chancery-lane, W.C. Its scope is sufficiently indicated by its title. There is an interview with Mr. J. Fletcher Moulton, Q.C., M.P., the eminent

authority on British invention, in the course of which that gentleman gives his ideas on the subject of patent law reform. We have only space for one extract: "Mr. Moulton would simplify patent law by the removal of certain grievous difficulties, some of which were provided for in the Bill which he presented to Parliament in 1895, but which, like most private members' Bills of that time, was sacrificed to make way for public or Government measures. On the vexed question of official examination of applications, for novelty, by the Patent Office, Mr. Moulton is in accord with those who know most of the actual working of the present system. He believes in free trade in patent grants, provided only that publicity for opposition, as now existing, is given to the applications before they are sealed." That the actual working of the present system of Patent Office procedure should receive support from Mr. Moulton is matter for surprise. The office takes an inventor's fees readily enough, but gives him in return nothing which can reasonably be called protection. Reform in our patent laws urgently called for.

\* \* \*

A MEETING of the Council of the Photographic Convention of the United Kingdom was held in London on Thursday, January 25. The arrangements for the Newcastle-on-Tyne meeting were discussed. It will be held in the week commencing Monday, July 9, and there will be excursions to Durham, Alnwick, Hexham, &c. Considerable other business concerning matters of detail was transacted by the Council, vacancies in which body were filled up by the election of Messrs. H. Vivian Hyde, S. Herbert Fry, W. E. Dunmore, and J. Pattison Gibson.

\* \* \*

AT Maidenhead last week there was a town's procession in aid of the War Fund. In the description of the proceedings a local newspaper had a paragraph about a camera-maker's car, provided by Mr. W. Allen, a photographic apparatus maker in the town. The car was said to be most appropriate to the exhibitor's trade. At the rear of the vehicle, and at the back of a huge camera, we are told, there was a large illuminated photograph of Lord Roberts, whilst specimens of cameras were exhibited. A couple of men were at work, and circular saws were in motion. This is the first time, to our knowledge, that camera-making has been illustrated in a public procession.

\* \* \*

WE clip the following advertisement from a contemporary: "Your own photo. Fifty for 1s. Postage 1d. extra. Copied from any size photo. Delivered following day. Size  $1\frac{1}{4}$  inches, with adhesive back. Just the thing for your memos and cards. Best finished and cheapest in the world. Your photo returned uninjured. Crossigraph Copying Company, 25, Lime-street, Liverpool." We hope the Crossigraph Company find that they can do business at a profit on these terms, which are low enough in all conscience. Hitherto a dozen small photographs for a shilling was considered cheap enough—but fifty! What next?

\* \* \*

MESSRS. TAYLOR, BOXALL, & Co., 98, Lewin-road, Streatham, inform us that they have just made an enlargement in bromide of a somewhat unusual size. It is nineteen feet four inches by twenty-eight inches, and on one piece of paper. Messrs. Taylor say: "So far as our experience goes, it is the largest ever

made in one piece. We should be very glad and interested to know if it is the largest bromide enlargement made. Perhaps readers of the JOURNAL may be able to inform us."

#### SIZES IN PHOTOGRAPHS AND THE COVERING POWERS OF LENSES.

PHOTOGRAPHERS have often expressed disappointment that lenses said to embrace an angle of so many degrees on a plate of such and-such dimensions do not do so, although, as a matter of fact they do. But it must be explained that the optician and the photographer usually consider the angle in different ways. The latter often expects that it means on the base line of the picture, whereas the former means on its diagonal, the correct way when speaking of the covering power of a lens; because the same lens will include as well a wider angle on the base line, if we use a longer plate and at the same time curtail its width, so that the diagonal still remains the same, and this it does without reducing its aperture.

How the present standard sizes in photography came to be adopted it is difficult to conceive. In the old Daguerreotype days there were the following sizes: the one-ninth, the one-sixth, the quarter, the third ( $5 \times 4$ ), the half, and the whole plate, and these sizes remain unchanged up to the present time. The next larger sizes, adapted for calotype negatives were  $10 \times 8$ ,  $12 \times 10$ ,  $15 \times 12$ ,  $18 \times 15$ , and  $22 \times 20$ , and these are still in vogue. Why they were fixed upon it is equally as difficult to surmise, seeing that they are so erratic as to their proportions as regards length and breadth. The camera-manufacturers have always supplied cameras for those sizes, and the opticians catalogue their lenses to suit them.

In later years the *carte-de-visite*, the size of which is about three and a half inches by two and a quarter, the cabinet which is from five and a half to six inches by four, and afterwards the seven and a half by five size were introduced. Some of the old workers affirm that the great success of the *carte-de-visite* and cabinet portraits was largely due to their pleasant proportions, and, for the same reason, they say the  $7\frac{1}{2} \times 5$  size found so much favour amongst amateurs. Now it will be noticed that in all of these favourite sizes the picture is just about one-half longer than it is broad, and it will be found that these proportions, to about one-third longer, according to subject, obtain in most paintings and engravings.

Now, let us look at the proportions of these standard photographic sizes and see how inconsistent they are with one another. In the first place, although the quarter-plate is really a quarter of the whole-plate, the half-plate is larger than half a whole-plate, being half an inch wider, and consequently is squarer in shape. Then the  $12 \times 10$ , that, like the whole-plate, is two inches longer, only, than it is wide; but the proportion of the latter is, roughly, one third longer than its width, whereas the former is but one-fifth. If the one is a pleasing shape, it is clear that the other is not. If we take the next two sizes, we see that that the  $15 \times 12$  is one-fourth longer than it is in width, while the  $18 \times 15$  is but one-fifth longer, another discrepancy. Then, coming to the largest size we have quoted, namely,  $22 \times 20$ , we find but two inches difference between the length and breadth, just the same as exists in the whole-plate. Here it will be noted that the length of the plate is but one-tenth more than its width—almost a square—while the cabinet size and the  $7\frac{1}{2} \times 5$  is one half longer.

Let us next consider the covering power of lenses, with reference to the size, or, rather, the proportions of the plates. The field of a lens, as is well known to our readers, is a circle, and it follows that it will cover any size or shape that can be cut from that circle. Take, for example, the  $12 \times 10$  size, which in trimming for mounting is usually very considerably reduced in its width, its diagonal is fifteen and a half inches; it follows, therefore, that the lens that will cover  $12 \times 10$  will also cover a plate of any other proportions that can be cut out of a circle the diameter of which does not exceed the fifteen and a half inches; one, for example,  $13 \times 8\frac{1}{2}$ , and these are about the same proportions as the cabinet picture. Of course, a picture with these proportions includes a much wider angle, on the base line, than is the case with the  $12 \times 10$  when the same lens is used on that size plate.

Next let us take the  $18 \times 15$ . In this the length exceeds the width by only one-fifth, and its diagonal is twenty-three and a half inches. Here we can get a  $20 \times 13$ -inch negative out of our lens, and these again are about the same proportions as the cabinet picture; we also obtain a correspondingly wider angle on the base line of the picture. Let us finally look at the largest size to which reference has been made, namely, the  $22 \times 20$ . How these proportions came to be adopted it is still more difficult to speculate upon, but see we the size quoted in an old catalogue of the late Andrew Ross, in the fifties, and we find it also adhered to in the latest catalogue of Dallmeyer, notwithstanding its ugly shape for a photograph, as it is almost a square. Any lens that will cover that size plate will quite as well cover one  $24 \times 18$ , or one  $25 \times 17$ , and here again we get nearly as possible, the same pleasing proportions as in the favourite cabinet size, and, as a matter of course, a much wider angle length-wise on the plate, or as the photographer usually judges the angle of view. Some have imagined that to take a negative on a plate  $24 \times 18$  a lens the next size larger to the  $22 \times 20$  is required. That is not so, as the lens that will cover the latter size will cover the former equally as well, and indeed a trifle better.

It is not to be expected that the sizes and proportions that have been in vogue for cameras, &c., since the earliest days of photography are likely to be altered now. Our object here is simply to point out, to those who may not be aware of it, that the lenses they have may be used on plates of different proportions from those they are catalogued by the makers to cover, so as to include a wider angle, in the direction usually desired, without in any way curtailing definition throughout the field, and at the same time secure more suitable shapes for the majority of subjects.

**Formalin and Gold.**—The extent and variety of uses to which formalin may be put is remarkable, and continues to increase. Herr L. Vanino, in a foreign journal, has pointed out its extreme usefulness for precipitating and assaying gold. He says gold can be estimated quantitatively by adding ordinary commercial formalin to the solution of the chloride, and afterwards a few drops of caustic soda, and the whole heated for a few moments on a water bath. The metallic gold is separated by filtration, and the filtered liquid again tested by formalin to make sure that the precipitation is complete. The precipitated gold is washed with water, then with alcohol, and dried at  $180^\circ$ , or even heated to redness on a crucible. Formalin will throw down silver from its solution in nitric acid, whether heat be applied or not. Chloride of silver, also, is reduced by formalin, the reaction being capable of application not only in a qualitative, but in quantitative, work, and the preparation of pure silver from residues.

**Eclipse Arrangements.**—It is stated that the Spanish Government are making every arrangement for the successful reception of those astronomers who may go to Madrid to observe the eclipse on May 28. According to Reuter a better station than that city will be found at Naval-Moral on the Caceres line and about 200 kilometres from Madrid, the period of totality there amounting to two minutes. We have already referred to the British Association's arrangements, which will, on the whole, meet the views of most of the possible observers, for if, as the Iron Duke once said, "an army marches on its belly," so also must even a photo-astronomer conduct his observations under similar needs, and the question of hotel convenience must be considered.

**A New Photographic Photometer.**—In the *Astro-physical Journal* Dr. J. Hartmann describes a new photographic photometer he has invented for the purpose of determining stellar and other magnitudes as at the Potsdam Astro-physical Observatory. In instruments hitherto constructed the drawback has been the distances by which the standard scale and the object to be measured were separated. Dr. Hartmann has obviated this by conveying an image of each, side by side, to the eye by a special microscope, which might be termed a binobjective, in opposition to binocular, as it has two object-glasses which are directed respectively upon the standard and the object, the images being then sent into the one eyepiece after being reduced in size by being partially covered by screens with small apertures.

**Water Purification.**—The purification of water, whether from rivers or wells, is a subject of perennial interest to photographers, as there are cases where grave mishaps have resulted from the use of impure waters. Possibly the need for freedom from organic impurities is less urgent than it once was, but that the freer water is, both from organic matter, vegetable or animal life and mineral salts, the better it is for photographic purposes may be accepted as a fact. Permanganate of potassium and lime have long been looked upon as the best substances that could be used with simple appliances; but they are open to the objection that they leave free alkali in the water, and small quantities of lime, that being the alkali most frequently present, would utterly ruin the water for photographic purposes, and render it entirely unfit for potable use. In the *French Journal of Pharmacy and Chemistry* it is pointed out by M. Tixier that these difficulties can all be got rid of by using permanganate of aluminium and permanganate of barium in various proportions. With waters containing calcic sulphite the two salts would be used, while in the complete, or almost complete, absence of lime, the aluminium permanganate would be employed. M. Tixier states that the reactions entirely take place in the cold, and that the quality of the water may virtually be instantaneously ascertained, or, at any rate, always within five minutes of the addition of the first drop of the reagent.

**Estimation of Sulphite and Hyposulphite of Soda.**—In an article which is too technical for these pages, but which can be seen translated in full in last week's *Chemical News*, full details are given for the estimation of sulphydric, sulphurous, and hyposulphurous acids. The methods are mainly founded on the disengaging the acids, and passing the vapour through a series of wash bottles containing iodine in solution, with a final one to hold decinormal hyposulphite solution to absorb any traces of iodine that might be carried over. The details of the method show how to test for sulphite in the presence of hypo, and for hypo in the presence of sulphite. Such tests as these will be of increasing usefulness, seeing that in the growing refining of photographic methods great purity in the raw materials in common use is most desirable.

## THE PHOTOGRAPHER'S YEAR.

### FEBRUARY.

FEBRUARY is a peculiar month. Nothing of much importance seems to have happened in it. St. Valentine's Day, it is true, falls in the middle of February, but even the observance of that festival is rapidly dying out.

Fortunately Shrove Tuesday also comes in. This will act to a degree as a preservative of interest, for the ordinary Englishman loses grip less readily of an excuse for eating than anything else.

The reason for the general lack of interest in the month probably is that it comes between two seasons. The sharpness of winter has gone by, and the freshness of spring not come. This year there has not been much sparkle about the length of winter that has gone by. Snow, ice, and clear frosty air have not been so much to the front. But, if in such spots as Davos, to which people journey for their particular sake, and normally with the certainty of enjoying them, they have failed, we stay-at-homes must surely grumble the less.

The old saying has it:—

“February fill the dike  
Either with black or white;  
If it be white, it's the better to like.”

But the month of late years has certainly not been a wet one; on the other hand, dry and sunny. Possibly this has been due to there not having been any heavy snowfall in the preceding months, for melting snow, like rain, will fill the dike. The old rhyme, too, was made in earlier days of indifferent drainage. Science has modified in many directions the homely sayings of our forefathers, and this may be one instance; but, whether full dike and flood or otherwise, there is an evident deadness about February. Fortunately, in such circumstances, it is the shortest month. As, however, it must be passed through, better philosophically make the best use of it. It will thus be still further shortened. Things are not quite so bad as this, though; there are many possibilities open. The lengthening days naturally strengthen photographic interest. Things look very different under similar amounts of increasing and waning light. There is none of the accumulated haze and fog of the year that marks the latter to qualify the former. Objects, if bare and lifeless, look clean and clear cut. It is a phase of nature that lends itself readily to photographic record. A view of a favourite bit of landscape taken in February, apart from its intrinsic value, would act as an excellent foil to one of the same spot taken in June or July. The one has everything at its barest, the other at its fullest life. In the closer realisation of the marked difference thus graphically shown, it is also not unlikely that, in many cases, thoughts may rise above the mere fact of the difference to its causes, and the thinker be mentally broadened in deeper grooves than mere artistic or photographic ones.

But, if bare hardness and lack of life in general be the characteristic tone of February, there is a particular life dependent upon these special conditions. In much the same fashion that the death of the leaves in the autumn is an essential condition of the life of the following spring ploughing and harrowing go on. Here is a chance for a capable man—capable not merely in the sense of being able to turn out a creditable picture of the ploughman, plough, and horses, but of turning it out showing the worker intent upon his work, and nothing else, the horses moving, the ridge turning over, and “the dusky thieves, the rooks,” following in search of worms. The motion is slow enough for an instantaneous exposure, even at this time of the year; and under such conditions the result would be far better than with the usual careful posing, and the evident perspective pint of beer in the ploughman's face.

The sap in trees being at about its lowest in this month makes it the best for tree-felling. Wood-cutters, timber wains, and strings of horses are items that lend themselves well to the making of a picture. Artists of repute have found them such; the photographer need not hesitate to try his hand.

The foregoing are offered not in any strained, exhaustive fashion, but scappily, to the acknowledged end of showing the practicability, advantage, and pleasure of keeping the camera steadily employed throughout the year. The town dweller need not fight shy of work in the month from the fact that the subjects suggested are country ones. There is plenty of material to his hand if he have not the opportunity of going to the country—winter portraiture, for instance. The portraits we have of our friends, sweethearts, wives, and children are generally summer ones, of the straw-hat and muslin type. And very naturally so, for thoughts turn far more readily to being photographed in summer than in winter. The doing so under summer conditions is also very much easier. But we undoubtedly lose a great deal in allowing ourselves to be over-dominated by photographic best conditions. Thought as a consequence does not turn naturally and easily to the taking of a desirable picture when photographic conditions are some way from being at their best. Friends in shooting and hunting dress look well. So do children wrapped up to meet the cold. If we do, or did, any of our sweethearting in winter, remembrances of sweethearts and wives in sealskin cap and jacket are sure to have been pleasantly preserved upon the tablets of the fancy. There is, too, a

piquant air, begotten of clear cold, about the face and attitude in winter that is lacking under the conditions of summer, particularly of summer a studio, in the afternoon.

February, as the dullest month in the housewifely calendar—for Christmas decorations have been taken down, and spring cleaning has not commenced—would probably find the women folk in the best humour to meet the suggestion of being photographed in winter dress. Let the hesitating doubter try it. Let him aim, say, at a picture of his most dearly beloved about to start for an afternoon's skating. Dressed in a appropriate style, with the skates hanging over her arm, she will present the happy suggestion of anticipated pleasure and rapid motion a picture quite as pleasant as, if not pleasanter than, one under more languorous summer conditions. If there be no ice, and no skating, there are plenty of other distinctive winter requirements.

Many a would-be worker will be in the unhappy position of having attend exclusively to his business during the hours of daylight. Evenings at this time of the year are long and hang heavily. The festivities of Christmas and the New Year have gone by. The fare at the music-hall and theatre, from reaction, seems insipid and not over-nourishing. The introduction of paper that prints, and can be developed by gaslight, should prove a boon to his wearied soul, if it be a genuinely photographic one. He can try at his ease and comfort any number of experiments with his summer negatives. They need not run in the drier channels of mere technical manipulation, but can find expression in an artistic one. Local brush development may be instanced as one. A perfect negative is great rarity; and it need not follow that even a perfect negative will yield a perfect print. These truisms are not quoted for their own sake valuable—but a trifle stale—though they be, but to emphasise the fact that by local brush development a perfect print can be got from a negative imperfect as a whole. Undesirable portions in a print from such a one can be easily left undeveloped, and, with a little practice, the desired portion so shown as to make a very different affair of the finished result to that obtained by any of the alternative methods of blocking out vignetting, &c.

But enough, it is trusted, has been said to at least given the stimulus to individual thought to the working out of the photographic possibilities of the present month of February.

#### MODERN INTENSIFIERS FOR GELATINO-BROMIDE PLATE AND THEIR EFFECT.

[Translated from the *Photographische Correspondenz*.]

AMONGST intensifiers in practical use for gelatino-bromide plates, the which form a black deposit upon the negative play a very important part as they offer the greatest facility for judging the strength of the image.

Of the old intensifiers of this sort, that formed by a mixture of bichloride of mercury and bromide of potassium, followed by sulphite of soda for blackening the image, has been justly popular for portraits and landscapes. A new method of intensification with iodide of mercury and sulphite of soda has recently been introduced by Lumière Frères Seyewetz, of Lyons. This consists of a solution of one part of iodide of mercury and ten parts of anhydrous sulphite of soda in 100 parts of water, and the negatives, after fixing and washing, are immersed therein. By reciprocal action of the iodide of mercury and the silver, a dark deposit of mercurous iodide is formed ( $2\text{HgI}_2 + 2\text{Ag} = \text{Hg}_2\text{I}_2 + 2\text{AgI}$ ), which latter is converted to mercury and iodide of mercury by the action of the sulphite, according to the following formula given by Lumière Seyewetz:—

The negative is then washed and treated with alkaline pyro, hydroquinone, para-amidophenol, or some other developer, to blacken the image. The iodide of silver is reduced to silver and the negative rendered permanent.

Another new intensifier has also been recently introduced by the Berliner Actiengesellschaft für Anilinfabrikation under the name of “*agfa intensifier*.” This method has been worked out by Dr. Andrese of Berlin, and his assistant, Dr. Leupold, and depends upon the use of double salts of sulphocyanide of mercury. The intensifying solution is sold in a colourless, concentrated form, which has to be added to nine parts of water for use. The gelatino-bromide plate after being fixed and washed is immersed in this solution. The intensification proceeds gradually, and the deposit is of greyish-black colour. By prolonged action great intensity may be attained, even more than with bromide of mercury and sulphite of soda. The *agfa intensifier* does away with the separa-

blackening process, and this is not only a simplification, but it also permits of the effect of the intensification being more readily controlled than is the case when the image has to be blackened by a separate operation. The agfa intensifier is excellent, and the question which now arises relates to the effect of this and Lumière's iodide of mercury intensifier in comparison with the older method with bromide of mercury and sulphite. For this purpose I have made a series of measurements of opacity, as described below, by means of Hartmann's micro-photometer. Gelatino-bromide plates were used, and, after exposure by means of a Scheiner sensitometer, developed with ferrous oxalate and fixed.

1. I wished in the first place to ascertain by measurement the difference between the action of the ordinary mixture of bichloride of mercury and bromide of potassium (1 part of bichloride of mercury, 1 part of bromide of potassium, and 50 parts of water) and a solution of bichloride of mercury (1:50). The test plates were exposed with the Scheiner sensitometer. The bleaching of the silver deposit was much slower with pure bichloride of mercury than when it was mixed with bromide of potassium, and the subsequent blackening of the image was much more intense where bichloride of mercury and bromide of potassium were used, as compared with bichloride of mercury only. The latter did not intensify very appreciably. Both processes showed some loss of density in the finest shadows after prolonged action of the sulphite of soda (evidently due to the solvent action of sulphite of soda upon silver chloride and silver bromide; but, as the former is much more soluble intensification is less).

2. Lumière's iodide of mercury intensifier blackens the negative slowly and continuously, and the colour tends to a brownish shade which becomes rather more pronounced by subsequent washing. The treatment with a developer, according to instructions (pyro soda was used), darkens the image, but insufficient washing after intensification gave rise to slight red fog, which was inconvenient. Intensification is, however, very full, and more density is obtainable than with bromide of mercury and sulphite.

3. The agfa intensifier is preferable to Lumière's, because there is only one solution, and there is, moreover, no risk of red fog, as in the case of Lumière's intensifier, if the plates be insufficiently washed. Density can be pushed very far with agfa. In this respect it surpasses the bromide of mercury intensifier, and is nearly equal to Lumière's.

The following table gives the numbers of the opacities of the strips of the intensified plates:—

Table of opacities of dry plates after use of different intensifiers:—

Exposure in candle metre seconds.	Opacities of negative before intensification.	After intensification with bichloride of mercury and sulphite of soda.	After intensification with bichloride of mercury x bromide of potash and treatment with sulphite of soda.	After intensification with Lumière's iodide of mercury intensifier.	After intensification with Agfa's.
1.0	0.36	0.32	0.33	0.37	0.37
1.26	0.41	0.35	0.39	0.43	0.43
1.60	0.47	0.40	0.45	0.52	0.55
2.05	0.51	0.45	0.57	0.63	0.72
2.61	0.64	0.57	0.71	0.75	0.90
3.3	0.73	0.68	0.87	0.93	1.10
4.2	0.80	0.77	1.07	1.18	1.31
5.4	0.87	0.87	1.27	1.40	1.50
6.9	0.97	0.97	1.47	1.65	1.70
8.8	1.07	1.09	1.69	1.89	1.85
11.2	1.18	1.20	1.85	2.03	1.94
14.3	1.32	1.34	1.98	2.15	2.00
18.2	1.41	1.47	2.07	2.27	2.19
23.2	1.48	1.55	2.12	2.33	2.28

It follows from these observations that the old method of intensification with bichloride of mercury and bromide of potassium, followed by blackening with sulphite of soda, is sufficient for most cases, and is still to be recommended. But the agfa intensifier, from its simplicity and its greater power of intensification, seems superior, and is doubtless an improvement.  
DR. J. M. EDER.

PYROXYLINE.

Of all the articles used in photography, probably none is so difficult and unpleasant to manufacture as pyroxyline. Certainly it is not so important now as in the early years of photography, although it is still largely used for enamelling and collodio-chloride emulsions.

The writer has tried numerous samples by different manufacturers, all of which vary more or less. This partly shows how difficult a matter it is to lay down a definite formula for its manufacture, and how intricate the manufacture is. Not only are there great variations in the quality of commercial pyroxylines, but the variation in price is quite as great, ranging from 9s. to 40s. per pound.

The literature bearing upon the subject of its manufacture is of a very limited nature. The only works which contain any exhaustive treatises upon the matter with which the writer is acquainted are Hardwich's *Photographic Chemistry*, Abney's *Instruction in Photography and Photography with Emulsions*, and Leaper's *First Principles of Photography*; and, by reason of the enormous varieties of pyroxyline which can be manufactured, hardly any two formulæ agree, for every variation in the quantity or quality of the acids, and every degree of temperature at which it is made largely affects the solubility and other properties of the resulting pyroxyline.

Pyroxyline is what is chemically known as a nitro-cellulose, varying from the highly explosive and almost insoluble gun-cotton to the beautifully soluble high temperature. The explosive varieties differ very slightly in appearance from the original cotton, and from six to ten grains per ounce of ether-alcohol form a thick and glutinous collodion of a very contractile nature and slightly yellow colour, while the high-temperature variety forms a limpid collodion, even with twenty grains per ounce, giving a film which is non-contractile, almost colourless, and rather rotten, while that given by the low-temperature is strong, tough, and contractile, and, when quite dry, can neither be developed nor toned.

Pyroxyline is made by immersing any form of cellulose (usually the finest cotton-wool) in a mixture of sulphuric and nitric acids at any desired temperature according to the kind of pyroxyline required.

As Hardwich advises in his *Photographic Chemistry*, when starting to manufacture pyroxyline, a carboy of each acid and a good stock of cotton-wool should be obtained, as any variation in these articles causes a change in the pyroxyline.

Cotton-wool, as obtained commercially, is generally somewhat greasy, and in this state the acids do not act upon it properly, so the first necessary stage in the manufacture is to boil the cotton in a weak solution of soda or potash. One of the most reliable tests of the freedom from grease is, as Captain Abney says, to drop a piece of the dry cotton upon cold water. If it contains grease, it will float; but, if free from grease, it absorbs water and rapidly sinks. Before proceeding further, the cotton must be thoroughly dried. A very good and rapid method of doing this is to hang a sheet horizontally by the four corners, distribute the cotton well over it, and, especially if it stands in a draught, the cotton will dry very quickly. The next process is to remove the little brown specks which are found even in the best cotton-wool. The kind of pyroxyline required must be decided upon before starting, as the temperature must be studied, and this also regulates the strength and relative quantity of the acids, for, strange though it may seem, the higher the temperature required, the stronger must the acids be, or the cotton will dissolve. In using acids it is generally found that the application of heat to the acid largely helps to dissolve the article immersed therein, and in making pyroxyline the action of heat has a very peculiar effect, for, with an acid mixture which is very successful for a certain class of pyroxyline, an increase of heat will tend to dissolve the cotton, but, if the acid mixture be made stronger, the cotton does not dissolve, but instead makes a more soluble pyroxyline. Hardwich, in his *Photographic Chemistry*, gives a temperature of 140° F., but at that temperature, with the proportion of acid that he gives, the writer has been unable to get anything but a tough and contractile collodion. This may be accounted for by the difference in the quality of the acids, as, for economy's sake, the writer has been in the habit of working with ordinary commercial sulphuric acid of specific gravity 1.843, and nitric acid specific gravity 1.42. The mixture of these with water gives in his hands a temperature of about 190° F. against that given by Hardwich of 165° to 170°. The resulting collodion was very tough, contractile, and left a heavy flocculent deposit, the mixture apparently not containing enough nitric acid, as this seems to be the principal element in the conversion of cellulose into pyroxyline, the main function of sulphuric acid seeming to be, as Leaper says in his admirable work, *The First Principles of Photography*, to dehydrate the nitric acid, which cannot at present be obtained sufficiently concentrated, in addition to some secondary reactions. The writer is of opinion that excess of sulphuric acid has a tendency to produce a tough and horny collodion, but whether this is exactly the case it is rather difficult to say. In many formulæ the proportion of sulphuric acid to nitric acid is in the ratio of three to one, or nearly so. This often produces a strong and contractile collodion, apparently owing to the parchmentsing action which sulphuric acid exercises upon cellulose.

In a very comprehensive and exhaustive article upon "Photography" in Spon's *Workshop Receipts*, vol. iv., it states that the three-to-one proportion of sulphuric acid to nitric acid is not found to be the best for the soluble varieties of pyroxyline, and this somewhat coincides with the writer's experience and opinion, although he has not tried the formulæ given by Spon, which are in the proportion of two to one and three to two; the writer inclines to the opinion that the proportion of nitric is too great in the latter formula, yet, on the other hand, he believes that,

within certain limits, increase of nitric makes for greater solubility, although it is difficult to say that such is absolutely the case, but he is of the opinion that the best proportions will be found from 2 to 3 parts sulphuric to 1 part nitric; but it must be distinctly understood that this is merely the writer's idea, and may not work out so in all cases, for from the varying accounts given of the different actions of various formulæ, it seems there must be some slight difference in the quality or quantity of the acids used or in the temperature obtained. The writer believes that the following will be found a very good formula for soluble pyroxyline:—

Sulphuric acid (1.842-3)* .....	10	fluid ounces.
Nitric acid (1.42) .....	4	„ „
Water .....	1½	„ „
Cotton .....	½	avoirdupois ounce.

Immerse at a temperature of 158° F. or 70° C.

Leaper, in his *First Principles of Photography*, gives a very good formula as follows:—

Strong sulphuric acid† .....	12	fluid ounces.
Nitric acid (1.45) .....	4	„ „
Water .....	17	„ drachms.
Cotton .....	270	grains.

Immerse the cotton at a temperature of 158° F. or 70° C.

The writer believes that the ordinary commercial sulphuric acid of 1.842-3 sp. gr. is quite strong enough for making pyroxyline, especially in the quantity given above, and, as nitric of 1.42 sp. gr. is about twenty-five per cent. cheaper than that of 1.45, 4½ ounces of the former may be used instead of 4 ounces of 1.45, and 15 drachms of water instead of 17. This formula gives a fairly soluble pyroxyline, making a collodion with a strong and not too porous film; but, for a high-temperature pyroxyline, Leaper says that the water should be reduced to 12 drachms, and the temperature raised to 74° C., or 165° F. Should 1.42 nitric be used, it would be necessary to reduce the water to 10 or perhaps even 9 drachms.

When a weaker acid is used than is contained in a given formula, the quantity must be increased. The writer has generally increased the nitric and decreased the water until the quantity and the sp. gr. of the combination of the weaker acid and the water equals the quantity and sp. gr. of the stronger acid and the water. Thus, suppose we take two formulæ such as those given in Abney's *Photography with Emulsions*, as follows:—

Sulphuric acid (1.842) .....	18	fluid ounces.
Nitric acid (1.456) .....	6	„ „
Water .....	4½	„ „

And—

Sulphuric acid (1.842) .....	18	fluid ounces.
Nitric acid (1.42) .....	6½	„ „
Water .....	4¼	„ „

On comparing them it will be found that, by adding together the nitric and the water of the first formula, a sp. gr. of 1.2545 is obtained, and, by adding the same ingredients in No. 2, we get a sp. gr. of 1.254 nearly, the difference being practically *nil*, while the aggregate quantity remains the same.

Formulæ are sometimes given where nitre is used instead of nitric acid. This, no doubt, answered very well in the early days of photography, when nitric acid was difficult to obtain, and even then not in a very pure state; but at the present time, when good and reliable acid can be easily obtained, it is not easy to understand where the advantage comes in.

It is very necessary that indiarubber gloves should be used when making pyroxyline, as the nitro-sulphuric acid mixture is of an exceedingly corrosive nature, and the hands, if unprotected, will soon be covered with yellow burns; it is also advisable to use a rubber apron. The clothes worn during the operation should be of no value, as it is almost impossible to prevent the acid splashing slightly, because the operations have to be conducted very quickly; if the clothes should get splashed, apply ammonia immediately to neutralise the acid. A quantity of cotton waste, tow, or rag should be kept handy to wipe the lips of the bottles free from acid after using.

It is necessary that plenty of ventilation should be obtainable in the apartment used for manufacturing pyroxyline, as the fumes from the hot acid are very unpleasant. The best kind of room is one with an opening at the top, so that the fumes can easily get away, as it is impossible to work with any large quantity of acid in a very enclosed space.

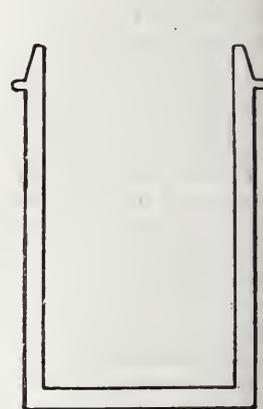

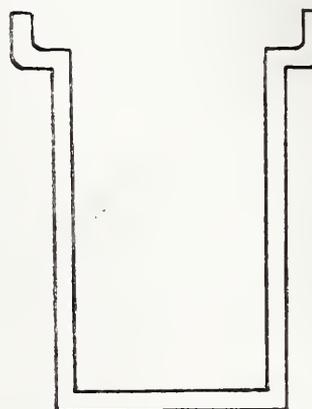

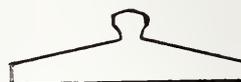

Do not use a wooden tub to wash the pyroxyline in, as the acid attacks the wood and turns it yellow, and if used for anything else will either mark or contaminate it. Be very careful to pour the water into the containing vessel first, then the nitric acid, and lastly the sulphuric acid. Should this method be reversed and the water added last, splashing will occur, on account of the great affinity for water which sulphuric acid has.

Thick glass spatulas are generally advised to be used for manipulating

\* This is the strength of the acid usually sold as commercial sulphuric acid.

† He does not state the sp. gr. of the sulphuric acid, but presumably 1.845 is meant.

the cotton in the acids; but the writer cannot recommend them, as he has almost invariably found that the hot acid cracks them, more especially so with the high temperatures, and, as the ends sometimes fall off in the acid, it is very awkward to get the cotton out, and, should they break off while raising the cotton from the acids, the latter may splash up into the operator's face and eyes; therefore the writer recommends the use of earthenware spoons instead. It is much safer to use an earthenware vessel for the acids, for, should glass beakers be used and the vessel get a knock and break, the results are disastrous. The best kind of jar to use is a deep, narrow, cylindrical one; two very good pattern jars are those known in the earthenware trade as shut-over and upright covered, as shown in the following figures.

Upright Covered Jar.

Shut-over Jar.

A jar, where the neck narrows in with a ridge, should not be used, as the ridge prevents the easy extraction of the cotton, the jar should be as small in diameter as possible, so as to allow only a very small surface of acid exposed to the air.

It is absolutely necessary that a thermometer should be used; the best type are those with a long narrow bulb, as they are more quickly sensitive to slight changes of temperature.

The writer does not think that pyroxyline should be manufactured at a less temperature than 155° to 158° F., or 69° or 70° C., although the lower temperatures may be used for enamelling and wet-plate work where a strong tough film is required, and of course, in the latter, the plate is only worked while the film is in a wet and porous state.

When the acids are mixed, it will be found that the temperature generally rises to about 190° F. The mixture must be allowed to cool until the desired temperature is reached, and this must be maintained upon a water bath; the writer has usually found that large quantities behave somewhat differently to small ones, and that it is often necessary to keep the water bath at a slightly higher temperature than the acid mixture is required, or, if the jar is much exposed to the air, it loses heat quickly and the pyroxyline varies, this being especially the case with small quantities. The acids should be well stirred, so that the temperature may be even throughout, or, if the jar happens to be a thick one and very cold, the temperature round its sides and bottom will be less than in the centre, as heat does not diffuse very quickly through acids; to make sure that the temperature is even, stir the mixture with the thermometer, and move the latter up and down, noting if the mercury remains stationary while doing so.

While the acid is cooling, the cotton should be made up into about half a dozen balls, so that the acid may permeate well through it, and act equally upon it; when the right temperature is reached, each ball must be put into the acid separately, well pressed down into the acid, and stirred about, this must be done as quickly as possible or the first ball will differ from the last; when all the cotton is in, the acid must quite cover it or the cotton will decompose, this partly shows the necessity for thoroughly cleansing the cotton from grease, so that it may not rise in the acid. At first it will be advisable to look at the cotton occasionally to see that it keeps under the acid, as sometimes it has a tendency to rise even when clean, this is generally indicated by a bubbling noise in the jar; the cotton should be covered and left for about ten minutes, after which, quickly remove it, press out as much acid as possible, plunge into a large body of cold water, and move it about in the water to remove the acid as quickly as possible, or very likely the temperature may rise and decomposition set in; after being in this water for a quarter to half an hour, the cotton should be removed and placed in fresh water, after the lapse of an hour or

wo place in a third lot of fresh water, or a small stream of water should be allowed to trickle through until all trace of acid is removed, it must then be taken from the water and thoroughly dried, the sheet as described or the first drying answering well for this. Artificial heat should not be used for drying pyroxyline, or an accident may ensue. As the pyroxyline often breaks up into small pieces which are rather difficult to collect, it is a good plan to have a calico bag with a cane fastened round the top to keep it open and rigid, and then to pour the water and cotton into this, when the cotton is easily collected.

Unless very great care is exercised in the temperature and strength of acids, the first attempt at manufacturing pyroxyline will result in complete dissolution of the cotton. This is caused by too high a temperature or too weak acids. Sometimes, on removing the lid from the jar, dense red fumes are seen at the top, which is the result of the cotton rising above the acid, and, if the pyroxyline has been much exposed to the air while in the acid, on removing it from the jar it will spontaneously decompose as if burning, making a hissing noise and emitting very thick red fumes. This may be stopped by quickly plunging the cotton into water, but the collodion from this kind of pyroxyline is hardly likely to be of the best quality.

For getting rid of the acid, the writer is in the habit of using an earthenware colander to place the cotton in. The colander resting on top of a jar, and then, with a flat earthenware jar cover, similar to the cover of the upright covered jar shown in the sketch, quickly press out as much acid as possible into the jar underneath; it is best to have a knob on the jar cover, as it can then be held better. This will be found a much better way than trying to press out the acid with a glass rod or spatula.

Hardwich advises using the acid over twice, adding slightly more sulphuric to take up the water formed by the hydrogen abstracted from the cotton combining with the oxygen from the nitric acid; but the writer's experiments in this direction hardly justify him in recommending it, as the pyroxyline made lastly differs from the first.

There are one or two tests by which an experienced hand can get a fairly good idea of the quality of the pyroxyline without dissolving it. One way is to tear the cotton, and, if it is almost as strong as the original cotton, the resulting collodion will be tough, contractile, and horny; if, on the other hand, it appears rotten, and breaks easily, a porous and powdery film may be expected. Another way is to ignite a small piece; if it burns slowly and evenly, it is probably of the high-temperature variety, while, if it blazes up quickly with a kind of slight explosion, a strong and contractile film may be looked for. Another way to test it roughly is to put twenty to twenty-five grains into one ounce of ether-alcohol; if it dissolves readily and is fairly limpid, it may be judged as giving a non-contractile and porous film, while, if it dissolves in lumps, giving a thick, viscid collodion, a horny and contractile film will result. Properly made pyroxyline should weigh from twenty-five to seventy-five per cent. more than the original cotton, the greater the increase of weight the more contractile will the collodion be. A slight fluffy sediment will be deposited from the collodion when made up even with the high-temperature pyroxyline, and this is more pronounced with the low temperature; but, if the deposit is very heavy, the quantity of nitric acid should be increased.

C. T. SUTTON.

#### COPYRIGHT NOTES.

SOME of the editors of illustrated journals have learnt, through expensively bought experience, that there is such a thing as copyright in photographs. Most of the leading professionals are members of the Copyright Union, whereby their interests are protected, and, if the Copyright Law is infringed, the photographer in question has a remedy, and damages can be obtained. Many photographers, however, consider the advantages of membership of the Copyright Union a mixed blessing. As is well known, the minimum reproduction fee that members of the Copyright Union may charge is half a guinea. Presumably, if the reproduction is no more than a square inch, this minimum fee would still have to be charged.

The advantages of membership of the Copyright Union may be very well for the prominent professional photographers, but for lesser workers the benefits that would be derived are not so apparent, and there are many capable professional photographers, non-members of the Copyright Union, who are prepared to accept a smaller reproduction fee for their photographs. Of course, it is still open to them to copyright their work and to charge a higher fee if they think fit. The same remarks apply to amateur photographers. They can, and do, protect their work, and proprietors of illustrated papers have, before now, to pay dearly for illegally making use of amateurs' photographs. A friend of the writer some time ago contributed a striking snap-shot to one of the leading papers. I think he charged five shillings for it; and it was cheap at the price. Some time later, he chanced to see this same photograph reproduced (probably it was the same block) in a small volume dealing with a subject, which the photograph in question appropriately illustrated. An explanation was demanded, which was not readily forthcoming.

The editor of the paper in which the photograph originally appeared claimed that he had purchased the copyright of the photograph. My

friend knew better. He was not in the habit of parting with the copyright of his photographs for five shillings, when it frequently costs him more than this sum to obtain the negative, there being travelling expenses, cost of materials, cost of registering the photograph, and various incidentals. The contributor of the photograph referred the editor to the receipt. The editor found the words, "including copyright," had been struck out, and the editor in question had to pay heavy damages.

On one occasion the writer contributed a rather effective photograph to illustrate an article, which duly appeared. Some time later the same photograph made its appearance in another journal run by the proprietors of the paper in which the photograph originally appeared, without either fee or acknowledgment. The remuneration received in the first place was five shillings, and it was a non-copyright photograph.

A somewhat curious incident occurred to me some time ago. I had occasion to obtain a photograph of a prominent person who had died, and this, living near the deceased gentleman's residence, I had no difficulty in doing. The photograph was duly published, and some weeks later the writer was surprised to receive a copy of a claim for very considerable damages made by one of the best-known portrait photographers of the day for infringement of copyright. I was away on holiday at the time, but, with as little delay as possible, I made inquiries of the photographer who was credited with having taken the photograph.

To be brief, it turned out that the photograph which the writer received from a relative of the deceased was really a copy of a photograph which had been taken many years previously by the photographer who was claiming damages. Rightly or wrongly, most professional photographers copy photographs when asked to do so. This had been done in this case, owing to the fact that the person in question would not be photographed again, and his friends desired more copies. The local photographer was in no way to blame for the publication of the photograph, and he knew nothing about the matter until it was brought under his notice. The writer was chiefly to blame, for an examination of the photograph would have shown that it was a copy, and, moreover, the word, "copy," was written beneath the photograph by the side of the local photographer's name. The writer at that time assumed this to refer to the photographer's name, emphasising the fact that he desired his name mentioned. Nothing was received, nor would it, under the circumstances, have been expected, and the incident caused much annoyance and inconvenience all round.

Competition in illustrated journalism has become very keen. While there are editors who are prepared to offer good prices for photographs which suit them, there are others who prefer to do without if they cannot have the use of them at what they consider a reasonable figure. The writer was asked by the editor of a well-known journal to furnish the photograph of a lady who is very prominent in connexion with the war in the Transvaal; but, as the photographer required a reproduction fee of one guinea, he decided to do without it.

Happily, we do not hear so much nowadays of those competitions in which a big figure is offered as a prize for the best photograph submitted, the editor reserving the right to use any photographs sent in; but, as the illustrated journals must have striking photographs, we will, doubtless, see other schemes announced very shortly by which the desired photographs may be obtained.

J. A. REID.

#### PLAIN SALTED PRINTING PAPERS—THEIR TREATMENT AND PERMANENCY.

THERE is little doubt but some of the most exquisite results in photographic printing that have ever been obtained have been produced by means of rough-surfaced drawing paper, salted, and finally sensitised by means of ammonia nitrate of silver, and, were it not for the widely accepted belief that these samples of printing paper lacked one of the chief essentials in photography, viz., permanency, there is no question but they would be in much greater request at the present day than is the case.

The question of permanency in the results obtained by the use of these papers when silver is employed as the sensitising agent is, no doubt, to a very large extent dependent upon the treatment those printing papers receive at the hands of photographers, both in the preparation of the paper and also in the after-treatment of them when the printing stage is reached, and any one preparing and using these papers for the first time ought to understand that in several respects their manipulation will require to be differently conducted from that ordinarily bestowed upon the smoother classes of printing papers so much in use at the present time.

Many years ago the writer gave a considerable amount of thought and attention to the preparation and after-treatment of both thick rough and thin smooth samples of plain salted paper, and the results now seen after a considerable lapse of time are highly instructive, and go far to demonstrate that lack of permanency is traceable in a great measure to the faulty treatment of these papers.

In the preparation of rough-surface drawing-papers for photographic purposes a beginner will be struck with the apparently extreme ease and

simplicity of the various manipulations required in their production, for it is quite within the scope of any lady or gentleman who may feel inclined to bestow a little thought upon the operation.

Hand-made samples of drawing-paper of almost any degree of texture are readily obtainable from any respectable stationer or artists' colourman, and of the various brands perhaps there is none more reliable than those of Whatman's manufacture, any size sheet or portion of which can be salted and sensitised as occasion requires, for a period of about half an hour's time is sufficient, not only to salt, but likewise to sensitise and dry a sheet or so in perfect condition for the printing frame.

In the operation of salting, the writer has no hesitation in giving it as his opinion that many of the hints published from time to time regarding the best means of performing this operation are, to a beginner, misleading, or at least do not convey information that is most likely to lead to ultimate success. For instance, in very many cases where instruction is given how to prepare a salting solution for rough-surface papers, gelatine is recommended as the proper medium to employ in combination with chloride of ammonium or sodium. The writer is far from wishing it to be understood that gelatine is not suitable for the purpose. In the hands of experienced parties it has been employed from the earliest days in photographic printing; but the chances are about ten to one against a novice who for the first time essays to sensitise a sheet of paper, being able to salt his paper satisfactorily when gelatine has been used. A far better medium is found in arrowroot worked up into a very thin paste or mucilage.

And here let it be noted that different samples of paper require varying strengths of salting solution. In the early days of silver printing, the preparation of the paper previous to the silvering was considered a separate branch of photography, for the work of the printer was understood to begin with silvering the paper, and it was only by the experience he possessed in dealing with one and the same brand of salted or albumenised paper that he was enabled to arrive at the best strength of silvering solution to employ for the particular class of paper being used, and it was no uncommon event for an experienced printer to find out that one brand of paper, owing to some property it possessed, would give beautiful results when silvered after a formula that would yield nothing but failure under different circumstances. Therefore, when dealing with these papers, a beginner ought never to adopt some particular formulae that he or she sees heralded forth as most suitable, and rigidly stick to it, expecting it to work equally well in every case; rather should he study closely the behaviour of a particular quality of paper when treated with a well-conceived formula of salting and silvering, and, when he has arrived at the best results, to note carefully how these results were obtained, and follow such in their after-working.

One of the objects of employing such organic substances as gelatine, starch, arrowroot, or tapioca, is with the view of filling up the pores of the paper so as to retain the printable image as much as possible upon its surface, thereby giving the picture the utmost amount of brilliancy and vigour, and this function of whatever organic substance be employed, in conjunction with the chloride used, should be kept in view by whoever is undertaking the operation, and the mode of applying it to the paper, as well as the proper consistency of the chlorine solution used, should receive careful consideration.

In the case of gelatine, when used as an organic substance in conjunction with chloride of ammonium, it is not infrequently recommended that, after a salting solution is prepared by thoroughly dissolving a quantity of gelatine in the proportion of ten to twelve grains per ounce of water along with about sixty grains of chloride of ammonia, that the paper should be *immersed* in this solution. This treatment, however, is far more liable to yield poor results than when it is merely applied to the surface only of the paper by floating or swabbing; the latter, however, requires some practice to enable any one equally distributing the salting solution over the entire surface of the paper, and here we have just another instance in photography, where an operation is lightly passed over, with the briefest possible description, that ought to be most fully explained, so that any novice could be guided to do the operation successfully.

The coating evenly of an entire surface of a small sheet of paper is by no means so easy as many imagine, and, if the gelatine solution is not kept at the proper temperature during the operation uneven sensitising will be the result. Floating, again, requires practice to avoid air bells, &c. If, however, swabbing be decided upon, then let a good flat swab be made by taking a sufficiency of flannelette to form three thicknesses of the material, and, having provided a long strip of glass about four inches wide, lay the flannelette over the end of same, so as to allow of about one inch of cloth to act as a swab; this is far and away the best tool to employ for the purpose; any one can make it for themselves, and it will work better than any camel's-hair brush ever did for this purpose. In doing this, the paper should be laid flat on any convenient support, and a large sheet of clean white paper placed underneath that, being coated, will prove cleanly and useful.

When evenly coated, the sheets are pinned up by one corner to dry in close proximity to a moderately hot fire. A few minutes of time will suffice for drying, and when so will keep indefinitely; a cross mark being applied on the wrong side will help to satisfy the operator which is the correct side to sensitise when the silvering stage is reached.

Some of the finest prints the writer has ever seen on plain salted paper have been produced with a salting solution made with arrowroot and chloride of sodium. The latter, in its proper proportion, when quite dried in a clean porcelain saucer, is dissolved in clean water, and the latter is boiled in an enamelled saucepan. A sufficiency of arrowroot is then mixed in a clean basin to form (when the boiling water is added) a very thin paste of about the consistency of cream. This, when nearly cold, is swabbed over the surface of the paper in exactly the same manner as described above. Some writers advocate the immersion of the paper, but this is apt to yield a sunken appearance to the prints, the final sensitising with silver not being kept sufficiently on the surface.

With ammonia nitrate of silver the solution is likewise applied by means of the glass and flannelette swab, one being provided for each purpose.

To make the sensitising solution, strong liquor ammonia is added to a solution of nitrate of silver (say of a strength of about sixty grains per ounce) until the dark brown precipitate formed is redissolved, and the solution turns water white again. Half of the quantity thus made is taken in a clean glass measure, and made just acid with a drop of pure nitric acid. This is then added to the other portion, and, when filtered, will form an efficient sensitising solution for some salting formulae and brands of paper.

In applying this solution, the paper ought to receive at least two coatings. After the first has been applied, the paper is dried near a bright or brisk fire; it is then allowed to get quite cold, when another coating of silver solution is applied, then dried again, and is ready for the printing frame. Paper prepared in this manner will not keep in good condition for any length of time; but, as the sensitising is so easily and rapidly performed, there is no need to keep a supply ready-sensitised.

Printing is conducted in exactly the same way as other samples of printing papers; but it is when we come to the toning and fixing stages that special precautions require to be observed, so that permanency in the resulting pictures may be obtained.

One of the first essentials towards permanency will be found in the *almost* complete removal of the free silver from the paper prior to the operation of toning, and this must be strictly attended to both when dealing with thin as well as thick samples of paper, for every fibre of the paper must be thoroughly reached with the washing water before toning be attempted. Several changes of washing water will be required before this will be effected, and, if it is inadequately performed, it is easy to see what mischief will result.

When the paper received its coating of ammonia nitrate of silver, by reaction with the salting material employed, chloride and organic salts of silver were formed in and on the surface of the paper, both of which are necessary; but, in addition, there is always more or less free silver present. Now, if this latter is only affected by a mere slight operation of washing prior to toning, the soluble silver becomes as it were diluted, and in such a condition is very liable to soak into the paper instead of being retained on the surface, and, if this happens, not only will the operation of toning be interfered with to a certain extent, but, when the fixing operation is reached, the imperfectly washed print is sure to give trouble by reason of the available silver in the print becoming converted into hyposulphite of silver, which, in its turn, must be dissolved in an excess of hyposulphite of soda.

As a further precaution, all samples of these papers ought to receive special treatment between the operations of toning and fixing. This means subjecting the toned prints to an immersion for ten to fifteen minutes in a fairly strong bath of salt and water, from which they are removed to the fixing bath.

It follows therefore that plenty of water must be applied to remove *nearly all* the free silver prior to toning, and that the most thorough fixation should be given; and, if this be carefully seen to, the image on these papers will be as permanent as those of any others having silver as their base.

Where the washing and fixing has to be so thoroughly performed, the printing must be carried deeper than with other samples of paper, and perhaps there is no more suitable toning formula than acetate of soda and gold, the function of which is to attack the light-changed image of silver and nothing else, so that there ought to be little or no free silver present to interfere with the action of the toning bath.

Another method of toning these papers has been recommended, viz., by chloro-platinite of potassium, which can be obtained in small quantities from the Platinotype Company. By means of this, pure sepia tones can be obtained as well as black tones by merely altering the strength of the toning bath, but when properly treated these papers can be made to yield with gold and acetate of soda almost any tone that may be desired from reddish-brown to purple-black, whilst, on the much-abused score of permanency, there need be no fear.

A. T. NEWTON.

#### ON MOUNTING PHOTOGRAPHS.

LOOKING over a collection of an ardent amateur a short time since, I was struck by the very small number of mounted specimens of which it could be said that they were *properly* mounted. I do not mean only

from an artistic point of view, but as work carefully carried out, and when I gently and very timidly drew attention to a ragged corner, and a plister, my friend said, "Oh, I don't pretend anything about the mounting! I care only for the picture."

Now an effective photograph, properly and carefully mounted, is like an elegant lady in tasteful attire, and, if I see a corner coming up or an edge not secured, my eye is drawn to that directly, and away from the beauty of the picture.

I do not propose to describe all the various mounts now in use; a trade catalogue and a little taste will generally decide what is suitable, but I want to speak of the way in which a photograph can be most easily mounted and keep its place.

First, as to the trimming, for in mounting on cardboard, which is now quickly regaining popular favour, we must very carefully square, and cut straight and true, without jaggings or tearing the print.

The best material to cut on is the smooth side of a thick piece of ground glass, and it should be large enough to prevent the knife passing away over the edge, or the cutting power of the knife is quickly lost. It is well to grind the edges of this slab to protect the fingers, and always put it away with care to prevent chipping the corners. When, by frequent use, it has become cut and scratched, it is better to have a new one, as cutting over scratches makes bad edges and spoils knives and tempers.

The knife must be of good steel and not too sharp, and no notches at the point, or they will tear the print. The handle should be strong, and comfortable to hold in the hand. In cutting, it should slope only enough to prevent dragging the print; an angle of forty-five degrees is best as a rule.

The cutting shape should be a very true piece of stout glass, and, if the lower side is coated with negative varnish, it will seldom slip.

Some mounters turn the print round to get at it, but it is well to endeavour to move and regulate the hand instead, as it saves much time in doing many.

Before cutting, see that you have your print quite upright, and, if there is a line of distant sea, that line must be perfectly horizontal. If the negative has a building distorted by tilting up the camera, so that the uprights at the sides lean together, it is generally a good plan to give a little each side, or let the principal lines rule the balance, and so keep the spectator's eye from annoyance as much as possible.

If prints are much curled or cockled before being taken in hand, they are much improved by being flattened in an old volume of bound music, as the music paper is slightly absorbent, and will do much to "smooth" matters generally.

Now, as to the mountant. There are many in the market sold ready for use, but none are so good as freshly mixed cornflour. It can be used warm or cold, and needs no hot-water bath to keep it in working order. To mix it, the best plan is to put a spoonful in a small basin, and add a little water just to moisten it; then pour *boiling* water on it and stir till it thickens, and add a very little more water, or it will be too stiff for use, especially as it cools.

The brush should be an ordinary sash tool or painter's brush, of a size suited to the work. If a new one, soak it for an hour in cold water, or the bristles will come away on the back of the print, and cause much trouble.

Next procure a nice, well-made drawing or pastry board, and also one or two good sponges and a couple of white handkerchiefs. Have a basin of clean warm water at hand and thoroughly wet the board; place a print face down on this board, and paste the back till the print lies flat. If the prints are on gelatine, it may be best to lay on the board a stout piece of wet calico, as the gelatine might stick to the board, but it will not to the calico. When the print lies flat, put down another alongside to soften, while you put the first one in its place on the mount. Lay a piece of clean blotting-paper over the print, and pass over it a roller firmly and evenly to roll out bubbles. Lift the paper, and with a sponge carefully remove any paste that has rolled out; lay the print aside to dry, and sponge over the board and lay another down to soften while you treat No. 2 print as you did No. 1. When the mounted print is surface dry, put it under a weight to keep it flat.

Pictures that are to go under cut-out mounts should never be trimmed, as sometimes they are cut rather too small by mistake. When all are mounted, go carefully through them to see if edges and corners are well down, and then let them rest all night, if possible, under a heavy weight.

ALFRED SEELEY.

#### TABLOIDS.

At the meeting of the Richmond Camera Club, on January 22, Mr. Ardaseer in the chair, Mr. John H. Gear gave a demonstration on the use of Tabloids. Mr. Gear did not, however, confine his remarks to the subject of Tabloids, for he commenced by some practical illustrations of the improvements to be effected in pictures of "Nature just as she is" by the judicious use of cloud or water negatives (or both) in combination with the original negative and by trimming the print so as to exclude what was superfluous, or to improve the balance of the composition. Some slides by Mr. Gear, which admirably illustrated his remarks, were passed through the lantern.

Mr. Gear then addressed himself to the subject of Tabloids, and showed a very compact leather wallet, which, although of moderate size, contained sufficient material to develop, fix, tone, &c., a large number of negatives or prints. It was clear that the tabloids (which are made by Messrs. Borroughes & Wellcome) must be a great convenience to the traveller who wished to develop his negatives or produce prints thereof in the course of his journey. No liquids need be carried, it being sufficient to crush and dissolve one or more tabloids in the prescribed quantity of water to produce the various solutions required. The tabloids were also useful to the amateur, who need not make up more developer, toning bath, &c., than he actually needed, thereby saving the loss often experienced through the stock solutions becoming spoiled by keeping.

Mr. Gear's wallet also contained tabloids of persulphate of ammonia, and its value as a reducer was well shown by means of a lantern slide which Mr. Gear had brought with him. The slide was first shown on the screen in its original state, and again shown after the ammonia persulphate solution had been applied to the over-dense portion with a brush. No care was taken to avoid brushing the solution over the delicate detail of a church tower, which was surrounded by the dense deposit, and the effect of the persulphate in attacking only the dense portion without affecting the detail in the tower, was very remarkable, and was well shown on the screen.

Mr. Gear concluded by showing some more slides of a miscellaneous character. Some of these, which were copies of architectural drawings, illustrated the power of hydroquinone in giving a dense black deposit without affecting the white background.

#### CRISTOID FILMS.

BEFORE the Photographic Section of the Croydon Microscopical Society on January 24, Mr. F. J. Townsend in the chair, a demonstration on "Cristoid Films" was given by Mr. J. H. Baldock, F.C.S. These films differ from anything else which has been produced inasmuch as they are just films, and nothing but films, no support of any kind, either paper, celluloid, or glass. They are composed of two films, a rapid one and a slow one, superposed on one another (the Sandell double plate without the glass in fact), so that the effect can be varied according to which of the two surfaces is placed towards the lens and receives the first impact of light. They can be used in any ordinary slide by employing either a backing card or some form of film-holder. The amount of exposure to be given them, although, of course, there is what is termed a "correct exposure," does not really much matter, as you will see, provided it is sufficient. "I show you two films to which I intended to give exposures of 10 and 100 seconds respectively, at *f*-32, but, forgetting to put in a stop, they consequently received at *f*-8 the enormous exposures of 160 and 1600 seconds (about 2½ and 26 minutes); but, as you see, printable negatives were obtained from both of them. Development in this case was carried on for 15 minutes to get density, and then they were reduced. I show you two more of a Welsbach mantle alight, one had 15 and the other 60 seconds, at *f*-32; observe that in both cases the crutch supporting the mantle, the chimney and its support, and even the meshes of the mantles itself are plainly visible; compare these with this negative on an ordinary glass plate in which not a single one of these details is present, the whole being completely lost in a vast circle of halation extending far beyond the glass chimney. Another of a window, which had 40 minutes at *f*-22, the light was not very bright, and there was not much inside the room, but you will see that the outline of the window, and the fringe at the edge of the curtains, are as distinct as possible, not the smallest trace of halation; compare this with an ordinary plate, the difference is striking.

"I shall presently develop four films, which have had exposures of 2 seconds, 20 seconds, 1½ minutes, and 6 minutes respectively, and you will then be able to see that it is possible to get almost identical results in each case. I need not give the several processes employed, as they are succinctly stated on the paper of instructions issued with the films, and which I hand round, but I will just show you practically." The various processes of development, fixing, reduction, squeegeeing on to glass, and varnishing were then gone through successfully, Mr. Baldock concluding by saying that he thought it was self-evident that these films possessed certain advantages which pertained to no other negative surface, because exposure and printing, besides the other operations just shown, could be performed on *either side of the film*. For carbon printing and cloud effects this was obviously an advantage, as it saved the trouble and expense of making reversed negatives. Reduction, too, taking place, as it did, on both sides, could, as seen, be done with Farmer's reducer, so that there was no occasion to use the new and very valuable ammonium persulphate reducer.

"The only difficulty, if such it can be called, lies in the drying; this, being of necessity from *one side only*, takes rather long, consequent on the thickness of the film; and, if the film leaves, or is taken off the glass before it is *quite dry*, it buckles thus (as shown), and cannot in that state be printed from, but must again be thoroughly wetted, and again squeegeed. This, however, can easily be got over by placing the films, after washing, in methylated spirit for a few minutes. This allows them to dry in less than half the time, and reduces them to their original size

as in the processes above described they have expanded about twenty per cent. in area. Obviously, too, if it is intended to varnish it on *both sides*, it must be *quite dry* before the top layer of varnish is applied, although, of course, the second coat of varnish can be put on *after* the film is taken off the glass. There is one other and very important advantage in these films, *i.e.*, their non-inflammability, which should make them invaluable for cinematograph purposes, as they would at once cause the removal of the restrictions which have been placed on these exhibitions. I believe, too, it is the intention of the Sandell Company to prepare them in spools for use in roll-holders for daylight changing."

### "COLLEGIATE" PHOTOGRAPHY.

OUR American professional brethren have amongst them, in Illinois, a "College" of Photography, where it is to be presumed the students engage in the pursuit of photographic knowledge, on what we may term the University plan. But, to judge by some notes from the College, which were recently published in an American contemporary, the work of the students is agreeably diversified by marriages and jokes—other jokes, a cynic might say. Thus: We have again been thrown into raptures over the fact that one of our number has seen fit to take unto himself a mate to "boss" and rule him for evermore. This time it is Mr. E. E. Godfrey, Milton, Wis., who married Miss Mayme Arendt, of our city. Mr. Godfrey has recently opened a studio in Waukegan, Ill., where we feel sure he will make a success. We hope the *lighting* and *shadow* of Mr. Godfrey's married life may be so *blended* as to produce the best *gradations*, and that Mrs. Godfrey may keep a close *focus* on all his actions and cause him to *retouch* out all the faults that he, in common with the rest of mankind, may be heir to, and we hope that between them they may *develop* a picture of married life of *positive* beauty, and that the *negative* side of this life shall only be prominent enough to relieve the monotonous effects of too much pleasure; that the *duplicates* of the Godfrey family may be in evidence, and that *family groups* may rise up and call them blessed.

AGAIN: A few days ago Mr. Hickman was giving instruction in printing to a party of young ladies, when one of them accidentally knocked a drachm graduate off the toning table. Mr. Hickman remarked "Please pick up that d(r)a(ch)m graduate." "Oh!" said all the ladies in chorus. "No offence," said Mr. Hickman.

ANOTHER: In giving instructions in making up plain lighting calls the students' attention to the high lights on the face being on the forehead, the nose, the lip, and chin. A few days ago the little six-year-old son of one of our lady students came running to his mother and said, "Oh, mother! I have fallen down and skinned all my high lights." His face was skinned on the forehead, nose, and chin. Who says he will not be a photographer some day?

FINALLY: A young lady, who is a student of the Illinois College of Photography, was entertaining a young gentleman, a classmate. With a longing desire to make the young man's visit more pleasant, she turned to him and exclaimed, "Shall I sing 'Because I Love You'?" "No," replied the good natured brute, "if you really love me, don't sing." Then they played a game of "Freeze-out."

### THE SOUTHSEA EXHIBITION.

WE need not hesitate to say that the Twelfth Annual Exhibition of the Southsea Amateur Photographic Society takes a position well ahead of any previous Exhibition of the series, and well in rank with other provincial society Exhibitions. The improvement upon last year's record, both in the members' and in the open classes, is most marked.

In spite of the great general advance in the members' classes, the Secretary (Mr. F. J. Mortimer) easily holds first place. He is to be congratulated on his determination not to accept all the medals he has so ably won this year, and we think that next year he might enter the open classes only. His best works are, perhaps, the two in the Architectural Class, for which he receives 1st award; but the set of four hand-camera studies (1st prize), the figure study (1st prize), the enlargements (1st prize), the lantern slides (1st prize), and the landscape (certificate) are all good, and are backed up in almost every class by many other good things.

In Class A (Landscape), Mr. L. Dyer scores 1st with one out of eight good, broadly treated landscapes. Mr. H. J. Hissett (2nd) has seven attractive things of the birch-and-bracken school; and Mr. P. Denham's estuarine quay-side well deserves its certificate. Mr. G. Wood has three good but unequal little things, and the rest of the class is of good quality.

Class B (Figure Studies and Portraits), besides Mortimer's has a study with a good characterisation, but curious cutting of two of the figures, by L. Dyer (2nd), a pleasing, simple portrait, with detailless background, by P. Denham (certificate), two excellent birds' nests and one bird by Dr. J. H. Kelso, and two good ordinary groups by Mr. A. Fisher.

Class C (Architecture) is very strong, and amongst other good work are five interiors by Mr. G. Wood, three well-chosen bits in Canterbury crypt by Dr. G. H. Newby (2nd medal for one), a good relieve panel (certificate)

by Mr. A. Fisher, and commendable work by Messrs. L. Dyer and S. Arnold.

Class D (Hand Camera) is weak in typical snap-shot work, the most genuine snap-shooting being *The Major's Yarn*, for which Mr. W. J. Lewis receives a certificate. Mr. L. Dyer's three sets are good landscape, &c., and one takes second medal. Mr. F. O. Field has three pretty little shipping studies.

In Class E (Enlargements), Mr. L. Dyer (2nd prize) has much striking work—perhaps over-enlarged; and Mr. F. O. Field would probably have received the third award had there been more entries in the class.

The Open Landscape Class is very strong and very even in quality. Mr. W. A. I. Hensler's *Stormy Sunset* (1st prize) is run close by his other picture. Mr. W. E. Dunmore has four good things, and takes second medal for a deserted beach (untitled). Mr. A. R. Read takes the certificate with a charming little peaceful marshland homestead; and there are worthy things by Mr. F. W. Bannister, Mr. James Critchley, Mr. H. Quilter, Mr. E. A. Price, Mr. W. F. Slater, Mr. Charles J. Hankinson, and others.

Class H (Portraiture, *Genre* and Still Life), brought out such a good competition that the Judges divided it into two sections (portraits, and *genre*), and gave in each more awards than were offered for the whole. Mr. W. J. Byrne's large direct portraits, though not medalled, could not fail to arouse admiration. The portrait awards were: (1) Mr. Leslie Shawcross, for a noble *head of an old man*, treated with reverence and entire success; (2) Mr. F. W. Fielder for *Daydreams*, an admirable piece of portraiture. Bracketed together for certificate are Mr. Graystone Bird and Mr. F. Fielder. In the *genre* branch of this class Mr. Fielder would surely have scored again, had not the Judges felt that two medals could not well go to one man. Mr. Charles Sweet's, *The Scotsman*, took a well-won 1st, with Mr. W. E. Dunmore's *Talking Shop* and an excellent smithy interior, with smith at work, bracketed equal for second prizes. Three equal certificates were given to Mr. C. Skelton Tyler, Mr. R. S. Harding, and Mr. H. C. Leat. These awards by no means exhausted the noteworthy work.

Class I (Hand-camera Work) is not so strong as a whole, but the six rural scenes by Mr. J. Kearney, jun., well merit their silver medal. The bronze goes to Mr. W. Fisher Ward, and the certificate to Miss Alice Worsley, for good but not very distinguished work.

The Beginners' Class (K) is a decided surprise, and, if the competitors are all genuine beginners, the older men may expect strong new competitors ere long. The prizes go (1) to Mr. S. A. Pitcher for a beautifully treated *Scriptorium, Gloucester Cathedral*; (2) to Mr. W. P. Baker, for a portrait study; and certificates (equal) to Mr. A. Seed and Mrs. W. F. Clark.

The lantern slides, again, are numerous and very good, so that in both classes the Judges have given extra awards. In the Open Class we find (1) Mr. John Beeby; (2) Mr. A. T. Crane and Mr. E. R. Bull (equal); (3) Mr. Graystone Bird and Mr. A. E. Smith (equal). In the Members' Class the awards go to (1) Mr. F. J. Mortimer; (2) Mr. L. Dyer; (3) Colonel H. W. B. Bruno and Mr. A. Fisher (equal).

In each class the first prize is a silver medal, the second a bronze medal, and the third award is a certificate of merit.

The Judges were Messrs. H. Symonds, H. Snowden Ward, and G. West. In addition to the competitive classes there is an extensive collection of pictures "not for competition," and there are the extra attractions of tea and light refreshments, mutoscopes, and lantern-slide and cinematograph displays. Moreover, the admission is free. Verily, Southsea is a place of enterprise!

### EXHIBITION OF THE LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE annual competitive Exhibition of this Society, which opened on Friday, the 12th ult., contains a smaller number than usual, counting the photographs themselves, though the tale of competitors is, perhaps, not so much reduced. To some extent this apparent diminution of interest may be accounted for by the fact that, on the present occasion, each of the competitive sets had to contain three pictures only, instead of, as lately, four, and, dating further back, six. Possibly also, as the Judges suggested, the permission to send the photographs framed acted as a deterrent among the more diffident members. As a matter of fact, every picture sent was enclosed in a frame, greatly to the enhancement of the decorative effect.

The Judges were Messrs. W. T. Greatbach, Thomas Huson, and Watmough Webster. The Challenge trophy and gold medal were awarded to Mr. J. E. Coney Wilson, one especially of whose works, *Sunset Glories*, we shall hope to see at the next display at Pall Mall. This is a noble study of sky and water, which commands instant attention by an unusual luminosity in the light streamers of cloud illuminated by a low sun hidden by dense, dark cumuli. Two meritorious prints—*Quiet Pastures*, a flock of sheep herded under the shadow of tall pines, and *Light of Even*—complete the set.

The Society are lavish in their medals, four of silver being at the Judges' disposal for the best four sets of three (open to all members of the Society). The successful competitors are Mr. Joseph Appleby, who is medalled for two studies of wave and cloud and one Alpine view of less merit. The effect of waves breaking over a semi-submerged rock is very fine.

Dr. Llewellyn Morgan's medalled set has two life studies, which deserve a high meed of praise. An old fisherman's head with a sou'-wester cap, taken in strong sunlight, is a portrait of considerable power, marred only by a background devoid of shadow or variety, "as smooth as paint." His other figure picture shows us a woman standing at the top of a steep path looking, with hand-shaded eyes, seawards. It is composed well, and has breadth of treatment and poetical feeling.

Dr. Jno. C. Saunders (gold medal)—medical men seem strong at Liverpool—is to be congratulated for his view of a hillside clothed with low shrubs, one solitary tree jutting out from the sloping outline of the hill, clear cut against the sky, giving great value to the whole. With a little more vigour in the immediate foreground this picture would have been perfect. In another of his set we have a stranded flat, with telling, broken reflections in the shallow water of the ebbing tide.

Mr. F. Anyon has a fine sea picture, with waves breaking over low rocks; in another otherwise excellent marine picture, the sky is a little too heavy. *At the Well* represents a village maiden posed leaning against a tree trunk, with logs of wood at her feet. The same figure and pose transferred to other surroundings would have been worthy of much praise, but as now seen the composition is imperfect.

Mr. Jno. H. Tower also essays figure compositions, with a fair measure of success. A portrait of a man seated in the light of a window is good, but the shadows of the figure want vigour and roundness. An Eastern picture of remarkable character, showing a long row of figures in attitudes of devotion, their faces to the wall, is very striking.

Dr. Llewellyn Morgan exhibits a good interior. Mr. Depree is to be congratulated upon one of his three figure studies, a beautiful almost life-sized head and bust of a woman, with the face directed upwards; the whole is most naturally posed, well conceived, and well lighted. His *Lord of the Desert* is ambitious, and technically excellent—a handsome man's head with Arab head-gear, but smacking rather of the studio than the desert.

Mr. Carruthers' *Dinner Time* is a good photograph of a difficult subject—horses in the middle of the road—but the interest is scarcely sufficiently centred.

Mr. A. J. Booth exhibits three Alpine scenes of quiet, silvery tone, very pretty.

Mr. W. E. Inston's are small in size, one representing a quiet mere, or river broad, with trees on each side, and a low hillside in the distance, only wanting size to make a very telling picture.

Mr. J. A. Appleby shows *Sand Dunes*, effective, but the subject is rather played out. His two figure pictures are evidently the result of considerable work, but they do not attract us; besides, there is too much evidence of the brush.

Mr. Jno. Parkinson, in a little view (half-plate size), gives us a capital group of cows.

Mr. F. Anyon exhibits three fruit compositions, printed from what we should imagine to be perfect negatives, but the arrangement of the objects is open to improvement—the interest is too scattered.

Mr. Harvey has three exquisite little interiors from quarter-plate negatives, taken, we imagine, with lantern-slides in view.

Mr. F. B. Sutton, in *Music by Handel*, shows a well-composed figure group brought together by a barrel organ, the street seen on one side vanishing into dull distance being effective. He has also a pastoral scene: a group of sheep with central figure of the herd behind them; a difficult subject, well photographed, but deficient through being so completely symmetrical. The herd is exactly in the middle of the sheep, and the bushes behind exactly equal on each side of his herd. If he had had the fortune to have placed the shepherd a little to one side the photograph would have been a true and beautiful picture.

Mr. Harvey has further small views of river bend and cows by river-side. We should imagine that if he had selected his views differently as to arranging for sets, he would have received a medal, though small photographs, judged by the side of those of much larger dimensions, need to be of such passing excellence to have their merits recognised. We think that class at these exhibitions specially for small photographs, or hand-came<sup>2</sup>a work, would be advantageous. We believe this Society formerly had such a class.

Of Mr. A. A. Booth's three Alpine views, one showing cows on the margin of a sloping hill silhouetted against grey distant rocks is the most attractive.

The President of the Society (Mr. Paul Lange) offered a silver medal to be competed for by ladies only. There was only one competitor, but the award was made for a set of photographs of still life. Sprays of flowers, birds' nests, with other objects were included and showed evidence of considerable pains. We suggest that if the exhibitor would include fewer objects and devote all her attention to the simple arranging and illuminating them she would obtain pictures that would appeal more to her own judgment.

In the Class for Scientific Photography were exhibited some carefully executed photo-micrographs, one medalled photograph showing one half of a particular diatom which is a most difficult object to photograph (enlarged 3000 diameters). *Amphipleura pellucida* gave the transverse striae (they are about 100,000 to the inch) with great clearness.

Mr. J. Chrichton Timpany's (bronze medal) set of views of Peel, included a very pretty representation with vessel in the near foreground

and the castle in the distance the sun striking its outlines at a few salient lines with considerable effect.

The Class for Lantern Slides showed, for Liverpool, a remarkable falling off in numbers. We cannot refrain from drawing attention to Mr. H. J. Houghton's set of six, which included some most beautiful winter scenes and one most picturesque representation of Eastern life.

Mr. J. Parkinson's river scenes were excellent, the set being marred by one very ineffective view mainly of a rhododendron bush which by accident or design was suffused with a pink tone. Mr. Gostenhoper's and Mr. S. Cann's bronze medalled slides were good, but the competition was not close. We feel that in this direction Liverpool has not done herself justice, having regard to the small number of slides sent in for competition.

## Our Editorial Table.

A SELF-TONING LINEN FABRIC.

O. Sichel & Co., 52, Bunnhill-row, E.C.

We drew attention some time ago to the agreeable effects producible on the self-toning papers of Messrs. Sichel & Co., purple or sepia colours being obtainable by simple fixation and washing. The latest introduction of the self-toning series is the "S. T. Linen Fabric," which is treated in the same manner as the paper, and sold at the same price. Having a stout back, as Messrs. Sichel point out, it is not necessary to mount rough specimens, although for finished prints it can easily be mounted. We append the principal working instructions to illustrate the simplicity of the process, which, as we have said, gives capital results:

Print (under tissue paper if in the sun) a shade darker than is desired in the finished prints.

The prints may be put directly from the printing frame into the hypo bath; but, to prevent getting spots from air blisters or hypo fingers, it is advisable to place them first in clear water until thoroughly soaked, and then into a solution of one ounce of hyposulphite of soda (crystals) and twenty ounces of water, hydrometer test 20. Keep the prints moving in this solution for five minutes, then wash in running water until the hypo is entirely removed, which takes an hour; or, if washed by hand, take at least eight changes of clear water. Mount as usual. Burnish like albumen pictures, using as little soap as possible for lubricating; the brilliancy of tone of the prints is brought out by burnishing. For matt a cold burnisher is used.

For carbon (black-and-white) effects, print several shades darker than desired in the finished print. Wash the prints in three changes of clear water, and then place them in any good platinum bath until the reddish brown disappears from the deep shadows. After this, give one wash in clear water, and then place in hypo solution as above directed.

In sending us a copy of their twenty-four-paged, neatly produced price-list of printing and enlargements, Messrs. Elliott & Son, of Park-road, Barnet, ask us to intimate that they will be pleased to supply all professional photographers with a copy on application.

THE HELIOTYPE MATT PAPERS.

Agents: Holmes Bros., 24, Southall-street, Manchester.

For this new series of papers the following are claimed as the chief characteristics: 'Great range of tone, from bright red to dark purple and from sepia to dark brown with a simple gold toning bath; also to the purest black with a platinum bath. Absolute purity in the high lights; an entirely new surface in the basis of the paper; great ease in manipulation; uniformity of results; absolute permanency if instructions are carefully followed; no cracking, curling, or discolouration; keeping quality good; no special negatives required; great economy in working, it requiring very little gold.'

The paper is supplied in three qualities, coated upon different raw paper: T, rough paper, with a grained surface, suitable for large portrait work, &c.; E, smooth grain, suitable for small portrait work, &c.; A, medium rough grain, suitable for landscapes and also portrait work. We append the principal working instructions:—

Before printing, hold the paper from four to six minutes over a dish containing liquid ammonia (880), the coated side downwards, so that the ammonia vapour can penetrate it. Print rather vigorously until the shadows appear bronzed and all the details are out in the high light. Wash in various changes of water for five to ten minutes. Immerse the prints for two or three minutes in a bath of 2½ to 5 drachms of table salt to 5 or 6 ounces of water. Wash again in several changes of water until the latter is quite clear.

No. 1.—RED (LIGHT AND DARK) AND BROWN TONES, &c.

Tone in the following solution, taking 10 parts of A to 2 parts of B:—

A.	
Distilled water.....	¼ pint.
Refined borax.....	½ drachm.
Acetate of soda.....	¼ " "
Citric acid.....	2½ grains.

B.	
Distilled water.....	$\frac{1}{4}$ pint.
Chloride of gold .....	$2\frac{1}{2}$ grains (or 15 grains to $1\frac{1}{2}$ pints).

Stop toning when the desired colour is reached. By leaving the prints for two or three minutes at the utmost in this bath, with its minimum of gold, tones of a very vivid brown red are obtained. After washing, immerse the prints for five minutes in a sulphocyanide bath— $3\frac{1}{2}$  drachms of sulphocyanide of ammonia to  $1\frac{1}{2}$  ounces of water. The fixing by sulphocyanide of ammonia is superior to hyposulphite of soda, especially for the red and brown tones. Wash again in one or two changes of water, then complete fixing by a five to ten minutes' immersion in a hypo bath: strength,  $\frac{1}{2}$  ounce of hypo crystals to 60 ounces of water.

No. 2.—FOR BLACK TONES.

After washing, immerse the prints in the following bath:—

Distilled water.....	$2\frac{1}{2}$ ounces.
Chloro-platinite potassium .....	2 grains.
Lactic acid (acid of milk) .....	$\frac{1}{4}$ to 1 drachm.

According as more or less of the lactic acid is added, the results are from a warm black (dark brown) to cold bluish tone. Wash the prints in several changes of water and then fix.

Some excellent testimonials as to the qualities of the prints and their permanent nature are published.

DIE CHEMISCHEN VORGÄNGE IN DER PHOTOGRAPHIE.

By DR. R. LUTHER.

Wilhelm Knapp, Halle a/S.

THIS work forms Volume XXXVI. of Wilhelm Knapp's well-known *Encyclopädie der Photographie*, and consists of six lectures on the chemical processes of photography, delivered by the author at Leipsic. They are written in a popular style, and, being characterised by great lucidity, will be very valuable to those who wish to know something of photography in its chemical aspects.

DEUTSCHER PHOTOGRAPHEN-KALENDER. TASCHENBUCH UND ALMANACH FÜR 1900.

Verlag der Deutschen Photographen Zeitung, Weimar.

THIS is a very handy reference pocket-book for German photographers, issued under the editorship of Herr K. Schwier. The collection of formulæ is very extensive and good, and considerable care has been bestowed upon the table of chemical compounds. The peculiarities of English weights, however, seem past comprehension abroad. If German photographers take the pound avoirdupois according to the components given in the book, they will be hopelessly muddled, as the drachm is said to consist of three scruples of seventy grains each.

THE "RAY" AND "KORONA" CAMERAS.

Agents: A. E. Staley & Co., 35 Aldermanbury, E.C.

FOR some time past Messrs. Staley have possessed the agency of several makes of American cameras, and at the present time they hold a very

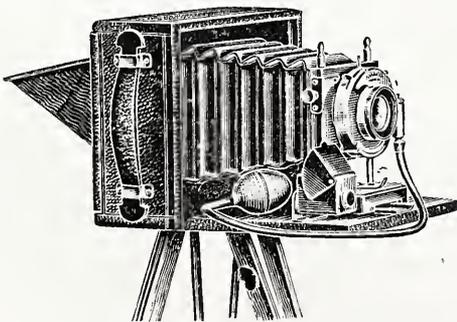

FIG. 1.

considerable stock of them to meet the demands that may be safely anticipated in the season now imminent. Whether regarded as instru-

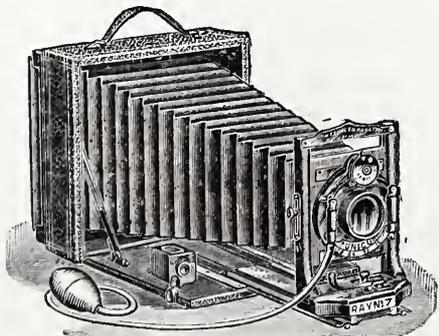

FIG. 2.

ments for taking photographs or as products of mechanical ingenuity, one cannot help admiring these cameras. They are compact and in-

expensive, and as regards movements are adapted for most kinds of work the ordinary amateur is likely to undertake. Both the series named at the head of this notice (figs. 1 and 2) are supplied with three double dark slides, achromatised single lenses, time and instantaneous shutters. They are well covered in leather and neatly finished. A feature is made of an extensible Korona for long-focus work. The Ray Special (fig. 3) is made

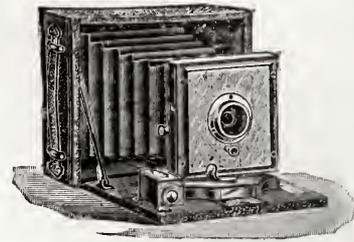

FIG. 3.

of pine wood, covered in leather. It is adapted to take daylight cartridge-holders as well as dark slides; has a Bausch & Lomb single lens, with time and instantaneous shutter; reversible view-finder and focussing scale; polished brass fittings; three double dark slides, and a case. This camera is sold for 35s. complete. All these instruments are excellent value for the money, and are of a kind to successfully appeal to many amateurs.

THE "LUXIA" PRINTING PAPERS.

Manufactured by Berger & Co., Southill Works, Hampstead, N.W.

To the list of printing papers for which they are steadily gaining an excellent reputation, Messrs. Berger & Co., have recently added the manufacture of bromide and "gaslight" photographic printing surfaces. The first-named is issued in six varieties: smooth slow; rough slow; smooth rapid; rough rapid; enamel surface slow; enamel surface rapid. The "gaslight" paper is in three varieties: smooth matt; rough matt; enamel surface. From an examination of the samples sent us we conclude that the "Luxia" papers are very carefully made and are capable of giving exceedingly good results in these methods of photographic printing and enlarging. We append the substance of the makers' instructions for working the papers; but it should be added that in addition to the formulæ mentioned the papers work well in amidol, adurol, or any of the usual developers:—

*Bromide Papers.*—With negatives of average density, expose the slow paper for about thirty seconds at twelve inches from the flame of an ordinary No. 4 gas burner, and the rapid paper for about five seconds at the same distance.

*Development.*—The following developer is recommended as being clean, economical, and thoroughly under the worker's control:—

Sodium sulphite crystals.....	1 ounce.
Water (boiled) .....	20 ounces.
Sodium carbonate crystals.....	1 ounce.
Hydroquinone .....	60 grains.
Metol .....	10 "
Potassium bromide .....	5 "

For use, add 1 ounce of above to 2 ounces of water.

Before developing, dip the exposed paper into water for an instant to prevent bubbles forming on the surface. Several prints in succession may be developed in the same solution. Immediately development is complete, immerse the print for a minute (without previous washing) in a little of this clearing solution:—

Glacial acetic acid .....	1 ounce.
Water .....	80 ounces.
Common salt.....	120 grains.

Then, after well rinsing, place the print for ten minutes in the following fixing bath:—

Hyposulphite of soda .....	4 ounces.
Water .....	20 "

*Gaslight Paper.*—This paper may be unpacked, placed in the printing frame, removed, developed, &c., at a few feet from the subdued flame of any ordinary gas or lamp light. It is only necessary that the direct rays of light should be screened off by the worker's back being kept opposite the flame so as to throw a shadow upon the paper during the above operations.

*Exposure.*—With average negatives, expose for about thirty seconds at twelve inches from the full flame of an ordinary No. 4 gas burner.

*Development, &c.*—Precisely the same as for Luxia bromide paper (see above), except that the work may be freely done, as already described, in ordinary gas or lamp light, of which sufficient may be used to enable the worker to see with comfort.

## News and Notes.

PHOTOGRAPHIC CLUB.—February 7, at eight o'clock, lecture by Mr. H. J. Klosz, "A Holiday in Norway."

AFTER February 20, Mr. Theodore Brown's address will be the Stereoscopic Supply Stores, 34, Castle-street, Salisbury.

THE Earl of Crawford, who was in town last week to attend the wedding of his son, Lord Balcarres, has returned to Naples to pass the remainder of the winter.

ROYAL PHOTOGRAPHIC SOCIETY.—On Tuesday, February 6, at eight p.m., Mrs. Catharine Weed Ward will give a lecture entitled "Shakespeare at Home," illustrated by slides from her own photog.aphs. Ladies are specially invited.

EALING PHOTOGRAPHIC SOCIETY.—The next meeting of this Society will be held at the Public Buildings, Ealing, W., on Monday, February 5, at 8.15 p.m. Lantern Evening. Subject, "A Cruise to Northern Capitals," by Mr. T. Simpson.

KODAK (Limited) will shortly place on the market a print-out sepia paper, which is described as giving warm brown shadows and half-tones, with mellow, creamy high lights. The prints are said to be especially effective when made from broad, sketchy negatives. The paper is about three times as rapid as blue paper. It is developed by washing in plain water and fixed in hypo; short fixing gives red tones, longer fixing brown tones.

THE GOLDSMITHS' INSTITUTE CAMERA CLUB, NEW CROSS, S.E.—A popular lecture will be delivered in the central hall of the above Institute on Thursday, February 22, at 8.15 p.m., by Mr. F. O. Bynoe, entitled "The Camera, an Instructive and Amusing Companion." The lecture will deal with the various phases of camera work, including the hand camera in modern warfare, and will be magnificently illustrated with limelight views, diagrams, and mechanical slides. Tickets and programmes free of the Hon. Secretaries, or of the principal City photographic dealers.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.—At the Annual General Meeting the election of officers resulted as follows:—*President*: Mr. J. T. Middlemore, M.P.—*Vice-Presidents*: Messrs. J. F. Hall-Edwards, L.R.C.P., F.R.P.S., C. J. Fowler, F.R.P.S., E. C. Middleton, and T. W. Robinson.—*Council*: Messrs. C. S. Baynton, P. W. Brown, W. T. Greatbatch, F.R.P.S., W. W. Hollingsworth, J. Hewitt, F. Lewis, T. Taylor, and E. Underwood.—*Lanternist*: Mr. B. Moore.—*Hon. Librarian*: Mr. G. Whitehouse.—*Hon. Treasurer*: Mr. Richard Hames.—*Assistant Hon. Secretary*: Mr. Lewis Lloyd.

THE COLOUR SENSE IN MAN.—Dr. Rikers dealt with the colour sense in the second of his series of lectures at the Royal Institution last week. His investigations among the savage tribes of Torres Straits and Australia tended to prove that there had been, within historic times, a development of the colour sense; but, whether that were so or not, there certainly had been a development of colour language. It was in 1858 that Mr. Gladstone drew attention to the vagueness of the colour terminology used by Homer, who seemed to appreciate little more than the differences between bright and dark colour. In hardly any of the ancient literatures, indeed, was there a term for blue; and this coincided with investigations made among savages, who under "black" included all violets and blues.

MR. W. HOLT, of Fairholme, Manor-road, Barnet, sends us proofs from process blocks, illustrating his new patent vignetting machine, of which he also supplies the following notes: The copy is placed on the board, and, after regulating the size of vignette required, the machine is set in motion, with the result that a perfectly natural, graduated, vignettted negative is obtained without any artist's work on copy. I claim several advantages for vignettes executed in this way, the principal being the absence of the snow effect so pronounced when obtained by the air brush; second, the varnishing away of the picture where the actual white begins; third, any subject can be treated with this machine. Water colour, copies with black backgrounds, any squared-up subject or oval can be vignettted to look most artistic by its aid.

DEATH OF A PHOTOGRAPHIC PIONEER.—Just as the fleeting hands of time indicate the approach of the centenary of Fox Talbot, one of the pioneers of photography, on Wednesday week, passed into that bourne from which no traveller returns; in other words, the Rev. Dr. Graham, minister of the parish of Errol, died on January 24 at the advanced age of eighty-two years. For over forty years he attended, unaided, to the spiritual wants of the parish, but two years ago declining vitality told its tale, and an assistant was appointed. Before his induction at Errol he was for a number of years minister of Abernethy, and here he enjoyed the friendship of Lord Kinnaird. In the early days of photography Sir David Brewster, brimful of the new discovery, paid a visit to mine host of Kinnaird Castle, and while resident there Sir David received further details of the new discovery, that was then the topic of conversation in scientific circles. With that insatiable desire for knowledge that is inseparable from scientific men, it was determined to experiment in the new-born science. Lord Kinnaird, himself a scientist of no mean reputation, was well acquainted with the scientific leanings of the parish minister, sent for the worthy parson, and the three enthusiasts forthwith began their experiments. The privacies of the domestic apartments were invaded, and pails, tubs, and all sorts of receptacles were pressed into the service to assist in the work. After the departure of Sir David Brewster, the two local men continued their investigations. Dr. Graham had prior to this date made a hobby of optics; this leaning was particularly useful in the new pursuit, and the doctor made and ground the necessary lenses. Up to the present time the old doctor has taken a deep interest in photography, although for a considerable time past he has ceased to practise it. His collection of lenses, mostly all made by himself, is a very fine one, and his intimate knowledge of the earlier struggles of the art made his "crack" highly interesting to the photographer of to-day. A kindly, genial man, his death will be a sad loss to his congregation and the district in which he laboured.

## Commercial Intelligence.

MR. W. D. WELFORD has commenced business at 19, Southampton-buildings, Chancery-lane, W.C., as a manufacturer of photographic preparations—developing and toning solutions, cloud negatives, vignettes, printing sets, &c.

MESSRS. WELLINGTON & WARD, of Elstree, announce that the Wellington film is now ready. The following are the prices: Cut films, quarter plate, 1s. 2d.; 5x4, 1s. 8d.; half-plate, 2s. 6d., &c. Daylight spools (twelve exposures), 2½ inches, 1s. 3d.; 3½ inches, 1s. 6d.; 4 inches, 2s. 3d., &c.

MESSRS. TAYLOR, TAYLOR, & HOBSON, of Stoughton-street Works, Leicester, inform us that many requests reach them to fit their Cooke lenses to Kodaks and other American cameras. They add: "It is found that the comparatively dull light of the English climate necessitates, for many purposes, a lens of larger aperture than these cameras possess." Messrs. Taylor, Taylor, & Hobson have decided to make a speciality of the work of refitting such cameras with Cooke lenses, and they are issuing a price-list for this work.

## Patent News.

THE following applications for Patents were made between January 15 and January 20, 1900:—

ANIMATED PHOTOGRAPHY.—No. 922. "Improvements in or relating to Apparatuses which Photograph and Reproduce Moving Scenes." A. ST. V. BURNABY.

COATING APPARATUS.—No. 994. "Improvements in Apparatus for use and in connexion with the Coating of Photographic Films and Plates with Sensitive Emulsions." C. E. HEARSON.

CAMERAS.—No. 999. "Improvements in or relating to Photographic Cameras." H. B. SHARP and H. C. HITCHMOUGH.

BALLOON PHOTOGRAPHY.—No. 1060. "The Automatic Photo Detective Balloon." C. H. H. TIFFIN.

VIGNETTER.—No. 1108. "A New or Improved Vignetter." Complete specification. A. MAURICE.

SHUTTER.—No. 1187. "An Improved Photographic Shutter." A. J. E. HILL.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 25,—Mr. A. L. Henderson in the chair. With reference to the question of the relative exposures required for backed and unbacked plates, Mr. A. J. BROWN said it was well known to old wet-plate workers that, if one were short of time and the plate required a little

more exposure than could be given in the ordinary way, it was usual to back the plate with white paper. This expedient tended to quicken the plate, although strictly the effect was merely to add the reflected light.

The CHAIRMAN mentioned a dodge, which was not generally known, of preventing halation. A plate that has been as evenly coated as possible is placed in contact with the plate upon which the exposure is to be made, film to film. The exposure is made through the additional plate, allowance being made for interference with definition by the intervening layer of glass and sensitive film. There seems to be no diminution of definition, and a plate exposed under the protection set forth, even to an interior subject with great contrast, would exhibit no signs of halation. The exposure, of course, is prolonged. The protective plate may be used for the same purpose again and again if not developed. By using a highly restrained developer, however, even this front plate may be developed satisfactorily, the result, of course, being a reversed image, which has its advantages.

**Brixton and Clapham Camera Club.**—January 16, Eleventh Annual General Meeting, Mr. J. W. Coade in the chair.—The report of the Council was read, showing the Club to be in a far more satisfactory state than last year, its position and prospects better and brighter. The membership had increased, and the financial position was good, with a balance to the credit of the Club, large assets, and no outstanding liabilities. The thanks of the Council were tendered to those who had supplied the excellent series of papers, demonstrations, &c., during the year. The Council also expressed their satisfaction at the increased attendance at the Club meetings. The election of officers for the current year was declared as follows:—*President*: Mr. W. E. Dunmore.—*Vice Presidents*: Messrs. J. W. Coade, W. Fraser, and F. W. Levett.—*Council*: Messrs. A. R. Clench, R. Fisher, L. E. Mongiardino, W. H. Stoneman, and W. Redman.—*Librarian and Curator*: Mr. L. W. R. Cundell.—*Lanternist*: Mr. R. G. Mason.—*Hon. Secretary*: Mr. R. McKinley Milne, 77, Atlantic-road, Brixton.—*Assistant Secretary*: Mr. L. E. Mongiardino. Votes of thanks to the retiring Committee were carried. The recommendation of the Council that an Exhibition should be held in March next was discussed and adopted, substantial support being guaranteed by the members present. Mr. Dunmore, on his election, addressed the members, asking for their hearty co-operation and support in maintaining and increasing the position of the Club.

**Hackney Photographic Society.**—January 23, the President in the chair.—Mr. HUDSON showed some lantern slides developed with metol, to which had been added some hydro solution. A very good brown tone was the result. One of the best lectures that the Society has ever had was that given by Mr. R. CHILD BAYLEY on the subject of

#### SOME RECENT DEVELOPMENTS IN PHOTOGRAPHY.

The potassium-permanganate reducer, discovered by Dr. Namias, and Mr. Ferguson's copper ferricyanide toner were both successfully demonstrated and shown to be very valuable aids to the photographer. Mr. Bayley also dealt with developing after fixing, the theory of the latent image, hand-camera work and its associated subject, enlarging, and, finally, with the development question.

#### FORTHCOMING EXHIBITIONS.

1900.	
February 10-24	Edinburgh Photographic Society. J. S. McCulloch, 10A, George-street, Edinburgh.
„ 24-March 3	Birmingham Photographic Society. Lewis Lloyd, The Hollies, Church-road, Moseley.
March 3-10	South London Photographic Society. Hon. Secretary, Frank Goddard, Woodlands, Vanbrugh Hill, Blackheath, S.E.
„ 26	Twentieth Century International, Birmingham. Walter D. Welford, 19, Southampton-buildings, Chancery-lane, London, W.C.
„ 26-31	Photographic Society of Ireland. W. F. Cooper, 35, Dawson-street, Dublin.
April 3-7	Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

#### THE MANUFACTURE OF CINEMATOGRAPH FILMS.

To the EDITORS.

GENTLEMEN,—Our attention has been called to an inspired article in the *British Journal of Commerce* in which it is erroneously stated that our film factory at Walton-on-Thames is under the control of the Warwick Trading Company. This mistake has obviously arisen from the fact that we do a very large proportion of the film work of this company,

while they handle the bulk of the output of our own series of "Hepworth" films. We are fully sensible of the honour done us by the coupling of our name with that of a firm the quality of whose work is well known to be second to none, but we feel it to be only due to ourselves and in justice to the trade generally to contradict the impression conveyed—doubtless inadvertently—and to state that we are not connected in any way whatever with this or any other firm.

We should also like to point out that the patent developing machine—which is also credited to the same Company—and by virtue of which alone it is possible to develop and print from negatives of 1500 feet in length in one piece, is in reality part of the equipment of our Walton factory, and we are sole possessors of the entire patent rights.

We are equally certain that the Warwick Trading Company would be the last to wish to convey an erroneous impression, and the first to desire that it should be corrected if by any accident it should gain currency.

Apologising for thus trespassing upon your space, and thanking you for the courtesy which permits us to do so,—We are, yours, &c.,

Walton-on-Thames, January 23, 1900.

HEPWORTH & Co.

#### AMMONIUM PERSULPHATE FOR REMOVING PYRO STAINS.

To the EDITORS.

GENTLEMEN.—A large proportion of your readers adhere to pyro, the good old developer which I prefer, but, like myself, object seriously to resultant staining of the hands. For the benefit of such I beg leave to state personal experience. I do not claim a discovery. Some months ago I saw, in one of the JOURNALS, the suggestion of the use of ammonium bisulphate made into a paste with water. Obtaining one ounce from a prominent manufacturing chemist (who was unable to state whether or not it was applicable to the purpose, or as to its stability in solution) I dissolved in six ounces of distilled water. Since, my custom has been, when having completed development and put the dark room in order, to thoroughly wet the hands, pour a thimbleful, or less, of the solution in the palm of the left hand, put the fingers of the right hand into it and work down the fingers of both hands. With me the result has been most satisfactory, the stains proving rapidly fugitive. The quantity used is so small, that at three months from the date of preparation of the solution the bottle is not exhausted, and that it remains effective is a guarantee of its stability. I should add that I have not tested its efficiency for stains of more than a few hours' duration, nor for those which have been exposed to daylight.—I am, yours, &c.,

J. HARMANUS FISHER.

16 South-street, Baltimore, January 12, 1900.

#### ARTICLING PUPILS IN PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Your reply to "Guardian," in Correspondence, I very much admire; but why not go a little further, and advise him to invest the 75l. in a studio and apparatus all complete? then, with a few packets of plates and paper, some ready-mixed developer, &c., &c., the youth would be able to start as a professional photographer, without wasting three years and 75l., and no doubt by next year we should have the pleasure of seeing some of his work in the Salon, and an article or two written by him specially for THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1901, such as "A Use for Over-exposed Bromides," or "Will Backing a Plate shorten or lengthen Exposure."—I am, yours, &c.,

11, Knowsley-street, Bolton, January 24, 1900.

A. WEBER.

To the EDITORS.

GENTLEMEN,—Nothing to learn indeed! I can only say that, after my son had learnt his business here well, I should, a few years ago, have been very willing to pay a hundred guineas to learn what he could at any first-class London or large town house, simply to be there six months and keep his eyes open! It is quite true that bricklaying often pays better than photographic assistantship, but the mere knowledge of how to lay a brick does not make a bricklayer, he must practise. While, on the other hand, I'll turn out a photographer in two hours after his first lesson; but I won't pay him a cent for his services. I want a man who knows his work, knows good work when he sees it, and can remedy matters when he or his subordinates get wrong. I want a man used to handling things, who can do his work deftly and quickly, and it wants a precious lot of practice to do that, I assure you, and to know and be able to fulfil the requirements of a first-class portrait studio. One of my old apprentices paid fifty guineas as improver, though he had already paid me a hundred. His employer says he is the best trained hand he has had. So much for the value of training. I don't say a word about whether photography, as a profession, is worth taking up "that is another story." I am, yours, &c.,

PHOTOGRAPHER.

To the EDITORS.

GENTLEMEN,—Many photographers will be pleased you have again touched upon the question of premiums. Though I fully endorse much you have said, I fear you miss the point from which the cause of much of the depression emanates. With your permission I should like to state my own views, which may not in every way coincide with yours, but are

the opinions of one who charges a premium. Taking the question of remuneration first—in the advertisement you quote "Operator and Retoucher, quick and good. Open Sundays. Wages, 21s." What the advertiser would consider *good* would probably be considered *very bad* in a good-class studio; but surely such men do not charge premiums. There are unquestionably a great number of duffers in the trade, and it is here where the shoe pinches. The labour market cannot be said to be overstocked with clever men. As an example, last year I had occasion to advertise three successive weeks for a retoucher; the first week brought me three replies, the following two weeks I had about half a dozen more. Judging by their specimens, there was only one I should have cared to make shift with—his terms were 35s. per week; he wired later to say he had been engaged in the mean time. I answered all advertisements, and scarcely any replied to my letters, by which I concluded they also had been engaged before my letters had reached them. Now, the only reason I can assign for the great number of duffers in the trade is that so many people are under the same wrong impression as yourself, *i.e.*, "that there's so little to learn in photography now that everything is supplied ready for use, with full directions for using them."

I once knew a young mechanic (who for some reason had been out of work for some time); he took up photography, and persevered with it until his friends flattered him his work was as good as anybody's in the town; he then opened a studio; he did his best, I will give him credit for that, but, for the want of that knowledge which is not printed on the instructions with the goods we buy, he went to the wall. I believe he is now an assistant in some small studio at a starving wage. His experience, for which he has paid so dearly, is of no value to his employer.

Every parent or guardian apprenticing a youth to photography should have a full understanding what is to be taught. Operating (that means assisting the operator in the studio), dark-room work, enlarging, printing, mounting, and working up enlargements in black and white, should all be stipulated. The term of apprenticeship should not be less than three years, and, as his services during that time are not of much value to his master, it is only to be expected a premium will be required, the greater portion of it being returned in the way of salary or pocket-money, optional according to circumstances. Another vital point is that all complaints of indolence or carelessness should be made at the time to the parents; it is mistaken kindness to the youth not to do so. Then, if, when his time is up, he is not worth a journeyman's wage, I should say the fault lies with him.—I am, yours, &c., J. W. BEAUFORT.

Colmore-row, Birmingham.

### FREAK PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Reading THE BRITISH JOURNAL OF PHOTOGRAPHY, January 19, 1900, I see in Correspondence, under the heading of "Freak Photography," A. Levy speaks of a friend of his taking some photos on a Kodak film, and a clerk or dealer (by mistake) changing them for a new reload. He then says that a future customer, after taking twelve more pictures on the before exposed reload, would be surprised to find double photos. This could not be the case, as Kodak films, after being rolled off once, cannot be rolled back on again, as the latter end of the film is not attached to the black cover paper, also the word "exposed" is stamped in white on the end of each spool. Could you in your next issue let A. Levy know of this, you will oblige.—I am, yours, &c., W. BLOOMFIELD.

14, Guildford-road, Tunbridge Wells, January 24, 1900.

### THE METRIC SYSTEM.

To the EDITORS.

GENTLEMEN,—I read with much pleasure "Free Lance's" dissertations as regards the metric system. He seems to ignore that a kilogramme is divided here into two pounds, and that a Frenchwoman buys just as easily here as an Englishwoman in England one pound of bread or half a pound of coffee (more used here than tea), and she asks just as easily for one quarter pound of butter, and if she does not say one-eighth of a pound, nor 125 grammes, she knows how to ask for half a quarter of a pound. I fail to see why the English pound has more adaptability to subdivision than the French pound.

Outside of this little explanation I feel not the slightest concern about England using the easy kilogramme as against their much easier and less complicated measures and weights, called miles, yards, feet, inches, or their stones, pounds, ounces, drams, scruples, grains, minims, which are simplicity itself, even when they are divided again into *avoirdupois* and *trois*.—I am, yours, &c., A. LEVY.

Asnières (Seine), January 24, 1900.

### PARIS EXHIBITION, OR ENGLISH EXHIBITION.

To the EDITORS.

GENTLEMEN,—In your issue of January 19, 1900, the Paris International topic is again creeping up. The closing time for application to

exhibit at the same was August 1898, and only now is the fact leaking out that two prominent amateurs have the sole right to select from among their friends (therefore not restricted to applicants) the material for making a representative show of English photography. Where are you now, you poor professionals? Even if you applied for space at the proper time, you are not considered worthy to receive even courteous treatment. After such a slap in your face, I trust the few professional photographers who have attained the amateur standard, and are invited to exhibit, may politely decline, as a protest against the treatment meted out to a body of respectable, hard, and honest workers.

For some years we have had a fortnightly review of amateur work, which are not much good to the professional. Would it not be possible to hold a national, or even international photographic exhibition this year for professional photographers and applied photography, naturally with prize competitions, say two per cent., first diplomas; ten per cent., second; and twenty-five per cent., third class?

You will say we had one two years ago. Yes, it was a nice show of plates, paper, apparatus and other material, little huts and kiosks, a lot of ancient photographs, with a small amount of modern photographs from nearly a dozen professional photographers. We want a show representing 500 photographers, don't we?

Who will take the lead in starting such an enterprise? I feel sure our Editor, and worthy champion for professionals, will act *ad interim*; therefore all those who are eager to show in the above way what the professional can do should write a letter of support to him, and, if our Mr. Bedding sees there is support, he would arrange a constituency meeting of the would-be exhibitors, at a London terminus, to elect an acting committee.—I am, yours, &c., OTTO PFENNINGER.

Brighton, January 27, 1899.

### "THE ABSENT-MINDED BEGGARS."

To the EDITORS.

GENTLEMEN,—Our respected and esteemed townsman, Dr. Hall-Edwards, so well known as a skilful amateur photographer and as an expert in X-ray work, has been commissioned by Government to go to the front for hospital work.

Dr. Hall-Edwards is appealing for donations of suitable apparatus and photographic materials, and informs me he is in special need of a good dynamo to light the operating theatre. Now, I feel sure there are hundreds of photographers who will be ready to help in this object, and who, not being able to fight, will be willing to "pay, pay, pay."

I will give *twelve quarter-plate Tit Bit hand cameras* to be distributed among those who contribute 1s. to enable me to accomplish my design, and I will find all the necessary clerical work involved to carry it to a successful issue.

A friend has already promised to supply all the printed receipts free of cost.

To every one who sends twelve penny stamps and a directed and stamped envelope a printed receipt bearing a number will be sent. This receipt must be kept, and in the first March issue of the photographic paper where you saw the notice a list of twelve numbers will be published by the courtesy of the editors. Any one holding a receipt bearing one of these numbers will be entitled to receive a Tit Bit camera free on application.

A committee of well-known Birmingham gentlemen will be formed to see that the drawing of the numbers is carried out in a proper manner.

In Birmingham a safety bicycle offered in this way realised 260l. It will be interesting to know what the twelve Tit Bits will realise. If the sum is a large one, then I propose to divide it in two portions, and devote half to the photo-medical staff requirements and half to one of the funds for the relief of "those Tommy has left behind him."

Address your letter clearly—"The Absent-Minded Beggar Fund, W. Tylar, 41, High-street, Aston, Birmingham." Hurry up your shillings, please, and let the postman flood us at every post; let the world see what the photographic section can do.—I am, yours, &c., W. TYLAR.

41 High-street, Aston, Birmingham.

[We trust Mr. Tylar's laudable efforts, which have for their object the alleviation of the pain and suffering caused by the War, will be heartily seconded by our readers.—EDS.]

### FOGGED PLATES.

To the EDITORS.

GENTLEMEN,—I am much interested in your letters on foggy plates. I have had another such a Christmas as H. C., with whom I sympathise; but, instead of fog around edges, my plates were fogged all over in patches. As they were fresh from maker, I returned an unopened box, and they admitted the fact, and, I am bound to say, very kindly sent me new plates for all the faulty batch I had free of expense.

Re dealers, last year I had a box of plates sent me that were totally fogged. On inquiry of the plate-maker, I discovered they were made in May 1891.—I am, yours, &c., OTHELLO.

## THE THORNTON GLASSOLINE FILM.

To the EDITORS.

GENTLEMEN,—I read with interest your notice of the Thornton Film Company prospectus in the current JOURNAL, and as one of the existing celluloid-film makers, and as the introducer of "Setoloid," I thank you for the fairness of your criticism. I am so used to seeing the existing films condemned in each new prospectus, and the condemnation copied into the photographic papers, that your innovation comes with a pleasant shock.—I am, yours, &c.,

AUSTIN EDWARDS.

Photographic Film Works, Warwick, January 27, 1900.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

## PHOTOGRAPHS REGISTERED:—

W. B. Samuel, 7, Claylands-road, Kennington, S.W.—*Photograph of Princess Wales Theatre, Kennington.*

W. H. Bustin, The Studio, Palace-yard, Hereford.—*Two photographs of the Bishop of Hereford in his study Photograph of a bull.*

J. A. Horsburgh, 4, West Maitland-street, Edinburgh.—*Photograph of the Right Hon. J. B. Balfour, Lord Justice-General of Scotland.*

SEPIA BROMIDE.—The tones you require may be obtained by means of the uranium bath. For formulæ see the Formula Section of the ALMANAC for 1900.

RECEIVED.—PROFESSIONAL; STUDIO; CENSUS; W. T. DRAY; COL. MITCHELL; K.; E. J. H.; ENQUIRER; CONSTANT READER; and many others. These will be answered in our next.

SUBSCRIBER.—We fear that you will find it an impossibility to remove the image without affecting the support. Aqua regia (nitro-hydrochloric acid) is a solvent of the platinum, but it would also attack the paper.

APPRENTICE.—We believe that you must conform to the hours prescribed by your employer. There is no recognised rule as to hours in the profession. If the matter is of importance to you, we should advise you to consult a solicitor.

C. R. (Spalding).—1. The tones you refer to are obtained by using suitable negatives and implicitly following the printed instructions. We imagine that you have erred in these respects, but it is impossible for us to guess to what extent.

T. KING.—1. Use orthochromatic plates and a screen and you will find no difficulty in securing clouds in your negatives. It is such a simple matter that you do not require any further hints. 2. Much obliged for the enclosure; we retain it for reference.

VICTOR SELB.—We doubt if you will easily obtain such a lamp. Mr. Pringle, in the last edition of his book on *Optical Projection*, states that the Swan-Edison Company (address, Parliament-street, London) makes a special form of lamp for projection purposes. A letter to the Company would bring you further particulars.

PORTABLE STUDIOS.—M. E. BRADFORD writes: "Will you tell me to whom to apply for particulars as to dimensions and price of Herr Schaezter's portable studio?"—In reply: We are unable to say if the apparatus, which is of German origin, is on the English market. Some reader may possibly supply the desired information.

COPYRIGHT.—T. ERWIN asks: "Can I prevent the editor of a certain illustrated paper publishing some unregistered photographs of mine without express permission from me? The photographs I gave gratis to a customer of mine, who in reply to a letter from the said editor sends on the photographs."—In reply: Without registration you have no legal protection of your photograph.

A COPYRIGHT QUESTION.—EXCELSIOR says: "A client has been photographed with a certain article in several positions, and I have discovered these positions are copied from a celebrated illustrated magazine. Am I liable under the Copyright Act, or is my client, or either?"—In reply: We think not. The mere imitation of a position scarcely amounts to a "copy" of a picture; hence, in our opinion, there is no infringement.

CELLULOSE COMPOUNDS.—R. T. WALL says: "I have written to Bevan & Cross to inquire for aceto-cellulose. They say they do not sell it commercially. In THE BRITISH JOURNAL OF PHOTOGRAPHY, December 8, 1899, I saw that tetracetate of cellulose and hydrate of cellulose are now produced on a large scale. I think hydrate of cellulose would suit me best. Can you advise me how to obtain it?"—In reply: We are sorry we cannot indicate the source of supply. Some chemical reader may, however, supply the information.

COPYRIGHT IN MUSIC.—CURATE writes: "I am getting up an entertainment in our village, and I propose to make lantern slides of two songs, with the music, to throw on the screen for the children to sing. The songs are marked copyright and must not be sung in public without permission. Would doing what I propose be considered an infringement? Does the copyright cover lantern slides made by photographic means?"—Yes, certainly; it would be illegal to do what you propose without the consent of the publishers.

DAN.—1. The ceramic process would give the most permanent results. 2. The picture should be protected from atmospheric influences. 3. Nothing better than cement. 4, 5, 6, 7. *Induction Coils*, by Alsop, published by E. & F. N. Spon, 125, Strand, and *Practical Radiography*, published by Dawbarn & Ward, 6, Farringdon-avenue, E.C., should be of service. 8. By unscrewing the back cell softened definition is obtained; probably the marks you describe have reference to this power. 9. Quite rapid enough for studio work. 10. We know of no such book. 11. Not yet.

STUDIO REPAIRS.—C. J. J. asks: "Whose place is it to paint the inside and repair the roof of the studio, the landlords or the tenants? I took the place for three years, and the landlord painted it inside and out at the time. Now it has got very shabby and the roof leaks in places. The landlord says, if I now want anything done, I must do it myself. Can I compel him to do the needful, for it wants doing badly?"—It all depends upon the agreement. Unless it is stipulated that the landlord is to do the repairs, the tenant will have to do what he requires to be done. If it is for his comfort, and not for that of the landlord.

SULPHIDE TONING.—OTHELLO says: "I find I can get a nice chocolate tone on bromide prints by immersing them in a weak solution of sulphide of potassium (liver of sulphur) all night. What I should like to know is, Do you consider the resulting effect permanent, or as permanent as the black bromides? I never read of this plan of toning bromides, but should imagine it too simple to be novel. What is your opinion on this point?"—In reply: If the prints have been thoroughly washed and fixed, the result should be permanent. Silver sulphide is alleged by photographic chemists to be a very stable compound.

CINEMATOGRAPH.—1. The principal precaution to take is to avoid mixing the gases. 2. Yes; you may exhibit the pictures in the way mentioned—indeed it is very commonly done. As you state that you are a novice, and we cannot afford the space to answer you as fully as is necessary, we suggest that you procure and study a book on lantern projection work. For your purpose a little volume by Dr. Manton, published by Messrs. Iliffe, of 3, St. Bride-street, E.C., would be just the thing. It is published at 6d. or 1s. For the entertainment, write Messrs. Hepworth & Co., Walton-on-Thames. They may possibly meet your requirements.

RESIDUES.—"G" asks for the best way to throw the silver down from old hypo fixing solutions. Liver of sulphur, he says, is no good; is there any other way?—Although this correspondent says that liver of sulphur is no good, it is, in practice, the best and simplest material to use, and is the one universally employed. A current of sulphuretted hydrogen passed through the solution will throw down the silver, but that, though theoretically better, is less convenient than the liver of sulphur. If the hypo solution be boiled with scraps of zinc, or the zinc is left digesting with it for a time, the silver will be precipitated; but, as we have just said, liver of sulphur is the best in practice—that is, of course, assuming that the material is good.

STEREOSCOPIC PHOTOGRAPHY.—W. WILKINSON says: "I am greatly interested in the question of stereoscopic photography and attempts to produce stereoscopic effects on the screen. If you can give me particulars in next issue of any articles and where obtainable, you will greatly oblige. I have also read with keen interest your article in the ALMANAC for 1900. Can you please direct me where I can get, and price of, the following: 1. 'Binocular Vision and the Stereoscope' (footnote, page 643 of ALMANAC)? 2. Particulars of demonstration at the Camera Club by Mr. Knight, mentioned on page 664 of ALMANAC? 3. Also particulars re reflecting stereoscope, partly described on page 674, and illustrated at page 670, fig. 4, of ALMANAC?"—In reply: 1. The paper appears in THE BRITISH JOURNAL OF PHOTOGRAPHY for July 19, 1899. 2. The number of the Camera Club Journal containing the paper in full may be had of the Secretary of the Club, Charing Cross-road, for 1s. and postage. 3. The description referred to is the fullest published. See the JOURNAL of January 26 for diagram. Write again if we can be of further use in the matter.

TESTING THE SILVER BATH.—BURETTE says: "I have for some time past been dissatisfied with the argentometer, and have lately purchased a single burette for testing the strength of my silver bath, but I cannot find out exactly how to use it. I want a simple method of testing with a standard solution of salt, and shall be glad of your kind assistance. I may say that the burette is graduated in cubic centimetres and in tenths."—As the burette was sold as an argentometer, doubtless the formula for a standard solution for a chloride was supplied with it. Here is the method of quantitative testing given by Hardwich: Take pure, dried chloride of sodium in the proportion of 8½ grains to 6 fluid ounces of distilled water, each drachm of this will precipitate half a grain of nitrate of silver. This can easily be adapted to the burette you have, but it will be better to use the formula supplied with the instrument. At the photographic warehouses are sold argentometers for from one to two shillings each. They are simply hydrometers and are quite accurate for newly made silver solutions, indicating the grains per ounce. Theoretically, they are not strictly correct with solutions that have been much used, but, practically, they are accurate enough for all photographic purposes. They are what are almost universally used by photographers.

### EX CATHEDRA.

THE balloting papers for the election of officers and Council of the Royal Photographic Society for the ensuing twelve months were issued to members last week. They are returnable to the Secretary of the Society not later than noon on Monday next, February 12. As we mentioned last week, Mr. Dallmeyer is the only gentleman nominated for President, and is therefore elected. For the four Vice-Presidencies eleven gentlemen are proposed. Mr. Scamell is the sole nominee for the office of Treasurer, a position by no means of the nature of a sinecure. A Council of twenty has to be selected from fifty-one names appearing on the paper. On the whole, the somewhat formidable-looking balloting paper, with its great cloud of names, is indicative of a healthy interest on the part of members in the *personnel* of the executive responsible for the direction of the Society. Some familiar names are missing from the sheet, amongst them that of Sir W. de W. Abney, who, we regret to hear, finds himself unable to accept office in the Society this year.

\* \* \*

THE ballot papers for the election of Judges for the Society's

Exhibition at the New Gallery next autumn have also been sent out, and are returnable, like those for members of Council, next Monday. In the Pictorial Section eighteen gentlemen are proposed, and from that number a choice of five has to be made. In the Technical and Scientific Sections there are six nominations and three names have to be chosen. The Judges' ballot paper does not this year contain so many names as last, when it will be recollected that, in consequence of the attention directed to the matter by this JOURNAL, the interest of members was so strongly aroused that, instead of a nomination list and ballot paper of only eight Judges, as in 1898 (just the number required), the ballot paper for 1899 contained a list of no fewer than nine names in the Pictorial Section and twenty-five in that of the Technical and Scientific Section.

\* \* \*

THE editors of the *Photogram* are good enough to send us three excellent proof impressions from photogravure plates made by Fox Talbot in the year 1866. The subjects are French architectural studies, and the pictures are on plate-sunk mounts, thus rendering them suitable for framing. Through the courtesy of Mr. C. H. Talbot, the son of the late W. H. Fox Talbot, our contemporary is enabled to issue 100 prints from each of the plates, the proceeds from which, at 5s. each, are to go to the Fox Talbot Memorial Fund. The prints are being specially printed by the Art Reproduction Company, of Fetter-lane, E.C. The specimens before us are exceedingly well done, and, aside of their historical interest, are very good examples of a process which is universally conceded to be a most artistic method of reproduction by photography.

\* \* \*

FOX TALBOT was born, just 100 years ago, on February 11, 1800. One may reasonably demur to his right to the title of the "inventor" of photography, which some of his more enthusiastic admirers would confer upon him, but there is no doubt that a comparison of his work with the silver salts on paper with that of Daguerre on sensitised silvered plates singles him out for the distinction of having laid the foundation of modern photographic negative and positive work. It would be rash to say that, but for Talbot, photography as we

know it to-day would not be in existence; we can now perceive, by the light of recent knowledge, that the Daguerreotype, as General Waterhouse has reminded us, would have formed a very good starting-point in the evolution of photography by development; still, it cannot be denied that, from whatever aspects they are studied, Fox Talbot's contributions to photographic progress must rank as the most important that have been made. Of the "fathers" of photography he is admittedly the greatest.

\* \* \*

IN connexion with Fox Talbot's centenary, the suggestion has been revived that a memorial to him, to take the form of the restoration of the chancel of Lacock Church, Wiltshire, should be instituted. With that object the Committee has been reconstituted, and it now consists of the following ladies and gentlemen:—The Right Rev. the Lord Bishop of Bristol; Miss Awdry, Notton House, Lacock, Chippenham; C. H. Talbot, Esq., the Abbey, Lacock, Chippenham; J. E. Gladstone, Esq., Bowden Park, Chippenham; Mr. E. Eyres, Ray Bridge, Lacock, Chippenham; Mr. A. J. Tanner, Lacock, Chippenham; the Rev. H. W. Armstrong, the Vicarage, Lacock; Miss Talbot, Lacock Abbey; the Rev. W. G. Clerk-Maxwell, Clunbury Vicarage, Shropshire; Mr. T. Pike, Lacock. Subscriptions will be received by the Treasurer, Mr. C. H. Talbot, Lacock Abbey, Chippenham, Wilts, or they may be paid to the Fox Talbot Memorial Fund, Capital and Counties Bank, Chippenham, Wilts.

\* \* \*

IN their appeal the Committee state that, in 1878, immediately after the death of Fox Talbot, which took place on September 17, 1877, it was proposed to restore, or, more strictly speaking, remodel, the chancel of Lacock Church, as a memorial to him. Owing to unavoidable circumstances, the matter fell through at the time, but has never been lost sight of, and it is felt that the time has now come when definite steps towards the attainment of that object should no longer be delayed. There is at present no other monumental record of Fox Talbot than a short inscription on his gravestone in the Lacock Cemetery. With the chancel he was, as lay rector, intimately connected, and many of his ancestors, from the sixteenth century, including his father, are buried in a vault under the adjoining Lady Chapel. There is an obligation upon the present lay rector (Mr. C. H. Talbot) to keep the chancel in repair. The present chancel was rebuilt in 1777, and is in substantial repair, but it is incongruous and out of harmony with the rest of a large and fine church. To remedy this defect by local effort alone would demand a long time, but it is thought that an appeal may be made to the public, particularly those who are interested in photography, with some prospect of success. Plans have been prepared by Mr. Harold Brakspear, A.R.I.B.A., architect, which include the conversion of the chancel, the addition of an organ chamber, and the provision of the necessary fittings, at an estimated expense of 1000*l.* Any surplus that may be obtained would probably be applied to form the nucleus of a fabric fund, applicable to any part of the church or chancel, as the above-mentioned sum by no means represents the whole amount that might with advantage be expended on the fabric.

\* \* \*

WE have been asked to recommend the memorial to the attention of our readers, and do so with much pleasure. Subscrip-

tions for the proofs from Fox Talbot's photogravure plates, to which we have already referred, should be sent to Mr. Snowden Ward, 6, Farringdon-avenue, London, E.C. Any contributions that may be forwarded to us for the Memorial Fund that is being raised at Chippenham will be duly acknowledged in these pages, and forwarded to the proper quarter. We especially commend the matter to the notice of those of our American readers who may be desirous of associating themselves with the proposed memorial to one of those fathers of photography whom we know to be regarded with especial reverence by numerous photographers in the United States.

#### COLLODION IN THE SILK LOOM.

COLLODION in its time has played many parts; it is not half a century since it became the especial handmaid of photography through Archer's discovery, yet meanwhile it has been put to an infinite variety of uses, either in its own form or in modifications of its pyroxyline base. It is used in surgery, it forms an excellent varnish, is equally good as a lacquer, or as a water-proofing for paper and other substances. As for celluloid, mainly composed of pyroxyline, to name it is to bring before one a thousand forms, from the humble knife-handle or card of buttons which seemed its early fate, when known, after its inventor's name, as Parkesine, down to the present day in its use for the most expensive articles for personal use, and as a carrier for gelatine films in countless thousands the whole world over. Thirty or forty years ago we saw balloons made from collodion; the inside of a glass carboy was coated with collodion, and, when dry, the delicate skin was deftly withdrawn, and then formed a splendid substitute for silk. Unlike the well-known indiarubber spheres, collodion balloons could be filled by simply placing them over a gas-burner, and turning on the tap till they were fully expanded.

This is, perhaps, the earliest recorded use of collodion as a substitute for silk—sufficient as a scientific amusement, but full of infinite horror of fire if used for purposes of dress. Yet to this end, after the lapse of four decades, has it come, but with a difference; for, whereas the balloon silk was inflammable almost to explosiveness, the celluloid silk of the present day is as harmless, so far as fire dangers are concerned, as the natural product of the silkworm itself.

As regards this most modern use of collodion, the *Journal of the Society of Arts* lately had a full report of Mr. Joseph Cash's paper on artificial silk, which, as we have on former occasions informed our readers, is simply collodion spun out into minute threads as fine as the silkworm's web, then dried, and afterwards submitted to further treatment to remove the nitrogen, and thus destroy its explosiveness, this being the very essence of the process. A silk of ordinary collodion fibre would not be permitted for a single second, but denitrified would be welcomed with acclaim. Mr. Cash, in his paper, drew attention to the extreme care needed in the manufacture of the constituent pyroxyline, and stated that, even at the long-established factory of Besançon, in France, mistakes would, at times, occur. It seems to us that a little photographic experience might with advantage be applied to the process of manufacture as described in the paper. For instance, the gun-cotton was explained to be dissolved by placing in a cylinder with a mixture of ether and alcohol, which was then kept slowly revolving for twelve hours. Now, there is no secret in the best way of making a solution of the pyroxyline, seeing

that it has been published thirty years ago. It consists in first adding the alcohol to the pyroxyline, well wetting the latter with it, and then adding the ether. It must be an immense cylinderful that would not be dissolved in one-fourth of the time named. The method of filtration is good: the liquid is pressed, under a force of fifteen atmospheres, through cotton-wool imbedded between two sheets of calico. Again, it is stated that the quality of the gun-cotton cannot be discovered in a simple manner. It might be remembered that Hardwich, in his classical paper, pointed out that the amount of weight the raw cotton gained during the action of the mixed acids was, *ceteris paribus*, an exact criterion of its quality. Further, as old hands at the manufacture for photographic collodion-making, we may say that, when the fibre was in the washing water, we could, with our eyes shut, almost tell exactly what its quality would be like merely by handling it in its wet condition, a limpid collodion being produced when the cotton felt soft and velvety to the touch, and a crapy thick collodion when it felt harsh and wiry.

It appears that this material is the best to use for the manufacture of the mantles for the well-known incandescent gas burners, as the rare-earth salts that form the skeleton can be more readily introduced into collodion, and hence into the skeleton, than by any other means.

The amount of pyroxyline made may be judged by the output of the "silk"—Besançon 7000 lbs. per week; Sprietenbach, 3600—and extensions on a large scale are in progress to double this output. We are, in deference to popular etymology, using the terms gun-cotton and pyroxyline as convertible, but they really are not, for the former material contains a larger proportion of nitrogen than the latter, and is not soluble in ether and alcohol, as is the latter. The former may be termed *tri-* and the latter *di-*nitrocellulose. But, interesting to a photographer as must be this new industry arising out of the use of his old servant, collodion, and large as is the output already, we must confess we share with some of the members of the Society who took part in the discussion the feeling that such a mode of manufacture is a species of *pis aller*. First to impart nitrogen by a costly process to cellulose, afterwards dissolving the product in a costly liquid, and then to remove the nitrogen by another process, is a roundabout way of doing things. The moment a method is discovered for bringing into practical use one or other forms of what might be termed gelatinous cellulose—as opposed to fibrous cellulose—in such way as to enable it to be spun like this artificial silk, so soon would the present industry collapse, and its only value consist of the huge manufactories for its production, and these might be utilised for the new kind of cellulose silk.

**The Coming Eclipse.**—As the time approaches for the eclipse of the sun, the various arrangements made in different countries become known, and a wider co-ordination in consequence possible. On the part of France we read that Baron Pluvinel has been over to Spain to investigate the probabilities in regard to meteorological conditions, and will have reported to the French Astronomical Society on the 7th inst. the results of his mission.

Few persons are aware of the amount of labour, care, foresight, and time given to the preparations for observing this wonderful phenomenon, and a recent illustrated account in *Nature* of the arrangements made in connexion with the eclipse observations at Vizaiurg in 1898 will be found most interesting. Photographs are given of the six-

inch and the nine-inch prismatic cameras, and of the kinematograph and its special hut. As need not be said, photography plays an ever-increasing part in these eclipse-observation undertakings; indeed, if it were not for photography, our knowledge of the sun would be far less than it now is. At these expeditions everything is more thoroughly rehearsed than at a dress rehearsal at the theatre. Each observer has one definite work to perform at a definite time, and he practises at it till he is perfect. As an example of the thoughtfulness shown, it may be noticed that the plans were laid so that the most important observers only "worked half-time," *i.e.*, when the eclipse was half through, their duties ceased, and they would not be deprived of the interesting opportunity of actually viewing the eclipse after having travelled so far.

**United States Naval Observatory Report.**—This report, for the year ending June 30, 1899, has been issued. We note that the result of many measurements made with the great twenty-six-inch equatorial has been to show that the irradiation error observed in measuring the diameter of Venus and Mercury was proved to be a function of the magnifying power used. Almost all the spectroscopic measurements were made by photographic means. A number of good negatives in connexion with the spectra of certain well-known stars were obtained, but great difficulties were experienced with the telescope owing to the objective being corrected for the visual rays only. This, however, is now put right, for the Government have purchased a new corrector, 2.09 inch aperture, which alters the minimum focus without materially interfering with the length of the chief focus. We observe the public are admitted once a week—every Thursday evening—and the total number of visitors during the twelve months (this including those who came in the day-time) was 1623.

**The Projected Copyright Bill.**—Parliament has met again, and, of course, nothing has been done at this early period with reference to the Copyright Bill introduced in the House of Lords last session by Lord Monkswell. This Bill, it is well known, is framed entirely in the interests of painters and publishers, and against those of photographers. We are pleased to learn that the petitions against it that have been supplied to most of the photographic clubs and societies have been very largely signed by them, and there is little doubt that, if the Bill is introduced again this session, they will have some weight. Just now the House has much business of vital importance before it, and will have for some time to come; therefore there is little prospect of domestic legislation receiving much attention at present. But there is little doubt, if time will permit, that the Bill will be brought up again this session and, as it will be introduced in the Lords, it may be little discussed if passed to the Commons. Therefore it will be well that those who have the matter in hand, on behalf of the photographic profession, should keep their eyes open in case any attempt is made to bring the subject forward again.

**The Free-portrait Swindle.**—One would have thought, after all the exposures in the photographic and the lay press, that the free-portrait swindle had been laid by the heels in this country before now. Such seems not to be the case, however, if one may judge from letters that have recently appeared in some of the daily papers. From these it seems that the affair is still running in France, though the victims are here. Some say, "Serve them right, after the many exposures that have been made." But the British public—or rather a certain portion of it—are easily "gulled" by the promise of getting a "handsome picture," or anything else, for nothing. However, we suspect, after all that has been said in the press, that the game is not now so profitable as it once was, though it doubtless still pays or it would not be continued.

**Weather Forecasting and the Meteorological Council.**—The report of the Meteorological Council for the year ending March 31, 1899, has just been issued. It will be noted that

the year's report has taken no less than ten months to compile and issue. In the report it is claimed that fifty-five per cent. of the weather forecasts were a complete success, and twenty-eight per cent. partial successes. The proportion of complete successes claimed to have been scored is certainly not great, seeing that during settled weather, say in summer, it is not difficult for any one to forecast what it will be for the next twenty-four hours without the advantage of telegraphic reports from all parts of the kingdom. It would be interesting to know how the terms "probably," "possibly," "perhaps," &c., which so frequently appear in the daily forecasts, count in the complete and the partial successes. Really reliable, or even moderately reliable, forecasts of the weather would be very useful to photographers and agriculturists, but we know that both these bodies have long ceased to place any reliance upon them, preferring to pin their faith to their own judgment of what weather to expect.

WE understand that the Meteorological Council have given notice to the Directors of the Ben Nevis Observatory that their grants must cease at the end of the year 1901, owing to the inadequacy of the funds at its disposal. Ben Nevis Observatory is the highest in the United Kingdom, being nearly four times the height of the next highest. It is 4405 feet above sea level, and the mountain is the highest point in the British Isles. The Meteorological Department costs the country between fifteen and twenty thousand pounds a year, and not a few are of opinion that it does not get good value for its money. Some of us, whose work is largely dependent upon the state of the weather are, naturally, more interested in what we are to have than in what we have had in the past. Seeing the advantages the Department has of its some two or three hundred stations and telegraphic communications, we might well expect more reliable forecasts of the weather, only twenty-four hours in advance, than we get at present.

#### JOTTINGS.

"I SEE," writes a friend of mine who often sends photographs to the "great" exhibitions, "that you are going to allow the Judges to hang, after all." He is alluding to that most momentous question of last autumn, Shall the R.P.S. Judges take part in the work of selection? Looking back six months, it seems difficult to realise that the excitement over this vitally important matter rose to such a terrible height that at least two persons in the photographic world were very charmingly affected by it. What brave things they said and did in defence of the sacred claims of the Judges to select the photographs that were to be put on the walls for adjudication! Ah, my brothers, we may never look upon such noble doings again! At any rate, for the sake of my risible faculties, I, for one, hope that we shall not. So much laughter as the selecting incident of last autumn caused me makes my jaws ache.

BUT to my friend and his views on the participation of the Judges in the work of selection says he, "I'd have hung them first." Unlike my friend, I would not hang *all* Judges, however objectionable some of them might be. I would have them pass before a selecting committee consisting of disappointed exhibitors, and let them take their chance of the rope's noose. So much for that matter. This year members of the R.P.S. are voting for Judges at the same time as they are choosing members of Council. About the latter election there is no excitement at all. How different to the days of the famous "new blood" agitation of three or four years ago! This year, in the ordinary course of things, and what with retirements and so forth, at least five or six new men will be added to the Council, and thus time, in its slow and peaceful way, has worked a revolution which it was sought only a little while ago to effect by violent means!

As to the choice of Judges for the Pictorial Section of the Exhibition, which is to be opened next autumn at the New Gallery, Regent-street, much interest, I know, is felt by members of the

Society. The ballot papers have to be returned by Monday next. If any readers of these Jottings, who are members of the Society, have not voted, and they are anxious to be in line with the large majority of their fellow-members, who wish to have their annual Exhibition judged by a group of men in whom the exhibitors, the Society, and the photographic public can have confidence, they are welcome to what the sporting writers would term my "wire from the course"—in other words, a "tip" just before the start of the race.

HERE it is, with a paragraph all to itself, as it deserves. For the Judges in the Pictorial Selection, then, vote for

F. P. Cembrano.  
Dr. P. H. Emerson.  
Colonel J. Gale.  
B. W. Leader, R.A.  
J. B. B. Wellington.

These men are all friends of the Society, and they can be relied upon to make their awards to the best of their judgment. To readers at a distance who may not know for whom to cast their votes, let me say that the above list is an expression of the views of these members of the Royal Photographic Society in London (many of them exhibitors) best competent to express an opinion on the question of suitable Judges for the Exhibition.

I NOTICE a suggestion that Kodak and similar cameras are fitted with lens apertures too small for the "comparatively dull light of the English climate." But you may have your light so "dull" that an aperture of  $f/4$  is of no more practical use than one of  $f/16$ . To open out the aperture of the lens because the light is "dull"—I am here speaking of hand-camera exposures, of course—is theoretically right, I admit, but in practice it very frequently partakes of the nature of a forlorn hope. In the "dull" light of winter, such as we have mostly been having in London since November, I doubt if a change of aperture from, let us say,  $f/16$  to  $f/4$  would have meant the difference between success and failure in hand-camera work. Below a certain power of actinism, rapidity of lens and sensitiveness of emulsion do not facilitate matters. "The light isn't good enough for instantaneous work," says the practical man; it is too "dull," in fact, and so he doesn't attempt it, even with an enlarged lens aperture.

THE powers of the Kodak shutters, lenses, and films are by no means used so much as they might be on favourable days in the English winter. Only on December 31 last, I successfully used my No. 2 Folding Pocket Kodak for a little snap-shooting work. True it was in sunlight; but, unless the sun is shining, the opportunities for snap-shots near London in winter are very few, no matter what aperture is used. I remember, in the November of '96, passing a day at Winchelsea and Rye with that accomplished photographer, Mr. Algernon Brooker. It was fairly bright for the time of year—sunny in fact—and I carried a bull's-eye Kodak. My companion rather doubted if the light were strong enough for some of my "snaps"—the end of November is not ordinarily rich in hand-camera possibilities—but, on development, they proved to be fully exposed. My experience and observation show me that the working rapidity of the Kodak cameras—I refer to their use in England—is very much under-rated by many photographers in the winter sunlight.

A LITTLE reminder to those interested in the subject of photographic copyright. On February 21, Mr. Edwin Bale, R.I., is to read at the Society of Arts a paper on "Artistic Copyright." Mr. Bale is said to be the Art Director of the eminent firm of Cassell & Co., Limited, and he has been credited with having a hand in the drafting of those portions of the House of Lords Bill (to which such vigorous exception was taken in these columns last year) which proposed to interfere so seriously with copyright protection enjoyed by photographers under the excellent Act of 1862. In his paper it is possible that Mr. Bale may touch on photographic copyright; let me, therefore, advise those readers of Jottings who are interested in the

matter to make a note of the date of the meeting (Wednesday, February 21), at the Society of Arts, John-street, Adelphi, at eight. Mr. Henry Wood is always glad to see photographers at his meetings, and would, no doubt, send tickets to applicants who are non-members.

A WORD of praise is due for the excellent lantern shows which have recently been given at the beautiful house of the Royal Photographic Society at 66, Russell-square. The displays of transparencies by Mr. Evans, Mr. Speyer, and Mrs. Weed Ward have been signally fine, and the R.P.S. monthly lantern nights should do much towards restoring this kind of meeting to favour in the eyes of London photographers. Credit is chiefly due to Mr. J. J. Vezey, who is in charge of the section, and who, in the old days of the Lantern Society, at 20, Hanover-square, arranged many an enjoyable evening. By the way, a rumour reaches me that Mr. Vezey is likely to be asked to take the Honorary Secretaryship of the Society. COSMOS.

### THE CAMERA IN THE CAMP.

WHEN touring, how often one takes delight in wondering what it is like 'round the corner?' Again, how frequently, when flying down a steep incline, does the cyclist tremble at what the unknown, hidden by a bend in the road, has in store for him?

From these instances one may guess the risky predicament of troops who, either by night or by day, advance through unknown regions, consisting of hilly, broken, or wooded ground, diversified by river, morasses, and rock-boulders.

Such, alas! has been the case on too many occasions during the operations in South Africa. Constantly have the troops not only been obliged to locate the enemy, but have been hurried from one position to another *utterly unprepared* to cope with the physical features which await them. The results of this (should one say culpable?) ignorance are that thousands of our men have been either killed, wounded, or captured.

### FORESIGHT AND PHOTOGRAPHY.

And yet in many an instance this might have been, had foresight and photography been employed, of a surety avoided. Of course there are sketching and other reconnaissances, and also balloon observations, and very valuable, in their own way, they are; but, because howitzers are most potent, one does not neglect the Lee-Metford.

Similarly the camera, supplemented by the projection lantern, cannot be superseded by any other manner of imparting personal knowledge of the actual aspect of a country to a large body of men.

At the moment of writing, Buller has for over two months been trying to get from Frere to Ladysmith, and, in the course of his operations, every ounce of help from every one of his men has been of almost priceless worth. For many weary weeks his 30,000 men have—more or less—been killing time while preparations for an advance have been in course. Now either before or immediately after Kruger's ultimatum, it would have been perfectly easy for half-a-dozen or so of photographic experts (and photography is one of the sciences practised by the Royal Engineers) to have thoroughly scoured the district between, say, Dundee and Pietermaritzburg, and with the camera's aid have obtained a complete series of *likenesses* of the face of the country. Let me illustrate the value of such a proceeding. Suppose I wished to send a stranger, who could neither read nor speak English, from, say, Charing Cross to the Angel at Islington. A map would be no doubt useful, but, as we all know, risky. If I wanted to make absolutely sure, I could only do so by means of photographs; by their aid I could point out to him how he should pass along Duncannon-street, leaving St. Martin's Church on his right, then, turning round at Trafalgar-square, proceed between the Portrait Gallery and the Garrick Theatre, and so continue along the Charing Cross-road, with various landmarks to guide him, such as the new Hippodrome, and the Palace Theatre, until Oxford-circus and the Horse Shoe were reached.

Similarly, every inch of the way might be made so familiar that, when the lesson had been properly learnt—not of necessity the first time of asking—the pupil would be able, unhesitatingly, to walk straight to his destination, and would, moreover, know before turning a corner whether it was a 'pub.' or a church which was the main feature he was coming to.

### INFORMATION BOUGHT WITH LIVES.

In like manner a large proportion of our troops could have been taken, step by step, all over the ground to be traversed during an advance on Ladysmith, by either of the alternate routes, so that, instead of dashing forward over rising ground into much-exposed positions, and only finding out their mistake by serious loss of life, the soldiers would, in each

instance, be prepared for the dangers of the position, and would, by one or another expedient, be able to discount the special risk to be met with.

It is, however, needless to labour this point, as the great advantage which accrues to those who know the ground they have to fight over is surely self-evident.

The required series of topographical photographs have first to be taken in complete continuity and displayed in orderly sequence. On this last point the value of the information entirely depends. The procedure to observe may be figured in the mind by the analogous impression conveyed by traversing any route. If, for instance, an average person were to be driven, say, from London to Brighton by the main road, he would subsequently be able, with tolerable certainty, to find his way down by himself. Any how, did he not know every furlong of the road, he would recall all the important aspects at the second time of seeing, would know when he came to the North Downs, recollect Redhill, recognise Leith Hill, the Balcombe "Kopjes," the stretches of fairly level ground, the South Downs, and their folds. All this, or nearly all, could be drummed into him by means of photography. In the case of large bodies of men, the only effective way of making the photograph imprint itself indelibly and vividly on the memory is by means of the optical lantern. This not only because of the intense brilliancy and great size of the pictures shown on the screen (forty feet square is by no means the limit), but because a lantern view may be seen by hundreds, if not thousands, at once. Moreover, the instructor—and, of course, a fully conversant and specially trained one is a *sine-quâ-non*—is able, with much greater effect than if he were referring to a small print, to direct attention, by means of a pointer, to important details which his audience should specially bear in mind.

In such lantern displays of topography it is absolutely necessary, in order that the full benefit may be imparted, that the screen exhibits, side by side with the view shown, a map of the district, so that, as each salient or important feature is displayed, its bearings and distances as regards other parts may be pointed out and impressed on the memory. But, as already indicated, what is of prime importance is that the pictures should be presented in the *exact order* in which an advance or a retirement is to be made. To return to my simile of learning the way from Charing Cross to the Angel. It stands to reason that if one should show the various landmarks in irregular order, or in any order except that in which they occur to any one walking from the one point to the other, no great advantage would follow. Another detail which is far too often lost sight of is that the scenes should be taken from the point of view at or near a given line of advance, and, moreover, should be shown in complete series as seen looking from, say, S. to N., or N. to S., but not mixed, *i.e.*, not one view looking N., and the next S., the third W., and the fourth N.E.

### PLAYING THE SPY.

If troops are advancing from S. to N., they will successively come upon the various natural features as seen from S., and without hesitation recognise the landmarks, the other aspects will not so much need to engage their attention. If the photographs have been judiciously taken, and are intelligently explained, there is no reason why any one of the officers and non. coms. should fail to be able, at first sight, to locate all the main strategical points, and further to know what is the lie of the land hidden from sight by hills and woods. Besides this quite invaluable way of educating an army as to its environment and the physical obstacles which have to be overcome or which may be taken advantage of, photography could, and should, take a most important part in playing the spy upon the intrenchments and other preparations of offence, or defence, made by the enemy. How, by the aid of the tele-photo lens, this may be accomplished, is deferred for another article.

In contributing these lines to THE BRITISH JOURNAL OF PHOTOGRAPHY, I do so in the hope that the *cachet* given to my remarks by the mere fact that they appear in the leading photographic technical journal of the world, will lend such weight to my representations that, in the future, military authorities will see to it that a more extensive, systematic, and intelligent use is made of the incomparable advantages in imparting topographical knowledge placed at their disposal by the camera and the lantern.

HECTOR MACLEAN, F.R.P.S.

### PHOTOGRAPHY IN WEAVING.

THE following description of Herr Jan Szczepanik's latest application of photography for the preparation of the pattern cards for the Jacquard machine for weaving, which was recently given by him before the Vienna Photographic Society, and reported in the current number of the

*Photographische Correspondenz*, may be of use and interest to our readers.

A material is a combination of two systems of threads which cross one another at right angles. The threads of one system run parallel to one another in the direction of the length of the fabric; they form the warp, and in weaving they must be stretched on the loom in the desired

FIG. 1.

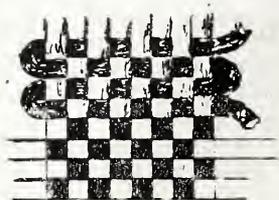

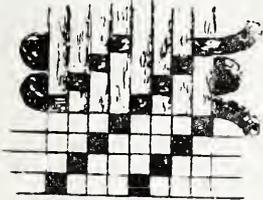

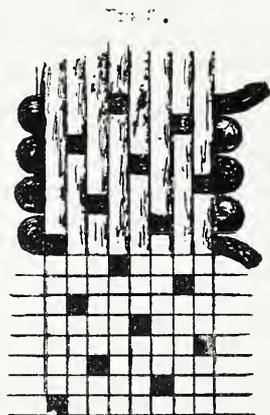

FIG. 2.

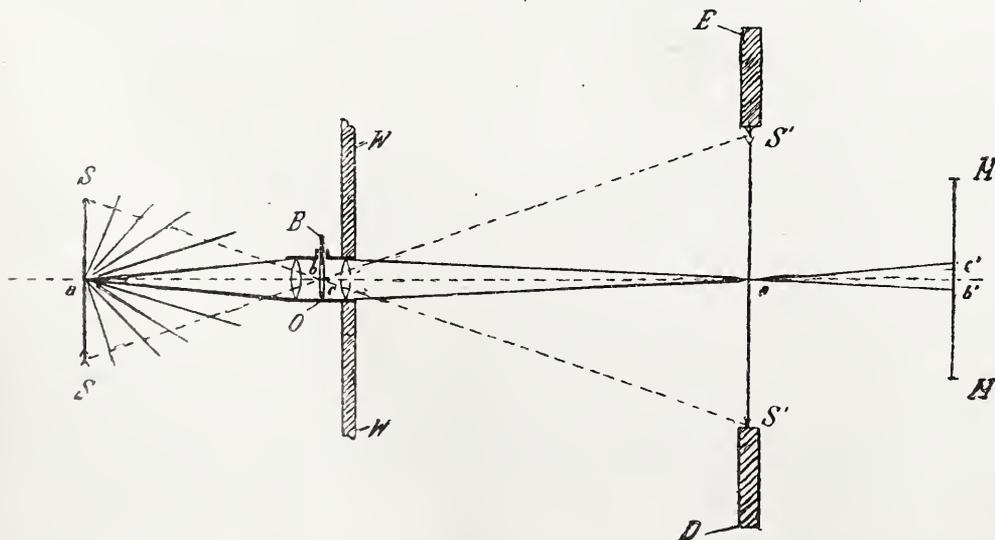

number and of equal length close to one another. The other system of the threads is the woof or weft, which, in the simplest cases, is one thread which runs in the breadth of the material once from left to right, then from right to left without break, between the threads of the warp, and crosses the same according to a desired plan. In order to obtain the crossing, part of the warp threads are raised and part allowed to lie flat,

and through the lease or shed thus formed the weft is thrown by means of the shuttle. The lifting of the warp threads is effected in the Jacquard machine by means of perforated cards. These cards represent the various crossings which are formed in weaving and make the pattern. If we assume the warp to be white and the weft black, there is formed, if the

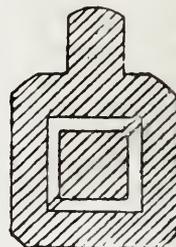

FIG. 4.

Crossing takes place regularly, and, for instance, if one thread is lifted and the other lowered, a fabric, the crossing of which, if enlarged, will appear as in fig. 1. This crossing is called taffeta-weave, and in the technical drawings or patterns, which are necessary for the preparation of the perforated, so-called Jacquard cards, this combination will be drawn as shown in the lower part of fig. 1. Figs. 2 and 3 represent

other methods, the so-called four-thread twill and eight-thread satin. In fig. 3 there will be even fewer black points than in fig. 1, and the material will be bright, almost white; fig. 1, on the other hand, appears rather dark. Without the points of intersection there would be, in the ground, and also in the figure, close to one another, long loose threads, and this is obviated in weaving by choosing for the ground and the figure dif-

FIG. 5.

ferent points of intersection corresponding with the pattern. The crossing has the effect, not only the purpose, of fastening by warp or weft loose threads, but also for marking tone effects.

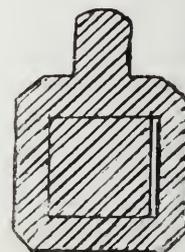

If it is desired to prepare any pattern in material, various crossings must be made visible, thus: for the ground, fig. 3; for the ornament, fig. 1.

Herr Szczepanik has succeeded in producing the pattern cards, which

FIG. 6.

a Schenienplatte.

b Blende heizzu.

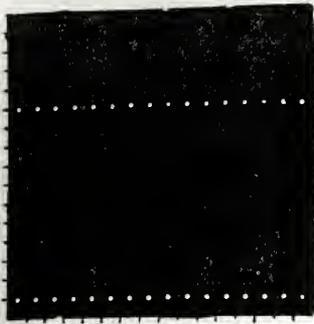

are made one metre square and over, by photography, and to prepare in a few minutes what previously took weeks and months. The whole process has by this means become purely mechanical.

The fundamental principle underlying this process is the action of the diaphragm of a photographic lens through a perforated plate (fig. 4). In this figure *ss* represents a negative, *o* is the lens fastened in the wall of the dark room, *s's'* the projected enlarged image. Every point of the object to be copied, in this case *a*, sends the rays in all directions, and those which reach the objective form a pyramid of rays, in this case *abc*. The rays of this pyramid are so refracted by the lens that they combine at the other side of the lens at *a'*. Behind the lens there is, therefore, the pyramid, *a'bc*. Both pyramids have different heights, but the same base, *bc*, which is dependent on the shape of the diaphragm between the lens. If the bundle of rays is now intersected with a ground glass or a light-sensitive paper in the plane, *mm*, there is formed there a base of the pyramid, which is equal to the base, *bc*, common to the two pyramids, *abc* and *a'bc*, and therefore equal to the diaphragm.

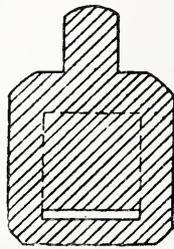

With this new system an enlarging apparatus is combined with a line plate. If a square diaphragm be placed in the objective of the enlarging apparatus, and the lantern be lit, the image of this square is formed behind each aperture on the ground glass, and, by pushing this to and fro behind the perforated plate, these squares may be made to close up to one another, so that the whole surface of the ground glass or the paper appears in squares or check-patterned. If it is desired to produce a stronger lining, a covering plate is placed in front of the perforated plate

that it covers completely a number of the squares, which shall be distributed according to the paper which is to serve as a pattern. It is only necessary to place in the lens a diaphragm like fig. 6 or 7, but with a

Fig. 7.

a Schenienplatte.

b Blende hierzu.

rather broader slit than in the squaring stop used in the first place.

Up to now the lens has been focussed on a ground-glass screen, *s's'*. If in front of the ground glass is placed the negative of the model which

Fig. 8.

Fig. 9.

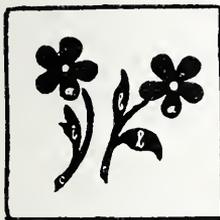

Fig. 10.

Fig. 11.

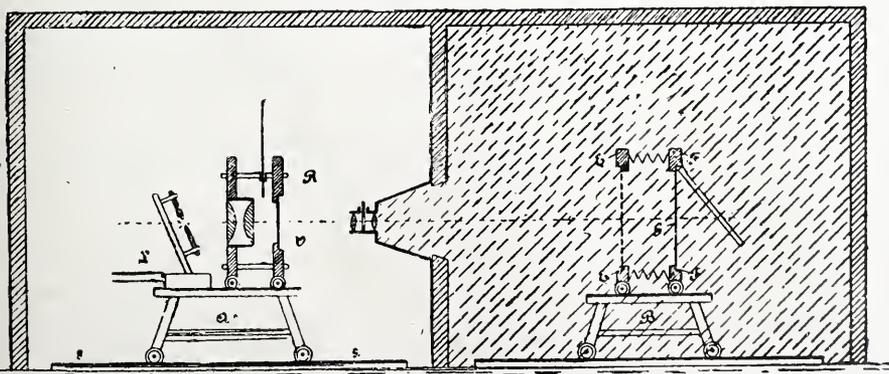

is to serve as a pattern, and projects this negative, enlarged, on to the perforated plate, the rays of light which pass through the transparent parts of the negative will also go through the perforated plate, and

simultaneously give the image of the diaphragm, *B* (fig. 4), on the matt screen.

For preparing the enlarged pattern from the negative, a paper sensitive

Fig. 12.

to light is placed in the place of the ground glass. The diaphragm which is destined to cause the squaring of the image is placed in the lens and exposed without the negative. There is thus obtained that check paper which is known commercially as "Cartarigatta Papier."

The image of the subject is now projected on to the check, and impressed in the same way by placing the negative in the lantern and using the corresponding square stop in the exposure of the negative. If in the ground, or in different parts of the figure, various points of intersection are to be made, the process is carried out as follows:—

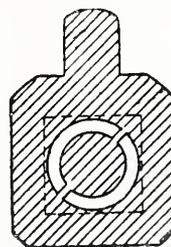

From the subject one transparency (fig. 8) and up to four negatives  $6 \times 9$  cm. are prepared, then there are as many parts of the negative covered so that on every plate only those places shall be transparent as

Fig. 13.

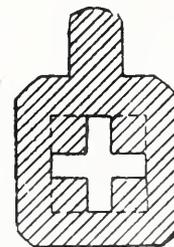

shall have the same crossing (figs. 9, 10, 11). These plates are projected one after another, by means of a lantern (fig. 12) through the perforated plate, *EE*, behind which a glass plate, *FF*, is placed for holding the silver bromide paper. If, for instance, the negative (fig. 11) is sharply projected on to the perforated plate with a square stop, there appears, on the gelatino-bromide paper or the ground glass the whole figure in squares. If an aperture of the perforated plate is illuminated, it gives the whole shape of the diaphragm; thus the whole square, by this means the graduated outlines, is explained.

Fig. 14.

a

b

c

The crossings are so effected that certain points on the perforated plate are covered by the so-called crossing plate (fig. 13). To make the patterns about thirty such plates are required. Different negatives or positives with different crossings can be used one after another, and thus prepare a pattern with various crossings. The squares in the ground are produced by the transparency and the diaphragm (fig. 5).

Obviously, if in the figures certain crossings must appear, instead of the negative, must congruent transparencies produced from the same be inserted, and for this purpose special stencil frames are used, by means of which the transparency can be placed in the exact position of the negative.

If, in different figures of one and the same pattern, various crossings should appear in colours, so must, on the negative or transparency, those surfaces be covered in which these crossings are not to appear. If, therefore, various colours are to be apparent on the same pattern, so must analogously these places be transparent in the negative or positive according to the ground or figure which must carry these colours. Certain diaphragms can be chosen for certain figures, which can be done by means of such diaphragms as fig. 14 (*a b c*).

For shaded ornaments a plate (fig. 15) is used which consists of various-sized openings, which form the crossings, is called a shading plate. As every opening is a pinhole camera, the larger diaphragm openings will always print in a shorter. If such a plate is exposed for a

very short time, only the very large points can be impressed, and we obtain fig. 16; with longer exposure, we get fig. 17; with an exposure of one minute, all apertures will be impressed (fig. 18). If, instead of

FIG. 15.

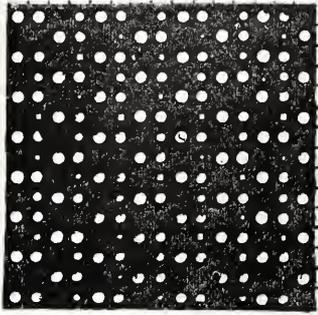

FIG. 17.

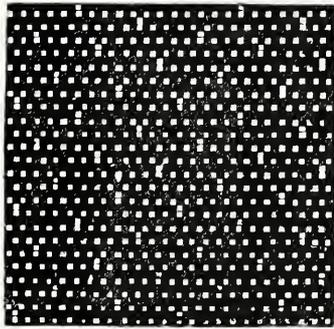

FIG. 16.

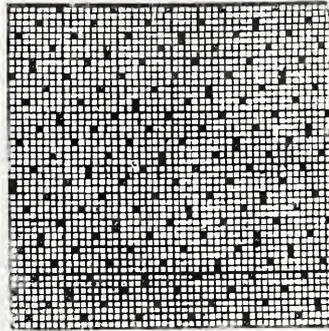

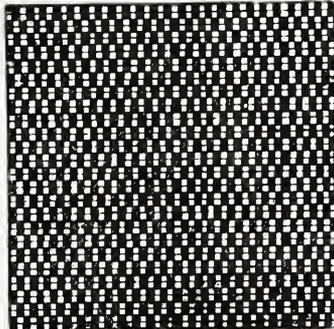

FIG. 18.

different exposures, a negative is placed in front of the lens, and this exposed through a perforated plate on gelatino-bromide paper for a certain time, the brighter portions print more squares than the less

FIG. 19.

transparent. A portrait appears as in fig. 19. The various-sized points of the perforated plate are placed according to certain rules, which correspond to those of weaving. This work far exceeds hand work as regards plasticity, as the preparation of lights and shades by crossing is extremely difficult.

The first experiment, according to this process, was the preparation of a pattern for a silk tapestry, 148 x 120 cm. The patterns used were 176 cm. square, and prepared in six hours, and a pattern-cutter, who could scarcely obtain the same effect by hand work, requires several years.

It should be mentioned that the inventor is now busy in the preparation of fabrics in natural colours on the basis of trichromatic printing. The principle is as follows: Three negatives are prepared from the picture to be woven, similar to those for trichromatic printing, but without the cross-lined screen, and these were so used, with particular shading and covering plates, that for each negative another line was printed. Such a pattern card represented the colour intensities in points of intersection, in which every first line represented the red, every second the yellow, and every third the blue. This naturally recalls the well-known Joly process. If there is in the fabric, that is to say, as warp close to one another in the same order, a red, a yellow, and a blue thread, and these patterns are woven through, there is formed a picture in natural colours. The delicacy of the reproduction depends upon the fineness and thickness of the threads.

Szczepanik's experiments in this direction, with 180 threads to the square centimetre, gave beautiful results, but the colours were somewhat too bright. In weaving in natural colours one does not meet with any of the difficulties of trichromatic printing, since all the colour lines must run parallel, and consequently the superposition of the colours or non-coincidence of the same is completely excluded.

#### HAND-CAMERA WORK.

[Paper read before the Oxford Camera Club.]

THERE were two things which induced me to offer to read a paper on "Hand-camera Work." In the first place, I had been so frequently asked for information and advice on hand cameras that I thought some remarks on the subject might be of interest. In the second place, members of this Club often say of a bad print, "I suppose that is a hand-camera shot," and I have felt a longing to defend this method of photography, and to try and induce members to appreciate it at its true worth.

Unfortunately I am unable, for various reasons, to show slides from some of my best hand-camera negatives, so that members must not go away with the idea that the work they see to-night is the best that can be done by an ordinary photographer with the hand camera. Still, I hope the examples shown will sufficiently illustrate the different things to be considered in such work.

First of all it would, perhaps, be best to enunciate the different points which would go to make an ideal instrument. It should be light, small, and unobtrusive, with all the working parts to some extent hidden, and none of them projecting. It should have a good rapid-rectilinear lens, working at *f*-6, and covering a plate about half as big again as the one to be used.

The lens should also be of a fair focal length—at least five and a half inches for a quarter-plate, and should have a focussing arrangement, with an accurate scale plate. There should be two finders properly marked, and a rising front, both ways, to the extent of a third of the edge of the plate used, while a circular level should be placed close to each finder.

The shutter should be easily adjustable, from time exposures up to at least one hundredth of a second, and the aperture of the lens should be alterable without opening the camera.

#### THE CHOICE OF A CAMERA.

It is almost needless to say that a camera with all these attributes is not to be found at the present day, though there are several excellent instruments which boast of a sufficient number of the essential points to do first-class work. The consequence is that the photographer has first to decide for what work he will chiefly require his camera, and then make his selection accordingly. To take the points *seriatim*, it is hardly necessary to say anything about the advantages of the camera being light and small, but the fact that it should be unobtrusive is not so often considered. In a busy town, or, in fact, anywhere where there are many people about, the advantages of working with a camera that looks like a small dark-coloured box are enormous, as can be easily proved by any

one who has used, under these conditions, both a small box-like camera, and also one that has bellows and opens out.

The next point, that as little as possible should project, is fairly obvious, for, in carrying the instrument in the hand, a projecting part is easily damaged.

The superiority of an R.R. lens requires no demonstration, and the fact that it should be workable at  $f-6$  is to make hand exposures possible on dull days. That it should cover a plate half as big again as the one used is to facilitate the free employment of the rising front, while the focus, being at least five and a half inches, will give the work a more natural appearance than that done by the four or five-inch lenses usually put in hand cameras.

A focussing arrangement is indispensable for near objects, and it is most easily managed by rack and pinion. Magnifiers are distinctly to be avoided, for they are always left at home, or lost, whenever they are wanted. In fact, the camera should be complete in itself, with nothing loose to carry about.

Levels are most important, and, when used intelligently in conjunction with the finders, will make all the difference between good and bad work. With the plane of the sensitive surface absolutely perpendicular to the ground, architectural distortion is impossible. A rising front is a necessity for architectural work and street scenes, while, if regularly used in landscape, a great improvement will be noticed in the character of the results. It will be noticed that no mention is made of a swing back, but, with a lens of large covering power and a good rising front, it is a useless addition, besides making the camera more bulky and unwieldy.

Both shutters and diaphragms should be easily adjustable from outside, because they both have to be constantly altered, and everything that tends to speed and efficiency is valuable.

#### HAND VERSUS STAND CAMERAS.

From what I have said it will be obvious that no hand-camera worker need produce photographs with the buildings all tumbling down; and, considering the present speed of plates, there is no reason why, even on dull days, he should have any more under-exposed plates than if he used a stand camera. For my own part, however, I do not see why any distinction should be made between a hand camera and a stand, and I think the time is not far distant when every camera below half-plate will be a hand camera usable with a stand, if required. As Mr. Welford said the other day, it is ridiculous for people to say in disparagement of a bit of hand-camera work that it might have been just as well done with a stand, for the remark ought to be just the other way about, it being obviously absurd to carry about and set up a tripod when the same result can more easily be obtained by holding the camera in the hand. There is one thing that I am quite ready to grant to the opponents of hand cameras, and that is that it is far better for the absolute beginner to start operations with the full complement of tripod and double dark slides. In the first place he will not expose so many plates before he starts development; and, in the second, if he forgets to draw the dark slide, or set the shutter, or some other important trifle, he will spoil one, or at the most two, plates, instead of a dozen. The most important point of all, however, is that a beginner does not usually get a really good instrument, and some of the cheaper forms of hand cameras are veritable training grounds for all the worst habits that a photographer can fall into. I do not mean to say that good work is impossible with a cheap camera.

As regards working a hand camera, the first consideration is how to hold it, and, as far as I have been above to judge, close to the side under the arm is by far the most convenient place, and only in exceptional cases does it alter the point of view sufficiently to interfere with the success of the picture. It requires some practice to hold the camera steady for even so short an exposure as  $\frac{1}{20}$  of a second, but very soon the knack is acquired, and an exposure of  $\frac{1}{8}$  is easily managed, while many can hold the camera quite still for a much longer period.

The plates to be used and their speed must, of course, be governed by circumstances, but it is better to carry too fast a plate than one too slow, as it is easier to stop down and increase shutter speed, but not so easy to make a long exposure in a very dull corner.

In photographing street scenes, and incidents at fairs, and suchlike places, where there are many people, the best procedure is to notice the object you wish to take, and estimate the distance from it to the spot where you require to stand. Then focus your camera accordingly, casually walk to the spot, and with your side, or possibly your back, towards the object, look at it only through the finder, and get your picture unobserved. It is often useful to be able to take photographs from the top of a moving train, but in such a case it should be remem-

bered that the shutter speed will have to be over  $\frac{1}{80}$  of a second to attain anything like sharp definition.

A new hand camera should never be taken on an expedition or a journey without at least forty or fifty plates being first exposed in it, in order to get thoroughly into its working, and to make sure that it has no fault; also, I am sorry to say, that in many cases some of the parts want proper adjusting. For instance, in many of the cheap cameras, the lens is not quite at the right distance from the plate, while in nearly all, including even some of the most expensive, the finders do not give the exact view which falls on the plate. Again, I only know of about one make in which the rising front works the finders simultaneously with the lens. It is therefore generally necessary to make a few experiments in order to mark the finders in such a way that one can tell exactly how much rising front is required on any particular view. To do this, measure the extent of the rise; say it comes to a third of the length of the plate used, then put a mark on the side of the finder one-third of its height from the bottom.

To work with this arrangement, the view should be properly composed on the finder, regardless of the level, and some point in the foreground noted that just touched the bottom of the finder. Next, without altering the sides of the view, the front of the camera should be depressed till the instrument was quite level, and the rising front should be used according to how high up in the finder was the point in the foreground that had been previously noted. If the point was above the highest line of the rising front, of course another position for the view would have to be chosen or the perspective would be wrong.

As to the best size for a hand camera, anything above a quarter-plate becomes too bulky and heavy for general use, while anything below  $3 \times 2$  is too small for satisfactory work. The best way for any one to proceed who wishes to get a hand camera is first to decide the price he is prepared to give; second, to make a list of all the hand cameras about that price; thirdly, select from the list those that have a really good and reliable method of carrying the plates or films. After this, the question of what work the photographer chiefly requires to do influences the selection, but for all-round purposes the following points should be considered in the order named: lens, rising front, shutter size, and focussing, while finders and levels can always be altered or added afterwards if no satisfactory in the original.

CLAUD RIPPOU, M.A.

#### THE RATHENOWER OPTICAL WORKS.

IN reference to the forthcoming centenary of the foundation of the Rathenower Optische Industrie Anstalt, Mr. H. F. Purser, of 33, Hatton-garden, E.C., has kindly supplied us with the following interesting historical details:—

The year 1900, in addition to its distinction as being the last of the old or first of a new century, is of great interest to the optical and photographic world, in that it marks the arrival of the hundredth anniversary of the foundation of the optical industry in Rathenow, and with it the firm of Busch, known as the "Rathenower Optische Industrie Anstalt."

This foundation of an industry and a firm forms a remarkably interesting and unique page in optical history, for it owes its origin to the work of a clergyman, who, having been appointed to the pastorate of the then small agricultural village of Rathenow, and, having some knowledge and interest in optics, later obtained permission to grind lenses, &c., in order to augment his income and that of the parish, that the needs of the poor might be more plentifully supplied.

Thus commenced an industry which has made the town of Rathenow famous, and given employment to thousands of men and women during the past hundred years, and which now supports about 7000 workmen.

The parson mentioned was August Duncker, who worked in the business, and later handed it over to his son, who had received a good education, and who commenced the work of optical construction on strict laws and mathematical rules. During this time the manufacture of spectacle lenses, magnifying and other lenses, had been carried on, a considerable increase being made in the business, so that, when Emil Busch, the nephew of Edward Duncker, came into the business, he found seventy men in employment.

From this time the business developed in a rapid way, and a reputation was built up by the really original creations and discoveries of this man, which earned him the title of councillor of commerce.

He also commenced the manufacture of telescopes, field, and opera glasses, and the firm was soon busily engaged in this department on behalf of the armies and navies of the whole of Europe, Germany, Russia, and Austria being large and continual buyers of the glasses which

experience in many hard campaigns has proved to be of first-class optical and mechanical construction.

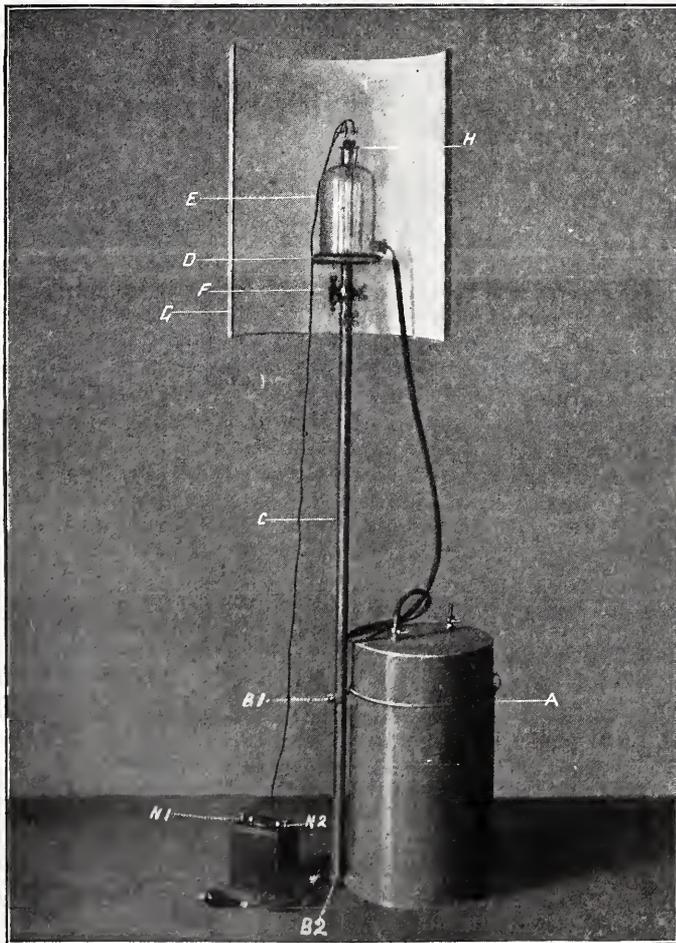

Emil Busch, having no son to succeed him, sold the business to a company now known as the Rathenower Optische Industrie Anstalt. Since the foundation of the industry by this firm, many competitive houses have grown up, but the factory, started in such a remarkable way by a clergyman and carried on later by Emil Busch, still maintains its reputation for first-class optical work, and has added very considerably to that reputation during the past few years by the production of their Aplanat photo lenses and field glasses, &c., which have been made known in this country largely through the agency of Mr. Henry F. Purser.

The centenary festivities are to be held in August of this year, when the whole population of Rathenow and many scattered over the country (for it is a fact that some of the most renowned of modern opticians received their optical education in the factory of Emil Busch) will take part in various events expressing their gratitude to the founder and successors of the optical industry who have done so much to raise the once unknown village to a position of world-wide renown.

Among the items forming the festival programme will be the unveiling of a monument of August Duncker and Emil Busch, and the firm as well as the town have a busy time before them in making the necessary preparation so as to interfere as little as possible with the regular routine of work.

### THE PLATINOTYPE COMPANY'S PORTRAIT LAMP.

On several occasions we have referred to the new oxymagnesium lamp of the Platinotype Company, and its adaptation for portrait purposes in the studio. We have seen many photographs produced by the light which, in softness and naturalness of effect, are not excelled by pictures made in diffused daylight. Appended we give a full description of the system. The first illustration shows the whole of the apparatus, which is exceed-

ingly portable and can be easily stowed away in the corner; the second shows the method of using the light by reflection.

The apparatus consists of an oxygen gas-holder, A, with two sockets, B<sup>1</sup> B<sup>2</sup>, to hold a telescopic rod, C, to the top of which is fixed a wooden table, D. On this is placed the glass vessel, E; below the table, D, is an adjustable socket, F, holding the reflector, G. The glass vessel is connected with the gas-holder by a rubber tube, one end being attached to

the stop-cock on the top of the gas-holder, the other to a bent tube passing through a rubber cork in the opening at the base of the glass vessel.

A rubber stopper is placed in the neck of the glass vessel; through this stopper a metal rod passes with a screw clamp to hold the magnesium ribbon. On opposite sides of this rod are two smaller rods to which are attached two brass caps fixed to the conducting wires, the other ends of these wires being fixed to the battery at points. A switch is provided, by means of which the magnesium is ignited.

For the method of working, the principal directions are as follows:—

1. See that the inner vessel of the gas-holder, A, can be raised and lowered freely.
2. Open both stop-cocks to allow the air to escape.
3. Put sufficient water into the tank, A, to just cover the top of the inner vessel.
4. Turn off one stop-cock and to the other attach a tube from a cylinder of oxygen, allowing the oxygen to pass into the vessel, A, until the top of the inner vessel rises about six inches above the rim of the outer vessel. This will take about half a foot of gas.
5. Shut off supply from

the oxygen cylinder, turn off stop-cock and disconnect the tube. After the insertion of the magnesium in the holder (simple directions for which are also given) the apparatus is ready for use. By pressing the button at the end of the push the electric circuit is completed, which causes the fine wire to become hot enough to ignite the fuse at the end of the magnesium, which then burns, giving a light of great actinic power.

The stop-cock being left open allows the oxygen, which expands with the heat, to pass back into the gas-holder, and the amount of oxygen consumed to be automatically replaced. The entire apparatus costs about 8*l*. We have seen it in operation several times, and can testify that it is exceedingly simple and effective to use, and that the results it gives are excellent. For studio portraiture in dull weather the photographer could not make a better investment.

### THE GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION'S ANNUAL EXHIBITION.

This important fixture, which in the past was generally held during Christmas week, has this year been arranged for a month later, and for several reasons the change has proved to the Association's advantage.

A radical change has been introduced by the Council this season in the matter of judging. In previous years the services of three local gentlemen were requisitioned, but on the present occasion the awards have been decided upon by the voting of members of the Association. This occupied two days, and was completed late on Saturday night last so far

as the framed pictures were concerned, the Lantern-slide Section being decided by the meeting of the Association on Monday night. A very large gathering of members turned out to vote upon the fifteen sets competing, and the large lecture hall of the Society presented a busy scene on the occasion, much fun and merriment taking place as the various sets were projected on the screen.

The Exhibition, in point of quality, is a distinct advance on previous years, and as to numbers is practically the same as last year. Doubtless, the fine season of 1899 has had something to do with the excellence displayed, notwithstanding that several of the best workers are not represented, among whom may be mentioned the names of Mr. Archibald Watson and Mr. J. C. Oliver.

Carbon is the most popular printing process, and platinotype is conspicuous by its almost total absence.

The enlargement class includes some fine examples by Mr. Donald Dove and Mr. Gossman.

In the Landscape Classes Mr. W. J. B. Halley shows to much advantage, and the class for pictures obtained during the Association's outings during the summer proved very attractive.

As in previous years, the Exhibition remains open for fourteen days. The following are the awards:—

Class I.—Landscape (including Architecture), sizes above half-plate: Mr. W. J. B. Halley, silver; Mr. James Douglas, bronze.

Class II.—Landscape (including Architecture), half-plate and smaller: Mr. Alexander Allan, silver; Mr. A. J. Kay, bronze.

Class III.—Portraiture (including Groups and Figure Studies), any size: Mr. James Douglas, silver; Mr. Robert McMillan, bronze.

Class IV.—Hand Camera (camera must be held in the hand), any size: Mr. James Douglas, silver; Mr. W. L. Primrose, bronze.

Class V.—Lantern Slides: Mr. W. J. Resch, silver; Mr. W. Bryson, bronze.

Class VI.—Bromide Enlargements (Portraits, Groups, and Figure Studies), not less than 10×8: Mr. R. T. Armour, silver; Mr. G. Campbell-Dickson, bronze.

Class VII.—Bromide Enlargements (other than Portraits, Groups, and Figure Studies), not less than 10×8: Mr. J. W. Resch, silver; Mr. Donald Dove, bronze.

Class VIII.—Best Picture taken at an Outdoor Meeting of the Association in 1899, any size: Mr. W. J. B. Halley, silver; bronze not decided (a tie).

Class IX.—Landscape or Seascape (open only to Members who have begun photography since January 1, 1899, and who have not won an award anywhere):

Class X.—Landscape or Seascape (open only to Members who have not won an award anywhere): Mr. J. W. Downs, silver; Mr. William Neilson, bronze.

#### PROPOSED PHOTOGRAPHIC BRANCH OF THE HAMPSTEAD ASTRONOMICAL SOCIETY.

We are asked to state that photographers are invited to attend a meeting to be held at the Hampstead Library, Prince Arthur-road, for the purpose of discussing the desirability of forming a Photographic Section of this Society, on Thursday, February 15, 1900, at 8.30 p.m., when Mr. E. Compson Crump will take the chair.

The objects of such a Section would be: The holding of meetings for the reading of papers, &c.; an annual exhibition; summer excursions, &c.; and, if deemed desirable, the acquisition of a dark room, or rooms, for the use of members.

Membership of the parent Society (the minimum subscription to which is 5s. per annum) would entitle members to the privileges of the proposed Section.

Mr. F. Lubbock Jermyn, of 3, The Wilderness, Holly-hill, Hampstead, a member of the Council, has consented to act as Honorary Secretary of the Photographic Section, should it meet with sufficient support.

Ladies or gentlemen who are unable to attend the meeting, but who may be desirous of becoming members of the Section, are requested to communicate with Mr. Basil W. Martin, Hon. Secretary of the Society, 7, Holly-place, Hampstead.

#### NOTES FROM THE WEST OF SCOTLAND.

THE statement which has appeared in several of the photographic journals to the effect that the Glasgow *Evening Times* Camera Club was on the eve of being wound up, was, to say the least of it, premature and misleading. This important photographic association, with its very large roll of members, has for a long time felt the desirability of making some change in the constitution, whereby a more befitting name might be adopted than that of hitherto. It being felt that the scope of the Club should have a wider sphere than its name implied, and so for a long time past it was recognised that, were the Club's name changed to the Glasgow Camera Club, it would convey a much better idea of the Society's position, which, in reality, has never been confined to the immediate surroundings of the *Evening Times* newspaper. This step has now been taken, and in future it will be known as the Glasgow Camera Club, and, under its new constitution, we have no doubt it will have a long and prosperous career.

The Glasgow and West of Scotland Horticultural Society has arranged

for another photographic exhibition in connexion with its autumn flower show to be held in St. Andrew's Halls in August next. Some change will be made in the classes over those of last year, and money prizes will, this year, give place to medals and photographic apparatus. The Judges will be Mr. Dewar, Curator of the Botanic Gardens; Mr. Wm. Goodwin, Hon. Secretary of the Glasgow and West of Scotland Amateur Photographic Association; and Mr. Archibald Watson.

Several gentlemen, well known in the West of Scotland, are in Africa, and we are now beginning to see the pictures they have secured with their cameras. One interesting series shown for the first time last week embraced a photograph of the action at Magersfontein, and Messrs. Geo. Mason and Co. are showing this week, in the Corporation Galleries, another fine series of views under the auspices of the exhibition organized by the Artists' War Fund in Glasgow.

## Our Editorial Table.

### THE "EASY" SERIES OF CLOUD NEGATIVES.

Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.

IN sending us a sample cloud negative, Mr. Welford says he makes a feature of having a very large variety to choose from, and of the fact that the cloud is finely gradated into an opaque foreground, thus rendering the necessary shading easier in combining with another negative. The sample sent bears out the claims that are made for it, and the series can be recommended to the attention of those who make negatives yielding white skies in the positives, and who therefore desire a ready means of printing in clouds. These negatives are obtainable from all dealers, the wholesale agents being Messrs. Charles Tyler & England Brothers, Ltd., Copenhagen-street, London, N.

## Studio Gossip.

MR. T. C. TURNER, the well-known photographer of Regent's-terrace, Hull, informs us that the studio of Turner & Co., Limited, of Barnsbury-park, London, N., has been closed. The premises have been found too large for modern business requirements. The studio in Upper-street, Islington, will, however, be conducted as usual under the style of T. C. Turner & Co. This concentration of the firm's affairs will give Mr. Turner greater opportunity for attending to his rapidly increasing Hull business.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, February 14. Members' Open Night.

ROYAL PHOTOGRAPHIC SOCIETY.—The Annual General Meeting will be held at 66, Russell-square, at eight p.m., on Tuesday, February 13, when the report of the Council and the Treasurer's accounts will be submitted to the members, and the result of the ballot for the election of officers and Council will be announced.

THE G.E.R. MECHANICS INSTITUTION (Photographic Section) will hold their Seventh Annual Exhibition on March 13 and 14, at the G.E.R. Mechanics Institution, Stratford, E. There will be an open class for general work. The Judges will be Messrs. Seyton Scott and Basil E. Lawrence. The Exhibition Secretary is Mr. C. W. Harris, 29½, Cam Hall-road, Leytonstone, E.

THE Exhibition of photographs by Mr. J. Craig Annu, of Glasgow, now hanging upon the walls at the Royal Photographic Society's house, 66, Russell-square, will remain open until the end of February. It is hoped that everybody interested will take the opportunity of examining the collection, which numbers about eighty examples. Admission on presentation of card, between ten and four o'clock.

OUR contemporary, *The King*, which is making a speciality of its war photographs, advertises that it consistently uses war photographs, and not war sketches, because people want truthful snap-shots taken in South Africa, and not fancy drawings worked up in London. It adds: "*The King* does not tamper with its war photographs.—It does not 'fake,' and the titles of the photos are as nearly as possible in the actual words of its correspondents."

A DAILY contemporary states that, during the recess Sir Benjamin Stone, M.P., has secured a number of photographs of the exterior and interior of Windsor Castle, for which the special permission of the Queen had first to be obtained. In all, between 600 and 700 pictures were taken, many of them being of portions of the Castle which had never before been photographed. A copy of each of the photographs taken is to be forwarded to the new department at the British Museum.

CRIPPLEGATE INSTITUTE.—An advanced class in photography, consisting of twelve lessons on bromides and enlargements, carbon printing, combination printing, and lantern slides, will commence on Tuesday, February 13. Lecturer, Mr. John H. Gear, F.R.P.S., Certificated Teacher of Photography, City and Guilds of London Institute, and of the Polytechnic, Regent-street, W. Full particulars can be obtained on application to the Manager, Cripple-gate Institute, Golden-lane, E.C.

**THE FALLOWFIELD BOHEMIAN CONCERT.**—This always pleasant little function, held by the employees of the firm and their friends, takes place on Friday evening next, February 16, at the Champion Hotel, Aldersgate-street, E.C., under the presidency of Mr. F. W. Hindley. A copy of the neatly printed programme has been sent us. It contains between thirty and forty items, and it may therefore be anticipated that a very pleasant evening is in store for those who purpose attending the concert. As usual, Mr. F. J. Goode is Hon. Secretary, and he is assisted by an efficient committee.

By the death of Mr. Andrew Stewart, Editor of *The People's Friend*, on Thursday, Dundee has lost one of its most enthusiastic amateur photographers. Mr. Stewart occupied the presidential chair of the Dundee and East of Scotland Photographic Association for two seasons, and his annual addresses were models of good sound common sense, garnished with a poetic appreciation of the beauties of nature. Mr. Stewart had toured much in America, Norway, and the Continent, and camera and pen combined to give the readers of the popular miscellany over which he presided many bright and informative articles. On the occasion of his editorial jubilee in 1896, he was presented with his portrait, painted by Mr. Charles Martin Hardie, R.S.A. Mr. Stewart was a self-made man, having started life as a paper-ruler, and by sheer merit gained his present position.

## Commercial Intelligence.

MR. W. D. WELFORD, of 19, Southampton-buildings, Chancery-lane, says he will be removing shortly to larger premises. Mr. Ernest Human, late of Taylor's Drug Stores Photo Department, High Holborn, W.C., is Manager to Mr. Welford, who has two new hand cameras and many other novelties coming out shortly.

MESSRS. BERGER & Co., of South Hill Park, N.W., inform us that the extension of their works and machinery is now quite complete, and that, in addition to the new papers they recently placed upon the market, other productions of a very striking nature are well in hand, and will be shortly introduced into the photographic world. Mr. Edwin Banks, the well-known photographic chemist, has joined the firm, and, in conjunction with Mr. Maurice S. Berger, is in charge of the chemical laboratory and emulsion rooms at South Hill Works, Hampstead.

A CONTEMPORARY states that intending exhibitors at the Paris Exposition will do well to protect their inventions by means of foreign patents before sending their devices, for international exhibitions have always offered a splendid opportunity for unscrupulous imitators of new devices and inventions to pirate them if they are not covered by foreign patents. It is also believed that trade marks will be infringed in the future as in the past. The Parisian Inventors' Academy is also attempting to do an unusually large business, and there are so many pitfalls arranged for the inventor that it would be well before making contracts of any kind to make sure of the standing, financial and otherwise, of the firms which are to attend to exhibits. Our quotation has reference to American exhibits; the hint, however, may apply equally to those firms in this country who propose being represented at the Exposition.

By the courtesy of Mr. John Carbutt, the well-known plate-maker, &c., of Wayne Junction, Philadelphia, we have received a copy of the *Philadelphia Public Ledger* of January 12, which contains a brief account of a meeting recently held in New York for the purpose of organizing the Photographic Manufacturing Association of America. It appears that the meeting was held at Waldorf-Astoria, and was attended by representatives from the Scovill & Adams Co., of New York; John Carbutt, dry plates, films, and paper, Philadelphia; Wills & Clements, of Philadelphia; the Bullard Camera Company, Springfield, Mass.; Manhattan Optical Company, New York; the Cozy Camera Company, Boston; Defender Photo Supply Company, Rochester, N.Y.; Vive Camera Company, Chicago; Gundlack Optical Company, Rochester, N.Y.; New York Dry Plate Company, and the G. Gennert, New York. The organization is a co-operative association for the benefit of its members and retailers, and especial emphasis was placed in the statement, "It is not a trust, but organized to oppose any coalition having for its object the concentration to one source of the supply of photographic goods, and for the dealer to assert his right to buy such articles as he may choose from any source whatever." Mr. W. I. Lincoln Adams was elected President, Mr. M. B. Hoyt, Secretary, and Mr. F. H. Hoge, Treasurer. The new association will be immediately incorporated under the laws of New York State, and every action taken to get the support of retailers throughout the country.

Re FREDERICK GEORGE FRY, recently in partnership with T. E. Parkin, and trading as Parkin & Fry, dealers in photographic materials, the Etna Mills, Old Swan, Liverpool. The adjourned public examination of the above-named debtor was held at the Liverpool Bankruptcy Court on Thursday, February 1, before Mr. Registrar Bellringer. It appeared that in January of last year Fry advertised for persons to join a syndicate to bring out a secret process which he had discovered for making bromide paper. In the result, Mr. T. E. Parkin, of Doncaster, agreed to join the bankrupt in partnership, and to provide the necessary capital. Articles of partnership were entered into accordingly, and the production of the article was commenced. On being practically tested it turned out a failure, and in August last Parkin determined to give notice of dissolution of the partnership; but, before this could take effect, creditors obtained a receiving order against the partners. In the subsequent bankruptcy proceedings, Parkin alleged as the cause of his failure his unfortunate partnership with Fry; whilst Fry's reason was that Parkin had only put into the business 700*l.* instead of 3000*l.*, and, further, the taking possession by a building society of the mills at Old Swan, on which they had expended 1600*l.* Parkin's story was that he found 1117*l.* in cash for the business and 230*l.* for law costs, and his reason for not finding more was that the bromide paper manufactured under Fry's process was found to be worth-

less, and he had utterly lost faith in it. Parkin's public examination was closed several weeks ago. Fry's reply was that his process was a valuable one, and would have proved so if his partner had provided the capital agreed upon. A sealed envelope was produced, and said to contain particulars of the process, but the Registrar declined to go into the question of the merits, and the envelope was taken possession of by Mr. Terry, the trustee in bankruptcy. In the course of his examination, Fry stated that some years back he was appointed liquidator of the Liverpool Musical Supply Company, Limited, of 89, Islington, Liverpool, and that he had handed over 200*l.* to J. H. Yates, a Liverpool solicitor, who was nothing in the matter, and was now serving a term of imprisonment for fraud, and that that 200*l.* had not been accounted for by Yates. Later on, Fry denied that he had ever acted as liquidator, and that the real liquidator was one Charles Rhymes, of whom he knew nothing. Mr. Welby (for the bankrupt) now produced the Registrar of Joint Stock Companies' certificate to the effect that Rhymes was the liquidator. The Official Receiver said he did not yet believe that Rhymes was the liquidator of this particular company, there having been two companies with the same name, the one having taken over the other, which was voluntarily wound up. It had also transpired that Rhymes was discharged, and that a W. G. Duff, a clerk to J. H. Yates, was appointed in his stead. The bankrupt said that, as far as he was concerned, Duff had nothing to do with the matter. He denied that he, as chairman of the meetings and managing director, and Yates, as solicitor, had the whole thing between them, and added, "And don't you dare to say such a thing." He denied that he got the money. The Registrar remarked that that was certainly what the debtor had said. The bankrupt, continuing, said he could prove that Rhymes had received the money. The books of the Company had all gone to Yates's office, and he knew nothing more of them. The Official Receiver said he did not think the matter could be carried further on the public examination. The Registrar: Then I shall close the examination; but I do so, expressing my opinion that a more unsatisfactory examination has never been before me.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

February.	Name of Society.	Subject.
12.....	Bradford Photo. Society .....	Demonstration: <i>Enlarged Negatives.</i> Percy Sheard.
12.....	Camera Club .....	<i>Mountaineering in Switzerland and Scotland.</i> Professor Norman Collie, D.Sc., F.R.S., &c.
12.....	Kingston-on-Thames .....	Demonstration: <i>Platinotype Printing.</i> The Platinotype Company.

17.....	Glasgow and West of Scotland .....	Close of Exhibition.

### ROYAL PHOTOGRAPHIC SOCIETY.

FEBRUARY 6,—Lantern Meeting,—Mr. J. J. Vezey in the chair.

#### SHAKESPEARE AT HOME.

Mrs. CATHERINE WEED WARD gave, to an overflowing and deeply interested audience, her charming lecture on "Shakespeare at Home," which was illustrated by a large number of lantern slides from negatives made primarily in connexion with the book which Mr. and Mrs. Ward issued some two years ago, on the subject of the Shakespeare country. Shakespeare, she said, was essentially the product of his times, and she therefore began by briefly sketching the condition of England, socially, politically, and religiously, in the sixteenth century. Then the life of the poet at Stratford-on-Avon was described and pictorially illustrated from his birth; views were shown of Snitterfield, Arden, Bidford, Charlecote, Clopton, Luddington, Tiddington, and all the scenes associated with his childhood, boyhood, school days, courtship, and marriage, with photographs of the Memorial Theatre and museum, and a number of portraits and busts, the whole subject being dealt with in a most enthusiastic and painstaking manner, which was thoroughly appreciated and enjoyed by all present. Mrs. Ward concluded with a few words of advice to those who think of visiting the Shakespeare country, to the-

following effect: When you go to Stratford, make your headquarters in the town itself. Go there in nightingale time, if you can; but, whenever you go, try to get behind the great facts, and buildings, and objects of interest to the real life, and poetry, and sentiment of the place. The singing birds, the rippling river, and the whispering trees are much the same to-day as they were 300 years ago. If you realise the position of the son of the bailiff in the day when books were few, and if you can but partially understand the character of such a genius as Shakespeare—receptive, observant, with great memory, and a great, living, human sympathy—you will need no anti-Baconian argument to convince you that whoever wrote Shakespeare's plays was a poet by birth rather than a scholar by books.

A very hearty vote of thanks having been given to Mrs. Ward, The Rev. F. C. LAMBERT mentioned an interesting and little-known fact connecting Shakespeare with London, that two of Shakespeare's companions, Jack Heminge and Harry Condell, are interred in the church of St. Mary Aldermanbury, near Moorgate-street. He also said that there was in that churchyard the only statue of Shakespeare to be found in London, with the exception of the one in Poets' Corner in Westminster Abbey. It will be remembered that Heminge and Condell edited the first folio of the Plays, published in 1623, and that to them and Burbage—all of whom were associated with him at the Blackfriars Theatre—legacies were bequeathed by the will which "the poet for all time" made a few weeks before his death. We may add that, on the north side of the altar of the church referred to, there lie the remains of Judge Jeffreys, of notorious memory.

COMING EVENTS.

February 13, Annual General Meeting. February 20, Photo-mechanical Meeting, subject to be announced. February 27, Technical Meeting, "Electricity in Connexion with Photographic Action," by Mr. W. Friese-Greene. March 6, Lantern Meeting, "Some Beauty Spots of English Scenery," by Mr. J. A. Hodges.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 1.—Mr. A. Mackie in the chair. Mr. GRANT, of the Sandell Films and Plates, Ltd., gave a demonstration of the new Cristoid film. The Cristoid film consists of the double emulsion film of the Perfect plate, coated more thickly to make it independent of any base, such as paper or celluloid. The emulsion is double-coated on plate glass and afterwards stripped, and, consisting altogether of emulsion, the operations of development, fixing, and washing take place on both sides at once, thus quickening these processes. Lightness is a strong point in favour of the films, as also is flatness during the operations. The two coatings of which the film is formed are of different speeds. The glossy side of the film, which is that which was first coated, is a slow emulsion, the matt side being a fast emulsion. The latitude in exposure allowed is tremendous. This was shown by developing films which had been exposed for 1, 15, 60, and 300 seconds respectively under like conditions of light, &c. In the Cristoid film one has a material capable of receiving far more light work than is necessary to make a perfect negative. The film receives a certain amount of light—it may be a correct or incorrect exposure—and a certain action takes place. The essential point is that a developer of one strength, the function of which is purely mechanical, be used. With this the film is developed until the whole of the light action is utilised. When fixed, the negative will show the nature of the exposure; if correct, the negative will be correct. If over-exposed, there will be a corresponding excess of density, which, if too great for printing purposes, can be readily reduced by ferridcyanide of potassium and hypo. The two films of emulsion are on the matt side, of a speed of 100 H. & D., and on the glossy side 10 H. & D. Either side may be used; the rapid for instantaneous exposures, or the slow where greater contrast is wished for. Halation is impossible, and frilling cannot occur. The stumbling-block of all photographers is exposure, but with this film, if one only gives enough, one can go on to 300 times, and yet get a useful and printable negative. It has been found that for X-ray work the film is specially useful, notably in cases where a plate cannot be employed when the film is twined round a body, &c. For carbon printing the negatives are also very convenient, dispensing with double transfer or a reversed image, as the negative can be printed from either side. There is another quality peculiar to the films, and that is that they enlarge during development and subsequent operations twenty-five per cent. in area. This expansion is regular and constant, depending upon the initial thickness of the film. Once enlarged, it can be dried at the enlarged size by squeegeeing upon glass or ferrotype plate. Should it be desired to restore the film to its original size, however, it can easily be done by using a bath of methylated spirit after washing, and then squeegeeing. The standard thickness of film now adopted is one two hundred and fiftieth of an inch, and it is found that this expands exactly twenty-five per cent. Whatever the exposure, one should always develop for the same length of time, six minutes, with the solution at from 55° to 60° F. Before development the exposed film is soaked in a bath of—

Formalin .....	2 ounces.
Potassium bromide .....	60 grains.
Water.....	to 1 pint.

The bromide tends to retard the otherwise accelerating influence of the formalin. After a few minutes in this, the films are transferred to a developer, of which the stock solution is composed thus:—

Pyrocatechin .....	1 ounce.
Potassium bromide .....	30 grains.
Sodium sulphite .....	4 ounces.
Sodium hydrate .....	½ ounce.
Water (boiled or distilled) .....	1 pint.

For the standard developer, one part of the above is diluted with seven parts of water. If developing with developers other than pyrocatechin, it is advisable to wash the film well after the formalin bath; otherwise, with some reducing agents, a sherry-coloured film will result. Pyrocatechin is considered best, however, as a developer. Of course, nothing can equal a correctly

exposed negative; but, with this enormous latitude of exposure, and acting according to instructions, an excellent negative, though much over-exposed, can be obtained. Mr. Grant then went through the operations of developing films with exposures ranging from one to 300 seconds, finally comparing those which, through over-exposure, were so dense that they had to be reduced, with the correctly exposed film (one second).

A vote of thanks was passed to Mr. Grant for his demonstration.

Mr. BROWN remarked that, at the last meeting, he had commented upon the fact, that in the old days a piece of white paper placed behind a plate gave an apparent increase of exposure. He had exposed a plate partially backed with caramel and partially with white paper, and found that where the caramel was present undoubtedly the exposure was diminished; where the white paper had been placed, the difference in density was plainly discernible.

Mr. P. EVERITT said that it had been stated that a backing of white paper added ten per cent. to the exposure. He suggested that two exposures should be made on subjects requiring respectively exposures of nine and ten seconds, giving the nine seconds exposure on a plate backed with white, and the ten seconds exposure in the ordinary way. It was suggested, however, that a difference of ten per cent. in exposure was really inappreciable under ordinary conditions.

Mr. E. HUMAN showed a very compact hand camera for use with Cristoid films, so made that either the slow or rapid side of the film could be used. It takes thirty-six films in sheaths, which are changed by means of a changing bag. The storage chamber is separated from the exposing chamber by a partition, and there is little to go wrong. Of course other films can be employed, but, as a means of exposing films having a front and back sensitive surface, it is worthy of notice.

North Middlesex Photographic Society.—January 29.—Mr. CHILD-BAYLEY (the President) demonstrated the method of obtaining warm tones on bromide paper by means of copper toning:—Ten per cent. solution potash citrate, 2 ounces; sulphate of copper, 140 minims; and ferricyanide of potass, 120 minims; both ten per cent. solutions. This formula toned quickly to a pleasing brown tone of various shades, according to the length of immersion. If carried too far, the tone was unpleasant. Mr. PUDDY showed comparative results obtained by the action of various reducers. Permanganate of potash and sulphuric acid appeared to come between Howard Farmer's and persulphate of ammonia in its action on gradation. He also tried the addition of various chemicals to the solution of persulphate. Sulphocyanide of potass. seemed to cut out the lower tones very markedly.

FORTHCOMING EXHIBITIONS.

- 1900.
- February 10-24 ..... Edinburgh Photographic Society. J. S. McCulloch, 10A, George-street, Edinburgh.
  - "   24-March 3 Birmingham Photographic Society. Lewis Lloyd, The Hollies, Church-road, Moseley.
  - March 3-10 ..... South London Photographic Society. Hon. Secretary, Frank Goddard, Woodlands, Vanbrugh Hill, Blackheath, S.E.
  - "   13, 14 ..... G.E.R. Mechanics Institution (Photographic Section). C. W. Harris, 294, Cam Hall-road, Leytonstone, E.
  - "   26 ..... Twentieth Century International, Birmingham. Walter D. Welford, 19, Southampton-buildings, Chancery-lane, London, W.C.
  - "   26-31 ..... Photographic Society of Ireland. W. F. Cooper, 35, Dawson-street, Dublin.
  - April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

Patent News.

The following applications for Patents were made between January 22 and January 27, 1900:—

- CINEMATOGRAPHS.—No. 1319. "Improvements in Consecutive View Apparatus." Complete specification. W. K.-L. DICKSON.
- CINEMATOGRAPHS.—No. 1320. "Improvements in Consecutive View Apparatus." Complete specification. W. K.-L. DICKSON.
- DEVELOPING PLATES.—No. 1351. "Adjustable Frame for Developing Photographic Plates." L. VANINO.
- PRINTING AND DEVELOPING.—No. 1530. "Apparatus for Photo Printing and Developing." J. W. VICKERS and J. H. W. RUMSEY.
- CINEMATOGRAPHS.—No. 1627. "Improvements in the Method of and Apparatus for Photographing and Displaying Animated Pictures." P. A. THOMAS.
- CINEMATOGRAPHS.—No. 1643. "Improvements in Apparatus for Photographing and Exhibiting Cinematograph and Mutoscope Pictures." H. W. H. PALMER.
- HAND CAMERAS.—No. 1672. "Improvements in Hand and other Magazine Photographic Cameras." F. H. ALSTON and the BIRMINGHAM PHOTOGRAPHIC COMPANY, LTD.
- CINEMATOGRAPHS.—No. 1467. "Improvements in and relating to Cinematographs." HAYDON & URRY, LTD.

## Correspondence.

### STEREOSCOPIC PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Your correspondent, Theodore-Brown, in the JOURNAL of January 26, refers to an apparatus, the stereophoto-duplicon, for taking stereoscopic pictures direct with a single lens. Judging from the query put to you by Colonel Gubbins in the previous week's JOURNAL, and the reference by Mr. Brown, the stereographs by this method are produced in one operation by an arrangement of mirrors, and, both views being in their correct position, the negative may be printed from direct, no transposition, as you imply, being necessary before mounting. The method, if effectual, is certainly ingenious, and I should much like to see one of the stereographs produced by this means.

It will be within your recollection that I gave a description, with drawing, of an improvement on the original method devised by the late Latimer Clarke for taking stereoscopic pictures with a single camera and lens. It was described in the JOURNAL for September 1, 1899, pp. 70-71. The only drawback to this arrangement is that instantaneous pictures cannot be taken by it. In other respects the arrangement is perfect for taking stereographs with a single lens either of distant views or of objects close at hand. No transposition is necessary when mounting the print, and the pictures combine perfectly in the stereoscope.—I am, yours, &c.,

THOS. MITCHELL.

Newport, Mon., January 30, 1900.

### ARTICLING PUPILS IN PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Doubtless, from your vantage ground, you have had the opportunity of seeing further than some of us confined to a somewhat limited area, although our experience covers the greater portion of time that photography has been commercially worked. It neither transpires from the question of "Guardian" in your columns of January 19, nor in your reply thereto, what was supposed to be included in the sum named (75*l.* for three years). As far as it appears, it may have included residence with the photographer or not. Be that as it may, it seems a sweeping assertion to make, "there is not much to learn in photography now that everything is supplied ready for use, and the remuneration small." First, it implies that the tools, and not the man behind them, do the work; and, secondly, that the remuneration paid by some is set as a gauge for all, and thus "Guardian" may be deterred from putting his son anywhere to learn thoroughly what it is said he has taste for.

I respectfully submit this is unfair to all. Your article of January 26 says: "We regret to say that they (*i.e.* salaries of operators) are generally very low *nowadays*, for the reason that there is at the present time so very little to learn, and as a consequence the labour market, as the *unskilled* labour market *always was*, is overstocked." On the one hand, you speak of what is *now* as what *always was*. I venture to say that what the market is—"overstocked with unskilled labour"—is the result of lack of training, and the supposition that, if you only get the tools, all will work right. But let such recollect the *naïve* reply given by a great artist on being asked how he mixed his colours, "With my brains." There have been geniuses in most directions, but I question if any guardian would be justified in giving a lad a few hairs from a cat's tail, and telling him to make his own brushes, if he wished to be an artist, because a genius in poor circumstances had done so. I think his course should be to find out the best artist he could who would allow him to work with, and under him, on such terms as the one would accept or the other afford; and this principle I consider holds good still in photography, where there is always something to learn, but in which many flounder about from the want of proper instruction and arrive at no excellence, and so help to swell the crowd of the unskilled, who, if perchance they get a berth, soon lose it again on that account.

It does not seem to me fair to quote the advertisements you have in support of "remuneration." One can see at a glance the style of them, and the charges obtained, probably 2*s.* 6*d.* per dozen, for, after all, this must depend largely on the prices obtainable and the number of population available.

I should not have troubled you with this reply, but for what appeared to me a libel on the profession, *viz.*, "that there is nothing to learn."

If that be true, how is it that men get paid from, say, 40*s.* to 100*s.* per week? Even taking the lowest figure, it is equal to many skilled mechanics, none of whom, however, would have obtained that if they had not first been apprenticed, in some cases seven years, at a very nominal remuneration. And I have known several cases where young men have gone through this in a country shop, and very soon after have found their way into London shops (where they generally learn one thing), but these have passed them by and become foremen at good wages. One

thing more, you say, "It is seldom a photographer in good practice cares, even with the inducement of a premium, to prepare a possible rival." I should take it for granted that it would be exceedingly bad taste for a pupil to start in opposition in the same place to his tutor and, if such were probable, there are means to prevent it. I think one who is fond of his profession would feel some pleasure in instructing others if some arrangement be made that both are satisfied with. No one has a right to expect that any man would take the responsibility of instructing others without any remuneration whatever, as tyros will always spoil as much as they do, at least for some time, except in cases that are exceptional, and these would amount to an act of charity and cannot be reckoned on business lines at all. The remuneration any one will secure, either as journeymen, if I may use the term here, or in their own business, must largely depend on themselves, but I contend that the properly trained has the advantage at the start.—I am, yours, &c.,

PROFESSIONAL.

### WHAT ONE WANTS TO KNOW.

To the EDITORS.

GENTLEMEN,—The more one reads the more one wishes to know. Having read the current ALMANAC, I am seized with the desire to learn—

(1) Where Burton's actinometer (mentioned by Mr. Coysh) can be obtained; also, who supplies Warnerke's standard sensitometer screen?

(2) On page 964 I find a note on white silver. Does the immersion in the solution follow, or take the place of, ordinary development? Does the result possess sufficient contrast to permit of its being satisfactorily rephotographed? I have tried mercurial bleaching and rephotographing on an enlarged scale. The result generally lacks contrast, and is inferior to an enlarged negative produced in the usual manner.—I am, yours, &c.,

DABBLER.

[We believe that Burton's actinometer can be obtained of the Autotype Company, 74, New Oxford-street, W. The Warnerke standard sensitometer screen was, we believe, formerly to be had of Messrs. Marion & Co., Soho-square, and perhaps that house may still be able to supply it. We should imagine that the immersion in the solution mentioned referred to takes the place of ordinary development.—EDS.]

### THE KEEPING QUALITIES OF EXTRA-RAPID PLATES.

To the EDITORS.

GENTLEMEN,—Will you kindly give me your opinion on the following question with reference to extra-rapid plates fogging after being kept, which has been usual with me during the three years I have taken up photography as a hobby; also kindly give a remedy, such as a solution to put the plate in previous to developing.

After the packet of extra-rapid plates has been opened (I have tried many makers with the same result) I find they will not keep beyond a month or six weeks, as, although I get fine, clear, crisp negatives when the box is first opened, yet, after the time named, a thin veil of fog comes over the plate during development, although exposed and developed under the same circumstances. I may say I am most particular to keep the plate covered during development; my dark room and camera are light-safe, as other plates developed by the same method are quite clear, although kept much longer. My developers are pyro soda, and since reading Mr. Welford's articles in your JOURNAL I feel that I think very good.

When I hear of other workers keeping their summer snap shots till winter before developing them, it makes me wonder how it is done.

Hoping you can put some light on this query for me, and thanking you in advance,—I am, yours, &c.,

W. T. DRAY.

27, Landells-road, East Dulwich, January 30, 1900.

[In our opinion, the fact that our correspondent's extra-rapid plates do not keep well for more than such a very short time as six weeks points to some such theory as the presence in his dark room of damp, vitiating gases, or exhalations which attack the sensitive layer. We ourselves have frequently kept extra-rapid plates for periods of over a year, and have produced perfectly clean negatives on development. At p. 1093 of our ALMANAC for 1900 formulæ are given for restoring fogged plates.—EDS.]

### THE METRIC SYSTEM.

To the EDITORS.

GENTLEMEN,—M. Levy's letter, in your last issue on the subject of metric weights, deals implicitly with a point on which there has been a great deal of misunderstanding and misrepresentation.

It has never been contemplated by the reasonable advocates of metric units that the use of convenient fractions should be forbidden. Possibly there have been a few partisans who have gone this length, but the assertion that these fractions are to be forbidden is generally made by the opponents of the system. That for many purposes the notation 125 for  $\frac{1}{8}$  of a superior unit, and that it is in accordance with a notation

which admits of all quantities being accurately expressed, is true beyond all doubt, but it does not deny that the same fraction is also an eighth of the same unit, nor does it forbid the expression of that truth.

But there is another way of looking at the matter, which is commonly neglected. When a customer asks for a couple of ounces of tea, it is not, as a rule, because there is any decided preference for that precise amount, but because it is one convenient to ask for; and it is quite certain that the demand would adjust itself to the new weights and moneys. People would still, perhaps, call the half kilo a pound, and I rather think that this was at one time proposed in Germany, as it was certainly sanctioned by the *Système Usuel* in France, but the wisdom of the German Parliament refused to give such a practice legal sanction. It is quite certain that, if a law as to weights and measures were enforced, language and trade customs would in no long time accommodate themselves to it; but of that desirable solution there seems to be no prospect at present.—I am, yours, &c.,  
J. F. T.

To the EDITORS.

GENTLEMEN,—I have not seen "Free Lance's" letter, but can assure him that there is no difficulty whatever in using metres and grammes.

With regard to the use of the former, I can speak with experience of more than a quarter of a century of the use of metric measures in English bridge and engineering works. I have found that after a very short experience the workmen prefer the metric measures.

As an example of the comparative safety of metres as compared with English measurements, I will give an actual experience. In work abroad, a flange was ordered 2 ft. 7 $\frac{3}{8}$  in.; but the dimension was not clearly written, and the flange was sent out 27 $\frac{3}{8}$  in., or 2 ft. 3 $\frac{3}{8}$  in. diameter. Now, if the dimensions had been given in metric dimensions, such an error could not have occurred. An exactly similar mistake in the diameter of a flange was made at the General Post Office, I believe, but I cannot at the moment lay my hands on the report of it.

So much for measurements; but how about weights, which more nearly concern the photographer? I have opened the ALMANAC at random at page 1034, and read, 70 grains in 20 ounces. Although a fair hand at figures, the above conveys no sense of proportion to my mind, and I can hardly think that "Free Lance" could tell one without.—I am, yours, &c.,  
CHAS. LOUIS HETT.

#### FREAK PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—I do not know if you will think it worth while to say anything more about freak photography and changing films, but here is my answer to Mr. W. Bloomfield, p. 79 of THE BRITISH JOURNAL OF PHOTOGRAPHY. As I said before, it is not of my own experience I was speaking, but of a friend's, and I have very little experience with Kodaks and the pools of films, but I have seen a spool put in place wrongly, and taken out again and replaced; however, opened. I therefore conclude that, as in the case I mentioned, the spool once inserted, four or five views may have been taken, as was the case in this instance, the whole outfit then taken in a dark room, the spool taken out and rolled back in its original place and gummed up, to put it back when repaired. Then the mistake of the spool (one for the other) made, and in the end the possible experience I mentioned. I do not pretend to say that this would have been possible, or as easy, if the whole spool would have been exposed at first.

As I said before, this is only a personal answer to Mr. Bloomfield, and of very little interest to the public, and I give it to you for what it is worth.—I am, yours, &c.,  
A. LEVY.

Asnières (Seine) February 4, 1900.

#### PYRO STAINS.

To the EDITORS.

GENTLEMAN,—Seldom many weeks pass without some reference in your JOURNAL to "pyro stains" upon the fingers. I ask why *have* these stains, when they can be so easily avoided by simply using glass-bottomed developing dishes? To gauge density, it is only necessary to pour the developer back into the graduate and hold the dish to the light; the negative can be washed without taking it out of the dish. To facilitate its removal, drive into the wood a pin with the head cut off, leaving a portion on the surface of the glass for the negative to rest on.—I am, yours, &c.,  
S. J. CASTLE.

Whitstable.

#### CRISTOID FILMS.

To the EDITORS.

GENTLEMEN,—As there seems to be a difficulty with many of your readers as regards the formalin to be used with "Cristoid" films, I should be much obliged if you could mention in your next issue that the formalin intended is the photo formalin of Schering.—I am, yours, &c.,  
Norwood Junction, London, S.E.  
J. T. SANDELL.

#### THE SOUTHSEA EXHIBITION.

To the EDITORS.

GENTLEMEN,—In the list of awards in the Southsea Exhibition you give my name as F. Fielder, whereas it should be F. Fielding. Will you kindly correct in your next issue and oblige.—I am, yours, &c.,  
49 Langham-street, Blackburn.  
FRANCIS FIELDING.

#### "THE ABSENT-MINDED BEGGAR FUND."

To the EDITORS.

GENTLEMEN,—I am pleased to say that my offer is being taken up with spirit, but I shall be pleased if you would remind some of the absent-minded beggars at home of the conditions under which this offer was made. I distinctly specified in my offer that they were to send me a stamped and directed envelope, yet many of them do not do so, hence more labour for me.

Many people have expressed a wish that my efforts will be successful in this matter, and several have suggested that the plate-makers should devote a penny from each box of plates sold to go towards the Absent-minded Beggar Fund, in the same way that the Vinolia Soap Company have done, whose fund has now reached 4000 guineas.

All who wish to take part in this fund must send their applications and their shilling by February 24. 133 shillings were received up to February 6.—I am, yours, &c.,  
W. TYLAR.

High-street, Aston, Birmingham, February 6, 1900.

## Answers to Correspondents.

\*\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\*\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\*\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

#### PHOTOGRAPHS REGISTERED:—

E. Eccles, 15, Broad-street, Bury.—Photograph of the Rev. J. M. Bury.

P. Swift, 260, Waterloo-road, Burslem.—Photograph of His Worship the Mayor of Burslem.

R. A. B. Sharpe, 13, Three Bridges, Ulverston.—Photograph of Professor Ruskin, lying in state.

H. Jancowski, 3, Old Market-place, Grimsby.—Photograph of group of Grimsby volunteers who offered for service in South Africa.

RECEIVED.—SIDNEY RALPH; ACCESSORIES; A. G. M. DYMOKE; STUDIO: R. W. B.; ENQUIRER; DARK LIGHT; G. P.; CONSTANT READER; J. H. B. These and others in our next.

K. (Leeds).—We think you may depend upon the assurances of the firm named. It has command of very great practical knowledge.

R. W. B.—As good a book as you could have for the purpose would be *The Half-tone Process*, by J. Verfassor, published by Percy Lund & Co., Bradford.

POSITION OF LENS.—W. GARDNER.—As the lens is a symmetrical one, it does not matter which combination is used as a single lens; but, whichever is employed, the convex surface of it should be next the focussing screen.

NOVICE.—*The Science and Practice of Photography*, by Chapman Jones, published by Messrs. Iliffe, 3, St. Bride-street, E.C., might serve as a useful introduction to the study of photography; but, if your friend is to engage in studio work, one or two works on lighting, posing, and retouching should be obtained for him.

VESSEL FOR ALUM SOLUTION.—ALPHA says: "I am going in for the carbon process. Will you please inform me if one of the zinc developing dishes can be used for the alum solution, or would porcelain be better?"—Zinc vessels are not suitable for alum solutions, as they would quickly destroy the metal. Better use porcelain.

SPOTS.—E. H. & Co. say: "Will you kindly state causes of spots on enclosed photo?"—We are sorry we cannot tell, as no data are given on which we could form an opinion. We may, however, say that they are due to faulty manipulation, probably imperfect fixation. The spots may, however, be due to other causes than that.

CRYSTOLEUM WORK.—CRYSTOLEUM asks: "Could you let me know where I could get some crystoleum work done? I have written to some of the big houses, but could get no information."—In reply: At the moment we cannot recall the name of a trade house undertaking crystoleum: some reader may, however, be able to help.

WAVY MARKINGS ON PLATINOTYPES.—S. ROUSE sends some platinotype prints, saying that, as he has only just taken up the process, he cannot find the cause of the marking on them.—They are evidently due to a scum on the surface of the developer. Probably the dish was not clean when the solution was put into it.

- LENS FOR HAND CAMERA.**—T. T. J. says: "I have a single lens by A. Ross of six inches focus. Would that do for a hand camera I am making?"—Yes, though it would be slow. If we remember rightly, the largest aperture of these lenses is about  $f/15$ . It will, however, be as rapid as any other lens stopped down to that aperture.
- ENAMELLED TRAY.**—W. W. says: "Our large enamelled tray, which we use for developing platinum prints in, has the enamelled surface much scratched and cracked. Can you tell us where we can get it re-enamelled?"—We cannot; and, if we could, we should expect that the re-enamelling would cost much more than the purchase of a new dish.
- INFORMATION ABOUT PATENT.**—T. BEGG says: "In one of your recent issues I saw that a patent had been applied for in connexion with a subject in which I am, just now, much interested. How can I ascertain what the patent contains?"—Only from the inventor. Until the complete specification has been "accepted" at the Patent Office, its contents are secret.
- MATERIAL FOR BACKGROUND.**—H. HOWE asks: "What is the best material for a background, and where is it to be obtained; it must be seven feet wide and in one piece, without joins?"—The best material is unbleached sheeting, which may be obtained from any upholsterer's or furnishing warehouse. It may be had wider than seven feet if required.
- LARGE DIRECT PORTRAITS.**—H. H. W. The fault your sitter finds with the portrait is, no doubt, due to its being taken with a lens of too short focus. Although the lens, by being stopped down, has covered the  $18 \times 15$  plate to the edges, it is only twenty inches focus, consequently the perspective is necessarily very violent, hence the unpleasant appearance complained of.
- STUDIO-BUILDING.**—W. CLEGG says: "I propose building a small studio at the back of the house, but the light, through trees, will, I fear, be much broken up. Can you tell me of any book that will help me in selecting the form of the studio and its position?"—We should advise you to get the work by Mr. Bolas on the subject. It is published by Marion & Co., Soho-square.
- MIXING GELATINE AND ALBUMEN.**—N. KNOWLES asks: "Can albumen and gelatine be mixed together? If so, how, and in what proportion without the albumen coagulating?"—Albumen and gelatine may be mixed in any proportions. The only precaution to be taken is that the temperature of the solution of gelatine is kept below the coagulating point of the albumen.
- ENAMEL PLAQUES.**—E. SCHWARZ asks: "Could you kindly inform me where I could get enamel plaques up to  $15 \times 12$ ?"—If copper enamel plaques are meant, we doubt if they are stocked by any one of that size. We imagine that they will have to be made specially to order. Perhaps some reader may know where they are to be obtained, and will kindly give our correspondent the information he desires.
- COLOURING P.O.P. PRINTS.**—CONSTANT READER says: "I am wanting to colour some P.O.P. prints, but cannot get water colour to adhere to surface of P.O.P. Can you give me recipe for applying to prints previous to colouring?"—Wash them over with very weak oxgall. Prepared oxgall for the purpose is sold by all artists' colourmen. Licking the surface of the print with the tongue also facilitates the flow of the colours.
- PHOTOGRAPHERS AND THE 1891 CENSUS.**—CENSUS asks us to "give him the number of professional photographers recorded in the census of 1891? and what estimate would we give of the numbers to-day? The figures for 1881 are 7614."—We are sorry we cannot give the figures for 1891, neither can we speculate on what they will be in the next census. Perhaps some reader may give the desired informations for the year 1891.
- CHONDRIN.**—X. W. asks where he can obtain some chondrin, as he wants it for a special purpose and it must be pure chondrin?—So far as we know chondrin is not really an article of commerce, and we cannot find it quoted in any lists we have referred to. Chondrin is a gelatine obtained from cartilage, and is contained in very many gelatines, and, if our correspondent wants pure chondrin, we expect he will have to make it himself.
- ASSISTANTS' REFERENCES.**—PRINTER writes: "Is not an employer compelled to give an *employé* a reference after he has left? I was in an employ for six months, and then the governor and I had a row and I left at once. Now he positively refuses to give me a character. Will the County Court compel him to do so?"—No. A master is not compelled to give a discharged servant a character, though one is seldom refused; but it is quite optional.
- ANTI-FREEZING MIXTURE.**—S. asks: "What would you advise to keep water from freezing round acetylene tanks; I have tried an enormous quantity of glycerine, but of no avail."—The best suggestion we can make is to keep the atmosphere in which the tanks are placed at a moderate temperature. The next best thing we can suggest is to keep them closely surrounded with several thicknesses of close felt; that, with the glycerine, will possibly avoid the freezing.
- FAULTY TONES ON P.O.P.**—E. J. H. says: "What is the cause of prints (vignettes especially) becoming yellow in the whites before they are carried far enough in toning? I get a nice tone; in fact, all that I could desire, but am troubled with this yellowing, sometimes bleaching, edges of vignettes, and high lights, too. I use the ordinary sulphocyanide and gold only. I should be glad if you could enlighten me on the means to get rid of this yellowness."—There ought to be no yellowing if the manipulations are carefully carried out. Are the vessels in which the prints are washed, prior to toning, and the bath, in good order? If not, that will account for the trouble. See that all the free silver and acid are thoroughly washed out of the prints before they are put into the toning solution.
- HIRE OF APPARATUS.**—Small Way says: "I am expecting an out-door job to take some  $15 \times 12$  pictures, and the largest camera and lens I have is for  $12 \times 10$ . Is there any one from whom I could hire a  $15 \times 12$  camera and lens for a week or so, as it would not, of course, pay me to buy them expressly for this job?"—Messrs. Morley & Cooper, Upper-street, N., and Messrs. Sands & Hunter, Cranbourne-street, W.C., lend apparatus on hire. Apply to either of them.
- BLACK VARNISH.**—C.K.T. asks: "Can you give me a formula for black varnish for glass positives? I do not find one in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC."—Most of the black varnishes are compounded of bitumen dissolved in benzole or turpentine, sometimes with the addition of a little lampblack. You will probably find it more satisfactory to purchase the varnish than to make it. Bates' black varnish is very good, and at the same time is cheap.
- AUTOMATIC PHOTOGRAPHIC MACHINES.**—C. W. E. says: "I have heard of but have not seen, an automatic machine that takes one's photograph and delivers it by putting a penny in the slot, and, for another penny, frames the same. Can you please tell me name and address of manufacturers, or whether I could purchase one, or is the patent in the hands of a company, such as the Automatic Sweetmeat Delivery Company?"—In reply: We are not sure that machines such as described by our correspondent are now commercially available. Can some reader say?
- COPYRIGHT.**—H. L. G. asks: "Am I allowed to copy the photograph (cabinet size) of the Queen (taken by W. & D. Downey, Ebury-street, London) in an oil painting? I should like to make an oil portrait from it, but do not know if it is allowed, and, as we always take your paper, thought you would be kind enough to give me the necessary information?"—In reply: If our correspondent copies one of Messrs. Downey's photographs, which are assuredly copyright, that eminent firm would probably proceed against him for infringement. He had better write them, and see if permission to copy the photograph is obtainable.
- IMPROVING LIGHT OF OIL LAMP.**—H. B. COX writes: "I have a three-wick lamp in my lantern, and I am told that, if I add two or three lumps of camphor to the paraffin oil, I shall get a better light, less smoke, and less smell. Can you tell me if that is correct?"—We have heard the same thing, and also heard it contradicted so far as the light and smoke are concerned, but have not ourselves thoroughly investigated the matter, indeed, we do not use an oil lamp. We should advise our correspondent to add a few small pieces of camphor to the oil the next time he uses the lantern and see for himself. The camphor can do no harm.
- VARNISH TO BE APPLIED COLD.**—A. BEST asks: "Can you please tell me of a varnish that can be applied to a negative or transparency without its having to be warmed and yet dry quickly like collodion, as I often want to varnish one when a fire is not available? Of course the varnish must dry quite transparent and be colourless."—Yes, a solution of dammar resin in benzole will answer the requirements. From an ounce and a half to two ounces of the resin to the pint of benzole is a good proportion. The benzole should be the best, and the dammar of good quality. The negative must be perfectly dry before the varnish is applied.
- LACK OF SHARPNESS IN ENLARGEMENTS.**—H. CLEMENT writes: "I have a —'s lantern, with three-wick lamp. The image is excellent on the screen, but, when I use it for making a bromide enlargement, it is not sharp, though it is focussed perfectly sharp on the piece of cardboard which is replaced by the bromide paper. Can you account for this, as every care is taken in the focussing of the image?"—In these circumstances it is clear that the visual and chemical foci of the objective are not coincident. That is the case with many lantern objectives, unless they are specially supplied for enlarging as well as for projection purposes.
- STUDIO-BUILDING.**—STUDIO says: "I am about to build a studio, a rough plan of which I have enclosed with this (quarter inch to the foot). Will you please let me know if you think it could be improved upon? If so, in what way? I cannot have it any longer, as I have not room. The light is from the north-east."—The design of the studio is very good, and, if it cannot be made larger, cannot be much improved upon. If, however, the glass portion be increased top and side, then both end could be used for the sitter. This, we should surmise, would, at times, be found a convenience; say, three feet six inches each end opaque, and the rest glass.
- INJURED WAX-PAPER NEGATIVE.**—A. & J. write: "We have had brought to us an old wax-paper negative ( $12 \times 10$ ) to print from. It has been much crumpled and creased, and it seems useless to print from it as it is. Can you tell us what to do with it?"—Probably, if it is ironed with a tolerably hot iron between blotting-paper, the creases will be obliterated. If not, it must be rewaxed. This is done by putting the negative on a hot iron plate and rubbing it over with white wax, the plate being sufficiently hot to melt the wax. Then the negative must be ironed between-blotting paper, different changes, so as to absorb the superfluous wax.
- GAS-BAGS.**—PHOTOPHIL says: "I should feel greatly obliged if you could mention the maximum weight that can be placed upon a fairly good oxygen English-made bag, without fear of injuring it. I have always difficulty in getting sufficient pressure. Is there no house in England which could supply a hand-pump (duration of labour in working it being of little consideration) for compressing oxygen in cylinder?"—With the usual pressure-boards a good bag will stand a hundredweight. We have frequently seen two hundredweight employed. Any maker of the finer kinds of pump will supply a hand force-pump that will answer the purpose, though perhaps with it you would not be able to get the same pressure as that supplied by the commercial compressors.

### EX CATHEDRA.

PROFESSOR R. W. WOOD'S system of colour photography with diffraction gratings formed the subject of a paper at the Society of Arts on Wednesday evening last. We shall probably refer to the matter next week. All the papers and articles that the Professor has hitherto published with regard to his interesting process have duly appeared in our pages, and are summarised at pp. 830–838 of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1900. Perhaps the simplest description of Professor Wood's process appears in a note we have received from Sir Henry Wood relating to it. "This we quote for the information of those readers who may be unable to realise the underlying theories of the representation of colour by diffraction. White light passing through a plate ruled with fine lines (a diffraction grating) is resolved into its component colours, and a spectrum produced similar to that produced by a prism. By using gratings, the lines of which are at different distances apart, different colour effects are obtained; and, if a plate be ruled with different sized gratings on different parts of its surface, each grating, when viewed from the same standpoint, and with proper optical means, will show a different colour. By a

development of this principle, and by printing from suitable photographic negatives, such as are used in the three-colour process, through gratings of different dimensions, Professor Wood is able to produce a picture which, colourless in itself, shows colour when viewed by transmitted light through a lens fixed in a suitable position."

\* \* \*

THE important subject of the fading of images of stars in gelatine negatives is again touched upon in the *English Mechanic* in the course of a review of Dr. Isaac Roberts's classical *Photographs of Stars, Star Clusters, and Nebulae*, which has just issued from the press. The writer points out that Dr. Roberts has experimentally discovered that, with every conceivable care in the development and fixing of negatives, the images of faint stars fade out of the films after a comparatively few years. In illustration of this he gives two instances: one of a plate on which, soon after it was taken in February 1886, he counted 403 star images on the negative, whereof, in May 1895, only 272 remained; and the second of a negative of the same region taken in March 1886, on which 364 star images appeared, but upon which, on re-examination in May 1895, only 234 were left. "Now, one purpose of capital importance which such photographs are taken to serve is that of presenting an irrefragable facsimile of the region depicted at the given date for comparison with others made at future and distant ones, by which any actual objective changes in the heavens would be instantly rendered apparent. If, however, details disappear after the fashion indicated by Dr. Roberts, it is abundantly evident that the negatives must in future ages become simply valueless." The cause of the disappearance of these faint images is a subject well worth investigation. It involves the proposition that the silver image in gelatine is liable to fade, more or less, a condition of things which we imagine to be apprehended by few photographers.

\* \* \*

IN these pages, for a great many years past, we have often advocated the systematic photographing of disappearing London, and we are glad to have our views endorsed by so eminent an authority as the Chairman of the London County Council, Lord Welby. In the course of a recently published

interview, his Lordship remarked: "A good many of the old familiar features of London are passing away, and new scenes are rising in their places, and I am of opinion that we ought to form a collection of pictures of the vanishing buildings and streets. The area which will be affected by the new street to be made between Holborn and the Strand will, I hope, be photographed to a large extent, and will furnish many interesting pictures. The various committees of the London County Council, in the course of their work, make a good many drawings and take a good many photographs, and I hope the time will come when we shall have the taking of these pictorial records of vanishing London thoroughly systematised, and when, moreover, we shall have a central collection of these pictures under the control of the County Council. There is a good deal of material for such a collection already, but we have not the space. Until we get our new headquarters—which, I am afraid, will not be for some time to come—we have no opportunity for the formation of a central collection. Of course, such a collection would have a great legal value, as well as being of distinct antiquarian and historic interest." The London County Council would, no doubt, welcome the co-operation of the National Photographic Record Association and the survey branches of photographic societies in the matter. It should not be a difficult thing to elaborate a common scheme of working whereby Lord Welby's ideas could be put into operation.

\* \* \*

So far, the photographers at the theatre of hostilities in South Africa have not succeeded in securing negatives of fighting at close quarters, although every other phase of the war, including long-distance firing, appears to have been shown in the illustrated papers. We note, however, at a London place of amusement, The Palace Theatre, a series of animated photographs is being shown which take us very near to the representation of the actualities of carnage by means of photography. These include views of the bridging of the Tugela; mounted Colonials returning from a reconnaissance; the bombardment of Colenso; and the seizure of a kopje near Spion Kop. Hand-to-hand encounters have yet to be photographed, it would seem, although some of the stay-at-home artists have given us, in the illustrated papers, some vivid and striking pictures of such subjects.

\* \* \*

THE Derby Photographic Society sends us a calendar for 1900—the first production of the kind we remember to have received from a photographic society. It consists of a brown-toned card, with a list of the Society's officers and summer and winter meetings. Monthly date leaflets are attached, and the principal embellishment consists of a capital sepia platinum view of Tickhill Castle gateway by Mr. H. Burkinshaw. The card, which bears the honoured name of Richard Keene, Ltd, as the producer, is a most tasteful production, and we congratulate our Derby friends upon it. We note that Sir W. de W. Abney is Patron of the Society, and Mr. C. B. Keene, President.

\* \* \*

WE are pleased to observe that on Wednesday evening last the Manchester Amateur Photographic Society, from whose annual report we elsewhere give some interesting extracts, held a musical and lantern entertainment in aid of the local War Fund, started by the Lord Mayor of Manchester. It is to be

hoped that a hearty response rewarded the Association's efforts. The suggestion that the photographic societies might help the War Fund by holding lantern entertainments has already been made in our columns. Southsea took the lead in the matter, and raised 45*l.*; we trust Manchester will be equally successful. Is it too late for some of the London photographic societies to lend their assistance to such a deserving cause as the relief of those who are suffering on account of the terrible struggle in South Africa?

\* \* \*

THE *London Gazette* recently gave notice that it is proposed to submit to her Majesty in Council the draft of an Order in Council providing that acetylene, when in admixture with atmospheric air or with oxygen, shall be deemed to be an explosive within the meaning of the Explosives Act, 1875, and that it shall not be manufactured, imported, kept, conveyed, or sold. Notice is also given that, in accordance with the provisions of the Rules Publication Act, 1893, copies of the proposed draft Order in Council can be obtained by any public body at the Privy Council Office, Whitehall.

\* \* \*

THE latest departure in stripping film photography that has been brought to our notice, is the invention of Mons. G. Macaire, of the Automatic Printing Company, of Rickmansworth, who has secured patent protection for his process in several countries. The details have not been communicated, but this is an outline of the system adopted: Stout paper, or thin card, is coated with the sensitive emulsion. After exposure, and before development, the film is stripped from the card and passed through the developing solutions. The card has a surface, the nature of which is such that the negative may be squeegeed upon it in order to remove curl, &c. The inventor tells us that he is engaged in coating great lengths of the paper for experimental and other purposes.

#### EXPERIMENTS IN THE KEEPING QUALITIES OF DRY PLATES.

AUTHENTICATED data on the keeping qualities of sensitive plates and films under predetermined conditions must always interest plate-makers and plate-users. Perhaps no subject in photographic practice lends itself to such a variety of contradictory views and experiences. Only last week we published a letter from a correspondent, complaining that his extra-rapid plates would not yield negatives free from fog after being kept for six weeks. Against such an experience as this it would be a simple matter to set that of many photographers who have not perceived deterioration in very rapid plates at the end of a much longer period. The "unstable equilibrium" of the silver haloid in a highly sensitive film may be, and probably is, liable to disturbance by atmospheric and other causes more readily than the excited salt of a slower plate, but, properly packed and kept, the former kind of plates are by no means so prone to spontaneous decomposition as the thoughtless might suppose. The matter hinges largely on the method of keeping or storing the plates—a very wide subject indeed.

If it does not add much to our stock of positive wisdom on the matter, a summary of some recently published experiments on the keeping qualities of dry plates will at least be interesting and, to some extent, instructive. It appears that the

Technical Committee of the Photographic Society of Philadelphia some time ago received for testing purposes three boxes of plates, purchased and dated in the spring of 1884—that is, sixteen years ago—by one of the members.

It need scarcely be said that the plates were of American manufacture, and they appear, so far as we can form an opinion on the matter from the distinctive names of the brands, to have been of a “rapid” or “instantaneous” kind. Such information, in these days of the photometrical determination of the speeds of plates, may strike the scientific eye as vague and indefinite; but it must be recollected that in 1884 speed-marking was an undiscovered science. In those days—and here we speak from personal experience—a box marked 25 W was meant to convey the *ne-plus-ultra* of sensitiveness. And so it did; in the numerical sense, at any rate.

Calling the three brands of American plates that were experimented with A, B, and C, it appears that A was packed with a soft white string (apparently cotton fibre), wrapped round them in such manner as to separate the opposed film surfaces. When developed, some of the plates showed a faint mark where the string had crossed the film, but this mark was not sufficient to prevent a good print. Exposed on an average landscape, and developed with metol-hydroquinone, all the plates showed a moderate tendency to fog, but, by somewhat restraining the developer, this fogging was easily overcome, and very fair negatives could be produced. Some of the plates showed faint streaks an inch or so in width, but these were not distinct enough to seriously mar the negative. Except for these occasional delicate streaks, the surface of the plates was perfectly uniform.

B were also packed with frames. There was some tendency to general fog, but this could be largely overcome by free use of bromide, and, with a corresponding increase in exposures tolerable negatives could be obtained. Some of the plates were quite free from the heavy band of fog inside the frame, mentioned in connexion with the C plates, while, in other instances, a slight band made its appearance, but never reached any considerable density. Sometimes this band appeared on only one or two sides. The film of all the B plates was very soft and frilled extensively, a defect which was not met with in either of the other brands.

Of the C plates the report says that they were packed with cardboard frames between the sensitive surfaces. Every plate showed deep fog except that portion of the film around the edge which had been covered by the separating frame. Here the fog was much less apparent, and, by using a restrained developer, could be almost entirely prevented. This clear edge of a few millimetres was the only portion of the plate upon which a satisfactory image was obtained. Just inside, at a point corresponding to the inner edge of the frame, and for a few millimetres inwardly, appeared regularly a heavy band of fog so dense as to utterly spoil the negative. Inside of this band the fog became less dense, but it was still sufficient to make the plate worthless for any ordinary purpose.

The Committee's conclusions were that none of the plates could be used for quick work requiring an unrestrained developer, but that the A, and perhaps the B, were still available for certain purposes. On account of the resulting fog when a very active developer was used, it was difficult to form an idea as to the speed of the plates, but “our impression is that they have lost little or nothing in rapidity, though this sensitiveness is of no practical use, owing to the impossibility of employing

an energetic developer.” The Chairman of the Committee, Dr. C. W. Miller, in a supplementary note, added that the results seemed to suggest several points as to the packing of plates. Cotton seems to exert no prejudicial effect on the sensitive film. Those plates separated by cardboard frames showed no action under the cards, and, if the Manila paper gives no injurious action, the sensitive films can hardly hurt each other; the only reason they are not packed together is that they are apt to rub against each other. The method adopted by some plate-makers, according to Dr. Miller, is to place the two plates film against film, and around the edge of the plates bend two bits of pasteboard. Chemically this is good, because the films are together, and, as the plates are held together when packed, it is good mechanically.

In two out of these three instances it will be observed that sixteen-year-old gelatine plates, packed in the ordinary way, but kept, we may suppose (although the report is silent on the point), under careful conditions, yielded, after all that lapse of time, by the judicious use of restraining bromide in the developer, negatives described as fair and tolerable. Such a result is matter for equal congratulation and surprise to all concerned.

The report of the Philadelphia Committee, though it is obviously of little scientific value, as the whole of the conditions were not ascertainable, is yet of great practical interest, for it shows that gelatine dry plates may retain their workable qualities largely unimpaired for a greater length of time than was suspected, we may conjecture, when the three boxes of plates on which the experiments were made were dated and put away.

In conclusion, we may say that we are indebted for the data we have quoted to the *Journal of the Photographic Society of Philadelphia*, a most admirable publication, to which we always turn in the assurance that it contains matter of very great practical interest to photographers.

---

**Forecasts of the Weather by Balloon.**—Last week we made some comments on the forecasts of the weather as issued by the Meteorological Department, and alluded to the fact that it proposed to give up the Ben Nevis Observatory, the highest one in the United Kingdom. We now read that the Royal Prussian Meteorological Institute in Berlin is about making arrangements for the systematic examination of the higher strata of the atmosphere by means of special apparatus. In the grounds of the Aeronautical Observatory, in a suburb of Berlin, registrations of the atmospheric conditions at a height of three to five thousand metres will be carried on, if possible, day and night, with kites and kite balloons. The automatic registering apparatus, which notes the pressure, temperature, humidity, and wind velocity at these heights, is to be taken up by a kite balloon connected with the earth by wire, and is to be inflated with hydrogen. From the report it seems that the greater height will be obtained by a series of these kite balloons, each some 500 metres below the other. It has been found that by this system a height of 4500 metres has been attained by kites without balloons. It is added that, judging from the experience hitherto gained in casual experiments, the regular investigations which it is proposed to conduct should lead to important results. It is to be hoped that our Meteorological Department will watch the results that follow the Berlin systematic investigation of the upper strata of the atmosphere and profit by them. These elevated observatories can be established anywhere, without the aid of mountains. One might be instituted in a suburb of London—say at Brixton—and its cost need not be great. Any how, the idea is well worthy of consideration, as it might lead to more accurate forecasts of the weather than we now get.

**Free Portraits.**—Some photographers have announced that they will take, free of charge, a portrait of any volunteers who are going to serve their country in South Africa. In an evening contemporary we read that a photographer in the suburbs of the metropolis had intimated that “any soldier going to the front may have his photograph taken, free of charge, on applying at \_\_\_\_\_’s Studio \_\_\_\_\_.” All this reads patriotic enough, but one cannot help wondering if it is really done out of genuine patriotism, or whether it is undertaken with a view to ulterior profit? It may appear, perhaps, a little ill-natured to even suggest such a question, but it is not altogether an unnatural one when we consider the facts. Of course “Mr. Atkins” will give the first proof to his wife or “best girl,” but probably parents, brothers and sisters, and others, will want duplicates, and, of course, they will have to be paid for, hence a profit to the public-spirited photographer. Further business will probably accrue to him in the shape of enlargements in the event of the soldier being unfortunately killed. With these facts in mind, one is inclined to question if this “generosity” is actually so disinterested as appears on the surface. One thing, is however, certain, and that is, it will bring grist to the mill of the plate, paper, and mount-makers, as they are not sufficiently “patriotic” to supply their goods gratuitously to the photographers who take the portraits of those leaving for the seat of war.

**The Lantern in Church Services.**—“White’s Weary Wait,” illustrated by limelight views of Ladysmith and district, was the topic of the Rev. W. Carlile, at the St. Mary-at-Hill Church, on Sunday last. It is now some years since the Rev. Mr. Carlile adopted the lantern as an adjunct to his services, and it has proved the means of attracting congregations that he would not, presumably, have had otherwise. Mr. Carlile’s innovation might well be followed in other localities in the poorer districts, as a means of securing a congregation and then ministering to it, and thus bring about good. Many of the lower classes in London would, no doubt, be induced to visit a place of worship on Sundays if there were something interesting to see, and would possibly profit from what they would hear. As the Rev. Mr. Carlile’s experiment has proved so successful, it is a little surprising that it has not been followed by other clergymen who minister in some of the poorer and lower districts of this great metropolis. But there—the Church is very conservative. By the way, the title, “White’s Weary Wait,” suggests that views taken in beleaguered Ladysmith during the prolonged siege—and, no doubt, there are many photographers there—will, if published hereafter, command a large sale, whether as lantern slides or as paper pictures. No doubt, enterprising publishers already have an eye to that, and the profit to be derived therefrom.

**Balloons and Photography in Warfare.**—At the end of last week surprise was very freely expressed as to the reason for General Buller again retiring across the Tugela. It now transpires that he was guided to do this from a balloon observation. The balloonist found that the enemy had a large battery of powerful guns, cunningly masked, which could not have been discovered except from a balloon, and thus the troops were saved from a carefully laid death-trap. The observations were made with the aid of field glasses, and we do not read that photography was invoked. Had it been, and a tele-photo lens employed, the general himself would have, perhaps, been able to better realise the state of affairs than he could by the verbal description of the balloonist.

**Eclipse Suggestions.**—At the meeting of the British Astronomical Association, held on the thirty-first ult., a number of suggestions were made for the valuable application of photographic aid, even with small and simple apparatus. Photographs of the corona, the President said, should be taken on a sufficiently satisfactory scale with fixed camera, and therefore they need have neither equatorial nor driving clock. Instantaneous exposures might be given, and exposures up to one second, if they had the image of the

corona on a scale of not than half an inch to the sun’s diameter, would be quite permissible, and would secure a fairly dense image, even to a considerable distance out.

THEN there were a large number of miscellaneous observations that a photographer might make. Miss Bacon, the President pointed out, took, in 1898, in India, a series of photographs of the landscape at regular intervals before the eclipse, and the result was to give a very striking picture of one way in which the illumination diminished as the eclipse came on. It seemed to him that the experiment might be repeated, and with a very much larger number of photographs on the next occasion, and this at several stations. Again: he would like to see repeated the experiment (for which Mr. Gore and Mr. Johnson prepared the plates, the exposures being made by Mr. E. W. Johnson) of the brightness of the general corona. A plate was exposed for a graduated series of seconds, or else under a sensitometer, to the full light of the corona, not in the camera, but simply by exposing the plate. In that way they might obtain a useful record of the total brightness of the corona from eclipse to eclipse, such as before the Indian eclipse had never been secured. It will thus be seen that ardent photographers desiring to help the cause of scientific investigation might do well to make their holiday at such a time as would enable them to join one or other of the eclipse observation parties we have on previous occasions referred to.

**CHLORO-CITRATE EMULSIONS, WITH CHLORIDE OF COBALT AND A LARGE PROPORTION OF ORGANIC ACIDS, OR THEIR SALTS.**

[Translated from the *Photographische Correspondenz*.]

MONSIEUR A. BLANC has recommended the use of chloride of cobalt for the preparation of chloro-citrate of silver emulsion, in place of the chlorides in general use for the purpose, such as chloride of ammonium or soda. The emulsion which he recommends is prepared in the following manner:—

A.	
Gelatine .....	9 grammes.
Five per cent. solution of chloride of cobalt .....	6 c. c.
Neutral tartrate of ammonium .....	2 grammes.
Citrate of ammonium .....	0·5 ”
Water .....	70 c. c.
B.	
Citric acid .....	2·3 grammes.
Water .....	20 c. c.
Citrate of silver .....	2·5 grammes.

The two solutions are mixed together at 70° to 80° C., and to the emulsion thus prepared 5 c. c. of shellac solution and 10 c. c. of alcohol are added. The paper should be coated after the emulsion has stood twenty-four hours. Blanc calls the shellac solution “preservative emulsion.” It is a very dilute solution, formed by dissolving 5 grammes of pale shellac in 15 c. c. of alcohol (ninety per cent.) and pouring it into 100 c. c. of boiling water. It is then filtered through cotton-wool. When the alcoholic solution is diluted with water, most of the shellac is, of course, precipitated in a mass. A rather cloudy fluid remains, containing very little resin, which is mostly held in free suspension.

In 1897 I published directions in the *Photographische Correspondenz* for the preparation of a chloro-citrate emulsion, with which printing-out paper of very good quality might be made.

According to these directions the following solutions should be prepared:—

A.	
Nitrate of silver .....	32 grammes.
Citric acid .....	8 ”
Water.....	160 c. c.
B.	
Gelatine.....	96 grammes.
Chloride of ammonium .....	2·8 ”
Water.....	700 c. c.
C.	
Tartaric acid.....	2·8 grammes.
Bicarbonate of soda.....	1·4 gramme.
Alum .....	2·8 grammes..
Water.....	140 c. c.

- A. The nitrate of silver is dissolved in hot water.
- B. The gelatine is first allowed to swell in the water, and then dissolved by heat. The chloride of ammonium is subsequently added.
- C. The tartaric acid is first dissolved in the water, then the bicarbonate of soda, and lastly the alum.

B and C are heated to 50° to 60° C. and mixed together. C is also heated to 60° C. and added to B and C in yellow light. The emulsion is kept a short time at 40° to 50° C. to ripen. It is then filtered and ready for coating.

Paper of comparatively high sensitiveness and great brilliancy may be prepared with this emulsion.

In its composition it differs considerably from Blanc's emulsion, as may be seen at a glance from the following table, in which both emulsions are set out side by side for 1000 parts of solution:—

Constituents.	Monsieur A. Blanc's Chloro-citrate Emulsion.	E. Valenta's Normal Chloro-citrate Emulsion.
Gelatine ... ..	82 grammes.	96 grammes.
Chloride ... ..	2.7 grammes $\text{CoCl}_2 = 55$	2.8 grammes $\text{NH}_4\text{Cl}$ .
Tartrate of ammonium or soda ... ..	18.2 grammes of ammonium tartrate.	2.65 grammes tartrate of soda.
Citrate of ammonium ... ..	4.5 grammes.	—
Citric acid ... ..	21 „	3 grammes.
Tartaric acid ... ..	—	1.55 „
Nitrate of silver ... ..	22.7 grammes.	32 „

Disregarding the substitution of chloride of cobalt for the usual corresponding salts of sodium, or ammonium, which offers no appreciable advantage, as shown by the experiments which I made some years ago, we find, in comparison with other published formulæ for the preparation of emulsions of this class, that this new process is characterised by an exceptionally large proportion of citrate and free citric acid, whilst the amount of silver is also smaller than in the emulsion associated with my name.

From these circumstances it is not difficult to foresee that M. Blanc's emulsion should give very pure and vigorous prints, and that the paper should be of good keeping quality; but, on the other hand, its sensitiveness should leave much to be desired.

In order to ascertain the correctness of these suppositions and to obtain some idea of the value of M. Blanc's formula for the preparation of a printing-out emulsion, I made a certain quantity according to his directions, and coated some sheets of paper with it by means of a coating machine. The emulsion coated very smoothly upon good baryta paper and the film was even and of yellowish colour. The tests made gave the following results:—

The sensitiveness was 0.3, taking freshly prepared albumen paper as 1.

The range of gradation was 15° according to the scale of Sawyer's photometer. Degrees 0 and I were bronzed.

The prints were of a muddy violet tone. With the combined bath the prints toned very evenly, but with the sulphocyanide bath there was a tendency to stain. The colour of the finished prints was an excellent photographic tone and the high lights were pure white.

Printing-out paper prepared according to the formula recommended by me had the qualities of a good gelatine paper, with regard to resistance to mechanical influences; but, taking freshly prepared albumenised paper as 1, its sensitiveness was 3 to 4. It was consequently as fast as good commercial collodio-chloride paper.

Its range of gradation was also much larger, being 17° by the scale of Sawyer's photometer. The prints are purple brown and tone easily and evenly, whether in the combined or the sulphocyanide bath. With a plucky negative the prints are vigorous and pure.

With reference to the keeping quality of M. Blanc's printing-out paper, this should be due to the large quantity of citric acid which the emulsion contains rather than the addition of the "preservative emulsion." The small quantity of resin which the latter contains should not exercise much influence.

Although Blanc's emulsion gives very fine prints, full of detail, and the paper prepared with it certainly keeps well, I do not think it satisfies the requirements of the professional photographer. The paper prepared with this emulsion is much slower than albumenised paper, whilst most of the commercial gelatino-chloride papers are much quicker. This advantage is not compensated for by the better keeping quality of the paper.

PROFESSOR E. VALENTA.

REMARKABLE PHOTOGRAPHS OF ELECTRICAL EFFECTS.

In last week's *Nature*\* appeared a letter over the signature, "Sydney Webb, Dover," followed by a long explanatory article by Professor Sir G. G. Stokes, illustrated with a number of most singular photographs taken by the first-named writer at Dover. The interest of these pictures lies in the hitherto unnoticed effects shown in them as following upon lightning flashes. During the course of a thunder-storm the camera had been pointed at the direction in which the flashes were most vivid, and, in so doing, one or more of the electric lamps that supply Dover with its artificial light were necessarily included. "Upon developing the few exposures made it was noticed that, whether or not the picture took in the flash—and in many cases this did not appear at all—there was exhibited upon the films the light of the permanent lamps, and that from them a flow of electricity proceeded towards the ground in an irregular line."

The first photograph with no flashes showing gives us three large discs representing the arc lights; from such there is a pendent dotted line. Then we have a flash picture with the lamp "tails" forming a knotted intricacy, while, in the next, the tails are more like a long whip lashed horizontally. Another gives us four perpendicular tails, while, in the fifth, their erratic course is perfectly bewildering, and still another shows a grand mingling of arc and glow lamps, but yet with the tails or streamers going almost perpendicularly to the earth.

Professor Stokes esteems the subject of sufficient interest to justify a long argument as to the various possible explanations, but, these being more suited to the pages of an electrical journal, we do not deem it necessary to bring them before our readers, the more especially as the whole article may be found by the reference we give. We may refer to one of the Professor's possible explanations, as it links the whole with photography. He says: "If the wireless telegraphy theory which I have ventured to throw out be the true account of the Webb discharges, it seems that by imitating, with any necessary modification, the receiving apparatus, and introducing a telephone, as has been done with great advantage by M. Turpain in his researches, it might be possible simultaneously to see and hear a flash of lightning." Thus we should be in possession of a most remarkable triad of effects from a lightning flash—we should see it, hear it, and finally have it recorded by means of photography. It may be observed that Professor Stokes points out that at present we are not actually certain that the passage of the electric current through the arc lamps at the time of the flashes is a necessity for the production of the tails or streamers, but, "as the lamps are wanted for public lighting, the experiment could not well be made of disconnecting one from the works when a thunder-storm was impending in the evening, and seeing whether the one disconnected would give a discharge like the others." He thinks the current necessary.

We can cordially recommend to our reader's notice Mr. Webb's suggestions in regard to further elucidation by photographic means of the cause of these singular phenomena. He writes: "I need only add that I hope, when a thunder-storm visits a town illuminated by electricity, photographers will, both in daylight and after dark, expose a few plates for the elucidation of the thoughts suggested to us. I say in daylight, for the camera will often record impressions that our eyes cannot see because of other external surroundings, as instanced by my noticing upon one occasion with the unaided eye a stream of electricity descending from an arc lamp towards the earth, which I should assuredly never have seen had I not learnt from these photographs that such a phenomenon did exist." We may on our own account make the suggestion that it would be useful when setting up a camera under ordinary conditions to include if possible, and at not too great a distance, one or more ordinary gas lamps, and to observe if streamers were to be found emanating from them also, as a possible alternative referred to by Professor Stokes, only treating the standards holding the arc lamps as mere pillars of iron connected with earth, and not as necessary components of a disused series of artificial electrical conductors.

WINTER PHOTOGRAPHY.

THE weather during the past fortnight or so has been all that could be desired by those who have been anxious to secure photographs of winter scenes, and, if they have not availed themselves of the opportunity, they have only themselves to blame, as such a chance may not recur, perhaps, for a year or two. The snap of winter has been pretty general throughout the country, and, we learn, has brought with it considerable

\* *Nature*, February 8, pp. 343 et seq.

inconvenience to many in the shape of frozen and burst water-pipes, &c. These troubles, in most instances, might have been avoided had a few precautions been taken beforehand, such as we recommended a month or two ago. Then we reminded our readers that, in this fickle climate of ours, there was no telling how suddenly severe weather might be amongst us. We certainly had but short notice of this spell of it, and many of those who were not prepared for it have regretted it since.

There are other inconveniences, though unsuspected by some, arising from the abnormal and sudden cold. Since the severe weather has set in we have received several letters from correspondents, detailing troubles. These are mostly to the effect that, though the writers are convinced that the plates have been fully exposed, the image comes out very slowly and behaves very much as under-exposed plates would do, though, with prolonged development, full detail is obtained, but with a total lack of printing density. This trouble is simply due to the abnormally low temperature we have had of late. The remedy is to combat that in the dark room, keeping it up to from 60° to 65° F., and the developing solutions and the dishes up to a similar temperature. Another cold-weather trouble is blistering of the film on the plates and on prints. If either of them are taken straight from the fixing solutions and put direct into water as taken from the tap, where it is but a degree or two above the freezing point, blistering often happens—more often than not. The remedy should be obvious to all. Another trouble connected with cold weather is yellow stains on prints, due to the coldness of the fixing solution. When the fixing bath is very cold, its action is correspondingly very slow, and, unless a much longer time in it is given, imperfect fixation and yellow stains are the result. In this case, too, the remedy is obvious.

#### THE TREATMENT OF THE CUSTOMER.

HAVE you ever been visited by some one who knew some one who made lovely photographs? He or she will tell you of the altogether delightful work done by this friend until you feel that you are very small indeed. I do not object to the amateur—and I could not mend matters if I did—but I do not forget that I am a professional man who is making a living by the practice of his art. For the unfortunate photographer who considers it necessary to undertake business at rates reminding one of a Dutch auction I have more pity than sympathy, writes F. Bennett in *Wilson's Magazine*.

One of my best customers called on me some months ago accompanied by a younger lady friend. The new arrival was an amateur photographer, and wished to photograph her friend—my old customer—in my studio. She would do the posing and exposing, and I could “do the rest.” The exposures were duly made, on my plates, in my camera, and every one was satisfied. Then I asked to be allowed to myself make a few attempts. After my visitors had gone I duly developed the negatives; then came the diplomacy. From all the amateur attempts I made prints. The light was crude, and the results gave heavy shadows and a look of antiquity—a sort of grandmother look. From my own negatives I selected the two best, and did a little, just a little, of retouching. If ever I did good retouching, it was on those two negatives. When the proofs were submitted I knew that I had won the day. I have no doubt that the amateur work caused a spasm, but I never heard of it again. But I do know that I got a very satisfactory order from my own negatives.

I have more than once been asked to supply retouched negatives in order that my customers may do their own printing. I make it a rule that all negatives remain in my possession, and invariably refuse such requests. I cannot blame people for asking this, as some of us have to consider every dollar we spend, but I decided to take this stand, and have continued it. If you do take negatives in this way, get a good price for them. If you sell prints at 4 dollars a dozen, a negative is cheap at the price of a dozen prints. If you sell prints at 10 dollars a dozen, a negative is too valuable to sell. Just here let me digress a moment to protest against the mistake of fearing the “other man.” Too often we will work cheap to secure some little order. It is very doubtful business, and generally wrong. And now for a case where I did what I have just been objecting to. A wealthy but bargain-loving lady came to me for a 17×22 enlargement. She was very particular in inquiring the price, which was 12 dollars for one print on Aristo-platino. But this she scouted as absurd, and announced that she had seen enlargements offered for 2 dollars. I at last agreed to her terms, and she was to call in ten days. I made the enlargement—a bromide—and I did not waste any time over it. It came out somewhat hard as to shadows, and decidedly chalky in the whites, but, then, what can you expect for 2 dollars? At the same time I made an Aristo-platino, and I

made a beauty, one fit to be hung at the Convention. The appointed day came, and with it the lady. Her enlargement awaited her on an easel, and I had not subdued the light. I let her wait a moment with her effigy before going down to the reception-room. There was trouble then, almost tears, and much indignation. But I stood my ground boldly, and maintained that it was good 2-dollar work. After some argument, I suggested that, of course, the print was open to improvement—for instance, and I pulled some narrow strips of gummed paper from my pocket. A few of these I placed carefully over the heaviest shadows—I had studied it all before—and at once the picture looked better. Then I opened the attack. I had taken the liberty of making an enlargement to suit *my* ideas of the value of the subject, having seen in it an attractive possibility for my show-case. The lady was all curiosity at once, and nothing would suit her but that I at once show this work. So I led to where it was placed, in a neat black and gold frame, and tastefully draped. What a contrast! The Aristo-platino was just too charming, and she must have it. Would I sell it to her for 5 dollars? No! But it would be of no use to me, and it was made now. I smiled. As a show picture it would be of use to me, and after its day was past I would destroy it. Now, here was where I held the trump card; I was quite ready to lose the sale, though I hoped to be successful. And successful I was. I demanded 15 dollars, or with frame 25 dollars, and, after a long haggle on her part—for I simply remained firm—in an endeavour to get picture and frame for 20 dollars, she took the picture only and paid my price. I could not have worked such a scheme with most people, but I study my sitters.

#### THE NEW FAD IN PLATINOTYPE DEVELOPING.

WHEN a picture has a good and a bad portion, it is a boon to the photographer to be able to keep the good and eliminate the bad, and thus cover up one's sins and delude an innocent public into thinking that we always do such work. It is also a very valuable aid if we can, while developing, strengthen or tone down any portion of a print we desire to, and of these two advantages I offer a few suggestions in connexion with the new fad of partial development of platinotypes with the brush and several strengths of developer. The appearance of these fragments is quite refreshing after the long years of plain prints we have endured, and, while I don't want to call the effect “sketchy,” I should say that, for the lack of a better word, says Mr. Edmund Rawleigh in *The Photo-American*, they are best described by that one word, which saves a deal of further description.

The trick is simplicity itself, and it will require but a few words to describe it, and but few attempts on the part of my readers to accomplish it, though greater delicacy and judgment naturally come with practice. One requires a quarter-inch, half-inch, and inch camel's-hair brush, the first two round for the dainty work, the latter flat for spreading the developer over large portions at first. Provide three solutions of developer—using the W. and C. salts—one of full strength, one of equal parts glycerine and developer well mixed, and one not so strong in glycerine. A tablespoonful of each will do for a few prints.

Now, having our print ready, we pin it by its four corners to a board covered with clean blotting-paper, and with the largest possible-sized brush of the three, quickly paint over the main portions desired in the finished picture with the strong glycerine developer; taking care to have no excess of developer in spots, and especially not to lap over the edges of the main features that are being painted. The developer, being heavily retarded, will work slowly, but in a short time the portions painted over will appear, and it is then that judgment can be brought into play to the great advantage of the finished print from an artistic sense. Let us say we have a picture of a house, with long and deep verandahs about it, vines climbing up the sides of the house, and expanse of grass and pebble path for a foreground, and various inhabitants of the place seated in a scattering way from one end of the verandah to the other, while in the centre, before an open door, in a comfortable chair, rests the mistress of the house, with a couple of children playing at her side or listening intently as she reads an absorbing story to them. Fancy that picture! It was undoubtedly taken because the mother and children appealed to one's sense of the beautiful and artistic. In the shade of the verandah, with the vines dispersed around in a pleasing way, it attracted our notice, and we took it. But we took a lot of extraneous matter, some hard lines that did not balance well, and all those people scattered the length of the plate in anything but artistic grouping, and we don't desire those at all, yet we don't want to cut the picture down too much. We shall go about it thus: First make a platinotype print from the negative, pin it on the board, and we are ready

Dipping our medium brush in the glycerine developer, we at once cover, but do not overlap, the central figures, including in ragged strokes some portion of the right and a good deal of the left, where the ivy climbs up the house and posts so gracefully, making an irregular shape. After a short while, this all develops, and we are ready to see what touches are necessary to preserve the character of the picture, improve the composition, and strengthen the weaker portions if necessary. We need more strength on the mother's dress, as she is well under the roof of the porch, so with our small brush we apply strong, undiluted developer till proper values are gained. The ivy is very faint as yet, as it is green and requires something stronger than the weakest developer, so we apply a wash of medium developer, brushing it on in irregular strokes so that no edges are abrupt. Now, to finish the composition, we take the flat brush and the glycerine developer and wash on as much foreground as will help the composition, then with a few sketchy strokes complete sky and foreground, and the print is ready for the acid, which must be very strong for the first wash, say twice the usual strength advised by the makers of the paper. Two more baths in acid of the regular strength, a good washing, and the work is done in less time than I have taken to describe it. True, it's but a fragment, but it is after all, under the circumstances, like a snatch of an operatic air when that snatch represents a few bars of the most beautiful music in the whole opera. From that which was not pleasing we have made something that is pleasant to look upon; we have sifted the good from the bad, and made besides an agreeable change in our collection, something odd and out of the common. What more could be asked than these manifest advantages? The process will give pleasure to all, will afford free play to one's perceptions of the artistic, and will educate those who seek knowledge in composition. It is a great power in our hands which, used with discernment, will improve us and our work.

It is important in this work to avoid hard outlines, and yet I am sorry to say that will be the first, and probably the only, trouble the new fad will bring the beginner. It is not difficult to obviate this, after a bit of practice, by brushing with a not over-filled brush from within outwards, pushing the brush as one would a carpet-sweeper, rather than brushing with it like a painter would. The object of having the first acid bath very strong is to prevent the developer from spreading and thus destroying the arrangement so carefully made. The true inwardness of so many utterly bad pictures as are seen is that the photographer has seen a very beautiful bit in his expeditions, and, being attracted by that, has trained his camera upon it, and taken it, and, being unable to eliminate the surroundings, has produced a botch. Perhaps he has been keen enough to recognise the beauty of the picture, but inartistic enough not to recognise the fact that other elements are in the  $5 \times 7$  or  $8 \times 10$ , or any picture which detracts from the effectiveness of the thing which is admirable. Some one of greater perception may some day advise that man to cut the print down until the true picture only is included in the portion used. This state of affairs is now provided for in the new method, and will be found to satisfy all concerned better than the only other alternative, that of trimming the print. An  $8 \times 10$  sheet, with one of these sketchy fragments in the centre, is certainly a very agreeable change, if not a wonderful improvement, from the conventional method of mounting a small print in the centre of a large card, and I advise a trial of the method by all interested. EDMUND RAWLEIGH.

### DRAPING THE MODEL.

BEFORE the Photographic Society of Philadelphia recently Mr. William E. Partridge gave an illustrated talk on the subject, "Draping the Model." He said: Of all draped statuary that of the Greeks is the most beautiful. It was evidently based on their national costume, but I cannot give you a history of Greek clothing, nor shall I take the subject up in a scientific way. Two or three evenings would be required for a description, and as many more for showing the illustrating slides.

The Greeks differed from all other ancient people, so far as I know, in the one fact that they did not make clothes. The Egyptians, on the other hand, were tailors; that is, what you see of their clothing in the museums looks very much like that which adorns the clothes-line in the tenement house districts of New York on wash days. Many of their garments seem to have been transparent. The idea seemed to be to protect the body from the first rush of the wind or air, but allow it to be as cool and as transparent as possible. Their sculptors cut the figure in stone and indicated lines of clothing outside. In drapery the Egyptians followed the Assyrians and all the northern races in making clothes which conformed to the person.

The Greeks, on the other hand, did nothing of the sort. They apparently cut their cloth to the proper sizes, hemmed the ends, decorated the pieces with lines of coloured embroidery, and, to use the slang of the day, "sewed buttons on it." That was all there was to it so far as the tailor was concerned. Of their under-clothing I know nothing. The sculptors have ignored it entirely, and it is not necessary for our purpose this evening.

The cloth most suitable for drapery and best adapted for artistic work in following the Greek methods needs a word or two of notice. A great deal of the Greek drapery seems to have been made from some sort of knit material. We can imitate the lines of folds of many pieces of sculpture in a knit fabric better than in anything else. Fine silks and silk shawls drape beautifully. Bunting answers the purpose admirably, but for the artist cheese cloth is generally the best thing available. It is easy to get, it is wide, and, as it is the only thing which would drape at all that I could find to-day in the shops, I shall use cheese cloth this evening.

Now, do not try to make clothes for your models. Follow the Greek method. This was simply to use the figure to hang the cloth on. Do that and you will get beautiful effects. If you borrow silk or camel's-hair shawls, you can use them with perfect safety and return them in as good condition as you found them, because it is not even necessary to sew buttons on. If you take a large bead, put it under the fabric and tie a string round it, you have all the button that is necessary to hold the cloth in place by means of a loop.

Now we come to the first step in making what by courtesy may be called a garment. The width of your piece must be, for the long and flowing principal garment, equal to the height of the model. If it is not to be unusually long, measure from the shoulder to the floor. It is better in making up such a piece, if you have to use narrow breadths, to have the seams run vertically, for then they can be hidden in the folds. Unfortunately, the seams in my cloth this evening are horizontal. They would show badly in a photograph. The length of the garment, or main covering of the body, must be equal to double the distance between the extended finger tips; ordinarily this is also a little more than twice the person's height. Fold this, and on each side of the centre place a button so as to leave an opening for the head. This opening must be the width of the model across the shoulders. Along this upper edge other buttons or clasps may be placed at two-inch intervals all the way out to the ends. This garment, put on over the head, has a closed side at the left, leaving the right open. Draping this without other additions, we can get all the beautiful vertical effects that may be desired, and at will expose either arm, either shoulder, or the whole right side of the figure. Unbuttoning one or more of the buttons allows it to slip from either shoulder. With only two buttons we have a sleeveless garment. If all of them are in place and others put close to the neck, we have the figure completely covered, and yet may expose the right side at pleasure.

Putting the girdle around the figure, we introduce an entirely new set of folds. Pulling the garment up through the girdle, and allowing it to fall, we have the short Diana-like dresses. With a crossed girdle or cinchure over the shoulders we obtain a new series of folds. This confines the garment to the figure and develops its outlines. We still have the alternative of long sleeves or bare arms, and the open right side. Over this the Greeks frequently, for the beauty of the folds, put a mantle, consisting of a piece as long as the main garment, horizontally, but only half its vertical depth. This was buttoned on the shoulders and made the same exquisite series of folds as the under-garment. When the ends are cut off diagonally, or "bias," as the ladies say, they are exceedingly beautiful, and a set of diminishing folds like pleats can be obtained. Add to this a very long strip or scarf half a yard wide, and of indefinite length, to throw over the shoulders, to twist about the arms, or to festoon about the figure, and we have all the necessary materials for the ordinary drapery. To this the Greeks added something like a shawl, with this difference, that it was of lighter material and was not folded in the centre, but used in a single thickness. This they threw over the arm, carried around the figure, turned over the shoulder, and used it for a variety of wrappings. It makes an envelope for the head also.

### THE EVOLUTION OF A PICTURE.

BEFORE the Birmingham Photographic Society, on Tuesday, February 6, Mr. John H. Gear, F.R.P.S., gave his lecture on "The Evolution of a Picture." The lecture embraced a valuable series of hints for the guidance of those who aim at producing something more than an ordinary photograph.

For development Mr. Gear strongly advocated the use of tabloids,

which, in his opinion, offered the most convenient means of securing accuracy in the constitution of the developer. Especially were they of use for development on tour, and the lecturer showed an exceedingly compact case stored with all kinds of chemicals in this concentrated form. For after-treatment of dense negatives Mr. Gear recommended the use of ammonium persulphate, which possessed the valuable property of attacking the dense parts first. A slide which had been purposely developed to undue density in the shadow portion was treated with ammonium persulphate, and the after-result exhibited in the lantern; the difference in density was very striking, and most of those present recognised that a great power was placed in the photographer's hands by the introduction of this chemical.

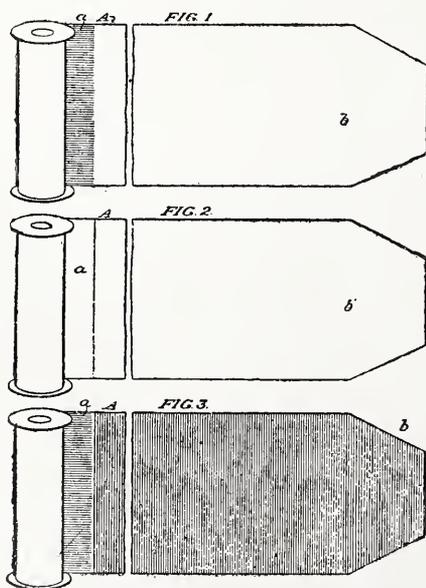

On the subject of picture-making Mr. Gear said that an ordinary photographic view, such as any one might take, could be converted into a picture by availing oneself of suitable conditions of lighting and by judicious after-treatment in mounting, &c. In illustration an excellent series of slides was shown, in which charming pictorial effects had been secured by the introduction of suitable clouds, &c.

In conclusion, Mr. Gear remarked that the danger of the modern tendency for broad effects in photography was that suppression of detail was often carried too far by persons who thought that, because Mr. So-and-So had secured a picture by throwing his lens out of focus, therefore similar procedure on their part would give a like result—a fallacy which, as Mr. Gear showed, has brought ridicule on the "fuzzy" school of photographers.

#### A NEW FORM OF DAYLIGHT CARTRIDGE.

THIS is the invention of Mr. A. W. McCurdy, of Washington, who, in the course of his description of it, says that, in the manufacture and use of daylight films or cartridges, it is the universal custom to provide a considerable length of black paper as a covering or enveloping body, to exclude the light and prevent the sensitised film from becoming "fogged" or "light-struck." A common plan is to extend the paper along the back of the film throughout its entire length, and to a considerable distance beyond each end; one end to be wound about the coiled or rolled film a number of times, and to fill completely the space between the heads of the spool so that no light may reach the film until the covering or enveloping portion of the paper is unwound therefrom. This is done mainly after the cartridge or roll is placed in the camera where it is properly protected.

Mr. McCurdy says he has ascertained, by repeated experiments and

working tests, and has demonstrated in actual working, that black paper is not essential. Celluloid prepared just as is the image-receiving surface, or ground or otherwise rendered impervious to actinic rays, will, if wound in several layers about the image-receiving portion of the film, effectually exclude all light rays that would affect the latter. The light-excluding or enveloping sections may, therefore, be mere extensions of the ordinary coated film, additional to the portion designed to receive the images. So, too, it has been found that white paper, and papers approximating white will likewise thoroughly protect the film.

Availing himself of this fact, and of the discovery that both celluloid and light papers will adequately protect the film, he makes or furnishes the film with a protecting section of such material. In other words, he provides the film with a covering or protecting sheet or section composed of material which is in the developing and fixing baths and out of them possesses only such ingredients or components as are chemically inert

under all ordinary conditions of storage, exposure, development, or fixing of the film. *a* indicates the body of a film, of celluloid or other suitable material, having the image-receiving portion, *a*, coated with the usual emulsion or preparation, and sensitised to adapt it to receive the picture or impression produced by the light transmitted by the lens of the camera. Formed with and as extensions of the film, at the ends of the image-receiving portion, are enveloping or light-excluding sections, *b b*, here represented as integral with the intermediate section, *a*. These sections, *b*, may be rendered opaque or semi-opaque by pigment, colouring matter, or dye, introduced into the celluloid in the process of manufacture, and hence free from liability of being affected by the baths or by the moisture of the atmosphere; or they may be ground, subjected to the action of a sand blast, or in any other convenient manner made semi-opaque. Thus prepared, or even without special preparation, other than such as is given the image-receiving portion, the enveloping or light-excluding portion, if made of moderate length so as to wind several times about the coiled film, will effectually exclude the actinic rays, and protect the film from injury by light.

In fig. 2, the end sections, *b b*<sup>1</sup>, are represented as formed of paper, or like material, which, however, will be free from any element or ingredient which shall be capable of separation out of the paper, either chemically or mechanically, under action of the atmosphere or of the baths, and at any temperature to which it would otherwise be safe to subject the film.

Fig. 3 shows the same construction as fig. 1, but indicates by surface shading the grinding, colouring, or other treatment of the celluloid or like material to render it impervious to actinic rays. It is found in practice that this is not essential, and that the celluloid may be left untreated, or in other words, that the emulsion or coating used on the body of the film, if carried over the ends or enveloping sections, will answer all requirements. It is to be understood that the enveloping portion will be provided at both ends of the film, and pointed to facilitate threading into the spools.

#### A "NEW REPRODUCTION PROCESS."

THE author of this invention, Herr Bierenz, of Vienna, employs, in the reproduction of pictures, photographs, drawings, and also of colour prints, original articles, and so on, a specially prepared plate, preferably of metal—such as zinc, copper, or the like—the surface of which is capable of receiving a device, transfer, or impression of the drawing, photograph, or the like, which it is intended to reproduce, as it already possesses that grained texture which is requisite for the "decomposition" pattern or design which reproduction necessitates.

The plate which he proposes to employ is produced as follows: After being first polished or smoothed down, it is, by any suitable means, subjected to the action of a sharp blast charged with sand, iron filings, or similar bodies, for an adequate length of time, whereby the "graining," already mentioned, is obtained, which renders the plate capable of receiving the image direct. It may be mentioned in this connexion that the resulting fine, though irregular, dotting in the graining of the plate is calculated to prove very beneficial to the effect of the reproduction eventually obtained, and that this advantage becomes manifest also in colour-printing, as it enables the possible unsightly effects of the juxtaposition of geometrical figures, into which the design has been divided (by means of stencil plates, squares, and the like) in the superposed printing of different shades of colour, to be obviated.

The following are the results which the process, involving the employment of the zinc (or other plate), grained as described, enables him to attain:—

1. Any given picture may be reproduced with suitable drawing materials, preferably fat chalk (crayons), or fat Indian ink, and so on, upon a plate, direct, so that it is ready for immediate etching, engraving, "rouletting," or photographing, it being important, in regard to these reproductions, that any necessary corrections in the picture, such as effacing, rubbing out, or retransferring, should be readily feasible. The fixing of a picture thus reproduced, in a manner adapted for printing, may be effected in a manner similarly to that hitherto employed, viz., by sprinkling it with some powdered substance, such as asphalt or the like, resisting the action of acids, and then dipping the plate in a bath prepared with certain acids, washing the same, and so on, until a plate adapted to be printed from is obtained.

2. Direct reproduction with the assistance of photography becomes possible owing to the fact that after the preparation of the grained plate with substances—such as chrome salts or the like—sensitive to the action of light, a picture drawing, or other object, may be directly photographed; the negative thus obtained may be developed, by the way, by the aid of a prism, even where the picture to be reproduced was, during the exposure turned down (or inverted). The grained sensitised plate (with gelatine film, which has been treated with chrome salts) is placed into the photographic camera in the same manner as an ordinary glass plate, and is then exposed. It is advantageous to have a strong light for exposing (full sunshine, electric light, or the like). The negative is then taken into the dark room and blackened in with soft or fat colour, treated with water and the shade portions cleaned from off the fat colour (which adheres to the gelatine which is still soluble) by the aid of wool or the

like. Hereupon it is dusted over with fine asphalt powder and the plate is now ready for burning and etching, by which latter procedure the picture is rendered ready for reproduction.

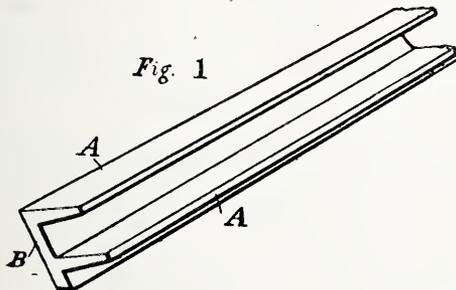

3. By the aid of photography the process will prove serviceable in directly preparing positive plates or images, as the decomposition of the photographic picture into variously shaded (dotted, hatched, and the like) parts, and consequently the employment of transparent, stencil, graining, or other similar plates or frames, avoided, the picture, or the like, to be reproduced, being taken in the well-known manner as a negative, upon a glass plate, the novel feature in this connexion being that the negative may be taken even by the dry, or gelatine, process. The negative plate is then placed upon the grained zinc, or other plate, which has been previously sensitised by being covered with a film of substances sensitive to the action of light, such as chrome salts and the like, the plate being then exposed to the light, whereby, upon the grained plate there is obtained a positive image, which in other respects, viz., for purposes of reproduction by printing, may be treated in the manner described in the concluding part of paragraph 1, so as to make it stand out more clearly and fix it more firmly for printing purposes.

4. The method, which consists in employing a grained zinc or other plate, is also suited to the purposes of chromography, the fineness of the graining causing the colouring of the image to appear clearer or purer than it would otherwise be; while in the case of parti-coloured designs, or pictures in more than one colour, the superposed colours become better assimilated and are brought out more fully; in addition to which the several successive photographic views of the picture or object, which have to be taken in this last-mentioned case, may—unless a transfer is intended—be conveniently treated by the simplified process above described, and be readily corrected in case of need.

5. Pictures may be transferred by fat printing from one plate—which may be lithographic stone, a heliographic plate, or the like—to a plate constructed in accordance with this invention.

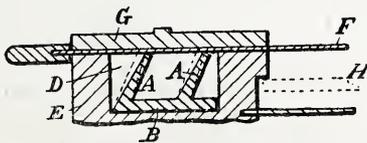

#### A FLEXIBLE SHUTTER FOR DARK SLIDES.

THIS is the invention of Mr. Bull, of Rochester, U.S.A. The shutter is formed of flexible indiarubber, and consists of the two yielding ribs, A, A, united together by the base, B, which is inserted in a suitable recess, D, in the frame, E, of the plate-holder, in such manner that the strips bear

against the slide, F, or, when that is withdrawn, spring outwards and make contact with the cap or cover, G, to the recess, and thereby exclude the entrance of light. It will be observed that, when the edge of the slide is passing through the recess, both shutters cannot be open at the same

Fig. 2.

time. This invention is applicable to any size or style of plate-holder, either single or double, and it effectually prevents fogging of the plates, H. The shutter is preferably made of a length somewhat greater than the width of the slide.

#### THE ROYAL PHOTOGRAPHIC SOCIETY'S ANNUAL GENERAL MEETING.

THE Annual General Meeting of the Royal Photographic Society was held on Tuesday evening, the 13th instant, at the Society's house, 66, Russell-square, when a large number of members assembled, in spite of the extreme inclemency of the weather. The chair was taken by Sir H. Trueman Wood, M.A., who moved the adoption of the Report of the Council for the year 1899, from which the following are extracts:—

“There has been a net increase during the year of sixty-two members.

The Council are glad to note the increased interest taken by fellows and members in the extension of the list of subscribers to the Society, which has resulted in the above accession of members.”

“During the year the Council have instituted a special monthly meeting for illustrated lantern lectures. The thanks of the Society are due to Mr. J. J. Vezey, who has undertaken the management of the lantern meetings, which have been an unqualified success, large numbers having been present on each occasion. The Council wish it to be understood that ladies are specially welcomed on these occasions.”

“The total receipts for the year, including a balance of 138*l.* 6*s.* 10*d.* brought forward, amount to 2245*l.* 11*s.* 11*d.* The total expenditure was 2001*l.* 1*s.*, leaving a balance of 244*l.* 10*s.* 11*d.*, the liabilities being half-year's rent of the Pall Mall Gallery 85*l.*, and on account of the affiliated societies of 55*l.* 9*s.* This amount received on account of the Guarantee Fund towards the expenses of furnishing 66, Russell-square, was 388*l.* 5*s.* 10*d.*, and the total amount expended was 533*l.* 15*s.* 3*d.*”

“For the first time in the history of the Society the amount received for subscription exceeded 800*l.*, the total, including back subscriptions, amounting to 886*l.* 17*s.* Exhibition receipts show a slight increase as compared with the previous year, total receipts being 485*l.* 5*s.* 6*d.*; but, in consequence of items for medals and Judges' expenses appearing this year, the expenditure also shows an increase, the net loss being 13*l.* 3*s.* 10*d.*”

“The amount invested in Consols remains, as before, 500*l.*, and the total balance in favour of the Society, after making a liberal allowance for depreciation, is 1387*l.* 8*s.* 5*d.* In accordance with the usual custom, no account has been taken for outstanding subscriptions.

“The Council are pleased to announce that arrangements have been made for the transfer of the Annual Exhibition to the large and convenient accommodation comprised in the New Gallery in Regent-street. The increased accommodation at the disposal of the Society will enable the Council to give attention to the generally expressed desire that the Annual Exhibitions should be more comprehensive and representative of photography generally than has formerly been usual. In the New Gallery limitations of space, which hampered progress in the old Gallery, do not exist, and the Council confidently expect that a new and successful era for the Exhibitions will commence with the acquisition of the New Gallery. The Organizing Committee has the arrangements now in hand, and the prospectuses will be issued at an early date.”

The motion for the adoption of the report was seconded by Mr. J. J. Vezey, and carried without discussion.

Mr. G. Scamell (Hon. Treasurer), in moving the adoption of the balance-sheet, compared it with that which he presented eight years ago, at the close of his first year of office, since which time some 13,300*l.* had passed through his hands. In 1892 the amount received for subscriptions (annual and life), and entrance fees was 411*l.*, and the income from those sources during 1899 was 1059*l.*, the number of members at present being 790, as against 453. The number of members elected was, in 1892, 30, and, in 1899, 129, and the increase in membership and income had been gradual and sustained. The actual loss on the last Exhibition at Pall Mall, taking into account certain matters which had transpired since the balance-sheet was made up, was only about 5*l.* All expenses in connexion with the furnishing of the Society's new house had been paid, and there was such a balance in hand that he thought it would not be necessary to call up any portion of the Guarantee Fund during the present year.

Mr. C. H. Oakden seconded the motion, and after a few remarks in which the Chairman referred to the very able manner in which the Treasurer had discharged his arduous and responsible duties, the balance-sheet was adopted.

The report of the Scrutineers, as to the voting for the election of officers and Council for the ensuing year, was then presented by Mr. E. Clifton, the result of the ballot being as follows:—*President*: Mr. T. R. Dallmeyer, F.R.A.S.—*Vice-Presidents*: The Earl of Crawford, K.T.; Mr. Chapman Jones, F.I.C., F.C.S.; Major-General J. Waterhouse, I.S.C.; Sir H. Trueman Wood, M.A.—*Treasurer*: Mr. G. Scamell.—*Ordinary Members of Council*: Messrs. Thomas Bedding; Thomas Bolas, F.I.C., F.C.S.; C. H. Bothamley, F.I.C., F.C.S.; F. A. Bridge; A. Cowan; W. E. Debenham; W. B. Ferguson, M.A., Q.C.; J. A. Hodges; Rev. F. C. Lambert, M.A.; A. Mackie; J. W. Marchant; Professor R. Meldola; E. Sanger Shepherd; J. A. Sinclair; John Spiller; J. W. Swan, M.A., F.R.S.; J. J. Vezey; E. J. Wall; H. Snowden Ward; and J. B. B. Wellington. The result of the voting for Judges at the forthcoming Exhibition was also announced, as follows: *Pictorial Section*: Dr. P. H. Emerson; Colonel J. Gale; B. W. Leader, R.A.; A. Horsley Hinton; and J. B. B. Wellington. The number of ballot papers received for the election of officers and Council was 232, of which 21 were invalidated from various causes; and, for the election of Judges, there were 231 papers, of which 14 were invalid.

The Chairman heartily congratulated Mr. Dallmeyer upon his unanimous election as President of the Society, and alluded to his long connexion with the Society, the valuable contributions which he had from time to time made to its *Transactions*, and his liberal gifts to the library and museum, especially his recent presentation of the focometer described by him in the first Traill Taylor Memorial Lecture.

The President then, amidst much applause, took the chair, and

expressed his sincere thanks for the honour which had been conferred upon him. He promised to use every endeavour to maintain all that was good in the traditions of the Society, to safeguard its interests, and to enhance its usefulness and influence; and, having regard to the valuable work which had been done by the able and distinguished men who had preceded him in the presidential chair, he asked the indulgence of the members if he came short of their expectations.

The proceedings closed with the passing of hearty votes of thanks to the retiring officers and Council, and to the auditors and scrutineers, the President alluding to the loss which had been sustained by the retirement of Sir W. de W. Abney, and expressing the hope that before long he would be persuaded to again give the Society the benefit of his highly valued counsel and assistance. Sir H. T. Wood also referred to the regret which was felt by every member at the fact that Major-General Waterhouse had found it impossible to continue to serve as Honorary Secretary, owing partly to other claims upon his time and attention, and partly to the ill health from which he had recently been suffering. The excellent services which had been rendered by Mr. A. W. W. Bartlett, the Assistant Secretary, were acknowledged in very complimentary terms.

The arrangements for future meetings include the following: On February 20, Professor R. W. Wood, of Wisconsin, will give a lecture, with a demonstration, on the subject of his diffraction process of colour photography, and will possibly also deal with sound photography. On February 27, Mr. Friese-Greene will read a paper "On Electricity in connexion with Photographic Action."

#### AFFILIATION OF PHOTOGRAPHIC SOCIETIES.

THE Annual General Meeting of the Delegates to the Affiliation was held on Tuesday, January 30, 1900, at 66, Russell-square, W.C., Mr. H. Snowden Ward in the chair.

The minutes of the last meeting were read and confirmed.

The annual report of the Executive Committee and the Treasurer's balance-sheet for the past year were read and adopted.

The report states that the number of societies at present in affiliation with the Royal Photographic Society is eighty-three.

At the Meeting of Delegates held on June 2, the direction of affairs was intrusted to an Executive Committee, composed of ten members with the Hon. Secretary and Hon. Treasurer, *ex officio*.

The Executive Committee have met six times since their appointment. Their chief efforts have been in the extension of the number of lectures available for circulation by the provision of the following:—

"Elementary Chemistry for Photographers," by C. F. Townsend. "Orthochromatic Photography," by E. Sanger Shepherd. "Flashlight Photography," by Alfred G. L. Philpot. "Photography in the Field," by G. T. Harris. "Printing Dodges," by G. J. T. Walford. "Rejlander—His Life and Work," by A. H. Wall.

During the year 1899 the Affiliation has been the means of filling over two hundred meetings by the loan of lectures and slides, and many more for the coming year are already similarly provided for.

A strong desire has been manifested for the encouragement of an organized interchange of lecturers. The success of such a scheme rests primarily upon individual action by the societies themselves, but the Committee have taken steps to draw the attention of the societies to the movement, and hopes to be in receipt of information shortly which will enable a start to be made during the present session.

The Committee have arranged for the despatch of lectures ten days before the date of the meeting, to facilitate attempts to procure a qualified reader. Abstracts of lectures containing formulæ and working instructions are in course of preparation, and will be issued in any number at cost price, for the convenience of those who desire to act upon the hints contained.

The travelling collection of pictures, many old pictures being replaced by later work, has been rearranged. It continues to form a valued feature of the work of the Affiliation, many applications for the year having been received and granted. The Committee would urge prompt application by societies wishing to burrow the collection to enable a satisfactory route to be marked out, and to reduce the expense of carriage to a minimum.

Early in the year the Council of the Royal Photographic Society invited the societies to express their views upon the utility of the Affiliation scheme, and a large number of suggestions was received, which were passed to this Committee for consideration.

Acting on the suggestions contained in the letters, the Executive Committee have arranged to issue an annual pamphlet to every member of the affiliated societies, giving concisely all information relating to the societies concerned, such as headquarters, conveniences, the list of lectures and slides, interchange of lecturers, travelling lecturers, and other benefits to which the subscribers may be entitled.

The Committee have taken steps to ascertain what might be done in the provision of travelling lecturers. They are in communication with a number of well-known lecturers on popular subjects, and hope to be able to announce an arrangement by which, if a sufficient number of societies

apply, these gentlemen will give their services at reduced charges for fees and expenses.

The Committee have arranged for the existing Board of Judges to undertake the judging of lantern slide as well as print competitions.

Mr. H. W. Bennett has kindly lent his lecture on the "Pictorial side of Architectural Photography," first read before the Royal Photographic Society on November 21. His lecture on the technical branch of the same subject has been in circulation for some time past.

Arrangements have been made for the revision, as opportunity offers, of the lectures which have been in circulation some time. The matter will be brought up to date, and damaged and broken slides replaced.

The Committee find that the slides now in the possession of the Affiliation have been lent to nearly, if not all, of the societies, and in some cases more than once. They hope before long that efforts now being made will result in the addition of new and interesting sets, but they feel sure that there must be many interesting slides, or sets of slides, in the possession of the societies affiliated which might be available for a season on loan to other societies. Societies willing to lend such sets are requested to communicate with the Secretary.

The Treasurer stated that, of the balance of 55*l.* 9*s.* in hand, some 35*l.* had been appropriated for lectures, &c., leaving about 20*l.* actually available.

It was agreed to request the Earl of Crawford to continue to occupy the post of Chairman of the Affiliation.

The following officers were appointed: Hon. Treasurer, Mr. George Scamell; Auditors, Messrs. F. W. Levett and F. W. Bannister; Secretary, Mr. A. W. W. Bartlett.

The following Delegates were appointed the Executive Committee for the present session: Messrs. R. Beckett (Hackney Photographic Society), C. Churchill (Woolwich Photographic Society), S. H. Fry (London and Provincial Photographic Association), C. G. Emery (Chiswick Camera Club), A. Mackie (Royal Photographic Society), J. C. S. Mummery (North Middlesex Photographic Society), E. Marriage (Woodford Photographic Society), C. H. Oakden (South London Photographic Society), J. A. Sinclair (Royal Photographic Society), and H. Snowden Ward (Royal Photographic Society).

A vote of thanks to the officers for their work during the past year was carried unanimously.

It was agreed that a meeting of the secretaries of metropolitan societies should be held twice a year—March and September.

It was agreed to instruct the Executive to approach the editor of the *Photographic Journal* respecting the announcement therein of affiliated societies' fixtures.

The matter of the provision of a set of slides of Tinworth's subjects was also referred to the Executive.

#### THE MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY.

FROM the fifteenth annual report of this large and flourishing photographic Society we take the following extracts, which show that the M.A.P.S. is in a very sound and healthy condition. We congratulate the members and the hard-working band of officers responsible for the working of the Society on the eminently satisfactory condition of affairs:

At the last Annual Meeting the Society consisted of 360 members, and since then 40 new members have been elected, making a total of 400. We have to record the loss of one member by death, 35 through removal or resignation, and 28 have been struck off the roll of membership for non-payment of the subscription, leaving 336 members on the books of the Society.

During the year ten Ordinary Meetings, one Special Lecture Meeting, the Annual General Meeting, the Annual Social Gathering, and the Annual Exhibition of Members' Work have been held.

During the year 114 issues of books have been made to members. This year 9*s.* 3*d.* has been received from fines, which, together with 6*s.* 7*d.* brought over from last year, makes 15*s.* 10*d.*; out of this 4*s.* 7*d.* has been paid for back numbers to complete volumes, postages, &c., and 11*s.* 3*d.* carried forward to next year.

The apparatus has been poorly patronised this year. It is surprising to find our members making such little use of our collection. This year the dark-room lectures have commenced at 7.30 instead of 7, the later time proving more convenient to the majority of our members.

The lectures and demonstrations have been fairly well attended, with the exception of those held during the summer months. These have been so sparsely supported that it is worth considering whether we should have fewer lectures in the summer. The Committee has considered the advisability of getting a better room for the dark-room demonstrations. An attempt was made to obtain the Magazine Room at the Athenæum, but unfortunately it was not available, and so for the present the matter lies in abeyance.

During the past year the Survey Committee have brought their labours to a close with a feeling of regret that much more has not been done to fulfil the ideal scheme as proposed by the late Rev. H. J. Palmer, M.A. The result of the survey is far from being complete, but the Council and Committee feel there is nothing to be gained by continuing the work. Two sets of prints have been offered and accepted by the Library

Committees of the Manchester and Salford Corporations, who have kindly undertaken to defray the cost of mounting and binding to the satisfaction of the Society's representatives (Messrs. Coulthurst and Wheeler). A third set will be mounted and bound for the Society's library, for reference only, the fourth and remaining set being placed in the hands of the Society's Treasurer for safe keeping until disposed of at some future time. The Committee, in closing their labours, beg to thank those members who have rendered such valuable help and assistance, and our only regret is that the band of workers was not much larger.

This year there has been organized in connexion with the Society a Postal Club for the circulation of prints for criticism, &c. At present the Club has a membership of twenty, each member receiving a folio of prints about every month. During the year upwards of one hundred prints, selected from the folios, have been exhibited at the Society's monthly meetings at the Athenæum.

The Sub-Committee have decided to reduce the subscription for 1900 to 1s. 6d., with an entrance fee of 1s. for new members. The Club is now in fair working order, and it is expected that during 1900 it will be more successful than ever, and by providing prints for exhibition at the Society's meetings will help to make them more interesting.

The following is a list of the officers elected at the recent annual meeting:—

*President*: J. W. Wade.—*Vice-Presidents*: S. L. Coulthurst, the Rev. H. W. Dick, G. E. Mellor, and G. H. B. Wheeler.—*General Committee*: W. M. Blackshaw, W. H. Bowman, H. B. Bradley, F. W. Burton, T. Glazebrook, P. Hancock, A. Handford, J. C. Hope, J. W. Price, L. Scholes, Jas. Shaw, J. Wood Smith, and J. W. Young.—*Librarian*: J. W. Young.—*Editor of Magazine*: J. Wood Smith.—*Hon. Treasurer*: Chas. Dawson, 10, Chepstow-street, Manchester.—*Secretary*: F. W. Parrott, 3, Elm-road, Altrincham.—*Sub-Committees*—*Record*: W. H. Bowman, the Rev. H. W. Dick, G. E. Mellor, J. Wood Smith, and J. C. Hope (Hon. Secretary); *Demonstrations and Rooms*: W. M. Blackshaw, S. L. Coulthurst, A. Handford, G. H. B. Wheeler, Jas. Shaw (Hon. Secretary); *Lantern*: P. Hancock, A. Handford, J. W. Price, L. Scholes, and F. W. Burton (Hon. Secretary); *Postal Club*: W. M. Blackshaw, J. C. Hope, and H. B. Bradley (Hon. Secretary).

The President and Secretary are *ex-officio* members of all Sub-Committees).

#### THE EDINBURGH PHOTOGRAPHIC SOCIETY'S ANNUAL EXHIBITION.

On Saturday the Annual Exhibition of the above Society was opened in their rooms, 38, Castle-street, Edinburgh. There is a total of 284 entries, which, compared with 301 last year, shows a slight falling off; but the Exhibition is a good one, well and tastefully hung, considering the disadvantages of the room in which the photographs are shown. The Society, it is needless to note, is an old one, founded in 1861, and seems to renew its vigour with the increasing years. There is an absence of any very outstanding work on the walls, but the general level maintained is good.

The most important classes, naturally, are the "open to all," and of these the "Landscape" has forty-three entries, and the "Portraiture" has fifty-four, comprising representative work from most of the leading district professionals, along with those from other parts, with a goodly sprinkling of "class" amateurs.

In Class I. (open to all)—Landscape, Seascape, and Architecture—the gold medal is awarded to Mr. James Patrick, Edinburgh, last year's winner of this award, for *The Miry Beasts retreating frae the Plough*. The brown carbon print shows two horses, the off-side one ridden by the ploughman, returning home from the day's work. The picture is diffused with the mist and mystery of the evening light, and is an entirely different view from his *A Stilly Hamlet Home*, the winner of last year. The whole picture hangs well together, although a little more definition in the shadow of the hedge to the right might be an improvement. Mr. Patrick has reason to be proud of winning this position two years in succession. The silver medal goes to *A Spring Pastoral*, by Arch. Cochrane, Hurler, a study of sheep and lambs under trees, through the branches of which the shimmering sunlight plays. This print was hung in the Royal, and reproduced in the official catalogue, so that it will be well known to most of our readers; the grouping of the animals is happy, but, unfortunately, the pose of the lamb to the right is not all that could be desired. Mr. Alex. Allan, Edinburgh, who had a series of victories at the Exhibition of last year, takes the bronze medal with *Landscape*, a river scene, decorative in treatment, and therefore hardly to be criticised as an ordinary photograph, otherwise it would be betokened hard; as it is, it is a good specimen of "decorative" work.

A number of exhibitors in this class show snow scenes; but, as a rule, they have missed the beauty of the snow and the results are "contrasty" and hard; now that the snow has come again, they should have another try and endeavour to render the snow with some appearance of texture.

In Class II. (open to all), Portraiture, Figure and Animal Studies, the gold medal is gained by that well-known and popular Birmingham amateur, Mr. W. Smedley Aston, with a portrait study, *Mrs. Arthur*

*Gaskin*, in warm black carbon, a break-off, for which we are thankful, from the almost universal brown tones now prevailing. The picture, like all Mr. Smedley Aston's work, is simple and free from eccentricities, the figure is shown in profile, the face in strongly lighted—it is a good face—and the lace shawl and the lady's hand are pleasingly subdued, so that it is the face that secures our attention, and this is an axiom of portraiture that is always being preached.

The silver medal is awarded to Mr. R. S. Webster, Edinburgh, for *At Home*, a picture that was shown at the Royal this season. The picture is one of those "at home" series of which Mr. Webster has been making a speciality of late—it would be worth the while of many of our professionals to follow his lead in this respect—it shows a lady dressed in white, seated beside a fireplace, the arrangement is good, and the treatment of the white dress is a splendid bit of work. The picture conveys a good idea of the softened light of an ordinary interior. Mr. W. Reid, Wishaw, gains the bronze medal with *Horses in a Harvest Field*, a fine trio of horses in a harvest field, the treatment betokening the influence of the Reid of Wishaw; the exhibitor is, we believe, a son of Mr. Charles Reid of "animal" fame. A certificate goes to Mr. James Auld, Edinburgh, for *In the Olden Times*, a modern girl in "olden" dress, but a pleasing portrait, withal.

Class III. (open to members), Landscape, Seascape and Architecture. Gold medal, Mr. James Burns for *'Tis Winter Fairly*, a very satisfactory attempt at the portrayal of winter, simple in treatment. Mr. George Clelland gains the bronze medal with *Barnclinth*, a good rendering of the play of sunlight through trees; the figure in the foreground is not an improvement.

Class IV. (open to members), Figure or Genre, including Animals.—Here the silver medal is gained by *The Wind Bloweth from the Sea*, by Mr. James Burns. This is also the best picture by an amateur member, and gains the President's gold medal. It is a small print in bromide of a Dutch girl, standing on the seashore, gazing seaward. Small in quantity but great in quality, it at once attracts the eye and rivets the attention of the onlooker. Simple in *excelsis*, it is yet complete and satisfying, and a picture to be remembered. Mr. Burns is to be congratulated on it. The bronze medal is gained by Miss Eleanor M. Gray, with a portrait of *Mason Hunters, R.S.W.*; a good honest bit of work, even although the smirk on the face of the sitter is distracting.

Class V. (open to members), Still Life, including Fruit and Flowers.—This is a very unsatisfactory class; only seven prints are forward, and the Judges very wisely give no awards.

Class VI. (open to members), set of pictures, not exceeding three, being work done by camera held in hand.—Mr. J. C. McKechine gains the silver medal with three seascapes, of which we prefer *A Stormy day at St. Abbs*. Mr. J. Yate Thomson gains the bronze medal with three views, showing good technique, of *Harbour, Scarborough*.

Class VII. (open to members), Lantern Slides in sets of six.—A set of beautiful "swan" studies, by Mr. C. M. Wane, gains the silver medal, while the bronze goes to Mr. George Clelland for a set (varied subjects) showing good technique.

Class VIII. (open to amateur members only), Landscape, Seascape, and Architecture, up to and including half-plate.—Silver medal is awarded to Mr. W. E. Carnegie Dickson, *A Highland Loch*, a well-composed picture, but printed in a rather disquieting shade of green. Mr. W. J. Croall is awarded the bronze medal for *Harvest—A Windy Day*, a simple little scene, brimful of life and motion.

Class IX. (open to amateur members only), Figure or Genre, including Animals, up to and including half-plate.—The silver medal is gained by a costume piece by Mr. H. Stewart Wallace, entitled *A Game at Chess—Will She Mate Him?* The arrangement on the whole is satisfactory, but there is a stiffness of pose about the figures that mars the effect. Mr. Alex. Allan wins the bronze medal with *Words of Comfort*, one of his "auld wifey" studies, with which he has been so successful.

Messrs. G. W. Johnstone, R.S.A., Edinburgh, Percy Lund, Bradford, and John Stuart, Glasgow, were the Judges.

On the Saturday evenings during the Exhibition, entertainments will be given. These include a lantern lecture, entitled "Rambles with a Camera," by Mr. James Patrick, the gold medalist.

The following is the complete prize-list:—

Class I. (open to all), Landscape, Seascape, and Architecture.—Gold medal, Mr. James Patrick, Edinburgh, No. 30, *The Miry Beasts Retreating frae the Plough*; silver medal, Mr. Archibald Cochrane, Hurler, No. 27, *Spring Pastoral*; bronze medal, Mr. Alexander Allan, Edinburgh, No. 39, *Landscape*.

Class II. (open to all), Portraiture, Figure, and Animal Studies.—Gold medal, Mr. W. Smedley Aston, Birmingham, No. 65, *Mrs. Arthur Gaskin*; silver medal, Mr. R. S. Webster, No. 60, *At Home*; bronze medal, Mr. William Reid, Wishaw, No. 59, *Horses in a Harvest Field*; certificate, Mr. James Auld, Edinburgh, No. 75, *In the Olden Times*.

Class III. (open to members), Landscape, Seascape, and Architecture.—Silver medal, Mr. James Burns, No. 119, *'Tis Winter Fairly*; bronze medal, Mr. George Clelland, No. 127, *Barnclinth*; certificate, Mr. Harry P. Wane, No. 105, *The Old Bridge*; certificate, Mr. E. L. Brown, No. 131, *Baptistry*.

Class IV. (open to members), Figure or Genre, including Animals.—Silver medal, Mr. James Burns, No. 146, *The Wind Bloweth from the*

*Sea*; bronze medal, Miss Eleanor M. Grey, No. 156, *Mason Hunter, R.S.W.*; certificate, Mr. W. J. Croall, No. 141, *Steady*; certificate, Mr. Douglas H. Watson, No. 147, *Portrait*.

Class V. (open to members), Still Life, including Fruit and Flowers.—No awards.

Class IX. (open to amateur members only), Figure or *Genre*, including Animal Studies, up to and including half-plate.—Silver medal, Mr. H. Stewart Wallace, No. 174, *A Game at Chess—Will She Mate Him?*; bronze medal, Mr. Alexander Allan, No. 189, *Words of Comfort*; certificate, Mr. E. L. Brown, No. 170, *Bubbles*.

Class VIII. (open to amateur members only), Landscape, Seascape, and Architecture, up to and including half-plate.—Silver medal, Mr. W. E. Carnegie Dickson, No. 205, *A Highland Loch*; bronze medal, Mr. W. J. Croall, No. 242, *Harvest—A Windy Day*; certificate, Miss M. G. Johnstone, No. 206, *The Clyde at Greenock*; certificate, Mr. James Burns, No. 208, *O'er Hill and Nale the Shadows Creep*.

Class VI. (open to members only), Set of pictures, not exceeding three, being work done by camera held in hand.—Silver medal, Mr. J. C. McKechnie, No. 259, seascapes; bronze medal, Mr. J. Yate Thompson, No. 255, *Harbour, Scarborough*; certificate, Mr. W. J. Croall, No. 256, various; certificate, Mr. A. J. Cameron, No. 257, landscapes.

Class VII. (open to members), Lantern Slides, in sets of six.—Silver medal, Mr. Charles M. Wane, No. 284, *Swans*; bronze medal, Mr. George Clelland, No. 269; certificate, Mr. George Clelland, No. 270; certificate, Mr. W. J. Croall, No. 266.

President's Gold Medal for the Best Picture in the Exhibition, the work of an Amateur Member.—Mr. James Burns, No. 146, *The Wind Bloweth from the Sea*.

## Our Editorial Table.

CATALOGUE RECEIVED.

C. P. Goerz, 4 and 5, Holborn-circus, London, E.

THE production of this catalogue reflects very high credit indeed upon Mr. Goerz. Bound in a light green cover, with a graceful design in blue and gold, it instantly secures attention and pleases the eye. And between the covers there is something more than a mere trade list. The section devoted to lenses gives the photographer much information, not only about the principles of construction adopted in the Goerz lens, but also many optical hints, which will assist him in his work. Here, for instance, is a recommendation as to focal length, of which, for the sake of pleasing perspective in photography, we would make it a criminal offence in a photographer to be in ignorance.

"It has been generally recommended that the focus of the lens for any particular size of photograph should be the length of the longest side of the plate, *e. g.*, a 5-in. lens for a 5 x 4 plate, a 6½-in. lens for a half-plate, and an 8½-in. lens for a whole-plate, &c. The better rule, however, is to select a focus equal to the diagonal of the plate, the perspective given by such a lens being much more natural, *i. e.*, more closely approximating to the human eye."

The many beautiful half-tone and collotypic reproductions in the book do the Goerz lenses full justice. Remaining sections of the book are devoted to prisms and screens, the Goerz-Anschütz folding camera, the powers of which are well illustrated by studies of German cavalry in rapid motion; the Goerz photo-stereo binocular (noticed in our pages a few months ago), &c., &c. Finally, there is a detailed account of how a Goerz lens is made. With reference to Series III. of the lens, Mr. Goerz writes us: "I take this opportunity to inform you that new calculations having been made at my manufactory, it has been found possible to construct all the Double Anastigmats, Series III., up to the No. 6, with a working aperture of *f*.6·8, with which aperture they are now supplied, instead of *f*.7·7 as formerly; the prices, however, are unaltered."

Altogether this is a catalogue which, in its own sphere, almost assumes the position of a work of art. In the history of modern optics nothing has been so remarkable as the growth in favour of the Goerz Double Anastigmats. Their high optical qualities are very widely acknowledged.

### THE USEFUL ARTS AND HANDICRAFTS SERIES.

Published by Dawbarn & Ward, 6, Farringdon-avenue, E.C. Price 6d. each.

THIRTEEN numbers of this valuable series of little books have now been published, and although there is nothing of a strictly photographic character included, those interested in the minor arts and crafts constitute a wide public, amongst which, doubtless, many of our readers are to be found. We can cordially recommend the series to the notice of those who practise the self-culture of some particular form of craftsmanship. Plainly and clearly written, the books could not be excelled as simple guides to the subjects mentioned in the following list:—

Design and Drawing. C. G. Leland. Wood-carving. C. G. Leland. Picture Frames; making and decorating. C. G. Leland and Thos. Bolas. Dyes, Stains, Inks, Lacquers, Varnishes, and Polishes. Thos. Bolas. Decreated Wood-work; by carving, colouring, and wire-in-laying. C. G. Leland and C. E. Dawson. Gouge-work and Indented Wood-work.

C. G. Leland and Rev. F. C. Lambert. Wood-engraving and Placard Cutting. C. G. Leland and Thos. Bolas. Bent Iron Work. Geo. Day, F.R.M.S., and C. G. Leland. Pyrography, or Poker-work. On Wood, fabrics, &c. Thos. Bolas and C. G. Leland. Stained and Leaded Glass. W. T. Whitehead. Artificial Wood; and shavings in decoration. C. G. Leland. Venetian Marquetry and Inlaying. C. G. Leland. Church Decoration (permanent). W. T. Whitehead.

### THE "VANGUARD" STAIN REMOVER.

Manufactured by the Vanguard Manufacturing Company, Maidenhead.

In order to test the value of this stain remover we selected for experiment one of our own negatives which we developed with pyro-ammonia, without sulphite, over fifteen years ago. The negative was of a fairly deep yellow colour. Immersion in the Vanguard stain remover (which is a clear colourless solution) diluted in the proportion of one to eight, took away the yellow colour in a few minutes. There could be no better testimony of its efficacy. The Company inform us that at the dilution mentioned the solution may be used to clean engravings, by simple immersion, and that in its concentrated form it removes stains from the hands. Moreover, it does not contain any poison scheduled in the Act; and when the cleared negative is washed the stain does not reappear. Taking these properties for granted we are satisfied to find by actual trial that as a remover of stains from negatives the Vanguard Company's latest introduction fulfils its purpose perfectly.

From the Photochrom Company, 121, Cheapside, E.C., we have received a frame of three views in Florida. It need scarcely be remarked that the pictures are in colours by the process which has of recent years made the world familiar with innumerable beautiful "photographs in the colours of nature." It is interesting to speculate whether pigmentary natural colour-photography, if discovered, would yield more attractive results than the charming examples of photo-mechanical work that are before us. Probably not. By the way, we learn that the business of the Photochrom Company has grown to such an extent that all the frames required for the enormous number of pictures sent out are made by the Company's own staff. These amount to some hundreds of thousands in the course of the year.

## Studio Gossip.

THE Star Photographic Company, 536, Oxford-street, announce that they will take the photographs of any of the volunteers for the Transvaal War entirely free of charge, provided they will attend their studios in khaki uniform and at any time before 9.30 p.m.

A WELL-KNOWN photographer has converted into practical shape his sympathy with the gallant fellows who have volunteered to fight in South Africa. Mr. Marshal Wane, of 82, George-street, Edinburgh, announces that he is prepared to photograph free any volunteers (officers and men) under orders for the front, and to supply each with two cabinets.

WITH reference to the recent articles and correspondence in our pages relative to the articling of pupils, a provincial friend writes us that in the town in which he resides there are two photographers making between 2000l. and 3000l. a year, two between 600l. and 1000l., and many about 300l. Our friend says he knows of twelve apprentices who have been taken during the last few months at premiums varying from 30l. to 105l.

CRYSTOLEUM WORK.—In reference to a query from a correspondent in last week's JOURNAL on this subject, the following ladies and gentlemen have written to say that they undertake this kind of work: Miss Robotham, 30, St. Luke's-road, Clapham, S.W.; Mrs. Cooper, 21, Station-street, Walsall; Mr. G. H. Drake, Mackenzie Studio, Slough, Bucks; Miss Wolfe, Hydes Farm, Forest Side, Waltham Abbey, Essex; Mr. E. Goodfellow, 47, High-street, Wincanton; Mr. Alfred Underhill, 32, Clarendon-road, Croydon; Miss Cox, The Elms, Stow-on-the-Wold, Gloucestershire; and Mr. E. Knott, The Gainsborough Studio, Kingston-road, South Wimbledon.

At the North London Police-court, on February 7, Mr. Thompson Fisher, a photographer, of Mare-street, Hackney, appeared to answer adjourned summonses taken out at the instance of the London County Council, (1) for erecting a structure beyond the general building line, and (2) for erecting a structure without the consent in writing of the London County Council. Mr. Chilvers appeared for the Council, and Mr. C. V. Young represented the defendant. In this case the defendant had erected a show-case in the fore-court of his house, and the Council, contending that this was a building, took these proceedings. In giving judgment, Mr. Fordham said that on the cases cited he was bound to hold that the show-case was a structure within the meaning of the London Building Act. He had adjourned the summons from January 17, in the hope that some arrangement would be come to between the defendant and the Council, because the show-case was an obstruction to nobody and impeded nobody's light but the defendant's. He had to hold that this was a structure; but, as it had been erected on land where a similar structure had stood previously, it was reasonable for the defendant to think that he was in the right. As this old structure was erected without officia

sanction, it was not legally there, and the erection that followed was not legal. Still he (the magistrate) could not see why the Council pursued the defendant. Mr. Chilvers: Mr. Young has asked the Council to allow the show-case to remain, and the Council has granted a licence for twelve months. Mr. Young: I accept that as an instalment. Mr. Fordham: I must convict in the face of decided cases, but shall only inflict a penalty of 5s., with 2s. costs on each summons.

## News and Notes.

PROFESSOR RÖNTGEN, who has accepted the call to the University of Munich, has been appointed Director of the State Institute of Physics and Metrology.

PHOTOGRAPHIC CLUB.—February 21, at eight o'clock, exhibition of prints and slides of "The Belgian Photographic Excursion, 1899," arranged by Messrs. W. D. Welford and W. F. Slater.

WE are asked by the Hon. Secretary of the South London Photographic Society to remind our readers that February 17 is the date for entry forms to be received for the coming Exhibition.

ROYAL PHOTOGRAPHIC SOCIETY.—Tuesday, February 20, at eight p.m., Professor R. W. Wood will read a paper on "The Diffraction Process of Colour Photography," or other subject. The exhibition of photographs by Mr. Craig Annan will remain open from ten to four to the end of the month.

THE Annual Dinner of the South London Photographic Society was held on Saturday last with its usual success. Owing to the heavy fall of snow, many visitors were unable to travel. The photographic press and senior societies were, however, well represented, and, notwithstanding outside discomforts, all within went merrily.

HAND CAMERAS.—Mr. J. Kennerell, of 7, York-road, Wisbech, writes: "The paper read by Claud Rippon, M.A., before the Oxford Camera Club, on the 9th instant, on 'Hand-camera Work,' interested me very much indeed; but there is one thing, and, I think, most important, he did not say how he proposed to change the plates. If you can by any means bring this before him, it might induce him to give him another paper on the subject, if he would be so kind."

THE Hackney Photographic Society, in lieu of an annual dinner, which has been held by the Society for many years, decided this year to make a change, and arranged a *soirée* and dance at the North-East London Institute on Thursday last, February 15. The nature of the entertainment was sociable; pictures, albums, microscopes, stereoscopes, &c., were on show, and a variety of vocal and instrumental music commenced the evening, followed by a dance, for which an efficient band had been engaged. Messrs. Newell & Co. provided refreshments.

THE Fifteenth Annual Exhibition of the Birmingham Photographic Society will be held at the Royal Society of Artists, New-street, on February 26, 27, and 28, and March 1, 2, and 3. In addition to the competitive pictures, in the Open and Members' Sections there will be a loan collection of photographs by some of the most eminent British workers, specially organized for this Exhibition, vocal and instrumental music, cinematograph and lantern entertainments, the kromskop, the lantern microscope, mutoscopes, cohesion figures, and projection of solid bodies on the screen, &c. There will also be a display of the latest novelties in apparatus.

A CONTEMPORARY remarks that "a memoir has been recently presented to the Paris Academy of Sciences, by M. Frillat, which is of interest to students of the science of photography. It refers to the transformation of the photographic image of a negative into the lamellar state by exposing it to the vapours of nitric acid, which dissolve the precipitated silver, and cause the disappearance of the image. The silver is reprecipitated by exposing the plate in an atmosphere of moist sulphuretted hydrogen, when the image reappears in colours, not necessarily the true colours of the objects, although, it seems, there is some possibility of exercising a little control."

## Commercial Intelligence.

THE metric system of weights and measures is allowed to be used in Russia now with the system at present in use.

THE Process and Engineering Company have removed to 66, Deptford-green, London, S.E. At the new premises they will have so much more space (about 18,000 square feet) and new machinery at their disposal, that they will have greater facilities for the execution of orders.

"PRICE-CUTTING."—Last week, at a representative meeting of grocers, held under the auspices of the Grocers' and Allied Trades' Proprietary Articles Association, at the Holborn Town Hall, a resolution was passed in favour of joint action with the Chemists' Association to obtain a uniform rate of charge for all proprietary articles from the manufacturers, with a view to stopping the cutting of prices.

MR. J. H. STEWARD, of 406, Strand, is exhibiting a photograph of a portion of a consignment of powerful telescopes on stands he has supplied from stock, finished and delivered at Woolwich within four days of receipt of order. They magnify from fifty to ninety diameters, and have object-glasses, in the majority of instances, of two and a half inches to three and a quarter inches

diameter to ensure good field of view and clearness. Mr. Steward also made and supplied, within fourteen days, 500 binoculars to the Yeomanry, 100 of them being for the Bucks companies.

Re EDWIN WESLEY ROBERTS, photographer, Royal-arcade and St. Mary-street, Cardiff.—The statutory meeting of the creditors interested under this failure was held at the offices of the Official Receiver on Friday last, under the presidency of the Assistant Official Receiver for the Cardiff district. The statement of affairs filed by the debtor disclosed gross liabilities amounting to 3312*l.* 5*s.* 7*d.*, of which 1790*l.* 5*s.* 8*d.* was due to unsecured creditors. The debtor alleged his failure to have been caused through want of capital and pressure by creditors, with consequent heavy costs. Mr. Lewis Morgan, on behalf of the debtor, submitted an offer to the meeting of 6*s.* in the *l.*, but the Official Receiver said he was of opinion that the debtor's stock would realise more than sufficient to pay 7*s.* 6*d.* in the *l.* One of the creditors ventured the opinion that the assets, as estimated by the debtor, showed something like 12*s.* in the *l.*, and yet he expected them to accept 6*s.* in the *l.* Eventually it was decided to adjudicate the debtor bankrupt, and Mr. C. E. Dovey, chartered accountant, of Cardiff, was appointed trustee of the estate and property of the bankrupt, under the supervision of a Committee of Inspection, which was also appointed.

THE Managing Director of the Yost Typewriter Company writes us: "The bad taste and bitterness of feeling displayed by the yellow press of France in connexion with our military operations in South Africa has naturally and rightly caused much resentment throughout the Queen's dominions. Since the old axiom that "in order to hit a man you should try and go straight for his pocket" has been translated by many people into the desire and resolve to establish a partial Exhibition boycott by inducing British traders to withhold from exhibiting at, and the British public from frequenting, the forthcoming world's show at Paris, a timely warning will not be out of place. Those people who merely visit exhibitions for pleasure sake can, of course, please themselves as to whether they ought to go or stop away, and if, in their view, they are punishing the Frenchman by holding aloof, they may be right in giving practical expression to their righteous indignation. But it is quite different with the British trader. He would be wrong in letting his feelings overcome his better judgment. The American, the German, and the Belgian manufacturer would only be too pleased if Great Britain were not properly represented at the Paris Exhibition, since it would give him an opportunity of alleging a superiority of his goods which does not exist, and, under certain conditions, such a contention could not be repudiated on the spot, owing to the lack of enterprise of representative British exhibitors. Space will not permit me to enlarge as fully upon this subject as I would like, but sufficient indication has been given to the trading community of this country to be careful, and not to forget to provide new trade outlets for the future by making as brave an effort as possible at the Exhibition (although it may go against the grain), to let the world see that, in spite of the frontal and flank attacks, the British and colonial trader is as anxious as the British soldier to uphold the supremacy of the Empire in the eyes of the whole world."

ROYALTY AND ELECTRICAL INKLESS PRINTING.—Recently the Electrical Inkless Printing Syndicate have been engaged in the production, by their improved process, of a quarto booklet on *Interesting Dovercourt*, describing the illuminated window recently presented to the parish church by the German Emperor in memory of German soldiers buried there, and the lych-gate presented by Her Majesty the Queen, both of which are illustrated by fine copper half-tone prints. The text, old style, with wide margins, is printed on both sides of the paper, perfected; the impression, in a dense black, is solid, sharp, and clear, and there is not the slightest sign of any chemical reaction either in the paper or in the print. To the ordinary printer it might be a good 2*s.* black the work was done with, and few printers could tell the difference; but it is in the half-tones that the greatest success is achieved. These are printed on highly finished coated paper, and are veritable photographic presentments, bright, brilliant, sharp, and clear in every detail, and of the right photographic tone. An expert printer, who is also a photographer, on being shown one of the first proofs, remarked, at first sight, that it was a photograph, and was immensely surprised when a closer examination showed him the screen lines of the half-tone process, and he was told it was printed by electricity on a letterpress machine. Copies of this booklet have been presented to Her Majesty the Queen and to His Royal Highness the Prince of Wales, with an explanation that they were the first copies of any publication executed by electricity without printing ink. Her Majesty and the Prince expressed their interest in the new process of printing, and pleasure at the results as presented to them. A copy has also been presented to the German Emperor. An edition for the press and the trade is in preparation, when the immense progress that has been made with electrical printing will be seen and its prospects as the printing of the future more fully estimated.

## Patent News.

THE following applications for Patents were made between January 29 and February 3, 1900:—

FILM-CHANGING.—No. 1872. "Improvements in Means for Loading and Exposing Films in Cameras." W. F. STANLEY.

CAMERAS.—No. 2076. "Improvements in Cameras." Communicated by O. H. Peck. Complete specification. O. IMRAY.

CINEMATOGRAPHY.—No. 2132. "Improvements in Kinematographs, or Means for Displaying a Series of Pictures." L. E. GRANICHSTAEDTEN.

CINEMATOGRAPHY.—No. 2133. "Improvements in Kinematographs." L. E. GRANICHSTAEDTEN.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

February.	Name of Society.	Subject.
19.....	Bradford Photo. Society .....	<i>An Alpine Borderland.</i> J. W. Wade.
19.....	Camera Club.....	<i>With Rifle and Camera in East Africa.</i> E. N. Buxton, M.A., D.L., M.P.
19.....	Cripplegate Photo. Society .....	<i>Outdoor Photography.</i> A. Horsley Hinton.
19.....	Ealing .....	<i>Pictorial Photography.</i> John H. Gear, F.R.P.S.
19.....	Glasgow and West of Scotland .....	<i>Photographic Optics and Description of the Cooke Lens.</i> Mr. Taylor.
19.....	Kingston-on-Thames .....	<i>From Athens to Olympus.</i> A. Vandendriesche.
19.....	Southampton .....	<i>Flashlight Work.</i> H. Emery.
19.....	Stafford Photo. Society.....	<i>How a Lens is Made.</i> Reader, H. Cliff.
20.....	Brixton and Clapham .....	<i>Colour Photography.</i> E. J. Wall, F.R.P.S.
20.....	Gospel Oak .....	<i>Demonstration: Rollable Films.</i> W. J. Ramsey.
20.....	Hackney.....	Members' Annual Sale.
20.....	Redhill and District .....	<i>Demonstration: Printing in Clouds.</i> T. Percivale Padwick.
21.....	Ashton-under-Lyne.....	Special Meeting of Members.
21.....	Borough Polytechnic .....	<i>Practical Photography in the Field.</i>
21.....	Croydon Camera Club .....	<i>The Snapshot Up-to-Date.</i> John H. Gear, F.R.P.S.
21.....	Photographic Club .....	<i>Exhibition of Prints and Slides of the Belgium Photographic Excursion, 1899,</i> arranged by W. D. Welford and W. F. Slater.
21.....	Southsea .....	<i>Exhibition of Prize Lantern Slides.</i>
21.....	Woodford .....	<i>Some Practical Hints for Photographers in Pictorial Composition.</i> J. T. Ashby.
22.....	Camera Club .....	<i>Arrangement and Construction of Picture Landscape.</i> Arthur Burchett.
22.....	Darwen .....	Social Evening.
22.....	Derby .....	<i>Pictorial Photography.</i> A. Horsley Hinton.
22.....	Liverpool Amateur.....	<i>English Cathedrals.</i> William Harvey.
22.....	London and Provincial .....	Open Night.
22.....	Oldham .....	<i>Portraiture.</i> Reader, C. H. Barlow.
23.....	Borough Polytechnic .....	<i>Practical Evening: Tones on Bromide Papers.</i>
23.....	Bristol and West of England .....	<i>Somersetshire Churches.</i> F. Bligh Bond.
23.....	Croydon Microscopical .....	Conversational Meeting.
23.....	Southport .....	<i>Demonstration: Secco Films.</i> Representative of the Company.
24.....	Birmingham Photo. Society .....	<i>Fifteenth Annual Exhibition.</i> Private View and <i>Conversazione.</i>

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 8,—Mr. T. E. Freshwater in the chair.

Mr. A. J. BROWN showed some tests confirming his statement that a white backing had the effect of reducing the exposure required to produce a given result as compared with an unbacked plate, or one backed with, say, caramel. As suggested by Mr. Fry, he had exposed upon a subject of an equal tint, having no pattern, the better to determine the truth of the matter and to make the difference more apparent.

Mr. T. E. FRESHWATER showed a number of slides copied from the sketches sent home by the artist correspondents in South Africa, the subjects, of course, being all connected with the present war.

Mr. LEWIS MEDLAND showed on the screen some reminiscences of his residence in the Transvaal in 1874. There was his claim on the Lydenburg gold-fields, his licence in English and Dutch, views of the digging and washing-out of the alluvial gold, Kimberley and its diamond-fields, Zulul, &c. He also showed slides of some further additions to his series of animal studies, penguins, apes, skunks, ostriches, black leopard, and a boa-constrictor or two.

Other miscellaneous slides concluded the business of the meeting.

### PHOTOGRAPHIC CLUB.

FEBRUARY 7,—Mr. H. Vivian Hyde in the chair.

Mr. KLOSZ gave an interesting lecture on a trip along the western fjords of Norway, accompanied by slides from his own negatives, which drew forth their due meed of praise. The visit was made in 1897, after one in 1896, which served the purpose of bringing the lecturer to resolve upon another and extended tour. The start was made from Newcastle on the *Ragnvald Jarl*. Bergen was reached in due course, and a few slides were introduced to show the wide streets, the fish industry, and the important part played by the women of the country in the fields, the boats and markets. Excursions were made to various places—Fantoft Church, &c. Many of these churches were over 700 years old, but still preserve a very durable appearance and the quaint design of the period. Hardanger Fjord, Odde, Laatefos, Sojne Fjord, Naerodal, Gudvangen, Merok, the Romsdahlorn, Molde, Trondhjem, Christiansund, &c., were in turn visited, and many pictures of the beautiful scenery, noted for its grandeur throughout Europe, were shown. Mr. Klosz made good use of his opportunities in the land of the midnight sun, and was enabled to engage the best attention of his audience throughout the lecture.

Bath Photographic Society.—February 7.—Mr. AUSTIN J. KING gave

### SOME CAMERA NOTES ON ITALY.

The lecture was illustrated with lantern slides from Mr. King's own negatives, wherein the more interesting points received due attention. At the con-

clusion the CHAIRMAN and Mr. G. F. POWELL thanked the lecturer for his able paper and illustrations, Mr. Powell remarking that theirs was the third or fourth meeting Mr. King had assisted at that day. The members felt very grateful to him. Mr. GREEN had visited some of the places referred to by the lecturer, and held similar views to those already expressed. He considered St. Peter's to be the finest specimen of architecture in the world, without a single exception. The SECRETARY (Mr. W. Middleton Ashman) drew attention to an improved system of packing plates for amateurs' use, and announced demonstrations shortly on Dekko, Gravura, and other papers.

Liverpool Amateur Photographic Association.—At the last weekly meeting, Dr. J. W. ELLIS lectured on his trip to Belgium. Starting from Antwerp, the lecturer described Malines, Brussels, the field of Waterloo, Oudenarde, Courtray, Ypres, Ghent, Bruges, and Blankenberghe. While on the subject of Waterloo, Dr. Ellis gave a minute description of the disposition of the opposing forces, the château of Hougomont, as well as other historical places of interest. The lantern slides, which were of a most excellent quality and made by the lecturer, comprised very interesting examples of architecture, notably the hôtels-de-ville of the various towns, the Cloth Hall at Ypres, and the beautiful belfry at Bruges.

Redhill and District Camera Club.—February 6.—Mr. J. O. GRANT gave a lecture on

### ANIMAL PHOTOGRAPHY.

The President (Mr. William Brooks) was in the chair, and there was an appreciative audience. The lecturer claimed for animal photography a wider interest than ordinary landscape work. Photographs that were mere mementos of a summer holiday had but little interest for any but those who took them, while, on the other hand, every one was pleased to see a good set of animal studies. He believed that many people did not take up this branch of photography, because they thought it an extremely difficult one. This was not the case really; indeed, it was much easier to produce a presentable animal study than an interesting landscape; but, to be successful, two important items were required, namely, a large amount of patience and perseverance, and a real love for animals. Mr. Grant then related some of the difficulties he had met with and overcome when photographing wild animals in captivity, and brought his interesting lecture to a close with a lantern exhibition of animal photographs taken at the Zoo. Many of these were very fine, and gained the hearty applause of his audience.

### FORTHCOMING EXHIBITIONS.

- 1900.
- February 16-24 ..... Edinburgh Photographic Society. J. S. McCulloch, 10A, George-street, Edinburgh.
  - „ 24-March 3 Birmingham Photographic Society. Lewis Lloyd, The Hollies, Church-road, Moseley.
  - March 3-10 ..... South London Photographic Society. Hon. Secretary, Frank Goddard, Woodlands, Vanbrugh Hill, Blackheath, S.E.
  - „ 13, 14 ..... G.E.R. Mechanics Institution (Photographic Section). C. W. Harris, 294, Cam. Hall-road, Leytonstone, E.
  - „ 26 ..... Twentieth Century International, Birmingham. Walter D. Welford, 19, Southampton-buildings, Chancery-lane, London, W.C.
  - „ 26-31 ..... Photographic Society of Ireland. W. F. Cooper, 35, Dawson-street, Dublin.
  - April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### NEGATIVES BY POST.

To the EDITORS.

GENTLEMEN,—Lest others may be treated to the same course of action, may I state a case that has just occurred? A few weeks back a photographer in Leicester sent me on a small parcel by parcel post consisting of three negatives and three prints. The prints were supposed to be put in the tube. The three negatives arrived safely with the tube tied on to the box (cardboard) containing the negatives. The box was not even damaged at its corners, the string was not broken round the box or round the tube, the tube is perfect at its ends, which, I fancy, speaks well for the handling of the packet. But on arrival I tore off the outside paper of the tube and found no prints wrapped round it, so pulled off the paper from

ends of tube to look through it. I found no prints. I then wrote to the Leicester gentleman, and he coolly informed me that it was my duty to make inquiries at the post-office, as the lost articles were my property. I then ascertained at the Hammersmith sorting office that a postal form was procurable, but was to be filled in by the sender. Can any gentleman recommend me the best course to take? I have the tube and box by me. I ought to say that I had to forward the cash beforehand.—I am yours, &c.,

F. G. WILLATT.

101A, Fulham Palace-road, London, W., February 8, 1900.

## SULPHIDE TONING.

To the EDITORS.

GENTLEMEN,—The method of toning with "liver of sulphur," mentioned by "Othello" in the JOURNAL of February 2, is practically the same as that given by Abney (with ammonium sulphide), the latter being less tedious; but my experience with it some thirteen or fourteen years ago was that it was very uncertain, and the tones obtained variable.—I am, yours, &c.,

F. S. WELLS.

Southgate, N., February 2, 1900.

## A CORRECTION.

To the EDITORS.

GENTLEMEN,—In your report, in the number of the JOURNAL for Feb. 2, of Mr. Webster's lecture on Röntgen rays, at the Camera Club, you state that the "President of the Röntgen Society" entered into the discussion at its close. I made no remarks, as I was not present, being detained elsewhere by another engagement.—I am, yours, &c. WILSON NOBLE.

Tangley Park, Guildford, February 8, 1900.

## THE CAMERA IN THE CAMP.

To the EDITORS.

GENTLEMEN,—I have been a good deal amused by the paper, or lecture, on "The Camera in the Camp" by Mr. Maclean, in your last issue.

Has it occurred to the writer that such information as he recommends could only be procured at a time of profound peace, and that it would require constant revision? Even then it would not give the changes which are inseparable from war, and the formation of entrenchments, breaking up of roads, destruction wholly or in part of houses, &c. Nor in any case could it give information as to what positions had been occupied by an enemy, or in what force they were held and what reinforcements would be available. It is ignorance of these points mainly which has been felt.

Moreover, it is one of the main essentials to success in war that plans should not be known before the time comes to carry them out, and, even if all the information required for all possible routes were available, not only would time be necessary to hunt up the needful detail, but it would be necessary to take into confidence many more people than now.

I need hardly say that such photographs as are proposed would never be available of any but our own country, where they would be least wanted. But, if Mr. Maclean still thinks that he could work the oracle, I would advise him to take his camera out to South Africa and try the experiment he suggests; he would soon find out that even the general in command cannot ensure the carrying out of an exact order of advance, still less that of one of retreat; and that the officer in immediate command of the troops would be too busy watching what was happening to hunt for the proper photograph for his want, even if he had at hand what was needed.

If Mr. Maclean cannot go to South Africa (and many things may render that impossible), I would suggest that he make complete sets of photographs of the country in which he resides, or even of a large town, showing all the possible routes, and so arrange and index them that any one shall be available at any moment. He will then have some notion of the task he wishes to place on the shoulders of that well-burthened body, the Royal Engineers. Doubtless he meant to pay them a compliment in suggesting for half a dozen of them so great a labour.

I have said nothing about the lectures on topography, &c., because it is manifestly impossible that they should be given after the route is selected, and to expect that men such as we see about us should carry in their heads a complete knowledge of the topography of a country from hearing a few lectures on it is too absurd.

Believe me that, to a properly instructed officer, a route survey and report is infinitely more informing than a photograph would be, or a series of such. No doubt, photographs of special objects, as well as sketches, aid; but the latter allow of the emphasising of objects to which it is desired to direct attention, while the former have the disadvantage that they do not truly represent the contrasts of colour, so that objects which are really relieved against each other are not so in the same degree in the photograph, &c.

As you know, I am an old photographer (it is more than forty years since I first took to the art), and am certainly not disposed to undervalue its utility; but I am disgusted when I see men, who know nothing of the practical business of my old profession, hurry to assume that their crude,

undigested hints are to be taken up and worked out by others who have their own duties to attend to.

Excuse the length of this letter; it would have been much shorter to ridicule Mr. Maclean than to attempt to show where he was wrong, and I fear that I have only imperfectly succeeded now.—I am, yours, &c.,

J. F. T.

## ARTICLING PUPILS IN PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Referring to the above question, does it not occur to you that the whole gist of the matter lies in a nutshell? for the simple fact is this, whilst amateurs are given the opportunities they have through the dealers, the professional cannot possibly expect pupils as in years gone by. Now every man, woman, and even child that can afford it, has a camera of some sort, that with a shilling manual helps to carry out the familiar saying, "A little knowledge is a dangerous thing." Every present-day photographer can vouch for one thing, whenever a parent or guardian has asked him to negotiate for the articling of a youth in question, invariably the remark is, "He already photographs very nicely and has taken some of the best likenesses various friends have ever had." Now, this sounds very clever, but it is without exception most objectionable to an experienced man whose years of study and work seem to count as nought if all is as easy as our friends the amateurs make it out to be.

The dealers have undoubtedly done a great injury to the profession, and that sooner or later, every one will acknowledge (take, for instance, the view trade alone).

It should be borne in mind that what the amateur undertakes is for amusement, and satisfies friends easily, for it is not a question of £ s. d. The professional, on the contrary, receives the most exacting criticism in return for having to charge for his skill, labour, &c. To become a practical photographer takes years of study and experience, as we well know, but this fact does not impress itself upon the amateur with his 1s. or 2s. book. It has become a serious matter. Photographers who years ago would receive 100 guineas, and even more, with a pupil, did teach them not only the art of taking photographs, pictures, &c., but turned them out good, clever, business men as well. Now all is altered. Things have been allowed to slide too long, and the amateurs have it all in their own hands; therefore guardians and parents are under the impression there is but little to learn, and offer only a small premium accordingly. I am sure many of your readers will endorse my feelings. In conclusion, let me suggest that, if cameras (as well as bicycles and cats) were taxed, the Inland Revenue would reap a grand return. Thanking you in anticipation for inserting this tirade,—I am, yours, &c., FAIR PLAY.

## PHOTOGRAPHY IN WARFARE.

To the EDITORS.

GENTLEMEN,—The following extract from an evening paper, published very recently, may both interest and amuse:—"The Rome correspondent of the *Daily Chronicle* states that an officer of the Italian army has invented a system of telegraphy (*sic*) at a distance. By his method photographs can be taken at distances as great as eighteen kilometres (ten to eleven miles). This discovery is expected to prove of great military importance." Further particulars will, doubtless, be welcomed. In view of what has been stated in your pages recently on the subject of tele-photography and warfare, I am sure the paragraph I have quoted will be duly appreciated.—I am, yours, &c.,

J. A. REID.

Cutcliffe-grove, Bedford, February 9, 1900.

[Tele-photography has long been employed in the Italian army. The *Chronicle* correspondent is obviously unfamiliar with his subject.—EDS.]

## METRIC MEASURES.

To the EDITORS.

GENTLEMEN,—My letter, in yours of the 9th inst., appears to have got somewhat mixed towards its conclusion. Of course this could be no fault of mine, although I found one of the sheets of copy a long way from London. I now enclose the last sentence, with the missing matter added.

"So much for measurements; but how about weights, which more nearly concern the photographer? I have opened the ALMANAC at random at page 1034, and read, 70 grains in 20 ounces. Although a fair hand at figures, the above conveys no sense of proportion to my mind; and I hardly think that 'Free Lance' could tell one, without pen and paper, the proportion which the ingredient (hydroquinone) bears to the whole. A glance at the formula, as given in metric measures, shows that it is 8 grammes (or parts) per 1000. The same is equally applicable to the other ingredients."

There is an impression that the metric system requires learning; but, really, there is practically nothing to learn. Certainly the array of jaw-breaking names given in most English text-books looks rather alarming. A great number of these names are never used on the Continent, as they have been found quite unnecessary.—I am, yours, &c.,

Brigg, England, February 10, 1900.

CHAS. LOUIS HETT.

Re PARKIN AND FRY.

To the EDITORS.

GENTLEMEN,—I have read with some surprise your account of the Bankruptcy proceedings. This is evidently copied from a Liverpool paper, who on the following day inserted a letter from me, which showed that, practically, the whole of the statements made were either false or misleading. You should take more care in saying that certain things occurred in Court, which, in this instance, are entirely at variance with facts. As an instance, by referring to the records you will find that what the Registrar said was: "as far as he was concerned, he was satisfied that the paper could be made by me." Bromide, and other paper, is now being made by me, and is being used in the enlarging business now carried on by my father at the above address, the reason being that the proper machinery is now provided to make it. You can have some samples of the paper if you desire.—I am, yours, &c.,  
FREDERICK GEORGE FRY.  
31 & 33, Sandstone-road, Old Swan, Liverpool, February 12, 1900.

[The report to which Mr. Fry refers was supplied to us by a News Agency. We shall be pleased to have samples of the paper referred to.—Eds.]

## Answers to Correspondents.

\* \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24, Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

W. Hughes, Mostyn Arms Hotel, Llandudno.—*Photograph of Llandudno Yeomanry.*  
J. Ingham, Winton House, Ashton-upon-Mersey.—*Photograph entitled "Shall I be of any use, father?"*

A. J. Ashbolt, 29, High-street, Southampton.—*Two photographs of A. Millward.*  
*Photograph of A. Chadwick.*

J. W. D.—We know of no such book.

R. W. B.—Such goods, we believe, are obtainable of Messrs. Fallowfield, 146, Charing Cross-road, W.C.

A. BUTCHER.—Messrs. Marion & Co. supply a solution for the purpose (King's Solution), which you might try.

STUDIO.—Generally speaking, the three types of instrument, A, B, and C, may be bracketed equal for your purposes.

FLASHLIGHT.—Messrs. Fuerst Bros., of 17, Philpot-lane, E.C., supply a powder which might answer your purpose.

CONSTANT READER.—We recommend you a little book on the process by Mr. W. J. Warren. It is published by Messrs. Hiffe, St. Bride-street, E.C.

CONDENSER.—As we understand your question, if you alter the position of the condenser so that its focus comes at the position of the stop, the colour will disappear.

J.—If you are a weekly servant, a week's notice is all that you can claim. The notice you refer to in, our opinion, was legal. We regret it is against our rules to answer questions through the post.

SCRATCHED DAGUERRETYPE.—SMEAR says: "I have a Daguerreotype which has been sent to be framed. It has been wiped over, which has caused a smear. Can the scratches be worked out in any way?"—In reply: We fear not.

PHOTOGRAPHING IN SPAIN.—R. S. G. writes: "Have any of your readers a knowledge of photographing in the south of Spain? I hope to be in Andalusia in May, and would be glad of hints."—Will some travelled reader oblige our correspondent with a few hints?

MESSRS. MARION & Co., of Soho-square, announce that their Annual Stock-taking Sale will be held from March 5 to 17. Catalogues with description of clearance lines from all departments, photographic and fancy, will be ready about March 1, post free on application.

PUZZLED.—As we understand your question, according to a decision given some years ago the copyright is not legally your employer's unless you assigned it to him. But we should not advise you to contest the matter, as morally, at any rate, the copyright is his.

PAPER FOR PLATINUM PRINTING.—PAPER writes: "Can you give me the address of one or two firms that can supply me with plain paper suitable for manufacturing platinotype paper?"—In reply: Inquire of Messrs. Marion & Co., Soho-square, W., or Messrs. Otto König & Co., 27, Cross-street, Finsbury, E.C.

INQUIRER.—1. The supplementary lens is perhaps best at the back, although we do not believe that in practice it makes much difference. 2. Such glasses as you require are, we believe, obtainable of Sharland's, Thavies-inn, London, and other wholesale dealers in optical goods. 3. Practically the coincidence of the foci would not be interfered with.

STAINED PRINT.—MOUNT says: "Will you please give me your opinion as to the stainings upon accompanying print? You will observe that the red part or stain on face is on the other side of that part which is free from the dye from mount."—The colouring matter on the mount is soluble, and, when the damp mountant is pressed in contact, it becomes stained and the stain shows through the print.

PHOTOGRAPHS ON PLUSH BLOCKS.—B. S. O. asks "the best way to stick a photograph on to the plush block after putting it on the glass. I tried gelatine and it stuck fast enough, but, when I took off the weight and looked at it, it was all over red blotches. Some one said to use glue, but wouldn't glue fade the print?"—Back the picture with a thick hard paper before cementing it to the plush, then the dye will not stain the photograph.

BOOKS ON EMULSION-MAKING, &c.—DRY PLATE asks: "Which are the best works published on emulsion-making and photographic chemistry?"—In reply: Sir W. de W. Abney's *Photography with Emulsions* (published by Sampson Low & Co., Fetter-lane, E.C.) and the *Science and Practice of Photography*, by Mr. Chapman Jones (published by Messrs. Hiffe, St. Bride-street, E.C.), would probably suit our correspondent's requirements.

VALUE OF GLASS POSITIVE.—SIDNEY RALPH says: "Enclosed you will find a glass positive of the Prince Consort, from which I think the well-known steel-plate engraving was executed. Will you inform me whether I am right, and as to its value?"—In reply: The photograph appears to us to suggest the picture. With regard to its value, we should say it is probably very little. The simplest way for our correspondent to find out would be to advertise it.

STUDIO-CONSTRUCTION.—S. H. WOOD asks if a studio about seventeen feet long would answer for general portrait work. "We have a room where we could take the ceiling away and put top light in the roof, if it would do. I have made a rough sketch, which I trust you will understand."—The proposed studio would answer very well so far as the light is concerned, but it will be very short indeed for general portrait work, and would necessitate the use of lenses of very short foci. Such lenses would, of course, give violent and displeasing perspective.

PRINTING-OUT BROMIDE PAPER.—PHOTOPHILUS says: "I should be glad to know the formula for sensitising a rapid blackening paper, which blackens without development, such as is used in photometers. It can, I suppose, be fixed in hyposulphate of soda. It is wanted for a rough photograph of oxyhydrogen spectrum on a large, rough scale."—In reply: For your purpose, the immersion of ordinary sensitive bromide paper in a solution of potassium nitrite, of a strength of thirty or forty grains to the ounce, would probably answer. Immerse and dry in the dark.

YELLOW STAINS ON PRINTS.—W. BALL writes: "Kindly tell me the cause of the stains on these prints. They are on —'s paper, toned in the sulphocyanide gold bath, and fixed in hypo (two ounces to the pint). Time of immersion, eight to ten minutes."—The cause of the stains, undoubtedly, is that the prints are imperfectly fixed. Eight or ten minutes' immersion in a solution as weak as two ounces to the pint is not nearly enough to properly fix prints, particularly when the temperature is low. Use four ounces to the pint, and allow the prints to be in the solution for a quarter of an hour.

POSITION OF DIAPHRAGM IN R.R. LENS.—R. MATHER says: "I have a 6-inch R.R. lens of symmetrical construction; at the present time the rotary diaphragm is situated equidistant between the two combinations, but I am desirous of having it removed and placed closer to the front lens, so as to allow of greater length of screwed cell for focussing (please see rough sketch herewith); in doing so, shall I impair the efficiency of the lens?"—Yes, inasmuch as it will no longer yield straight lines at the margins of the picture. With a symmetrical lens the stops must be midway between the two combinations or it will not be retilinear.

SLOW DEVELOPMENT AND LACK OF DENSITY.—BEDFORDSHIRE AMATEUR writes: "I have exposed a lot of plates on snow scenes, and I know that they are not under-exposed, but I cannot get sufficient density in the negatives. The plates are the same as I always use, and the developer (metol hydroquinone) also. The image is a long time coming out, and is then full of detail, but there is no printing density."—The trouble is, no doubt, due to the cold weather. Develop the plates in a room where the temperature is not less than 60° F., and see that the solutions are of a similar temperature, or a little higher, and all will go well.

THE LANTERN IN THE SHOP.—DARKLIGHT says: "I have a shop window on which I should like to exhibit some war pictures by means of the magic lantern. There are two panes of glass each measuring forty-two inches, and the depth of the shop from the window is five yards; can I exhibit same inside the shop, so that the people could see it outside, and what would be the best form of instrument for this purpose and also for the screen? Had I not better only exhibit on one pane of glass, as there is a partition between?"—Yes. The ordinary lantern fitted with a lens of suitable focus. On page 1128 of the ALMANAC you will find a table of distances with lenses of different foci for given size screens. A sheet of tracing linen will form a good screen for the purpose. It would be better to use one pane of the window if it will take the size of image you desire.

ETHO-OXYGEN LIGHT.—G. P. asks: "What quantity of oxygen does a saturator consume per hour? Is it double that required if burnt in an ordinary mixed jet? Could a saturator be used with an injector jet?"—In reply: It is some time since we used the oxy-ether limelight, but our experience then was that less oxygen was required per hour than with a mixed gas jet. One reason for this was that the nipple of the jet used at that time was small ( $\frac{1}{8}$  inch bore), but the light was very good. The size of the jets used with the pendent saturators is, we believe, much larger, and, when employed with cylinders containing the oxygen under high pressure, gives good results. Three feet of oxygen per hour per light was about the average for the jet we used. Regarding the injector jet and saturator, we have had no experience, and would suggest you write to the Manchester Oxygen Company, or Messrs. Willway & Sons, engineers, Bristol.

### EX CATHEDRÂ.

PROFESSOR R. W. WOOD, the distinguished young American physicist, who is quite the lion of the hour at the chief London scientific societies, gave the members of the R.P.S. on Tuesday evening a series of three discourses of the very highest interest. His subjects were zone-plate photography, the photography of sound waves, and his own very elegant system of colour photography with diffraction gratings. The lecturer's remarkable lucidity of exposition enabled the meeting to readily grasp the principles upon which his valuable work has been founded, but it was obvious that the Professor had so much information to impart on the application of photography to physics that it would require a great many evenings to exhaust it. The meeting was wholly charmed, surprised, and absorbed by the three lectures (of which we give a brief report elsewhere), and not least of all by the explanation of zone-plate photography, and the excellent illustrative examples shown on the screen. What is a zone plate? the ordinary photographic reader may ask. Simply a reduced photograph in bichromated gelatine on glass of a series of concentric rings, the original having a resemblance to a target. This little piece of what

appears to be almost plain glass may be substituted for the lens or the pinhole in impressing an image on the sensitive plate; but the rays are diffracted instead of being, as with a lenticular system, refracted. Hence there is produced in the negative what is equivalent to a duplication of outline, although, in the lantern transparencies from the negatives taken by Professor Wood with his zone-plate objective, blurring was not very noticeable. His pictures (landscapes) were made with an exposure of half a second; thus a zone plate is more rapid than a pinhole. We should not be surprised if zone-plate photography attracted much attention.

\* \* \*

Most instructive results in the photography of sound waves were next exhibited and described by Professor Wood, but lack of space here prevents a lengthy reference to them. Suffice it to say that he amply showed, by photography, that most of the phenomena undergone by light waves are characteristic of waves of sound. A series of the Professor's diffraction transparencies (for such they are) were on view, and they attracted very great attention. Those of our readers who have seen specimens of Joly's colour lineature transparencies and Ives's kromscopic transparencies may mentally form a good idea of what Professor Wood's diffractographs (may we be allowed to coin this word for temporary use?) are like. They are viewed by direct transmitted light, and the colours of the objects appeared, so far as we could judge, to be brilliant and spectrally pure. We regard Professor Wood's process of colour photography as the simplest yet devised, for it can be readily put into practice, and the results can easily be duplicated. Taking advantage of the simple process of printing with gelatine and bichromate of potash, the superposition of diffraction gratings on positives produced from three-colour negatives is obviously not a very difficult matter, and the pictures may be almost indefinitely reproduced. The finished result is an almost colourless picture, which, when viewed through a lens by direct transmitted light, gives an image in pure spectrum colours. This is the practical aspect of the matter. Scientifically regarded, Professor Wood's application of the phenomena of diffraction to colour photography is a valuable and original piece of work; and he deserves the thanks of British photographers for having personally brought it before them.

*Our Patent Laws* is the title of a little pamphlet by Mr. James Keith, C.E., of London and Arbroath, which discusses the system of patent protection now in force from a standpoint decidedly and deservedly unfavourable. We have often commented on the gross imperfections of the British patent system, and, on reading Mr. Keith's pamphlet, his condemnation of that system appeals to us in an aspect the reverse of unfamiliar. The author summarises the principal shortcomings of our patent laws by pointing out that a patent at present is simply a contract entered into between the Government and the inventor, by which the inventor is bound to make public every detail of his invention, and produce drawings so that any ordinary practical man can afterwards work from them. The inventor thus hands over the result of his brain labour to the nation, and he only gets the privilege of exclusively using and controlling his invention for at most fourteen years on his paying certain fixed charges. Should any of these fees not be paid, the patent from that moment becomes null and void. If, again, the fees are all regularly paid, after the term of fourteen years has been completed the invention becomes public property. As to protection, no real protection is given farther than, if the inventor has to go to law to uphold his rights, and ultimately wins his case—after having, perhaps, been practically ruined in law costs—the decision is upheld. It is this fact, that no protection whatever is afforded an inventor, which constitutes the greatest flaw of the British patent system. Mr. Keith's pamphlet should be useful in sustaining the agitation for an amendment of the Act of 1883. By the way, we are not in agreement with the author in his estimate of the United States patent system as "almost perfect." Our information, from reliable sources, is that nowadays it is little better than our own, the once valuable process of examination having been practically abandoned.

\* \* \*

SOME information of an encouraging nature with regard to the progress of the movement in favour of adopting metric weights and measures is given in the recently issued report of the Decimal Association, which states that early in the past year a very influential deputation was organized by this Association to wait upon the President of the Board of Trade to urge the Government to fix a time for adopting the metric weights and measures compulsorily. In his reply to the Deputation, Mr. Ritchie recognised that the proposed change would be an advantageous one for the country, but he was of opinion that the public demand for it was not yet sufficiently strong to justify the Government in making it compulsory. He promised to assist in obtaining more efficient teaching of the system in the elementary schools, to have more attention given to it by H.M. Inspectors, and to do all he could to make known the merits of the system and the advantages which would follow its adoption. He also said that he was in communication with officials regarding its use in the various Government Departments. The strength of the growing movement in Great Britain has attracted renewed interest in the United States, and soon after the deputation to Mr. Ritchie the question was brought to the front again. In his Annual Report to Congress, delivered on December 6 last, the Financial Secretary to the Treasury at Washington strongly recommended the compulsory adoption of the metric weights and measures, and a Bill to secure this has been submitted to Congress. In Canada also a strong movement in favour of the metric

weights and measures has been organized, and there is evidence that the need of making the change is fully realised by the Government at Ottawa.

\* \* \*

THE report further states that much correspondence with the leading School Boards of the country has taken place during the year, and over 100 of the most important School Boards in England and Wales have given renewed pledges to use their influence in support of the metric weights and measures. These Boards represent over ten million people. Although all the School Boards in the kingdom were written to, not a single one expressed an adverse opinion. Several instances have been reported where the metric system was being properly taught in the public elementary schools, and these have been brought under the notice of the Committee of Council on Education. It is hoped that, as a result of the representations, the new code will contain more definite instructions for the teaching of the subject and for examination therein by H.M. Inspectors. Steps are being taken to organize a special conference in Paris of official delegates and others representing Great Britain, the United States, and Russia, in favour of the adoption of the metric weights and measures in those countries. It is believed that this Conference may have important results.

\* \* \*

IN our article last week, on experiments in the keeping qualities of dry plates, we mentioned that the plates were of American manufacture, and we surmised that, inasmuch as their keeping qualities were to be tested, the plates were stored under careful conditions during the years they were stowed away. Our reference to this matter has been the means of eliciting the interesting fact that British-made plates are quite equal, and perhaps superior, to their American competitors in the valuable property of retaining their original good qualities unimpaired. In a letter on the subject, Mr. C. F. Jarvis, the well-known photographer of Birmingham, quotes his experiences of some Ilford white label plates, which he had had in his dark room for some thirteen years. Upon development, these plates yielded results as good as could be obtained on newly made plates. Evidence of this nature is exceedingly valuable. Mr. Jarvis probably took only ordinary precautions as to keeping; indeed, he says he had forgotten the existence of the particular box of plates. The results on the American plates appear to have been more or less faulty, whereas the Ilford plates, after thirteen years, were good as ever. On general as well as on particular grounds, this testimony to the good keeping qualities of British-made plates is most welcome.

\* \* \*

A FEW extracts from the annual report of the Geological Photographs Committee of the British Association will give some indication of the progress of the work in organizing a collection of photographs of geological phenomena in Great Britain: During the year 324 new photographs have been received, bringing the total number in the collection to 2324. The average yearly income during the decade has thus been 233. In addition to this, 61 prints and 6 slides have been given to the duplicate collection, making a total of 391 photographs received during the year. Mr. A. S. Reid has carried out a photographic survey of the Island of Eigg, and has already presented to the collection twenty-seven enlarged photo-

graphs, to illustrate the Scur of Elgg and its remarkable history as told by Sir Archibald Geikie. Another connected series illustrating the physical history of the Yorkshire rivers communicated by Mr. Godfrey Bingley, who took the photographs at the suggestion of Mr. Kendall.

\* \* \*

To Mr. A. K. Coomara Swamy the Committee are indebted for a large series of prints, taken mainly during excursions made by the Geologists' Association into Scotland, Devon, Dorset, Kent, Gloucestershire, and elsewhere; volcanic phenomena, unconformities, denudation, weathering, contortion, and the position of important rock zones are all illustrated by this series. Mr. Welch contributes, through the Belfast Naturalists' Field Club, forty-three platinotypes of glaciated surfaces and transported blocks, the Silurian district of Mayo and Galway, the volcanic district of the North-east of Ireland, and various tectonic phenomena are illustrated by the photographs. One set illustrates a new industry in the country, the excavation of the diatomaceous clay of the river Bann for use as Kieselguhr. The Midland district is beginning to be better represented in the collection, chiefly owing to the contributions by Mr. W. Jerome Harrison, Professor Allen, Mr. Myers Swindell, Mr. Watson, and students of Mason University College.

\* \* \*

The photographs received during the year have been mounted, and are bound up and deposited with the rest of the collection at 28, Jermyn-street, where they may always be referred to on application to the librarian. The collection is arranged geographically in twenty-seven albums under the heads of counties and their natural topographical divisions. The report states that many geologists, British and foreign, have expressed a desire to possess examples of geological photographs which they have seen in the collection. The Committee are willing to undertake the publication of a small experimental series if a guarantee fund can be formed as a safeguard against loss. The publication would take the form of the issue of about twenty photographs in platinotype or carbon, or high-class process reproductions, accompanied by descriptive letterpress. If the subscribers preferred, lantern slides might be issued instead of prints, or in addition to them.

#### DISCURSIVE NOTES ON GELATINE PHOTOGRAPHY AND GELATINE.

THERE is at the present time scarcely a photographic process in practice in which gelatine does not play a very prominent part. The gelatine processes may be divided into two distinct sections which have no relation whatever to each other—those in connexion with the alkaline bichromates, and those in connexion with the silver salts. The former is the older of the two. The first really practical applications of gelatine in photography were the carbon process of Mr. J. W. Swan, and the Woodburytype printing process of the late Mr. W. B. Woodbury, both of which were introduced in 1864, and each of which is now worked essentially the same as published by their inventors. It might, however, be mentioned that the photo-lithographic and the photo-zincographic methods were about contemporaneous with them. Then, a little later, we had the collotype and the "swelled gelatine" process, which

is dependent upon the expansive properties of gelatine when wetted; also photogravure and process blocks. These are all bichromated gelatine processes.

It is now twenty years, or a little more, since gelatine, in connexion with the silver salts (gelatino-bromide), superseded collodion for negatives in the portrait studio and in the field, though that still holds its own for negatives for some special purposes. Next we had gelatino-bromide paper for development, which took the place of collodion transfers for cheap enlargements, as well as those of a better class; and, within the last few years, gelatino-chloride printing-out papers, which, to a great extent, have taken the place of the old albumen paper. Indeed, it has pretty generally ousted it from the field amongst amateurs, but albumen and collodio-chloride are still much used by a considerable number of old-fashioned professional photographers. Whether these papers yield such good results, or the prints made upon them are as permanent, as those by the older processes, it is not now our purpose to inquire. Neither is it our intention to raise the question as to whether gelatine negatives are as good, or better, or are more stable than those made by the collodion process. One thing is certain, and that is, that gelatine photography with silver, is far more convenient in practice than the older methods, and it is for this reason mainly, more particularly with the paper processes, that it has assumed its present proportions.

When the gelatino-bromide process was first introduced, it was surmised by some of the first experimentalists that the kind of gelatine employed was of minor importance, it being looked upon by them as merely a vehicle to carry the bromide of silver. That, however, proved to be a mistaken idea, for it was soon found that it had a material influence on the resulting emulsion, whether for plates or for paper.

Gelatine is a very indefinite compound, no two manufacturers' being alike, and rarely are any two batches of the same make strictly identical, chemists even differ as to what is its composition. Now, if we consider the two sections of gelatine photography—those in connexion with the silver haloids and those associated with the chromium salts—we shall see how totally dissimilar they are in principle, and then it will be readily understood that the gelatine that might be suitable—indeed, the best—for one would be quite unsuitable for the other: for example, a gelatine may contain an impurity that would render it useless if it were employed in the silver processes, yet that impurity might be inert in any of the bichromated processes. On the other hand, a gelatine that contains other substances—say alums or other artificial hardeners, which may be harmless in connexion with silver, might yet be fatal if it were used in the bichromate processes. Hence it will be seen that the gelatine which would be suitable for one purpose in photography may be just the opposite for another.

As the majority of our readers are not interested in the manufacture of the plates and papers they employ, preferring rather to purchase them ready for use, we shall dismiss this portion of the subject and consider the other. In the different bichromated gelatine processes the *character* of the gelatine is, if anything, a more important factor than it is in the silver processes, for what may be the best for one may be, possibly, the worst for another, although the latter may be of a better quality as a gelatine. Take, for example, the carbon process: Here we require a tolerably soluble kind of gelatine, free from alum, acid, or such substances as would tend to bring about an

insolubility that was not due to the action of light; in fact, we require a rather poor quality from a manufacturer's point of view. If carbon tissue were made with a very high-class gelatine, such, say, as Nelson's X opaque, or Coignet's gold medal, it would prove very difficult of development, and have but short keeping qualities. If, on the other hand, it were made with a gelatine of too soluble a nature, the image would wash out in the lights during development, and the picture would be deficient in half-tone.

In the Woodburytype process the gelatine that is the best for making the reliefs is not the most suitable for producing the prints or casts from the leaden mould. Again, in the swelled gelatine methods a gelatine is required that will absorb a large proportion of water, and consequently swell up in high relief where it is not acted upon by light. But such a gelatine would be a very undesirable one to employ in the preparation of collotype plates, as it would yield too much relief when moistened for printing from.

From the above it will be gathered that the worker in the bichromated gelatine processes is largely dependent upon the kind of gelatine employed. Therefore he must study this subject, and, if he cannot get, commercially, a kind that will answer his purpose, he must perforce mix or blend together two or more sorts to suit his requirements. We allude to this subject more particularly, as we often notice in published formulæ so much water, so much gelatine, so much bichromate, and other materials, without any reference whatever to the character of the gelatine, which is generally the most important element in the case. This omission has led to innumerable failures on the part of experimentalists.

**Modern Astronomy.**—Prof. H. H. Turner, F.R.S., Savilian Professor of Astronomy at Oxford, has given the first of a series of three lectures under the above title. After referring to the revolution in astronomical methods that has taken place since the last quarter of a century, culminating in the immense size of the instruments now employed, he refers to the innumerable ways in which photography is now available. He laid particular stress upon the wonderful development of photographic apparatus, and pointed out that, by an instrument named the *coelostat*, the whole sky was made to appear quite still for photographic purposes, though, of course, if one star can be made to appear stationary, it follows that the whole of the heavens included in a plate must also be equally free from movement. From the published abstract of the lecture, Professor Turner would appear to have referred to the invention of dry plates as having helped in the revolution of observing methods. This is a somewhat common error. The fact is, there were dry plates in use in photography before even the discovery of the collodion wet-plate process. What has rendered photography of such value is the discovery, not of a dry plate, but of the method of making it of extreme sensitiveness. The lecturer expressed the belief that the photographic lens would play a most important part in the astronomy of the future; and he described the *spectro-heliograph*, which enabled solar views of great accuracy to be made.

#### **Monochromatic Screens for Corona Photography.**

—It was suggested, at the last meeting of the British Astronomical Association, that it would be very desirable for one photographer to undertake corona photography by means of plates specially sensitive to a certain ray, and to use a screen capable of filtering out all other rays. It was pointed out that this would be a far more economical mode of procedure than the use of a large and heavy spectroscopic battery, and would be almost as effective. Objection was taken that it would be difficult to find such a combination of plate

and screen; and the President said that, if the member suggesting this mode of work could determine a range of wave-lengths that he thought would be useful, and would give particulars at the next meeting, it was probable that a standard screen for the purpose might be evolved from the labours of some members who had been giving particular attention to the use of monochromatic screens.

**Aeronautic Photography.**—Possibly there is no subject of a scientific nature having any connexion with military operations upon which so much nonsense has been published as the attractive looking one of photography and balloon work. The snap-shotting tele-photographer working at any distance and in any weather is a very familiar figure in print, though not in fact, as need scarcely be said to our readers; yet, at the same time, the camera and the balloon have done splendid service at the front, and will be capable of still more valuable work. If the familiar enthusiasm of the inventor is not playing us false, we are on the eve of a great revolution in ballooning, for the *Scientific American* has published a description by Dr. R. Danilewski of a dirigible balloon which he has now brought to perfection under the protection of the Russian Government. The disadvantages of the ordinary aerostat are its weight, the time taken to fill it, and the number of men required to put it into action. Dr. Danilewski's apparatus can be fixed up by three or four men and set going in half an hour. In shape it is like a stumpy cigar, with the point uppermost. It is inflated with pure hydrogen, and once set free can travel in any direction, and return to its starting place, at least, so the inventor states, and a picture of the balloon and aeronaut in the air is given. With such a small apparatus it is obvious that large weights cannot be carried, and thus the picture represents the one occupant, if we may so term him, suspended by tackle and not sitting in a car. But he is in an excellent position for snap-shotting, and, as he roams about in any direction, could obviously take an invaluable series of negatives and return for them to be developed quickly enough to be of practical use. According to the inventor's account he, at one of the trials, ascended out of sight for a couple of hours, and then returned close to the shed from which the balloon started. It appears that the impression his exploits produced was so strong that a number of Russian experts have given their opinion that he has solved the problem of aerial navigation.

#### **THE DIFFRACTION PROCESS OF COLOUR PHOTOGRAPHY.**

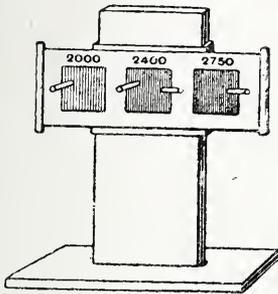

At the Society of Arts, on Wednesday evening, February 14, Professor R. W. Wood, of Wisconsin, read a paper on his system of colour photography with diffraction gratings. The first part of the paper consisted of a brief summary of the theoretical and practical outlines of the process. This having been fully reproduced in the *JOURNAL* of last year, from Professor Wood's former papers, we confine our present extracts from the Society of Arts paper (owing our indebtedness therefore to the Society's *Journal*) to the description given of the process of printing the diffraction pictures from the positives:—

“A sheet of thin plate glass is flowed with a solution of 5 grammes of gelatine in 125 c. c. water, to which has been added 4 c. c. of a saturated solution of potassium bichromate. The plate should be drained for a few seconds, and set on a level slab to dry, after which it is cut to the required size. I have employed several different methods of building up the composite diffraction grating, which forms the colour photograph, and am at present using the following arrangement as offering the fewest difficulties.

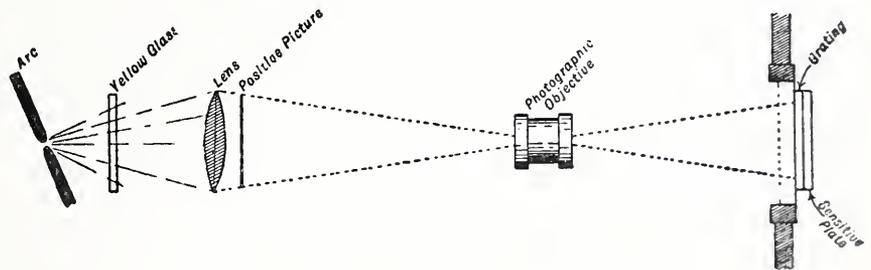

“The three gratings are mounted behind square openings in a thin board, which slides on a horizontal support in such a way that the gratings can be brought in succession into the same position. The positive corresponding to the *reds* of the picture is projected by means of an arc lamp and a photographic objective on to the 2000-line grating, the ruled surface being away from the lamp. A yellow glass is placed in the path of the rays, and the bichromated plate placed with its sensitive film in contact with the ruled surface. In-

asmuch as the projected image can be seen on the grating surface, it is possible to register the position of the plate by means of two or three minute ink dots on the back. The use of the yellow glass is to prevent any transfer of the grating lines until the plate is in position and pressed firmly against the grating by means of a spring. An exposure of from one to two minutes is sufficient to impress the 2000-line spacing on all portions of the plate corresponding to the clear parts of the red positive. The yellow glass is again put in place, the green positive substituted for the red, and the operation repeated, using the grating with 2400 lines to the inch, registering the plate before the exposure by means of the ink dots. The same is now done with the blue positive and the third grating, and, on washing the plate in warm water at 32° C., the colour photograph is finished. The picture once formed in this way can be very rapidly duplicated by contact printing in sunlight on the bichromated plates, copies being made as quickly and with as little trouble as ordinary blue prints.

"To see these photographs in their proper colours we require a simple viewing instrument, consisting of a double convex lens on a light frame, with a small screen perforated with an aperture, mounted in its focus. The picture is placed in front of the lens, and the instrument pointed a little to one side of a gas flame or other narrow source of light. On looking through the aperture we shall see the picture in the most brilliant colours imaginable. The disadvantage of having to use but one eye led me to seek a method for viewing the pictures binocularly. The superposed spectra being formed, both to the right and left of the image of the flame thrown by the lens, if we can arrange matters so that the two points where the red, green,

Grating support used in making diffraction photographs.

Arrangement of apparatus used in printing the first diffraction picture.

and blue are superposed are at the same distance apart as the eyes, we can employ both sets of spectra, and cut two peep-holes in the screen. This arrangement was found to work very well, but, owing to the varying distance between the eyes, is impracticable. Mr. Ives, of Philadelphia, suggested to me a very ingenious plan of arranging the grating lines horizontally on the picture, instead of vertically, and viewing the picture through a long, narrow, horizontal slit, instead of two apertures. Moving the eyes to the right or left would then produce no change in the colour, since the colours are arranged in a vertical instead of a horizontal band. Mr. Ives tried this method, but found it was necessary to employ two horizontal gas flames as sources of light, arranged at just the right distance apart, which is an undesirable complication. I have recently overcome this difficulty by using a viewing stand with two square lenses, mounted side by side, and a double or stereoscopic diffraction picture, which is viewed through a horizontal slit, in front of which are mounted two thin prisms for combining the pictures. This is by far the most satisfactory form of stand, for we can not only use both eyes, but see the pictures in full stereoscopic relief.

"Very promising results have already been obtained, though the distribution of colour is not yet satisfactory. The defects in the pictures thus far made are largely due to the very imperfect gratings that I have had to work with. The spacing of the gratings is not quite uniform, and they have, in consequence, a ribbed or corrugated appearance when placed in front of the lens. These corrugations show in all of the pictures, and are very detrimental to proper synthesis of the colours. A set of perfect gratings has just been ruled on one of Professor Rowland's engines in Baltimore, but, un-

fortunately, they were only finished on the day of my departure from America, and I have not had an opportunity of trying them.

"A grating, with 2000 or more lines to the inch, ruled on a first-class engine such as the one at Baltimore, illuminates uniformly when placed before the lens, and is as structureless as a piece of stained glass. As I have said before, the lines visible in most of the pictures that I am at present able to show are due to errors of ruling, the grating lines themselves being, of course, quite invisible.

"There are other ways in which the process may be modified. We may, for example, combine the diffraction method with that invented by Dr. Joly. It is found impracticable to rule coloured lines to the number of more than three or four hundred to the inch; but we may rule as many as 1400 grating lines to the inch, and by arranging the engine so that it will rule at a variable rate, first a few lines at such a distance apart as to give red, then a few a little closer together so as to give green, then a few still closer together giving blue, we could produce a Joly plate which would appear absolutely structureless. It, of course, could not be used in the same way. This plate once ruled could be multiplied indefinitely by contact printing; and diffraction pictures could be made from it in several different ways, but, as I have as yet made no experiments along these lines, I shall not take the time of the Society in guessing at what may be done. It has been reported in some of the photographic journals that Mr. Thorp, of Manchester, has made and exhibited diffraction pictures showing all the colours of nature by employing a single grating. I must confess that I am at a loss to know how he has accomplished this, unless he had anticipated me and ruled a grating of variable

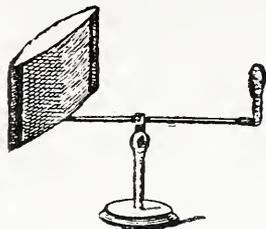

spacing. If he is with us to-night, I know we shall be very glad to hear from him.

"There are still some difficulties to be overcome, and I do not feel sure that bichromated gelatine forms the best film for receiving the impression of the lines. It is interesting to note the theoretical possibility of producing one of these diffraction pictures directly in the camera, by bringing three diffraction gratings, ruled or photographed on three coloured screens, in succession in contact with the film of a fine grained plate. I have done this already with a single grating, but have not yet attempted the use of all three. Special plates would, of course, be required.

"Another peculiarity is that all distinction between positives and negatives disappears. A diffraction picture printed from another is identical with it both as to light and shade, and colour distribution."

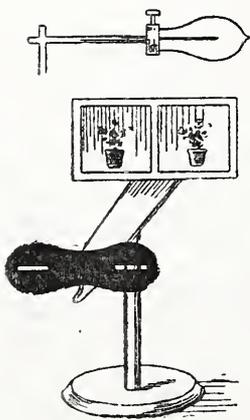

In the course of the subsequent discussion, Mr. Thomas Thorp said he was glad to have the opportunity of showing and explaining some of the work he had been doing in connexion with colour photography; but he disclaimed any originality in the conception, which was entirely due to Professor Wood. Mr. Butler, of South Kensington, described to him some of Professor Wood's first results, just at the time when he was engaged in taking copies of a diffraction grating of about 15,000 lines to the inch, which he was very successful in doing by casting. It had often occurred to him that such films ought to be of use in connexion with colour photography; but until Professor Wood showed the way it did not occur to him how they could be utilised. He found it was impossible to take copies of these films on gelatine on account of the closeness of the lines; up to 2000 or 3000 lines it was not very difficult, but it was almost

impossible to get anything satisfactory with the higher numbers by contact only. Then he added a little glycerine, so as to make the surface tacky, and then pressed the films into the gelatine; this produced a ridgy effect, and they were afterwards hardened by exposure to light. It was an astronomical subject he was dealing with, one of the mountains in the moon; he exposed on it about one and a half minutes; detached the film, washed it, and got the picture in hardened ridges. Then it occurred to him that he might get three pictures from one grating; he adopted the plan of horizontal lines to begin with, and he tried crossing two sets across the horizontal lines at a slight angle, and downstairs the effect could be seen of a photographic slide which had been printed in this way. He could not, however, print three copies on one plate; he must have three

Viewing apparatus.

plates. To use a film for each picture was rather troublesome, and he managed to take copies of a picture by simply pouring over it a solution of celluloid, allowing it to dry, and then tearing it off. The results, which could be seen downstairs, were obtained over six months ago, and had not been touched since. He wished to show the pictures in the lantern, but found it nearly impossible, and then it occurred to him to design a new set of lines which would allow of this being done, and at the John Hopkins University they said they were willing to try to assist him in the matter. He wanted a grating which, instead of showing a central image and spectra on each side, would throw all the light into one spectrum, and almost suppress the central image, and in that he had succeeded. By a grating of that character, having 15,000, 20,000, or 40,000 lines to the inch, he hoped Professor Wood would be able to make pictures

Position of lamp and stand for viewing stereoscopic pictures.

which would come out very brilliant. These lines were produced, not by diamond scratches, but by a kind of steam-hammer process, producing grooves of a saw-tooth section  $\frac{1}{20000}$  inch in depth and  $\frac{1}{1000}$  inch from ridge to ridge. The original metal ruling gave no spectra at all, but when copied in a celluloid casting it acted perfectly, as would be seen on the screen.

Professor Wood said the idea of getting all the light into one spectrum had been sought after for a long time, and Lord Rayleigh, in his article on the wave theory in the *Encyclopædia Britannica*, called attention to the fact that, if it were possible to produce a form of ruling, such as this saw-tooth pattern, this concentration could be effected. That this had now been done was an exceedingly interesting experimental verification of theory. If you got all the light

concentrated in one spectrum, it would be possible to project a diffraction photograph with a lantern; but, when it was scattered in several supernumerary spectra, the picture was not brilliant enough to allow of that being done.

Professor C. V. Boys, F.R.S., said he must express his admiration for the ingenuity Professor Wood had shown in, first of all, devising such a beautiful method of producing coloured photographs; and, secondly, in overcoming the numerous practical difficulties, and making it actually successful. Professor Wood had referred to Lippmann's method of coloured photography as being like a soap-bubble film, in which the thickness varied to suit the colour, but it was more than that, it was rather equivalent to a series of soap bubbles—he did not know how many—arranged one behind the other, with the thickness of a soap bubble between each, so that there were alternate films of more or less reflective or transparent material equi-spaced, and it was this constant repetition of the reflecting surface, or dissimilarity of optical property over constant intervals, which produced the extraordinary brilliant effects Lippmann had shown. There was, again, a curious similarity between the Lippmann colour photography and this method, from a theoretical point of view. In each case it was simple, having given the theory, to produce a colour photograph when you had merely one of the three primary colours, red, green, and blue, in any part of the picture; but in both cases it was puzzling how the effect was produced when you had two or three of the primary colours acting at the same spot simultaneously. In the Lippmann case, the fact that there were three series of films, all interlaced at three several distances asunder, occupying the same space at the same time, was so puzzling, that it was hardly possible to imagine how the optical result described could result. Lippmann set to work to obtain a mathematical expression which represented mixed colour light as met with in nature, and said, if that expression were worked out in practice, that light would result; and when he ultimately succeeded in producing the three sets of strata, all superposed and interposed through one another, that result did occur. Here, again, we had the curious effect of three sets of gratings superposed. He did not know whether Professor Wood felt confident before he tried it, but they would all work independently of one another—he certainly should not have done so, and it seemed to him a discovery, as well as an invention—that they did so act without getting confused with one another. The beautiful result Mr. Thorp had described in the grating the lines of which were not mere scratches, but grooves of a definite pattern, was a practical advance of the very greatest importance in the construction of optical instruments. We had also been much interested in learning that a celluloid film cast of a grating could be made, and he was surprised at the brilliant effect produced. For optical purposes, where the utmost definition was required, it was essential that the grating should be absolutely uniform, and that in no part of it should an accumulated error arise sufficient to bring a line where there ought to be a space. With 1000 lines to the inch there was no difficulty on this head, but, with gratings of 10, 20, or 40,000 lines to the inch, it required the highest precision such as could only be obtained by such a machine as Rowland's engine; and it occurred to him to ask whether there would not be a possibility of the film irregularly shrinking or being distorted to an extent sufficient to interfere with its value. He should have thought it possible to avoid this; but, if it were, they had here, again, a method of producing large optical gratings, sufficiently accurate for exact work cheaply, for which they were much indebted to Mr. Thorp.

Mr. Thorp said there was a slight shrinkage in the film, but there was an easy method of testing its accuracy. If the film were reversed and placed on the original grating, you saw certain interference bands, which afforded an easy mode of counting the lines. If there were any imperfect places, these bands would not be equidistant. He was some months before he could get the bands perfectly equidistant; but, by very careful stoving of the films, they dried absolutely level, and when mounted on good frames they had shown four lines between the D lines. Dr. Ames, of John Hopkins University, had congratulated him on their excellence. One of them had 14,438 lines to the inch.

Sir William Abney said he must congratulate Professor Wood on an excellent and clear exposition he had given of the subject. Mr. Thorp must not take the credit of being the first to have a grating which gave one spectrum only, for he had one about three inches square, which was given him by Professor Rowland, many years ago, which had that property. It was a beautiful grating, and whenever he wanted to photograph the invisible part of the spectrum, beyond the red, he always employed it, because the photographic intensity of that part of the spectrum was so small. Of course there were ghosts of spectra of the second and third order, and on the other side a faint spectrum also, but, practically, all the light was concentrated in one. He believed that was the first grating of the kind brought to England, and the grooves in it, when examined under the microscope, were somewhat of the shape Mr. Thorp had described. This was a reflection grating, whilst Mr. Thorp's was transparent. That was hardly the place to enter on a controversy with regard to Lippmann's photographs, but he must say he preferred Mr. Wood's simple description of the matter to Professor Boys', for, although Lippmann had given an equation for the colours in his photographs, the colours which were reproduced were not pure spectrum colours, they were to a certain extent mixed. The method now shown was, to his mind, a more beautiful conception, and he only regretted that Professor Wood, like Mr. Ives, came from the other side of the water. He should like to know what light Professor Wood used for taking his photographs, because, to his mind, the difficulty was rather in the production of the originals than in the printing afterwards. With Mr. Ives's principle you could not use a monochromatic beam, you required a large portion of the spectrum.

Professor Wood, in reply, said he knew very little about the colour sensibility curves or colour filters, and therefore he contented himself with using Mr. Ives's kromograms for printing from, thus sparing himself the trouble of preparing original negatives, because they were far superior to anything he could produce with colour filters which he had at his disposal. With regard to parallelism of the lines, a slight deviation from exactitude made very little difference. If the lines were placed at right angles, one set would diffract horizontally and the other vertically, and the spectra would not be superposed at all, and would not fall on the aperture. With regard to the single grating with lines at different angles, Mr. Thorp would speak for himself; but he fancied that he broke up the light by mirrors into three sources, so that the direction was slightly different, and they were all brought to one focus. With regard to the complicated effect you would expect to get where two or more gratings were superposed, he was not quite sure; but he thought you got two sets of lines, and in addition shadowy bands, which sometimes, but not often, introduced spurious colour, by acting as lines of wider spacing.

Mr. Thorp said Professor Wood had explained the matter very well. He used three mirrors which acted as sources of light, and by moving the mirrors about you could get any colour you liked.

#### THE PREPARATION OF THE LINED SCREENS FOR THE JOLY PROCESS OF COLOUR PHOTOGRAPHY.

BEFORE the London Section of the Society of Chemical Industry, Mr. J. W. Hinchley, A.R.S.M., F.C.S., recently read a paper on the Joly process of colour photography. We are indebted to the Society's *Journal* for that portion of the paper and discussion we here reproduce. It deals with the subject of the preparation of the lined screens, and, after a brief outline of three-colour photography, proceeds:—

It is to Joly, in 1894, that we owe the step from composite colour photography to the true colour photograph. His idea, he says, referring to the Young-Helmholtz theory, "is to carry the appreciation of physiological principles still further, and divide up the plate like a hypothetical subdivision of the retina, so that all over the plate there should be minute regions uniformly distributed, wherein the sensitive silver salt is excited to become reduced to the 'photogenic' material in the same degree in which the sensations of redness, greenness, violetness, would have been actually excited in the several nerves of the retina, had the image been formed upon

it." The essential point of the process is a method of colour mixture which does away with optical superposition, and is at the same time extremely simple. If strips of colour sufficiently narrow be placed side by side and viewed from a suitable distance, the eye will perceive the colour due to their mixture. Acting on this, Joly combines the two sets of three screens into two, one a taking screen, and the other a viewing screen. Each consists of a glass plate carrying lines of the three colours side by side, these lines being less than  $\frac{1}{225}$  of an inch wide, and in contact with each other without overlap. By means of these screens the production of a colour photograph is comparatively a simple operation; the interceptor being placed in the lens of the camera, the plate and taking screen are arranged in the dark slide, film to film, in such a way that on exposure the lined screen filters the light before it reaches the plate. On development, a negative is obtained, recording in density of silver deposit under the three lines the degrees in which the several colours of the object have power to excite in the eye the three fundamental colour sensations. A positive printed from this negative, and adjusted in contact with a viewing screen, so that the red record line of the positive coincides with the red line of the screen, and the other lines similarly coincide, will reveal the object in its true colours. The ease and accuracy of the method are remarkable, for all the difficulties which the worker in composite colour photography has to face are overcome in the manufacture of the screen. If the taking screen in photographing a white object gives an equal density of silver deposit under each of the lines, then the colours of any object will be correct; should one of the lines be too dense, an alteration of the interceptor, by tinting it slightly to cut off the particular colour, will bring about the equality easily.

It will be readily understood from this description that the manufacture of the screen is not a simple process. The glass plates on which the lines are to be placed are thoroughly cleaned after the manner adopted in dry-plate manufacture, except that the necessity for perfectly clean glass is, if possible, greater; they are then coated with a film of gelatine, somewhat thicker than that of a dry plate; the gelatine used must be very hard, and, at the same time, as absorbent as possible; and, since the certainty of chemical action on the dyes prevents the use of antiseptics, the gelatine solution must be freshly made at as low a temperature as possible.

The operation of lining the plates is a most difficult one, and is carried out in exceptionally accurate ruling machines, ordinary drawing pens, carrying reservoirs of red, green, and violet inks, being the means of producing the lines. The pens are trailed across the plate, and, the pressure allowable being very small, the lightest pen consistent with rigidity that can be made is used.

In the early machines the spindles of the pens rested in V grooves, the lateral movement being prevented by little magnets attracting a disc on the spindle against the adjusting screw. Ruling took place in both directions of movement, each side of the pen being used alternately. It was found, however, that a great many difficulties, mechanical and photographic, could be avoided by ruling with one side of the pen, and in one direction only. In the latest machines the pens swing in jewelled bearings, rule in one direction, and are lifted on the idle or quick return stroke. Time for the absorption of each line is provided by each pen ruling a few lines in advance of that following. About one and a half minutes is required for efficient absorption. The inks are water inks, aniline dyes being used to produce the intense colours necessary, and gums to give them viscosity.

After much experiment and failure, it was found that regard must be had to the following points:—

1. The hygrometric state and temperature of the air.
2. The shape of the pens and the pressure they exert on the film while ruling.
3. The viscosity of the ink at the temperature of ruling.
4. The rate of ruling.
5. The correct adjustment of the pens.
6. Absolute uniformity of conditions during ruling.

Of these the hygrometric state of the air is perhaps the most important factor, for, should the air be too dry, the ink in the pens becomes too thick and refuses to rule, and too much moisture causes

difficulties from the non-drying of the ruled lines. The evaporation of the water from the ink line is negligible in comparison to its absorption by the gelatine, and since gelatine is very sensitive to changes of temperature and hygrometric state of the air, there are limits to the temperature of ruling, and at any given temperature there are definite limits of hygrometric state. At low temperature (10° or 12° C.), the dew point may be 7° or 8° below the temperature of ruling, without serious consequences, but every degree above this temperature narrows the hygrometric limits considerably, until, at 19° C., the limit is between 1° and 2° C., and above this temperature ruling becomes practically impossible.

The shape of the pens is also an important factor; the nibs should slope evenly together, their inclination to each other being about 3°. The points must be semicircular in form, corresponding to the natural shape of a drop, and the diameter of the semicircle must not be more than two mm., or it becomes difficult to maintain the exact width of line. The ends of the nibs must be carefully shaped and brought to knife edges, which are finally rounded to prevent the cutting of the film, by rubbing on wash-leather. One pen will rule about 100 plates before requiring to be reset; thus its point will rub on gelatine for two miles before the wear is such as to cause bad or faulty lines. The pens are trailed across the plate, their own weight giving the pressure required to maintain a continuous line. Under ordinary conditions, they are inclined about 5° or 8°, for the pressure on the plate must not be more than one and a half grammes. If one nib is a little longer than the other, or if it touches the ridge formed on the gelatine by the previous line, a wavy line is the result, and the screen becomes useless.

It was speedily found that the quality of the screens depended on the viscosity of the ink, and the necessity arose for the measurement of this property. The inks being opaque, ordinary methods were unsuitable, and, finally, the measurement of the rate of flow through a capillary tube into a constant partial vacuum was found to provide the simplest and easiest test.

The rate of ruling will depend on the viscosity of the ink. With ink giving the best results, the speed is about seven-eighths of an inch per second.

The adjustment of the pens was a mechanical question which gave a great deal of trouble, but was solved by means which need not concern us here. The distance apart of the nibs was usually found to be about seven-eighths of the width of the line ruled. With too viscous ink, however, the nibs are found to be wider apart than the width of the line ruled, and in this case the ruling becomes very erratic.

Perhaps no more important factor in any manufacture is uniformity, and no product could suffer more from lack of this than the Joly screen. A rise in temperature of only 1° C. means at some temperatures a lowering of the viscosity of the inks to less than half their former value, with the result that the lines, on account of an increased flow of ink, widen. A correcting tendency, however, appears in the increased rate of absorption of the gelatine, so that the after-spread of the line will be less. Again, should the hygrometric state of the air alter, the absorption of the gelatine increasing or diminishing will bring about similar changes; also, while ruling, the slight drying of the ink in the pen produces a secular narrowing, so that it is necessary to commence with a wider line than would produce a perfect screen.

All these changes have their corresponding colour changes, which make it imperative to ensure absolute uniformity of conditions, for true colours are just as essential to perfect results as perfect ruling.

After the ruling of the screen is an accomplished fact, it is dried by warm air for some hours and protected by varnish. A satisfactory varnish, which would not attack the colours or dissolve them, could not be found, and, finally, a compromise was made; and, though the medium of the varnish slightly dissolved the green dye, the loss of colour, with a very concentrated varnish, was so small as to be quite inappreciable.

The manufacture of celluloid films and interceptors is a subject great enough for a single paper, and calls for no special mention at the end of this.

All [methods] of testing [the inks for the truth of colour were

found to be unsatisfactory unless applied to the ruled line, and the greatest difficulty was found in preserving uniformity in this respect; perhaps the greatest need of all was that of a green dye, whose absorption would enable the adopted curves to be imitated more closely.

All the attempts to photograph landscapes by the Joly method were, for a reason which remained mysterious for some time, failures; natural greens, illuminated out of doors, were hopelessly wrong, while the same greens photographed in a studio were reproduced correctly. The failure was proved to be due to a defect in the old spectrum plate, which was very sensitive to a band of no colour value on the border of the visual spectrum at the red end. All attempts at cutting out this band (it was transmitted by all three lines) were unsuccessful until, by accident, it was found that a trace of mercuric chloride, added to an ethyl-green solution, would do so. A method based on this was too complicated for practical work, and, when the new spectrum plate appeared, was rendered unnecessary. By means of this plate correct renderings of all colours could be obtained.

The discovery of permanent dyes, of film materials, &c., must proceed further before any great advance in this work can be expected, and we can only hope that the results of the diligent workers of the past may encourage those of the present to make colour photography still more of a practical success, rather than a laboratory experiment.

In the course of the discussion which followed Mr. Hinchley's paper, Mr. J. Cadett said he would not say that it was necessary that every chemist should be a photographer, but it was unquestionable that every photographer ought to be a chemist, and it would not be amiss if the Society took more account of photography than it did at present. The chemical reactions that were involved in photography were even more puzzling than those in the average range of chemical research, for in photography they had not only chemical reactions, but also physical conditions to consider, and these were often baffling. For this reason photographic manufacturers needed the aid of the chemist. For instance, very little was known of the nature and properties of gelatine, the principal basis of the modern dry plate. That body had been the bane of his existence. What they wanted was a chemist who would devote his life to gelatine, and until some such help was forthcoming photographic manufacturers would be condemned to flounder on in helpless ignorance. The paper to which he had listened that night had given him an insight into the Joly process which he had never possessed, and had enabled him to appreciate its difficulties, especially as to the production of the beautiful screens they had seen. With regard to the plates themselves, it was easier to make a plate sensitive throughout the whole range of the spectrum than to make one with a gap in the extreme red such as his own sensitive plates had. It had taken him two years to do this. Plates sensitive throughout the whole of the spectrum could only be made by working in total darkness; such a procedure was absolutely impossible in a factory where tons of plates had to be produced. The author, in speaking of Maxwell's curves, had omitted, no doubt unintentionally, to mention the curves given by Sir William Abney in his lecture before the Royal Society. Sir William had drawn the curves in such a manner that the various colour sensations were represented as the various fundamental colours, *plus* white light excepting the red; and since the reading of that paper they had had something tangible to go upon. The only fundamental sensation they could have in perfect purity was the red; in the green, one must have white light or mixtures with the blue and red, and, if those curves were drawn so that they crossed each other *plus* white light, the purest effects of colour were maintained. Sir William Abney had given us these particular curves for the first time, and to manufacturers and all interested in the future of colour photography they would be of the utmost value. What was really required in the sensitive colour plate? It must be affected by the various portions of the spectrum so as to give densities proportionate to the logarithms of the intensities of light in the spectrum itself. It was impossible to single out the colour-sensation curves. They must have admixtures, but, if the plate followed those curves, they had all

at was necessary. With regard to the future, he thought they need not sigh for a material which would give all the colours of nature, for in getting those they would lose all that reproductive power which tricolour printing gave them. If they could make greens which would give results on the plates comparable with the curves, and printed in inks transparent in themselves, which were the complementaries of the colour-sensation curves, they would have all that would be necessary to reproduce colour. From three negatives and half-tone blocks, twenty million prints had recently been made, and the prints from them were chosen in preference to some of the best lithographic artists' work. The author had given so able a description of his process that it was unnecessary for him to say more. He believed that before long trichromatic printing would become the general process in use. The regular illustrated journals would probably be printed by these means, and the eye would be satisfied by its rendering of colour.

Dr. S. Rideal said the point that interested him most was the difficulty which the inventors had had in ruling the lines of their screens with viscous gums. He had done considerable work on the viscosity of gum solutions, and had encountered most of the difficulties referred to by the author, due chiefly to variations of temperature. If he remembered rightly, he had managed to get what he called a gum solution of standard viscosity by using ordinary gum arabic mixed with an insoluble gum. The viscosity of a gum depended on the presence of insoluble metarabin, and the amount of metarabin varied with gums grown at different temperatures and under different conditions; but, by taking a soluble gum and adding insoluble metarabin, such as occurred in the cherry, it was possible to make a body of constant viscosity, and he ventured to think that this course might be found useful by the author.

Mr. W. F. Reid asked if it was absolutely necessary to make the screens of gelatine. From the details which the author had given them it seemed to him that a substance had been chosen for those screens which offered the utmost difficulties. Would it not be possible to use, say, celluloid or another substance which he had exhibited not long ago? If some such material were employed, it seemed to him that it would be possible to produce the lines by merely pressing the sheet of celluloid or similar material against a metal plate upon which depressed lines had been engraved. The colour could be applied to the raised lines thus produced by means of a roller in one operation, and, if necessary, the raised lines could be flattened by pressing on a level plate. Then, again, the author had chosen for his inks aniline dyes soluble in water. But water itself, from the hygroscopic nature of our climate, produced difficulties of its own. Why not choose a liquid in which aniline dyes are soluble, and which might produce very good lines upon such a substance as celluloid? There was a great deal of truth in Mr. Cadett's remarks as to the necessity of investigating the properties of gelatine; for the irregularity of those properties brought about difficulties in the various processes in which gelatine was used. It would be quite possible to use gelatine as a thickening material for the ink, which could be done by denuding it of its gelatinous properties, and thus the ink would not be so susceptible to atmospheric variations as gum arabic was.

Mr. J. W. Hinchley, in reply, said that in writing the paper his great difficulty was, not to find matter to put in, but to decide what to cut out. He had cut out what he had wished to say with regard to Sir William Abney's curves in order to give more prominence to the practical part of the subject, which he deemed would be more interesting for the Society. Referring to Mr. Reid's remarks on the manufacture of the screens in some other way, he had made a great many attempts to use celluloid and other substances, but all his attempts had ended in failure, and he was hopeless of finding any substance which would compare with gelatine in its wonderful absorbing properties. The suggestion of adding insoluble gums to the gum solutions used in making the inks was a valuable one, but in a short time precipitation of the dyes might occur. He had attempted to overcome the difficulties of the hygrometric state of the atmosphere by providing an artificial atmosphere in the instrument itself; but this attempt failed, because variations could not be avoided, and the slightest change altered the lines. With regard to

Mr. Reid's suggestion as to producing the lines by pressing a roller on the material employed, it must be borne in mind that they must be of a certain width throughout, and transparent. It was easy to merely draw lines, but the difficulty was to draw them of such an exact width as to join without overlapping, for even the overlapping of one-twentieth the width of a line would make a perceptible difference on the screen. Owing to the absorbent character of gelatine, it was possible to draw the lines so that they filled up the space completely without overlapping, whereas with another material they would have to wait for the lines to dry. The great difficulty, however, was to make the atmospheric conditions constant.

FOREIGN NEWS AND NOTES.

**To Remedy Over-exposure.**—The Belgian photographic paper, *Helios*, gives prominence to the following method of curing over-exposure, which was communicated to the Berlin Photographic Society by H. Schmidt, of Munich. If the plate shows signs of over-exposure by flashing up immediately it is placed in the developer, it should be taken out at once and well washed under the tap. The plate should then be bathed for a few minutes in a solution of 5 grammes of nitrate of silver in 100 c. c. of distilled water, and development should afterwards be effected by pouring a small quantity of developer upon the plate held by one corner as in coating with collodion, the object of this being, of course, to retain as much nitrate of silver in the film as possible. If this process of physical development does not give sufficient density, the negative must be intensified, and for this purpose H. Schmidt prefers the following pyro-silver intensifier:—

- |   |             |
|---|-------------|
| No. 1.                                    |             |
| Pyrogallic acid . . . . .                 | 10 grammes. |
| Alcohol (strength 96 per cent.) . . . . . | 100 c. c.   |
| No. 2.                                    |             |
| Nitrate of silver . . . . .               | 4 grammes.  |
| Citric acid . . . . .                     | 6 "         |
| Distilled water . . . . .                 | 200 c. c.   |

For use dilute 4 c. c. of No. 1 with 100 c. c. of water, and when about to intensify add 4 c. c. of No. 2. For a half-plate, 25 c. c. of solution should suffice, and, as the solution should be freshly mixed, it should not be prepared until wanted. It is preferable to intensify before fixing. Herr Schmidt says the process gives excellent results with plates which have received six to ten times more than the normal exposure. Although this limit is within the control of the ordinary means of development, the process seems worth consideration.

**Grained Screens and the Salon.**—In the same periodical M. Léon Vidal recommends MM. Puyo, Demachy, Brémard, and their imitators, who affect the peculiarities of style associated with the gum-bichromate process, to try the effect of a grained screen. M. Vidal recommends that the primary negative be made in the usual manner, but that a good positive be then produced, and from it a printing negative by copying through a grained screen. From this second negative the print may be produced by the gum-bichromate, carbon, platinum, bromide, or any other process. The print would have the characteristics of a crayon drawing, and, if necessary, might be produced upon rough-surface paper. The process would lend itself very effectively to polychromatic work, and by it the monotony of large areas of half-tone could be considerably relieved. The suggestion appears to be one of great promise, but it would be a remarkable instance of the irony of fate if the apotheosis of artistic photography were attained by means recommended for the obliteration of the mechanical effect of process work.

**The Combined Toning and Fixing Bath.**—In speaking upon this subject at the Berlin Photographic Society, Dr. E. Vogel stated that it was not advisable to use the combined bath for commercial photographs, notwithstanding its convenience and the fine tones it produced. It was capable of giving durable prints when in good condition, and he had found that the pictures faded less rapidly when a fresh bath was used. There was no definite explanation of the causes of fading with this process, but the atmosphere, without doubt, was a factor. It was an extraordinary fact that there was no fading where marks upon collodio-chloride paper were due to perspiration from the fingers. Professor Raschdorff stated that he had noticed that the combined bath would keep good in summer, but not in winter. He used a mixture of old and

fresh solutions, which gave him satisfactory results. Herr P. Hanneke said that, as a test, he had mounted a collodio-chloride print, toned in the combined bath, and poured a solution of hyposulphite of soda upon it, and allowed it to remain in that condition for several hours. The print was then slightly rinsed, and, after a lapse of two years, had not shown the slightest trace of fading.

**Silvering Mirrors.**—The *Chemiker Zeitung* gives the following directions:—I. Dissolve 30 grammes of nitrate of silver in 240 c. c. of distilled water, and add ammonia, drop by drop, until the precipitate first formed is redissolved. Avoid adding ammonia in excess. Filter and re-filter through the same double filter paper until the liquid is quite clear. Make up the quantity with distilled water to 480 c. c. Keep the solution in a clean flask, in a cold, dark place.

II. Dissolve 0.75 grammes of Rochelle salt in 300 c. c. of water, heat to boiling point and add 0.166 gramme of nitrate of silver, stir with a clean glass rod, and boil for ten to fifteen minutes, until the solution acquires a grey colour. After filtering, dilute the solution to 480 c. c., pour it into a clean flask, and let it stand from six to eight hours in a cool, dark place.

For use, take 30 c. c. each of Nos. I. and II., mix, and add 120 c. c. of distilled water. Clean the glass very carefully, pour the fluid upon it and let it stand for about an hour, for precipitation of all the silver. Rinse the glass with water and stand it on end to dry.

**Photographic Journalism.**—The *Wiener Freie Photographen Zeitung*, in reply to the question, "Where did the first photographic newspaper appear?" states that the *Journal of the Daguerreotype and Photographic Arts*, published in New York, in 1849, by S. D. Humphrey, may claim the premier position. In the following year, *The Daguerrian Journal* also made its first appearance in New York. The third place may be claimed by a Parisian paper, *La Lumière*, published by A. Gaudin. The first German photographic paper, the *Photographisches Journal*, was brought out, in 1853, by W. Horn, of Prague, and in 1857 the *Photographisches Album* was issued by Weingartshofer, of Vienna. From the reference in our issue of January 5, our readers will be aware that THE BRITISH JOURNAL OF PHOTOGRAPHY made its first appearance in 1854, and it is with pardonable pride that we note the remark of the *Wiener Freie Photographen Zeitung*, that THE BRITISH JOURNAL OF PHOTOGRAPHY is truly the best professional photographic journal in the world.

**Panchromatic Emulsion for Colour Photography.**—In the *Photographische Rundschau* Dr. Neuhaus confirms the observations of Professor Valenta that glycinroth (obtained from Kinzelberger, of Prague) is an excellent sensitiser for red. By the addition of this dye to the grainless emulsion for Lippmann's process, he obtained plates which not only rendered all the colours of the spectrum from red to violet, but also correctly reproduced mixed colours. The sensitising solution is prepared as follows:—

Alcoholic solution of cyanine (1 in 500).....	3 c. c.
" " " erythrosine (1 in 500) ..	2 "
" " " glycinroth (saturated) ..	10 "

This quantity should be added to 100 c. c. of freshly prepared emulsion. Place the emulsion on ice to set it as quickly as possible, break it up and wash it in the usual manner. The 15 c. c. of sensitising solution raise the temperature of the emulsion 1.5° C., and, as it is desirable not to allow the emulsion to exceed 40° C. to prevent ripening, care should be taken that its temperature does not exceed 30° C. before adding the dye. The washed emulsion keeps very well; but, if left in the unwashed state, the emulsion ripens and loses its transparency.

**Technical Education.**—We read in the *Photographische Chronik* that the firm of Carl Zeiss has offered to build an Institute for Technical Chemistry and Physics in connexion with the Jena University. Dr. Otto Schott, of the Jena Glass Works, will also contribute 2000*l.* for the equipment of instruments.

#### A FUNCTION AT THE LONDON AND PROVINCIAL.

THERE was an unusual sound in the Editor's office. It was mid-day. The unusual sound was the scratching of a pen-nib. It was interrupted by a tap at the door. "Come in," said the Chief. "Please, sir," said a junior clerk, "here's a letter for you, and the man says he is to wait for an answer." The Editor opened the letter, and, as he read, various expressions flitted over his face, though they were but momentary. Indifference gave way to interest, this was followed instantly by incredulity, which in turn gave way to hope, and finally ended in a beam of agreeable

surprise. The letter contained an enclosure—the enclosure was a ticket for the Second Annual Supper of the London and Provincial Photographic Association, to be held at their Headquarters, at the sign of "The Swan," in Tudor-street, Whitefriars (of ancient memory), on the evening of Thursday, February 15 (century uncertain).

The look of indifference on the Editor's face was caused by the sight of the supper ticket (they are so very numerous just now); the look of interest was created by the request set forth in the letter wherein he was desired to preside at the supper; the incredulous look owed its origin to the promise of a better supper on this occasion than heretofore; and the look of agreeable surprise came from the perusal of the musical programme to be provided by Mr. Vivian Hyde.

After "careful consideration" (that divine gift vouchsafed to all journalists and to editors in particular), the Chief returned a reply "pardon bearer" that he would be delighted to accede to the cordial request of the honourable member for Chancery Lane, to take the chair on the auspicious occasion referred to in his letter of even date.

The postscript to this letter was somewhat of a private nature and contained language of a highly technical character, not intelligible to the public mind, but of great interest to members of the Society, and it might not be out of place to mention it here.

The Head suggested in this letter that the Society should negative the use of strong developers as these are calculated to interfere very materially with the theory and practice of stereoscopic vision, as advocated by him at the last Convention at Gloucester. The effect of these developers in the solution (the photo-chemical equation of which was  $WSKY + H_2O^2$ ) would be to multiply the object once or more if used in excess or in the wrong quantities.

He said he advocated one part of WSKY to two parts of  $H_2O$  as the proper proportions.

A friend of his (the Chief's) used these in the wrong quantities, putting one part of  $H_2O$  to two parts of WSKY, and the result, he said, was to interfere with the normal vision to such an extent as to land him in a serious dilemma.

It happened like this.—He (the Chief's friend) had been using this developer rather freely, and in the evening went home. He lived at No. 111, Bunkers Hill, S.E.

Silently he opened the door and stole up on tip-toe up to bed. He sat down on the bed, or what he thought was the bed—but it was the wrong one—his optical vision was slightly out of focus, and he sat on the floor.

The noise brought up the proprietor of the house, who was below, and the Chief's friend was escorted to No. 111. He had gone to No. 11 by mistake; such was the effect of the patent developer on the image on the retina.

The correction for this kind of visual refraction, the Editor said, was an application as soon as practicable (when dry) the following morning of a little clearing solution. This will always neutralise the effect of over-development.

I am told that the above letter, although of a semi-confidential kind, will be preserved by the L. and P. Society amongst their most treasured possessions; but it does not shed any light upon the next question, "at what point should this development be discontinued?"

\* \* \* \* \*

"The supper waits, sir."

So spoke the resplendent white-beshirted waiter at "The Swan" to the Chief, as the latter chewed the cud of reflection and the end of an anti-festal cigarette.

Some thirty-five members and guests were already assembled in the supper-room, as Chamberlainlike with ornate button-hole and inscrutable but smiling countenance, the Chief took his seat at the table amid applause.

Then a mammoth edition of the auctioneer's hammer fell with a thud (like a "Little Bobs" bomb), and grace was said, whilst each member unconsciously fidgeted with the bottom button of his waistcoat.

Then we fed—wisely perhaps—but not *too* well. The supper was served much more creditably than last season, though the viands were neither numerous nor costly, yet, wholesome withal.

The Hon. Secretary subsequently explained that the landlord, last year, only provided, for those who were expected (about thirty-five), whereas about fifty turned up. This, doubtless, accounted for much adjectival invective concerning the prior function at "The Swan."

There was a good piano too, not the defunct anatomy of an eighteenth century spinet, as on the former occasion.

After supper the hammer descended again, and the Chairman 'owled "ere's y'r 'ealth, gentlemen," which he drank by himself. This was very kind of him, no doubt.

The first toast was the patriotic one to the "Greatest woman on earth," which was drunk with enthusiasm and in a true and warlike spirit as became a "Fighting Society."

The toast list was not a long one, but it included "The London & Provincial," "Our Officers," "Absent Members," "The Visitors," and "The Chairman and the Photographic Press" (God bless 'em).

The intervals for refreshments were frequent.

The music was good, so was the singing, and the other entertainers were excellent.

After a few intervals the toasts and the music and the singers and the

ories got slightly out of focus, but that must have been the tobacco smoke.

Somebody called the London & Provincial a "Pugilistic Society." Somebody else said it was an "Expectoration Club." A third thought with all those personal toasts that it was a "Mutual Admiration Society"—any how, it spent a very pleasant evening, and Mr. Hyde although disappointed in two of his friends was well supported by Mr. Aubrey Wills, Mr. W. E. Dunmore, and Mr. F. Godfrey for the lighter comedy of the evening, whilst the gentleman who presided at the piano gracefully charmed our senses with his digitorial proficiency on the keys, and, as the Chief said at the conclusion, "it will all remain in the archives of one's memory." Doubtless it would but for that tobacco smoke.

A VISITOR.

EXHIBITION OF THE WEST LONDON PHOTOGRAPHIC SOCIETY.

THE Eleventh Annual Exhibition of the West London Photographic Society, which was open at the Lecture Hall, Broadway, Hammersmith, W., on the evenings of Friday and Saturday, the 16th and 17th inst., showed that the Society still maintains its high standard.

It is to be regretted that the Society cannot find a more congenial surrounding than the doleful schoolroom to which we make our annual pilgrimage on the occasion of the Society's Exhibition. In these days, when the importance of the education of the people in technics and art beginning to be recognised, it should be a duty of those who have the local management of such things to assist the Society in this respect. The Society, which is not a large one, and not a wealthy one, cannot do more than it does, but it can, and does, form a collection of photographs every year which at a very slight expense might be made to afford both pleasure and instruction to a vastly larger section of the community than now have the opportunity. In London we are very far behind the northern and midland manufacturing districts in matters like this.

We must say that our impression of the Exhibition was not an exciting one. There was nothing there that raised our enthusiasm, and nothing there sufficiently bad to give us the opportunity of delivering a lecture upon. The beginners even, if there were more than one, had perpetrated nothing that deserved a more emphatic word of condemnation than "uninteresting." The beginner, if he was the sole representative of his kind, condoned his faults, the want of interest of his subjects and such inattention to details as not trimming his prints, so that perpendicular lines were perpendicular, by admirable technical photography.

To us—and perhaps a long succession of visits to photographic exhibitions has somewhat blunted our appreciation of many works that would please the majority—the prevailing feature of the Exhibition was its unevenness. There was not a great variety in the subjects, and some, portraiture and figure subjects, for instance, seemed to be almost entirely neglected. The members seem to be content to draw their inspiration from one another. The fact that each member's work is hung together facilitates the recognition of any marked individuality or mannerism that exists, but so little was any such thing apparent that we could quite have believed that the Exhibition consisted of the work of three or four members instead of the fourteen that we understand contributed to it. We think it a great pity that the Society should follow so closely its old traditional style, for, though we willingly concede that the work of the present year is equal to any of that of the past, in comparison with the progress made during the past two years by some of the other metropolitan societies which hold exhibitions, the West London Society does not keep its place. The lines upon which the Exhibition is run, no classes and no awards, are undoubtedly admirable, but the system does not seem conducive, at any rate in the present instance, to the encouragement of that variety which is absolutely necessary to make an exhibition interesting. We have mentioned the neglect of portraiture and figure studies. We have noticed one picture of the kind really worth regarding as a serious attempt. Architecture, again, was hardly represented, and we do not remember to have seen a single flower or fruit piece. In pointing out the direction in which the Exhibition could be improved we do not wish to be understood that we are condemning the work that was exhibited. A large proportion of it showed considerable appreciation of the pictorial possibilities of photography, and, generally, it was tastefully got up. The principal exhibitors were Messrs. Leslie Selby, W. Selby, G. Lamley, F. Holding, F. C. Hart, W. Gillett, M. W. Cockerell, A. E. Cockerell, M. Bartlett, E. C. Beard, and G. F. Blackmore. There were lantern shows each evening. The series we saw on our visit, illustrating the scenery of one of the wildest parts of Ireland, were admirable, and the description by their author, Mr. Lamley, most interesting.

Our Editorial Table.

NOTES ON ILFORD PURE PLATINUM PAPER.

Published by the Britannia Works Company, Ilford, E.

The Britannia Works Company inform us that they are now adding 4x4 Platona paper to their list, twenty pieces being supplied in a sealed

tube for 1s. 8d. The little pamphlet, whose title is given at the heading of this notice, is a neat specimen of the typographic art, and the cover is effectively and strikingly bordered in green and gold. In the course of the sixteen pages the reader is told in simple terms how to make prints on Platona paper. There is not a superfluous word in these simply written instructions, which are so much to the point that the photographer who finds any difficulty in following them must be past praying for. We note that the few formulæ mentioned are given in metric as well as Imperial equivalents. This is what the instructions say regarding the kind of negatives suitable for platinum printing. Whole pages have from time to time been written on a subject which is here well condensed into half a dozen lines:—

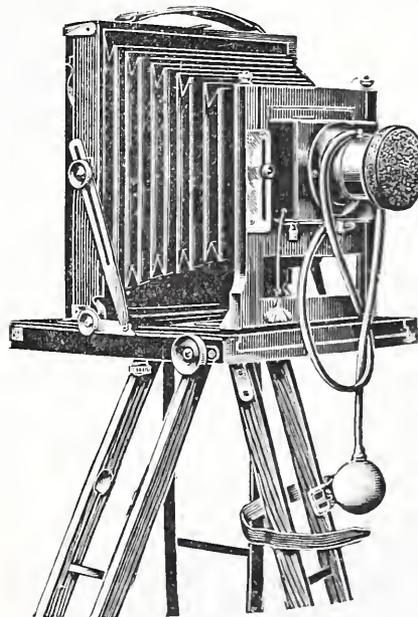

"The negatives used for Platona printing must be of good quality, with a fair degree of opacity, and good, but not excessive, contrasts. Thin and flat negatives will not yield good prints on any kind of platinum paper. On the other hand, no special type of negative is needed for the process, provided that they are reasonably good, and negatives that will give really good prints on P.O.P. will also give first-rate prints on Platona paper if properly printed. Negatives with very strong contrasts, from which it is difficult to obtain satisfactory prints by any other process, will often yield useful results on Platona paper, especially if printed in sunlight."

By the way, the Britannia Works Company ask us to contradict a statement which has been made that Platona paper is not a true platinum paper. Of course, it is nothing else but a platinum paper.

THE HALF-PLATE "APEK" SET.

Manufacturer: Wilfred Emery, 3, Soho-street, W. (and Brondesbury).

THE illustration will convey to the intelligent reader an idea of the principal characteristics of this set of apparatus, which, from personal examination, we can certify to be well made throughout and good value for the money. Here are its "leading features:" The camera has reversing frame, leather bellows, swing back, rising front, double

extension wide-angle movement (giving a focal range of from five to fifteen and a half inches), book-form slide, folding shutters. The lens is a rapid rectilinear with iris diaphragm, the shutter a Thornton-Pickard with pneumatic release, and the threefold tripod has a turntable top. A special feature is the brass turntable with sunk screw, enabling the camera to be used on a table or studio stand, without any wobbling, for copying, &c.

THE MANHATTAN OPTICAL COMPANY'S CAMERAS.

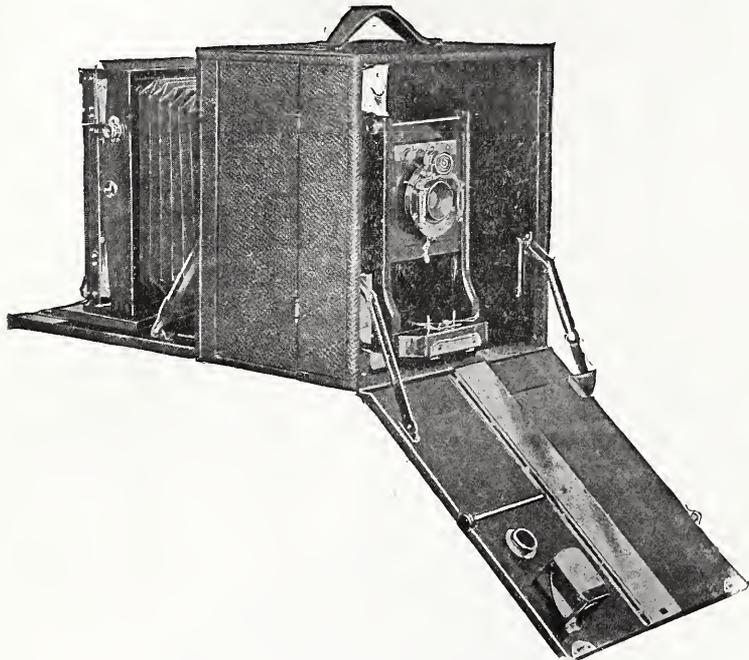

British Agents: Seabrook Bros. & Co., Edmunds-place, Aldersgate-street, E.C.

A CAREFUL examination of a number of the Manhattan Optical Company's cameras, which were recently submitted to us, apprises us that those instruments possess the best features of American manufacture. Mechanically regarded, they are well finished, are compact and portable, and are capable of producing excellent photographs in the hands of those taking up glass-plate photography, in the hand or on a stand. We select three typical cameras from the series for descriptive mention.

THE LONG-FOCUS WIDE-ANGLE WIZARD.—The box is of back and front focus type, this giving a very long bellows. Both the front and back focal adjustments work with great smoothness, the front being provided with a rack and pinion, which permits of fine focussing. The movements in the rising, sliding, and falling fronts are all of great range. The reversible back enables one to make either vertical or horizontal pictures without changing the position of the camera, and is of the double swing type. The horizontal swing is controlled by a worm screw. The

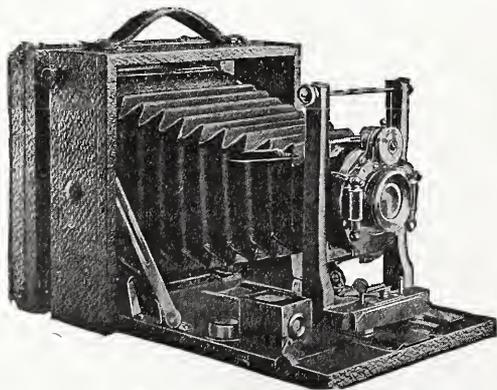

ground-glass frame is spring-actuated, adjusted to the true focal plane, and can be removed when the roll-holder is to be used. On the front bed are a view-finder and spirit-level. When it is desired to use only the front focus, the back bed is dropped as shown, the plate-holder being inserted and the slide removed, through either the side door for horizontal, or the top door for vertical, views. The length of bellows makes the instrument adapted for copying and tele-photo work. When the wide-angle lens is used, the front bed is dropped below the horizontal as shown, and the back focal adjustment is employed.

The box is made of polished mahogany, and covered with black seal grain cowhide; the handle is of sole leather. The metal fittings are finished in nickel. Pressure on the hidden buttons provided for the

purpose causes the beds and doors to open automatically. The long-focus Wizard has a carrying capacity of three double holders, as well as a carrying case for two holders, which fits into the back of the camera.

**THE LONG-FOCUS CYCLE WIZARD.**—The long-focus cycle Wizard occupies the same position in the Company's cycle series as the long-focus Wizard does in the box series, being very compact, and combining all the movements and adjustments which it is possible to introduce in this construction. The box is made from polished mahogany, covered with seal grain leather, and provided with a sole-leather handle. The bellows is of red leather, and all metal parts, with the exception of the shutter, are finished in nickel. Pressure on a hidden spring causes the bed to drop, and the front can then be drawn out and clamped to the track for focussing. A rack and pinion is provided for delicate adjustment of the focus, and is also used to rack out the extension bed for

long-focus work. In this box will be found a long bellows for various sizes. The ground-glass frame is spring-actuated, receding when the holder is inserted. The reversible swing back works at centres, and enables one to take either horizontal or vertical views without changing the position of the camera. Each box is provided with a view-finder, spirit-level, and tripod socket. In addition to one plate-holder, a black or tan sole leather or leather-covered carrying case for the camera and five holders, fitted with a nickelled spring lock and shoulder or bicycle strap, is included.

A less expensive form of camera is the Wizard A, the box of which is made of mahogany, hand-polished, and covered with black seal grain. The handle is of sole leather. The bellows is of red leather, and there are nickelled metal fittings. As in the other cameras, the bed is lowered by pressure on a hidden button, and the front, after being drawn out to the

required point, is clamped to the track by a turn of the lever under the front board. The latter has a rising and falling movement. The ground glass frame is spring-actuated, and can be removed when a roll-holder is to be used. The bed and the focussing and side doors open automatically when the hidden buttons are pressed. Each camera is provided with a reversible finder and two tripod sockets. The Wizard A has three plate holders.

#### SELL'S DICTIONARY OF THE WORLD'S PRESS.

Published by Sell's Advertising Agency, Ltd., 167, Fleet-street, E.C.

THIS is a wonderful book. What it does not tell one about the world newspapers can scarcely be worth knowing. There are over 200 pages of articles on the always attractive subject of journalism and its ramifications, and the dictionary proper takes up another thousand pages or so. The volume is full of interest to those whose business brings them in touch with the press, while even that mysterious person, "the man in the street," could not fail to find something of a readable and informative nature in Mr. Sell's mammoth production. In a note touching upon some of the main features of the dictionary, Mr. Sell says: "I have this year had the book printed on a special paper, and have also reset the magazine lists in two columns, and have thus reduced the bulk of the book, although the matter contained is far more than hitherto. Just at this period the views of the representatives of our great colonies, and the particulars as to how their interests are promoted in the United Kingdom are, I think you will believe, of great interest. All the newspaper and the magazine lists have been thoroughly revised and brought up to date and, in addition to the maps of the counties of England and Wales, &c. I have this year added maps of the less known parts of the world in connexion with the Colonial lists. It will interest you to know that the number of newspapers published in the British Isles is 2473 (London, 521 Provincial, 1952). In addition to the newspapers there are altogether 1685 magazines and 684 quarterly reviews published in Great Britain and Ireland." The book is well worth the 7s. 6d. charged for it.

#### VIGNETTES AND BORDER NEGATIVES.

Walter D. Welford, 19, Southampton-buildings, Chancery-lane, W.C.

FROM Mr. Welford we have received samples of his "Easy Vignette," "Straight-edge Vignette," and "Artistic" border negatives; all these are made on films. The first-named are designed to obviate the hard or harsh effects of other vignetting mediums, without recourse to cotton wool, shading, bending of edges, &c. Being perfectly graduated from transparency to opacity, they may be used close to the negative.

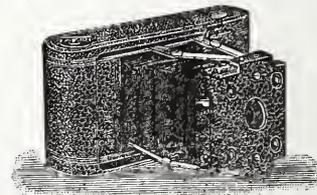

With the Straight-edge Vignette the result is a plain, straight, graduated effect across the film or plate, at different heights, to suit varying subjects. It does away with blocking or shading in combination printing either when printing the foreground or the cloud, and it can also be used for shading the weak parts of a negative.

In the Artistic border negatives the space for the photograph is quite opaque, giving a clear white upon the print, into which it is easy to vignette or print a portrait or landscape. Some effective designs are included in the latter series, which, together with the vignettes above referred to, should be found of very great use in the niceties of photographic printing.

#### THE NO. 1A FOLDING POCKET KODAK.

Manufactured by Kodak, Ltd., 43, Clerkenwell-road, E.C.

AN addition has been made to the popular and convenient series of folding pocket Kodaks in the shape of the No. 1a Folding Pocket Kodak which takes a film  $4\frac{1}{2} \times 2\frac{3}{8}$  inches, thus giving a picture of pleasing proportions. The new Kodak, as will be seen from the electro herewith, is

of the usual folding pocket type, opening and closing with one rapid simple movement. It has an ever-set shutter, and separate levers for time and instantaneous exposures, while a third lever actuates a set of three stops. The dimensions of the No. 1a Folding Pocket Camera are: 8 inches long,  $3\frac{7}{8}$  inches wide, and  $1\frac{1}{2}$  inches thick when closed. It takes spools of daylight films for twelve exposures and for six exposures. The new Kodak sells at 2l. 10s., and the extremely pleasing proportions of the size of picture it takes should ensure it very great success amongst the trade and photographers.

#### Studio Gossip.

It is stated that Lord Monkswell hopes to introduce the new Copyright Bill in the House of Lords during the present session. It follows the recent inquiry which has been made regarding the whole subject. A daily contemporary is of opinion that the best description of it would probably be this—a measure codifying English copyright law, and giving effect to such new conditions as may be thought advisable.

## News and Notes.

MR. JOHN H. GEAR, F.R.P.S., is giving a course of twelve lessons on bromide enlarging, carbon and combination printing, and lantern slides, at the Cripplegate Institute, on Tuesdays, at eight o'clock. Further particulars can be obtained from the Manager, Cripplegate Institute, Goldenlane, E.C.

THERE will be a meeting of the National Photographic Record Association at the Midland Grand Hotel, St. Pancras, on Tuesday, 27th inst., at four o'clock, to receive a report of the work already accomplished, and for having a discussion as to the best means of increasing the usefulness of the Association. Some recent contributions will be laid upon the table.

ROYAL PHOTOGRAPHIC SOCIETY.—February 27 (Tuesday), at eight p.m., at 36, Russell-square, "Electricity in Connexion with Photographic Action," by Mr. W. Friese-Greene. We are asked to state that Mr. J. Craig Annan's Exhibition will close on Wednesday, February 28. The March Exhibition will be provided by the National Photographic Record Association, and will be opened at eight p.m. on Wednesday, March 7, by Sir Benjamin Stone, M.P.

PHOTOGRAPHIC SECTION, G.E.R. MECHANICS' INSTITUTION, STRATFORD, E.—The Seventh Annual Photographic Exhibition will be held at the Institution, Store-street, Stratford, on Tuesday and Wednesday, March 13 and 14. There will be cinematograph displays each evening at 8.15 p.m., lantern shows at 9.15 p.m., vocal and instrumental music at intervals, and photo-chromosome and other photographic attractions. The Exhibition will be opened on Tuesday evening, March 13, at 7.30 p.m., by Mr. Horace Wilmer, F.R.P.S. We may remind interesting exhibitors that one silver and two bronze medals are offered for competition in the open class, and that entry forms should reach the Hon. Secretary not later than Monday, March 5.

WE have seldom been present at a more enjoyable entertainment of the kind than the Fifth Annual Bohemian Concert held by the employees of Messrs. Fallowfield at the Champion Hotel, Aldersgate-street, on Friday evening, February 16. Mr. F. W. Hindley presided over a large gathering, for whose amusement a capital programme of songs, sketches, and instrumental music had been provided. Mr. C. E. Johnson was an excellent pianist, and particular praise must be awarded to the contributions of Miss Marie Kehrein, Miss Milbanke, Mr. Owen Way, Mr. John Probert, Mr. Carl Brandt, Mr. Tom Day, Mr. Aubrey Wills, Mr. Louis Mackenzie, and Messrs. Quinton and Guernsey. Master H. J. White sang "The Absent-minded Beggar" with first-rate effect, and the usual tambourine collection resulted in the addition of a sum of 4l. 2s. to the *Daily Mail* Fund. Mr. H. J. White was in the vice-chair. The courteous Committee consisted of Messrs. J. T. Craig, H. W. Fellows, W. C. Hardman, and J. C. Preece, the Hon. Secretary being Mr. F. J. Goode, who was as hard-working and attentive as ever. A vote of thanks was passed to the Chairman for presiding, and the most successful concert yet held by Messrs. Fallowfield's employees terminated to the great satisfaction and enjoyment of all concerned.

## Commercial Intelligence.

MESSRS. R. & J. BECK, of 68, Cornhill, E.C., are now supplying the No. 00 Frena camera covered with khaki at 3l. 12s., including forty celluloid films. Messrs. Beck are also exhibiting in their window a Frena enlargement of a 7-inch naval gun on trolley landed at Durban, and now in use at Ladysmith.

MARION'S ANNUAL STOCK-TAKING SALE.—Last week, owing to the information reaching us at the moment of going to press, we could only make a very brief reference to Messrs. Marion's Annual Stock-taking Sale, an event always of the greatest interest to photographers and the trade. The Sale will be held from March 5 to 17. Catalogues, with description of clearance lines from all departments, photographic and fancy, will be ready about March 1, and will be sent post free on application.

DR. CARL SCHLEUSSNER, one of Germany's most prominent theoretical and practical workers in the different branches of photography since its early days, died recently at Frankfort-on-the-Main, at the age of seventy years. He had a large laboratory for the manufacture of chemicals, particularly collodion and nitrate of silver, but he was more extensively known by his dry plates, which enjoy a high reputation in Germany. For many years he was President of the Verein zur Pflege der Photographie at Frankfort.

MR. A. C. BALDWIN, of the Paget Prize Plate Company, writes us: "Will you kindly allow me, through the medium of your columns, to tender my apologies to the members of the following societies, Bolton, Ashton-under-Lyne, Leigh, Bootle, for not appearing to give my demonstration on Gravura? Unfortunately influenza has claimed me, and the doctor forbids my going out. I am just on the point of concluding a most successful tour, and this is the inglorious manner in which I, perforce, must finish it." We wish Mr. Baldwin a speedy recovery from the fashionable ailment.

MESSRS. GAUMONT & Co., of 25, Cecil-court, Charing Cross-road, W.C., inform us that the Prince of Monte Carlo some time since arranged a competition among cinematographers, with the idea of encouraging and developing this branch of photography. The prizes, of which there were eleven, were personally awarded during the last few days by the Prince to the successful competitors at Monaco. Nine of the prizes were obtained by competitors possessing Demeny's Chrono-photograph Machine made by L. Gaumont & Co. The machine is better known in this country under the abbreviated title of "The Chrono."

THE AUSTIN-EDWARDS MONTHLY COMPETITION.—The following is the list of awards in the lantern-slide and film-negative competition for February: lantern-slide competition: 3l. cash prize, Mr. J. Gunston, Wimbledon, *The Riffelhorn*; 2l. cash prize, Mr. W. M. Dodson, Bettws-y-Coed, *Late Autumn*; 1l. cash prizes, Mr. E. R. Bull, Forest Hill, *Panel, St. George's Chapel, Windsor*; Mr. J. A. Wilson, Liverpool, *A Winter Afternoon*; Mr. P. H.

Grandin, Jersey, *Portrait of General Don, Governor of Jersey, 1806*; Rev. E. Healy, Leamington, *Return from Market, Interlaken*; Mr. G. H. Schafer, Balham, *Summer Sunshine*. Film-negative Competition: The Frena camera given each month for the best negative on an Austin-Edwards film has been secured by Mr. V. Thompson, Wellingborough, for his negative *Ornamental Gates of Castle Ashby Norths*.

## Patent News.

THE following applications for Patents were made between February 5 and February 10, 1900:—

- OXYGEN.—No. 2232. "Improvements in the Manufacture of Oxygen." J. BILBIE and J. A. WANKLYN.
- ANIMATED PHOTOGRAPHS.—No. 2283. "Apparatus for Use in Taking, Printing, and Exhibiting what are known as Animated Photographs." E. L. DOYEN.
- ANIMATED PHOTOGRAPHS.—No. 2284. "Apparatus for Perforating, more especially intended for Perforating Cinematograph Photographic Bands of Film." E. L. DOYEN.
- ANIMATED PHOTOGRAPHS.—No. 2285. "Improvements in Apparatus for Taking and Exhibiting or Viewing what are known as Animated Pictures, and other Pictures or Representations." E. L. DOYEN.
- SENSITISED PAPER.—No. 2373. "Improvements in Sensitised Paper for Photographic Printing." Communicated by R. B. West. Complete specification. H. H. LAKE.
- CAMERAS.—No. 2624. "Improvements in or relating to Photographic Cameras." THE BRITANNIA WORKS COMPANY, LTD., A. C. SMITH, and A. A. SMITH.
- X-RAY APPARATUS.—No. 2638. "Improvements in Röntgen-ray Apparatus and in Interruptors applicable for use in connexion therewith, or for other purposes." J. M. DAVIDSON.

### ROYAL PHOTOGRAPHIC SOCIETY.

FEBRUARY 20,—MR. T. R. DALLMEYER, F.R.A.S. (President), in the chair.

#### THE RETIRING PRESIDENT.

At the opening of the meeting, the President alluded in terms of the highest appreciation to the very valuable services which had been rendered to the Society by the Earl of Crawford, his distinguished predecessor in the chair, and at his instance a most cordial vote of thanks was accorded, with acclamation, to his lordship in recognition thereof.

Professor R. W. WOOD, of Wisconsin University, gave a most interesting lecture upon the subject of his researches in three directions. In the first place he dealt with

#### ZONE-PLATE PHOTOGRAPHY.

The zone-plate is made by drawing on a large sheet of paper a number of concentric circles, forming a black and white target with rings decreasing in width as the distance from the centre is increased, making a reduced negative of the target, and then a transparent positive on a glass plate—about the size of a shilling—coated with bichromated gelatine. Professor Wood said he had made a small telescope with a zone plate in lieu of an object-glass, and it would show, although not very distinctly, some of the larger volcanic craters on the moon; and he exhibited two lantern slides from negatives taken in a camera, with a zone plate instead of a lens. A peculiarity which it possessed

was that it had three or four different foci, and in its action it differed both from a lens and a pinhole in that it gave a fairly sharply defined image which had superposed upon it the blurred image due to its multiple focus. The exposures were about half a second, with a rapid plate.

#### PHOTOGRAPHY OF SOUND WAVES.

PROFESSOR WOOD next showed a series of photographs of sound waves, which he had made quite recently, the sound being that of an electric spark. He explained that the time of exposure must be so short that the wave will not move any appreciable distance, and that the exposure must be made at just the moment when the wave of sound is in the field, and he drew a diagram showing how he had fulfilled these conditions by starting the wave with one electric spark, and then illuminating and photographing it by a second spark caused by the first, behind which it lagged just long enough to allow the wave to get fairly started. He exhibited many slides showing the behaviour of sound waves under different circumstances, and dealt very fully with the subject and with the methods and apparatus which he had adopted for securing the photographs.

#### DIFFRACTION-GRATING COLOUR PHOTOGRAPHY.

The final division of Professor Wood's address was devoted to his process of diffraction-grating colour photography, the main features of which have already been detailed in THE BRITISH JOURNAL OF PHOTOGRAPHY, and particularly in the ALMANAC for 1900 (p. 830), and the principle of which was simply summarised in Ex Cathedra last week. About a dozen of the lecturer's results were exhibited in the Council Room, with the necessary viewing instruments, and they were examined with much interest both before and after the lecture by the large number of members and visitors who were present.

The PRESIDENT referred to the researches of Du Hauron and Joly in three-colour heliochromy, and to Professor Lippmann's process of interference colour photography. The latter, he said, was a physicist's work, founded entirely on theory, and Professor Wood had followed with a similar highly scientific achievement. He asked whether there was any limit to the reproduction of diffraction gratings by means of bichromated gelatine, so far as the number of lines to the inch was concerned.

Professor WOOD said he had made satisfactory copies of gratings with 14,000 lines to the inch.

Mr. DANDO showed a copy of a 14,000 line grating, made by Mr. Thorpe, of Manchester.

Professor WOOD remarked that the problem had been attacked in a very ingenious manner by Mr. Thorpe, who had devised a means of working with only one grating.

Mr. E. J. WALL, after complimenting the lecturer on the extremely valuable and lucid nature of his communication, referred to the colour photographs which were exhibited, and said that, although they showed brilliant spectrum reds, blues, and greens, he had been unable to detect any half-tones or gradations of colour. He asked whether this might not be due to the fact that the rulings of the gratings—which were respectively 2000, 2400, 2750 lines to the inch—were a little too far apart, and also whether this lack of intermediate colours arose simply from the negative or was inherent in the process. He had made some experiments with the method, and had met with the same difficulty himself. He also asked for information as to the proper thickness of the film of bichromated gelatine employed for printing and the strength of the solution.

Professor WOOD admitted that the lack of intermediate shades of colour was at present the great drawback to the process, but it was not inherent in the theory; it was caused by the mechanical difficulties in printing diffraction gratings, and these would be overcome. The gelatine solution was made by dissolving 5 grammes of Nelson's photographic gelatine in from 125 to 150 c. c. of water, and adding 6 or 8 c. c. of a saturated solution of bichromate of potash; a clean glass plate was coated, and drained until the drops falling from the edge fell every two or three seconds, when the plate was levelled and dried.

#### COMING EVENTS.

February 27, "Electricity in Connexion with Photographic Action," by Mr. Friese-Greene. March 6, Lantern Evening, "Some Beauty-spots of English Scenery," by Mr. J. A. Hodges. On March 7, Sir Benjamin Stone, M.P., will open an Exhibition of work contributed by the National Photographic Record Association. He will give an introductory address at eight p.m., and the Exhibition will continue during the remainder of the month.

**Croydon Camera Club.**—February 14, Tenth Annual Meeting.—From the statement made by the PRESIDENT it would appear that the Club has passed through one of the most successful of its years. Forty evening meetings have been held, when special programmes have been provided. At these the attendances, excluding public lantern shows, when the audiences ran into hundreds, averaged thirty per meeting. The third Exhibition held at the Art Gallery proved in every way successful, the accounts showing a profit to the Club, while the total attendance is calculated to have been over a thousand. It was unanimously decided that in future the Exhibition should be held annually during February, the next one to be in February, 1901. The roll of members is larger than ever. There are no outstanding liabilities, while on the other hand a considerable amount of cash and property represents the assets. The following were appointed to act as officers and Council:—*President*: Mr. Hector Maclean, F.R.P.S., F.C.S.—*Vice-Presidents*: The Mayor of Croydon (Councillor N. Page), Sir David Salomons, Bart., The Right Hon. C. T. Ritchie, M.P., Sir Frederick Edridge, J.P., Mr. James Glaisher, F.R.S., and Alderman G. G. Allen, J.P.—*Council*: Messrs. Isaac, Jenkins, Noaks, Packham, Wratten, Irving, Chadwick Taylor, Willcocks, Ben. E. Edwards, W. H. Smith, Stanley, and Jeffery, of whom the last four named are fresh blood.—*Hon. Lanternist*: Mr. A. E. Isaac.—*Hon. Treasurer*: Mr. H. E. Holland, 69, Lansdowne-road, to whom, in future, all subscriptions should be forwarded direct.—*Hon. Secretary*: Mr. W. H. Rogers, 46, Bensham Manor-road, Thornton Heath. Amongst other matters of interest, it was decided to hold the annual dinner about the last week in March. It was

resolved that on March 14 a grand special lantern entertainment in the Large Public Hall be held, in aid of the war fund for the widows and orphans. The PRESIDENT, in pressing the matter forward, reminded those present that at a moment when the empire was passing—he ventured to hope safely—through a crisis, the like of which, he trusted, would not recur, those who were obliged to stay at home should not count their coppers nor spare their shillings, but strain every nerve, not only to help provide for those who become needy through the loss or disablement of the bread-winner, but also see to it that the spirit and ardour of their neighbours were not allowed to flag. With much more to the same end, Mr. Maclean asked the meeting not merely to approve the project, but to also resolve that they individually would make it a great and striking success.

**Richmond Camera Club.**—At the meeting on the 5th inst., to which ladies were invited, a lecture entitled

#### ATHENS TO OLYMPIA

was given by Mr. A. VANDERDRIESCHE, of the Kingston Photographic Society. Notwithstanding the bad weather, there was a good attendance.

At the meeting on the 12th inst., Mr. G. McK. MUNRO gave a paper on

#### ANIMATED PHOTOGRAPHY FOR AMATEURS,

illustrated practically by the Biokam. Mr. Munro commenced by giving a short history of animated photography, and then he showed fully the working of the Biokam (which is about the size of a small hand camera) by means of an admirable set of lantern slides. He then showed the method of developing the negative film and printing positives therefrom, and concluded by showing a large number of living photographs, in which the absence of flickering was particularly noticeable. Mr. Munro was most efficiently assisted in his lecture and demonstration by Mr. Coysh.

**Southsea Amateur Photographic Society.**—February 8, the Twelfth Annual General Meeting. Mr. H. T. Lilly, M.A. (President), in the chair.—The HON. SECRETARY (Mr. F. J. Mortimer), in submitting his report on the year, congratulated the Society upon its sound position both as to its sphere of usefulness and popularity, and more particularly financially. The Society was steadily progressing, and the standard of work amongst the members had risen much higher than in any previous years, and signs were not wanting of a still greater advance in the future. The membership had increased twofold, and the sustained interest taken in the Society's affairs was largely to be attributed to the introduction of this newer blood, which was eminently desirable as maintaining the vigour of the Society, and imparting to its proceedings that liveliness which was the surest sign of health and the best basis of success. The expenses during the year had been heavy, but the Treasurer's report would show that the Society was never in a sounder financial position than at present, and there was a substantial balance in hand. The demonstrations and lectures had been well attended, and the lantern nights had become more numerous and interesting. The Society continued affiliated to the Royal Photographic Society, and made full use of all the advantages the parent Society offered. The outings during the year had been successful, more particularly those not prearranged, and it was thought advisable during the coming year to aim chiefly at a series of small parties under the leadership of some member chosen for each occasion at the time. The fine rooms of the Society in Pembroke-road, Portsmouth, had been entirely renovated, and the upper stories rebuilt, and increased facilities were offered to the members, as, in addition to the rooms for the use of members and the library, which now included most of the standard works on the art, as well as all the periodicals, there was also a completely fitted developing room and daylight enlarging apparatus. Since its foundation in 1888, the Society had steadily increased in importance, and, at the successful Exhibition held in January, the Judges (Messrs. H. Snowden Ward, G. West, and H. Symonds) had expressed the opinion that the Society would now compare favourably with any other provincial society. That the Society was capable of doing good in other directions was evidenced by the success of the Dickens' Land lecture by Mr. H. Snowden Ward. This lecture, given at the Town Hall in December last, and organized entirely by the Society, enabled 45l. to be handed over to the War Fund for the relief of the dependants of the "gentlemen in khaki" now fighting in South Africa. The TREASURER then submitted his report, which was highly satisfactory, showing a good balance in hand. The accounts were passed, and the HON. SECRETARY then read a balance-sheet of the Exhibition, which showed that, as a result, a sum nearly equal to the entire balance of the Society would be handed over, the Society thus entering on the thirteenth year of its existence with the rosiest of prospects. The officers for the year were then elected as follows:—*President*: Mr. H. T. Lilly, M.A. (re-elected).—*Vice-President*: Dr. C. H. Newby.—*Council*: Colonel H. W. B. Bruno, Dr. F. Lord, Messrs. G. Whitefield, E. H. Purvis, H. Canning, and P. Denham.—*Treasurer*: Mr. F. G. Lewis.—*Hon. Secretary*: Mr. F. J. Mortimer.—*Assistant Hon. Secretary*: Mr. F. O. Field. Mr. Luther Dyer was appointed Hon. Lanternist to the Society. It was resolved to hold meetings at the rooms on Mondays and Fridays in addition to the usual Wednesday meetings, and it was proposed to form a ladies' section, and a Committee was appointed to consider the details.

#### FORTHCOMING EXHIBITIONS.

- 1900.
- February 23, 24 ..... Edinburgh Photographic Society. J. S. McCulloch, 10A, George-street, Edinburgh.
- " 24-March 3 Birmingham Photographic Society. Lewis Lloyd, The Hollies, Church-road, Moseley.
- March 3-10 ..... South London Photographic Society. Hon. Secretary, Frank Goddard, Woodlands, Vanbrugh Hill, Blackheath, S.E.
- " 13, 14 ..... G.E.R. Mechanics Institution (Photographic Section). C. W. Harris, 294, Cam Hall-road, Leytonstone, E.

March 26 ..... Twentieth Century International, Birmingham.  
Walter D. Welford, 19, Southampton-buildings,  
Chancery-lane, London, W.C.  
" 26-31 ..... Photographic Society of Ireland. W. F. Cooper,  
35, Dawson-street, Dublin.  
April 3-7 ..... Birkenhead International. C. F. Inston, 25, South  
John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

## Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### PORTABLE STUDIOS.

To the EDITORS.

GENTLEMEN,—Reading THE BRITISH JOURNAL OF PHOTOGRAPHY, February 2, 1900, I see in Answers to Correspondents that M. E. Bradford asks for information about "Herr Schaetzer's portable studio."

I therefore beg to inform you that the portable studio in question has been invented and is made by Herr Felix Schaetzke (not Schaetzer), photographer, of Bochum, Germany, who has applied for patents in Germany and thirteen other States. It is a flashlight studio, but may be equally well used as a daylight studio with a very perfect lighting arrangement. It may be erected in every studio and in every room, and can be removed within fifteen minutes. Its price is 750 marks. The portraits and groups taken in this studio, and which I have seen, were of a very remarkable good lighting, and made not at all the impression of flashlight pictures.

All further particulars may be obtained at the under-mentioned address.

—I am, yours, &c., HERMANN SCHNAUSS, Editor "Apollo."  
"Apollo" Redaction, Dresden, February 14, 1900.

### TYLAR'S "TIT-BIT" HANDICAP FOR THE "ABSENT-MINDED BEGGARS' FUND."

To the EDITORS.

GENTLEMEN,—I should like to jog the memory of your readers who have not already sent their shillings, and a stamped directed envelope, to secure a ticket in the distribution of twelve "Tit-Bit" hand cameras, which I offered for the purpose of raising a fund to supply requisites for the use of Dr. Hall-Edwards in connexion with his work at the seat of war. The latest date I can receive contributions is February 26. Up to date, February 15, 1900, I have received 297 shillings; this gives an average of one chance to about each twenty-four competitors.

Messrs. Lennon & Co., of London and Cape Town, have kindly offered to deliver the case of goods to Dr. Hall-Edwards free of charge. Now, you professionals, spare five minutes and rush off to get those stamps, and send your shilling and a stamped addressed envelope to me at once, as I am anxious the photographers of England should show their brethren at the front that they are not forgotten.—I am, yours, &c.,

W. TYLAR.

High-street, Aston, Birmingham, February 15, 1900.

### STEREOSCOPIC PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—Being a subscriber of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, and more than amateur in stereoscopic photography, I take leave in asking you a favour. Could you kindly give me the address of sellers or loaners, single or in series, stereoscopic glass transparencies or prints on paper of foreign countries. Having re-awakened the interest of the Bohemians for stereoscopy, a friend of mine mounted two panoramas at Austria, where my pictures from my last travels through Asia and Indo-Australia are exposed. It has met with such success that the public have a strong desire to see more.

The object is wholly educational, and therefore my friend asked me to inquire whether it is possible to obtain views from the English colonies, South Africa mostly desired. Thanking you for your future services, and at all times at your service,—I am, yours, &c.,

E. ST. VRÁZ, *Scientific Explorer.*

150, West 12th Street, Chicago, Ill., February 8, 1900.

[Messrs. Lévy, of Rue Louis Le Grand, Paris, supply stereoscopic transparencies. Amongst the firms who make a speciality of stereoscopic slides may be mentioned Messrs. Underwood & Underwood, 26, Red Lion-square, London; Messrs. Seaman & Sons, Chesterfield; Mr. W. Tylar, High-street, Aston, Birmingham; Messrs. Catherall & Prichard, 326 Camden-road, London, N.W. Perhaps the firms named will send our correspondent their catalogues.—EDS.]

To the EDITORS.

GENTLEMEN,—I beg to enclose a few stereoscopic prints as a token of my appreciation and enjoyment of your interesting article in the ANNUAL.

The tenth section of your article was of special interest, as it shows me that what I have hitherto regarded as an original idea of my own is already in use. I refer to the illustration of books by stereographs, for the benefit of those who possess the faculty of focussing, by acquired control of the eye muscles, without the use of a glass.

I have never seen a book illustrated in that way, and have intended for years to make an attempt to produce one.

If you will kindly refer me to the publishers of any such books, I should esteem it a great favour.

One single point occurs to me, which possibly may have escaped your attention, in connexion with focussing with the eyes alone, which, in my own practice, I have found of great value. In taking the picture, when focussing on the ground glass, to reverse the process employed with prints, which, being transposed, need to be viewed axially, and instead, getting the stereoscopic effect on the ground glass of the camera itself by "squinting" at the unreversed pair of images. Again thanking you for your able article, I am, yours, &c.,

OREGON.

[We thank our correspondent, who also writes from the United States, for the interesting series of stereoscopic pictures he is good enough to send us. It is a pleasure to us to know that so much interest is taken in stereoscopic photography by our American brethren, and we are always glad to answer questions on the subject. Messrs. C. Arthur Pearson, Limited, of Henrietta-street, London, publish a book illustrated with stereoscopic views. It is termed *Impressions of America*, and is by Mr. T. C. Porter, M.A., a well-known amateur photographer and President of the Eton College Photographic Society. The price is 10s. 6d. With regard to viewing the image on the ground glass stereoscopically, this is done by crossing the axes. We have heard of persons possessing this power; but we imagine it is exercised at the risk of contracting some form of strabismus, or permanent squinting.]—EDS.

### THE CAMERA IN THE CAMP.

To the EDITORS.

GENTLEMEN,—Your correspondent, "J. F. T.," in his attempt to belittle the utility of photography as an aid in military operations, has adopted controversial methods which are more time-honoured than convincing. Thus, he asserts that the camera will not do things that I have not in my article claimed for it; he also suggests that I should try the experiment myself, failing which I should, inferentially, hold my peace.

Again: He states, "To expect that men . . . should carry in their heads a complete knowledge of the topography of a country from hearing a few lectures is absurd." Certainly; but not much more absurd than being content with complete ignorance.

If plan and sketch are found best, by all means use them; but they were in Buller's case not available, while, as indicated in my article, photographs *might* have been obtained. In such a climate a horseman might cover twenty or twenty-five miles a day, and, by means of a hand camera, obtain some fifty photographic notes far more full of possibilities of useful information than are included in sketches and plans taken at the same rate. To be sure, route surveys and sketch plans will have a value all their own, particularly where the man who makes the plan has a definite object in view—i.e., to locate positions for guns, or indicate river fords, &c.; but where general, as distinct from particular, information is required, despite "J. F. T.'s" letter, I remain of the opinion that, properly used, the camera is an easy first as a reader of topography.

It is so quick in gathering its information, which is only accurate in outline, but exceedingly comprehensive in character.

Having during the past ten years presided over more than a hundred lantern shows, I am able from personal experience to speak of the great educating power of the photograph shown on the screen. Certain parts of England, and of Europe, have, by means of repeated displays of sets of slides illustrating the districts in question, been so strongly impressed upon my mind, that I seem to know these regions in some respects probably better than do half the people who live amongst the scenes referred to.

And to-day "the man in the street" pictures in his mind—sometimes very vividly and accurately—the physical aspects of South Africa entirely by means of, generally, smudgy process blocks reproduced from negatives which oftentimes have been either hastily or unskillfully taken. If under such happy-go-lucky circumstances, without special skill or system, so much may be imparted, how much more could be taught by the methods advocated in my article!

We have been out-classed in big guns, and yet would not have "Pompoms." We lack maps, and yet scorn photography. This attitude may be wise, but such is not the opinion of yours, &c.,

Croydon, February 17, 1900.

HECTOR MACLEAN.

### NATIONAL PHOTOGRAPHIC RECORD'S EXHIBITION AT THE PHOTOGRAPHIC CLUB.

To the EDITORS.

GENTLEMEN,—I have to inform you that on 28th inst., at this Club's meeting at Anderton's Hotel, an Exhibition of Prints by the Photo-

graphic Record Association, will be held, and a number of lantern slides, illustrating the same subject, by Sir J. Benjamin Stone, M.P., will be shown.

Members of photographic societies generally, and all interested in the object of the Association, are invited, and will be cordially welcomed by the Club on the occasion, when it is hoped that parliamentary engagements will permit Sir J. Benjamin Stone to attend.—I am, yours, &c.,

W. R. STRETTON, *Hon. Sec. and Treasurer.*

4, Queen-street-place, London, E.C., February 17, 1900.

### NEGATIVES BY POST.

To the EDITORS.

GENTLEMEN,—In this week's JOURNAL I observe a letter respecting some prints lost in the post, the writer insinuating that they had never been dispatched.

I am much surprised you should publish such a letter without knowing further of the matter, as the pointed manner in which it is written leaves little doubt to many people as to whom it refers.

I have proof of delivery of goods to the post-office, who plainly state they give owner compensation for loss or damage.

On receiving notice of prints missing, I advised your correspondent to send in his claims. This he evidently has done, as the only particulars the postal authorities have asked me are the date and place of posting. And yet he asks what course he should take. Does he expect compensation twice?

Out of many hundreds of parcels similarly sent, I have had but one other complaint of contents missing. These were found shortly afterwards loose in the post, as, probably, those of your correspondent have been. In the other case, rather than my customer should be inconvenienced, I sent on a second lot, as I would have done in this case had not Mr. Willatt sent me an abusive letter, stating that he knew they had never been sent.—I am, yours, &c.,

HENRY M. WARD.

41, Belgrave-avenue, Leicester; February 17, 1900.

[With reference to the second paragraph of the above letter, we may point out that the communication we published last week referred to a "photographer in Leicester." Besides Mr. Ward, there are about twenty other photographers in Leicester, hence his theory that we ought to have known that our correspondent referred to him is, to say the least of it, remarkable.—EDS.]

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

E. F. Richards, 12, Victoria-road, Penrith.—*Photograph of Captain W. H. Parkin.*  
McLucas & Co., Vaughan-street, Llanelly, South Wales.—*Photograph of Mrs. Gwilym Evans.*

J. Owen, 49, Broad-street, Newton, North Wales.—*Two photographs of groups of S.W.B. Volunteers ordered to South Africa.*

R. S.—If you will give us the name of the camera to which the changer is fitted, we may be able to assist you. Without that information it is impossible for us to trace the makers.

PUZZLED.—If the photographs are registered in your late employer's name, the copyright is, *de facto*, his, and you must obtain an assignment of it before you can benefit by it. This is the legal position of affairs.

J. CHATTERELL.—Messrs. Epstein & Co., Bristol; Marion & Co., Soho-square, London; Sichel & Co., Bunhill-row, London, may be able to supply. See the advertisements in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1900.

E. C. L.—Paper suitable for the purpose may be obtained from Messrs. Otto König & Co., 27, Cross-street, Finsbury-pavement. With regard to methods of coating, you will gain some useful information from Dr. Just's book on bromide papers, published by Messrs. Percy Lund & Co., Bradford.

STAINED PLATINOTYPES.—ALPHA writes: "What is the cause of the fading of this platinotype? It has not been done a year, and I have several others like it."—The print has not faded, but the paper has become yellow through the iron not being thoroughly removed when the print was produced.

APPARATUS QUERIES.—C. G. KERR (Edinburgh). 1. We have examined the camera and lens referred to; they will give good results. 2. We have made no tests of comparison, and, if we had, it is strictly against our rule to give such information. 3. We have seen really first-rate results produced with the apparatus named. See also answer to No. 2. 4. Most of the large houses now issue sets of half-plate apparatus ranging in price from 3*l.* to 5*l.*, with which good photographs can be taken. We do not answer questions through the post.

NIGGER and DAVEY have not sent their names and addresses. In every number of this JOURNAL it is stated that "no notice is taken of communications unless the names and addresses of the writers are given." The queries of "Nigger" and "Davey" have therefore gone into our waste-paper basket.

SIZE OF CONDENSER.—W. E. SEARLE writes: "What size condenser must I have for enlarging from seven and a half by five inch negatives, using the limelight?"—A condenser of nine inches diameter will be required. Nine and a half inches would be better if the whole of the subject is to be included in the enlargement.

BOOK ON STUDIO-BUILDING.—E. JONES says: "I want to build a small studio. Will you please tell me of a book (and where I may get it from) that will tell me how to make the studio?"—In reply: *Studio-construction*, by Mr. Thomas Bolas, published by Marion & Co., Soho-square, W. Price (we believe) 2*s.* 6*d.*

COLOUR OF ENLARGEMENT.—H. H. sends a portion of an enlargement on bromide paper, and asks the reason of the heavy cold blacks and absence of detail in the shadows. He adds that the paper is —'s, and that ferrous oxalate is used.—The cause is under-exposure and forced development. The remedy is a much longer exposure. Also see that the temperature of the developer is not below 60° F. while this cold weather lasts.

OIL BUBBLES ON OPALINES.—R. SELLERS asks: "Can you kindly tell me the cause of the small glistening specks on the enclosed opaline? All I mount have them more or less. The one sent is a bad case."—The defects are due to small bubbles of air imprisoned between the photograph and the glass. In mounting, take care there are no air bells in the gelatine, and see that there are none between the print and the glass before the squeegee is applied.

TRICOLOUR.—The plate named should, in accordance with its spectrum sensitiveness, answer for the production of the three negatives. With regard to the screens, if you address Messrs. Penrose & Co., Upper Baker-street, E.C., they may be able to supply you. The work is perfectly possible both by collotype and photo-lithography. On the latter subject, Fritz's book—published by Dawbarn & Ward, 6, Farringdon-avenue, E.C.—is perhaps the best. Write again if we can be of further help.

DAMAGED LENS.—L. E. N. S. says: "I have accidentally dropped my 10 × 8 R.R. lens and it has cracked one of the glasses of the back combination, the other is all right. Can you tell me the cheapest place to get a new glass put in?"—We should recommend you to send the instrument to its maker. By so doing you will ensure the lens being restored to its original quality. That will possibly not be the case if it is put into the hands of another optician, and who probably will have to charge more for the work.

WATER SUPPLY.—AQUA writes: "I have a small private house, in fact, a six-room cottage, in which we do the printing and mounting. The Water Company have given me notice that in future I must pay for the water by the meter, and not as a rate, as hitherto, because I am using it for trade purposes. Can the Company compel this, as it will make a great difference to me, as I leave the prints in running water all night, and that uses a lot?"—The Water Companies can, if the water is used for other than domestic purposes, compel you to pay by meter.

ANXIOUS.—No one book contains all the information you require, but you would gain much assistance from *The Studio and What to Do in it*, by H. P. Robinson, published by Sampson Low & Co., Fetter-lane, E.C. Just's book on bromide printing and enlarging would also be useful. It is published by Percy Lund & Co., Bradford. Our ALMANAC for three or four years would be found of service, as it contains a great many practical hints. With regard to the lens, one of the anastigmatic type, of about sixteen inches focus, would, perhaps, be the most suitable for all-round purposes.

VALIDITY OF PATENT.—X. A. says: "Last year I took out a patent for a piece of photographic apparatus and I wish to sell it. I am now told that the patent is not valid, as two of the five claims in it are for what has been done before. I find, on referring to a back volume of the JOURNAL, that such is the case, but the other three claims are admitted to be original. Will not the three claims to originality sustain the patent?"—No. If one claim is bad, the whole patent is invalid. You can, however, disclaim the two bad claims, then the patent will be valid, that is, supposing the others are for what is original. Better consult a patent agent in the matter.

STUDIO-BUILDING.—J. T. asks: "1. I have built a studio out of an existing building, the roof being all glass. I wish to block out the light on the south side. I have thought of pasting over with brown paper, white-washing afterwards to make it look presentable. Can you tell me a better method than this? 2. A good substitute for ground glass? 3. What colour curtains do you recommend for studio?"—1. Brown paper will do very well. A little blue added to the whitewash will be an improvement. 2. Fluted glass, if it is intended merely to prevent its being seen through. 3. Pale or dark green, according to the aspect. If that is north, light green will be a good colour.

SUBSTITUTES FOR GROUND GLASS.—C. F. RATCLIFF asks: "What best can I use as a substitute for ground glass when used for the backing of stereoscopic transparencies? I have used sugar of lead in collodion, giving a kind of opal backing. Is there anything better than this, or is there anything one could stain the transparency film with that would serve the purposes of backing better. I have also used as a backing tracing paper of fine grain, but this is only permissible when there is no sky or clear glass in the transparency.—In reply: An emulsion of oxide of zinc and isinglass has been found satisfactory. Carbonate of lead, trinitrate of bismuth, or alum white, may, we believe, be substituted for the oxide of zinc.

### EX CATHEDRÂ.

THE "historic birthplace of artistic copyright," as the Society of Arts was termed by one of the contributors to the discussion which took place there on Wednesday week, after the reading of Mr. Edwin Bale's paper on the subject, was the scene of a meeting which we hope no photographer in these islands will ever forget. It is best at once to be plain-spoken in the matter. The objects of those in whose interests the meeting was called are to secure better protection for copyright in paintings, sculpture, and other works of art, and to rob photography of the rights conferred upon it by the Act of 1862. We are grateful to Sir Henry Wood and the Executive of the Society of Arts for having allowed this meeting to take place, as it gives us the opportunity of again directing the attention of photographers to the fact that their copyright interests are menaced by a number of people who can scarcely be credited with either justice or fairness towards photography; in other words, an attempt is to be made to use the legislature for the purpose of throttling photography once and for all, and thus to prevent it competing in the open market for public patronage with other methods of graphic expression. We say

deliberately that, if the promoters of the Copyright Bill discussed at the Society of Arts the other night get the measure passed in the form it possessed last year, photographic progress will be seriously impeded, and all photographers in the United Kingdom, from the highest to the lowest, will be made to materially and permanently suffer.

\* \* \*

THE right of painters, sculptors, black-and-white workers, and others to seek better protection for their copyright interests, if it be needed, cannot be denied; and, in so far as their demands are reasonable, Mr. Bale and his *protégés* are entitled to public sympathy and support. But how do these gentlemen derive a mandate to propose legislation for copyright in photographs? They have received no such mandate. Their intervention is uncalled for, and is grossly impertinent. Next, who is Mr. Edwin Bale, R.I., that he takes upon himself to define the exact form of copyright protection which photographs should have? Mr. Bale, if we are rightly informed, is Art Director of the publishing firm of Cassell & Co., Limited. We ask photographers all over the country to bear in mind the fact that their copyright interests, as defined by the Act of 1862, are not favourably regarded by the publishing firm of Cassell & Co., as represented by its Art Director, Mr. Edwin Bale, R.I.

\* \* \*

THE identity of Mr. Bale will explain to the reader at a distance why in his paper, which we partly reproduce elsewhere, a distinct vein of hostility to photography is apparent. We allow at once that Mr. Bale and his fellow artists have cause to fear photography, but we shall lose faith in the wisdom of the British legislature if, under the cloak of the attempted amendment of copyright law, these jealous people are permitted to inflict injury upon the most popular method of graphic expression in existence. To proceed with our analysis of the motives of the new Bill's promoters: The draughtsman, Mr. T. E. Scrutton, we are told, formerly acted as Counsel for the Photographic Copyright Union. Now we find him in the opposite camp. Why, we do not know. He is credited with a threat to "make photographers sit up" by the terms of his Bill, which, however, judging from the tenour of

the copy we had in our possession last year, will probably not achieve that object in virtue of the clearest draughtmanship. Mr. Scrutton's idea that photography is "merely the use of a Kodak," and "the mechanical operation of copying with the aid of light some pleasing scenery," emphasises, no doubt, in the minds of his instructors his qualifications to act as a draughtsman of a Bill dealing with such a simple subject as photographic copyright.

\* \* \*

BESIDES Mr. Bale and Mr. Scrutton, a number of painters, bearing well-known names, have had a hand in the preparation of the Bill. This brings us to the most amazing thing in connexion with that monument of jealousy and injustice, viz., that, in the draughting of a measure designed to affect the commercial and other interests of thousands of photographers, not a single one of their number was called into consultation by the St. John's Wood conclave. Half a dozen painters take upon themselves to draw up a Bill striking vitally at a profession the members of which are numbered by thousands, and deliberately ignore that profession's claims to be heard in its own interests. Sir Lawrence Alma Tadema, the Chairman of Wednesday week's meeting, said his Committee (upon which photography was not represented) "sent a copy of the Bill to the photographic societies, with a request that they would be good enough to express their assent or dissent. He did not think they received an answer from those societies." To which societies did the Committee send the Bill? and when? Is Sir Lawrence aware that there are some 250 of these bodies in the United Kingdom? We are in touch with most of them, and do not recollect the Bill coming before a single one of them. We are strongly of opinion that Sir Lawrence has been misled in the matter.

\* \* \*

ON the other hand, we have a distinct recollection of the meeting of a Committee appointed by the Royal Photographic Society to consider the proposed Bill. We had the honour of being a member of that Committee. Mr. G. A. Storey attended and read the Bill to the meeting. Its provisions affecting photographic copyright were viewed with disfavour. On Wednesday week Mr. Storey said he did not remember saying the Bill could not be altered. May we inform Mr. Storey, whose memory is probably not good, that at the meeting in question he was asked if his Committee would not meet a small committee of photographers to discuss the Bill? Mr. Storey said clearly and emphatically, No! We have a distinct recollection of this incident, for it was the Editor of this JOURNAL who put the question to Mr. Storey and received his answer. The St. John's Wood Committee, by the mouth of its representative, declined point-blank to listen to the representations of those whose commercial interests were most seriously affected by the Bill! We cannot find words strong enough to condemn this attitude of the Committee, the individual members of which would find it somewhat difficult to defend.

\* \* \*

IT did not transpire at Wednesday week's meeting that in June last a representative body of photographers met, under the chairmanship of the Earl of Crawford, at the R.P.S. House, 66, Russell-square, and unanimously passed the following resolution: "That, in the opinion of this meeting, it would be an injustice to those practising and utilising photography to

interfere with the rights and privileges enjoyed by them under the Fine Art (Copyright) Act, 1862." All photographers ask for is to be left alone in the matter. There is a general agreement amongst them that the Act of 1862 has worked well in the interests of all concerned. The painters and sculptors are asking for more copyright protection; the photographers are content with what they have. The former are not satisfied to confine themselves to pressing forward their own claims, but they go out of their way to injure—or attempt to injure—a profession not quite so rich in the rewards and remunerative commissions which find their way to St. John's Wood and La Belle Sauvage. The conduct and aims of the promoters of the Bill are the reverse of fair, and the whole business is one which does not cast the most favourable reflection on those concerned in it.

\* \* \*

OPPOSITION to the Bill is anticipated when it is reintroduced into the House of Lords, and we hope those anticipations will be fully realised. According to Mr. Bale's paper the provisions of the Bill do not differ from those which characterised last year's "dropped" measure. We fully exposed the gross injustice of that Bill at the time, and we shall take an early opportunity of renewing those objections if occasion demands. For the present, considerations of space oblige us to reserve further comments on Mr. Bale's paper and the discussion. Our object this week has been to arouse photographers to a knowledge of the grave dangers by which they are threatened, and to indicate the working of the wires by which it is sought to move the British legislature to legalise a very great injustice towards photography. The Bill promoted by the St. John's Wood conclave is the retaliation of those who, some years ago, were taught by the Photographic Copyright Union that a photographer's copyright interest was property in which he had a legal claim to be protected; it is the outcome of the jealousy of those who fear the progress and development of pictorial photography, and it is against the attacks of these two classes of enemies that we ask our readers to join us in protesting.

#### THE PHOTOGRAPHIC HISTORICAL COLLECTION AT SOUTH KENSINGTON.

WE wonder how many photographers, or, indeed, how many students of photography, have visited the collection of historical photographic exhibits in the South Kensington Museum. Not many, we apprehend, or surely the authorities before this would have seen reason to arrange what for years past has been, as the tickets in the cases give the visitor to understand, "in course of arrangement."

This collection is located in the Science division of the Museum, the entrance to which is in the thoroughfare called the Imperial Institute-road, and finds itself in the same room with a goodly and glittering assembly of physical apparatus. Two large glazed cases contain the whole of what England can show in the way of a State collection of specimens illustrative of the history of photography. Though the contents of these cases are disposed "any how," they will well repay an hour or so's examination by any interested in the early, and by far most important, chapters of the history of photography.

Among the apparatus is a lens eight inches in diameter, made by Andrew Ross, with which, so it is stated, Talbot's *Pencil of Nature* was taken. Ross, it will be remembered,

figures rather prominently in the earliest days of the art-science as having been Talbot's informant as to what the Rev. J. B. Reade was doing in experimental work. A frame of the portraits of these pioneers—Daguerre, Niépce, J. B. Reade, Mungo Ponton, and, the greatest of them all, Sir John Herschel—is at hand.

Of specimens of the Daguerreotype process there are several, remarkable rather for their early date than for their technical excellence. One is of Madame Daguerre, taken in 1839. Others are of Blot, Becquerel, Foucault, and Faraday. Another specimen is a "direct" Daguerreotype, *i.e.*, taken by means of a reflector, to avoid the right and left reversal otherwise inseparable from the process.

Next in historical order, and one of the most interesting objects in the collection, is the first photograph on glass. This was produced by Sir John Herschel by the extremely tedious process of allowing silver chloride, suspended in water, to deposit on a glass plate, siphoning off the supernatant liquid, and afterwards, when the plate had been dried, exposing to light.

The collection of calotypes is entirely unrepresentative of the place of this process in photographic history. The prints and negatives are good, especially a series of Peterborough Cathedral, but the date of their production is some years after the perfection of the process by Fox Talbot in 1842.

Collodion is represented by positives by the "Archetype," "Ambrotype," and "Ferrotypes" processes, in 1851, 1853, and 1855 respectively, by a collodion negative intensified with Schlippe's salt, and by some collodio-albumen prints and negatives.

Printing processes form the subject of much more interesting exhibits. Prints on albumenised paper made from waxed negatives in 1853 are to be seen. Then Niépce de St. Victor's process of printing in iron and uranium salts is represented by a frame of prints of various colours, in various conditions of preservation.

There are some well-preserved ferro-prussiate prints made in 1850, some fairly good uranium prints, some made by the ammonio-nitrate of silver process, by J. B. Reade and Alfred Taylor, and one in faint bluish-grey, made in potassium bichromate.

The most complete series, however, is that showing the development of the platinotype process, lent by W. Willis. Here is the first print, made on October 25, 1872, with ferric oxalate and platonic chloride, and developed on neutral oxalate of potash; the first print made with a platinous salt; an early print, in which paper was coated with a lead salt before sensitising with ferric oxalate and platonic chloride. The first patented process (1873) is here recalled by a print of an agreeable colour, the image of which consists of platinum, silver, and copper. Other early prints (1878) show the result of using platinous and lead salts in the coating and developing with a mixture of potassium chloro-platinite and potassium oxalate.

That other process of Willis's, the aniline *Lichtpans* process, is called to mind by a large line print. Sir W. Abney lends the first print made with vanadium.

Of special interest just now, when the tele-photographic lens is being used in warfare, is the first negative taken with the tele-photographic lens in 1891. The magnification is equivalent to that of a lens of 100-120 metres focal length, and the subject includes a crow hurrying home.

Of pictorial photography, Rejlander's *Two Ways of Life*, and some prints from negatives by D. O. Hill serve, unintentionally, no doubt, to remind us.

The cases contain a number of specimens illustrating process work. These include the first Woodburytype, and an admirable specimen it is. There are three proofs from Fox-Talbot's photographic plates, some examples of Husband's "Paprotint" process, and of Abney's "Paprotypes." Other examples of phototype printing on zinc, colotype, and of heliogravure on stone, complete a very incomplete collection of "process" processes.

That a Photographic Museum should exist, even the most utilitarian reader will not deny. The South Kensington officials are not apparently in the slightest degree engaged in arranging what they have the charge of, or in adding to it; and, indeed, it is to be questioned whether they are the best people to be intrusted with the scheme. Apart from the question of the dignified deliberation with which Government departments move, and the comparative inaccessibility of South Kensington to visitors to London, it cannot be expected that the Museum officials can be so in touch with current progress in photographic and photo-mechanical matters as to enable them to judiciously add to the collection. Now that the Royal Photographic Society has a home worthy of its objects, it is to be hoped that it will turn its attention to the establishment of a permanent historical collection. It is work which it can and ought to do, and one which will entitle it, if it does not gain it, to the gratitude of photographers of all classes.

---

**The Combined Toning and Fixing Bath.**—Our readers are quite aware that we are no advocates of the combined toning and fixing bath when the permanence of the results are a consideration, notwithstanding its convenience in use, unless it be employed with much greater judgment than it generally is. In the *Foreign News and Notes* last week it will be seen that Dr. E. Vogel, no mean authority in matters photographic, at the Berlin Photographic Society, fully endorses our views. He said that it was not advisable to use the combined bath for commercial photographs, notwithstanding its convenience and the fine tones it produced. At the same time he added that it was capable of giving durable prints when in good condition. That has always been admitted, but the difficulty is, with those unfamiliar with its reactions, to know when it is in good condition, for it will yield as good tones, often better, when it is in a very bad condition as regards the stability of the pictures. At the meeting at which Dr. Vogel brought the subject forward Herr P. Hanneke stated that, as a test, he had mounted a collodio-chloride print, toned with the combined bath, and poured a solution of hyposulphite of soda upon it, and allowed it to remain in that condition for several hours. The print was then slightly rinsed, and, after a lapse of two years, it had shown no signs of fading. It was demonstrated many years ago that even something more than a mere trace of hyposulphite of soda had no influence on the stability of a photograph; but it must be mentioned in this case that it was hyposulphite of soda, pure and simple, applied after all the hyposulphite silver compounds had been eliminated from the prints.

---

**The 5×4 Size.**—A few weeks back we, in a leading article, commented upon the standard sizes of plates and cameras now in use, and mentioned that it was a little difficult to see how they came to be adopted, as they were so erratic in their proportions. Up to the present the quarter-plate has been the favourite small size amongst amateurs and for hand cameras, but will it remain so? In America the 5×4 seems to be more popular than the English quarter size. Will that obtain in this country? Hitherto it has been a size not

much in vogue here; at least, of late years. We note that the cheap American productions, cheap as compared with English prices for cameras of the same efficiency and quality, are mostly of the 5×4 size. Till lately that size was not easily obtainable except at the risk of its being a long time in stock at many dealers', particularly in small provincial towns. Now we learn they are being more generally stocked by dealers. As an evidence that there was not much demand for this size, it is only just now, as we mentioned last week, that the Britannia Works Company has added the 5×4 size to their list of Platona paper, which shows that there is now a demand for that size. Some consider that the proportions of the quarter-plate are too square for pictorial purposes; but the 5×4 proportions are squarer, though for hand-camera work they may prove an advantage rather than otherwise, particularly when lantern slides are the object in view, as they will the better enable the picture to be taken from the negative either way without having to work the camera on its side. It also allows a greater margin in trimming of the finished picture. It remains to be seen if the 5×4 will supersede the old and now universal quarter-plate.

**Phosphate of Silver Process.**—In a paper on a phosphate of silver printing process, which Dr. R. C. Schüppaus recently read before the New York section of the Society of Chemical Industry (see p. 131), he makes some remarks on the comment we made in *Ex Cathedrâ* in our issue for November 17 last year on Dr. Johannes Meyer's patented process. In these remarks we said that Dr. Meyer was probably unaware that a phosphate of silver printing process was published in this country something like fifty years ago, which was not materially different from his, in both methods the sensitive salt being the phosphate of silver. Our reason for that supposition is to be found in the Doctor's Patent Specification, No. 17,098, dated August 23, 1899 (see p. 714 of our issue for November 10 last). In it he says, "The silver phosphates *have so far not been employed for photographic or other purposes*" (the italics are ours), "and the only mention of any application made of them is to be found in Hardwich's *Manual of Photographic Chemistry*. He writes: 'Other insoluble salts, such as the phosphate and citrate, render the paper more sensitive than when it has been treated with a soluble salt of silver only.' From this we naturally assumed that the patentee was not aware of the prior use of phosphate of silver in printing. In Hunt's *Researches on Light*, 1854 (p. 120), from which we quoted, the author gives the working details of Dr. Fyfe's phosphate of silver process, which, he adds, was published *at a very early period* (italics again ours). Dr. Fyfe's process differs somewhat from that of Dr. Meyer's, inasmuch as the former dissolves the sensitive salt, the phosphate of silver, in ammonia, whereas the latter dissolves it in tartaric or citric acid. We here reproduce the last paragraph of the comments that brought forth Dr. Schüppaus' remarks: "The above rediscovery of one of the oldest processes of printing exemplifies what we have more than once said, namely, that experimentalists and would-be discoverers would do well to give attention to some of the older processes of photography in conjunction with modern knowledge of the principles upon which they are based. The outcome would probably be that some very useful processes might be evolved, and with great credit to the investigator." This sentiment, it may be added, has been re-echoed more than once in the States.

#### MR. CRAIG ANNAN'S PICTURES AT THE ROYAL PHOTOGRAPHIC SOCIETY.

WE have hitherto refrained from making any comment on the Exhibition at the Royal Photographic Society's rooms, but we think, before Mr. Craig Annan's pictures are removed, a few words about the gifted gentleman's work would perhaps not be out of place. That Mr. Craig Annan is a gentleman of high culture and artistic ability goes without saying, but we are inclined to think that he sacrifices quality for the sake of versatility.

In photography, a one-man show, to be even of comparative interest, must contain a variety of different subjects. In this respect this Exhi-

bition goes beyond the comparative stage, but does it enhance the reputation of the exhibitor? We should say not, except as regards the attribute above referred to, viz., versatility. But why, we ask, court this at the expense of quality? Many of the works are quite familiar to us. Much is inspired by the Dutch school, which, strange to say, again gives way to the æsthetic, a curious combination.

One can quite imagine from the treatment of Mr. Craig Annan's work that he could turn out with his numerous models a very fine show, entitled, "Types of Old Masters." The expression "with his numerous models" is not, however, comprehensive enough, for Mr. Craig Annan goes further, and carries his veneration for the earlier schools to such an extent as to actually penetrate into the countries where their artists loved to paint. But has the operator attained that measure of success in his efforts that careful study of his favourite masters should inspire? On the portrait side perhaps he has. At any rate, he has seized upon their salient points, and turned them to his own advantage, and traces of their influence are visible everywhere in his work. [Query: Is the absorption of antiquated ugliness compatible with modern photographic ideals?]

We like Mr. Craig Annan best when he is original. To us the simple Scotch lassie and the little child treated in Mr. Craig Annan's graceful and artistic manner appeal more strongly than the heavy Dutch stiff-necked models. The one is original, graceful, even Greuze-like in ideal; the other is Boer-like in solidity. And who does not prefer to note the dainty shoe of the English maiden to the heavy Dutch sabot?

We admit much, very much, is to be learnt from the early schools of Dutch and Flemish painting; yet, by following it too far, there is a fear of degenerating into a mere copyist, and it is then only a few degrees farther down the scale to become a servile imitator (a fate we, however, do not fear for one possessing Mr. Craig Annan's abilities).

On the landscape side there is a similar trace of some of the heavier Dutch or Flemish masters, but without their gift for lightness. Nearly all Mr. Annan's landscapes are dull. Whilst one picture, at least, is obviously inspired by Hobbema, there is no corresponding attempt, perhaps wisely so, to depict the masterful lighting of Cuyp.

Even in the exhibitor's picture of *A Lombardy Ploughing Team*, where there is strong sunlight casting strong shadows on the backs of the cows, the effect is sombre. It does not suggest noontide heat, there is no suggestion of sunlight, the whole is subdued to the extent of apparent falsity. It is clever, no doubt, but there is an æsthetic-cum-Dutch feel about it. This is a curious mixture.

Then, there is a *Veronese Vineyard*, oxen ploughing *almost in the dark*, with a dwarf-like "man with a muck-rake" doing something to the ground. It is an Egyptian hieroglyphic kind of subject, long, panel-shaped, but it is not true to nature, although it may be considered clever; at any rate, it is a change from the everlasting mud-flat school of some of Mr. Craig Annan's contemporaries. This subdued heaviness is taken even into that glorious land of light and colour, viz., Venice.

Let us look at the *San Maria della Statute*, and what do we find? A comparatively indifferent picture, *minus luminosity*, in a land that is always luminous. The Thames, even on a dull day, with St. Paul's in the distance and barges in the foreground, would turn up its nose in sheer disdain at its gloomy rival.

*A Lombardy Landscape* is evidently a Hobbema inspiration; it is an over-exposed black mass of Flemish eccentricity, a remark that may also be applied to *A Utrecht Pastoral*. In the latter, however, the Hobbema treatment is more marked, and has the addition of big, bulbous sheep at more or less regular intervals on the right. Still this picture is not unpleasing.

We have dealt with these things as they occurred to us, and have not taken the pictures in order; in fact, there is neither beginning nor end, the pictures are "just hung." Whilst on the landscape side, however, we think we had better complete our remarks thereon.

Another *Lombardy Pastoral* contains long hills, lanky trees, and leggy sheep. The trees are at regular intervals, some with balloon-like tops, which, however, serve to break the long, liny look of this somewhat sombre picture.

*Geneva* is a commonplace study of three horses and shipping—still, a dull day, and no clear Continental light visible.

*The Dark Mountains* borders on the mystic. Four dark figures in almost prayerful attitudes stand—at least, we take it for granted that they stand—on a mass of blackness, presumably *terra firma*, but is so black that we could hardly tell what it was they stood on. Their backs are to the spectator. Black middle distance and very dark mountains, with a terribly weird cloud effect and two rather strong light patches of water, complete the mystery.

*A Haarlem Canal* is a square, uninteresting picture—all bank and canal, and a little bit of reflected landscape in the water. It matches sheep, which is rather fuzzy—all bank and not much sheep.

*The Road through the Dunes* is better; the composition is capital, but there is still that look of "dim religious light" about it.

*A Canal of Holland* is another capital picture. It is, of course, a typical scene of the country, and there is a swirl about the waters that carries conviction with it. Here the operator's meaning is made clear at a glance, but there is a want of "atmosphere" about the picture. There is a sea piece—the *Adriatic*, we think, is the title—that also appeals to us very much; the waves gently beating on the flat, sandy shore are extremely well done. Then, there is more light here, though that is too subdued, in view of the fact that the figures appear almost black against the background. Still, the *Adriatic* is not like Mr. Craig Annan's interpretation of Lombardic scenery, from which one would judge that Lombardy was a country of perpetual night.

There are one or two other pictures we ought to mention. *The Fishers' Lives* we like as well as any of the sea studies. Here we have one of Mr. Craig Annan's happiest bits. The whole picture is in harmony. It is simple and natural and full of interest; it requires no interpretation, only lacks light.

*On a Dutch Shore* is another nice composition, strongly reminiscent of the sea-painter G. de Beaumont for its life and movement—especially in the boats. But, alas! the blackness of it—black sky, black sails, black people, and black foreground. This is a fault not traceable to the Dutch landscape school, we are sure.

We will finish the landscape side by noticing about two and a half feet *Zand Voort Beach*. What is there artistic, or even of interest, to take an elongated mass of humanity dotted at more or less regular intervals along the seashore—a picture, when finished, that looks from a distance like a silhouetted cinematograph film?

Now, *A Potato Field* is better; it is the antithesis of the other. It is long and narrow, it is true, but the white garments of the peasant women make a pleasing contrast with the darker background; there is not that wrong mass of black figures as in the other picture, which is so detrimental to its success, in spite of the toning-down process.

On the portrait side Mr. Craig Annan is happier. The subdued lighting is more suitable in many cases to the sitter and his or her surroundings. There are two attempts that we think go beyond the prosaic province of photographic delineation. The soul is an ideal capable of being depicted by an artist of the brush, and not of the camera, and but few men in the higher branch of art have succeeded in presenting us with anything like an adequate idea of the soul. We have one only in mind at the moment, viz., Rosetti.

Mr. Craig Annan's picture of *Eleanore* is not, of course, new. From a photographic point of view, no doubt, it is most excellent, except as to the baggy figure, which appears to be neither sitting nor standing, and looks in consequence stunted.

The other picture, *The Church or the World*, is more allegorical than truthful. For those who have not seen this work, we may say that the models are a man with a cowl to represent a monk, a Highland pony (presumably Shetland), a girl with a subdued landscape as a background. The girl is dressed in white, and decorated with a garland of flowers. She is seated on the Shetland pony near the centre of the picture. The cowed monk stands at the head of the animal. He is almost too dark to be seen, and the Shetland pony looks restive, and the girl as if she would step off its back. There is a painfully vacuous look on the girl's face. The world does not seem to have much charm for her on the one hand, nor do the spiritual attractions of the Church appear to appeal to her on the other. The picture is very subdued—so were we when we saw it. The motif may be excellent, but—

*Maidie*, a child study, was perfect. *Agnes*, another, was commonplace. *Phyllis and Prue*, a fine light-and-shade study—not new, but none the worse for that. *Nancy*, a child, simplicity without effort, and with very little detail, but excellent. *Molly*, a fuzzy-wuzzy, over-framed baby face—a beautiful child, but its own mother wouldn't recognise it, in spite of the care lavished on the aluminium frame. This in itself is a work of art, though a combination of crabs and butterflies is unique.

*Sisters* is rather spoilt by the straight arm and long sleeve, and there are three heads of Dutch women—beautiful studies, and careful—that are well worthy of notice.

*A Painter's Page* has not the refined look one associates with the artistic fraternity even in the lowest ranks, his ruffles at neck and wrist however, made him look like a superior kind of Pierrot, and his feet, which are large and match the paint brushes, which are exaggerated in size.

*Mr. Orchardson*, as a portrait, is perfection. *James Guthrie, R.S.A.*, is slightly out of focus, but the pose is good; and *Jan* is better than his master's opposite in *A Dutch Dog Cart*.

The portraits, in fact, all round were nearly all excellent examples of Mr. Annan's work, but there was one particular study that took our attention in passing out of the room, and that was *The Marble Cutter*.

We don't know whether Mr. Annan got his inspiration from *Wright of Derby* or Rembrandt; but, judging from this work, we should surmise that he got his idea from the former.

The picture of the marble-cutter represents a sculptor at work. There is a strong light falling on him, and his work, as well as on several other pieces of sculpture, the rest is in darkness and semi-darkness.

It is just one of those efforts that mark the man as an artistic photographic genius.

The frames are not always in keeping with their subjects; for instance, take that of *A Little Princess*, in white enamel contrasted with a deep sepia.

The enamel is old and yellow and the contrast too vivid.

Take again *Jan* and his opposite neighbour in the dog cart; the frames are more noticeable than the pictures, the fluted or lined woodwork causes more notice than the picture itself.

Versatility or variety in frames is apparently just as necessary as it is in the show itself.

CRITICS.

#### SOME MORE COLOUR SENSITISERS.

VALENTA has been continuing his researches on the sensitising action of the aniline dyes, and in the current number of the *Photographische Correspondenz* gives his results. The dyes, as in his previous experiments, were used for bathing the plates in a strength of 1:25000 to 1:50000 with one to two per cent. of ammonia.

DYES FROM THE COLOUR FACTORY, FORMERLY FR. BAYER, IN ELBERFELD.

Benzoroth SG\* gives a vigorous band from B to D  $\frac{2}{3}$  E, with maxima at C  $\frac{1}{2}$  D, and D  $\frac{1}{3}$  E.

Tronaroth 3 B, and Tronaviolett B, act as weak sensitisers; the former gives a faint band from C  $\frac{1}{4}$  D to D  $\frac{2}{3}$  E, with maximum at D; the latter a band from D  $\frac{1}{4}$  E, with maximum D  $\frac{1}{2}$  E.

Plutoorange G sensitises from D to C; with long exposure, maximum at D  $\frac{2}{3}$  E.

Plutobraun, of which several kinds were tried, gives generally unsatisfactory results on gelatine plates; but, the kinds marked N B, G G, and R acted well with collodion emulsion, and, with long exposure, a closed band, extending from A to beyond E, was obtained, so that, with the use of a pale yellow screen, almost a closed band was obtained, from A to H. G G gives two indistinct maxima at D and E. Plutobraun R gives a band from C to D  $\frac{1}{2}$  E, the action of the blue was greatly lowered, so that it was less than the yellow and red.

Azosäureblau 6 B gives on collodion emulsion a band from A  $\frac{1}{2}$  a to D  $\frac{1}{2}$  E, maximum at C  $\frac{1}{2}$  D.

Victoriaviolett 4 BS gives on collodion a band from B to D  $\frac{2}{3}$  E, maximum at C  $\frac{1}{2}$  D.

Wollblau N gives, on gelatine plates, a narrow but vigorous band at C.

Diazoindigoblau M colours neutral silver bromide intensely, and gives with long exposure a band from a to E. The action of the blue was very much decreased.

Benzoldunkeldrum GG does not sensitise gelatine plates, but collodion emulsion strongly. With short exposures it gives a narrow band from a to B; with long exposures, almost a closed spectrum from A to H.

Plutoschwarz BS gives with long exposure a vigorous band from a to D, with maximum at C. Plutoschwarz FR gives with collodion a band from A to D  $\frac{1}{2}$  E, with maximum at B.

Diamantschwarz FR gives with long exposure a vigorous band from A to D, with maximum at B  $\frac{1}{2}$  C.

Directblauschwarz 2 B gives a weak band from a to D  $\frac{1}{2}$  E with short exposure; with long exposure, two maxima at B  $\frac{1}{2}$  C and D  $\frac{1}{2}$  E appears.

DYES FROM THE ACTIENGESELLSCHAFT FÜR ANILINFABRIKATION.

Greyneviolett 4 B acts vigorously on gelatine plates, but causes red fog; band from C to D  $\frac{2}{3}$  E, with (2) maxima at C  $\frac{1}{2}$  D and D  $\frac{1}{2}$  E, the former of which is vigorous.

Greyneagrün B extra gives with long exposure a narrow, tolerably vigorous band at C  $\frac{1}{2}$  D.

Laubgrün (without ammonia) gives a narrow, and only with long exposure a vigorous, band from B  $\frac{1}{2}$  C to C  $\frac{1}{2}$  D, maximum by C.

Aethylgrün (crystallised) gives a narrow, sharp band from B  $\frac{1}{2}$  C to C  $\frac{1}{2}$  D.

\* In all cases the German names of the dyes are given.—Trans.

Mandarin G extra and RL gives with long exposure a broad band from A to D, in which are two maxima, at B and  $C\frac{1}{2}D$ . TRL dye gives a fairly strong band from C to D, with maximum  $C\frac{1}{2}D$ ; with longer exposure a faint band appears between D and E.

Echtblau R (for wool) behaves very much like the nigrosines, and gives (3) bands: one very vigorous from  $C\frac{1}{2}D$  to  $C\frac{3}{4}D$ , then a weaker from A to B, and finally a third from  $D-D\frac{1}{2}E$ . With somewhat stronger concentration of the bath red fog appears.

Wollschwarz 4 B is a very vigorous sensitiser, which acts vigorously with short exposure, and gives a broad band from A to beyond D, with indistinct maximum at B; with long exposure, another band from  $D\frac{1}{4}E$  to E almost. This dye lowers the blue sensitiveness somewhat, as it hardly exceeds that of the yellow and red, and it ought to be useful in practice.

Columbiaschwarz B gives a vigorous band from A to  $C\frac{1}{2}D$ , with maximum at C, and strong red fog.

Formylsaett S 4 B, made by Casella, of Frankfort, which is synonymous with Säureviolett 6 B of Geigy, of Basle, and with Säureviolett 4 B of Bayer, of Elberfeld, is a very good sensitiser, which acts vigorously even with short exposures, and gives with short exposures a vigorous band from C to D, with plain maximum at  $C\frac{1}{2}D$ ; with long exposure, another from D to  $D\frac{3}{4}E$  appears, so that the sensitising action extends from C to E, and it is not far behind the action of the blue rays.

#### A SILVER PHOSPHATE PRINTING PROCESS.

BEFORE the New York Section of the Society of Chemical Industry Dr. R. C. Schüppaus recently read a paper on a new process for sensitising paper and other surfaces. This new process of sensitising paper and other surfaces, he said, is the invention of Dr. Johannes Meyer, a practising physician of Brooklyn. It is based upon the application of one of the phosphates of silver to the surface to be sensitised in conjunction with an organic acid. THE BRITISH JOURNAL OF PHOTOGRAPHY speaks in its issue of November 17, 1899, of this invention as the re-discovery of one of the oldest printing processes, namely, Dr. Fyfe's, and accidentally charges the inventor with a lack of familiarity with the older literature of the art. In this particular instance I think it is well that Dr. Meyer knew nothing of the earlier work and comparative failures of Dr. Fyfe and Mr. Maxwell-Lyte, for such knowledge might have prevented him from making an invention which, in its simplicity and beauty, is a boon to every photographer. The friendly critic is in error, however, when he speaks of Dr. Fyfe's process as "not materially different from that which has just been patented," meaning Dr. Meyer's. He quotes quite freely from Hunt's *Researches on Light*, published in 1854, in support of his position. I quote from the same author's *A Popular Treatise on Photography*, Glasgow, 1841, p. 21:—

"Dr. Fyfe appears to have been the first to suggest the use of the phosphate of silver as a photographic material, but I am obliged to confess it has not, in my hands, proved anything like so successful as, from Dr. Fyfe's description, it was in his own."

And this same passage appears in Hunt's *Manual of Photography*, London and Glasgow, 1854, p. 120. What Dr. Fyfe actually did was this:—

1. He produced a precipitate of silver phosphate in the fibres of the paper by double decomposition between sodium phosphate and silver nitrate.

2. He coated paper with a solution of silver phosphate in ammonia or ammonium carbonate.

3. He spread a paste made of precipitated silver phosphate, dried in the dark, with spirits of turpentine and Canada balsam on canvas.

Dr. Meyer was searching for a paper more sensitive than the ordinary commercial article, and certain theoretical considerations led him to experiment with the silver phosphates. After establishing their solubility in certain organic acids such as tartaric, citric, and succinic acids, he applied silver phosphate dissolved in an organic acid to paper, and, in further pursuit of this kind of work, discovered the emulsion of silver phosphate and tartaric acid. It took many months of patient research before the conditions were determined under which this remarkable emulsion is formed. Before going into the details of preparation, I will say that the metaphosphate and pyrophosphate do not differ materially in their behaviour from the orthophosphate, but that, by phosphate simply, the orthophosphate of silver is meant. To make the emulsion of silver phosphate and tartaric acid, which has given such good results in making photographic prints, 4 grammes of silver nitrate in aqueous solution are precipitated by 4.7 grammes of sodium phosphate dissolved

in half a litre of water. The precipitate is washed carefully by decantation, and by tapping and cautious removal of water brought to the volume of 32 c. c. From 18 to 20 grammes of tartaric acid are dissolved in an equal number of c. c. of cold water, and, while this solution is added as rapidly as possible to the phosphate precipitate, a quick rotary motion is imparted to the containing vessel, preferably a wide-necked bottle made of yellow glass. The experienced observer will notice a change of colour, the yellow phosphate held in suspension turns into a whitish cream. We have now about double the volume of the original mixture of a stiff jelly. By keeping it at a temperature of about 33°C., it is rendered more fluid. In this fluid condition it is suitable for coating paper, plain, albumenised, or otherwise prepared, by means of a flat brush or of suitable machinery. The proportions above given are the best for practical work, they also yield good results when much larger quantities are employed. It is possible, however, to obtain the emulsion with a good deal less of tartaric acid, say 8 grammes in 8 c. c. of water to the 32 c. c. of mixture previously referred to. With these proportions the emulsion will set more readily, and it may be better for a beginner to first try these. When the emulsion is left in the cold, crystallisation sets in after some time, and only a portion of the silver remains in solution. The chemical reactions coming into play are so far entirely obscure. It would appear probable that acid phosphates might be formed, yet the ordinary silver phosphate is deposited unchanged from its solution in acetic acid.

Of acid solutions the citric-phosphate solution has been most tried. With 32 c. c. of the phosphate mixture 48 grammes of citric acid yield a clear solution of great sensitiveness. Both emulsion and solution have been applied to materials other than paper, such as wood, celluloid, lithographic stone, marble, silk, cotton, and linen, and prints of great beauty and durability been produced thereon. They may be applied to the surfaces as such, or these surfaces may first be coated with albumen, gelatine, or the like. In the latter case a print can be obtained, either in direct or diffused sunlight, in less time than with the ordinary photographic papers, and there is no difficulty in printing out by arc light just as quickly as in shaded daylight, the emulsion permitting more rapid work than the solution. While the ordinary albumenised papers will not keep, papers sensitised after this new method will keep indefinitely in any climate if only protected from dust and light. The prints can be toned and fixed in the ordinary way, with only this difference, that a dilute hypo bath must be employed. Toning and fixing may be done at any time, even months after printing. The predominant colour of the prints being a very pleasant brown or auburn, toning may, in a good many cases, be dispensed with. Very agreeable reddish effects can be obtained by giving the prints a citric acid bath before fixing. If this method is followed, the prints are washed with water before transferring them to the hypo bath. The latter should be composed of 35 grammes of sodium hyposulphite, 2 to 3 grammes of carbonate or bicarbonate of soda, and 1 litre of water. After leaving the prints from one to two minutes in this solution, they are washed for five to ten minutes in cold or warm water. In this alkaline bath the tone is not changed, though the colour appears considerably lighter in the wet state than it does after drying. Only the slightest over-printing is required if the prints are removed directly from the printing frame to the fixing bath. They need no over-printing at all if they are toned, as they gather strength in the toning bath. If left too long in the hyposulphite solution, sulphuration of the prints will set in. Yet, if not too long continued, the sulphur-toned prints obtained are permanent.

The sensitiveness of the emulsion may be still further increased by the addition of a small quantity of citric acid. When the ordinary silver bromide emulsion is added to it, direct prints can be obtained by the light of a petroleum lamp. The silver phosphate papers can be used for developing out just as well as for printing out.

In the course of a short discussion, Mr. S. V. Haus asked what were the proportions of phosphate and tartaric acid?

Mr. M. Toch, asked what was the effect if the prints were subjected to sulphuretted hydrogen gas? It was very essential that that should be tried, because the permanency of the print depended on it. Five or six years ago, when gelatine printing-out paper was invented, photographers welcomed it, as it did away with the old method of silvering albumenised paper; but after a year the prints turned greenish and then faded out in spots. Dr. Leo Baekeland and himself had attempted independently to find out the cause of this fading, and they both came to the conclusion that sulphuretted hydrogen was the cause.

Mr. Haus asked if the emulsion had ever been microscopically examined to see whether it was true emulsion, and if they had ever tried to tone it down to a blue colour?

Mr. Herman Poole asked if the author had ever used lactic acid? Dr. R. C. Schüpphaus, in reply, said that the proportions were 4 grammes of nitrate to 4.7 grammes of sodium phosphate. Some of the prints exhibited that night were over two years old, and had been kept under the most varied conditions without any apparent change. It was a true emulsion. They had tried to tone it down to a bluish colour, and it had stood the precipitation from the toning in the case of gold. Lactic acid had not been tried so far.

GLASGOW INTERNATIONAL EXHIBITION, 1901.—THE PHOTOGRAPHIC ARRANGEMENTS.

It has already been announced that the Executive of the Glasgow 1901 Exhibition intend to allow "hand" camera photographs to be taken by visitors in the grounds of the Exhibition. The right to photograph outside the buildings and to use a stand camera in the grounds is to be set for a "consideration." The successful contractor will be prohibited from photographing in the Fine Art Section except by special permission, and, while permitted to sell general views of the Exhibition and exhibits, he must obtain the consent of the individual exhibitors. He shall have the right to erect a studio with an area of 625 square feet, and shall be allotted a stand with an area of 100 square feet for the erection of a stall for the sale of photographs. The Executive reserve the right to employ the contractor or any other photographer to take and reproduce photographs of the opening or other ceremonies within the buildings or grounds. They also reserve the right to use, and license for use, mutoscopes, biographs, kinematographs, and automatic machines for the exhibition of photographs. The contractor shall erect, decorate, equip, and maintain the studio and stall to the satisfaction of the General Manager. The studio shall be used for taking, reproducing, and selling photographs, and for no other purpose. The stall shall be used for the sale of photographs only, the word "photograph" excluding "fancy goods" with photographs printed upon them. A tariff of charges for all standard sizes of photographs must accompany the tender, and the contractor shall be bound not to charge more than this tariff. The prices are to include any charge for sittings or proofs. The contractor must also satisfy the Executive of his ability to carry out the contract, and pay one half of the sum tendered at the time of signing the contract, and the other half on March 1, 1901. Tenders are to be delivered at the office of the General Manager, 36, St. Vincent-place, Glasgow, on or before March 15, 1900. The contract during the Exhibition of 1888 was held by Messrs. T & R. Annan, Sauchiehall-street, Glasgow, who paid a certain percentage of their drawings as the sole occupiers of the Exhibition photographic studio and stall, which they had to build and equip at their own expense. The coming Exhibition, like the last, will open early in May and close at the end of October.

DOUBLE TONES IN GELATINO-CHLORIDE PAPER.

DOUBLE tones in the gelatine printing-out paper are generally attributed to the use of sulphocyanide of ammonium or potassium in the bath. Whether this chemical really predisposes the paper to take on this seamy appearance I cannot say, but I have noticed that the sulphocyanide when used with a scanty proportion of gold chloride caused the image to drift in the undesired direction of double tones. The defect of one is most noticeable in the half-tones of the print, says a contributor to an American contemporary, and especially at the edge of vignettes.

Probably a properly constituted sulphocyanide bath would give as even tones as any other baths, but most of the toning formulæ seem to me to have a dangerous amount of the sulphocyanide in proportion to the quantity of chloride of gold.

The double tones are associated with weak bath, and therefore I use a larger proportion of gold than is set down in the formula for toning, and, besides, I never use an exhausted bath. I believe that there is no saving in the homœopathic formula with gold.

In albumen printing days we estimated that one grain to the sheet of paper was the limit on the side of economy, but few printers then kept to this ebb point in gold, but sought to increase the beauty and richness of the tone by stronger gold bath. Other things being equal, I think we should not use less than two grains of gold to the same amount of gelatine paper. The permanency would be better assured, for it stands to reason that gelatine paper requires more gold even than albumen paper.

The gelatine paper requires a bath sufficiently concentrated to change the colour of the print without subjecting it to a prolonged toning, which is sure to run the print into double tones.

A rather quick-acting toning bath, free of sulphocyanide, is made as follows:—

Chloride of gold .....	15 grains.
Carbonate of soda.....	230 "
Chalk .....	70 "
Water.....	32 ounces.

After twelve hours the bath becomes clear and is ready for use.

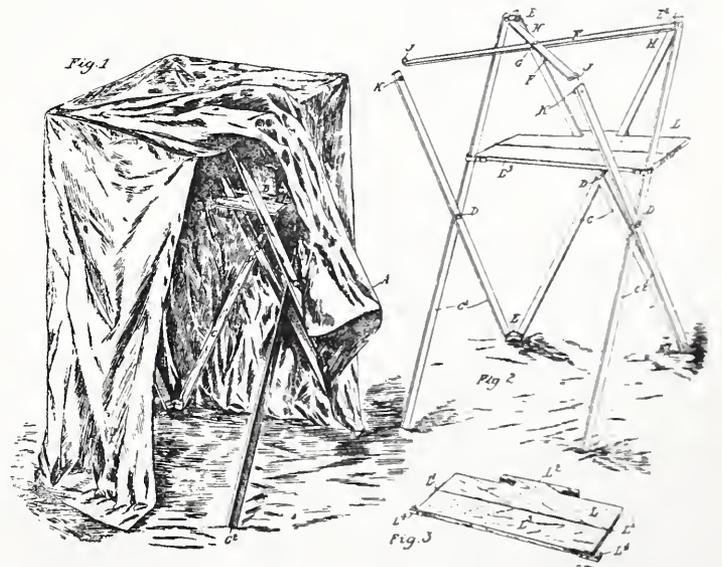

The prints are to be first well washed in several changes of water before subjecting them to the toning operation.

The trouble, however, with the use of too rapid toning solutions is that it is difficult to get more than one tone, and that has a tendency to coldness, and there is also a liability to eat away the lines of demarcation between the lighter tones and destroy the gradations.

COLLAPSIBLE DARK ROOMS.

THE invention here described is the subject of a patent by Mr. A. E. Anderson and the "X" Chair Patents Company, from whose specification we take the following particulars:

The outer cover, A, may be made of any convenient flexible material, made up into the form the dark room is desired to take, and is provided with a window, B, also of flexible material. The cover, with its window, B, may be made after any well-known method to prevent the penetration of the actinic rays of light, and, if desired, may be waterproofed. The sides of the frame by which the cover is supported comprise in this instance three pairs of members, c, c<sup>1</sup>, c<sup>2</sup>, respectively. These members may be of any suitable material, such as wood, and of any convenient cross section, and are made to cross each other preferably at their centres, where they are secured together by a rivet, D. Each pair of members is free to turn about its pivot, D, and the ends of the members, c, are secured to the ends of the members, c<sup>1</sup>, by brackets, E, and at the other side to the ends of the members, c<sup>2</sup>, by brackets, E<sup>1</sup>. The members are preferably riveted to the brackets, E, E<sup>1</sup>, and are free to pivot about the rivets as described with reference to the rivets, D. The members

thus arranged form three collapsible walls for a four-walled room, and a top is provided comprising another pair of cross members, F, riveted together at G, and hinged on one side by loops, H, to the upper brackets, E, E<sup>1</sup>, of the members, c. The ends of the members, F, remote from those secured to the members, c, are provided with hooks or claws, J, adapted to fall into loops or catches, K, at the end of the members, c<sup>1</sup>, c<sup>2</sup>, and remote from the brackets, E, E<sup>1</sup>.

It will be seen that so long as the hooks, J, are not in engagement with the catches, K, on the members, c<sup>1</sup>, c<sup>2</sup>, the members, F, may be swung down upon the hinges, H, so as to hang approximately parallel to the members, c, and the whole frame collapsed by bringing the bottom ends of each side together. When, however, the hooks, J, are in engagement with the catches, K, on the members, c, c<sup>1</sup>, the upper ends of the members forming the walls or sides of the frame are prevented from coming together, and a suitable covering may be placed over the whole.

As placing a separate covering over these members might be found inconvenient, the cover, A, is preferably secured at its corners to the tops of the members, c, c<sup>1</sup>, c<sup>2</sup>, and, when the frame is collapsed, remains attached to and folded over the collapsed members.

Detachable brackets or carriers may be arranged within the dark room, and may be made either in two parts hinged together or in one piece.

A shelf or carrier, L, is shown in figs. 2 and 3, which may be folded about its centre at L'. The shelf, L, is provided with a projection, L<sup>2</sup>, somewhat resembling a cleat, that end of the projection remote from the shelf being of greater length than that part by which it is secured to the shelf. This formation of the part L<sup>2</sup> permits the shelf to be placed over the members, c, for instance, above the point where they cross one another, so that the extended portion of the projection comes behind the members, c, and the members are engaged in the recesses formed between the extended portions of the projection and the shelf; the neck of the projection thus becomes wedged between the two members, c, and serves as an additional support or strut, which keeps these members from collapsing. The forward part, L<sup>3</sup>, of the shelf, connected by the hinge, L<sup>4</sup>, may be provided with hooks or other devices, L<sup>4</sup>, formed to engage the members, c<sup>1</sup>, c<sup>2</sup>. In the arrangement shown in fig. 2 this is effected by lowering the forward part, L<sup>3</sup>, of the shelf down upon the members, c<sup>1</sup>, c<sup>2</sup>, so that the hooks or catches, L<sup>4</sup>, embrace the members upon which they fall. The forward end of the shelf is by this means supported, and the shelf made to serve as a tie between the members, c and c<sup>1</sup>, c<sup>2</sup>. It is obvious that the hooks or catches, L<sup>4</sup>, may be arranged to drop into loops secured to the members, c<sup>1</sup>, c<sup>2</sup>, instead of embracing the members as described. When only a small shelf or bracket is required, the hinged portion, L<sup>3</sup>, may be dispensed with, and the bracket supported only by the part, L<sup>2</sup>, as shown in fig. 1.

Guy ropes may be used secured to pegs in the ground, or weights, to prevent the dark room from being overturned by wind or other cause.

It will be observed that the covering at the side corners of the dark room is not supported by any part of the frame, but hangs from the top of the frame. These may, however, be supported, if desired, by a flexible connexion, such as a cord or elastic band, connecting the tops and bottoms of the members at each corner of the framework. If elastic is used, the whole may be closed up without detaching these ties; but, if some non-elastic material is used, each piece must be secured at one end by some means equally detachable.

The bottom ends of the members, c, c<sup>1</sup>, c<sup>2</sup>, may either rest direct upon the ground, or be provided with spikes to enter the ground, or they may rest upon, or be secured to, horizontal members serving as struts to give greater stability to the whole structure. As a rule, however, it is not found necessary to use struts in this manner, except in some cases, one at the front end connecting the members, c<sup>1</sup>, c<sup>2</sup>, on that side where the dark room has no framework. This side serves as the entrance to the dark room, and the one side of the cover, A, is made to lap over the other a sufficient distance to exclude all light. Any well-known form of fasteners may be provided to prevent this part of the cover from being displaced whilst using the dark room.

## ARTISTIC COPYRIGHT.

[Abstract of a paper read at the Society of Arts.]

It was not until the year of the second International Exhibition in London, the year which saw Captain Fowke's great brick exhibition building erected at South Kensington on the ground now occupied by the Natural History Museum, the year after the death of Prince Albert, that it is to say, not until July 29, 1862, that the law came into force, the preamble of which begins as follows: "Whereas by law, as now established, the authors of paintings, drawings, and photographs have no copyrights in such their works, and it is expedient that the law should in that respect be amended. Be it therefore enacted," &c. And so it comes about that there is no copyright in any painting, drawing, or photograph, executed and dealt with before the middle of the year 1862. It is a fact, somewhat difficult of realisation, that some of the most important works produced by the pre-Raphaelite brotherhood, by Sir John Millais, and Mr. Holman Hunt, who is still with us, have not, and never had, any legal claim to copyright protection.

The term of this 1862 Act differed from its predecessors by being made dependent on the life of the author, to which life seven years were added. In the Literary Copyright Act there are two terms—the life of the author and seven years, or forty-two years, whichever may prove the longer. But in taking a fixed term like forty-two years, it is necessary to have something to start from, and with a literary work it was easy to start from the date of publication, and there was consequently no difficulty in giving such choice of terms; but there exists no such thing as the date of publication of a painting, although, in the endeavour to bring painting and literature under one Act, attempts have been made to invent for the purposes of the law some action, which should be called or considered as publication; but the difficulty was evidently before the author of this Act, and the artist's term was made his life and seven years after his death, without any alternative. This term applies, of course, equally to photographers.

A most important point arises in answer to the question, In whom is the copyright vested? The Act, says "the author," and the Courts have decided that, as regards photography, that is to be taken to mean the person who takes the negative, not the person who employs him, but the operator himself. A case came before the Courts in which a firm,

consisting of two persons, employed a number of photographic assistants. One of the managers, thinking that a photograph of the Australia cricketers would find a good market, made arrangements with the cricketers to photograph them without charge, and the firm sent one of their photographic operators to make the negative, which he did, and prints were taken from it in the usual way. The photograph was pirated, and the firm who had registered themselves as the owners of the copyright brought an action for infringement; but it was held by the Court that the assistant who actually took the negative was the author of the photograph, and that its registration in the name of the firm was consequently null and void. There are other cases bearing on this ruling.

I said just now that this Act was originally initiated for the protection of the painter only. I believe it was, so to say, an accident that it came ultimately to include photographs. It was thought that they were protected by the Engraving Acts with the addition of the clause covering lithographic prints taken by any mechanical process, and the inclusion of photography was not originally contemplated, but the photographers feared that their prints being of a different character from those taken from engraved plates or lithographic stones might not be protected, and ultimately photography was included.

I trust I have thus far succeeded in giving you an intelligible idea of the history of artistic copyright down to the present moment, but it remains for me to review the whole result, and to ask, How does the matter stand to-day?

We have five Acts. Three deal with engraving, one with sculpture, one with painting, drawing, and photography, between which there seems to be little or no relation. We have, first, three terms of duration of copyright—twenty-eight years for an engraving, fourteen for sculpture, with a second fourteen if the artist be alive at the end of the first; life and seven years for a painting, drawing, or photograph.

There are two different relations of the artist to his copyright. The sculptor's right to sell his work and retain his copyright has never been questioned. The retention of the painter's copyright is made to depend upon the signing of a document by the purchaser of his work.

Two modes of treating artists, as to registration, also exist. The engraver and the sculptor comply with the law by putting their names and dates on their work, and they are not required to register. The painter cannot protect his copyright without registration; while registration itself, as it is now required, is a snare, a delusion, and a pitfall. Designed to give the public information as to ownership and duration of copyrights, the uncertainty of its operation simply results in the prevention of information on these very points.

And now we come to the consideration of the proposed new Artistic Bill. As its memorandum states, it is intended to simplify and amend the law relating to copyright in artistic works. Its main features are—

1. To secure greater uniformity in the terms and conditions of copyright.
2. To reserve to the artist—with certain exceptions—the copyright until expressly assigned or disposed of by him.
3. To make registration of copyright—and of all dealings therewith—with certain exceptions, compulsory.
4. To improve the remedies for infringement.

There are two terms of copyright conferred by the Bill:—

1. For an original work of fine art, the life of the author and thirty years after his death.
2. For a work of fine art made by one person from the design of another; for a photograph, for a cast from nature, thirty years from the first day of the month of registration.

There can be no kind of doubt that, under the existing Act, the artist is placed in a position of great disadvantage when compared with the photographer, and the proposal of the new Bill is to do away with these disadvantages, and, taking into consideration the differences which exist between various forms of art and photography, to devise a term of copyright protection which shall meet the needs and circumstances of all of them without injury to any.

Works of art divide themselves naturally into two classes, the division between which is an intelligent one and readily perceived.

An original work of art is, from its inception to its completion, the work of the artist, imagined and thought out by his brain, and embodied in some graphic or plastic form by his hands. The highest art is the expression of a thought or feeling in forms suggested by nature, and put into shape with the skill of the craftsman. Art and nature are quite distinct things. Art is nature that has passed through the alembic of the artist's brain, and has been embodied by his hands; and there is a clear distinction here between such original work and the translation of such works after they have been produced into some other form by engraving, or other similar process, or the mere reproduction by mechanical means, like the casting of simple natural forms; this is a distinction not of better or worse, but merely of kind, and this difference of kind is of vital importance. The man who works with high artistic aims has almost always to work and wait for long and perhaps weary years before he commands his public. The painter, the sculptor, the inventive engraver, works not for the public but for himself. He works at subjects that please himself, and in a manner which he alone approves. He has to educate his public before he can reap his reward; often he

never reaps it, and still more often it is not till he is well on his career, and close upon the end of his life, that his works have any copy-right value. The photographer, the translator engraver, who mainly works on commission, enters upon his harvest at once, and the difference of terms proposed in this Bill is to give the children of the artist some chance of reaping what the father in his lifetime failed to win.

The difference in this and in other respects between the photographer and the painter was recognised by the Royal Commission, who themselves recommended the proposed difference of terms in the following words:—

"We therefore propose that the term of copyright for all works of fine art other than photographs shall be . . . the life of the artist and 30 years after his death." [C. 95.]

"Photographs, however, present some difficulty. At the present time they are coupled by Act of Parliament with paintings and drawings, and are subject to the same law; but as we have before pointed out, we believe this circumstance arose merely from the fact that before 1862, when the Act was passed, there was no copyright protection for either of these subjects and it was then thought right that photographs should be protected as well as other works of art. On consideration, however, it will be seen that photographs are essentially different from paintings and drawings, inasmuch as they more nearly resemble engravings and works of a mechanical nature by which copies of pictures are multiplied indefinitely." [C. 118.]

"We propose that the term of copyright in photographs should be 30 years from the date of publication." [C. 119.]

But it must be asked, Does the proposed extension of terms to the artist do injustice to any one? At present photographs have life and 7 years of the operator, the engraver 28 years, the caster from nature 14, and a possible other 14 years. It is proposed to give to each a fixed term of 30 years. At present the photographer has an uncertain term, which may end in 7 years and a day, and I am not aware that any one has objected that the term of 30 years is not as good, if it be not better, than the uncertain life of the operator and 7 years. With the other two cases the term is an actual extension on what they now enjoy. In considering this question it is well to look abroad and see how it is dealt with in other countries.

In France the artist has a copyright for his life and 50 years. A photograph has not of necessity a copyright at all; but, if it can be shown that it is artistic in its character, it can claim protection as a work of art. In Germany, Austria, Hungary, Norway, Sweden, Denmark, Spain, Portugal, Switzerland, the artists' term varies from life and 20 years to life and 50 years. The term for photographs is a uniform one of 5 years only.

Registration in the next important matter dealt with in the Bill. The primary object of this is to afford information to the public as to the ownership and duration of copyright. Under the present Act, the owner of a copyright must register if he wishes to take proceedings for an infringement; but in practice a large number of copyrights go unregistered. The public, who are unversed in the ins and outs of the law, do not understand this; and, indeed, those who do are in little better position. You want to find particulars as to some work, and you search the register, there is no entry. Knowing the condition of the law which causes so many copyrights to lapse, the presumption is that the work is within the "public domain;" and, if so, it is actually public property and any one may use it. At the same time, you know that if you do, it is at your peril, for an unknown and undiscoverable copyright-owner may suddenly appear out of space, and, having registered his work after your publication, may obtain an injunction and stop your work. Now, it must be manifest that to leave things at a loose end like this is fatal. Registration must either be abolished, and the public left without pretence of information, or it must be made compulsory. Once more one looks back to the report of the Royal Commission, and this is what we find:—

"We are satisfied that registration under the present system is practically useless, if not deceptive." [C. 137.]

"We have been satisfied by the arguments in favour of registration, that it is advisable to insist upon it, and that it should be made more effective and complete. To this end it should be made compulsory." [C. 138.]

This recommendation is embodied in the Bill.

But the Bill exempts from registration the copyright of an original work of fine art so long as it remains in the possession of the author; but, should he dispose of it, the person to whom it is assigned must register. The reason for this is simply that, as under the Bill the copyright is always vested in its author until disposed of, if there is no entry of a work the public will know that the copyright is still in the hands of the artist and will apply to him for information, and this method is made effective by the compulsion to register within six months after it leaves his hand.

But the onus of registration remains with photographers, engravers, and others who under the Bill have a fixed term of copyright. This becomes a necessity because this term starts from a certain date. Under the Bill it is date of registration, and the public have a right to know when that term begins and ends, and in England registration is the only accepted means of effecting this. In foreign countries a system is adopted whereby photographs have to be issued stamped upon the face with the name of the firm to whom they belong and the date of original issue, so that the public may see at a glance how many of its five years have expired.

There is a special reason why in the public interest photographs should have a fixed term which should be registered, a reason which does not apply to original works of fine art.

Under the present law the copyright of a photograph is vested in the operator for his life and 7 years; but, assuming that the copyright is registered in the name of the operator, what means has the public of knowing anything about him? He is an *employé*, unknown to the public, who passes maybe from the service of one firm to another, and passes ultimately away, and even the person who employed him may know nothing of his end. It is probable that at the present moment there are thousands of photographs upon the market in which copyright is claimed, the rights in which have long since expired under the terms of the present Act. The present Act is, and any Act giving life and a term of years to the photographic operator must be ineffective, owing to the conditions of the photographer's business. That this should be so is scarcely in the public interest.

Turning once more to the report of the Royal Commission, we find, after the proposal of compulsory registration:—

"We recommend that registration of paintings and drawings should not be insisted on so long as the property in the picture and the copyright are vested in the same person, but that, if the copyright be separated by agreement from the property in the picture, there should be compulsory registration." [C. 158.]

"With regard to such works as engravings, prints, and photographs . . . We think that they should be subject to compulsory registration." [C. 159.]

I have put before you the main features of the Bill. There are others I can only mention:—

The Bill enables an American to secure copyright in this country. At present he cannot do so, while we can secure copyright in America.

It attempts to simplify and make clear the relation between an employer and his assistant, whether he be employed to make a photograph or to assist in carrying out a work of art, in which cases it is proposed that the copyright remain with the employer.

It defines more clearly the relation between the publishers who employ an artist to draw, or a photographer to photograph, for publication. It amends and strengthens the provisions for repressing the commission of fraud, and gives to the print-seller, the photographer, and fine art publisher, powers of which he has long felt the need, and for want of which he has been largely at the mercy of the pirates, *viz.*, power of search and seizure of pirated copies in houses and shops, and on hawkers.

These are powers which were also recommended by the Royal Commission.

In so far as they can claim to be works of art, the Bill protects the drawings of the architect and the designs of the art worker in all materials. It does not directly concern itself with International Copyright, nor with the Berne Convention, though indirectly it touches both, and these subjects are far too wide for me to enter upon.

I have tried in the time at my disposal to give you a brief sketch of the rise and progress of artistic copyright, to show you the weak spots in the present state of the law, and the reasons for the chief proposals made in the new Bill now before Parliament. As a matter of fact, it is a subject which concerns pounds, shillings, and pence only, it is a mere question of business; and yet I know of no question into which more sentiment can be and is imported. And one knows what a weighty factor is sentiment. Its introduction, however, only interferes with a true perception of the real matters which have to be considered, but painters, and sculptors, and engravers, and perhaps I shall not be far out if I add photographers, have all a good deal of sentiment about them. Sentiment is a fine thing, it belongs to the highest in man, but it is out of place in such a mere matter of business as copyright. It is as a matter of business that the Bill will be dealt with by the Committee of the House of Lords, and as a business measure it will have to pass through the fire of criticism not only before the Committee, but before Parliament; and only if it can stand this test will the Committee which is answerable for its existence feel they have succeeded in that which was their main object in framing the measure. EDWIN BALE, R.I.

In the course of the discussion Mr. T. E. Scrutton said he was the unfortunate draughtsman of the Bill before the House of Lords, and, having had the advantage or disadvantage on two occasions of being thoroughly cross-examined upon it by the House of Commons Committee, he had found the most extraordinary number of traps lurking beneath apparently the simplest language, and how possible it was for words which he thought were perfectly clear to be misunderstood in the most startling way by comparatively intelligent people. He felt, therefore, rather diffident in speaking about it, and it had been said that the worst possible person to interpret an Act was the person who draughted it. He, therefore, quite agreed with Mr. Basil Field that any discussion should deal not with details, but with the principles it endeavoured to carry out. Those principles were laid down for him by the Committee, and were, first, that the Bill should include every work of genuine art, making a broad distinction between original works of the higher arts and those which involved in the main mere reproduction, so that the author of a painting, an original statue, or an original engravings, should have higher

rights and a longer term than the man who merely used a Kodak, and went through the mechanical operation of copying, with the aid of light, some pleasing scenery. The second principle was that the present absurd chaos with regard to commission works should be swept away. At present, if he went to the Chairman, caught in a thoughtless moment, and bought a picture of him without anything being said about copyright, Sir Lawrence Tadmor would have no copyright, nor he either, because nothing had been signed by one or the other, either reserving it to the artist, or transferring it to the purchaser, and so the copyright was lost entirely. This appeared to be the result of a series of amendments in Parliament, no doubt for the purpose of ensuring that, if members of Parliament had portraits of any of their families painted they should not be reproduced without their consent. The principle of the new Bill was that the copyright should remain with the artist, unless something in writing took it away from him, but with this protection to the purchaser, that the artist could not reproduce it without the purchaser's consent. In that way the artist retained control and would be spared the pain of seeing his work used as an advertisement of somebody's soap; he would be able to control the forms of reproduction, but would not be able to circulate against the wish of the purchaser reproductions so like the original that two purchasers might stand and discuss which was the original and which the copy. The great difficulty with the Bill was that the tribunal which would settle the Bill were not artists, but gentlemen who had portraits painted, and who approached the subject from that point of view. Artists were unanimous as to the desirability of some such provision, but Parliament was a tribunal which would probably take the opposite view, and he had no doubt that the most serious difficulty would be with the clause relating to commission works. Another important principle involved was that affecting registration. The present system was a ridiculous sham; it did not really enable the public to know whether a work was copyright or not. After looking at the volumes at Stationers' Hall and finding no entry, a firm might issue an elaborate book at great expense with reproductions, and next day find themselves stopped by an injunction. The system was extremely technical, and when he had the honour of appearing for pirates, as he sometimes did, the first thing was to see if any fault could be found with the registration, and very frequently it could. An elaborately technical system lent itself to ingenious pirates. Another difficulty was the absurd complexity of the various Acts. Under the Art Act you must register before the infringement complained of or you could not sue; in the case of a book you could register the day before the issue of the writ. If registration was intended to protect the public, it did not do so; and, if it was intended to protect the artist, it failed, on account of the technicalities. You might sweep away registration altogether, and say that any one who copied a picture did so at his own risk; that would not hurt the artist, but it might hurt the enterprising gentleman who stood between him and the public—the publisher, who generally knew his way about Stationers' Hall, and it might hurt the public more than the present system, as it would make it more difficult to know whether they were getting a copyright picture. The other system would be to make registration effective by making it compulsory, and that the Bill proposed. The public would then know, by inspecting the register, whether a work was copyright or not, unless it remained still in the hands of the original artist, of whom they could then inquire. The Bill had roused a great outcry from photographers, who asked why they should be required to register every photograph they took; why could they not wait until somebody copied it? He had not much sympathy with the photographers in this matter, because they were getting far more protection than was accorded them in any other country in Europe, where the term was generally five years, and in some they had to show that the photograph was an artistic production, which would cut out a great many altogether. This Bill proposed to give them thirty years, and for that extension, and for the money they might get from the illustrated papers in consequence, he did not think they could complain of having to tell the public that they claimed the copyright. The other matter in which the Bill made an advance was that it rendered it more easy to stop infringement. Some gentlemen present knew how difficult it was to stop piracy. There were three well-known firms in Jersey, where the Art Copyright Act was not in force, which made photographs of any number of copyright pictures, which they sent to England through the post. He had seen an admirable series of photographs of the Chairman's works. The Post-office would not stop them unless you gave information—which you could not do—what packets contained copyright infringements; and it was the same with the Customs, they required to have a copy of the original supplied to them, and also information as to what packages to search. The result was that, both by post and through the Customs, large quantities of these piracies were sent to England. The people who imported them were known, but there was no power to search or seize until they began to sell. Of course, they did not open a shop; they got a gentleman of no particular occupation, name, character, or residence, and sent him about the country with a basket containing other wares, and he called at city offices, and at the backdoors of houses, and sold these pictures one by one at about a tenth of the price at which they could be legitimately obtained. If, by chance, you caught him selling a copy, you could issue a writ, and you might be able to serve

it on him, and then in the course of a few months you would get an injunction to stop him; but where would he be then? He would be miles away, and would probably have transferred his stock to another gentleman of equal substance, against whom you had to begin *de novo*. This trade, which was followed both with regard to art and music, it was impossible to stop without an enormous expenditure of time and money. The present Bill endeavoured to meet that by giving power to stipendiary magistrates to grant a search warrant, and to police constables, armed with such a warrant, to seize piratical stock in trade. From his practical experience he believed these simple expedients would be found very effective. Those were the main features of the Bill, and he predicted for it rather a stormy life, both in Committee and in the House. The photographers were up in arms against it, the process engravers had a good deal to say, and the only people perfectly satisfied with it, as far as he knew, were the Royal Academy and the painters and sculptors. It had to go before a tribunal of country gentlemen who had their portraits painted, and he feared it would be difficult to get it, in its present form, through such a tribunal. It had been very carefully considered, and he could only hope that it would pass without alteration. However altered, it could not be worse than the present system, and he sincerely trusted that, when it became the law of the land, it would confer great benefits on artists, and justify the labours of the Committee in preparing it, and the Royal Academy in promoting it.

#### THE BIRMINGHAM EXHIBITION.

Our impression of the Fifteenth Annual Exhibition of the Birmingham Photographic Society, which has been open to the public this week, is that it excels its immediate predecessor in point of average quality, although it must be admitted that it would be no light task to back up the faith that is in us by actual demonstration. But, quitting matters of impression for those of fact, it is significant of the rapid march which pictorial photography has made at Birmingham that at the Society's Annual Exhibition the members themselves supply a collection of work which is as good as we are accustomed to see at a first-class London exhibition. Nay, it must be admitted that, from whatever point of view it is regarded, the present Birmingham Exhibition challenges comparison with both the last Exhibitions in Pall Mall and Piccadilly. Leaving the Open Section out of the question, that filled by members contains photographic work by Messrs. J. Page Croft, F. A. Bolton, W. Smedley Aston, G. Wilkes, and others, which is of the highest excellence, and quite as good as the best we are accustomed to see in London in the autumn.

Our inspection of the photographs on the wall of the fine circular gallery of the Royal Society of Artists, in New-street, preceded the declaration of the Judges' awards, more than two-thirds of which we anticipated. We mention this little fact to support our remark that long experience in the inspection and judging of photographs enables us not only to single out the kind of work which finds judicial favour, but also to pursue the trend of the fashion, if we may so express ourselves, amongst prominent exhibitors. At Birmingham, last week, we distinctly perceived evidences of Mr. Alfred Stieglitz' influence having been at work. It will be remembered that at the last Pall Mall Exhibition that gentleman received an award for a dainty little sketchy portrait, head in platinum and a somewhat similar subject by Mr. J. Page Croft (a prolific exhibitor) is successful at Birmingham. Mr. Cruwys Richards also appears to us to be under this influence when he is not directly imitating the painters in their effects on canvas. A portrait of the latter description so pleased the Birmingham Judges that it was medalled. Mr. Herbert Waters, and Mr. Pierre Dubreil were also successful with work of a similar kind. It must be owned that delicately rendered photography of the nature we are referring to separates itself from its more vigorous surroundings in the way of architectural interiors, highly contrasted landscapes or seascapes, or forcible portraiture of the Dudley Hoyt description, and by its low tones and quietness of effect commands an amount of notice and attention denied to other photographs of a more familiar type.

As we have remarked, the Members' Open Class was a strong one, and amongst the eighty or so examples we were pleased with the exhibits of, besides the gentlemen named, Messrs. G. Wilkes (his No. 60 was a very graceful portrait study), W. P. W. Browne, and F. A. Bolton. The Messrs. Peach show some large and striking work; but No. 68, a study of a man's head, is a crudely illuminated production which offends the eye. So, too, the lurid red tones of Mr. Page Croft's *Melody* (No. 7) "rise up" against one. The winding path in *A Weary Road* (No. 27), by Mr. Hugh Lewis, has a peculiar ribbon-like effect, the reverse of pleasing. But there is little to find fault with and much to applaud in the section, although, truth to tell, there is not a great deal that is out of the common in it.

Coming to the Open Section, we thought Mr. Topham's idea of *Babes in the Wood* (No. 88)—two uninteresting-looking children in a snowy wood—a rather poor interpretation of the nursery tale. The bluish tone of *Leafy June* (No. 91), by Mr. W. E. Dowson, is not suited to such a subject; something suggesting sunniness is needed. So, too, Pierre Dubreil's *Niège au Bois* (No. 181), a number of broad tree trunks of the

colour of the frame and against a snowy background—nothing more absurdly commonplace could be imagined. "A ha'porth of picture and n intolerable deal of mount" is the paraphrase of Falstaff, that occurred to us when contemplating Mr. Smedley Aston's *Ram Hall Farm* (No. 232), in which this distinguished worker gives us a little view about midget size on something like a 15x12 mount. Justification for eccentricities of this kind is not easy to supply.

With these few grumbles we must pass a word of commendation to many strikingly good pictures in the section by Messrs. R. S. Webster (portraits); J. Kearney, jun.; T. E. C. Wilson (sheep study); W. Illingworth (a very fine study of the head of a tramp); Wm. Rawlings; F. Page Croft (some excellent portraiture); Dudley Hoyt (portraits); W. T. Greatbach (this able worker being represented in many moods); H. C. Leat (for a singularly effective study of a lamp-lighter at work); W. Smedley Aston (Mr. Tree as King John, giving him the opportunity of excelling in a bit of theatrical portraiture); Bernard Moore (with a really beautiful and realistic study of reedmen, presumably in Norfolk); Alexander Allan; C. F. Inston (his Pall Mall pictures were hung at Birmingham); and R. N. Speight (an old fellow cautiously lighting his last match). Good architectural work comes from Messrs. Bland and Burkinshaw; and some Parsee studies from Mr. Bhedwar. But the chief triumphs of the section are earned by Messrs. Page Croft, Greatbach, and Smedley Aston. The first-named is perhaps unequal in his exhibits, but the others show some of the most charming landscape and portrait studies we have recently seen; indeed, their versatility is nothing short of astonishing.

Great pressure on our space this week obliges us to abbreviate our remarks, but we may note that there was a capital loan collection on view—a section open to members not hitherto successful in competitions, a Warwickshire survey collection, and a small exhibition of apparatus. We must congratulate the Society on having organized a very fine exhibition indeed, and to have simplified its classification. One year, if we remember aright, there were no less than twenty-two classes; this year there are practically only three—a distinct change for the better.

The following is a complete list of the awards made by the Judges, Messrs. Crooke, Wainwright, and Wellington:—

MEMBERS' SECTION A.

Silver medals, *A Sussex Shore*, Mr. W. Smedley Aston; *Toward the Western Sea*, Mr. Francis A. Bolton. Bronze medals, *The Lonely Margin of the Sea*, Mr. Francis A. Bolton; *Study of a Head*, Mr. J. Page Croft; *Fading Day*, Mr. W. Smedley Aston. Certificates, *The Picture-book*, Mr. W. Smedley Aston; *A Remnant of the Past*, Mr. H. J. Yates; *A Syren*, Mr. J. P. Croft.

MEMBERS' SECTION B.

Open to Members who have never taken a Prize (Insets of Three Prints).

Silver medal, Mr. George Whitehouse. Bronze medal, Mr. A. C. Scrivener. Certificates, Messrs. George Whitehouse and P. B. Rider.

OPEN SECTION.

Silver medals, *A Thames Tramp*, Mr. Hubert Waters; *A Stormy Sunset*, Mr. W. A. J. Hensler; *Words of Comfort*, Mr. Alexander Allan. Bronze medals, *Sentinels*, Mr. J. Page Croft; *J. H. Henshaw* (untouched head), Mr. Thomas Lewis; *Old Ann*, Mr. Alexander Allan; *The Day's Work Nearly Done*, Mr. W. T. Greatbach; *The Ford*, Mr. W. T. Greatbach; *After Mucha*, Mr. Heath John Haviland. Certificates, *Study of a Tramp*, Mr. W. Illingworth; *Portrait*, Mr. J. Cruwys Richards; *Eventide*, Mr. J. Cruwys Richards; *The Last Match*, Mr. R. N. Speight; *Portrait*, Mr. J. Cruwys Richards.

LANTERN SLIDES (SETS OF SIX).

Silver medals, Dr. J. W. Ellis and Mr. John Gunston. Bronze medals, Messrs. C. S. Baynton and John Beeby (New York). Certificate, Mr. J. Kearney, jun.

Our Editorial Table.

THERE is one fault that we must urge against the *Illustrated Annual of Microscopy* for 1900 (published by Messrs. Percy Lund & Co., Amen Corner, E.C.), and that is the omission from the title-page of an editor's name. The anonymous compiler has done his work excellently. Microscopists and photo-micrographers will find in the book a number of beautifully illustrated articles on those two branches of study to which we can scarcely render sufficient justice in this brief notice; we may, however, indicate a contribution by Mr. E. R. Turner on stereo-photo-micrography, chromo-photo-micrography, and stereo chromo-photo-micrography, as pointing to comparatively untrodden fields in photo-micrography.

IMPRESSIONS OF AMERICA.

By T. C. PORTER, M.A. With Diagrams and Stereoscopic Views. 240 pp., price 10s. 6d. London: C. Arthur Pearson, Limited, Henrietta-street, W.C.

In a paper read at the Gloucester meeting of the Photographic Convention of the United Kingdom last July, the subject of binocular vision and the stereoscope was briefly touched upon by the Editor of this JOURNAL.

Simple directions were given for controlling the accommodation of the eyes so as to enable stereoscopic pictures to be seen binocularly without a stereoscope, and, amongst other things, the suggestions were made that young children might advantageously be taught to develop this power over the ciliary muscles, and that, in course of time, our books might, to a very large extent, be stereoscopically illustrated. These suggestions provoked the jeers of a contemporary writer, who, it is only charitable to suppose, was ignorant of the fact that so far back as 1858 the late Professor Piazzi Smyth produced a book stereoscopically illustrated, and that, moreover, the construction of the human eyes admirably lends itself to the very slight amount of muscular effort demanded by their conversion into what may be termed a non-magnifying stereoscope.

Oddly enough, Mr. Porter's book was published about the time the paper above referred to was read, but until this moment no opportunity has come to us of giving it detailed reference in our pages. To photographers Mr. Porter's readable account of his American holiday and the data about some natural phenomena which it enabled him to collect will probably prove of less interest than the preface and the illustrations. The former gives very full instructions as to how the pictures may be seen in relief without the aid of a stereoscope, and we must congratulate Mr. Porter upon having gone so thoroughly into the matter. His directions are sound and practicable. We, however, are of opinion that his method of seeing lantern pictures in relief by projecting the two halves of a stereoscopic transparency out of register—necessarily so, of course—and regarding them with crossed axes, is open to objection on the ground that strabismus might possibly result in some cases. But this is a minor matter.

There are about forty stereoscopic illustrations in the book, reproduced in fine-grained half-tone, which, if not so suitable for the purpose as colotype, yet answer in this instance exceedingly well. Mr. Porter knows how to take a binocular photograph which shall give a good effect, and we have examined his views with much pleasure. A little stereoscope is supplied with the book, which, both on general as well as particular grounds, we can recommend to photographic readers. We hope to see it soon followed by other volumes illustrated in a similar manner.

THE PHOTOGRAPHER'S NOTE BOOK.

By SIR DAVID SALOMONS, Bart., M.A. London: Marlon & Co., Soho-square.

To the revised edition of this little book some additions have been made by the author. Besides many pages for recording particulars of exposure, the data relating to enlargement calculations, depth of focus, and rules for exposure will be found of permanent practical use. It is entirely a well-edited little book which the photographer will find as trustworthy as it is handy.

*To the Riviera and Italy for a 10l.* Note is the title of a neat phototypically illustrated little pamphlet, telling the traveller in search of sunshine how to reach that "better land" which the rigours of the English winter and spring compel so many of our fellow-countrymen to fly to (temporarily) every year. It is issued under the auspices of the London, Brighton, and South Coast Railway Company.

THE Vanguard Manufacturing Company, of Maidenhead, send us a quantity of their meto-quinol developer (which we tried in the development of some bromide paper with most pleasing results), put up in a bottle with a screw stopper specially devised for the purpose after considerable experiment. This stopper is deficient in the vices of ordinary stoppers, corks, and so forth, and possesses the supreme positive virtue of knowing its place and keeping it. It comes as a boon and a blessing in many respects, and not least as an obviator of bad language in the dark room; hence we accord it a hearty welcome.

WITH an intimation that applicants for copies may have them free of charge, Messrs. Mawson & Swan, of Soho-square and Newcastle-on-Tyne, send us a little book relating to the use of their dry plates and films. It contains numerous half-tone illustrations from negatives made on those justly renowned sensitive surfaces, one of them on a plate sold in 1884 and exposed and developed in 1898. Judging by the picture, the negative was perfect, and we do not think the well-known Castle plate could receive a better testimonial than the fact of some of that brand having kept well for the long period of fourteen years. The booklet also contains developing formulæ, useful hints and notes, and directions how to make transparencies for the lantern. Another little book which will be found useful in recording notes of exposures accompanies it, and, as we have said, the two are sent post free to applicants.

Studio Gossip.

A WELL-KNOWN artist went to a "book-tea" lately, wearing on his coat two photographs, one of Sir Blundell Maple, the other of Sir Thomas Lipton, and round his neck was hung a string, to which were fastened two old teeth. The meaning was *New Men and Old Acres*.

AN ERRAND BOY SENT TO A REFORMATORY.—At the Leeds Police-court, on Friday last, Harry Eaton, a lad of fourteen, residing at 4, Upper Bell Hall,

Halifax, was charged with having stolen a bag containing cash, cheques, and postal orders, the property of Messrs. James Bacon & Sons, photographers, 149, Woodhouse-lane, Leeds, by whom he was employed as errand boy. It appeared that he had only been in the service of the firm three days when he stole the money, that had been left in a drawer for banking purposes. He was subsequently arrested at Keighley. The prisoner pleaded guilty, and was sent to the Adel Reformatory until he was nineteen years of age.

MRS. CHAMBERLAIN, says the writer of an article on Mr. Chamberlain in the *Universal Magazine*, has a strong objection to her photograph being sold or exhibited in shop windows. An instance is on record of a Birmingham tradesman, who, soon after her marriage, introduced Mrs. Chamberlain's photograph into one of his advertisements, but who received a peremptory order from Mr. Chamberlain's solicitors to instantly withdraw it. Mrs. Chamberlain accompanies her husband on all his political missions, and takes a great interest in everything in which he is concerned. She is an admirable hostess, and, moreover, is a great favourite with the Queen, who has more than once shown her special marks of favour.

FIRE.—Early on Saturday morning an alarming outbreak of fire was discovered in the studio of Mr. Edward Kraus, photographer, of 2, Werter-road, Putney, and, had it not been for the timely assistance of the fire brigade, would have resulted in a disastrous conflagration. The cause of the outbreak has not been ascertained, but when Mr. Kraus retired to rest on the Friday night there was not the slightest sign of fire, and he was even working in the studio until a late hour. About three a.m. on Saturday, he was aroused by the presence of smoke in his bedroom, and on rushing downstairs he was greatly astonished to find his studio in flames. The police were at once called in, and they rendered valuable assistance, but, if it had not been for the arrival of the Battersea and Wandsworth fire brigade shortly afterwards, the effects of the fire might have been disastrous. The brigade soon got the flames under, but a considerable amount of damage was caused to the apparatus. The premises are insured in the Liverpool, London, and Globe Insurance Company.

## News and Notes.

PHOTOGRAPHIC CLUB.—Wednesday evening, March 7, at eight o'clocks "Electric Printing without Ink, and one of Colours Enigmas," by Mr. W. Friese-Greene.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Thursday, March 8, Lantern Night. Visitors are welcome at the White Swan, Tudor-street, E.C.

THE TWENTIETH CENTURY PHOTOGRAPHIC EXHIBITION.—M. Welford desires us to announce that he has arranged with Mr. F. Goddard, Hon. Secretary of the South London Exhibition for the prompt dispatch of exhibits from Camberwell to Birmingham, so that the same pictures can be entered at both Exhibitions.

The Exhibition of the South London Photographic Society will be opened by Mr. G. C. Whiteley, M.A., M.L.S.B., at the Public Baths, Church-street, Camberwell, S.E., on Saturday next, and will remain open until Saturday, March 10, when the awards made by Messrs. Bayley, Bedding, and Wall will be distributed at eight p.m.

At the last meeting of the Croydon Camera Club, Mr. B. E. Edwards announced his discovery of the useful property possessed by borotartarate of potassium, if added to a developer, in preventing over-contrast, for which purpose he advised a few drops of a ten per cent. solution should be added to each ounce of developer. Development is retarded by the above. An excess will entirely prevent any density.

A YEAR or two ago, says a daily contemporary, a tourist from Baltimore, while in Alexandria, purchased a mummy in a case, and took it home to the States with him. Lately, wishing to assure himself of the genuine character of his possession, he subjected the swathed figure to the Röntgen rays, when it was found to lack a skeleton. Tearing the mummy open in disgust, he found, besides straw and shavings, and English, French, and Egyptian newspapers of ten years ago, a ticket of admission to the British Museum Reading-room, which is dated 1880!

MR. ROBERT H. SCOTT, who has been thirty-three years in the Meteorological Office, retired from the position of Secretary to the Council on Wednesday last. His successor is Mr. W. N. Shaw, a present member of the Meteorological Council. Mr. Shaw is a Fellow of Emmanuel College, Cambridge, and has for some time been Assistant Director of the Cavendish Laboratory, and Lecturer on Physics at the University of Cambridge. Mr. Scott will retain the Hon. Secretaryship of the International Meteorological Committee, which he has held for twenty-five years, until the next meeting of the Committee in September.

The Röntgen Society's future arrangements are: April 5, Dr. Norris Wolfenden and Dr. Forbes Ross, "The Influence of the X Rays upon the Growth and Development of Micro-organisms." May 3, Dr. Dellpratt Harris, a short paper, "On a Form of Focus Tube Designed to be Self-heating." This is to be an Exhibition evening. Smoking will be permitted. Tea and coffee will be provided. Members are invited to bring skiagrams, or other objects of interest; but, if requiring more than a few minutes' description, to communicate previously with the Hon. Secretary, Mr. F. Harrison Low, M.B., 12, Sinclair-gardens, W.

At the Public Hall, Reigate, on Tuesday, March 13, in aid of the Transvaal War Fund, Mr. Henry Speyer will repeat his lecture, "Round about the Matterhorn and Aletsch Glacier," illustrated by 150 original photographs, which will be shown under the lantern management of Mr. William Brooks, President of the Redhill and District Camera Club. The chair will be taken by Mr. J. Topham Richardson, at 8.30 p.m. precisely. The bills announcing Mr. Speyer's lecture are appropriately enough printed on khaki-coloured paper. Mr. Speyer's first lecture on behalf of the Redhill and District Camera Club resulted in a net profit of 16*l.* 7*s.* We wish him even greater success in his efforts to benefit the War Fund.

WE regret to have to announce that Professor Charles Piazzi Smyth, late Astronomer Royal for Scotland, which office he filled for forty-three years, died last week at Ripon, at the age of eighty-one. He began his astronomical career at the Cape of Good Hope sixty-five years ago, afterwards assisting in the re-measurement of La Caille's South African Arc of the Meridian. When appointed to his Scottish post, he set himself to clear off some five years of arrears of work in computation. In 1859 he visited the Russian observatories, and made a report upon them. The work by which he is best known is *Life and Work on the Great Pyramid*. In August 1888 he retired to Ripon, where he devoted himself to spectroscopy and to the study of cloud forms. In former years Professor Smyth was a frequent and valued contributor to this JOURNAL and its ALMANAC.

ROYAL PHOTOGRAPHIC SOCIETY.—Applications for Fellowship will be received by the Admissions Committee on Wednesday, March 7. The following are the regulations which have been drawn up by the Council to govern the admission of Fellows: Admission is by the Council. Applicants must first become ordinary members of the Society. It is desirable that a candidate should furnish the names of one or more members of the Society to whom he is personally known. Every application shall be accompanied by a statement of the qualifications of the candidate in relation to one or more of the following heads: Important contributions to photographic knowledge, either in theory, practice, or invention; the production of notable work, either in pure photography or in the arts and sciences kindred thereto; work done in disseminating photographic knowledge; any public service tending to the advancement of photography. The heads specially dealing with students, as follows: The student must show, to the satisfaction of the Council, that he has received a suitable general education, and that he has a good knowledge of photography in general, or at least a fair knowledge of the general subject and a special knowledge or experience in one or more of its branches. As to general education, the Council suggest the following examinations: The matriculation, preliminary, or entrance examinations of the various universities and colleges, the Oxford and Cambridge local examinations, the higher examinations of the College of Preceptors. In photography and allied subjects the Council suggest the examination of the City and Guilds Institute in photography, especially the Honours stage, the examinations in chemistry, physics, drawing, painting, and other allied subjects, held by the Department of Science and Art, and the various educational bodies. Forms of application and all information may be had on application to the Secretary, 66, Russell-square, London, W.C.

## Commercial Intelligence.

SECCO FILMS, LIMITED, of 39, Lombard-street, inform us that they are now stocking films in cut sizes from quarter-plate to 15×12, and on spools for daylight loading cameras.

WE are sorry to learn that Mr. F. Parsons (Messrs. Hinton & Co., Bedford-street) has been laid up for about the last three months with rheumatic gout. He is now getting better, although two or three weeks will elapse before he can return to business.

THE decimal and metric systems of weights and measures are reported to be in use all over Brazil, and are employed throughout the tariff. Weights are always calculated in kilos. Measures vary according to the article, some being in English yards, others in metres, and others in Portuguese varas. When the English system is adopted in invoicing, it is stated, in a report on matters of commercial intelligence relating to Brazil, to be generally advantageous to give equivalents in the decimal system for Custom-house work and other purposes.

THE KODAK IN WAR.—In an interview with a representative of the *Daily Mail*, the Manager of Kodak, Limited, said that the war had caused a very marked demand for cameras and materials. Officers, as well as correspondents, took out cameras as a matter of course, and, although the war had to some extent thrown back the export business with South Africa, it had more than compensated for such loss. The Kodak Company had supplied innumerable outfits, and had a large collection of pictures sent home from the front by delighted amateurs. By means of the "daylight changing cartridges," men at the front had been able to secure dozens more pictures than would be possible with the ordinary plate. The number of pictures sent home was so large that the Kodak Company would have a practically complete story of the war, both in Natal and Cape Colony, in pictures. In fact, they had photographs of the troops from the time they went aboard ship at Southampton.

GLASS-MAKING IN HOLLAND.—According to native historians, the glass history of Holland dates back to the sixteenth century, and it is said that in that early day it had assumed large proportions. No trustworthy statement regarding this old-time industrial development exists, and authorities on the glass industry outside of Holland have failed to make record of any extensive manufacture in this line in that country. Delft ware, Hollands gin, linen, and Dutch paper have all been well known for centuries, and it is known that, for at least over 100 years, some very miserably made semi-green vials have been sold all over the world containing Haarlemensis and Haarlem oil; and for more than a century home-made bottles have been exported containing Hollands gin; but there is no reliable record of the existence of any bottle factory previous to the eighteenth century, and old Holland glassware is conspicuous by its absence. To-day, however, besides the plate-glass works in operation and the existence of several silvering and bevelling establishments, there are thirteen furnaces in operation producing flint and green bottles, nine of them being in Zuid-Holland, three in Geldern, and one in North Holland. Most of the bottles are used by the home distilleries, and are largely exported with domestic liquors. Some of the factories are excellently equipped and able to sell their ware in competition with French and German bottles, though some few of them are unable to cope with imported bottles, and are partially idle, except in seasons of excessive demand. There are four table-ware factories, one each in Maastricht and Leerdam, the product of which is equal to

foreign ware imported. Brown cylinder and bent glass is made in Utrecht, Utrecht, and Haarlem; about 3000 workmen are employed, and the annual value of the product is about 3,000,000 gulden, about 1,000,000 den-worth of which is exported.

**A PECULIAR CLAIM.**—In the Queen's Bench Division of the High Court, before Mr. Justice Ridley and a special jury, the case of *Ellis versus Eyre & Cottiswoode* came on for hearing. It was an action to recover damages for breach of contract and commission earned. The defendants denied that they had broken the contract, and counter-claimed for 51*l.* 14*s.* 11*d.*, moneys advanced to the plaintiff. Mr. Witt, Q.C., in opening the plaintiff's case, said the plaintiff had been employed by the defendants as a photographer for many years. In 1898 the plaintiff conceived the idea of photographing works of art abroad. In March 1898 an arrangement was entered into between the plaintiff and the defendants for the plaintiff to go abroad with photographs of pictures in our galleries, and obtain orders for them, also getting the permits. He went abroad and spent 50*l.* in getting the permits. The plaintiff then proposed that he should photograph a series of pictures in the Louvre and in the galleries of Brussels and Antwerp, and that the defendants should pay him 2*s.* for every negative he took. The negatives were to be 12 × 10 inches, and the agreement was to last for five years. On April 6 the plaintiff had an interview with the defendants' manager, and terms were discussed, the plaintiff saying that it was necessary that the defendants should push the sale of his photographs abroad. An agreement was drawn up whereby the plaintiff was to get 1*l.* 11*s.* 6*d.* for every negative, and a royalty of ten per cent. upon the sales of his photographs abroad. The plaintiff signed the agreement, believing that the defendants would push the sale of his works. The work on the continent cost the plaintiff 110*l.* The defendants said they were not bound to push the sale of the photographs. Mr. Bray, Q.C., for the defendants, said it was intended to add to the written agreement an implied obligation to send a traveller out. The defendants never sent travellers out. They had appointed an agent in Paris, and sent circulars out to agents abroad. Mr. Justice Ridley said there was no proof by the plaintiff that the defendants had not pushed the sale of the photographs, even assuming that there was an implied obligation on the defendants to push the sale, and there must be judgment in favour of the defendants on the claim and counter-claim, with costs.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
.....	Bradford Photo. Society .....	<i>Winter Sports in Norway.</i> Howard Priestman.
.....	Cripplegate Photo. Society .....	<i>Platinotype Process.</i> A. Horsley Hinton.
.....	Glasgow and West of Scotland .....	Demonstration: <i>Lantern Slides.</i> A. J. Kay.
.....	Kingston-on-Thames .....	Demonstration: <i>Carbon Printing.</i> Chas. J. Kirk, F.R.P.S.
.....	Southampton .....	<i>A Visit to South Africa.</i> Slides lent by the Union Steamship Company, Ltd.
.....	Stafford Photo. Society .....	Lantern Evening and Members' Slide Competition.
.....	Bristol and West of England .....	Elementary Technical Instruction Meeting: Use of the Society's Apparatus for Enlarging, Reducing, and Copying Work.
.....	Brixton and Clapham .....	<i>The Evolution of a Picture.</i> J. H. Gear, F.R.P.S.
.....	Gospel Oak .....	Demonstration: <i>Lantern-slide Making.</i> Messrs. Morris and Rayner.
.....	Hackney .....	Annual General Meeting.
.....	Redhill and District .....	Demonstration: <i>Ferguson's Method of Toning Bromide Prints with Copper.</i> John Sterry.— <i>Snowdon in Winter.</i> Henry Speyer.
.....	Royal Photographic Society .....	<i>Some Beauty-spots of English Scenery.</i> J. A. Hodges.

.....	Edinburgh Photo. Society .....	<i>Colour Photography.</i> J. Tudor Cundall, B.Sc. (Lond.).
.....	Photographic Club .....	<i>Electric Printing without Ink, and one of Colour's Enigmas.</i> W. Friese-Greene.
.....	Royal Photographic Society .....	Exhibition of Work contributed by the National Photographic Record Association. Introductory Address by Sir Benjamin Stone, M.P.
.....	Southsea .....	<i>A Tour through Dresden, Prague, and Savon Switzerland with a Camera.</i> H. T. Lilley, M.A.
.....	Woodford .....	<i>My Printing Methods.</i> A. Horsley Hinton.
.....	Darwen .....	Demonstration: <i>Secco Films.</i> The Secco Films Company.
.....	Liverpool Amateur .....	<i>Norway.</i> W. Mallinson, B.A.
.....	London and Provincial .....	Lantern Night.
.....	Ashton-under-Lyne .....	Elementary Photography Class.
.....	Borough Polytechnic .....	Practical Evening: <i>Photography by Night.</i> <i>Portraiture.</i> Harold Baker.
.....	Bristol and West of England .....	Prize Slides.
.....	Croydon Microscopical .....	Lecture by Member of the Club.
.....	Whitby .....	

### ROYAL PHOTOGRAPHIC SOCIETY.

FEBRUARY 27,—Technical Meeting.—Mr. T. R. Dallmeyer, F.R.A.S. (President) in the chair.

#### ELECTION OF OFFICERS.

The HON. SECRETARY (Major-General Waterhouse) announced that the Council had elected Mr. J. A. Hodges as Hon. Secretary, Mr. Horace Wilmer as Hon. Librarian, Sir W. de W. Abney, K.C.B., as Hon. Editor of the

*Journal*, and Mr. Francis Ince as Hon. Solicitor; and that Mr. W. Thomas had been appointed to fill the vacancy on the Council caused by the election of Mr. Hodges as Hon. Secretary.

#### AFFILIATION.

It was also announced that Messrs. A. Mackie, H. Vivian Hyde, and Snowden Ward had been appointed delegates to represent the Society on the Affiliation Committee; and that the Bromsgrove School Photographic Society had been admitted to affiliation.

#### THE FORTHCOMING EXHIBITION.

The HON. SECRETARY stated that the Selecting and Hanging Committee, in connexion with the Exhibition of 1900, had been constituted as follows:—*Pictorial Section:* W. Thomas, A. Mackie, F. C. Lambert, H. Vivian Hyde, J. C. S. Mummery, J. A. Sinclair. *Technical Section:* W. B. Ferguson, Q.C., Gen. Waterhouse, E. Sanger Shepherd, J. J. Vezey, E. J. Wall, F. A. Bridge.

#### ANOTHER COLOUR PROCESS.

Mr. FRIESE-GREENE showed the results of some preliminary experiments in connexion with a new method of colour photography. He had made discs comprising red, green, and blue sectors, either of coloured glass or of cells containing suitable dyes, the colours and the size of the sectors being arranged in accordance with Clerk-Maxwell's curves, and had exposed plates in the camera while the discs were rotated in front of the lens, and lantern slides from the negatives so produced were projected with the rotation of a similar set of sectors in front of the projecting lens. He claimed that the results showed colours fairly approximating those of the originals, the subjects being tiger lilies and other flowers, a stained-glass window, and a sunset cloud effect. It appeared that the same sectors were used both in taking the pictures and projecting them, and that sectors suitable for one subject would not be suitable for another; but Mr. Friese-Greene said the process was as yet quite in its infancy, and he expected to be able to devise a standard colour disc which would be universal in its adaptation and capable of the most satisfactory performances. In the course of a conversation which took place later in the evening, the process was rather severely criticised, and he was the victim of a good deal of heckling, but he said he was not unused to the adverse reception of early ideas with regard to an invention which had been received years afterwards with popular approval. He quoted some of the remarks which were passed upon his introduction of animated photography, of which he was admitted to be the originator, and caused some amusement by repeating the views which were expressed at that time by a member who had taken part in the heckling on this occasion.

#### ELECTRICITY AND PHOTOGRAPHIC ACTION.

Mr. FRIESE-GREENE then gave a demonstration of certain phenomena in connexion with the effects of electricity upon the action of the photographic plate. He mentioned incidentally that, in preparing solutions of developing agents for the purposes of experiments in this direction, he had been unable to make a metol solution of more than five per cent., but he had found that, by taking a twenty-five per cent. solution of pyro, he could dissolve in it twenty per cent. of metol. One drop of this mixture to two ounces of water, with one drop of ammonia '850, formed an exceedingly energetic developer. He had made experiments with every developer he knew, and found that all of them acted electrically. A piece of paper having been dipped for a minute in a ten per cent. solution of, say, aduro, and surface-dried, was placed upon a metal pad connected with a battery, and a coin was connected with the other pole of the electrical apparatus, and pressed in contact with the paper, which almost immediately showed a print of the coin. A dry plate, if left in contact with this print for a minute, also received a developable image of the coin, even though the plate had previously been exposed to light, and a similar result was produced if the reverse side of the paper was in contact with the sensitive film, and this could be done repeatedly with the same paper print. Mr. Greene also showed the method of electrical inkless printing, by means of which impressions are made from stereo blocks without ink or rollers.

#### COMING EVENTS.

March 6, Lantern Evening, "Some Beauty-spots of English Scenery," by Mr. J. A. Hodges. March 7, opening of an Exhibition of photographs arranged by the National Photographic Record and Survey Association, with an address by Sir Benjamin Stone, M.P. March 13, Ordinary Meeting, "The Illumination of Developing Rooms," by Mr. Howard Farmer. March 20, a demonstration of the Heliogravure Process, by Mr. Ignatz Herbst. March 27, "Some Developers Compared," by Mr. Alfred Watkins.

#### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 22,—Mr. J. E. Hodd in the chair. Mr. R. BECKETT said he had been trying the solutions recommended by Mr. W. B. Ferguson for copper toning, and found that there was much to be done in this way. Very pleasing tones could be obtained on bromide prints, their character could be altered to a considerable degree, and the process was of the simplest description. At a certain stage there seemed to be a brightening of the print, or intensification, and a half-minute's treatment gave a very nice brown-black. Such an example was shown, also one in which the toning had been carried yet further. In this there appeared to be a kind of selective action. In the deep shadows little change was wrought, while in the lighter tints there was a reddening action. This was probably due to the condition of the gelatine in the print. The dark portions seemed to be able to resist the solutions. This was seen in two or three of the subsequent examples until the whole image became wholly red. Carried beyond such a stage, Mr. Beckett did not think any further action would result. There was no staining of the bath caused staining; if increased, there was little chance of stains appearing, and the action was slowed, which was preferable to quick action. Mr. A. HADDON experimented in the direction of copper toning some seven years ago, but not in the same way as Mr. Ferguson had. As far as he could judge, they were still as good as when produced although he believed one or two had assumed a kind of iridescence.

Some discussion centered on the suggested influence of the developer used in the first place for making the prints. Different reducing agents had different degrees of tanning action upon the gelatine. Some of the prints were done with amidol, some with metol, hydroquinone, &c.

Mr. J. S. TEAPE suggested that copper had no advantage over uranium, with which all the tones shown could be obtained.

Mr. BECKETT believed copper gave a more permanent print. In the case of uranium one had also to be particularly careful to keep the print away from an alkali, which would soon ruin the tone. The price was also to the advantage of copper.

Mr. WALTER D. WELFORD showed some film negatives in which were some tear-like marks, not unlike development marks. They were not development marks, but were caused, he found, during the time the films were left soaking between fixing and washing.

Mr. HADDON considered that air bells were probably formed in immersing the fixed films in the soaking bath, and the hypo remaining in the film in contact with the air would, as was to be expected, reduce the image at that spot.

This explanation was generally accepted.

Mr. BECKETT remarked that, in different conditions, hypo baths had very different effects. A very old and much-used fixing bath will actually intensify a plate.

Mr. HADDON remarked that one approached very near to Wellington's intensifier in this case—a developer plus silver dissolved in hypo, and an old fixing bath was charged with silver.

Mr. FRESHWATER brought up the question of copyright and the new Bill which will shortly be laid before the House. At the Society of Arts Mr. Bale had read a paper upon the subject, and, from the report of the discussion, it seemed that there was an intention to convey an impression that photographers were not opposing the Bill, which aimed at depriving them of privileges so long enjoyed, and placing photography in a position of far less security than that now proposed for painting and the allied arts. He thought that this impression should be speedily contradicted, as photographers were strongly opposed to the Bill, and had entered a strong appeal against it.

#### PHOTOGRAPHIC CLUB.

FEBRUARY 21.—Mr. E. A. Newell in the chair.

Mr. Walter D. Welford and Mr. W. F. Slater, the organizers of the Belgian photographic excursion which took place last summer, had arranged an exhibition of the prize prints and slides which resulted from the trip. Mr. SLATER believed that the work shown, which was by beginners and old workers both, would finally dispose of an idea, which had gained considerable currency, that no serious work could be done by such excursions as these. Members of the party had offered prizes of medals for the work done in Belgium—two for slides, two for prints, and one for hand-camera work. Mr. A. Horsley Hinton had awarded the medals as follows: Silver medal for the best print to Mr. T. Lee Syms; bronze medal to Mr. Simmons, of Reading. For lantern slides, the first medal to Mr. Rogers, of Croydon, and the bronze to Mr. Dunning, of Usk. The medal for hand-camera work went to Mr. Rogers also. The slides shown were not those which are travelling the country, but were selected from those sent in for competition.

Mr. ZAEHNSDORF announced the formation of the Deal and Walmer Camera Club, and said that members of this Club would be welcomed there. The Secretary was Mr. White, of High-street.

Samples of Scholzig's Siennatype printing-out paper were passed round.

Goldsmiths' Institute Camera Club.—February 22.—Mr. F. O. BYNOE lectured in the Central Hall of the Institute on

#### THE CAMERA—AN AMUSING AND INSTRUCTIVE COMPANION.

Mr. J. S. Redmayne, B.A., took the chair, and Messrs. A. W. Green and J. W. Barlow were in charge of the lantern. In the course of his lecture Mr. Bynoe lucidly explained the working of hand cameras and the first principles of photography, illustrating his remarks with diagrams and mechanical slides. Some fine examples of the slide-maker's art, depicting hand-camera work in all parts of the world were thrown on the screen, and, thanks to the courtesy of the editor of the *King*, Mr. Bynoe was enabled to include in the series a number of the very latest Transvaal war pictures. It is needless to add that the latter especially were received with loud and continuous applause. The meeting was in every sense a brilliant success, an audience of upwards of 1600 people, from all parts of the metropolis, listening with rapt attention to the lecturer from start to finish. In point of numbers, last year's record was handsomely beaten.

North Middlesex Photographic Society.—February 19, Mr. Rawkins in the chair.—Mr. H. W. BENNETT, F.R.P.S., lectured on

#### EXPOSURE.

He commenced by saying that neither exposure nor development should be mechanical, but the procedure should depend upon what the subject was and what result was wanted. The least exposure that would give well-marked details in the shadows should be ascertained, and modifications should be based on that. He showed tables of the light for all times of the year, and the exposures required for different classes of subjects, from clouds to dark interiors, all based on personal experience. They showed variations from 1 to 40,000, and were all to be met with in ordinary work. He never met a photographer who could estimate exposure correctly by viewing the image upon the ground glass, and he considered meters, depending upon the darkening of sensitive paper, to be unsuitable, as in bad light the sensitiveness of the paper was much less in proportion to a dry plate. There were five things to take into consideration when making an exposure—subject, plate, lens aperture, time, and weather. If a rule was made always to calculate the exposure for one stop, say,  $f-16$ , and one plate, calling that stop 1, then it would be easy to calculate for any other;  $f-22$  would be 2,  $f-32$ , 4, &c. The subject and time (of day and year) could be found from tables, easily carried in the pocket. As to the weather, taking a bright day, with light white clouds about as the best light, then a cloudless day would require double when the

sun was obscured three times, and, on days when five times the normal would be required, not many people would be photographing. With regard to the plate, it was better to keep to one kind of medium rapidly, as constant changing from one speed to another upsets calculation considerably. The exposure required was obtained by multiplying the subject, stop, time, plate and weather as found in the tables, the product being the exposure in seconds. It should be said that in the tables all figures were calculated for  $f-16$  for on plate, the weather being the best possible. He gave the approximate relative speeds of a few well-known plates: Castle, 1; Ilford,  $\frac{2}{3}$ , requiring 1 to 3 times Paget XXX, 1; Edwards's medium isochromatic,  $\frac{2}{3}$ ; Imperial ordinary,  $\frac{2}{3}$ . At the close of the lecture Mr. Bennett kindly offered to supply any member with any or all of the tables should they wish to obtain them.

Liverpool Amateur Photographic Association.—At the last month's meeting Mr. WILLIAM HARVEY gave a lecture on

#### ENGLISH CATHEDRALS.

The chair was occupied by Mr. J. H. Welch (President). Mr. HARVEY, in his lecture, which was illustrated by about 150 lantern slides, the majority taken when on a cycling tour, visited York, Beverley, Lincoln, Peterborough, Ely, London, Windsor Castle (St. George's Chapel), Winchester, Salisbury Wells, Gloucester, Worcester, Lichfield, and Chester, dwelling on the various beauties of the structures, and tracing the development of ecclesiastical architecture in England, showing examples of different periods. The slides were of excellent quality, and reflected credit on the lecturer.

Redhill and District Camers Club.—February 23.—Mr. T. PERCIVAL PADWICK gave a demonstration on

#### PRINTING IN CLOUDS.

In the course of his introductory remarks Mr. Padwick said that he thought all interested in landscape photography would agree that most pictures were greatly enhanced by the introduction of suitable clouds. As it was not always possible to get the clouds on the same negative as the landscape, "printing in" had to be resorted to in order to obtain the desired result. Mr. Padwick then, with the aid of an enlarging lantern, gave a very clear and able demonstration of the manipulation of the cloud and landscape negative in obtaining a composite print. During the evening, Mr. William Brooks exhibited some lantern slides, to show the high quality and utility of the new optical lantern which the Club has just acquired. It is only necessary to say that the lantern was specially selected for the Club by Mr. Brooks and that it is the very best that could be purchased for the amount placed at his disposal. The Club is to be heartily congratulated on the acquisition of such a useful piece of apparatus.

Southsea Amateur Photographic Society.—The Annual Dinner of this Society was held on Wednesday, the 14th instant, at the Central Hotel, Portsmouth, when about thirty members and friends assembled. The President of the Society, Mr. H. T. Lilley, M.A., presided, and the vice-chair was occupied by Dr. Newby. After the toast of the Queen had been duly honoured, Colonel BRUNO proposed the Southsea Amateur Photographic Society. As a member of some nine years' standing, he could speak with authority as to the usefulness of the Society, and additional evidence was afforded by the fact that new members were joining, and, having joined, were regular in their attendance at the meetings, thus testifying to the advantages to be secured by membership. Only one thing was necessary to complete the happiness of the members, and that was that the fair sex should be admitted to share their privileges, and he hoped that a scheme which was being prepared to form a lady's section would be adopted, to the great gratification of the unmarried members, at any rate. Mr. LILLEY, in a humorous speech, responded. He said that only once in the history of the Society had the present membership been exceeded, and the Society had never before been so active or so healthy. They had some old members, such as Colonel Bruno and others, who represented the old "pyro" days, and also he was glad to note several young members who represented all kinds of things. In fact, the Society was in the position of the photographer who, knowing nothing of the plate he was about to develop, put into his developer every chemical he could think of, and at all likely to be of use, and trusted to fortune that some of them would have the effect of producing a good negative. No formula was of any service unless it contained a good accelerator, and this part was played with conspicuous success by the Hon. Secretary Mr. T. J. Mortimer, to whose energy the success of the Society was largely due. He would ask Dr. Lord to say what he (Mr. Lilley) had not said. Dr. LORD said that it had fallen to him to perform a very pleasant task. It was not necessary for him to say much about Mr. Mortimer, whose good qualities were well known to all the members. The success of the recent Exhibition was almost entirely due to the efforts of the Hon. Secretary, and at the annual meeting it had been unanimously decided to devote some portion of the surplus funds of the Society to the purchase of some photographic apparatus to be presented to Mr. Mortimer. It was now his duty, and a very agreeable one, to ask Mr. Mortimer to accept from the Society a whole-plate camera as some slight recognition of his services to the Society during the two and a half years that he had held the office of Secretary. Mr. MORTIMER briefly replied, expressing his thanks for the handsome present. Dr. NEWBY proposed the health of the visitors and Mr. BARRELL responded. During the evening songs were contributed by Messrs. Chase, Burvis, Summers, and Wood, and Messrs. Denham, Warren, and Mortimer performed selections on the banjo.

Blairgowrie and District Photographic Association.—February 20, Annual General Meeting.—Very satisfactory reports were submitted by the Secretary and the Treasurer. A vote of thanks was awarded to Mr. H. Snowden Ward for his kindly assistance as Judge during the session. It was decided to purchase an enlarging lantern for the use of members. Office-bearers for the session were elected as follows:—*President*: Mr. Alexander Geekie.—*Vice-Presidents*: Messrs. John B. MacLachlan and Thomas C. Gorrie.—*Executive*: Messrs. James Richardson, D. G. Monair, William Falconer, J. D. Petrie, and A. Mitchell.—*Treasurer*: Mr. John Cameron.—*Secretary*: Mr. Hugh B. Jamieson, The Photographic Club-rooms, Blairgowrie. The question of holding an open exhibition next spring was remitted to the Executive.

March 2 1900]

FORTHCOMING EXHIBITIONS.

1900.	
March 2, 3	Birmingham Photographic Society. Lewis Lloyd, The Hollies, Church-road, Moseley.
3-10	South London Photographic Society. Hon. Secretary, Frank Goddard, Woodlands, Vanbrugh Hill, Blackheath, S.E.
13, 14	G.E.R. Mechanics Institution (Photographic Section). C. W. Harris, 294, Cam Hall-road, Leytonstone, E.
26	Twentieth Century International, Birmingham. Walter D. Welford, 19, Southampton-buildings, Chancery-lane, London, W.C.
26-31	Photographic Society of Ireland. W. F. Cooper, 35, Dawson-street, Dublin.
April 3-7	Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those which the Exhibitions open.

Patent News.

The following applications for Patents were made between February 12 and February 17, 1900:—  
**SHUTTER REGULATORS.**—No. 2764. "A New Method in the Making of Pneumatic Regulators for Photographic Shutters." F. J. CHRISTMAS and W. WATSON.  
**ROLL FILMS.**—No. 2770. "An Improvement in Photographic Roll Films." Communicated by the Actien-Gesellschaft für Anilin Fabrikation, Germany. Complete specification. C. D. ABEL.  
**CAMERAS.**—No. 2859. "Improvements in Photographic Cameras." Complete specification. C. P. DIXON.  
**HALF-TONE ENGRAVING.**—No. 2942. "Diaphragm System for the Half-tone Photo-engraving Process." A. W. PENROSE and W. GAMBLE.  
**CAMERAS AND STANDS.**—No. 3017. "Improvements in Photographic Cameras and Stands." S. F. DUFTON.  
**EXPOSURE REGISTER.**—No. 3090. "A New or Improved Exposure Register for Attaching to Automatic Spring Fasteners for Shutters of Dark Slides." A. MAURICE.  
**DEVELOPING TRAYS.**—No. 3183. "Improvements in Photographic Developing Trays." J. E. BARNARD.  
**SHUTTERS.**—No. 3198. "Improvements in or connected with Shutters for Photographic Cameras." E. H. HAMILTON.  
**FILM BACKINGS.**—No. 3214. "Improvements in Backings or Wrappings for Photographic and Similar Sensitive Films or the like." J. B. B. WELLINGTON and H. H. WARD.

Correspondence.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
 \* We do not undertake responsibility for the opinions expressed by our correspondents.

COLOUR PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—In March last I wrote to you protesting against some remarks made by you in your articles on "Colour Fallacies." In looking over old photographs and lantern slides lately, I found a few lantern slides and papers which bear out, I consider, my remarks, and which, as well as I remember at so great a distance of time (1889), give a very fair representation of the tints as they were. They are now about twelve years old, have been lying away in a corner, and consequently not much exposed to light. They have only undergone the usual processes of fixing, toning, developing, &c.

I should like to submit them to you to look at and give an opinion; but, as they are of value to me as a record (though, perhaps, to no one else), I should require an engagement that they would not be tampered with, or experiments tried upon them, and that they should be returned uninjured. Will you let me know whether you agree to this? I would send three lantern slides.—I am, yours, &c., R. O'HARA, *Lieut.-Col.*

Galway, February 20, 1900.

[We shall be very pleased indeed to have the opportunity of inspecting Colonel O'Hara's lantern slides; and, of course, will return them in the same condition in which they reach us. Our opinion of their colour characteristics shall be stated with the utmost frankness.—Ed.]

THE CAMERA IN THE CAMP.

To the EDITORS.

GENTLEMEN,—I have no intention of entering into a discussion with Mr. Maclean. It would be useless to attempt to convince those who con-

sider ignorance of anything but one side of a question a qualification for dogmatizing. It is probable that photography will find larger opportunities in war, but I venture to think it will not be exactly on the lines urged by Mr. Maclean; and the best thing to be done to bring about the desired result would be to work out a scheme *thoroughly*, and be prepared to bring it forward when the pressure is over and it can be tested by those who have practically learnt what is wanted by our present arrangements.

I need say little to you as to the charge of belittling photography; such should have been prevented by the latter part of my letter (not the last paragraph, which was not meant for publication); if photography has its uses, it has also its limits of usefulness, and one whose experience is rather wider than ten years of superintendence of lantern shows will, I hope, be considered better qualified to form an opinion than Mr. Maclean.—I am, yours, &c., J. F. T.

To the EDITORS.

GENTLEMEN,—Whether the enclosed cutting, from the *Daily Mail* of February 22 is indicative that the War Office is acting upon the suggestions contained in my article in THE BRITISH JOURNAL OF PHOTOGRAPHY of February 9, is a matter of conjecture. Any how, it amply justifies the views that I advocated.—I am, yours, &c., HECTOR MACLEAN.

Croydon, February 24, 1900.

SNAP-SHOTTING THE BOERS.  
CAMERA TO PLAY ITS PART IN THE WAR.  
(Daily Mail Special.)

Everything is in readiness for the dispatch to the front by the War Office of a small but perfectly equipped party of tele-photographers, whose particular duty it will be to furnish pictures of important positions to the general commanding, or for the subsequent information of the Intelligence Department.

Those who will form the contingent are Corporal Thornton and Sappers Richardson, Dee, and Bullock, of the Royal Engineers, who will take the photographs, the development of which will be the duty of a printing party, composed of Corporal Bright and Sappers Hallett and McEwen.

The photographic outfit is compact, and is, of course, specially adapted for use in the field. It will consist of one large tele-photographic camera, capable of taking anything within a range of three miles, a smaller camera, and a number of pocket snap-shooters for close work.

The printing wagon will be fitted with all the necessaries, including a dark room and a gallery for the collection.

Daily Mail, February 22, 1900.

ORTOL IN INDIA.

To the EDITORS.

GENTLEMEN,—The praises showered on this new developer caused me to try it, so I bought, and am still using, my first bottle; probably it is also my last. As I was going to mix my first brew of developer, my friend, Charley Pritchard, alias the Butcher, came in with his dog. As I lifted the virgin cork the terrier began to display curiosity, and his master said, "Holla, something dead; 'ere, Boxer, find it!" "No, you've put your foot in it this time," says I, not looking at him. "Nothing of the sort," says he, looking at his boots, "'ere, Boxer, good dawg." Having weighed out the proper quantity of the slate coloured sooty-grey powder, I put it into the water and followed up with the other ingredients in order. The smell disappeared in time, as did Charles P., but the solution was not satisfactory. A blackish scum floated on top, and a brown cake formed at the bottom, and required continual crushing. Gas was being generated, and bits of the porous mass insisted on floating at the top. Each had to be driven to the side and carefully crushed; then, after considerable stirring and about half an hour's work, everything was dissolved; but where was the deep red solution I had expected? This was dirty brownish, and soon began to deposit a blackish powder. Never mind, all gold does not glitter. The first time of using (8 ounces for about twelve quarter-plates), the negatives were excellent, bright, dense, and quickly done. The next day, having kept the developer to see if it would develop the desired ruby tint, I tried a couple more plates, but they took ages to come up, and were thin and flat, and useless. There was by this time a considerable black precipitate in the graduate.

Mr. Watkins says, in the ALMANAC, that no developer can produce fog. I got real high-class fog on quickly developed films, using hypo as recommended in the developer. Without hypo the same films, and same treatment, produce clear negatives, at least as clear as one expects isochromatics to be when not developed in darkness. No forcing at all. The only advantage I have found in ortol, so far, is that it gives you a quinal negative in metol time, if you wish it and use fresh solution. The continuing action is remarkable, but less so than that of ammonium persulphate, which removed the whole image from a film of mine, even after a dip in hypo, and I thinking it was only getting itself washed! If my bottle of ortol was good, metol is better. If it was bad, it will not keep good, and so won't do for me. I tried putting in the ortol last, but no difference.—I am, yours, &c., TIPPON—1872.

APATHY OF BRITISH HAND-CAMERA MANUFACTURERS.  
To the EDITORS.

GENTLEMEN,—British makers of cameras must have their hands more than full, to judge by my recent experience. In the beginning of the

year, and since, I wrote twice to two of the most prominent manufacturers of reflector cameras, making a suggestion. The suggestion took the form of a query, and was to the effect, if it were not feasible for a reflector camera with reversing frame and full-sized pictures, vertical and horizontal, for daylight roll-holders and double backs, to be made, which, in its box form, would serve as a short focus hand-camera, but, that by adapting the hinged falling front as a platform, on which the lens front could be racked out, it could be used as a stand camera with greater focal lengths? In the latter case, the swing mirror focussing arrangement would still hold good, and, if the combined movement of it and the shutter were no longer practicable, these two could be then disconnected and reconnected when necessary. An ordinary focussing screen, as well, would be desirable.

The only difficult part of the problem would seem to be the devising of a sufficiently compact bellows extension to permit of a square picture being taken with a relatively short-focus lens, say for  $5 \times 4$  with  $5\frac{1}{2}$  in. Satz lens, extending to 12 or 13 ins.

A well-made camera of that type, with shutter and reversing frame, but without lens or roll-holder, ought not to cost much more than 4l. or 5l., and would be pretty certain to find many buyers. Failing to get a reply from British firms, I have now written to some Continental manufacturers, who seem to go in extensively for this form of camera.—I am, yours, &c., A. G. B.

February 21, 1900.

[Our correspondent, who writes from abroad, adds: "I am making the inquiry not only on my own behalf, but also for others here. I should have willingly given the preference to English makers, but, failing them, shall have to give the order to foreign or U.S.A. manufacturers."—EDS.]

#### DAYLIGHT CARTRIDGES.

To the EDITORS.

GENTLEMEN,—My attention has been drawn to your article of February 16, on "A new form of Daylight Cartridge." It will interest you to know that for some time past I have been making such a cartridge with our Cristoid film, the subject of a patent by Mr. W. F. Stanley.—I am, yours, &c., J. T. SANDELL, Manager, Sandell Films & Plates, Ltd. Norwood Junction, London, S.E., February 26, 1900.

### Answers to Correspondents.

\* \* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

#### PHOTOGRAPH REGISTERED:—

C. E. Weale, Victoria-road, Tamworth, Staffordshire.—*Photograph of group of Tamworth Volunteers.*

F. PATTERSON.—The Platinotype Company, Bloomsbury-street, London, W.C.; The Britannia Works Company, Ilford, E.

GELATINE RELIEFS.—W. BIGGS. As you do not get a sufficiently high relief, you are probably using an unsuitable gelatine for the work. See article on the subject last week.

J. D.—A nice point. Of course you could "safely" do so, but we do not think you would be quite justified in using the older name. Better employ the same name as the makers of the paper, and you can hardly do wrong.

CLARKSON & WILSON.—We are sorry we cannot be of assistance in the matter. The formula was published with the authority of Professor Valenta, of whom we will endeavour to obtain some explanation of the reason of its failure. We do not answer questions through the post.

BOOKS ON FINISHING.—G. M. B. says: "Will you oblige by telling me what you consider the most helpful books for teaching finishing in black-and-white?"—In reply: There are some chapters on the subject in *Retouching*, by R. Johnson, published by Messrs. Marion & Co., Soho-square, which might help our correspondent.

E. LIPPINCOTT (Portishead).—We have never heard of the individual named, but you may be quite sure that there is not in London a society whose object is to secure photographic records of interesting portions of England which employs a travelling photographer of the kind. We do not answer questions through the post.

BURNISHING.—BURNISHER writes: "Kindly let us know how to use a bar burnisher, and which would be the best lubricant for same?"—Simply make the bar thoroughly hot, and, having the right pressure applied, pass the prints through. Lubricate the prints with a solution of Castile soap—say, twenty to thirty grains to the pint of spirit of wine—methylated spirit will do.

IMPURE TAP WATER.—F. A. says: "Recently, when washing P.O.P. before toning, I have been troubled with small brown specks appearing on the prints, and when toned turn black. I have tried all ways of filtering and used boiled water and different makes of paper, but of no avail. How can they be avoided?"—In reply: From the appearance of the spots we should conclude that the water contained traces of iron or some other metallic compound.

SHUTTER.—R. CROSWAY complains that the shutter he has on his hand camera is not fast enough for his work, the highest speed being one-ninetieth of a second, and asks how he can make it work faster.—The highest speed the shutter he mentions is made to work at is that named. The same makers, however, supply others that work at a higher speed, one of which we should advise him to get. Possibly a focal-plane shutter would answer his requirements best.

LIGHT-STRUCK PLATES.—A. THOMPSON says: "I put a dozen plates that had been exposed in a grooved plate box and unfortunately left the lid open in the dark room, and its door was open for some hours. Of course, the plates are fogged, but the subjects are of great interest and cannot be taken again. Is there any possible means of counteracting this fog so that the image can be developed without it?"—No. Nothing can be done. The plates are completely spoilt.

DAMAGED GLASS POSITIVE.—C. C. says: "I have a very old glass positive, highly prized by its owner, to copy and make an enlargement from. The black varnish on the back is cracked all over. A photographic friend recommended me to rub the varnish over with lamplack to fill up the cracks, and it does so, but still they show badly. Can you advise anything better?"—Yes. Scrape off the old varnish altogether and apply fresh. Did not this occur to you?

S. LINDEN (Davos).—1. We have had knowledge of the camera named since its introduction five years ago, and we think you may safely take your friend's recommendation. We should regard the instrument as suitable for the classes of work named. 2. Optically, there is perhaps nothing to choose between the two lenses named, but the second gives you the greater variety of foci, and, possibly, should have the preference on that account. We do not answer questions through the post.

SCRATCHED LENS.—J. KOHLER says: "I am offered at a low price a R.R. lens by —, but it has a scratch on the front glass. Can you say if it will make much difference in its working if used as it is? also what would be the probable cost of getting the scratch removed by the maker of the lens?"—The scratch will make no practical difference in the working of the instrument. We cannot say the cost of removing it. Better consult the maker of the lens on this point if you wish it removed.

ANILINE DYES ON P.O.P.—NOVICE writes: "I wish to colour some photographs on P.O.P. of my own taking, and find it most difficult to do with water colours. In my business I make use of aniline dyes, and it has occurred to me to use them for the purpose with rather good effect. Can you tell me if there is any chemical in the photograph that will affect the dyes?"—Supposing that all the hyposulphites have been removed from the prints, there will be nothing that will affect the dyes usually employed for tinting photographs.

LEAKY ROOF.—R. W. writes: "I have just taken a studio, and the water comes through the roof as through a riddle. Can you tell me the best way to get the roof repaired?"—If the studio is an old one, probably the putty securing the glass is perished, in which case the best way will be to have it scraped away and fresh applied. When the old putty has been removed, it will be a good plan to give a coat of paint before the new putty is put in. The present is not a good time for the work. It had better be deferred till a little later on.

ILLUSTRATING CATALOGUE.—A. & Co. write: "We have to illustrate a catalogue of property for sale with  $10 \times 8$  views of it. There will be about seven or eight pictures, and the edition will be about 250 only. They must be photographs, but not silver prints, and carbon and platinotype will come too costly. We suggested process blocks, but they are refused. What can you kindly suggest for the purpose?"—The most suitable process we can suggest is collotype. It is specially adapted for that class of work, as the pictures can be printed with a margin, so that no mounting is required.

MOUNTANT.—MOUNTANT writes: "I have a large number of chocolate mounts, on which, when a photograph is mounted the colour dissolves and shows through print in bad blotches and streaks. Can you tell me of any mountant that could be used which would form a coating between the print and mount? would a gelatine mountant do, if so, would you give your receipt for making? I always use fresh starch."—There are many chocolate mounts now in the market which have this defect. We would suggest that the mounts be coated with a thin solution of gelatine and allowed to dry. Then, we surmise, if the prints be mounted upon them with starch in the usual way, the colour will not show through.

APPRENTICESHIP.—FATHER writes: "I apprenticed my daughter for three years to learn the photographic business. The first year to receive no wages, the second year two and sixpence a week, and the third year five shillings per week. She was to learn reception-room duties, retouching, printing, toning, &c. She has been at it now for over two years, and has been kept entirely at mounting and spotting, and occasionally, when the light is good, assisting in watching the printing frame. She has done nothing at toning, sensitising, retouching, or attending in the reception-room, and knows nothing about it. Have I any remedy? I only paid a small premium with her."—Yes. If the photographer does not teach the apprentice according to the indentures, the law will give you redress. Better consult your solicitor. Yours is not at all an exceptional case. Many unscrupulous photographers take apprentices more for the purpose of getting cheap labour than teaching them their business, though the practice is very disreputable.

## EX CATHEDRA.

LAST week the many claims on our space compelled us to leave out the principal part of the discussion which followed the reading of Mr. Edwin Bale's paper on "Artistic Copyright," at the Society of Arts, on Wednesday, February 21. We print the missing matter this week, and it will be seen that it contains several points of debate, which were overlooked by the opponents of the Bill at the meeting. The remarks of Mr. Alfred East, A.R.A., in particular, are extremely likely to create a false impression, which it is desirable to remove at the earliest moment. The attitude of photographers towards the Bill is not, as Mr. East appears to think, one of complaint that they had not been considered in the preparation of the St. John's Wood Art Club's precious measure, but rather that they are the victims of too much consideration. "Leave us where the Act of 1862 placed us," say the photographers. This is all that the meeting convened by the Royal Photographic Society last June asked for; it is all that the Copyright Union demands. Mr. Frank Bishop made this fact abundantly clear in the speech to which Mr. East replied. The latter gentleman's reason for abbreviating the term of photographic

copyright seems to be that the British photographer is better treated in the matter than his French *confrère*—a very desperate and far-fetched way of apologising for the uncalled-for interference in the rights of native photographers by a group of St. John's Wood artists.

\* \* \*

WE cannot agree with Mr. East and subsequent speakers that, in the preparation of a Bill affecting thousands of professional men, not one of the latter was consulted in the matter, is the very minor point it is said to be. The ignorance of photography and the position it has won for itself, which the promoters of the Bill display in every utterance they make on the subject, renders it lamentably plain that they have undertaken to legislate for a class whom they misunderstand as well as dislike. Photographers do not desire the sympathy of Mr. East and "every artist." They are perfectly willing to exchange this needless patronage for the non-interference of the Royal Academy and Messrs. Cassell & Co. in matters of photographic copyright. Mr. East talks of the "benefits" which the new Bill confers on photographers. It is hard here to take Mr. East seriously, but we suppose we must. If, therefore, the heavy tax of compulsory registration, a diminished term of copyright, an unworkable set of relations between photographer and sitter, and other absurd and unnecessary provisions, are what the St. John's Wood *coterie* considers beneficial to photographers, we must humbly say that photographers would very much rather forego such unpleasant kindnesses. Or was Mr. East only betrayed into a piece of unconscious cynicism when he used the word "benefits?"

\* \* \*

WE have not quite finished with Mr. East. He says that many inquiries were made of eminent photographers, and he understood they were satisfied with the time suggested in the Bill. We should like to know the names of those eminent photographers. Most photographers of eminence are supporters of the Royal Photographic Society and the Copyright Union, of the existence of which Mr. East could hardly be ignorant. We are astonished that he contented himself with questioning a few individuals, and did not refer the Bill to a representative body; but all through the piece the promoters of the Bill have

shown the most marvellous ingenuity in concealing that sinister production from the observation of the dreadful photographer. It is all apparently part of the generous scheme to "make him sit up." Mr. East further tells us that photography was introduced into this Bill as an afterthought. Quite so; when the painters and others had made up their minds what to ask Parliament to give them in the way of increased copyright protection, the opportunity of also praying the legislature to save the older forms of graphic expression from a persistently progressive young enemy, photography, was not to be neglected.

\* \* \*

So much for Mr. East, who, however, is known to have a more sympathetic and intelligently appreciative feeling towards photography than many of his *confrères* and some of the contributors to the Society of Arts discussion. Of the latter, Mr. Walter Field particularly distinguished himself in the endeavour to prove his admiration and knowledge of photography. He said that artists objected to a machine view of nature. We ourselves know nothing more objectionable, except an indifferent painting. In Mr. Field's opinion, "if a number of photographers took a scene, they all did the same thing; but a hundred artists, set opposite the same subject, would make a hundred distinct pictures. Art was quite distinct from photography." But Mr. Field amply atoned for all this antiquated fustian by saying that he did not know why photography came into the Bill at all. Precisely; and Mr. Field may be assured that photographers are only too anxious to be left out of the Bill. A subsequent speaker did not think a snap-shot ought to be classed in the same category as a picture. And yet Parliament is asked to make compulsory registration applicable to the former and not to the latter! Consistency is evidently not a strong point with the supporters of the Bill, who would belittle photography and penalise it at the same time.

\* \* \*

THE Act of 1862 classes photography with the fine arts; the St. John's Wood Bill proposes to place it in the same category as plaster-cast making. Objection to this needless interference with a classification that has stood for thirty-eight years is met by Mr. Bale and his friends with the rejoinder that it is all a matter of sentiment which does not allow of argument. Photographers, as a body, would probably trouble themselves very little over this point if an alteration of classification were unaccompanied by those penalising, spoliative, and confusing clauses of the Bill to which exception has so often been taken. The nominal degradation complained of is followed by the infliction of substantial pecuniary damages, so that the protests which have been made are based on a more solid foundation than that of sentiment. Of all persons to-day, photographers are the least concerned to prove that photography is a "fine art"—the old controversy over the point no longer interests them; but they have a right to insist that, as thirty-eight years ago it was so defined by the legislature, for purposes of copyright protection, the classification should not now be disturbed, unless it can be shown that the legislature had originally erred, or was misled in the matter. Besides, a little acquaintance with the subject (which Mr. Bale and his *protégés* clearly have not taken the trouble to acquire) would reveal the fact that, pictorially regarded, photography stands to-day in an immeasurably higher position than it did thirty-eight years ago, and that whatever claims it then possessed to be regarded as a fine art have been immensely strengthened in the

intervening time. But Mr. Bale, R.I., knows nothing of these things. He defines photography as "science," and complains that "some (*sic*) photographers thought the Bill was an attack upon them." Could anything be more delightfully artless. An attack that Bill certainly is, and we should not be doing our duty to the photographic profession if we did not insist upon the fact at every possible opportunity.

#### PLATE-BACKING AND SENSITIVENESS.

WE consider that we may take some credit to ourselves for having brought home to photographers the usefulness of backing plates to reduce halation. In season and out of season, persistently and consistently, have we urged the desirability of backing all plates where a possibility of halation existed; for a long time our advice fell upon deaf ears, while now there are few workers who do not admit the need for its use, or, indeed, who do not make use of it at times. It will be observed that we write of reducing, not curing, halation; no backing in the world will at all times prevent its appearance, though it may be in a modified degree. Yet plate-backing is no new invention, there were backed dry plates upon the market as far back almost as a quarter of a century ago. They were not, of course, gelatino-bromide plates, and they were not so efficiently backed as the more recent methods are capable of effecting. Plates backed by placing some dark paper in optical contact were in use in wet-plate work, yet the dry plates we refer to had a red pigment, but only in imperfect contact. The glutinous or gummy environment of the particles of pigment was mainly for the purpose of ensuring adhesion to the plate and preventing the pigment from rubbing off.

Modern theory points out that a medium possessing an index of refraction differing little from that of the glass plate is advisable to use with pigments, or as a constituent of or a diluent for transparent backings, such as caramel. Our own preference used to be given to a pigment held in glycerine and gum solution, and such a mixture cannot be excelled as far as the immediate purpose is concerned. It possesses, however, one very grave drawback in practice. Even with a mixture with ingredients exactly proportioned to avoid tackiness on the one hand or difficultly soluble hardness on the other, loss of time is involved in getting rid of the backing. It may be said that this backing may get rid of itself, that is, gradually come away in the operation of developing and fixing, and that would be quite true; but the pigment, if, as should be the case, a finely ground one, will meanwhile gradually attach itself to the film, and require extreme care to ensure its entire removal, and it will foul the fixing solution and cause it to stain all the plates afterwards fixed. The plate would need to be well rubbed with the palm of the hand or with cotton-wool, and well swilled with water. The best plan by far is to entirely remove the backing with a wet sponge or otherwise before beginning development. With caramel and that type of substance no such care is needed. Perhaps the typically perfect mode of backing is that employed by one firm, who attach a piece of black paper by a suitable medium of so very soluble a nature that the paper may be peeled off the back a few seconds after being wetted, and this though the plate may be several years old, as we can testify from personal experience.

In deciding on the merits of a plate as to comparative freedom from halation, it should always be remembered that, if the test object be a well-lighted window, forming part of an

interior view, it must not be imputed to the plate as a fault if a haze or glare surrounds the window, fogging, as it were, the dark parts immediately near to the glass, and making the mullions pale instead of almost black. This well-known effect is not true halation, it is an actual objective phenomenon, and due to the illumination of the atmosphere lying almost in a line with lens and window. This is capable of visual proof by interposing an opaque screen between the eye and the window, the atmosphere haze becomes distinctly visible.

A little while ago a discussion took place as to whether the use of backing did not slow a plate, some of the speakers taking the position that such slowing did take place. No satisfactory termination of the discussion being arrived at, and our own practice not having led to any such conclusion, we determined to put the matter to the test of a simple experiment. Cutting a half-plate into two, we backed one half of one piece, and exposed the backed portion under a Warnerke sensitometer to the light of a naked gas flame, burning at a constant pressure, for exactly one minute. We then immediately exposed the unbacked half in an exactly similar manner, and for the same length of time; after developing in a normal pyro-soda solution for four minutes at a temperature of 60° F., we closely scrutinised the results. They were absolutely identical as regards the sensitiveness. We repeated the experiment with the same result. We then reduced the intensity of the illumination. Duplicate experiments confirmed the conclusions from the first results. Finally, to assimilate the conditions to a dimly lighted interior, we still further reduced the illumination and gave twenty seconds' exposure; still there was not a particle of difference observable between the backed and the unbacked half.

We think these experiments, simple as they are, conclusively prove that the diminution of sensitiveness through backing the plate is a mere figment. In conclusion, we would remark that we incidentally noted that the Warnerke sensitometer, besides indicating the sensitiveness of plates, its legitimate function, is a most excellent test of the extent of the resistance or otherwise of a plate to halation. Thus the unbacked halves in each of the instances showed the indicating numbers in the thinner part of the sensitometer (1, 2, 3, &c.) thoroughly covered with "fog"—i.e., true halation; but in the backed halves this was reduced to a negligible minimum.

**A Useful Thing in the Dark Room and Outdoor Kit.**—There is a very handy thing to have in the dark room, or in the pocket when travelling, that seems to be less known amongst photographers than it deserves to be. We allude to what is known as American sticking plaster. Its uses in surgery—for which it is put on the market—is to take the place of the old lead or diachylon plaster of the pharmacopœia. One of its advantages to the photographer is that it does not require warming to cause it to adhere; it is simply pressed on any surface, when it holds on firmly, and is, moreover, waterproof. For temporarily repairing it is most useful. For example, a piece stuck over a crack in an ebonite dish or a glass measure will at once render it serviceable again. A crack in a dark slide or a hole in the camera bellows may at once be stopped by an application of a strip of the plaster.

We remember being at a meeting of the Photographic Club a year or two ago, when the repacking of dry plates after exposure was under discussion, and one of the members described his method. It was this. The plates, when taken from the slides, were dusted, and then placed, film to film, in parcels of six. Then a strip

of the plaster was pressed across two or three sides of the plates, which were then held fast, practically as a solid block of glass. They were then wrapped up in the black paper they came in, and replaced in the boxes. One advantage of this system is that the films are perfectly secured against atmospheric influences. Diachylon would, of course, answer the same purpose, but it would require the aid of heat to render it adhesive, which is not always available without light. One advantage of the American over the lead plaster is that the coating of resinous matter is more adherent to the fabric upon which it is spread than is diachylon, and consequently it is better suited for resisting water. This plaster is obtainable at most chemists' in rolls, from a quarter of an inch to three inches wide, in sixpenny and shilling boxes. It may also, we believe, be had to order up to a foot or more wide. We have found the material useful in our own hands in so many different ways that we should recommend our readers to make its acquaintance.

**War Prisoners and Photography.**—We read in a telegram from Orange River that, when the Boer prisoners of war passed through, from the joyful faces of the men, they were on a pleasure trip. Possibly they were, considering their past experiences. The correspondent says, "They crowded round the window as the train steamed through the camp, waving their hands to the troops, and evidently anxious to get into the pictures which were being taken by the ubiquitous photographer." Evidently from this there are "ubiquitous photographers" in South Africa, as almost everywhere else, but it is a little strange that people should desire to figure in photographs in what might almost be considered humiliating circumstances. However, some people have a strange fancy for figuring in photographs under any circumstances, as most photographers are aware, often to their annoyance, although the people must be fully aware that they will never see the pictures. Almost every photographer who has set up his camera in a country village, for example, has experienced the annoyance of the natives posing in the foreground, and the difficulty he has in getting his pictures without them, and the *ruses* he has to adopt. Evidently the same intrusive idea seems to prevail with the Boers as with our villagers.

**Balloon Photography in War once more.**—It is announced that Professor Cailletat, of the Institute of France, is carrying out some experiments at Toulon with a war balloon and a camera. We are told that, by placing the camera in the car of a captive balloon and operating on it by electricity from below, photographs can be obtained over an area of country six miles square, every detail of which is so accurately shown, and that in war the photographs would be invaluable, &c. The late Mr. W. B. Woodbury demonstrated the practicability of this, if we mistake not, something like twenty or twenty-five years ago, before the Balloon Society. His method was, if we remember rightly, precisely similar to Professor Cailletat's, namely to operate a camera, attached to a captive balloon, by electricity from *terra firma*, utilising the wire securing it as one of the conductors. Although Mr. Woodbury's idea received but little attention at that time, and there was no immediate occasion for it, it may be utilised in the future. If it is, Woodbury should be accorded the credit.

**The Kammatograph.**—This instrument, so named after its inventor, Mr. L. Kamm, an electrical engineer, is the latest contribution to the art of cinematography, and is remarkable for the circumstance that it does not employ celluloid or any other kind of film. The pictures to form what is popularly known as an "animated photograph" are taken, to the number of nearly six hundred, upon a circular glass plate coated with gelatine emulsion. This plate which is twelve inches in diameter, fits into the camera, and by turning a handle it is caused to rotate, to make the necessary stop for exposure at every fourteenth of a second and to execute a slow lateral movement, so that the pictures are impressed spirally upon its surface. The negative so taken is developed in a dish in the usual manner, and a positive, upon another circular plate, is printed

by contact. The positive disc, after development, goes into the camera, the whole contrivance is fixed up in front of a lantern body, and the animated picture is projected upon a screen. The Kammatagraph is intended for home use by amateur photographers, and the projected pictures are large enough for such a purpose. The instrument is thoroughly practical in character, and speaks well for the ingenuity of its inventor. The circular plates are supplied by Messrs. Marion, who will, doubtless, be able to afford further particulars concerning this very clever contrivance.

#### THE NASCENT SILVER THEORY.—A REPLY TO DR. EDER.

[Translated from the *Archiv für Wissenschaftliche Photographie*.]

ALTHOUGH I am convinced that no satisfactory result can follow from this discussion unless conclusive experiments be made, I would rather not leave unanswered the article\* which Dr. Eder has recently published.

In the first place, I wish to state that Eder does me too much honour in representing me as the principal champion of the nascent silver theory. The theory has been held for a considerable time by various photographic chemists, as Eder has shown in his very complete study of the history of photographic chemistry. The modest experiment which was put forward by me a short time ago† in favour of the nascent silver theory does not merit any such acknowledgment. The only service to which I may lay any claim is that I have awakened from its slumber the fundamental question of the nature of the latent image. If my views upon the question are less certain now than when I first expressed them, this is attributable to the numerous experiments which have followed as the fruit of the animated discussion which has taken place. But I must emphasise the fact that the experiments of the past, without exception, could only be explained by means of the nascent silver theory, and that Eder has never referred to them in opposing it. All the evidence to the contrary has been discovered since my article appeared, and is due to its publication. Until then the assumption of a sub-haloid was quite superfluous.

I would also call to mind the fact that Eder abandoned his important experiment of developing by contact with metallic silver, and attributed it to pressure, as soon as it was used as a proof of the nascent silver theory, with which it harmonised so well. But, as I at once remarked, the experiment supports neither theory. Yet, several experimenters (Abney, Abegg, Herzog, and Luther) have proved beyond doubt the specific action of silver.

I am of opinion that the first exact experiment deciding between the two theories was brought forward by Dr. Luther. He proved, firstly, the existence of silver sub-haloid, which, till then, was absolutely hypothetical. Secondly, he showed that the latent impression formed by light upon a film of silver halogen actually consisted of sub-haloid. But this was only for films devoid of any vehicle, such as gelatine or collodion. On account of its reductive power, the former does not exclude the possibility that the latent action of light is more extensive under such circumstances.

Although the evidence against the nascent silver theory is inconclusive so far as gelatine emulsions are concerned, Luther's experiments have added so much to the probability of the sub-haloid theory that I am unable to decide at present to which I should give my adhesion. This "triumph" of the sub-haloid theory is not, however, due to any of Eder's arguments, as his article would make his readers believe, for his experiments are inconclusive, as I believe I have shown on several occasions.

I must also strenuously protest against Eder's assumption that I have diverted the term "nascent silver theory" to a more promising purpose, in order to cover my "defeat." This assertion of Eder's is based evidently upon my use of the term "nascent silver" to denote the small particles of metallic silver, when writing upon the theory of photographic development. It implies that I then recognised an essential difference between the metallic particles of which I supposed the latent image to be formed, and those constituting the developed image. But, from the outset, it was my desire to emphasise the opposite, and to insist upon the essential similarity of these minute particles—the "nascent silver"—whether produced by development or exposure.

In the paper to which I have referred, where the expression "nascent silver theory" is introduced, the unprejudiced reader will find evidence in every paragraph of this meaning of the expression, "nascent silver."

\* THE BRITISH JOURNAL OF PHOTOGRAPHY, December 15, 1899, p. 788.

† THE BRITISH JOURNAL OF PHOTOGRAPHY, March 31, 1899, p. 146.

Consequently, it is Eder who perverts the term "nascent silver" from the implicit meaning I had given it, and concerning which there could not have been any doubt. The right to define assuredly belongs to the originator of the term.

Although, in my opinion, such purely personal explanations are highly unprofitable, I cannot allow this unfounded assertion by Eder to pass. I deeply regret that in the discussion of mere facts relating to both hypotheses a tone of personal animosity should have been introduced. This is contrary to my wishes, and cannot promote scientific knowledge which alone should be the object of this discussion. DR. R. ABEGG.

#### NASCENT SILVER VERSUS SUB-HALOID.

[Translated from the *Archiv für Wissenschaftliche Photographie*.]

I MUST confess that I am rather disappointed at the remarks which Professor Abegg has made in reply to my paper. Although the nascent silver theory has received a heavy blow at the hands of Dr. Luther by proof of the existence of silver sub-bromide, no fresh facts are adduced in support of the same. I will confine myself to two points. The possibility of development after fixing might be taken as a proof of the nascent silver theory; but, as it is now found that sub-bromide is reduced to silver by a solution of thiosulphate of soda, the sub-bromide theory is brought into harmony with experience. But there is a possibility that silver bromide forms compounds with gelatine upon exposure to light, and that they are very indifferent to thiosulphate. Sterry has described these as the latent organic image. Sterry also obtained an image with gelatine and nitrate of silver. By physical development silver was deposited where there had been light action.

According to the nascent silver theory, prolonged exposure should reduce the entire particles to silver, but we find that solarisation occurs. Abegg adopts Liesegang's hypothesis that a wall of silver protects the particles from the developer; but, as solarised films can be fixed, it is untenable, for the silver wall should prevent fixation. If we assume that the nascent silver is dissolved by the thiosulphate, it should be impossible to develop the image after fixation, but this is not the case.

G. MERCATOR.

#### PHOTOGRAPHY AND THE FORTHCOMING ECLIPSE OF THE SUN.

To *Knowledge* for March Mr. E. Walter Maunder, F.R.A.S., contributes an article on the eclipse of the sun, portions of which have a special interest for photographers. According to Mr. Maunder, the numerous methods of observation, photographic or visual, carried out or attempted in past eclipses, will be again tried next May. Photographs of the corona will be taken on all scales, from that giving the sun a diameter of four inches, such as the Astronomer Royal obtained in India with the Thompson heliograph of the Royal Observatory, Greenwich, to that which gives the sun a breadth of but a very small fraction of an inch.

Those photographers whose object-glasses have an effective ratio of aperture to focus not exceeding 1 to 15 or 16 will be well advised to discard any form of equatorial mount or driving clock, with its liability to shake, and insidious temptation to over-expose, and, rigidly fixing the camera, to give exposures not exceeding one second as a maximum.

Both before and after totality a series of photographs should be taken of the partial phase. Since but one photograph has as yet been obtained of the corona after totality was well over, no definite rules can be laid down as to the style of instrument that should be employed. Therefore, in this next eclipse, all sorts of cameras might be pressed into the service, and some range of exposure should be given. One thing is certain, that in all cases the development must be carried out with the special object of restraining the high lights and giving opportunity for the feeble radiations to register.

Mr. Nevil Maskelyne will kinematograph the corona at his station in America. A most interesting and instructive use for the kinematograph in the coming eclipse would be its adaptation to the experiments which Miss Gertrude Bacon carried out in India on the illumination of the landscape during the partial phase. In a series of five photographs, taken at equal intervals, Miss Bacon found the curious fact confirmed (hitherto believed to be an optical illusion) that the illumination returned more rapidly after eclipse than it diminished before eclipse. The kinematograph, if used for this purpose, would give a more even and continuous series, and, if it were possible to use more than one in the same locality, would decide whether the same effect held good when the in-

ument was pointed in the direction from which the shadow was proaching and towards which it was receding.

Akin to this observation is that of the general illumination of the corona, which may be determined by very simple photographic sensitometers. In India this was determined photographically by Mr. E. W. Johnson (using a sensitometer constructed by Mr. Gare) and by the Rev. M. Bacon, and visually by Mr. T. W. Backhouse and Dr. Irwin Sharp, at Buxar, and by Mr. Maunder at Talmi, by comparing it with the evening twilight illumination.

Spectroscopic observations of all sorts will be made, from those with ant slit spectroscopes or object-glass prisms to those with the humblest portable prismatic opera glass. Observers with the latter will probably confine themselves to the shape of the corona as seen in the green bromium ring, the red and blue hydrogen, and the yellow helium rings. To attain the same object without a spectroscopic apparatus, Mr. Backhouse suggests that it would be well to photograph the corona by light as nearly monochromatic as possible, obtaining this partly by using film of special colour sensibility, and partly by the use of a colour screen.

There are two classes of work that have been very generally omitted from systematic observation in recent eclipses. These are the observations of the shadow bands, of which very little is as yet known, and the usual study of a small portion of the inner corona. The latter is especially important for the true understanding of the curious formations that in photographs appear to enwrap the brighter prominences, and which lie at the base of the great rays and the polar plumes. Only a very small portion should be attempted by any one observer, since the time of visibility is very short, but the study of that portion should be thorough.

#### ARTISTIC COPYRIGHT.

FROM the last number of the JOURNAL we were obliged to omit the principal portion of the discussion which followed the reading of Mr. Bale's paper on Artistic Copyright at the Society of Arts last month. We here append it. Some remarks on the discussion appear in *Ex cathedra* this week:

Mr. Frank Bishop desired to say a few words on behalf of photographers, who he considered had not been treated fairly in this matter, the Bill having been settled without consultation with them at all. From a commercial point of view, photography was probably more important than painting; but a few artists met and drafted a Bill without taking the opinion of photographers about it. He also objected to a photographer being compelled to register every work within six months, or lose the copyright, whilst the artist was not. This was unjust, and would be a tremendous tax on photographers. What was copyright? It was rather a puzzle; but, after reading the article upon it in the *Encyclopædia Britannica*, he had a clear idea in his own mind that copyright was property, and demanded the protection of the law. The law gave protection against robbery, whether of a penny or 1000*l.* It was quite true a photograph was not a painting by Millais; but photographers could do all they could to assist artists if they were asked, although they expected some consideration in return. They were not so powerless that they could not protect themselves, and he thought the painters could find out in time that they had made a great mistake. If copyright was property, why need you register? Registration was only needed to mark an act of transfer of property. Ever since 1862, photographs had been claimed as fine art—he would not discuss what was art and what was not—that was the classification then adopted, and why should it be altered? Was photography of any less importance now, or were its productions any less perfect? On the contrary, it had made great strides, and many painters, if they were sincere, would acknowledge they owed much to photography.

Mr. Alfred East, A.R.A., said he was under the impression that photographers had been duly considered. He had great sympathy with artistic photography, and the artistic photographer had the sympathy of every artist. He could not see the point of Mr. Bishop's observations when he said that their claims were not considered. In no country in Europe had they such privileges as under this Bill; thirty years' copyright for a photograph was surely an equivalent for the protection given to the creative work of the artist; in fact, he should be inclined to say it had an undue advantage, in the light of the protection given in France and elsewhere. The point of Mr. Bishop's complaint was that they were not consulted in the draughting of the Bill, but surely that was a very minor matter; if he was willing to accept the benefits, he need not mind the method by which they were conferred. Many inquiries were made of eminent photographers, and he understood they were satisfied with the time suggested in the Bill. Photography was, in fact, introduced into the Bill as an afterthought. He should be the last to deny the right of photography to protection, or that many photographers produced works which were on a much higher artistic level than ordinary commercial photography, but protection for thirty years for a thing which cost the

producer so little, comparatively, to a fine work of art, which was the result of many years of special training and special capability, seemed to him ample. He must protest against the notion that the artist photographer had not been duly considered.

Mr. J. J. Elliott said he had listened with interest to the pathetic description given by Mr. Scrutton of the difficulties of the would-be pirate, whether proprietor of a journal or not, who wished to make use of the brains and money spent in producing a good photograph, in ascertaining whether it was copyright or not, and he should like to ask Mr. Scrutton or Mr. Bale why the so-called artist, because he painted half a dozen pictures in a year, should be exempted from registering, when the poor photographer, who produced thousands, was compelled to register.

Mr. Snowden Ward said he was sorry to hear an artist, so sympathetic to photographers as Mr. East, misrepresent the speech of Mr. Bishop. The complaint that photographers were not consulted was a very minor point, their real grievance was one of vital principle. At present the law was that the creator of a work of art had an inherent copyright in it, and what photographers objected to was the suggestion in the new Bill that Copyright was to be dependent on the creation of a work of art, plus registration, within six months of its production. He would not go into details, or he might point out what practical difficulties would result in many cases. Mr. Scrutton said there were only two alternatives—no registration or compulsory registration. Mr. Bale, however, was not of that opinion, because he said there might be a third course, which was adopted in Continental countries. Photographers felt that inherent copyright was a thing which ought not to be attached or taken away, and the statement that there were only two ways of dealing with it seemed not quite correct in view of Continental experience.

The Chairman said the Committee which set about draughting this Bill started with painting, but found that photography was so intimately connected with art that it had to be included; they sent a copy of the Bill to the photographic societies with the request that they would be good enough to express their assent or dissent. He did not think they received an answer from any of those societies. He could not enter further into the discussion of how far photography was a fine art, or how far artists thought it might be lightly treated. Mr. Bishop had put it on the right ground, viz., that it was of much greater commercial importance than painting; and he did not think it was right to claim for work of such great commercial importance the same rules and laws as art, which had really very little commercial capacity. A good deal had been said in favour of the Bill, and a good deal against it, but he was sure all would agree in passing a cordial vote of thanks to Mr. Bale for his paper.

Mr. Bishop said, when Mr. Storey brought the Bill before the Royal Photographic Society, it was in print, and, when asked if it would be altered if they made any suggestions, he said no. He was therefore practically right in saying that the painter did not consult the photographers.

Mr. Storey said he did not remember saying the Bill could not be altered; at that time it was merely tentative.

Mr. Bale said he had purposely refrained from introducing any question as to the relation between photography and fine art, which was one of those endless questions which could never be settled. The photographer said one thing and the artist another, but still he found that some of the best exponents of photography, such as Dr. Emerson, said that photographing was not fine art, it was photography, and never could be anything else. An artist could do a great deal in the way of arranging a picture and so on, but that was only preparatory; when you came to take the photograph, it was photography and nothing else. An artist might be a photographer and a photographer might be an artist, but the two things could never be mixed up. One was science and the other was art. Some photographers thought this Bill was an attack on them, but he had tried to make it clear that the object was to remedy the inconsistency at present existing, and which put the artist at a disadvantage compared to the photographer. The artist had scarcely any privileges at all, while the photographer had everything. His copyright was never questioned. Mr. Elliott asked why the artist should keep his copyright without registration when the photographer was called upon to register. The Bill divided art into two classes—original art and reproductive art, including photography. It assigned two terms—life and thirty years to the artist, thirty years to the reproduction artist and the photographs—because, as shown in the paper, the position of the artist was so different, and this, bear in mind, is the recommendation of the Royal Commission. It was absolutely necessary if you gave the photographer a fixed term that he should register, because you must give the public the information. Mr. Ward thought there was a difference of opinion between Mr. Scrutton and himself with respect to the need for registration, but that was a mistake. He had pointed to another system, adopted in other countries, which was simply a substitute for registration and answered the same purpose. It was recognised everywhere that it was absolutely necessary the public should know when a copyright terminated. It was not fair to punish a man for infringing a copyright without letting him know when the period began and ended. The information was given in the case of the artist under the Bill because, if there were no registration, a person wishing to copy could go to the artist and inquire; the photograph, dating from a particular time, must be entered somewhere.

Mr. Elliott said photographers were considered, thirty-six years ago, to be entitled to the same protection as artists, and he could not see why, after all the advance photography had made, and was still making, photographers should now be put on a lower level.

Mr. Bale said it was difficult to reply to a matter of sentiment. Mr. Elliott thought the photographer was degraded, as compared with the painter, by this Bill; but he had tried to show that, on the contrary, the object was to bring the painter up to the level of the photographer. He believed thirty years was long enough protection for a photograph, but the two terms were arranged to meet the requirements of the two kinds of work involved in fine art, and in photography and the reproductive arts.

### THE COMPOSITION OF A PICTURE.

[Reprinted from the *Transactions of the Edinburgh Photographic Society.*]

THE art, or I might say the knack, of composing a picture is a very important one, and is, to a great extent, a gift from nature. At the same time, like many other gifts, it can be cultivated by practice, as public speaking can be, and become comparatively easy to the student or artist.

Mr. Stacy Marks, R.A., in the course of an inaugural address to the students of the West London School of Art, in January 1880, said: "The facilities for the cultivation and study of art had, within the last forty years, become so numerous, that we were in danger of having too many painters of pictures. Everybody who had good eyesight could be taught how to paint and draw up to a certain point, but invention, feeling—all the qualities that go to make the painter as distinguished from the mere mechanist—could not be taught, but must be born. Our exhibitions, he grieved to say, were full of specious and bad pictures, painted by men who, with more humbleness of aim, might have been admirable art-workmen. Good art might be shown in a variety of ways, and the man who designed a good paperhanging, an effective piece of metal-work, or a good tile or pattern, was as much an artist, though in a lesser degree, as a painter or sculptor. It was much better to do a little thing thoroughly well than a great one badly, and he who could produce a well-designed chair or book-cover did more real service to art than he who painted an inferior picture."

Within the last thirty or forty years there has been a great change in regard to the treatment or method of composition. The old conventional lines have been to a great extent abandoned, and we find that newer methods have been adopted.

In landscape, for instance, we have the natural and truthful compositions of such works as those of John Constable, David Cox, Cecil Lawson, and other, in direct contrast to or with the mechanical arrangements of some of the earlier English masters of this century, such as Wilson, Stansfield, and others. Thomas Gainsborough was an exception, and broke away from conventionalism even in his day. There is no doubt that some of his best landscapes have had considerable influence on early British art during this century.

In regard to figure pictures, the change is even more noticeable. The somewhat hard and crude compositions of such artists as Benjamin West, Daniel Maclise, E. M. Ward, and others of less note, have been gradually improved upon by the modern schools of painting.

The use of the lay figure was no doubt much to blame for the mechanical way in which these artists worked. In these days most pictures are painted from the living model, and hence we have a healthier state of matters.

The works of the greatest masters of this century are good example of simplicity, truthfulness, and naturalness in composition. Breadth of effect, and balance in light and shade, are most predominant, while colour is subdued and rich in quality. We all know the names of Millais, Burne-Jones, Tadema, Orchardson, Pettie, Luke Fildes, MacTaggart, Paul Chalmers, and many others that I could mention. These men will, no doubt, rank amongst the leaders in figure painting towards the close of the nineteenth century. Some of the earlier masters of the English school, such as the Sir David Wilkie, John Philip, Fred Walker, and George Mason, had influenced several of these artists, and it is to them that we owe much of the success of the more modern painters.

These works, along with those of Constable, Turner, and others, will rank amongst the art treasures of the world, and will compare favourably with the masterpieces of the Continental schools. I cannot do better than commend the study of these masters' works to the student, either of art or photography. If you cannot get access to the original paintings, you will be able to see reproductions at any of the art galleries or free libraries.

There are many books published on the subject of composition, but in my opinion there is nothing like practice or observation for the amateur or student.

A lawyer friend of mine was anxious to learn skating, and informed me he was going to buy a book on the subject. I, of course, advised him to get a pair of skates and go to the ice, and learn by experience. The theory in anything is all very well, but, unless it is put into practice, there will be no perfection.

An earnest student, either in painting or photography, will very soon pick up a lot of knowledge from diligent observation and continued

practice in composition. If intelligence is applied to hard work, success is sure to come eventually, but patience is also required.

The black-and-white student, of course, may see a landscape or figure study quite in a different light from the artist, who is sometimes fascinated with the colour rather than with the light and shade.

It is impossible to fix any rules on the subject of composing a picture with any degree of definiteness. Nothing but experience can really teach.

As far as my own imperfect knowledge goes, I shall endeavour to explain my own individual method, acquired by continued practice and observation within the last twenty years or so. I do not, however, suggest that my method should be adopted as perfect, but that it might be improved upon wherever possible, and if in accordance with the ideas of the student.

In the choosing of a subject direct from nature, it is most important that the best point be selected. It is therefore necessary that the student be not content until he has arranged the subject from which he can get the most pleasing and artistic results.

As a preliminary, a good way to focus a subject is to hold up one of the hands—so, but a little experience will soon educate the eye to grasp the best point of view. If it be painting, the student will soon learn what to omit or what to modify in the subject. On the other hand, if he be using the camera, his hands will be tied, although he can still ensure that his subject is taken from the best point possible.

If care is taken to secure the best position either for painting or photography at the beginning, this will save much trouble and valuable time as well.

It often happens that a very slight movement, either to the right or left, will so change an object that that which was a defect from one point of view becomes a beauty from another, and *vice versa*. I have also found in my own experience that a subject improves often after it is committed to paper or canvas, but I have also experienced the reverse. Therefore, although the search be somewhat tedious at first, it will save much trouble and even expense afterwards, because there will be no wasted plates or unnecessary waste of paint, if the artist has thoroughly satisfied himself that he has secured the best point of view.

One of the most important things for a student to remember is, that he must not attempt too much. Beginners, both in painting and photography, are apt to overlook this, and to think that the more they can show in their picture the better it will be. This idea, of course, proceeds from the want of knowledge and experience, and, with a little practice carefully directed, it will soon become obvious that this idea is quite a mistake. All the best pictures, as I have pointed out to you, show simplicity of design, and, even where a panoramic view or large group of figures are painted, there is always one central object or figure to which all the rest of the picture is subdued or subordinated. In the painting of a portrait, for instance, it is always important that everything should be subordinate to the head.

One of the greatest difficulties the young student has to deal with at the commencement of his studies is to know what to put in and what to leave out of his picture. In painting, as I have said before, it will be found necessary sometimes to modify or even omit some parts of the subject altogether. A telegraph wire sometimes intrudes itself upon a picturesque street, and may spoil the beauty of it. In this case it is better to leave it out of the picture altogether.

Should the camera be in use, this will, of course, be impossible, but the student can still make sure that the picture is taken from the best point of view.

When I was a student at the Royal Scottish Academy, I sometimes went out sketching with some of the older students, and can remember my early experiences. On one occasion, I remember we went to New-haven, that favourite resort of Edinburgh artists, and found a subject out upon the pier. I was the youngest student there, and had done very little sketching from nature before, but my two companions were both pretty good painters. We had not worked long before we soon collected a crowd of boys and girls to watch us. This, of course, made me nervous, but my efforts were soon rewarded by our "would-be critics" remarking that *my* picture was the *best*. This, of course, I knew could never be the case, but my crude attempts were easier understood to these boys and girls than my student friends' work, which was too advanced for them to follow. I have always found, in my artistic career ever since, that the people who know most about art and pictures are the most sparing with their criticism. But to our subject.

If we examine a painting by a greater master, we will find that there is a balance in the composition. The eye instinctively travels to a certain part of the picture, and this is the spot to which the artist intended the spectator's eye to rest upon. The other parts of the picture are all there, but every part is subdued, and holds its place in relation to the most important part of the picture.

If, for instance, the subject be landscape with, say, trees, hills, and water, the trees will generally be the principal object, with reflections in the water, perhaps, and hills in the distance. If, however, the subject be a figure composition, the principal object will be the foreground figure or figures, and the middle distance and background will be subordinated to these. Take the well-known picture of *Napoleon on board the Bellerophon*, by W. Q. Orchardson, R.A., and you will see exactly what I mean. Napoleon is seen standing on the deck of the ship with folded arms in

the foreground of the picture, while his officers are very cleverly and naturally grouped in the middle distance, while the eye is carried instinctively out of the picture to the sea and sky beyond.

The arrangement and composition of this picture, including the rich colouring for which Orchardson is so well known, all go to make this one of the greatest masterpieces of British art. It is satisfactory to know that this fine work of art has been secured by the Chantrey Bequest, and may be seen in the Tate Gallery in London. The picture has been etched, and copies can be seen at most of the printsellers'. I am sorry I have not been able to get a lantern slide of this picture to show you.

There are other well-known pictures, which I might refer to, as demonstrating what I mean as good examples of composition, but, instead of doing this, I will call your attention to a very popular picture by Luke Fildes, R.A., called *The Village Wedding*. This picture, though exceedingly clever in many qualities, is, in my opinion, what I would call a crowded composition, and is wanting in simplicity of arrangement and general effect.

It is one of Mr. Fildes' earlier works, and he is seen to much more advantage in his famous picture of *The Doctor*, so well known by the reproductions which are seen everywhere. Here we have another splendid example of a pathetic incident, simply but powerfully treated. I remember seeing this picture at the Royal Academy when it first appeared, and was very much struck with the sentiment which it conveys. This picture was awarded the centre position in the great room that year, about 1889 or 1890, and was deservedly very popular.

The nation is again fortunate in having possession of another great picture, the late Sir. Henry Tate having presented it along with many others in his collection.

It was my intention to have a slide of this picture also as a good example of composition, but the copyright of most of these great pictures is strictly reserved, and it is a difficult matter sometimes to get permission. I have spoken of the arrangement in composing a picture, but the balance of light and shade is also very important to the success in making a picture.

If the subject be an out-door one, say on a grey day, of course there will be very little contrast or effect in light and shade, but under strong sunlight the same subject would be very different. It will, therefore, be evident that, if a picture is painted in sunlight, it will be much more difficult than on a grey day, although from a colour point of view artists prefer the latter.

One of the greatest masters in light and shade, as well as colour, is the famous Rembrandt, the founder of the Dutch school. No artist of any school has ever carried light and shade to the same perfection as Rembrandt, and most of us, no doubt, have heard professional photographers use the term "Rembrandt light and shade" for a photograph.

I may say that, personally, there is no other artist in the world appeals to me so much as this great master. Every time I go to the National Gallery in London, I never fail to feast upon the works of Rembrandt.

The depth of colour and breadth of effect, which gives such power to his work, is beyond all praise, and, so far as my art knowledge goes at present, he stands head and shoulders above any other painter the world has ever produced.

The modern schools of painting have all developed the influence of Rembrandt, but perhaps it is more evident amongst the modern French and Dutch schools than elsewhere. Joseph Israels, the Dutch painter, and G. P. Chalmers, R.S.A., were no doubt very much influenced by the works of Rembrandt.

In all the French ateliers there is very much stress put upon what the professors call "values," which means in this country "good tone." If a tree is darkened, or a foreground lightened, the painting will suffer or improve according to the tone or effect produced, but, when we find each object painted in relation to the whole effect, then we have "good tone," or, as the French term it, "values."

The modern "Impressionist School" depends almost entirely on "values" and light and shade, and this is just the other extreme of pre-Raphaelitism, which paid no attention whatever to tone.

The modern Dutch painters are, perhaps, the best examples for good composition, colour, and tone, all combined. Their works show a truthfulness to nature, combined with rare artisticness.

I am pleased to say that the modern British school is also paying great attention to tone or values, and there is no doubt that art in this country, within the last thirty or forty years, has made rapid strides, but it is for posterity to decide how the work of to-day will compare with the old masters. A German critic says: "The British school are the progressive party in the history of modern art; the French and Germans are the conservatives." "English art had this advantage in playing a pioneering part, that it had no old traditions to stand in its way; it had no great past. In the sixteenth and seventeenth centuries England had been content to offer hospitality to Holbein and Van Dyck, and to collect the works of foreign masters in her galleries. Her art sprang into existence suddenly and unexpectedly at the beginning of the eighteenth century, and thence developed exclusively on native lines." The same writer says we British live in an age in which freedom has arisen. Our civil liberty affords us a sufficient foundation, and our liberty conducts us to the absolute verity in art. All beauty is truth; the search after truth leads you to nature. Truth is the mightiest thing in the world, since it exercises

sovereign rights over the creation of the imagination. The character of British painting is apparent. It proceeds from an intellectual impulse, not only does it strive after beauty of form and physical development of sensuous grace, but in the first place after intellectual expression and sentiment.

From these and such like remarks it will be readily understood that this nation takes a prominent place in the art history of the world.

Let us who are still students aim at high ideals, so that we may be worthy successors of those who have gone before. We may not all be successful, but, if we have cultivated our talents to the best advantage, we will have the satisfaction of knowing that we have done our duty.

HENRY JOHN DOBSON, R.S.W.

#### GLEANINGS FROM AN EXHIBITION CATALOGUE.

THE catalogue of the South London Photographic Society's Exhibition, open this week, contains a number of helpful articles by some of the leading members of that Society, from which we take a few extracts. On the subject of Stereoscopic Photography, Mr. John T. French gives the following hints in regard to the selection of apparatus:—

"I prefer a half-plate camera, one with a square bellows is the best, although some cameras with a taper bellows can be adapted by making a division to hook on to the inside of the front and back; it need not be the exact depth of the camera, an inch or so top and bottom is not material. It can be made from a piece of black sateen, say 8 x 5 inches, which will allow for a hem top and bottom for a piece of elastic to run through, with a loop at each end to hook on to the four corresponding hooks, two on the reversing back and two on the inside front, the object of the elastic being to allow the division to expand or contract with the racking in or out of the camera; or, if expense is no object, a small spring roller division can be purchased, price about 5s. An extra front, with a pair of 5-inch or 6-inch focus lens exactly paired, either single or rectilinear, as may suit the pocket, mounted from 2 $\frac{3}{4}$  inches to 3 inches apart from centre to centre, completes your outfit, so that, having your ordinary front and lens, and carrying half-plates in your slides, by removing or adding the division, you may take either stereoscopic pictures or half-plate size at will. In taking a stereoscopic picture, be careful to see that both your lenses are stopped down to the same aperture, otherwise, on developing, you will wonder why one half seems exposed more than the other.

"By using a half-plate you get (providing your lens will cover) each picture 3 $\frac{1}{2}$  inches wide by 4 $\frac{1}{2}$  inches deep, less the rebate in dark slide, so that in printing you can leave out either sky or foreground, or a little of both, as you may desire."

Lantern-slide making is Mr. Edgar R. Bull's theme. In the course of his article he gives the following hints on development:—

"From thin negatives I endeavour to work on dull, cloudy days, if possible, and use a slow brand of lantern plates, taking care not to over-expose. Develop with hydroquinone, 1 ounce; water, 1 ounce; with a few drops of bromide added, thus striving to obtain contrast. Should, however, the high lights begin to show traces of veiling before the slide is sufficiently strong, development should be instantly stopped, the plate washed and fixed, again wash, after which it can be brought up to strength by intensification. I have found the following satisfactory, by which means a good strong slide of brownish-black colour is obtained. Bleach the slide in a solution of bichloride of mercury until white throughout, after well washing, to be followed by a bath of about 20 minims of ammonia ('880) to each ounce of water. To ensure success, care must be taken that the washings are thorough after fixing, and between bleaching and using the ammonia solution, otherwise stains will occur. For strong negatives just the opposite procedure is employed, bright days selected, proportionately increased exposures, and diluted developer used, say, hydroquinone,  $\frac{1}{2}$  ounce; metol, 1 ounce; water, 2 to 4 ounces, according to the density of negative and effect desired.

"For subjects having extreme contrasts of light and shade—take, as an example, a dark interior with clear glass windows in field of view—I should give a full exposure, and commence development with hydroquinone,  $\frac{1}{2}$  ounce; metol,  $\frac{1}{2}$  ounce; water, 2 ounces (having in a separate measure, metol,  $\frac{1}{2}$  ounce; water,  $\frac{1}{2}$  ounce; also a small camel's-hair brush). When development is about half complete, rinse the plate with water, and then carefully go over the highest lights, or other parts that hang back, with the brush and metol solution, until the details have been sufficiently brought out; then again pour on the original developer until completed. It is surprising what differences can be effected by this way of working against the ordinary method. Other instances of local treatment with the brush will, no doubt, suggest themselves to the worker."

Mr. C. Churchill offers the following method of negative classification:—

"Make or obtain an open wood box, the aperture at the top being equal to the aperture of the dark slide, a rebate being formed on the top inner edge, in which the negative lies as in the dark slide, obscuring the transparent margin so that only the developed portion is seen from underneath. For a half-plate negative the box should be about four inches deep, having a peep-hole in the side and a little door at the end.

The negative, as I have already stated, is laid in the rebate on the top, film down, the actinometer, already charged, is slipped through the little door, and the effect of the light passing through the negative upon it is watched through the peep-hole.

"For this work it is best to choose a bright day, when there are no clouds about; the light then is fairly constant, and more work can be done, although the process is workable at any time.

"We will now assume that we have four negatives to deal with, and in using the box as I have first described it is also necessary to take the time of the actinometer for the light falling upon the negative outside, as well as that which affects the actinometer underneath it.

"Suppose the following results are obtained:—

	Under negative.	÷	Over negative.	=	Comparative factor.
A	20	÷	5	=	4
B	25	÷	5	=	5
C	60	÷	10	=	6
D	110	÷	15	=	7½

By dividing the one by the other, we obtain a figure which we will call the 'comparative factor.' This, scratched on the edge of the negative with a sharp point, will be always available for future use.

"For the application of this factor we will assume that we have found out that a P.O.P. print from negative A requires 28 minutes when the actinometer value of the light is 10; then 28, divided by the comparative factor 4, gives a constant of 7, which permanently becomes our multiplier for this process.

"Under the above conditions the other three negatives would require:—

B	5 × 7	=	35 minutes.
C	6 × 7	=	42 "
D	7½ × 7	=	52½ "

Should the actinometer time be 20 or 5 instead of 10, as taken in the above example, the time for printing must be doubled or halved. Although we prefer to judge our prints by looking at them, we can by this means learn the time the printing frames can be left to themselves, and give instructions to others when to take them in during our hours of travail. This system can, perhaps, be better used in carbon or platinum printing, and also in lantern-slide making. The chief thing is to obtain a constant rack process from a standard negative; the other part is simple."

"Clouds" afford Mr. G. J. T. Walford the opportunity of making the following suggestions:—

"Well-marked storm and sunset clouds may be said to require no exceptional treatment; an ordinary plate, a medium stop, a quick hand exposure, should produce a satisfactory negative. Light, fleecy clouds on a summer sky, and clouds of a stronger nature, but illuminated from the front, should be photographed on a slow isochromatic plate, with a yellow screen, and rapid exposure. Yellow sunset clouds should also be taken on an isochromatic plate and with yellow screen, but the exposure will be longer. Red sunset clouds had better not be attempted, as they are seldom satisfactorily treated photographically; however, the conditions of success in this case are as follows: the use of a spectrum plate sensitive to red, a suitable colour screen, and correct exposure. To attempt to photograph such clouds without complying with these conditions is simply a waste of time and materials, and is foredoomed to failure.

"When photographing clouds, it should be remembered that three things concerning them are calculated to impress our minds and influence our selection: (1) form, (2) lighting, (3) colour. In our work we must be guided by the first two only, the formation and lighting of the clouds. However the colour may charm, we cannot reproduce its tints; consequently, if their great recommendation is beauty of colouring, such clouds had best be passed over as unsuitable to our purpose."

#### PHOTOGRAPHIC RECORDS.

At the meeting of the Photographic Club, on February 28, Sir J. Benjamin Stone, M.P., who was kind enough to attend in support of the objects of the National Photographic Record Association, of which he is President, and an exhibition of whose work was arranged round the room, made some interesting remarks about the aims of the Association. It was a great pleasure to him, he said, to be able to make a few observations in encouragement of those in whose power it was to do so much for the Association of which he was the head. He had been exceptionally favoured with access to some of the most interesting relics which the country possessed for the purposes of photographic record, but still every one may do excellent work in a smaller area. It was a matter of extreme importance to the future generation that objects and events now common should be preserved and handed down, and it was astonishing what great secrets could be exposed by putting together what looked like insignificant details. If he were merely a literary man engaged in writing a history of some county, period, and subject, he would make notes as he went along for future elaboration. But it was infinitely easier to take photographs.

They were far more complete than any literary composition could ever be. He went on to show how the humble tomb in the village churchyard was but a development of the ancient cromlech of this country in its pagan days, and what an interesting tale they told, arranged in chronological sequence, of the evolution of the modern tomb. None of these cromlechs, or their later forms, in themselves were of much interest, but pieced together, they made a wonderful chapter in history.

The work of the Record Association must be based, then, on attention to details, however small and insignificant. The slightest difference between any two things—the tombs of which we have just heard, or anything else—was a thing to be recorded. It told a tale which was necessary to build up the chain of history. To suggest a moral, he would say, Despise nothing at all, because of its familiarity. Get it by all means, and store it away. As with tombs, so with coins and tokens of prehistoric times. In many cases, the only existing records of kings, princes, and leaders of peoples in ancient times consist of these very coins. By their means the sequence of reigning heads in times prior to written history had been handed down. Sir Benjamin Stone told a delightful tale of the evolution of a certain coin. Its design had been carefully traced through successive years to one of the most beautiful coins ever made, and that by Philip of Macedon. What he had said he hoped would have its proper effect. Nine-tenths of the work that he himself had been doing, at Windsor-tower, Westminster, &c., would, he knew, fail altogether to be appreciated by the present generation, and it was quite natural. These records were nearer truth than words could be, and the motive for taking them was that of the historian and nothing more. If his word, Sir Benjamin concluded, would increase the numbers of workers in the preservation of pictorial records, he should be satisfied, and he earnestly appealed to those present to throw themselves heartily into the cause.

A number of lantern slides were shown, indicating the nature of the work being done. Mr. G. Scamell, the Hon. Secretary of the Association, stated that upwards of 11,000 prints had been collected and deposited in the British Museum. The Association now looked to the co-operation of the societies and photographers of the country, and, if to this end centres could be formed for the reception of prints, a great impetus would be given to the scheme. Whole-plate prints were preferred, but the official mounts would take two half-plate or four quarter-plate prints. Platinum or carbon prints, or by any known permanent process, only were received, and they could be addressed to 66, Russell-square, W.C.

Mr. W. R. Stretton, in the course of some remarks, expressed the belief that the Club might do a good deal by becoming agents, as it were, for the National Photographic Record Association. Familiarity bred the contempt of many beautiful spots and historical associations which were close at hand, any of which might cease to exist at short notice. He therefore had pleasure in moving that a Committee of the Photographic Club be appointed to take the necessary steps to act for the best interests of the Record Association.

Mr. F. Haes seconded the motion, which was duly carried, and with which Sir Benjamin Stone expressed himself as much gratified.

A vote of thanks was passed to Sir Benjamin Stone.

#### THE MULTITUDE OF PROOFS.

"THREE finished proofs submitted with each order for one dozen cabinets." Such or similar is the announcement that appears in so many photographers' price-lists nowadays. Does the practice tend to enhance the public appreciation of their photographs, or the reverse?

Let us try to imagine Reynolds or Millais, for instance, painting half a dozen different portraits of their sitters, and giving them their choice of the best.

Is photography so low down in the scale of things artistic that what would seem absurd and irrational in one case is quite the correct thing in the other? A portrait is a portrait, a work of art, be it on canvas or in carbon tissue, on porcelain or in platinotype, and needless duplication merely tends to vulgarise and lower its value.

"Oh, but," photographers say, "the sitters are easier to please if they have three or four proofs to choose from, when, perhaps, one only would prove unsatisfactory."

Why so, if it is the best one? An artist will make, perhaps, many sketches and studies before he completes his finished work; so, also, may his brother of the camera take several negatives, only showing the print from the one he considers most likely to satisfy his critical and exacting customers.

It is a settled delusion with some that several proofs will obtain a larger order than a single one. Of course, if this were so, the matter is settled, for we cannot afford to ignore the commercial aspect of the question. But is it really so? The sitter, presumably, does not burden himself with more photographs than he or she actually requires, and is, on the whole, more likely to loosen his purse-strings over one well-admired portrait than two or three of rival and clashing merits. Do we not all know the state of helpless despair some people are reduced to when they have to decide which proof to sanction? The Judgment of Paris were trivial in comparison. Friends and relatives are anxiously canvassed, and, perhaps, even the photographer's own preference sought for, though not received with too much reverence. Finally, in all probability, the one not

particularly cared for by the sitter is chosen, with lurking misgivings, in deference to a majority of other opinions, and that order is not so large as it might have been.

In the National Gallery may be seen two portraits of Cardinal Richelieu, in slightly different positions, framed together. Either of them is a masterpiece, instinct with character and vitality, showing perfect technique in every inch; and yet, seeing them together, one is conscious of a vague sense of disappointment. If we hold up a hand, so as to block out one of the pictures from view, the immediate gain of the other in interest and effect is surprising. The moral is sufficiently obvious and easily applied. Not only do two nearly similar effects in juxtaposition clash with and disturb each other, but one of them, also, is always in some single respect better than the other, and *vice versa*, and so they each serve only to point out their neighbour's deficiencies, instead of emphasising its merits.

But *revenons à nos moutons*. Let us suppose we have three proofs of the same individual, varying but slightly in position and lighting; it is almost certain that one of them will do more justice, for instance, to the sitter's eyes, another has not such expressive optics, but the nose is pronounced "just lovely," while the third has got such a nice mouth that it would take honours easily, only "the eyes and nose are not so nice as the others." The result is probably not quite so satisfactory from a purely commercial point of view as could have been wished; indeed, the unfortunate photographer will most likely be required to produce, after a resitting, yet another proof, that shall combine the good points of all the others, nearly always an impossible task.

Yet another argument against a multitude of proofs is the large amount of extra work they involve, and the inevitable necessity, in so many cases, of "rushing" the retouching and finishing. Be it artistic or not, there is no question that the amount and quality of the pencilling on the negative has a great influence on the sitter's mind, where all else may fail to attract his notice. Now, where there are stacks of negatives to be got off post haste, how can the unfortunate knight of the pencil be expected to devote too much time to each? Here is the genesis of most of the rough and hurried-looking finishing of to-day. How much more sensible it would be to do less and do it better! Is not the real secret of business success to give the best possible value to our clients, not in quantity but in quality? The by no means indiscriminating public soon learns this palpable fact, and gives its patronage accordingly to the man who has the sense to act on it.

The question of time also crops up in another direction. This is an era of sharpness and promptitude; our customers expect their proofs within a few days, and photographers themselves best know how often this fond hope is perforce disappointed. Perhaps enough has already been said to indicate at least one of the causes of delay, if not the principal, and the means of its avoidance. "Would you believe," said a lady to me once, "So-and-So has actually kept me waiting more than three weeks for my photos?" "Ah, madam," I replied, "how many proofs did you have?"

Photographers are such a conservative race, ever moving in a time-honoured groove, doing what their grandfathers did before them, and slavishly copying one another's methods, or perhaps the system complained of would not be so prevalent. "Oh!" they say, "A or B do so-and-so, and it pays them. Therefore, of a certainty, it will be the best thing for us to do." And, accordingly, they do it, and wonder dolefully why business is not what it used to be, never seeming to suspect for a moment that perhaps their own lack of originality and ability to adapt themselves to the ever-changing hour is principally to blame.

Regarding the question from a very bald and mercenary point of view, to give many proofs undeniably increases expenses at first hand, and reduces profits proportionately. I once heard a well-known man admit that, other things remaining the same, he would increase his turn-over at least ten per cent. by only giving one proof to each sitter, and a little calculation will show that, if anything, he rather under-estimated the result of the suggested change, for it is evident that less than half the former amount of retouching would have to be done, one-sixth of the printing would be saved, to say nothing of the gain in time and other things. And, as we must not selfishly forget the interests of the army of photographic assistants, they need not fear any possible loss of employment, for public appreciation of better work would stimulate business; besides which, no doubt, greater comfort and better conditions of labour would soon probably follow, to their general benefit.

Why is it that photographs are regarded with such slight respect as compared with paintings or engravings? Is not the reason obvious? It is not merely that they do not approach so high an artistic standard, nor that they are more cheaply and easily produced; it is mainly because we have made them too plentiful and commonplace, and have destroyed the public reverence for what we ourselves treat so lightly and they obtain with so little trouble, for it is a pretty universal weakness of humanity to value things in inverse ratio to the ease with which they are procured, on the principle that forbidden fruits are sweetest.

The practice of giving several rough or unfinished proofs does not deserve so severe a condemnation as that we have been considering, but must, at least, be described as risky and impolitic, for the generality of sitters are never greatly impressed with their counterfeit presentments in the state of fearless realism that the camera gives us before the gentle

and refining influence of the retoucher has made amends for nature's deficiencies. What even our clients themselves would probably consider the most sensible and practical procedure, if appealed to, is to take several negatives with all due care and consideration, and, selecting the best, devote all our artistic and technical skill to obtaining one satisfactory picture from it. How much more pleasure we should take in our work, and what a gratifying sense of having produced something worth keeping would be our reward! More immediate and tangible results, in the shape of increased receipts and reputation, would of a certainty follow in the wake of what, after all, as merely sentimental considerations, we could not afford to give too much attention to in a materialistic and profit-seeking age.

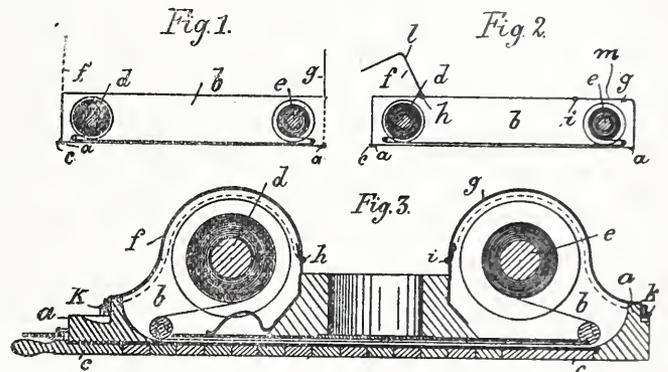

A. LOCKETT.

A ROLLER FILM-HOLDER.

[Patent No. 23,228 of 1899.]

THE invention of Mr. W. Beutler, of Berlin. The roller bearings, gearing, and draw table are inseparably connected to the film box, and are rendered accessible by the opening of the sides, and, it may be, of parts of the back of the film box. By shaping the box to suit the rollers, the latter may be given plenty of room, while a considerable saving is effected in the weight of the box.

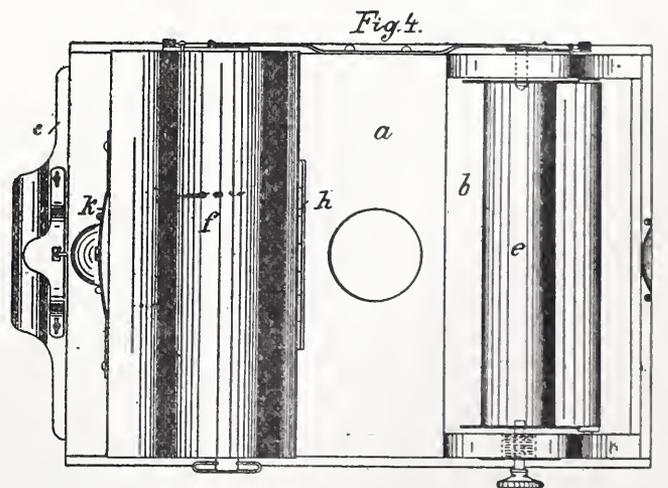

In fig. 1, *a* is the box frame, and *b* is the interior space of the box, *c* is the dark slide, which can be drawn back to expose the film, and *d*

and *e* are the film rollers. *f* and *g* are the sides of the box, which can be slid back, either horizontally or vertically, when it is desired to obtain access to the rollers and mechanism. By this arrangement the rollers can easily be fitted in or extracted, and the film may readily be placed in guiding grooves, to enable it to run smoothly.

Fig 2 differs from fig. 1 only in the fact that the sides, *f* and *g*, open on hinges, at *h* and *i*, instead of sliding open, parts, *l* and *m*, of the back of the box opening at the same time.

In figs. 3 and 4 the box is shaped to avoid all useless spaces, the back

being curved round the rollers. By this means a favourable position is obtained for the hinges, *h* and *i*, so that, when the lids, *f* and *g*, are folded back, the film rollers and mechanism are very much exposed and can readily be got at for manipulation. The lids are provided with any suitable spring or other catch, *k*. The lids, *f* and *g*, are preferably made of metal, say light plates of aluminium, whilst the rest of the box can be made of wood. By this arrangement it is quite possible to provide from outside, or from the dark slide, a handle which operates to indent the film so as to facilitate cutting it at a later period at the desired place.

## A PRINT-OUT PLATINUM PROCESS.

[Patent No. 5304 of 1899.]

THE inventor, M. L. Hanriau, in describing his process, the practicability of which is somewhat doubtful, says: "I prepare the following solutions:—

"1. A saturated solution of ferrous sodium oxalate for an ordinary temperature of fifteen to twenty degrees.

"2. A saturated solution of protochloride of platinum.

"I take equal parts of solutions 1 and 2, and coat the paper or other support with a uniform layer of the mixture by means of a brush, which must be kept scrupulously clean. The prepared paper or other medium is afterwards dried, and is then ready for use.

"When producing prints by this process, the prepared paper is exposed to the light beneath the negative in the usual way. When the image has made its appearance, the paper or other medium is removed from beneath the negative and passed directly through various baths consisting of water containing one per cent. of hydrochloric acid, the print being then thoroughly washed in water for one hour.

"It is then only necessary to dry the print and mount it upon a card or other suitable support."

## WAX SEAL IMITATIONS OF PHOTOGRAPHS.

[Patent No. 6122 of 1899.]

ACCORDING to the inventor, Mr. C. S. Jones, of High-street, Woodford Green, the photograph to be reproduced in imitation of a wax seal or other design is copied by means of a photographic camera, and a plate is produced containing one or more negative impressions. From this negative as many positive prints as are required are taken, or, where large quantities are required, they can be reproduced by means of one of the mechanical processes, such as colotype. The prints are subsequently coloured by means of a dye or other colouring medium to represent the colour of the wax to be imitated. Or they can be left uncoloured to represent white wax. The backs of the photographs are then gummed and allowed to dry. They are then embossed so as to represent a wax seal, and punched out of the sheet by means of a special die in a press. By varying the shape of the embossing die any shape of seal can be produced.

A slight variation of the mode of procedure above described, which specially lends itself to the production of imitation seals of a dark colour, is to punch out and emboss a suitable coloured paper, and then affix the photograph to it in such a manner that the imitation seal forms a kind of framework or border round the photograph. When this method is adopted, it is best to leave the photograph uncoloured, as the picture will not show up clearly if coloured with a dark dye.

## GELATINE RELIEFS.

[Patent No. 21,692 of 1899.]

THE invention of Messrs. Heimsoeth & Co., of Cologne, who say:—

"A plate of plate glass is covered with a sensitive film of gelatine, and exposed under a negative or a positive, and the gelatine film converted by washing into a relief, this last mentioned relief forming the printing mould.

"In order that the gelatine ink may not remain adhering to the mould, it must be saturated in a suitable manner with oil or grease. As the relief completely soaked with water would repel the oil or grease, and at the same time care must be taken not to conceal the finer details, only a decomposed layer of oil or grease must be put on. This must be so effected that the gelatine, which is not very resistant, may be preserved against pressure or friction.

"The relief is, therefore, for a certain time, placed in a bath consisting of a solution of soap and water, and then in a ten per cent. solution of chromate of alum or of an acid. The soap in the gelatine film will be hereby decomposed and the gelatine completely saturated therewith. On the surface a scarcely perceptible trace of grease will remain, which, however, owing to its consistency, separates the gelatine ink from the relief completely. By a further treatment with oil the residue of grease can be strengthened.

"In printing processes with metal, resin, or other hard moulds, the latter hitherto had to be vigorously rubbed with oil with a flannel rag. This rubbing in of oil had to be repeated after every printing; consequently the delicate outlines of the relief were dulled by the frequent rubbing, and the prints wanting in sharpness. In the present process the mould is steeped with oil, and this oiling needs only to be repeated after a considerable number of printings. As the moulds are not continuously rubbed with oil, they last longer than those formerly used and made of metal.

"As the relief is formed directly on a plate of plate glass, and remains thereon during the printing, a permanent evenness is ensured in the moulds, and thereby a novel, rapid, and inexpensive method of printing from gelatine moulds created, as hitherto it has not been known that reliefs in gelatine could be employed for this purpose."

## EXHIBITION OF THE SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE Eleventh Annual Exhibition of the South London Photographic Society was opened at the Public Baths, Church-street, Camberwell, S.E., on Saturday evening last, by an address by Mr. G. C. Whiteley, M.A., M.L.S.B., and will remain open until Saturday next, the 10th inst.

For a photographic society of the standing of the South London Photographic Society to hold an exhibition annually seems to us at the present time only a natural thing to do; and we are apt to forget to award the praise that is due to those who organize a work of such magnitude, not for their own personal benefit, but in furtherance of the aims of their Society and for the glory of photography. To run a big Exhibition for a week, to make it attractive enough to draw a sufficiently large audience at a nominal charge for admission, to leave a balance on the right side when the accounts are made up; to do all that is necessary in the preparation and carrying out of this work, in addition to following the avocation which earns the bread and butter, is more than creditable, it is praiseworthy. We are apt to forget, too, that in addition to the benefit the members derive from the opportunity of studying the works of their fellow-members, and comparing them with their own, such an Exhibition serves a most useful purpose in assisting in the education of the lay visitor in the capabilities of photography. We are told over and over again by professional photographers that the class of work that they do is that which the public insist upon having. We can quite believe there is a great deal of truth in this. The public are very conservative, and very many of them have never seen any other kind of photograph than a glazed silver print, and a glazed silver print therefore represents to them the ideal of a photograph. A better understanding of what photography is capable of ought to create a demand for work of a higher class, to the advantage of photography generally and the professional photographer of talent in particular.

The present Exhibition shows that the members are at least maintaining their position. Speaking of the Members' Classes generally, the best of the work is quite equal to any previously shown, while the tail end is distinctly improving. Still, a little judicious weeding out of some of the worst examples of misdirected ambition would have materially raised the general tone. In Architecture, in which the Society has heretofore excelled, the class was, on the whole, a disappointing one. Some of the work was quite up to the usual standard, but a considerable part only reached mediocrity. We notice a tendency to flatness in several of the pictures, which seems to arise from want of detail in the shadows of the original negative, the effect being intensified in enlarging. Some of the best work was shown by Messrs. C. Churchill, F. Goddard, E. H. Lamb, G. J. T. Walford, and C. W. Walker.

On the other hand, the Class for Portraiture and Figure Studies showed a marked improvement. Not only was the number of exhibits proportionately larger than one usually finds in a society exhibition, but a fair number of them were distinctly above the average merit. Naturally here, too, appears some of the work it was least desirable to hang, and a bad portrait or figure is more noticeable than a bad landscape. We have much pleasure in congratulating the Society upon the good show made in this class, and, if it means that the same special attention in future is to be directed to this kind of subject that architecture has previously had, there is even a greater scope for attaining a prominent position. In the class we especially noted as good or promising the work of Messrs. W. C. Boyce, A. Hunt, A. Glass, E. Mathews, C. W. Walker, and Mrs. Welford.

The Landscape Class, naturally the largest, called little for comment. Taken as a whole, it was a good average collection, and would have been a much better one for a somewhat rigorous selection. Some of the most ambitious of it was marred by the very evident attempt that had been made to copy the work of others, and naturally the faults were more faithfully copied than the excellencies. We noted in our catalogue work by Messrs. F. W. Bannister, F. A. Bolton, H. Esler, E. H. Lamb, P. H. Mason, J. Moyses, and C. W. Walker.

The Hand-camera Class, sensibly restricted to prints from the original negatives, was, we think, quite up to the usual mark, and the Beginner's Class, as one might expect,

The Class for Pictures taken on Excursions contained some of the best work in the Exhibition, thereby robbing the subject classes to which it belonged. There seem to be strategical reasons for instituting the class, but, for the benefit of the Exhibition, it is a pity that, if classes at all are necessary, a more rational system is not adopted.

The Members' Champion Class for pictures which have been medalled during the past year was an extremely creditable one to the Society. The nineteen pictures here exhibited at any rate proved that some of the members have done doughty deeds on other battlefields than their own. The lantern slides were numerous, and distinctly good in quality.

In the Open Classes the number of members of the Society competing was quite a feature, and three of the thirteen awards thus returned to the Society. Among the most prominent of the exhibitors were Messrs. W. Smedley Aston, F. W. Bannister, Graystone Bird, W. E. Brewerton, E. R. Bull, Mrs. A. M. Dumas, Messrs. Dudley Hoyt, C. F. Inston, W. E. Inston, E. H. Lamb, Viscount Maitland, Messrs. C. H. Oakden, C. Skelton Tyler, G. J. T. Walford, E. Atkinson, S. J. Beckett, A. Bedding, W. J. Byrne, H. Esler, Hilton Grundy, J. Kearney, jun., R. R. Rawkins, Leslie

Shawcross, Mrs. Welford, Messrs. J. Beeby, H. C. Leat, Eustace Young, F. Goddard, F. W. Gregg.

The trade exhibits were fully as interesting as usual, the principal exhibitors being Messrs. R. & J. Beck, Burroughs, Wellcome & Co., J. Griffin & Sons, J. E. Lockyer, Mackenzie & Co., the Prosser Roberts Drug Co., the Photographic Art Development Co., Rogers & Webster, and R. W. Thomas & Co. Demonstrations, cinematography, Röntgen rays, and Ives's colour photography were announced for each evening in addition to lantern lectures by such well-known people as Mrs. Catherine Weed Ward, and Messrs. J. A. Hodges, F. H. Evans, J. Carpenter, and C. H. Oakden.

We must not omit a word of praise for the catalogue, which, in addition to the usual matter, contained a capital series of six practical articles on photographic subjects by members of the Society, and we must also not omit to call the attention of those responsible to the unnecessary large size and prominent character of the labels used for numbering the pictures. The label, though necessary, is an evil, and particular care should be taken to place it so as not to spoil the picture.

JUDGES' AWARDS.

Members' Classes.

Class A (Portraiture, Figure Studies, and Animals).—Silver medal, W. E. Mathews; bronze medal, W. Page.

Class B (Architecture).—Bronze medals, W. H. Dawson, G. R. Nicholls.

Class C (Landscape, Seascape, and River Scenery).—Silver medal, C. W. Walker; bronze medal, P. H. Mason.

Class D (Hand-camera Work).—Silver medal, R. G. Goodwin; bronze medals, H. Esler, W. T. Tollett.

Class E (Beginners' Class).—Bronze medal, A. V. French.

Class F (Excursion Pictures).—Silver medal, G. Brown; bronze medals, W. Howell, T. Moysier.

Class G (Lantern Slides, sets of four).—Silver medal, E. Mathews; bronze medals, C. Churchill, C. F. Dickinson.

Class H (Members' Champion Class).—Gold medal, given by Mr. G. A. Maull, W. H. Rogers.

Open Classes.

Class J (Champion Class).—Gold medal, Dudley Hoyt; silver medal, Viscount Maitland; bronze medal, E. R. Bull.

Class K (Pictures—any subject).—Silver medal, E. Atkinson; bronze medals, R. R. Rawkins, C. Skelton Tyler.

Class L (Lantern Slides Champion).—Silver medal, E. R. Bull; bronze medal, R. R. Rawkins.

Class M (Lantern Slides).—Silver medal, F. W. Gregg; bronze medals, Eustace Young, S. J. Beckett.

Class N (Stereoscopic Slides and Transparencies).—Silver medal, F. Goddard; bronze medal, L. S. Wilkes.

Our Editorial Table.

FORMULES, RECETTES ET TABLES POUR LA PHOTOGRAPHIE.

DR. J. M. EDER. Paris: Gauthier-Villars.

THIS addition to the *Bibliothèque Photographique* is a translation by Monsieur G. Braun fils of Dr. Eder's work, and the publishers have had the volume carefully revised and brought up to date by the author.

It is an excellent collection of formulæ for all the important processes of photography, and the book likewise contains a very valuable collection of chemical and other tables, which will make it a favourite with the experimental photographer.

AN EFFECTIVE SHOW-CARD.

By Messrs. Wellington & Ward, Elstree.

A NEAT little price-list of the justly appreciated "Wellington" papers has reached us from the Elstree house. The Waltonian hand is visible in the design on the effective red cover, and in company with the price-list comes a show-card which not only strikes the eye but pleases it. This measures about 20x13 inches, and it is made of cardboard over one-third of an inch thick. Upon a khaki-covered ground the words "The Wellington papers" are sunk in white enamel, while the pictorial embellishment is a 11x9 bromide portrait print of exquisite quality. We must congratulate the firm on the refinement and good taste shown in this attractive card. It is sure to direct popular notice to the Wellington papers, and that without being unduly assertive.

Studio Gossip.

MR. P. R. SALMON, F.R.P.S., has entered into partnership with Mr. R. C. Vansittart of 12A, Lord-street, Liverpool, as stereoscopic view publishers.

PYRO DEVELOPMENT.—*Photographic Scraps* for March draws attention to the fact that in Dr. R. E. Liesegang's paper, *Der Amateur Photograph*, an article is published concerning pyro development which is well worth consideration. After pointing out that pyrogallic acid was the favourite developer with the wet-plate photographer, and was followed by ferrous oxalate, hydroquinone, eikonogen, and the aniline derivatives, the writer alludes to the fact that photographers are returning to pyro, and that this tendency cannot be due to pure conservatism. Dr. Liesegang has often referred to the compound nature of the image formed by pyro development, the negative being composed of metallic silver plus stain. This almost eliminates the risk of over-exposure. On the other hand, pyro is recommended by manufacturers of shutters as the best developer for instantaneous work. These two extremes suggest that pyro is probably the developer giving most latitude.

A SOUVENIR post card in honour of last week's stirring events, has just been issued by Messrs. Raphael Tuck & Sons. Majuba, with its fatal date, February 27, 1881, appears engraved on a broken stone at the top corner of the card, the wording "Paardeberg" with the same date in 1900, and "Ladysmith" with the date of the following day appearing below, while an infantry man in khaki, who has evidently been busy, judging by his broken chin-strap and his general determined martial bearing, is standing on the right, with his rifle leaning against his leg, and in the act of unfixing and sheathing his bayonet. The wording at the side, "Wiping something off the slate," is the key to the significant action. The figure is drawn by Mr. Harry Payne, the painter of the famous picture *Sons of the Empire*. The post card is issued at the price of one penny, so that Messrs. Raphael Tuck & Sons, the publishers, should be able to record an unprecedented demand for this patriotic little souvenir of the "beginning of the end."

WE are sorry to learn of the death of Mr. Thomas Edge, photographer, of Llandudno, which took place on the 26th ult., in his eightieth year. He was at one time a most successful portrait photographer for nearly thirty years in the earlier days, and by some of our older readers will be remembered for his improvements in studio construction and studio lighting, as well as for his method of double printing, with inserted foregrounds and backgrounds, a system frequently described in our pages. In the early days of carbon he was one of the best and most successful workers in that line, and in the early days of platinum he was also a pioneer. During the last few years an almost complete loss of eyesight caused him to give up photography, which he had continued as a hobby even after retiring from it as a business, and he then developed a method of building up various scenes from pieces of cork, lichen, sand, &c., which he could see to do in a good light, and photographing the results. In this way he produced very many fancy pictures.

LAST week a dozen gentlemen sat down at the Camera Club to what was perhaps the most remarkable meal that has been eaten in the country since Frank Buckland dined off jaguar steak. Mr. Henry Stevens, of King-street, Covent Garden, the well-known amateur photographer, some time ago conceived the idea of treating his friends to a luncheon, the distinguishing feature of which should be an emu's egg omelette. Sir Cuthbert Peek presented the egg, and Mr. Stevens successfully carried out his idea. First of all were served kangaroos' tails à l'Australienne and saddle of reindeer, and then followed the great event of the occasion—the opening of the emu's egg in order to hand over its contents, which weighed about 2lb., to the chef of the Camera Club. Amid quip and crank, waxing merrier and merrier, Mr. Stevens, dexterously sawed off one end of the shell, purposing to have the remains mounted in silver as a cup. Various savouries in the shape of crocodiles' eggs, alligator's egg, and even gigantic snails' eggs adorned the sideboard. Mr. Stevens had another surprise in the shape of the finest and most beautifully marked egg of the extinct great auk, which has come into his hands.

News and Notes.

WE regret to learn that Mr. C. Smerdon Roe, once well known as a contributor to the principal photographic exhibitions, died at Cambridge last week. He will be best remembered as the producer of *Sedge-gatherers*, a very telling photograph.

A REMARKABLE CAMERA.—A contemporary says that a camera that does it all is the "Helioider" of Herr A. O. Forsterling. It not only exposes a film, but develops the negative on this, and then prints positives on sensitised cards, of which the magazine of the apparatus carries 120.

THE TWENTIETH-CENTURY EXHIBITION.—The entries for the International Photographic Exhibition at Bingley Hall, Birmingham, close on Monday next, March 12. The Manager (Mr. Walter D. Welford, 19, Southampton-buildings, Chancery-lane) will be pleased to send prospectus on receipt of post card.

ROYAL PHOTOGRAPHIC SOCIETY.—Ordinary Meeting, Tuesday, March 13, at 66, Russell-square, at eight p.m. "The Illumination of Developing Rooms," by Mr. E. Howard Farmer. During the month of March an Exhibition of Photographs, arranged by the National Photographic Record Survey Association, will be on view daily from ten to four.

TWO ANCIENT BUILDINGS SAVED.—We learn that the Town Council of Southampton has decided, by a majority, to preserve the Undercrofts, a very fine example of Early Fourteenth Century vaulted architecture, which was threatened with destruction for street improvements. Archaeologists will feel rejoiced at this, and so will photographers who take an interest in ancient buildings. Henry the Eighth's Palace, or the most interesting portion of it, in Fleet-street, is also saved from demolition. For years this relic of the past has been used as a hair-cutting saloon. Shades of the past! King Richard's City residence, Crosby Hall, Bishopsgate-street, is still preserved as a restaurant, but it remains as a relic of the past.

**PHOTOGRAPHS OF BRITISH PLANTS.**—The *Pharmaceutical Journal* states that Mr. J. C. Sherstone exhibited, at a meeting of the Linnean Society, a collection of 700 photographs of British flowering plants, to show what could be accomplished by means of the camera in the direction of botanical illustration. He contended that photography was the only means by which the lines and masses of our flowering plants, as truly characteristic as the less subtle characters by means of which botanists group and arrange plants into orders, genera, and species, could be readily reproduced. He explained the various technical processes and apparatus necessary for successful plant photography, and alluded to the difficulties inseparable from the photography of plants in their natural habitats, &c. His remarks were illustrated by means of lantern slides.

**YORKSHIRE PHOTOGRAPHIC UNION.**—The Annual Meeting will be held in the large hall of the Grammar School, Bradford, on Saturday, April 7, when the proceedings will be opened by a meat tea at 4.30 p.m., followed by a short business meeting, address by the President, and a *conversazione* and exhibition of prints. It is hoped that there will be a large attendance, and, in view of the early hour at which the gathering opens, that the more distant clubs will be well represented. Contributions of mounted photographs, of an interesting or pictorial character, are invited, and the Committee are particularly desirous for each club in the Union to be efficiently represented. These prints should be sent to the Hon. Secretary (Mr. Ezra Clough) at the Grammar School, Bradford, so as to arrive not later than the Saturday morning on which the meeting takes place, or they may be brought in the afternoon by any members attending. No slides are required. Associates are also invited to bring with them any interesting apparatus they may possess, which, however, must be kept in their own charge during the evening. We are informed that the Union now represents eighteen societies, of about 1500 members in the aggregate.

In his concluding lecture at the Royal Institution on "Modern Astronomy," Professor H. H. Turner, M.A., F.R.S., mentioned the discovery of the minor planet Eros, which, at certain times, was a nearer neighbour to us than Mars. Photography, too, had revealed a new satellite of Saturn, not yet seen with the largest telescopes, and several new comets, while it had increased our accurate knowledge of the thousands of nebulae scattered over the sky, and enabled us to see in them a realisation of Laplace's nebular hypothesis. Finally, speaking of the spectroscope, he described the part it played in the investigation of the chromosphere, and said it bade fair to revolutionise eclipse work, even if it had not already done so. It had first revealed the existence of helium, a substance to which the light of a large percentage of stars seemed due, and which appeared of fundamental importance in the universe. By its aid, too, certain stars had been found to contain oxygen, which at one time seemed as though it were confined to this earth. Again, it had enabled Sir W. Huggins to reach a conclusion as to the distance of nebulae, and to show that the nebula and stars of Orion had the same spectrum, and were presumably composed of the same stuff at the same distance, while it had proved that the term fixed stars was a hopeless misnomer by supplying evidence of motion in the line of sight and of movements of stars round other bright stars or dark companions.

**CANTOR LECTURES AT THE SOCIETY OF ARTS.**—"The Photography of Colour," by Mr. E. Sanger Shepherd, forms the subject of four lectures during March. The first lecture was given on Monday last. The following is the complete syllabus of the course: Lecture I., March 5, "The Measurement of Light and Colour" (White light, How light waves travel, Composition of white light, The spectrum, The measurement of lights and shadows, The measurement of colour); Lecture II., March 12, "The Representation of a Coloured Object in a Monochrome Print" (Definition of the problem, Impossibility of representing colour contrasts in monochrome, The representation of colour according to luminosity, The preparation of a test object, colour-sensitive plates, light filters, Progressive orthochromatism); Lecture III., March 19, "The Representation of a Coloured Object in its Natural Colours" (White light, Young's theory of trichromatic vision, Spectrum colours and colour mixtures, Processes based upon Young's theory, Light filters for trichromatic photographs, The negative, The preparation of transparent prints in natural colours for the optical lantern); Lecture IV., March 26, "The Application of the Trichromatic Method of Colour Photography to the Printing Press" (Light filters, Suitable plates and negatives, Preparation of the printing surfaces, The half-tone process: its faults and difficulties; Inks, The printing of the three impressions, Colour-printing machinery).

**THE NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.**—At the Midland Grand Hotel, last week, a meeting was held in support of the objects of the National Photographic Record Association. Among those present to support the President were Major-General Waterhouse, Mr. L. Fletcher (of the Natural History Museum), Dr. H. R. Mill (of the Royal Geographical Society), Mr. Dallmeyer (President of the Royal Photographic Society), and many representatives of a number of photographic societies throughout the country. The report was read by Mr. George Scamell (the Hon. Secretary of the Association), who said they had received 1084 photographic prints, or, with those brought in that day, considerably over 1100, and most of the former have been deposited in the British Museum. The collection comprises the most interesting series by Sir Benjamin Stone of the Houses of Parliament (including a fine collection of the portraits of Members), of Windsor Castle, the Tower of London, the distribution of the Maunday money, and other subjects; by other photographers of Elgin Cathedral and the antiquities of the neighbourhood, Irish antiquities, a valuable contribution from Mr. H. T. Malby, and slum life in the East End of London; from Mr. E. Scamell of some old houses in London and studies of street life, &c. A number of photographic societies have associated themselves with the movement, letters asking for information and advice as to starting similar associations have been received from Philadelphia and Mysore, and M. Vidal (President of the Council of the Association Musée des Photographies Documentaires), of Paris, has written suggesting an international exchange of photographic documents. Sir Benjamin Stone congratulated the meeting on the success which had been attained since they last met in the room, and felt assured there would before long be a full recognition in the world of the value of the work they were engaged in. He himself had,

it seemed, recently employed himself in photography ancient customs in old villages, amongst them being that survival of an ancient celebration, the horn dance in Staffordshire. The President also dwelt upon the almost infinite wealth of material record photographers might work upon, and asked what would we not give for some pictures of Elizabeth's days, to go back no farther.

**AFFILIATION OF PHOTOGRAPHIC SOCIETIES.**—At a meeting of the Executive, held on Tuesday, February 20, 1900, Mr. H. Snowden Ward was reappointed Chairman of the Executive for the present year. The Secretary announced the receipt of a set of slides of Canadian scenery from the Toronto Camera Club for circulation amongst affiliated societies. A Committee was appointed to overhaul and revise the sets of slides already in circulation. It was agreed that the collection of pictures for circulation should be revised annually in time for it to commence its travels on December 1 in each year. On the proposition of the Brixton and Clapham Camera Club, it was agreed that the authors of Affiliation papers should be approached as to their willingness to personally deliver same, and upon what terms. After some discussion, it was decided that the Board of Judges should be revised annually at the first meeting of the Executive in each year; that six should form its number; and that the Board for the present year should be constituted as follows: Messrs. J. A. Hodges, A. Mackie, E. Marriage, J. C. S. Mummery, C. H. Oakden, and W. Thomas. It was arranged to call a meeting of the Executive for March 14 to consider the Rules of the Conference of Judges and the calling of another Conference. At a subsequent meeting of the Executive, held on Wednesday, February 28, 1900, Mr. H. Snowden Ward in the chair, Mr. W. Thomas was appointed a member of the Committee in place of Mr. J. A. Sinclair, resigned. It was decided to approach the various societies with a view to arranging a proper sequence of exhibitions so as to make it practicable for a collection of work to be sent from one exhibition to another without the exhibitor being required to have two and even three sets of his pictures, as is often necessary under the existing system. The Chairman reported that arrangements were about to be made for calling a conference of the Lancashire and Cheshire societies early in April, probably on April 2, at the rooms of the Liverpool Society in Eberle-street, kindly placed at the Committee's disposal. The offer of a set of slides from the National Photographic Record Association illustrative of its work was accepted with thanks. Mr. W. Thomas was added to the Lantern Slides Revision Committee. The Secretary reported that proofs of the Affiliation Annual would be submitted at the next meeting of the Committee, and that it should be ready for publication early in April.

## Commercial Intelligence.

WE understand that the business of David Allan, 157, Whitfield-street, Fitzroy-square, W., has recently changed hands, and will in future be devoted to the wholesale branch of the photographic apparatus trade.

THE *Daily Mail* of March 3 refers to an enterprising firm in Cornhill having in their window photographs, taken the day before, of the crowd round the Mansion House celebrating the relief of Ladysmith. The enterprising firm referred to was R. & J. Beck (Limited), and the photographs were taken with the Frena.

ON the occasion of last week's national rejoicing at the relief of Ladysmith a striking caligraphic notice occupied a prominent place in the shut-up establishment of Messrs. Hurman & Co., photographic dealers, St. Nicholas-buildings, Newcastle. Written in a very large hand was the following: "Ladysmith relieved. So are we" (then followed in smaller letters) "for the rest of the day."

RE EDWIN WESLEY ROBERTS, photographer, Cardiff.—The public examination of the above-named debtor took place at the Cardiff Bankruptcy Court, on Friday, before Mr. Registrar Cousins. Mr. J. T. Richards appeared for the trustee, and Mr. Lewis Morgan appeared for the debtor. Mr. Roberts said that he had been in business for seventeen years. In 1895 he made a composition with his creditors, chiefly on account of having to meet a bill of sale given to Messrs. Imberschein. He borrowed more money from Mr. S. Andrews, and soon afterwards found himself in difficulties again. Trying to keep up his repayments crippled him. Besides this, he had had an illness, and had incurred a considerable loss in law costs, as his other creditors had pressed him. It was true that his statement of affairs showed a deficit of 750*l.*; but, if his assets could be realised in the ordinary way of business, he could have met his creditors in full. When he borrowed the money from Mr. Andrews, the arrangement was that Mr. Andrews should take all the profits of the business. This was continued for some time, and then they agreed that he should pay 10*l.* a week, which he did for eighteen months. By Mr. Richards: "There was no agreement to that effect in writing. Since Mr. Andrews came into the business all the profits had gone to reduce his debts." "What do you mean by saying, 'Since Mr. Andrews came into the business?'" "It was agreed that the business should be formed into a company, and I was to receive two-thirds of the shares as my portion. But Mr. Andrews never carried out the agreement. He said that he must be paid off. I wish I had fled my petition then, because I was in a worse hole afterwards than I was before." "When was that?" "Last July." "And what was the capital?" "Five thousand pounds." "What price were you to be paid for the business?" "It never went further than registration. Mr. Andrews put his foot down, and the matter went no further." "How much money did you receive on deposit with applications for shares?" "Fifteen shillings." The examination was closed.

KODAK (LIMITED).—The Directors, in their annual report, state that the business was taken over on November 21, 1898, with the benefit of dividends on the shares of the Eastman Kodak Company as from October 1, 1898. The Company has also had the benefit of the European profits as from January 1, 1898, subject to the payment of certain dividends to the shareholders of the

Eastman Photographic Materials Company (Limited). After payment of these dividends, there remained from both sources a profit to the Company of 41,215*l.* 5*s.* 4*d.* As this formed part of the assets purchased, the Directors are advised that it is not available for dividend purposes. It has therefore been credited to capital account, and applied in reduction of the purchase price. The combined accounts show that the amount standing to the credit of profit and loss, being the total profits of the separate Companies for the period ending December 31, 1899, after deducting an amount written off for goodwill, is 345,778*l.* 9*s.* 6*d.* The separate profit and loss account of Kodak (Limited) exhibits a credit balance of 213,521*l.* 0*s.* 9*d.* In accordance with the wishes of the shareholders, informally expressed at the Statutory Meeting, interim dividends have been paid quarterly on both classes of shares. The full preference dividend has been paid, and interim dividends amounting to ten per cent. have been paid on the ordinary shares. The Directors now recommend the payment of a bonus of five per cent. on the ordinary shares, making for the year a total distribution of fifteen per cent. The following is the proposed application of the profits to December 31, 1899, namely: Dividend of six per cent. on the preference shares amounting to 39,111*l.* 12*s.* 7*d.*; dividend and bonus, equal to fifteen per cent., on the ordinary shares amounting to 150,000*l.*; surplus profit carried forward in Europe, 24,409*l.* 8*s.* 2*d.*; total, 213,521*l.* 0*s.* 9*d.* The surplus profits carried forward in America are 127,436*l.* 17*s.* 5*d.* The business shows satisfactory progress in all departments. New branches have been opened in Brussels, Vienna, and St. Petersburg, and the establishment of other branches is under consideration.

THE SANGER SHEPHERD PROCESS OF NATURAL COLOUR PHOTOGRAPHY.—Messrs. Sanger Shepherd & Co., of 5, 6, and 7, Gray's Inn-passage, Red Lion-street, Holborn, W.C., are issuing a pamphlet relating to their method of producing transparencies in natural colours, from which we make the following extracts: "The method of the preparation of the transparencies is very simple. The colour-record negatives of landscapes, portraits, still-life objects, microscopic sections, polariscopic objects, &c., are secured by means of a repeating back, which may be attached to any ordinary front-focussing camera. This repeating back is furnished with a set of measured three-colour filters, secured in a frame of the same size as the dark slide. The dark slide takes a plate 8×3½, and the three exposures are secured upon the same plate, a single movement of the dark slide changing both the plate and the colour filter. The impressions from the negatives are printed upon the specially prepared plates and films we supply, one being tinted with our staining solutions to a bluish-green colour (or *minus* red), another to a pink (or *minus* green), and the third to a yellow (or *minus* blue) colour. The three prints are then bound together in superposition to form the finished picture. The following are the prices of the necessary apparatus (it is presumed that the purchaser already possesses an ordinary quarter or half-plate front-focussing camera): No. 1 repeating back for attachment to any quarter or half-plate front-focussing camera, fitted with a set of Sanger Shepherd measured coloured filters for use with the Cadett rapid spectrum plate and one double dark slide, with best ebonite draw-out shutters, taking plates 8×3½ (10×8 plate cut in three), large enough for full-size lantern slides, allowing for the space taken out of ¾ inches square by the binding strips, 4*l.* 10*s.*; safe-light lantern, fitted with safe-light glasses for the rapid spectrum plate, 12*s.* 6*d.*; complete lantern-slide developing and printing outfit, containing all necessary apparatus, trays, special printing frames, clips, plates, films, solutions, and materials for developing the negatives, printing the separate sensation transparencies, and mounting, 4*l.* 4*s.*; total, 9*l.* 6*s.* 6*d.* Cost of materials for each set of three negatives and for each lantern slide: Set of three negatives, one Cadett rapid-spectrum plate, 8×3½, at 4*s.* per dozen, 4*d.*; developer, hypo, and varnish, 1*d.*; total, 5*d.* Lantern slides, one Cadett black-tone lantern plate, at 1*s.* per dozen, 1*d.*; one Sanger Shepherd special film for the pink and yellow prints, 6½×3½, at 4*s.* 3*d.* per dozen, 4½*d.*; sensitiser, staining solutions, varnish, cover glass, and binders, 2½*d.*; total, 8*d.*"

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
12.....	Bradford Photo. Society .....	Transparency Making. Frank Nicholson.
12.....	Glasgow and West of Scotland .....	{ Description of the Tella Camera, with Illustrations. Mr. Dunmore.
12.....	Isle of Thanet .....	Prize Slides.
12.....	Kingston-on-Thames .....	A Holiday Tour in Norway. John F. East.
12.....	Southampton .....	{ Demonstration: Bromide Printing. W. H. Trigg.
13.....	Birmingham Photo. Society .....	{ The Elan Valley, Site of the New Bir- mingham Waterworks Scheme. J. H. Pickard.
13.....	Hackney .....	{ Printing in Clouds. W. Rawlings.— Manipulating the Negative. S. C. Stean.
13.....	Leeds Photo. Society .....	Annual Lantern Exhibition of Members' Work.
13.....	Royal Photographic Society .....	{ The Illumination of Developing Rooms. Howard Farmer.
14.....	Borough Polytechnic .....	Paper by W. R. Stretton.
14.....	Croydon Camera Club .....	The Khaki Lantern Show and Enter- tainment.
14.....	Photographic Club .....	Members' Open Night.
14.....	Southsea .....	{ Demonstration of Film Photography. Secco Film Company.

15.....	Ashton-under-Lyne .....	Annual Meeting of Members.
15.....	Leigh .....	Portraiture. Harold Baker.
15.....	Liverpool Amateur .....	Demonstration: Czotype. Harry Wade.
15.....	London and Provincial .....	Paper by Ernest Human.
15.....	Oldham .....	Rambles in North Wales. W. Schofield.
16.....	Borough Polytechnic .....	Practical Evening: Enlarged Negatives.
16.....	Croydon Microscopical .....	{ Demonstration: Toning of Bromide Prints. A. P. Hoole.
16.....	West London .....	{ Lantern Meeting: Holiday Rambles. W. A. Brown.

## ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 6,—Lantern Meeting,—Mr. J. J. Vezey in the chair.

Mr. J. A. HODGES (the newly appointed Hon. Secretary of the Society) delivered a lantern lecture on

### SOME BEAUTY SPOTS OF BRITISH SCENERY,

which he illustrated by a large series of slides from his own negatives of views in England, Scotland, and Wales. Mr. Hodges is so well known as an expert in the making of lantern slides that it is needless to say that the photographs shown were of a uniformly high order of excellence. He explained that they did not profess to belong to that class which calls itself "artistic," but were, as he maintained lantern slides should always be, as sharp as the lens would make them, his main idea having been to convey, as truthfully as the means at his disposal would admit, a realistic impression of the scenery depicted. The first series of views were of the Western Highlands of Scotland, including Loch Lomond, Loch Katrine, the River Teith, Callander, and the Trossachs, the small but very beautiful Loch Achray, and some of the delightfully varied and picturesque scenery of Arran. These were followed by a set of pictures of North Wales, commencing with Llangollen, and then coming down to Dolgelly, and from thence to the incomparable estuary of the Mawddach, with Aberafnra Harbour, Tyraumawr, the precipitous shoulder of Cader Idris, and the Arthog marshes. Next, with Bettws-y-Coed as headquarters, the rivers Llugwy and Conway were illustrated, with the Fairy Glen and the Swallow Falls, the Lledr Valley and Pontypant, and several fine interiors of the old Elizabethan mansion called Plas Mawr. The first of the English views represented some of the most beautiful and interesting parts of Devon and Somerset, starting with the Guildhall and Cathedral at Exeter, and then going to Dartmouth, Chagford and Chudleigh in the south, and Dunster, Holnicote, Horner, Lynmouth, Rockford, and Clovelly in the north; and the concluding series depicted the scenery of the English Lake District—Furness Abbey, Amble-side, Thirlmere, Grasmere, Rydal Water, Windermere, Borrowdale, and Watwate. As usual at the Lantern Meetings at the Royal, there was a large audience, who evidently appreciated the beautiful views which Mr. Hodges had collected in our own country.

### COMING EVENTS.

March 13, Ordinary Meeting, "The Illumination of Developing Rooms," by Mr. Howard Farmer. March 20, Photo-mechanical Meeting, a demonstration of the Heliogravure Process, by Mr. Ignatz Herbst. March 27, Technical Meeting, "Some Developers Compared," by Mr. Alfred Watkins. April 3, "Slides Old and New" (Lantern Lecture), by Mr. F. P. Cembrano. During the month of March, and part of April, a collection of photographs, arranged by the National Photographic Record Association, will be exhibited at the Society's house, 66, Russell-square, the Exhibition being open daily, from ten to four o'clock.

## LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 1,—Mr. E. Human in the chair.

A member passed round some prints which he had toned with copper according to Mr. W. B. Ferguson's method. Some of the prints were upon ordinary bromide paper, and with these he had no difficulty, but one of the photographs, which was printed on Velox paper, remained quite unaltered until it was treated with a solution of bromide of potassium and transferred thence direct to the copper bath, when no further difficulty was encountered. Some discussion took place regarding the intensifying and reducing effects produced by different copper baths.

It was stated that Mr. John Sterry had shown that by Mr. Ferguson's method a negative was positively reduced, to all appearance intensified, that is to say, that, although visually the contrast was more marked, the images were thinner and printed quicker. If the ammonium carbonate form of the copper bath were used, there was a distinct intensification, and, by going further, and printing under green glass, a still farther degree of intensification was the result.

Mr. BECKETT, replying to an observation that continued washing of copper-toned prints took away much of the redness resulting from the use of the bath, said that he had not noticed anything of the kind. He expressed the hope that the subject brought forward by Mr. Ferguson's paper at the Royal Photographic Society would receive every attention by the members of the Association.

Richmond Camera Club.—On February 26, Mr. Smith, of the Platinotype Company, gave a demonstration of the process. Many very beautiful prints (some of which were from negatives lent by Mr. Sandell) were developed, and Mr. Smith showed the effect of mixing glycerine with the developer very effectively by developing some large prints supported on a tray by means of brushing the developer over them. He also showed the development of the sepia paper, which requires a hot bath; and the tone produced, as exemplified by some finished prints, was much admired. Mr. Cembrano, who was in the chair, moved a very hearty vote of thanks to Mr. Smith and the Platinotype Company, and took advantage of the opportunity to speak in very favourable terms of the process, which he described as one of the simplest and most satisfactory of them all.

Liverpool Amateur Photographic Association.—The general rejoicings militated greatly against the attendance, but those who were present had a thorough treat. The lecturer was Mr. J. W. Wade, Manchester, who took for his subject

### AN ALPINE BORDERLAND.

Mr. Wade's description of a tour through Belgium to the Lake of Lucerne was very fine, and his pictures were of the highest order. Many of the slides called forth enthusiastic applause, notably one or two done by the carbon process.

Longton and District Photographic Society.—March 1.—The President (Dr. Parkes) occupied the chair, and there was a good attendance of members.

The HON. TREASURER (Mr. S. Ashcroft) presented the accounts, which showed a balance of about 12% to the credit of the Society. The HON. SECRETARY (Mr. T. Mottershead) submitted the sixth annual report of the Committee, which stated that the past year had been the most eventful one in the Society's history. Satisfaction was expressed that the Society was now recognised by the Town Council as a valuable factor for good in the town by the granting of rooms in the Sutherland Institute in which to hold their meetings. The attendance at the meetings during the year had been fully maintained. A special feature in the proceedings was the presentation to Mr. Mottershead of a handsome marble timepiece, with bronze ornaments to match, subscribed by the members of the Society in recognition of his valuable services as Hon. Secretary. Mr. ASHCROFT said it had been unanimously felt that one who had devoted himself so heartily and so successfully towards the interests of the Society should receive some token of their appreciation of his services. Councillor C. S. MEIGH bore testimony to the ready aid which their Secretary was at all times willing to give to new beginners. The PRESIDENT made the formal presentation in terms of cordial congratulation, and Mr. MOTTERSHEAD, in expressing his acknowledgments, said it had been one of the greatest pleasures of his life to be of any service to the Society, and he should always value their handsome present, which would always be treasured by his family. The following officers were elected:—*President*: Dr. A. Parkes.—*Vice-Presidents*: Messrs. E. Hallam and W. T. Lucas.—*Hon. Vice-President*: Mr. E. Haigh, M.A., B.Sc., &c.—*Committee*: Messrs. A. W. Allin, W. Bates, G. V. Myatt, J. Bold, J. T. Mountford, S. Jackson, and C. S. Meigh.—*Auditor*: Mr. A. Shanton.—*Treasurer*: Mr. S. Ashcroft.—*Secretary*: Mr. Thomas Mottershead.

Newcastle-on-Tyne and Northern Counties Photographic Association. —At the last meeting of this Association Secco films were demonstrated, and a very favourable impression of the material was made upon the members present. When the English factory of the Company is completed and their operations fairly commenced, it is a certainty that the new film will have a host of advocates. Its development is the same as for ordinary plates with the slight difference of a short preliminary glycerine bath. After fixing and washing they are again placed in the same glycerine bath in company with a piece of support (supplied with the films) withdrawn and lightly squeegeed. After being allowed to dry, both the paper backing of the original film and the paper backing of the support are very easily stripped off, leaving the emulsion film protected on both sides by a special coating of Secco film, which renders the whole composite film perfectly waterproof. The finished film is beautifully flexible, having the feel of a piece of silk. Its strength and flexibility were shown in a remarkable manner by the demonstrator crumpling a large negative into a ball, after which he flattened it out again, and showed that it was not in the slightest degree injured. The film is so thin that it can be printed from either side without the slightest loss of definition, and a great point in its favour is that it is a thoroughly reliable cure for halation, not a trace of that trouble being visible in any of the numerous negatives shown, although several of them were of very difficult subjects.

#### FORTHCOMING EXHIBITIONS.

1900.	
March 9, 10 .....	South London Photographic Society. Hon. Secretary, Frank Goddard, Woodlands, Vanbrugh Hill, Blackheath, S.E.
„ 13, 14 .....	G.E.R. Mechanics Institution (Photographic Section). C. W. Harris, 294, Cam Hall-road, Leytonstone, E.
„ 26 .....	Twentieth Century International, Birmingham. Walter D. Welford, 19, Southampton-buildings, Chancery-lane, London, W.C.
„ 26-31 .....	Photographic Society of Ireland. W. F. Cooper, 35, Dawson-street, Dublin.
April 3-7 .....	Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

#### Patent News.

The following applications for Patents were made between February 19 and February 24, 1900:—

- DAYLIGHT CARTRIDGES.—No. 3299. "Improvements in Daylight-loading Photographic Film Rolls." J. E. THORNTON.
- WASHING MACHINES.—No. 3382. "Improved Machine for Washing Photographic Negatives." Communicated by J. H. Smith. Complete specification. R. W. JAMES.
- PROJECTION APPARATUS.—No. 3402. "Improved Means for the Projection of Cinematographic Films upon a Transparent Screen." A. DALLIET.
- SHUTTERS.—No. 3476. "Improvements in Photographic Roller-blind Shutters." J. E. THORNTON.
- BACKING PLATES.—No. 3605. "Improved Protecting Paint for Photographic Plates, Films, and the like, for Preventing the Formation of Halos ('Solarisation')." P. PLAGWITZ and F. FREUND.

## Correspondence.

\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*\* We do not undertake responsibility for the opinions expressed by our correspondents.

### TYLAR'S "TIT-BIT" HANDICAP FOR THE A.M.B. FUND.

(The twelve "Tit-Bit" Cameras realised over 30l.)

To the EDITORS.

GENTLEMEN,—I have great pleasure in informing those people who so kindly subscribed to the above fund that 605 tickets have been sold, hence I am able to send out to Dr. Hall-Edwards photographic appliances to the value of that amount.

The following gentlemen have acted on the Committee to see that the drawing was carried through in a proper manner:—

Dr. Hill Norris, J.P., President of the Aston Photographic Society.

F. Pilditch, Esq., Vice-President

Councillor Sydney Fisher, J. W. Salt, Esq., P. H. Morris, Esq.

This took place at my offices, 41, High-street, Aston, Birmingham, in the afternoon of March 1, 1900, the winning numbers being drawn by my youngest son, aged five.

The following are the fortunate recipients of the twelve "Tit-Bit" Hand Cameras, which have been duly posted to them:—

No. 64. Mr. G. W. Lindsay, 57, Crofton-road, London, S.E.

72. Mr. G. F. Jones, Quarry Bank, Malton, Yorkshire.

75. Mrs. Knight, Nine Ashes, Blackmoor Green.

83. Mr. Beilby, Ivy House, Roundhay, Leeds.

104. Mr. Miller, 19, Richmond-place, Brighton.

222. Mr. Cross, Bootmaker, Flamborough, Bridlington.

272. Mr. H. Nicholson, photographer, West-street, Fleetwood.

278. Mr. Baird, Broughty Ferry, N.B.

430. Nurse Barnes, Samaritan's House, Bow-lane, Durham.

502. Mr. H. J. Steevens, 13, Gillies-st., Kentish Town, London.

540. Mr. Fairbank, Clydesdale House, Hessle-road, Hull.

590. Mr. J. S. Daniels, Fern Cottage, Lightfield, Stroud, Glos.

I shall send out to Dr. Hall-Edwards the most suitable requisites I can think of, and which, I am sure, will be gratefully acknowledged in due course.

I sincerely thank the photographic friends for the hearty manner in which they have co-operated with me in this object.

I also thank Mr. Ladbroke, printer, High-street, Bordesley, Birmingham, for supplying the printed matter free of cost, and THE BRITISH JOURNAL OF PHOTOGRAPHY, *Photo News*, *Photography*, *Amateur Photographer*, and the *Optician*, for giving publicity to my offer.

I also tender my thanks to Messrs. Lennon & Co., 75, Leadenhall-street, London, who have undertaken to deliver the goods free of charge to Dr. Hall-Edwards; and to Mr. Kent, optician, 35 High-street, Staines, London, W., who has promised to send me twelve pairs of field glasses to be sent out for free distribution as Dr. Hall-Edwards deems fit.

In conclusion, I would mention that I am having a plate engraved for a beautiful stereo camera, among the articles sent out, with an inscription commemorating the event as presented on behalf of over 600 photographers.—I am, yours, &c.,

W. TYLAR.

### NEGATIVES BY POST.

To the EDITORS.

GENTLEMEN,—As you published a letter respecting enclosed, in which the writer suggested that some prints were never sent, I beg, in justification to myself, to enclose a notice just received from the Post Office.

Your remark as to there being twenty photographers here was hardly reasonable. I am the only trade photographer of this town advertising in JOURNAL, and, as your correspondent mentioned negatives and prints, it was clear enough he referred to a trade photographer, hence my theory that those who troubled to notice the letter would associate me with it; indeed, it was the fact that I heard of it from two or three quarters that prompted me to reply. Of course, the matter is all over now, I merely send this because I don't wish to have any misunderstanding on matters of this kind with the editor of the principal journal.

I can assure you the lot of a trade enlarger is not altogether a happy one. I have no end of work thrown upon my hands by persons "who require work urgently, and will forward cash on receipt of invoice," on the chance of getting it for nothing. I generally hold back negatives of these gentry, and am consequently frequently threatened with "letters to the Editor."—I am, yours, &c.,

HENRY WARD.

Leicester.

[COPY.]

General Post Office, London, March 2, 1900.

SIR,—I am directed by the Postmaster General to inform you that the photo missing from the parcel addressed to Mr. F. G. Willatt, referred to in your application of the 8th ult., reached the Returned Letter Office, having been found loose in the post, and has since been forwarded to its destination.

I am Sir, your obedient Servant,

G. H. MURRAY, Secretary.

COLOUR PHOTOGRAPHY ON LANTERN SLIDES.

To the EDITORS.

GENTLEMEN,—I send three lantern slides, as I proposed. They are scenes off the beaten track in the Rocky Mountains and British Columbia. I believe them to be the first specimens of colour photography (date 1889) fairly produced. Having, as I thought at the time, overcome the difficulty, I gave the work up for other subjects.—I am, yours, &c.  
West Lodge, Galway, March 2, 1900. W. R. O'HARA (Lieut.-Col.).

[Colonel O'Hara sends us three lantern slides. Two of the subjects are river and mountain views, with trees in the foreground and middle-distance; in the third, there are trees in the foreground and mountains in the distance. In the first two, the trees and their reflections show in shades of green, and the clouds of one are faintly blue; in the third the trees are coloured green, and there is a bluish tint in the other parts of the transparency. We have no particulars as to how these effects have been produced; they present the appearance of chemical agency having been at work. The green and blue colours are in no way comparable to the brilliant spectrum rays seen in the physical colour transparencies of Wood, Ives, and Joly, or the interference positive images of Lippmann. Will Colonel O'Hara oblige us with details as to how the tints in his lantern slides were produced? We return the transparencies with thanks.—Eds.]

BACKING PLATES.

To the EDITORS.

GENTLEMEN,—As the result of experiment, I have come to the conclusion that one of the best things to use as a backing for plates to prevent halation is the dull red paper, often used in the packing of plates, &c., applied with paste, and brought into optical contact by means of a roller squeegee; it is cheap, not messy, easily applied and easily removed; in fact, if, after pouring on the developer, the plate is lifted in the dish to allow the liquid to run under it, the paper will be ready to strip off by the time the development is well advanced. As a test I enclose print from the negative of the chancel of our church taken on a special rapid plate thus backed, and you will see that, while sufficient exposure was given to bring out the outlines of the dark oak roof timbers, the detail of the east window, two-thirds of which is clear glass, was thoroughly protected. What do you think of it? It is necessary to thoroughly damp the paper before applying the paste, otherwise the paper may cockle after squeegeeing, and optical contact be lost.—I am, yours, &c., T. STOKOE.  
Clare, Suffolk, March 1, 1900.

[There is no halation apparent in the print kindly sent us by Mr. Stokoe.—Eds.]

APATHY OF BRITISH HAND-CAMERA MANUFACTURERS.

To the EDITORS.

GENTLEMEN,—With reference to your correspondent's letter in the last issue of your JOURNAL, in which he complains of the difficulty of obtaining from English camera manufacturers a reflect camera such as he describes, I may say that I have had a somewhat similar experience. Like "A. G. B.," I have been desirous of obtaining a reflect hand camera of the box pattern. I have approached several of the leading camera manufacturers with the following specification: 5 x 4 camera, box pattern, reflect system, reversing back, full size finder (giving the picture both ways of the plate), focussing arrangement, camera to be built to take a 7½-inch focus lens, and to be fitted with a really efficient shutter (focal plane preferably), capable of giving exposures as long as one-tenth of a second.

In every instance I was informed that they (the camera manufacturers) could not undertake to build such a camera. A camera of this description for snap-shot work, pure and simple, would, in my opinion, be an ideal one. Apparently camera makers think otherwise.

It may interest "A. G. B." to know that a reflect hand camera has recently been placed on the market, having a bellows extension of fourteen inches, and fitted with a really good focal plane shutter; but as the size of this camera is very little less than a twin lens, and as the price is somewhat excessive (15l. 15s. for 5 x 4 camera and three D.D. slides, without lens), I doubt whether it would suit him.

Like "A. G. B.," I have come to the conclusion that I shall have to make known my requirements to an American firm, whose enterprise and reasonable charges I have taken advantage of on previous occasions.—I am, yours, &c., R. N. R.  
March 2, 1900.

ORTOL.

To the EDITORS.

GENTLEMEN,—A few months back an article appeared in the JOURNAL, by Mr. Welford, advocating the new developer ortol, and at intervals since I have noticed letters (some of them more or less frivolous) for and

against this reagent, the last one from a correspondent in India, appearing in your issue of the 2nd inst. Will you kindly grant me space to give my experiences of ortol? I first tried the stuff in Ceylon, a place that will try anything. On opening the bottle I found the contents perfectly good, nothing slate-coloured or sooty-grey about it. There was no difficulty in making up a solution as per instructions. No scum or sediment, but a straw-coloured solution, same as I have since got here in England. The negatives developed with that first solution printed remarkably well. I brought it under the notice of some expert amateurs, and I know that, at least in a few cases, it was adopted in preference to anything else, not excepting pyro, one of the best of them declaring that "he was delighted to have at last found a developer giving results equal to pyro without pyro's drawbacks."

I have given it a fresh trial lately, and I must say I consider it in advance of any of the other new (compared with pyro) developers. The formula is simple, and prints from negatives made by it are excellent. Its action is more like that of a properly constituted pyro developer than any of the others. The image appears in a reasonable time, and is completed in a reasonable time, and plate after plate can be developed in the same solution as long as there is enough to cover, and the last plate is just as good as the first—no hungry shadows, no chalky high lights. I advise the use of the formula, given with the bottle, omitting the hypo. Best results seem obtainable with the minimum of bromide, and the temperature should be constant.

I am a professional, and, of course, pyro and (I may add) ammonia is my sheet anchor; not from choice, but because nothing else is quite as good; but I am not silly enough to ignore another good thing when I find it, and ortol is a good thing.—I am, yours, &c., LAUKA.  
London, March 5, 1900.

Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

J. Robb, 164, Springfield-road, Glasgow.—Three photographs of Ruchill Hospital, Glasgow.

P. H.—You probably mean a camera lucida. Inquire of a dealer in optical instruments.

R. C. TURNER.—We would suggest application to Messrs. Newton & Co., 3, Fleet-street, or Messrs. J. H. Steward, Strand, London.

LT. MOUNTED RIFLES (India).—We are very much obliged to you for your letter, but it does not possess any photographic interest, so that we cannot publish it. Besides, you omitted your name and address, an infringement of a well-recognised rule.

DEVELOPERS.—T. S. M. W. says: "1. Which do you consider the best developer for snap-shots, not counting pyro or metol? 2. Does the use of ortol occasion any irritation to the skin such as is caused by metol?"—In reply: 1. Ortol would probably be considered by many to have the preference. 2. We have not heard of any such cases.

RESIDUES.—W. CRAMER asks for a simple method of getting the silver out of the hypo bath. He says he has tried zinc, and that does not work well in his hands. The best way is to precipitate the silver as sulphide by the addition of sulphide of potassium—liver of sulphur as it is sometimes called. Add a solution of that till all the silver is thrown down.

AN APPRENTICESHIP QUESTION.—ABBEY asks: "Is there any law by which a master can stop an apprentice from selling prints from an enlarged negative made from his own original?"—In reply: We know of no such law; but, without seeing the indentures, we cannot say if the apprentice in this particular case is permitted to sell the prints. Probably not. We do not reply through the post.

COPYRIGHT.—T. E. I. asks: "If I copyright a whole-plate view, will the same photograph reproduced on a post card (smaller of course) be protected? or, if I copyright the reproduction, will the whole-plate be protected?"—In reply: In the first case, the reproduction will enjoy the same protection as the original; but we imagine the same conditions would not hold in the second, inasmuch as the Act stipulates for the registration of the original photograph.

SILVER STAINS.—JAKEMAN & CARVER write: "Can you inform us how to treat silver stains on a negative, produced by getting wet while printing?"—In reply: Many remedies have been suggested. To treat the negative with alcoholic solution of iodine followed by solution of cyanide of potassium is an old method. The cyanide solution is sometimes used alone. Messrs. Marion, of Soho-square, sell a mixture, by Mr. H. N. King, which has been found to answer well in bad cases of stains.

**DISCOLOURED NITRATE OF SILVER.**—A. M'INTIRE writes: "I have five or six ounces of nitrate of silver that has laid (in a bottle) in a cupboard for several years. The crystals are a dark grey on the outside, though they are white inside when broken. Will the nitrate in this state do for sensitising albumen paper? if not, can you kindly tell me how to purify it?"—The nitrate will do quite well as it is. Simply dissolve it in water and filter. It will be found quite as good as if just crystallised.

**COPYING SAME SIZE.**—T. A. C. says: "I want to copy some photographs the same size as they are, but I cannot get them sharp. I can get them sharp enough when they are about two-thirds the size, but, when I put the camera nearer to get them the full size, I cannot get the image sharp. Why is that?"—Simply because the camera has not a sufficiently long extension. You must either use a shorter-focus lens or a camera with a longer extension. The camera must be double the focal length of the lens to copy same size.

**ALBUMEN SUBSTRATUM.**—S. BOWERS says: "How is the albumen substratum used in the collodion process made? and will it keep good for, say, a week or two, or must it be used freshly made?"—Take the white of an egg and, after separating the germ, put it into a Winchester quart bottle half filled with water. Add a few drops of ammonia, and well shake for a few minutes, then filter through blotting-paper. With the ammonia it will keep good for two or three weeks. After keeping for a time it may require to be refiltered.

**STEAMING OF SHOW-CASE.**—W. R. & G. write: "Can you tell us how to prevent the steaming of our show-cases? When they get warm with the sun the inside of the glass gets covered with steam and the pictures can hardly be seen."—This is due to moisture within the case, and, when it gets heated, it condenses as dew on the glass. It may be obviated by having ventilating holes in the case, so that the moisture can escape. Another way is to make the case completely air-tight, taking care, before sealing it up, that the mounts and pictures are thoroughly dry.

**SALE OF COPYRIGHT NEGATIVES.**—S. W. says: "I am in treaty for the purchase of a business with, of course, the negatives, a considerable number of which are copyright, indeed they are an important item in the purchase. Will the copyright in these be legally mine, supposing I were to pay a distinct price for them, and take a separate receipt for them?"—No. To acquire a legal copyright in them, the copyright in each negative must be separately assigned to you. If that is not done, the copyright still remains with the author of the work, though the negatives will be your property.

**WEIGHT OF NITRATE OF SILVER.**—CHEATED writes: "I bought 4 ounces of nitrate of silver, and used 4 drachms of it for a bath, then I weighed out another 4 drachms, and so on, and, after weighing the seventh lot, I found there was only a little more than a drachm left, so that I was defrauded out of nearly 3 drachms in the 4 ounces, a considerable item with such a costly thing as nitrate of silver. Ought not this sort of thing to be exposed?"—Hold, good friend, you have not been defrauded at all. You are, perhaps, not aware that nitrate of silver, like other things, is sold by avoirdupois weight, 437½ grains to the ounce, and you have been using it by apothecary's weight, 480 grains to the ounce.

**STUDIO WORK.—ARTIFICIAL LIGHTING** says: "I am thinking of taking a private house as a photographic business, but cannot get plans passed for erecting a studio. Now, as this is the only house available, and in an excellent position for the purpose, am anxious to see if I cannot use a room for studio (there is one suitable) with the means of artificial lighting. What could you recommend for lighting purposes, no light to speak of from window and no electricity laid on? Would the Platinotype Company's lamp answer my purposes for groups," &c. ?—In reply: The lamp named would answer our correspondent's purpose. It is worked by means of a battery. See the description of it which we gave on February 9.

**STUDIO-BUILDING.**—P. R. O. says, "Will you kindly express your opinion of the design and size of the enclosed sketches of studio I propose building? The sketches are not to scale, but I have marked the dimensions on them, which I hope you will be able to make out. The studio will be for professional work. You see, I only propose to make it twenty-five feet long, but I can get it thirty feet if you think it advisable, though I should like to save the extra cost, unless there would be a corresponding advantage."—The design of the studio could not be well improved upon. We should, however, recommend you to have the thirty feet; the extra length will be a great convenience at times, as in taking groups. It will also enable lenses of longer foci to be employed, so that more pleasing perspective in the picture will be obtained.

**COLOUR PHOTOGRAPHY.**—INQUISITIVE writes: "I take deep interest in tri-colour photography, and I also read all matters of your JOURNAL concerning same. In THE LANTERN RECORD of your last number, March 2, I see Captain Lascelles Davidson's and Colonel Osborne Pollock's, three-colour cameras are patented, Nos. 3560 and 14,364, and I make free to put you one question respecting these inventions. When three-colour negatives are taken with these cameras and positives printed therefrom, how can it be managed to have perfect superposition or register of the three images, as the angles from which every one of them is taken are slightly different? It is undoubtedly very desirable to have simultaneous exposure for red, blue, and green rays, so as to shorten the time; but this should be done only for as much as it should not be of any damage to the image; and, doubtless, the inventors have found a way to proceed."—In reply: We fear that neither of the cameras named would be of the greatest advantage in practical three-colour work, for the reason given by our correspondent, viz., that exact superposition of the three images would not be obtained. It is conceivable that the patentees overlooked this point.

**ENLARGING ON VELOX PAPER.**—B. PIPER writes: "Is it possible to make enlargements on Velox paper, as I like the colour it yields better than the ordinary bromide. I have an enlarging lantern with good three-wick lamp. I have tried, first with ten minutes' exposure then half an hour, and, last night, with three-quarters of an hour exposure, but with no success."—We are not surprised, as the paper is too slow for enlarging upon. When it is considered that the paper is sufficiently insensitive to be manipulated in ordinary gaslight, it will be obvious that it is quite unsuited for enlarging upon—with the three-wick paraffin light.

**BACKGROUNDS, &C.**—S. A. S. would like to know the cheapest and most simple method of making and painting a studio background, and what materials to use, also how to fix P.O.P. paper on opaline glasses.—We presume a plain background is meant. The simplest way to make that is to stain unbleached sheeting on a wooden frame, and then give it a good coating of Young's patent size, to be had at the oilshops, and allow to dry. Next mix together whiting, drop black, and water to the tint desired, and then add, hot, sufficient of the size to form a thin, tremulous jelly when cold. Apply with a whitewash brush, cold, working the colour evenly all over. 2. Clean the glass thoroughly, and, when the prints are taken out of the washing water, squeeze them on to the plates. The prints should not be alumed.

**CAMERA, VIGNETTES, &C.**—HARTLEPOOL says: "I have had two cabinet photographs sent me that were taken in America. They are of ladies taken in evening dress in front of darkish background. 1. From the bust it goes direct into background, and is, what I think, termed a camera vignette. I am experimenting, but, if you can give me a useful hint, would be extremely obliged. 2. I do a fair amount of X-ray work, and, being deeply interested in my work, I like to keep up to date. There is, I think, a Röntgen Society. What to do to become a member, please?"—1. Without seeing an example we cannot definitely say how it was produced. Cannot you send us one? Vignettes can be made in the camera by placing a black mask, with a serrated opening, some distance in front of the lens, keeping it moving backward and forward during the exposure, so as to soften the effect. You will then get the figure vignettted into clear glass. 2. Write to the Hon. Secretary of the Society, 12, Sinclair Gardens, West Kensington Park, W.

**STUDIO-BUILDING.**—EX UNO DISCE OMNES says: "May I trouble you with the following questions respecting a studio without any slanting skylight at all, as first proposed, I think, by Mr. H. P. Robinson? My present studio has a direct south light and comparatively flat roof, which roof I wish to alter to the enclosed plan, should it meet with your approval at all. First, Do you think the height would be sufficient for top light, taking into consideration reflection from the roof? second, and the length of glass sufficient to light the shadow side enough, as ten feet wide does not allow of diagonally working. May I say that I am not devoid of the knowledge of lighting in some degree, and the blinds being upright would be far more manageable than at present?"—We should prefer, ourselves, to have some slope to the light, say to one-third of the width of the studio. The length of the glass will be ample to enable the shadow side of sitter to be illumined. However, the studio, as proposed, will enable excellent portraits to be secured with a little skill on the part of the artist.

**SPOTS ON PRINTS.**—COLLO says: "I would feel much obliged if you will give me your opinion as to the cause of the spots on the enclosed prints; they have made their appearance after the prints have been mounted a week. I have also had some platinum toned go the same way. The mounts are supposed to be faced with Whatman's paper; what is your opinion? I may add that I have been working this same brand of paper for years, and have never had any trouble whatever; and these have been produced in my ordinary way of working. Thanking you in anticipation."—In reply: The mounts appear to be perfectly pure, and the spots only show on the surface of the image. Although, apparently, so simple, nothing could be more difficult to answer than such a question. We can only say that the spots are, in all probability, caused by the presence in the washing, toning, or fixing solutions of some chemical body which had no business there. The best advice we can give our correspondent is to make up fresh solutions, and see that all his operations are conducted in the cleanliest surroundings, and the spots, in all probability, will not recur.

**SATURATORS.**—A WEST-COUNTRY LANTERNIST writes: "For some time past I have been dissatisfied with the ordinary blow-through jet for lantern work, and am anxious to have the advice of friendly experts as to the best thing to obtain for use in this far end of the country. The lime-light is simple enough when near the town gas and a cylinder of compressed oxygen; but, when away from gas mains and a good light is wanted for lighting up tableaux, &c., then the difficulty begins. The two gases under pressure is not always convenient, besides being expensive. I have not looked with favour upon ether saturators, but now I am inclined to try them. Are they safe? What kind would you recommend? What is the best kind of jet to use with them? Is there any gain in light over the blow-through or mixed jet?"—In reply: Saturators are perfectly safe. In his excellent book on optical projection, Mr. Andrew Pringle remarks: "Of late years, very much more attention has been turned to saturators, with the result that perfect control of action, absolute safety, and an efficiency at least equal to mixed gases under the best conditions, has been attained." The Pendant saturator, manufactured by Messrs. Willway & Sons, Bristol, works outside the lantern, can be used with any mixing jet, or with Gwyer's jet, manufactured by the same firm. Our correspondent might find this saturator meet his requirements.

### EX CATHEDRÀ.

IN the *Daily Chronicle* of last Monday an article by Mr. G. Herbert Thring (Secretary of the Society of Authors) discussed the principal provisions of Lord Monkswell's Literary Copyright Bill, which is shortly to come before the House of Lords. With the exception of one clause relating to registration ("a most unsatisfactory method of obtaining copyright," as Mr. Thring characterises it) our authority is in favour of the proposed Bill. He says, in fact, that it deserves the support of all interested directly or indirectly in copyright property. It increases that property to its owner, it gives larger powers of dealing with it, and puts into one comprehensive Bill what is at present contained in disjointed and isolated Acts—Acts that in many points won't read with one another, whose draughting is often incomprehensible, whose language is involved. All the existing difficulties are here cleared away, and, though perhaps the Bill does not go far enough, yet as far as it goes it deals with the subject with method, clearness, and regularity. It has the support of the Incorporated Society of Authors and of the publishers. It only remains for it to obtain that of the House of Commons.

MR. THRING is the representative of one of the two societies the Copyright Association and the Society of Authors, which prepared copyright bills two or three years ago, but withdrew them in favour of one drawn up by that eminent Parliamentary lawyer, Lord Thring. It is the latter Bill of which Lord Monkswell has also charge, and that has elicited such high and almost unqualified praise from Mr. Thring. The contrast between the attitude of the literary men towards the Copyright Bill affecting their interests, and that of photographers towards the Scrutton-Bale-Royal-Academy attack on photographic copyright is wonderfully instructive. By the hand of Mr. Thring, their representative, the authors signify their approval of a measure which that gentleman declares "clears away all existing difficulties" in literary copyright. Vast interests, commercial as well as purely literary and journalistic, are touched by the Bill, which appears to have been so admirably cast that it has provoked little or no opposition from those on whose behalf it is presented to Parliament. Perhaps this need not be greatly wondered at, seeing that societies representative of literary men were consulted in the preparation of the Bill, the chief provisions of which were not jealously concealed from those most affected by them.

\* \* \*

FAR different stands the case with the publishers and painters who have united to attack photographic copyright. Not a single photographer was consulted in the drawing up of the notorious St. John's Wood Bill of spoliation and degradation. Throughout the length and breadth of the land not one person directly interested in photography has been found to give that measure a word of support. Last year, before the Select Committee, voluminous evidence was tendered against it; at the Royal Photographic Society, the Copyright Union, and many other meetings, the Bill has been strongly attacked and criticised; and there is absolutely no one in a position officially analogous to that occupied by Mr. Herbert Thring at the Authors' Society, to come forward and say a word in favour of the photographic clauses of Lord Monkswell's Artistic Copyright Bill. Yet, in face of the stern and unflinching opposition of those most affected by that measure, Mr. Bale, Mr. Scrutton, Mr. John Leighton, Mr. Alfred East, and other friends of the painters and sculptors, take up an evening at the Society of

Arts, calmly pooh-poohing the natural objections of photographers to having their copyright interests disturbed by a handful of publishers and painters.

\* \* \*

We trust that, when the LaBelleSauvage-cum-St. John's Wood Bill for menacing photographic copyright interests comes before Parliament, it will not escape the notice of some friends of photography in both Houses. We are sure that, if he is in his place in the Lords, Lord Crawford, with his keen sympathy for the bread-and-butter side of photography, will not allow the Bill to pass without pointing out the harm it proposes to inflict upon a none too prosperous profession. In the House of Commons Sir J. Benjamin Stone would find at hand a splendid opportunity for manifesting his keen interest in photography by opposing those portions of the Bill which attacked photographic copyright. Mr. Scrutton, at the Society of Arts last month, said the only people satisfied with the Bill were the Royal Academy and the painters and sculptors. The learned gentleman added: "It had to go before a tribunal of country gentlemen . . . and he feared it would be difficult to get it in its present form through such a tribunal." We hope that Mr. Scrutton's fears will be more than realised, and that the Bill, in its present form, will be rejected. If Sir Benjamin Stone, or some other photographic Member of either House, will lend a hand to that end, we promise him the gratitude of all photographers.

\* \* \*

PROFESSOR KENNEDY, who presided at a lantern lecture on "Round about the Matterhorn," given by Mr. Henry Speyer, at the Camera Club, in November last, is reported in the March number of that excellent institution's *Journal*, to have given utterance to the following remarks at the expense of some of our contemporaries and ourselves. He said that those who studied photographic weekly literature were aware that there was one pervading idea among the gentlemen who catered for them every Friday—namely, that it was impossible to photograph a cloud and anything else at the same time and on the same plate. He would ask the gentlemen who wrote in that peculiarly irritating manner to look at Mr. Speyer's slides, from which they would see that the extreme high lights in the clouds and in the snow could be included in the same negative with rocks which were in deep shadow, but which were at the same time full of detail. The fact of the matter was, that the people who insisted that this could not be done either did not know how to do it—which was quite possible—or, more probably, would not take the amount of pains that Mr. Speyer had taken.

\* \* \*

As we are among those who cater for photographic readers every Friday, the remarks of Professor Kennedy demand on our part a word of rejoinder. It is almost needless for us to say that we have never taught the absurd doctrine that it is "impossible to photograph a cloud and anything else at the same time and on the same plate." The inclusion of cloud and landscape in the one negative is a perfectly practicable matter in most cases, and there is no commoner remark amongst the many landscape photographers of our acquaintance than that "the clouds are in the negative" of such-and-such a view. The use of colour-sensitised plates and a light filter makes cloud photography of this kind a matter of the greatest ease and certainty—but it is remarkable to note how

successfully such work may often be accomplished on ordinary plates, as Mr. Speyer's beautiful photographs amply prove. In protesting against Professor Kennedy's sweeping remarks, we also consider ourselves justified in expressing surprise that those gentlemen who are responsible for the editorial control of the *Camera Club Journal* should have permitted that publication to be made the vehicle of such strictures.

\* \* \*

We have received two illustrated pamphlets dealing with the Illinois College of Photography at Effingham, Ill. One of them gives a view of the College, which is said to be the finest photographic building in the world. It appears to be a comfortably sized mansion, and the principal is Mr. L. H. Bissell, whose efforts to establish a college of photography have secured the unstinted recognition of the local press. Mr. Bissell gave 50,000 dollars for his mansion, and this is described as "the biggest real estate deal in years." The second of the pamphlets before us is the prospectus of the Illinois College of Photography, of which the following constitute the "officers and faculty:" L. H. Bissell, President, Department of Practical Business Methods of Photography; John W. Krauth, Superintendent, Department of Carbon and Platinotype; Ruby Winston Bissell, Department of Artistic Retouching; Felix A. Raymer, Demonstrator in Department of Lighting, Posing, Composition, and Process Work; John A. Mumper, Department of Retouching and Dark-room Work; Clara Weisman, Department of Artistic Retouching, Modelling, and Etching; Joseph H. Hickman, Department of Printing, Toning, and Finishing; Dr. Henry Eversman, Treasurer; Aurora L. Buckner, Secretary.

\* \* \*

THERE are portraits of the professorial staff and views of the reception room, parlour, retouching rooms, &c., in the prospectus. The college has a decidedly professional aspect, and its main object is obviously to impart to would-be professional photographers sufficient knowledge to enable them to successfully conduct a portrait business. The prospectus tells the inquirer that when a picture is taken with the camera it is made upon a glass plate, which, after development, shows the object in shades of black and white inversely. "This plate is called the negative, in which all little imperfections of the skin, together with the shadows, wrinkles, and facial blemishes, are necessarily exaggerated, and must be overcome by hand work in order to produce a correct and pleasing picture. It is to improve the picture by removing and softening these blemishes that the plate is sent to the "retoucher," who works upon the negative itself with fine pencils. The great secret why one photographer's work is better than that of another lies in the fact that he excels in posing and lighting. The photographer who has picked up his business in the ordinary manner does this work indifferently because he has not learned the best and most modern methods. To become a good workman in this requires careful drilling by expert instructors. Photography possesses an educational as well as a recreative value, since some knowledge of chemistry, physics, and the principles of art is necessarily acquired by practical work with the camera, aside from the training in accuracy and observation, which are not to be undervalued."

\* \* \*

THE vexed question of articling pupils in photography, which recently received some attention in our pages, comes in for

recognition in the Illinois prospectus, which points out that it is a difficult matter to get a first-class photographer to take an apprentice. "Good photographers have all the work they can attend to, and have no time to devote to a pupil who, in order to get into a studio, is obliged to take a place in some second or third-rate institution. Here he is expected to do the studio drudgery and perform all the odd jobs about the place. While this is possible for a young man, it is altogether impracticable for a lady to take a position under these conditions and derive any benefit therefrom. Occasionally an opportunity is offered to learn something of the real business, but it is fragmentary and unsatisfactory. If the photographer is a good one, he has all he can attend to, and, from want of time, can give only an occasional suggestion, thus allowing the student to fall into errors, serious in their results. In a year or two, such an apprentice, if he has any natural aptitude, may acquire enough of the business to get employment with some third-rate photographer. The advantage over this of a genuine course of study is apparent. Our instructors are secured with especial reference to their ability to *teach* the art, and are continually guiding the progress of the student. The smallest detail of the student's work is watched, and all necessary hints and helps afforded, thus fitting him in the shortest possible time to do the best of work."

\* \* \*

THE College is non-residential. The prospectus says that a student of ordinary taste, who will attend strictly to his study, can become proficient in from three to five months—rather a short time in which to turn out a skilled portrait photographer, we may point out. The College teaches, and frequent class demonstrations are given on, opals, plain transparencies, coloured transparencies, lantern slides, celluloids, collodion, gelatine and bromide papers, platinotype paper, carbon printing, X-rays, flashlight, posing, lighting and composition, copying, enlarging, retouching, dark-room work, landscape and architectural work, &c. Frequent demonstrations are also given by the leading dry-plate and paper demonstrators of the country. Four methods of retouching are taught—English, French, American, and German. It will be observed that the students obtain a great deal for their money, namely, a hundred dollars for the complete course. On the whole, we should judge that, while the Illinois College of Photography is not the place whence we should expect to receive a crowd of Crookes, Harold Bakers, Walter Barnetts, Craig Annans, Hollyers, Demachys, Hollingers, Dudley Hoyts, and other princes of pictorial photography, yet fairly good workmen may be turned out there, thanks to Mr. Bissell, his staff of lady and gentlemen professors, and his very full curriculum.

#### VIGNETTES WITH BLACK MARGINS.

SEVERAL correspondents have recently made reference to what is, to them, a novel style in portraiture that is being produced in America, and also in Australia, which is very effective indeed. While expressing their admiration of the pictures, they have desired information as to how they are produced. The portraits in question, it may be mentioned, are vignettes, chiefly head and bust, taken with a tolerably dark background, and then, instead of being vignettted into a white margin, they are vignettted into a black or very dark one. The effect of this is to give the lights of the picture extreme brilliancy, and

cause the portrait to stand out prominently from the background. Portraits of ladies in evening dress or in light drapery possess a striking brilliancy, very different from what they have in the usual style of vignette; so they have when the face is lighted in the so-called "Rembrandt style."

Those correspondents who have written to us on the subject have evidently looked upon them as quite a new style of portrait. It is not so, however, but a very old one revived. It was, if we mistake not, first introduced by Bergamasco, of St. Petersburg, nearly thirty years ago, about 1872 or 1873. In the Society's Exhibition of the latter year Bergamasco had a very fine show of these pictures, most of them of very large size for that time—18 × 15 or larger—head and bust framed up close, without mounts. They were very excellent, and attracted considerable attention and favourable comments at the time. Although they did so, no one here seemed to have made a special feature of them. Possibly that may to an extent be accounted for by the fact that the pictures involved some little extra trouble in their production, and that photographers then were pretty fully occupied in taking the "usual thing." Be that as it may, very few pictures in that style were done commercially in this country, then or since.

Now as to the means of production, and that is what some correspondents want information upon. They may be done in different ways. They may be done by double printing or by taking the negatives vignettted in the first instance. The latter is the simplest way in the end, and then the negatives can be printed from with no more trouble than printing "full-out" pictures from ordinary negatives in the usual manner. A vignettted negative may be taken in this way. In the camera a diaphragm, or mask, with a serrated opening of a suitable size and shape, is placed between the lens and the plate, at such a distance—to be found by experiment—that the image is seen softly vignettted on the focussing screen. The box form of camera is more convenient for the purpose than one of the bellows type, as the mask in that can be the more conveniently arranged; and a further convenience with it is that a means may be easily adopted by which the position of the mask may be readily adjusted to best suit the subject to be included in the picture when the image is focussed. In place of the serrated diaphragm one of the ordinary commercial vignetting masks or glasses may be utilised. When the negative is developed, it will have the figure vignettted into a clear glass space. Hence the prints are as easily made as ordinary full-out ones, without the trouble of vignetting in printing.

The above plan, though it answers quite well with lenses of long foci, is not altogether so satisfactory with those of short foci. Therefore a better way, in practice, is to have the mask—of course of a much larger size—placed between the sitter and the camera, and at such a distance that a soft vignettted image is seen upon the focussing glass. This mask, it is scarcely necessary to mention, should be black. It may be an ordinary mounting board, with a suitable opening, in a wooden frame fixed on a rod that will fit into a head-rest stand. Such an arrangement will be found a convenient means for adjusting its height and position to suit the sitter. The mask, as we have just said, should be black, or of a very dark colour, and the best thing, perhaps, is to paste over the board a piece of black cotton velvet before cutting out the opening. If the frame carrying the mask be pivoted in an outer one of metal, and has at its lower part a rod with a weight at the end, it

can be set swinging, perpendicular-like, during the exposure, and thus further soften the vignetting. In use the camera is first arranged so as to obtain the desired image, and focussed, then the mask or screen is placed at such a distance from it as will give a soft vignette. It will be well to have masks or screens with various shaped openings, so as to suit different subjects, whether merely head and busts, or pictures including more of the figure. The background before which the sitter is posed should also be black, or of a very dark colour, as that adds materially to the effectiveness of the picture.

We said just now that dark vignettes can be obtained by double printing, but it is obvious that the camera method is the less troublesome of the two, and, furthermore, it ensures all the prints being alike so far as the vignetting is concerned. The double printing system, however, has the advantage that negatives already in existence may be utilised, and the method of doing so is this: A vignette is first printed with a white margin in the usual way. Then, after printing, a mask is placed over the already printed portion, and the dark margin printed in to the depth necessary. This is really a very simple matter, particularly if the second mask be the piece of card or paper cut from the first one and stuck on a plate of glass, and that is placed at the same distance from the print as the original one was from the negative in the first printing. In this way a soft and even vignetting will be secured without difficulty. It is almost needless to mention that the second printing should be done in a very diffused light, so as to avoid any appearance of a sharp outline.

Other methods of double printing to secure the same end will, doubtless, suggest themselves to the ingenious photographer, but the one we have just indicated will serve as a guide as to how it may be successfully accomplished.

**The Projected Eclipse Expedition.**—We have, on a former occasion, given brief particulars of the expedition to Spain and Africa arranged by the British Astronomical Association. We are sorry, however, to learn that, through the operation of several causes, notably the difficulty caused by the war in making definite plans for the future, the number of names entered on the list of promised ticket-purchasers has fallen so far below the minimum that it is possible the whole contemplated tour will have to be abandoned. At the last meeting of the Association, Mr. Maunder made a statement to this effect. So much disappointment had been felt that one intended passenger had proposed a guarantee fund, and offered 100% towards it, and this had been increased by others to 600%; 2200% had been promised for tickets, but that still left a deficiency of 800%. It would be a thousand pities if the whole expedition should fall through, but with so much money already promised it is scarcely probable that it will. Possibly a boat of less imposing size may be chartered for the trip. The photographic harvest anticipated was so great, that we can but join in the hope expressed by Colonel Burton Brown that the efforts of the Eclipse Committee might yet be crowned with success.

**Cyanide Poisoning Antidote Extraordinary.**—A very strange tale is recorded in the *Paris Herald*. In New York a great murder trial has been going on for an unparalleled length of time, the death of the victim having, it is stated, been caused by the administration of mercury cyanide in bromo-seltzer water. According to this story, Professor Walter W. Scheele, a well-known authority on chemistry, called at the *Herald* Office, stated he had found that, if this cyanide were added to any liquid containing carbonic acid, it would be rendered innocuous, as the hydrocyanic acid would be discharged and the mercury precipitated in a harmless form. We are not told why the poisonous acid goes into the atmosphere instead of

remaining in solution in the liquid. At any rate, when the Professor proposed that he should there and then, in the office, take a dose of the poison, the editor declined, and proposed guinea pigs as the basis of experiment. But, when the cyanide was added to the seltzer and the guinea pigs prepared for the sacrifice, Professor Scheele snatched the cup and drank it off. In view of eventualities he put a tablespoonful of tincture of chloride of iron in a tumbler of water, and instructed the horror-stricken witnesses of his act to force this mixture down his throat if he showed any signs of collapse. We thus have a graphic presentiment of the suitable antidote for cyanide poisoning.

POISONING by cyanide is not so common as in the old wet-collodion days, when every photographer almost made use of it for fixing, and consequently there was no difficulty in obtaining the deadly compound. Its action is terribly speedy, and there is little chance of an antidote being of any service unless administered almost immediately. A singular case of prompt measures taken with success once occurred at Woolwich. A soldier had been using the cyanide to clean his silver accoutrements with. He was seized with a desire to commit suicide, and swallowed a lump of the deadly stuff. It stuck in his throat, and he quickly became almost insensible. A regimental doctor was passing the door at the time; he was called in. He at once, finding the lump of cyanide could not be extracted by the mouth in time, cut open the man's windpipe and extracted the poison, applied suitable antidotes, stitched the throat up, and had his patient all right, all in the space of a few minutes' time.

**Atomic Weights.**—The weights arrived at from time to time as representing the true combining proportions of the various elements are often the result of an immense amount of labour; but even then they are subject to revision, and periodically revised lists are published. We were pleased to see evidence of the fact that our ALMANAC is entirely up to date in this, as, indeed, we hope, in all matters. Last week's *Chemical News* contained a list of seventy-four elements and their atomic weights "compiled from the most recent data." On comparing it with the table in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, we found the two were identical in every respect.

**A New Hydrometer.**—The well-known argentinometer for ascertaining the strength of silver baths is fairly accurate as usually constructed, but, like all others, is capable of improvement. All who use this hydrometer know the loss of time and the uncertainty sometimes caused by the instrument clinging to the sides of the hydrometer jar, and Professor Guglielmo has devised a form to overcome this difficulty. He constructs the hydrometer so that the spindle, instead of, as usual, floating upright, takes a slanting position, at a greater or less angle according to the strength of the solution. A special means of reading off the amount of this slant is provided, so that great accuracy is obtained; indeed, instruments sensitive enough to show differences of density brought about by a change of temperature of only two or three degrees C. have been made under Professor Guglielmo's system.

**Contact-breakers or Interrupters for X-ray Coils.**—At a recent meeting of the Paris Academy of Sciences, M. Alfred Turpain read a paper giving details of comparisons made of various patterns of the Wehnelt Interrupter. He came to the conclusion that, from the point of view of duration and economy, the English pattern, the Caldwell variation, with holes, is superior to that with platinum wire. In last week's *Nature* a description is given of a most ingenious mercury contact-breaker, brought out by Messrs. Isenthal, Poetzler, & Co., which, it states, is one of the most perfect forms of break yet devised, and more serviceable than the Wehnelt electrotype interrupter. It consists essentially of a fine jet of mercury forming one contact piece, and a series of teeth cut in a cylindrical surface, forming the other contact piece. By an ingenious arrangement the ratio of contact to interruption can be

made to vary from zero to infinity, and thus the mean current strength made adjustable to any required value, without resistances. The number of interruptions can be carried through a wide range, so many as 72,000 per second being capable of being produced if desired, a rapidity sufficient for every practical purpose.

### ON THINGS IN GENERAL.

I DON'T think that what I wrote about the metric system was really read by the correspondents who disagree with me. I will quote myself: "For every-day life, our pound weight, &c., are infinitely preferable, and much more convenient, by reason of their adaptability to subdivision. . . . Any one who knows anything about buying goods in France will tell us the same thing. In the very home of the metric system the metric system, as a system, is practically non-existent, at any rate for domestic purposes." M. A. Lévy, in his courteous letter, says I seem "to ignore that a kilogramme is divided here (Asnières) into two pounds. . . . A Frenchman buys, just as readily here as an Englishman in England, one pound of bread or half a pound of coffee, . . . and asks just as easily for one quarter of a pound of butter." M. Lévy proves to the hilt my contention, for a pound is no part of the metric system, which is thus, in its own home, as I said, abundant for domestic purposes in favour of a system exactly analogous to the English. Mr. Charles L. Hett makes a stronger point against me apparently, but his parallel is not perfect. Seventy grains to twenty ounces, I think he will admit, shows at a glance the same thing as three and a half grains to the ounce. The fault lies in the way the formula is stated. How would it have panned out metrically if 160 grammes to 20,000 had been written, that being a just parallel? I do not say our system is perfect, far from it, but I do again say it lends itself much more readily to subdivision. A great advantage of the metric system is its non-elasticity; hence formulæ come to be written almost universally to one standard, and their mutual comparability follows. We do not read such formulæ as 324 c. c. water,  $1\frac{1}{4}$  grammes pyro, and so on. No! we almost always put the water expressed in litres, or else in 100 c. c., and there is then no trouble in comparing one with the other. Let every English formula be written in grains per ounce, and no trouble worth speaking of would arise in comparing formulæ. As it is, taking developing formulæ alone, as issued by plate-makers, the confusion, the want of system, the utter disregard of the workers' time and trouble, is carried on to such an extent as to be absolutely criminal. As things now are, every maker is so wrapped up in his own plates that it is quite impossible for him, from his sublime height, to give to the meek users of his plates "my" recipe, "my" instructions. If the formulæ were given by French makers, they would all be so many grammes or c. c. to the litre, and a man might get a dozen makers' modes of compounding developers, and see at a glance how one differed from another. But this is not because of any virtue of the metric system, but as a matter of common practice. If every English maker would reduce his formulæ to grains to the ounce, their mutual comparability would be instantaneous. As it now is, however, he would be a smart computer who would reduce them for ready comparison in the course of a morning's steady work!

*Verbum sap.*

I constantly see references to cutting prices, and the publishers of this JOURNAL very properly set their faces against such a system; but I should very much like to have a good definition of what "cutting prices" means; what, in fact, is the standard we are to go by? when is a price legitimate and when is it cut? what is the difference between "cutting prices" and "popular prices?" Can the Editors assist? This matter, be it understood, is not a sly hit at the upholders of the metric system; I have no desire to see it expressed in metres or kilos. Its elasticity would not be equal to that.

I noticed recently a query about a scratched lens, which the Editors very truly say need not affect the image at all. But I may narrate a very curious incident that once occurred in my own practice bearing on this point. I had a portable symmetrical, with

which I was taking an interior, and, no light apparently falling on the lens, I did not use any screen or shade. When, however, I came to develop the negative, there was, towards one corner, a series of markings which did not exist in the interior, and which I at first could not account for. After a tedious investigation I found the cause. The sunlight entering the building (a church) caught upon a polished brass object and was reflected obliquely to the lens. There it must have just caught against the small scratch on the lens and been projected on the plate. After this, I made a point always to keep the scratch covered over with black varnish. The loss of light was infinitesimal, and the effect upon the definition or upon the image itself was absolutely *nil*.

I have been following with much interest Mr. Fergusson's copper toning process, regarding which I observed, at a meeting of the London and Provincial Photographic Association, that one speaker stated that it had no advantage over uranium, with which all the tones shown could be produced. I entirely disagree with this. I do not deny the capacity of uranium to give varied tones, but it is, I believe, an admitted fact that uranium-toned prints are *not* permanent. That, I believe, is the view held by the inventor of the process, and the experience of most, if not all, who have practised it. Further, unless special precautions are taken, it is not possible to thoroughly wash a uranium-toned print without washing away some part of the deposit. It is not a simple matter to wash a number of prints for a sufficient time in water specially acidified. We shall hear more of copper toning, or I am much mistaken. The important point, of course, is its permanency, or the reverse. At the meeting, however, there was the experience of Mr. Haddon, who, with another copper toning process, had a picture seven years old which had not changed.

Just now I was writing of developing formulæ (again no *arrière pensée* as to metric system), and I may note one of extraordinary qualities. Here it is (extracted from a quotation from the South London Photographic Society's catalogue): "Develop with hydroquinone, 1 ounce; water, 1 ounce, with a few drops of bromide added." How am I to dissolve an ounce of hydroquinone in the same weight of water? Again: "For strong negatives . . . diluted developer used, say, hydroquinone,  $\frac{1}{2}$  ounce; metol,  $\frac{1}{2}$  ounce; water, 2 ounces (having in a second measure metol,  $\frac{1}{2}$  ounce; water,  $\frac{1}{2}$  ounce)," &c. Really this is nonsense, and it is impossible, too, to imagine what really was intended.

The unfortunate copyright imbroglio seems to be thickening, and there seems every probability that we shall have this unjust Bill thrust down our throats. It appears to me that a central authority (and who so fit as the Copyright Union?) should summarise the objectionable points as briefly as possible, and circular leading photographers in every town, asking them to request their Parliamentary Members to vote against the Bill upon the grounds given. At the risk of repetition I should, however, like to raise my protest against one standpoint taken by, I believe, the Committee of the Union which is fatal to gaining a popular verdict in their favour. I extract the following par from the *Gentlewoman*, where every week it is repeated: "IMPORTANT.—WEDDING PHOTOGRAPHS.—In the interest of our readers it is well they should be advised that, in the event of their accepting 'free sittings,' which certain photographers are systematically offering, the sitter loses all copyright in his or her own face. The photograph may then be sold, published, or otherwise displayed without the consent or even knowledge of the person photographed. It is *not sufficient* to order and pay for subsequent copies." That any photographer should contend that he has a right which he will exercise to "sell, publish, or display" a portrait against the will or consent of the sitter, whether a free sitting is given or not, is to me simply infamous. It is calculated to estrange all public and certainly all Press sympathy, and, until it is publicly repudiated, will do incalculable injury to the cause of photographic copyright. This has been said before in other words. I heartily and emphatically endorse them.

Before concluding, I would revert to a topic that a correspondent has started—the taking of photographs in a house where a studio may not be built. If the rooms of the house are lofty enough, and the windows large enough (it surely should be no great expense

to enlarge them, if too small), most satisfactory portraits can be taken without any other studio at all. At the moment of writing, I can point to two studios—one in the very heart of the busiest part of London, and the other in a street in Liverpool—where first-class work is sent out, the portraits being in each taken in an ordinary room, well lighted, but built with no reference to Photography at all.

FREE LANCE.

### THE PHOTOGRAPHER'S YEAR.

#### MARCH.

MARCH is the first month of spring. At least so it is set forth in the Calendar. A necessary notification, if the correct seasonal division of the year be of importance, for one would not be aware of anything very spring-like, in the earlier portions at any rate, of the ordinary March. This month, more than any other in the year, comes in for an unfavourable weather character. It is put comprehensively, if indirectly, in the well-known and often-quoted old couplet, that—

“When the wind is in the east,  
’Tis neither good for man nor beast.”

For the wind is characteristically in the east in March, and the month must so carry at least a share of its proverbial ill repute. We expect too much, perhaps, too early. The impression we have of spring has been built up from odds and ends of reading, generally in the form of poetic praise, combined with the personal remembrance of its more mature, pleasanter aspect later on. It is unfair to expect this to be satisfied at a first appearance. The season should be regarded more as one of organic growth, and its full wealth not looked for so soon after birth, more than the full proportions of manhood or womanhood are expected in a baby. It is not wise, either, to place over-much reliance upon a proverb. The fuller truth is very often sacrificed in it to a pithy or rhythmic effect. The peculiar smartness, too, that one naturally looks for in a proverb-maker is associated with a certain dilettantism rather than robustness. Your hearty man of brawn is too busy with the practical concerns of life to find time for selecting words and polishing phrases. Were he to turn out his proverb in this case, it would probably run in a reverse direction to the classical one quoted, and be in praise of the blustering wind, good for one of his firm and healthy stamp. The nearest he comes to it is in saying in a plain, English shopkeeping way, that “a peck of March dust is worth a king’s ransom.” Wind again, for dust clearly supposes wind. Wind is evidently a characteristic feature of the month from a proverbial point of view; one borne out by experience as correct, whatever of its effects and value. To form a necessary portion of the year’s record from our particular point of view, it must be photographed. An impossible-looking matter enough at first sight. But the apparently impossible, upon nearer acquaintance, often turns out easier of accomplishment than the commonplace. So wind, spite of the Biblical statement that “no man knoweth whence it cometh, nor whither it goeth,” can be photographed. Not, of course, in its airy invisibility, but by suggestion of its presence and effects; yet none the less effectively in this manner, but rather the more so. A suggestion, if a telling one, can create a far deeper impression than an elaborately finished picture. In the one the recipient is involuntarily forced to create his own picture—a pleasing labour if the scrap of suggestion take his fancy, and one far more likely to give satisfaction than in the alternative case of having to admire another man’s picture, which, in the lack of personal effort, is less closely interesting.

It is admittedly hard to give no more than a suggestion by photography; but it can be, and has been, done, and probably, if more thought were given to possibilities in this direction, photography would not be found to be so hard and unsuggestive an art as it is commonly held to be. The lines along which suggestion has hitherto been successfully and artistically presented have been more the quiet, restful, peaceful ones—a summer woodland scene, sand dunes, stretches of marshy foreshore intersected by muddy estuaries, a sailing boat moored at an old-fashioned jetty, or stranded at low ebb. The attempt to suggest action and motion has been rarer, and not so successful, partly from the technical difficulties in the way, partly from the tradition that it is without the pale of photography. The projected excursion is postponed if it be a windy day, even the breath of a breeze first allowed to pass over before an exposure is made. This is one item that helps to give its air of unnatural stiffness to a photographic picture. It is resented because it is not typical. Things are very rarely, and for but the shortest time, as still as they are represented. We fail to note, for instance, in one of a restful spot under the shade of trees, any suggestion of the slight swaying

and rustling of leaf and bough that we instinctively feel must be there. The photographer has waited to keep carefully out what, properly done, would have added immensely to its value. But the man who, to the necessary technical knowledge and skill, has added the higher faculty of thinking broadly of what he wants, and the best way of getting it, acts otherwise. Many, at present too mechanical in their methods of working, have the power of thinking. What their work would gain did they but do so can well be imagined, if only from its present technical excellence.

Gusty March wind can be shown in the bowing of tree and cloud of dust. Instantaneous exposures are practicable enough at this time of the year. It is an easy matter to show a bent tree without any blurring, to suggest a bending tree is a far more difficult one. Let any one wishful to try just keep his eyes observantly open during a walk. He will find in the progress of a blast a psychological movement, generally when the gust has passed and the tree is beginning to recover itself, when the photographic conditions are favourable. The largest practicable exposure at this particular instant—or fraction of one—will give the desired result. It is a delicate matter; the margin between failure and success, as in most human actions, is a remarkably fine one, but the result is well worth the trouble and waiting. An analogous case, where the same facts come into evidence, and are more generally known from its having been attempted oftener, is in the photographing of breaking waves. One man, short of powers of observation, or their non-use, and an unduly short exposure, will turn out waves of marble or congealed soapsuds, whilst another will present them so naturally that one almost waits expectant of the final break up and soft swish of the spreading water. Violently arrested motion pictured gives no satisfaction beyond that of having overcome a technical difficulty. The photograph of an express train gives no suggestion of the motion we naturally associate with and look for in it. The picture would be just as correct if the train were at a standstill. Conveying the appropriate sense of motion in some way is far and away a higher and more desirable object than demonstrating the rapidity of plate and shutter, the excellence of the lens, and the capacity to properly manipulate them. So with such other orthodox photographs as those representing cycling, skating, running, riding, sailing, footballing, and so on. It is extremely difficult to accomplish, but it can be done, and by the class of men it would pay best to have trying, those who think; and, as each subject will have its own peculiar difficulties, men who can think all round, and not merely in a photographic way, pinned down by the limitations of a special plate, lens, or formula. So, returning to our more immediate purpose and instance, a carefully selected, wind-swept corner, with sparing detail, patient waiting for time of action, and knowledge of the best length of that action, all in true proportion, will give the picture.

With a cloud of dust, again, the closer observer will find that it is not always a wholly obscuring one, fatal to photographic treatment, but a local whirl, recurring frequently in the same spot and assuming a distinctive form. This should suit the purpose. The thing is to catch the true position, and act at the proper moment.

If wind and dust do not offer attractions sufficiently strong to the normal photographer, or they be unsuited to his physical conditions, there are many other things he can do in March. The rarer, earlier ploughing of February has become general, and sowing added. The sower has already lent himself as a subject both to the artist and photographer. It is one particularly suitable to the latter, in its simplicity as a single figure, the slow movement, and graceful motion. There is to boot something in the act of sowing that is, and always has been, extremely attractive to a thoughtful mind—the opportunity it appears to be for the play of such feelings as blind confidence that the apparently wasteful scattering of valuable grain will be justified in future growth, the hidden nature of that growth, and its varying amount. A man is more likely to drift into thought watching a sower than any other man at his labour. It was so in pagan times, as we have ample evidence; we have the added charm and meaning of the teaching that began with “Behold a sower went forth to sow,” to help out our thoughts and imaginations.

Flashes of coming warmth and sunshine there also are in later parts of the month that are more grateful even than their fuller realisation and enjoyment further on, from more immediate contrast with the gloom and barrenness of winter. The earlier, hardier flowers offer promise of the approaching brightening of the world. A pity it is that we cannot as yet photograph them in their chief attraction of colour. This will, doubtless, come in due time. Whether we will be as pleased with it upon the whole as we now anticipate is questionable. Probably there will be at least some of the disappointment such as we now feel in the inclusion of excessive detail. The optical arrangement, whatever it may prove to be, that will give a faithful representation of colour will not register it in the

same way as the eye, more than the existing lens registers the same as the eye in the amount of subject, light and shade, proportion, and so on. We will have to select colour subjects as carefully with respect to their mechanical reproductions as we now do to amount and kind of detail. But the spring primrose, occasional violet, and spray of almond bloom, with their as yet spare framing of delicate green, will certainly offer suitable flashes of simple and suggestive colouring admirably adapted to the purpose. However, this must remain over for a future photographer's year. There is no lack of suitable subjects and possibilities in this with the tools at command, provided the worker know where and when, as much as how, to use them.

#### NEW EXPERIMENTS WITH LIPPMANN'S PROCESS.\*

It is a well-known fact that the sensitiveness of printing papers, especially albumen, may be considerably increased by fuming them before exposure with ammonia. Similar experiments were made with gelatino-emulsion plates in order to improve their sensitiveness. The plates were kept from five to twelve hours in a box, on the bottom of which was placed an open dish with ammonia in it. It was found, however, that the sensitiveness of the plates was not in the least affected by this procedure.

A still open question is, Of what do the films of the finished Lippmann pictures consist? Every one would at once off-hand answer, "of silver." The facts are, however, by no means so simple. In his latest publication on Lippmann's process Professor Otto Wiener† proves that the deposited particles need not be metallic silver; they may be molecular silver, or a silver compound. Wiener states "that it might be coherent metallic silver; on the other hand, when looked through, it is brown, whereas coherent silver is well known to be blue by transmitted light."

When trying to remove the surface metallic fog, which is, doubtless, the result of the action of the mercury, by bathing the plates in nitric acid the author observed that the image was extraordinarily unaffected by nitric acid. With twenty hours' immersion of the plate in dilute nitric acid the precipitate had undergone not the least change. This is the more remarkable, in that the image is quickly dissolved by sodium hyposulphite and potassium cyanide. All these things make it strongly desirable to institute accurate researches upon the nature of the precipitate in Lippmann's colour pictures.

Of extreme importance are Wiener's new experiments on the influence of surface reflection on the colours; ‡ that, when the surface reflection has been obviated by the cementing of a cover glass, the colours are more correct and more brilliant has long been known. The reason of this Wiener has explained in the clearest manner in the above-mentioned work. It is only necessary to place the finished image at an angle in a liquid which will not swell the gelatine, and which has about the same refractive index as gelatine—for instance, ether, benzole, benzine, or xylol—in order to prove without further trouble the extraordinarily favourable action of the obviating of the surface reflection. This is attained by cementing flat-glass prisms with Canada balsam on the picture. The author has observed on various grounds, the differentiation of which would carry us too far, with earlier cementing experiments of this kind, a disadvantageous change of the colours. With the experiments now repeated these changes did not show; moreover, the colours gained enormously in brilliancy and truth in nature. Pure white actually only appears in the picture after the destruction of the surface reflection.

Of great influence on the resulting colours is the refractive index of that substance which is brought into immediate contact with the gelatine surface. If the refractive index is low, all the colours tend more towards the red; if it is high, they tend, on the other hand, more towards the blue and violet. There is here, therefore, a possibility of subsequently improving small colour falsities, caused by incorrect exposure of the development. The best demonstration of this behaviour is obtained if, as intermediate film between picture and glass prism, there is used first ether, with a very low refractive index, and then monobromo-naphthaline with very high index. For the final cementing of the prism Canada balsam is alone used, which, on account of its refractive index, which is somewhat too high for that of gelatine, can easily cause a shifting of the colours towards the blue and violet. If it is desired to obviate this fault, the image-bearing film must be coated, before cementing on the prism, with a film not too thin of a substance which has a lower refractive index than Canada balsam. Zapon varnish§ has proved useful for this, but

better still, coating the image with a thick film of gelatine. For this latter a lukewarm five per cent. solution of gelatine is poured over the picture. One always runs the danger, however, that the gelatine solution penetrating into the image may drive apart the thin Zenker lamina, and the colour be finally shifted too far towards the red.

To obviate the fault of the shifting of the colours too much towards the violet by cementing with Canada balsam, the image-bearing film may also be breathed on. As regards the permanency of the image, it is, however, in any case better, instead of this, to warm the plates slightly before exposure. When using those kinds of Canada balsam with which the glass plate has to be warmed before cementing, it is absolutely necessary to warm the plate before exposure.

To obviate the surface reflection, it is not sufficient to cement on to it a simple piece of glass, it must be a flat prism or glass wedge. Prisms of this kind are prepared, of excellent quality and  $6.5 \times 8.5$  cm., by Gebr. Picht & Co., of Rathenow.\*

So that the full effect of the colours may be obtained, the reflection from the back of the glass plate must also be destroyed. This is effected by coating the back with black varnish, or by cementing on to it a black glass.

In his work on *Farbenphotographie durch Körperfarben und mechanische Farbenanpassung in der Natur*,† Otto Wiener remarks that a perfecting of Lippmann's process would be effected if it were possible to impart to the gelatine a higher refractive index by suitable additions, or to completely replace the latter with another substance of higher refractive index. The colours would not, or only very slightly, change by the change of the angle of incidence of the light, they would have the brilliancy of body colours without being them.

Experiments were made by the author in this direction during the last summer. Although they were absolutely negative, they will be briefly described, since possibly, with improved arrangements and experiments, the results may be favourable.

The author experimented with films of pure silver chloride, which, for the sodium D lines, has a refractive index of 2.06. As regards the high refractive index, the advantages of such a film over gelatino-bromide of silver are very considerable. Still more advantageous would be the use of pure silver bromide, which has a refractive index of 2.25.

The preparation of the pure silver-chloride films was effected according to the directions of Schultz-Sellack,‡ whose early death we must all deplore. As the author has not the essential apparatus for preparing this, Professor N. O. Witt, of the Technische Hochschule, of Charlottenburg, made some for him.

Small pieces of the silver chloride were laid on a well-cleaned glass plate, which was laid on a strong copper plate, which could be warmed by a Bunsen burner. Over the silver chloride a second glass plate was laid, so that the melting silver chloride would spread as a very thin film between the two glass plates. In order to keep the heat in better, and to prevent the cracking of the glass during the melting, which was effected at  $260^{\circ}$  C., the glass was covered with an asbestos cover.

When cold, the glass plates with the silver chloride film lying between them stuck fast to one another in an extraordinary manner. When placed in warmed concentrated nitric acid, which does not attack silver chloride itself to any marked degree, but creeps between the glasses by capillary attraction, the separation could be easily done. Instead of warm, cold nitric acid can be used, but the plates must stop in it for a day.

Obviously, all this must be done in the dark room, since we are dealing with a light-sensitive body; but the sensitiveness of pure silver chloride is very little.

There is obtained in this way extremely thin, glass-clear, flexible sheets, which can be used on a glass support the same as any other photographic plate.

The exposure was made in the usual way for Lippmann's process by the aid of a mercury dark slide and spectrograph. As pure silver chloride is only sensitive for blue and violet, one ought only to expect the appearance of these colours. Development was effected with the most varied developers, and also with physical developers. These did not show, however, the trace of a single colour. The dark silver precipitate caused by development rested on the outer surface, and quickly dissolved in sodium hyposulphite. After a short immersion in hypo, the film became again glass-clear; with long immersion the whole of the silver chloride was dissolved.

## INTENSIFICATION AND REDUCTION.

[A paper read before the Sutton Photographic Club.]

A PERFECT negative! described by Mr. Chapman Jones as an image "of pure silver in clear gelatine," with its shadows, high lights, and delicate half-tones all in perfect gradation; but, alas! how many of us fail to produce negatives which come up to this ideal standard. Muddy-looking negatives, caused by general fog; negatives much too dense in some parts, and much too thin in others, are but too frequently met with. The question therefore arises, what, in such cases, can be done to improve the *printing value* of such negatives. In what follows I propose to discuss briefly some of the principal processes employed for this purpose, and, if I should be thought by some to go into what they may think trivial matters, I would simply remark that this paper is not written for past masters of the art, but for those who have still much to learn, and are desirous of learning it; and, further, that it is very often upon trivial matters, often overlooked, that success or non-success chiefly depends.

## INTENSIFICATION.

I will take "Intensification" first, and, with regard to it, we may often tell as soon as a plate has been fixed and washed, before it is dry, whether the negative so obtained is suitable for printing from, or whether it requires to be intensified or reduced, in whole or in part. I will assume it is thin and requires to be intensified; the next point is whether it wants much or little intensification, because on this will depend the choice of which intensifier to use, some giving greater density than others. Another point is whether the negative is a clear one, or whether a slight veil is over it; this can be determined fairly well by the rebate, if that is clear all round, except, perhaps, against the sky line, then all is well, but if a thin film of deposit is on it, the assumption is that the entire negative also has this film, and it is desirable to clear this away, because, if left, it would partake in the general intensification. But to do this means reduction, and it will be referred to again under this heading.

## PRELIMINARY PROCESSES.

1. The negative must be *very thoroughly* fixed, and all traces of hypo must be absolutely removed; very thorough washing, followed, should there be any doubt, by immersion in—

(a) Peroxide of hydrogen, 8 c. c. of a 10 volume solution, to 160 c. c. of water. Soak in this for half an hour, then wash; or,

(b) Saturated solution of alum, acidulated with *pure* hydrochloric acid (about 15 c. c. to 600 c. c. of alum solution), soak for half an hour and thoroughly wash. The acid is necessary, not only for the more perfect destruction of the hypo, but to prevent the alum from unduly hardening the film, which would interfere with subsequent operations; or,

(c) Iodine, made by dissolving iodine in a strong solution of potassium iodide till of a black colour, adding some of this to water till of a sherry colour, and immersing the plate in this till a blue colour is persistent, which shows the hypo is gone; the negative is then rinsed, and placed in a ten per cent. solution of sodium sulphite to remove excess of iodine, and washed.

The absence of hypo in this or any other operations in which its presence is undesirable may be proved by testing the washing water from time to time with iodide of starch, the blue colour of which is destroyed by hypo; or with potassium permanganate, the pink colour of which is destroyed, and a brown precipitate of manganic oxide caused, by hypo.

2. Unless the freshly developed and still wet negative is going to be operated on, it is better to soak the dry negative for half an hour in water before proceeding to intensification, because, by so doing, more uniform results are likely to be obtained. Exception to this, however, may occur when *local* intensification or reduction is going to be resorted to, *vide infra*.

The negative is now ready for the actual intensifying process, and we have a good selection to choose from.

## THE VARIOUS PROCESSES.

1. The image is first *bleached* by the application of a certain chemical, and afterwards darkened by another chemical, producing greater density.

2. The image is darkened by the application of certain chemicals, *without* previous bleaching.

(a) Two-solution intensifiers.

(b) One-solution intensifiers.

3. The image, after being bleached, is treated like an exposed but undeveloped plate. This is called intensification by redevelopment.

## PROCEDURE.—TWO-SOLUTION INTENSIFIERS.

In the first case, where bleaching precedes the darkening of the image,

the chemical generally employed is mercuric chloride, but I shall give one formula in which a cupric salt is used. Take as follows:—

Mercuric chloride .....	6 grammes.
Potassium bromide .....	6 "
Distilled water .....	300 c. c.

Or—

Mercuric chloride .....	5 grammes.
Pure hydrochloric acid .....	1 c. c.
Distilled water .....	100 "

Or—

Mercuric chloride .....	20 grammes.
Sodium chloride .....	40 "
Distilled water .....	1000 c. c.

Acidulated with *pure* hydrochloric acid.

Dissolve either of these, and filter if necessary, because any undissolved particles of the mercuric salt would probably produce stains on the negative. Either of these solutions may be used again and again, so long as they produce the bleaching effect. Remember that they are all very poisonous. Into this solution put the negative, *well washed and free from hypo*, until it is *bleached right through*, and appears of a white, or greyish-white colour on both sides. Some authorities say that the bleaching need not go *through* if only a slight effect is desired, but this requires judgment and practice, and it is better to do it thoroughly. I may here say that Dr. Eder states, that the first of these three formulæ gives rather more density than the other two, and also that the image is less likely to be acted upon if sulphite of sodium is used afterwards; see translation of his paper, *THE BRITISH JOURNAL OF PHOTOGRAPHY*, February 2, 1900, p. 68; also *Photography*, same date. After thorough washing, the negative is ready for the darkening solution; there are several to choose from.

(a) A ten per cent. solution of sodium sulphite, till the bleached image is darkened right through. As stated in Dr. Eder's paper, above referred to, the plate should not be left too long in this, or a reduction may take place. This gives very good results, and gives a bright, sparkling negative. If insufficient density occurs, the process of bleaching and darkening can be repeated, a second, or even a third time.

(b) A solution of ammonia, containing, say, 1 c. c. of the '880 solution to 30 or 40 c. c. of distilled water, till the image is darkened through. This gives rather more density than the sulphite, and has always been a favourite.

(c) A solution of potassio-silver cyanide, made as follows:—

## No. 1.

Silver nitrate .....	6 grammes.
Distilled water.....	400 c. c.

## No. 2.

Potassium cyanide.....	6 grammes.
Distilled water .....	40 c. c.

Add No. 2 *gradually* to No. 1, till the precipitate first formed is *almost* but *not quite* redissolved. When the image is blackened right through, remove the plate and wash it, as, if left in too long, a weakening effect will probably result. This solution gives very decided results, and is useful for very thin negatives. Sir W. Abney has great faith in it. This is Monkhoven's formula:—

(d) A solution of ferrous oxalate, composed as follows:

Saturated solution ferrous sulphate .....	4 c. c.
Saturated solution potassium oxalate.....	24 "
Distilled water .....	12 or 16 "

No bromide is required, and the solutions should be acid. It is advisable, too, to use distilled water all through this process, or a deposit of oxalate of lime may be deposited on the film. Of course, the first washings, to remove the iron must be in distilled water acidified with acetic acid. This process is much recommended by Mr. Chapman Jones. Instead of ferrous oxalate, another developer may be used, these constitute intensification by redevelopment.

I now come to a bleaching process *not* dependent on mercuric chloride, viz.:—

Bleach in a bath containing 25 grammes each of cupric sulphate and potassium bromide in a litre of water. Wash, and immerse for a short time in a two per cent. silver nitrate solution. Again wash, and place in a bath composed as follows:—

Hydroquinone.....	10 grammes.
Sodium sulphite .....	75 "
Sodium carbonate.....	150 "
Distilled water .....	1000 c. c.

If sufficient density is not obtained, do not dry, but repeat the three operations (*Bull. Soc. Fr.* 15, 313, and *Phot. Journ.* for July 31, 1899, also THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1900, p. 950).

ONE-SOLUTION INTENSIFIERS.

There are many of these, some whose composition is secret, others whose composition is known; it is to these latter alone that I shall refer, and I will take first the—

Uranium Intensifier.

No. 1.

Uranium nitrate .....	1.5 gramme.
Acetic acid .....	16 c. c.
Distilled water .....	320 "

No. 2.

Potassium ferricyanide (clean) .....	1.5 gramme.
Acetic acid .....	16 c. c.
Distilled water .....	320 "

Mix these in equal proportions, and allow the *very thoroughly* washed negative, previously soaked in water if it has been allowed to dry, to remain in this till the desired result is obtained. If carried too far, washing will reduce it again, or the *very careful* application of a *very weak* solution of ammonia. This process gives very great increase of density.

The next three depend for their action on mercuric iodide, and are very simple and give good results. Full details of these processes may be found in the *Bull. Soc. Fr.* (2), 15, 472, the *Phot. Journ.*, November 30, 1899, THE BRITISH JOURNAL OF PHOTOGRAPHY, December 29, 1899, by Lumière and Seyewitz; also in THE BRITISH JOURNAL OF PHOTOGRAPHY, February 2, 1900, and *Photography* of the same date, by Dr. J. M. Eder. These authors, following Edwards and Professor Vogel, instead of using the simple solution of mercuric chloride in potassium iodide (No. 1 below) employ instead a solution of the mercuric iodide in sodium hyposulphite or sodium sulphite. I will give the three formulæ:—

No. 1.

Mercuric chloride .....	4 grammes.
Potassium iodide .....	12 "
Distilled water .....	400 c. c.

The quantity of iodide must be *just sufficient and no more* to redissolve the brilliant red precipitate at first formed.

No. 2.

Mercuric iodide .....	6.5 grammes.
Sodium hyposulphite .....	8 "
Distilled water .....	65 c. c.

Dissolve the two salts in the water, and the solution is then ready for use.

No. 3.

Mercuric iodide .....	1 gramme.
Sodium sulphite .....	20 grammes.
Distilled water .....	100 c. c.

Dissolve these in the same way as No. 2. M. Lumière says the *anhydrous* sodium sulphite is preferable, in which case use half the quantity of it. This salt is very useful, and keeps much better than the crystallised sulphite. Add it to the water and not *vice versa*.

With all these, intensification goes on evenly and steadily, and can be watched and controlled. Should a yellow colour obtain, it can be removed by the application of a ten per cent. solution of plain hypo. But I have a negative (shown) done six years ago in No. 1, it is as you see of a brilliant yellow colour, and gives a perfect print. Agfa and the Platinotype Company's Perfect Intensifier also give good results.

REDUCTION.

I now come to reduction, and, although this is the term generally employed, yet I think you will agree with Professor Meldola that it is not a suitable one, as it more properly applies to the action which takes place in developing a negative, when a reduction of the silver salt to metallic silver occurs. Professor Meldola suggests a weakening agent, which suggests conversely a strengthening one, so that we should have, instead of intensifying and reducing, strengthening and weakening.

Well, whichever term is adopted, I will take first the old and well-known Farmer's reducer, which consists, as you know, of, say, a twenty per cent. solution of hypo, to which has been added a few drops of ferricyanide of potassium, sufficient to impart to it a lemon yellow colour; or, the negative may be taken from the fixing bath and placed in an aqueous solution of the ferricyanide of the same tint. The action takes place quickly and must be carefully watched; the plate is then rinsed, placed for a short time in, say, five per cent. solution of plain hypo, and finally well washed and dried. For clearing off fog, previous to intensification,

*vide supra*, this reducer is well suited. But, inasmuch as this reducer unfortunately attacks the shadows more than the high lights, and consequently the half-tones, which it is so desirable to maintain, are damaged, therefore it was a boon and a blessing to photographers when, about a year or a little more ago, it was announced that a salt, not new in itself, but new in this application of it, was found which exactly reversed the action of the Farmer reducer. This salt was ammonium persulphate (see *Photo Journ.*, January 31, 1899, a paper by Lumière and Seyewitz, translated from *Bull. Soc. Fr.*, iv. 395), and a very valuable reducer it has proved, *vide* a most able paper by Professor Namias, translated in THE BRITISH JOURNAL OF PHOTOGRAPHY, April 13, and May 5, 1899. It should be used in a two per cent. solution, *freshly made*, as it is decomposed by keeping in solution; the freshly developed and wet negative, or a dry one, is placed in this solution, when reduction takes place uniformly all over—it takes longer with a dry negative—and can be stopped at any stage that may be considered necessary. It will be noticed that the high lights have been reduced very much more than the shadows, and the half-tones scarcely interfered with at all. This is due to the action taking place mainly at the back of the film, *i.e.*, the densest part, and explains why a dry film is more slowly acted on than a wet one. There is one exception to the above statements, *i.e.*, in the case of "Cristoid films," they having no support; if they are squeegeed *exposed side* to the glass, leaving the back of the film uppermost, then either of the two above-mentioned reducers has apparently the same effect. The colour of the persulphate reduced negative is of a grey colour, and easily printed from.

Then we have three more reducers, *i.e.*, Haddon's, the exact form for which I am not quite sure about, but the following answers very well:—

Potassium ferricyanide .....	1 gramme.
Potassium sulphocyanide .....	1 "
Distilled water .....	250 c. c.

In this the action goes on evenly and not too rapidly, and affords a good, easily printable negative. The next reducer is a very simple one, does not require the negative to be thoroughly free from hypo, and keeps well. Its composition, as given by Professor Namias, is as follows:—

Potassium permanganate .....	1 gramme.
Sulphuric acid (strong) .....	2 c. c.
Distilled water .....	2000 "

Dissolve.

This acts uniformly, fairly quickly, and yields a clean printing negative. It cannot be used again, as after once using it no longer keeps. Should a brown stain be produced, it can be removed by a one per cent. solution of oxalic acid.

The last reducer to which I shall refer is mentioned in THE BRITISH JOURNAL OF PHOTOGRAPHY, March 10, 1899, by Mr. J. S. Teape, who gives the following formula:—

Potassium bichromate .....	3 grammes.
Distilled water .....	32 c. c.
Dissolve, and take of this .....	4 "
Sulphuric acid .....	4 "
Distilled water .....	128 "

Mix, and add of this 2 c. c. to every 200 c. c. of water.

Reduction takes place evenly right through, and is more suitable for a negative which has been allowed to become dry than Farmer's.

For *local* intensification or reduction single solutions are better than two solutions, as the final action is at once observed; it is best to work with a brush on a *wet* negative, or a hard line may be produced, although, if only a *very local effect* is wanted, then a dry negative is best, as spreading is avoided.

Although I have not nearly exhausted all the possible intensifiers and reducers, I believe I have mentioned the best, and those, perhaps, most frequently used, but still it is true, as stated in an editorial article in THE BRITISH JOURNAL OF PHOTOGRAPHY, September 1, 1899, p. 547 entitled, "Reduction and Intensification in Professional Work," that the mercuric chloride followed by ammonia, or the mercuric iodide in hypo, and Farmer's solution, or ammonium persulphate, "really give us in four methods all we need or desire for portrait or landscape intensification or reduction."

In conclusion I will hand round a series of negatives which have been treated *by each one* of the different processes I have described, and Mr. Hoole will be good enough to throw on the screen lantern slides made from these negatives, you will then be enabled to judge of the effects produced; we will then have a look at those negatives which have been undergoing treatment during the time I have been reading this paper.

J. H. BALDOCK, F.C.S.

## FOREIGN NEWS AND NOTES.

**Intensification with Sulphocyanide of Mercury.**

—Dr. Eder reports, in the *Photographische Correspondenz*, that Dr. Eberhard has made further experiments with sulphocyanide of mercury (agfa) on the lines suggested by him. The experiments show that intensification can be very successfully carried out by means of sulphocyanide of mercury, followed by an iron developer. Dr. Eberhard prepared the intensifier by taking a few 100 grammes (generally 200) of bichloride of mercury, dissolving it in about 50 c. c. of hot water, and afterwards adding a saturated solution of sulphocyanide of ammonium in sufficient quantity till the powdered sublimate passed into a colourless solution. By repeated additions of sublimate, followed by additions of sulphocyanide of ammonium, a saturated solution of high specific gravity may be obtained. This should be reduced considerably for use by addition of water. It is desirable to prepare the intensifier with a slight excess of sulphocyanide of ammonium, otherwise a precipitate of sulphocyanide of mercury may be formed, especially if the plates have been rather imperfectly washed. After treatment with the solution of sulphocyanide of mercury, the plates should be blackened by means of oxalate of iron.

**The Speed Numbers of Plates.**—Dr. Eder also draws the attention of German plate-makers to the importance of following the example of many English plate-makers in marking the boxes with standard numbers indicating the speed of the plates. Although German plate-makers have hitherto shown themselves disinclined to supply their customers with the information, Dr. Eder thinks they will before long be compelled to meet the wishes of photographers in this respect. After citing the example of Messrs. Marion & Co., Cadett & Neall, and the Imperial Dry Plate Company, who all send out speeded plates, Dr. Eder draws attention to the practice of the Kodak Company, who mark their packets of films with a time limit, within which they must be developed. This notice saves the photographer many disappointments, and is highly commendable. The writer also points out that English manufacturers do not hesitate to affix low speed numbers to their boxes of ordinary plates, photographers being sufficiently well informed to appreciate a slow plate for qualities which are not usually associated with speed. Dr. Eder recommends the Scheiner system, which is a modification of Hurter & Driffield's. This is to be regretted, as a uniform system has important advantages. According to Dr. Eder, English ordinary plates measure about 10° Scheiner, rapid plates and Eastman films about 14 to 15°, and commercial extra-rapid plates up to about 17°. Messrs. Schattera of Vienna, have just adopted the Scheiner system of speed-marking.

**Dextrine.**—Dr. R. E. Liesegang, according to the *Chemiker Zeitung*, has found that nitrate of calcium enhances the solubility of dextrine considerably. He recommends as a mountant:—

Dextrine .....	800 grammes.
Nitrate of calcium .....	200 "
Water .....	1000 c. c.

Dextrine has not, however, enjoyed a high reputation in this country in relation to the permanence of silver prints.

**Starch in Emulsions.**—We recently drew attention to the lawsuit now pending in Germany concerning the validity of a patent for the use of starch in emulsions. The *Deutsche Photographen Zeitung* now attacks the subject from the historical standpoint, and begins a series of references with a translation of an article on hard gelatine, from the pen of C. Beckett Lloyd, which appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY on March 31, 1882. Exception is often taken to the English system of granting patents without inquiry as to the novelty of the invention. In Germany the opposite system prevails, but the *Deutsche Photographen Zeitung* remarks that the present case once more shows that the decision of the patent authorities as to the novelty of an invention is utterly valueless, the means of arriving at a true conclusion not being at their command. Our contemporary summarises Mr. C. Beckett Lloyd's article as showing that starch was used to lower the setting quality of hard gelatine, and to render it more permeable to the developer and fixing agent. The gelatine was used for emulsifying and the starch subsequently added, or *vice versa*. The starch was boiled in either case, precisely as in the "Junk Process" now being contested in Germany.

**The Camera at the Paris Exhibition.**—We read in the *Moniteur de la Photographie* that no restrictions will be placed upon the use of the hand camera for taking general views at the

Paris Exhibition. A charge of 50 cents will be made for each time a stand camera is used. Photographs of any special exhibit may only be made by consent of the exhibitor. These regulations appear to have given general satisfaction.

**The Kinematograph in Vienna.**—The *Wiener Frei Photographen Zeitung* mentions that a film ignited recently at a performance at the Vienna Colosseum, but the blaze was speedily extinguished, owing to the precautions imposed by the authorities. The apparatus had to be submitted to the head of the municipal fire brigade, who ordered it to be enclosed in a case lined with asbestos. During the performance two firemen had to stand near the apparatus, each with hose in hand, ready to throw water upon it in the event of accident. Communication between the apparatus and the stage had also to be established, so that the lights might be immediately turned up in case of need. It appears that a few sparks from the illuminant ignited the film, but the hose was immediately directed upon the kinematograph, and the spectators were reassured by the lights being turned up.

**Dragon's Blood.**—Concerning the solubility of this gum, C. Fleck writes as follows in the *Photographische Chronik*: Dragon's blood is partially soluble in oil of turpentine, and imparts to it an orange-red tint, in the proportions of 20 grammes of red gum to 100 or 120 c. c. of oil of turpentine. If the filtrate from this solution is poured upon a sheet of glass, it will be seen that a small portion of the gum has been dissolved. The film is extremely thin, dries smooth, is slightly iridescent, but without body colour. It takes the pencil, and would be a suitable retouching medium. Sixty grammes of dragon's blood were placed in 120 c. c. of oil of turpentine, well stirred, and, after standing a few days, filtered. The solution was of deep carmine colour. When the filtrate was again poured upon the dragon's blood at 60° C., the colour deepened to such an extent that the solution did not transmit any light. This solution gave a rather thick film, slightly yellowish-white, dried rather slowly, and became very hard. It would be a very good substitute for Japan lac, and useful as a negative varnish. The remainder of the dragon's blood (now somewhat purified) was treated with ether. A further constituent of the gum was removed, and, by repeated washings with oil of turpentine and ether, a black, amorphous mass resembling asphalt was obtained. This was only slightly sensitive to light when dissolved in crystallisable benzole, and the solution was of a dark, opaque colour, yielding a red film, which acquired greater intensity with heat. The solution is, unfortunately, of no practical value, as it is much less sensitive than Syrian asphalt. Dragon's blood dissolved in alcohol gives a dark red solution, and, poured upon zinc, formed an orange yellow film. Upon glass the film presented a dull yellow, iridescent colour, with a fine matt surface, which freely took the pencil. Further treatment with ether gave a deep red solution, but the film was colourless, although matt and iridescent. The surface was very delicate, and did not take the pencil. A reddish powder may be precipitated from the solution. It contains little resin, and would be suitable as a pigment for three-colour printing—the gum-bichromate process or carbon printing. Ten grammes of the powder were placed in 100 c. c. of crystallisable benzole. But very little was dissolved, and it stained the benzole red. When poured upon a zinc plate it did not yield a film. Ten grammes dissolved in 100 c. c. of chloroform gave a solution of deeper colour, but, although rather more was dissolved, the quantity was insufficient to produce a coloured film upon zinc. With caustic soda a very fine carmine lake was precipitated from a solution in alcohol and ether. The facility with which the colouring matter may be separated from dragon's blood makes it available for many purposes.

**A Giant Paper Machine.**—In the *Progrès Typo-Litho* some particulars are given of a new machine built for the Rumford Falls Paper Company, Maine, U.S.A. With this machine it will be possible to manufacture 35 tons of paper per day. Its length is 53½ metres, and its width 7.82 metres. Its weight is estimated at 610 tons, and it will produce a roll of paper 3.82 metres wide at the rate of 152½ metres per minute.

## IMPROVEMENTS IN PHOTOGRAPHIC LENSES.

[Patent No. 24,720 of 1899.]

MR. DALLMEYER'S invention is described in his complete specification, from which the following is an extract:—

"My present object in particular is to assist the user of the 'hand camera,' and the smaller sizes of cameras, to avoid 'exaggerated' per-

spective by enabling the operator to be at a greater distance from the foreground of his subject, and yet maintain a sufficiently large image ; also to obtain, by the addition of the enlarging system to his lens, enlarged details in subjects of general interest included by the ordinary lens used alone ; distant objects, &c.

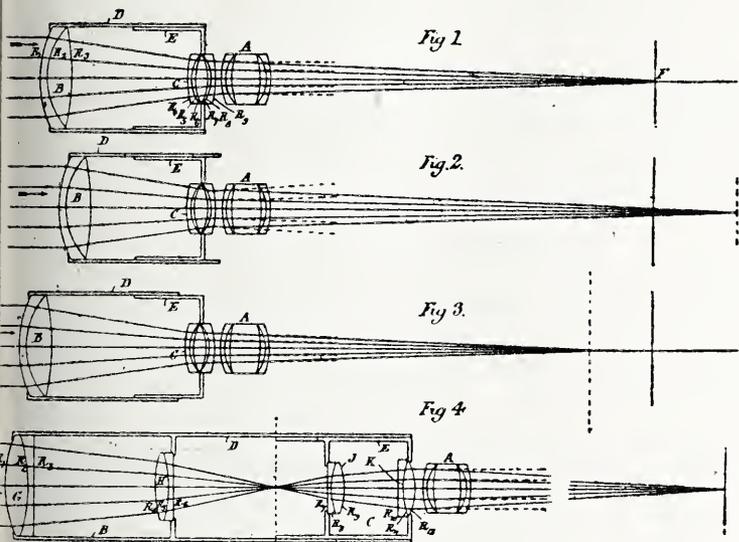

"The invention may, nevertheless, be applied to any ordinary lens to attain the ends of a tele-photographic system with greater mechanical convenience ; the additional system to screw into the place of the 'hood' of the lens.

"A is an ordinary photographic lens, and B and c are the lenses making up the enlarging system. B and c are mounted in tubes, D and E, sliding one within the other, so that the distances apart of B and c can be varied, as shown in figs. 1, 2, and 3. Fig. 4 is similarly constructed, but it has not been thought necessary to show more than one position.

"The lens, B, should be of the highest intensity possible, that is to say, of the largest diameter and shortest focal length convenient, so that, when combined with c for a given linear magnification, the initial intensity of the lens, A, to which it is added, may be maintained, or at any rate diminished in a less degree than would be the case with any posterior attachment to the original converging lens, A.

"The lens, c, should be of shorter focal length than that of the lens, A, again maintaining the largest diameter and shortest focal length possible, so as to maintain, in combination with B, the initial intensity for a given linear magnification when this is feasible.

"The power of the diverging lens, c (figs. 1, 2, and 3) should prefer-

ably be equal to or greater than the sum of the powers of the converging lenses, A and B.

"According to the degree of magnification required, I decide the ratio of the focal length of B to that of c.

"When the lenses, B and c, are placed at the normal separation, that is, at a distance equal to the difference of their focal lengths as shown in fig. 1, parallel rays incident upon B will, after refraction at c, emerge parallel. Now, if we place this supplementary system in front of any ordinary lens, A, which has been focussed for parallel rays (forming an image at F in its focal plane), it is obvious that the addition of this system, which transmits parallel rays, will not alter the plane of the focus, but will increase the linear dimensions of the image in a ratio equal to the ratio of the focal lengths of B and c.

"If the effective diameter of the aperture of the lens, B, is greater than that of A, it is evident that the loss of illumination, due to magnification may be compensated for partially or entirely.

"If the ratio of the effective diameters of B and A is equal to the ratio of the focal lengths of B and c, the illumination is identical ; if less, the illumination is diminished, supposing always that the full pencil of rays incident upon B is transmitted by c, which can be accomplished.

"If the lenses composing the supplementary system are brought nearer together, as shown in fig. 2, it becomes a system of variable diverging focal length, transmitting divergent rays from any object to the lens, A, thus permitting a still more enlarged image to be received at F, any distance beyond the focal plane of the lens, A, depending upon the separation between B and c for the time being.

"If the lenses, B and c are separated by any interval greater than the normal separation, as shown in fig. 3, it is obvious that it becomes a system of variable converging focal length. Parallel incident rays upon the supplementary system now emerge convergent, causing the image to be received upon a plane nearer to the lens, A, than its focal plane. In this case it will be seen that the linear magnification will be less than the ratio of the focal lengths of B and c, but the illumination may be greater than that of the lens, A, used alone. With the lenses separated as in fig.

3, it is evident that any near object may transmit parallel rays to the lens, A, with an enlarged image at its focal plane.

"It will be evident that near objects may be photographed with B and c, arranged as shown in fig. 2, but the plane of the image must be beyond the focal plane of the lens, A.

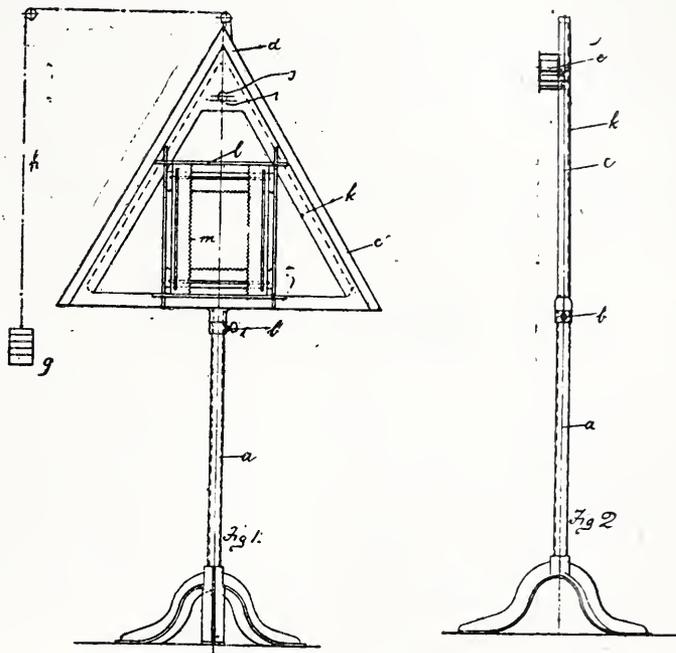

"The lenses, B and c, are each preferably aplanatic. The form ascribed to the lens, B, will determine that to be ascribed to c.

PRODUCING VIGNETTES IN COPYING.

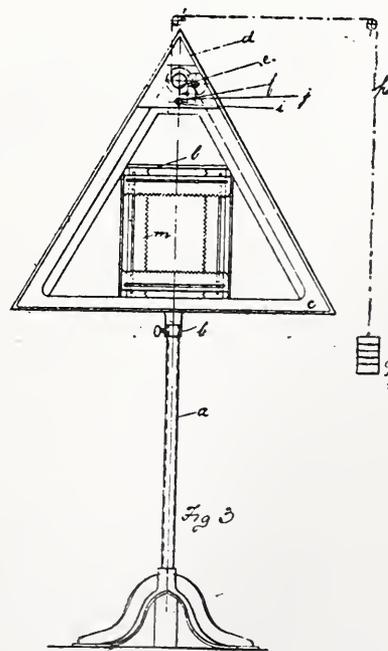

[Patent No. 5386 of 1899.]

The inventor, Mr. W. Holt, says :—

"I place an angular or other shaped frame, c, of a convenient size for photographing the picture to be copied, and at the apex, d, of this frame I place a chain of wheels, e. Figs. 2 and 3 ; actuated either by a spring

in a barrel (fig. 3), or by a weight, g, acting by means of a cord, h, on a wheel of any convenient size to react (by gearing) upon the chain of wheels, e, aforesaid. By either of the above means I cause the spindle, i,

to revolve, and upon this spindle, and revolving with it, I place an eccentric, j, upon which hangs the screen, k, constructed of any light material, such as aluminium, wirework, mica, cardboard, or otherwise.

"The motion given by the excentric, *j*, to the said screen, *k*, is an upward and downward, as well as a sidelong, motion, by which means a circular motion is produced towards the centre of the screen, where is fixed or hung the disc, *l*, carrying the serrated edges, *m*, which can be adjusted to any opening or position on the said disc by means of clips, set screws, or otherwise.

"I also regulate the speed of the said chain of wheels, *e*, by means of a brake or a fan, so that the rotary movement of the said disc, *l*, carrying the serrated edges, *m*, can be varied; and I also regulate the throw of the excentric, *j*, by means of a slotted sliding bar, so that the travel of the said screen, *k*, carrying the disc, *l*, and serrated edges, *m*, may be varied."

### THE BIRKENHEAD INTERNATIONAL EXHIBITION.

THE Hon. Secretary of this Exhibition, Mr. C. F. Inston, 25, South John-street, Liverpool, writes:—

"May I remind your readers of the fact that all entries for the above must be in my hands by Tuesday, 20th inst.

"I should also like to call the attention of those intending competitors, who already have copies of prospectus and entry forms, to an important alteration in one of the conditions, viz., the increase of limit in size of frame from 20 inches to 24 inches, at the entry fee of 1s. per frame.

"May I ask those workers who intend entering pictures to send on their entry forms in good time, as it will greatly assist in compiling catalogue, and to ask others who have not yet received prospectus to apply for them at once."

## Our Editorial Table.

### FERRIC AND HELIOGRAPHIC PROCESSES.

By G. E. BROWN, F.I.C. 130 pp. with Illustrations, price 2s.  
London: Dawbarn & Ward, 6, Farringdon-avenue, E.C.

As a practical guide to those iron printing processes which appeal to draughtsmen, engineers, architects, and surveyors, Mr. Brown's little book should prove of the very highest service. The working details of each process are fully and clearly given, and the illustrative examples convey to the experimenter a good idea of the capabilities of the various methods of printing; especially useful are the chapters on paper and sizing, and chemicals, but the entire book is one decidedly to be recommended to those interested in these branches of photographic printing.

### MR. LAMBERT MATTHEWS' LANTERNS AND SLIDES.

BESIDES sending us a catalogue of his optical projection apparatus, the portability, efficiency, and excellence of which have before now received recognition in these columns, Mr. Lambert Matthews, whose address is 97, Queen Victoria-street, E.C., has placed before us for our inspection a number of his lantern slides, which form the subject of a separate eight-page list. Amongst these are some very fine hoar-frost studies; their delicacy and brightness could hardly be excelled. Flowers and mottoes, South Devon, Haddon Hall, the Isle of Wight, North Cornwall, Suffolk, Norfolk, celebrated churches, and North London scenery, are illustrated by Mr. Matthews in his sets of lantern slides. The quality of these transparencies is remarkably good and brilliant, and we hope Mr. Matthews will find a large sale for them.

### THE PHOTOGRAPHIC DEALER'S ANNUAL.

Edited by ARTHUR C. BROOKES. London: Marshall & Brookes, Harp-alley, Farringdon-street, E.C.

ADDRESSED "to the trade only," and styled "a complete guide to photographic dealing," the scope of this new Annual will at once be realised. The contents include lists of trade addresses; trade names; scientific, photographic, and trade societies; formulæ; about thirty pages of articles addressed to dealers, opticians, &c.; legal information; weights and measures; and a mass of other data likely to be of service to those for whose benefit the book has been compiled. There are several illustrations, and the price of the Annual is 1s.

### THE BEAM CIRCULAR PRINT TRIMMER.

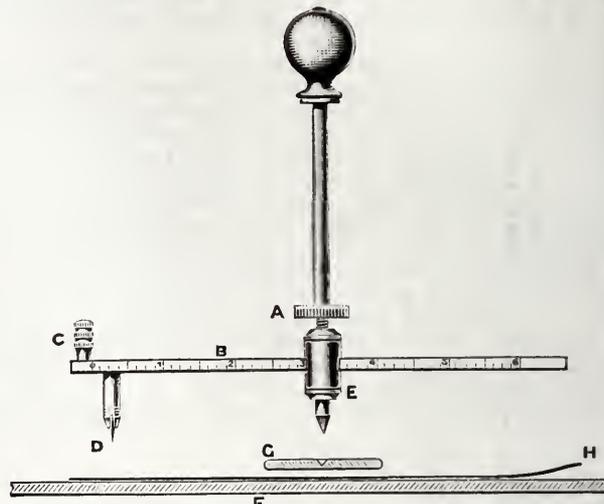

Manufactured and Sold by Geo. Houghton & Son, 89, High Holborn, W.C.

THIS is a simple and accurate little machine for cutting circular photographs. The method of using it will be obvious by a glance at the illustration. The beam, *B*, which is graduated in one-sixteenths of an inch, can be instantly set by means of the locking head, *A*, to any designed range from seven-eighths of an inch to six inches radius, and therefore circles from one-and-three-quarter inches to twelve inches diameter can be cleanly cut with one sweep round.

A one-and-a-half inch diameter plate glass circle, with a hole drilled partly through the centre, and the underneath part ground to prevent it slip-

ping, is supplied for the instrument to revolve upon, and the work clamped underneath is thus always in sight. For repetition work of a fixed size the position of the centre can be made to coincide each time with a predetermined point on the subject to be cut, thus guaranteeing an exact reproduction.

From personal examination we can say that the trimmer, which is

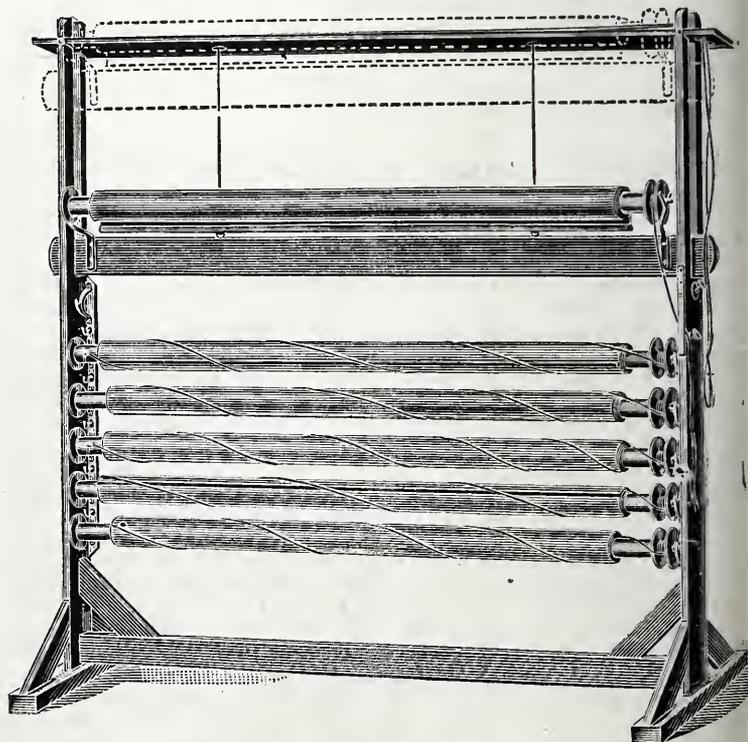

priced 7s. 6d., is light and strong. It is pointed out that all the parts are interchangeable, therefore the cutting wheel, or any other parts, can be replaced by new ones in case of accident, wear, or loss.

Circular photographs seem to be in greater favour than ever, and there could not be a neater or more expeditious method of producing than by this useful instrument.

### THE HOLBORN BACKGROUND STAND AND RACK.

Manufactured and Sold by Geo. Houghton & Son, 89, High Holborn, W.C.

THIS convenient system of storing and exhibiting a variety of backgrounds should be greatly appreciated by photographers who realise the importance of saving time in rapidly getting a background into position. In use, a background on a roller is attached to a sliding bar, which can be raised to any height, up to eight feet, by means of a double cord, or it can be fixed at any point by means of a side hook. Briefly, the back-

ground can be lowered from the top like a blind or fixed in any other desired position. The system is easy and noiseless to work.

Three rollers, with pulleys attached and three sets of rack fittings, are supplied with each stand, but any number of extra rollers, &c., can be had if required. Three iron rods are also included for inserting in the bottom hem of backgrounds to weight them. The price, complete with three rollers, &c., to take backgrounds 8 by 8 feet or 8 by 15 feet continuous, and any smaller size, is 5l. 10s.

## Studio Gossip.

**CAMERA VIGNETTES.**—M. Walde writes: "Replying to your correspondent from Hartlepool on the subject of camera vignetting, we place the vignette inside the camera behind the focussing glass. The background should be black velvet. We get fine vignettes this way."

**PROFESSOR NORSHEWESKI** is said to have invented an instrument, the principle of which is the sensitiveness to light of selenium and tellurium, both of which change their quality as conductors of electricity with a variation in the light to which they are exposed. In stating that the blind can see by this instrument, a relative meaning only is indicated. While the actual vision will be unaffected, they will feel the various effects of changing light by its action. It is claimed that a totally blind man has been enabled to find the windows in a room, and after some practice to distinguish approaching objects. The inventor hopes to make the instrument so efficient that the blind will be able to tell almost certainly when they are approaching an opaque or transparent substance.

¶ We read in a daily contemporary that some remarkable snap-shots of the war are being made in Paris. The French photographers have collected some old horses and guns, with some supers from one of the Paris theatres, who are made up as Boers or Englishmen, as occasion demands, the Boers being distinguished by their long whiskers and the Englishmen by their uniforms. Imitation breast works have even been built near Paris, and these are stormed by the supers, while the photographer takes his pictures. One single bit of truth is the picture of a ford. It shows a big tree at the left in the foreground, with a shallow river behind, and a few cows and sheep wading to the further shore. Whenever our forces have crossed a river anywhere, this picture has been used to illustrate the exact place of crossing.

**NATURAL HISTORY FOR LONDON CHILDREN.**—An interesting attempt is being made at the Passmore Edwards Settlement to awaken a taste for natural history among the children of the neighbouring schools who go to the Settlement. A natural history class is being formed for children in the higher standards, and Saturday expeditions into the country will be arranged as the spring comes on. As a preparation for this, a short course of popular lectures on "Bird Life" has been given by Mr. Richard Kearton, F.Z.S., to a large and eager audience of young people. The lectures were illustrated with lantern slides from the photographs which are familiar to readers of Mr. Kearton's "With Nature and the Camera," "Wild Life at Home," and "British Bird's-nests." Sir Edward Gray, M.P., whose interest in natural history is well known, took the chair at the opening lecture, and told the children in a few words who Mr. Kearton was, paying a high tribute to the value of his work.

**CAN PHOTOGRAPHY LIE?**—*Apropos* of the spring season, Mr. Martin R. Cobbett writes in the *Referee*: "Up to now, if one did not watch vegetable growth and the days' lengthening, particularly at the bottom end, taking the morning as the top, did not make you know a little bit where you were, you might be all abroad in your calculations in case you omitted to read your newspaper. I won't say that that instrument, like the photographic apparatus, cannot lie, because, in the first place, I am obliged occasionally to absorb the contents bills, which prove to me that newspapers, other than the *Referee*, are, some of them, talented liars, and as to the instrument in which Mr. Dion Boucicault reposes such confidence, I cannot too often repeat that, if that is truthful at heart, a skilful manipulator can make it misrepresent to his, the manipulator's, order and any extent. For instance, the proprietor of an American stud farm has sent me a photographically illustrated catalogue descriptive of his establishment, which comes out sweetly on paper. One of its most charming features is a picture of the 'home stretch' of a half-mile circular track. This the obliging instrument makes only about a hundred and fifty yards wide and three-quarters of a mile long for the particular section represented. The whole circuit calculated to this scale would be a few miles in length."

**FIRE.**—Shortly after seven o'clock on Friday evening it was discovered that the premises of Mr. A. E. Coe, optician and photographer, London-street, Norwich, were on fire. Smoke was seen issuing in dense volumes from the windows, and there was every appearance of serious mischief within. The Chief Constable, Mr. E. F. Winch, Engineer Shaw, and a portion of the fire brigade were on the spot within a few minutes of receiving information, taking with them a manual and a sufficient supply of hose. Mr. Winch divided his forces, sending part to operate at the back (in Castle Meadow), and with the other attacking the fire from London-street. The premises were closed for the night, and some little difficulty was experienced in locating the seat of the fire. All possible help, however, was afforded by the occupiers of the adjoining premises, Messrs. Allen & Daws, and Messrs. Cobbold & Son. As the emission of smoke from the top story windows seemed to indicate that the fire was on one of the upper floors of the premises, a fireman effected an entrance by means of a ladder through the top window. He found that the smoke was of a most suffocating character, and, having satisfied himself that there was no flame in that part of the building, he retired. In the mean time the fireman, who had gone to the Castle Meadow side of the building, found that the seat of the fire was in a little room at the back of the shop and adjoining upon the area. A length of hose was speedily run out, and a copious supply of water was poured upon the flames. The fire was at no time of any great dimensions, and the firemen were at first surprised to find that the water had little effect in subduing the flames. The explanation was that chemicals formed the greater part of the contents of the room where the fire originated, a fact that was made very apparent by constant little explosions, and by the pungent and stifling fumes given forth. The men worked for a couple of hours in a choking atmosphere, and finally removed all the smouldering goods and left the place in a state of security. The fire was confined to its place of origin.

## News and Notes.

**PHOTOGRAPHIC CLUB.**—March 21, at eight o'clock. "Orthochromatic Photography," by Mr. E. Sanger Shepherd.

The Brixton and Clapham Camera Club will hold a Smoking Concert at the Canterbury Hotel, Canterbury-road, Brixton (near Brixton and East Brixton Stations), on Thursday, March 22, 1900, at eight o'clock.

The West Surrey Photographic Society's Twelfth Annual Exhibition of members' work will be held at the Railway Hotel, 110, Rattersea-rise, S.W., on Wednesday, Thursday, Friday, and Saturday, March 23, 29, 30, and 31.

On each night during the week the South London Photographic Society held their Exhibition a collection was made on behalf of the *Daily Mail* A. M. B. Fund. During the collection, Kipling's poem was reproduced by means of the gramophone.

**ROYAL PHOTOGRAPHIC SOCIETY.**—Photo-mechanical Meeting, March 20, at 66, Russell-square, at eight p.m. A demonstration of "The Heliogravure Process," by Ignatz Herbst. The Exhibition arranged by the National Photographic Record Association is now open. Admission from ten to four on presentation of visiting card.

We have received a brief intimation relating to a competition in the production of lantern lenses for balloon tele-photography. This competition is open to French and foreign opticians, and particulars are obtainable of Lieutenant Renard, Directeur de l'Etablissement Central d'Aérostation Militaire de Chalais, Meudon (Seine et Oise).

**THE KODAK AT COURT.**—The privileged spectator of Saturday's Royal review at Buckingham Palace might have noticed, as I did (writes an *Echo* correspondent), that the Princess of Wales was preoccupied in taking snapshots of the Guards, and one ventured humbly to think that, if the "People's Princess" were graciously to bestow one of her khaki pictures on each soldier whose features have passed through the Royal lens, that photograph would be treated as a family heirloom for time immemorial. During the Queen's stay in town the Princess of Wales, both at Buckingham Palace and Marlborough House, has taken many photographs incidental of the war. Time and instantaneous photographs have been both secured, and then the negatives are, it would seem, sent to the Kodak Works at Harrow, where Messrs. Eastman develop and print the same with every care and despatch. Often it happens that some carefully timed exposure may reproduce so well in its original size that the Princess orders an enlargement; a visit to Sandringham would reveal several of these bigger pictures depicting memorable incidents in the busy life of the Princess. But it is in photographs of Tommy Atkins in company with his fellows and in khaki that the Princess has lately been exercising her stereoscopic zeal. It is understood that the Queen has been specially gratified to have seen, and to keep in her possession, permanent reminders of these stirring and loyal times which are the work of her own popular daughter-in-law.

## Commercial Intelligence.

MR. WALTER D. WELFORD has removed from Southampton-buildings: Chancery-lane, W.C., to new and larger premises at Warwick Lodge, 166, Romford-road, E.

The Process and Engineering Company, of 66, Deptford-green, London S.E., send us a copy of their new catalogue of dark rooms, &c., and add that they will be happy to send a copy of same on receipt of a card.

We are informed that the old established firm of Messrs. Blundell, whose business in the treatment of photographic residues has brought them into contact with our readers in all parts of the kingdom, are shortly removing from 162 to 190 Wardour-street, four doors from Oxford-street.

MESSRS. RAE BROS., of the Photographic and Optical Material Stores, 134, St. Vincent-street, and 77, Renfield-street, Glasgow, inform us that they have taken over the business of the late Mr. Campbell, 41, George-street, Perth, and intend carrying it on as practical opticians and photographic dealers.

MR. GEORGE MACAIRE, of 41, Charterhouse-square, Aldersgate-street, London, E.C., sends us his list of entirely new art electros, for illustrating books, magazines, catalogues, circulars, &c. The designs, which are numerous and varied, have been specially prepared for the use of up-to-date printers and publishers who desire their work turned out in an artistic and attractive manner.

## Patent News.

The following applications for Patents were made between February 26 and March 3, 1900:—

**PRINTING APPARATUS.**—No. 3728. "Improvements in Photographic Printing: Apparatus." B. J. HALL.

**EMULSIONS.**—No. 3736. "Improved Photographic Emulsion." Communicated by La Société Anonyme de Plaques et Papiers photographiques. A. Lumière et ses Fils, France. E. J. B. MILLS.

**CAMERAS.**—No. 3766. "Ophthalmic Cameras for Use in Ophthalmic Surgery and Attachments to an Ordinary Camera to effect the same purpose." K. M. MONTEATH.

- ROLL-HOLDERS.—No. 3771. "Improvements in or in connexion with Photographic Films, Film Rolls, and Roll-holders." J. E. THORNTON.
- PLATE-DRAINERS.—No. 3816. "Improvements in Appliances for Draining and Drying Photographic Plates." T. NORMAN.
- LANTERN SLIDES.—No. 3836. "Improvements in or relating to the Production of Lantern Slides." W. L. PARKINSON.
- PHOTOMETRES.—No. 4010. "Improvements in Apparatus for Measuring Intensity of Light." R. C. DRINKER.
- FOUSSING.—No. 4056. "Improvements relating to Mechanical Focus-finding Adjustments for Use in Photographic Enlargement and Reduction." A. FRUWIRTH.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
19.....	Bradford Photo. Society .....	{ Demonstration: <i>Practical Mounting and Frame-making</i> . Percy Lund.
19.....	Cripplegate Photo. Society .....	Secco Films.
19.....	Glasgow and West of Scotland .....	<i>Home Portraiture</i> . F. P. Moffat.
19.....	Kingston-on-Thames .....	<i>Orthochromatism</i> . James Cadett.
19.....	Southampton .....	Members' Lantern Night.
19.....	Stafford Photo. Society .....	{ <i>Notes with Illustrations on Messrs. Hurter &amp; Driffield's Researches</i> . H. E. Burn.
19.....	Whitby .....	Lecture: <i>Portraiture</i> .
20.....	Birmingham Photo. Society .....	{ <i>A Tour Across Canada through the Rockies and Selkirks to the Pacific</i> . A. H. Sharpe.
20.....	Bootle .....	{ <i>Kochin as a Developer</i> . Donald A. Nightingale.
20.....	Brixton and Clapham .....	<i>Colour Photography</i> . E. J. Wall, F.R.P.S.
20.....	Gospel Oak .....	General Meeting.
20.....	Hackney .....	{ <i>Rambles in Somerset and Devon</i> . Es T. Coombes.
20.....	Redhill and District .....	<i>Trip to New Zealand</i> . A. H. Dunning.
20.....	Royal Photographic Society .....	{ Demonstration: <i>The Heliogravure Process</i> . Ignatz Herbst.
21.....	Croydon Camera Club .....	Seventh Annual Rummage Sale.
21.....	Photographic Club .....	{ <i>Orthochromatic Photography</i> . E. Sanger Shepherd.
21.....	Southport .....	{ <i>The Photographing of Flowers</i> . H. T. Malby, F.R.P.S.
21.....	Southsea .....	Exhibition of Prize Lantern Slides.
21.....	Woodford .....	Demonstration: <i>Secco Films</i> .
22.....	Darwen .....	{ <i>A Month in North Wales with Caravan and Camera</i> . W. Allanson.
22.....	Liverpool Amateur .....	Auction of Photographic Goods.
22.....	London and Provincial .....	Open Night
22.....	South Norwood .....	{ Lantern Slides, Illustrating the Excursion of the South London Photographic Society to Belgium in 1899.
23.....	Borough Polytechnic .....	Practical Evening: <i>Carbon Printing</i> .
23.....	Bristol and West of England .....	{ Lantern Evening: <i>Architectural Slides</i> . Rev. T. C. Clark.—Exhibition of Prize-medal Framed Prints.
23.....	Croydon Microscopical .....	South London Society's Belgian Slides.
23.....	Glasgow and West of Scotland .....	Exhibition of Prize Slides.

### ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 7,—Major-General Waterhouse, I.S.C., in the chair.

#### THE NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.

Sir BENJAMIN STONE opened an Exhibition of about 130 photographs collected by the National Photographic Record and Survey Association. In the course of his address he congratulated the Royal Photographic Society upon the possession of adequate and suitable accommodation, and expressed the hope that it would avail itself of the magnificent opportunity thus afforded for doing a great deal of useful work. The Society occupied an exalted position as the head of the photographic world in this country, and as such it was called upon to give a lead to public thought and to exercise some little judgment in educating the public. From a photographic point of view, there could, in the speaker's opinion, be nothing more deplorable than the lamentable efforts at illustration which were at present disfiguring the public prints; in fact, there was scarcely a journal of which it might not be said that its pages were disgraced by the war pictures contained within them, the poverty of which must have struck everybody who fixed a standard such as that which he hoped was established by the Society. There were, however, occasional examples of excellent work and careful reproduction, and it should be the aim of the Society to do all in its power to foster such work, and to educate the public to recognise and appreciate it. Some of the lantern exhibitions, too, at places of amusement in London were equally bad, and steps should be taken to let the world know that that sort of thing was not the best photography that could or should be produced. With regard to the Exhibition now commencing, and to the aims and objects of the National Photographic Record Association, Sir Benjamin Stone said he hoped to be able to enlist a great deal of sympathetic assistance from photographers throughout the country for the purpose of preserving records of the current history of the time. Old woodcuts and drawings were often of immense value to historians and archaeologists, but incalculable importance would attach to accurate and precise photographic records of historic scenes and incidents, such, for instance, as the Queen's visit to her people in London under circumstances so full of interest and of pathos. At the present moment the work was not treated as a national duty, but the Association might so influence public

opinion that eventually—possibly even in our own time—the Government might appoint a public photographer, whose business it would be to make permanent records of suitable subjects for the information of generations yet to come.

The exhibits include twenty-three views of Windsor Castle, by Sir Benjamin Stone; Ely Cathedral and Romsey Abbey, by J. Bulbeck; old inns mentioned in Dickens' novels, by Mr. and Mrs. Snowden Ward; Old London, by E. Scamell; and others by Messrs. Oakden, Osborne, G. Scamell, Welch, Beck, Harold Baker, Oliver Baker, &c.; and the Exhibition will remain open daily from ten to four o'clock during the month of March and part of April, admission being free on presentation of visiting card.

MARCH 13,—Ordinary Meeting,—Mr. T. R. Dallmeyer, F.R.A.S. (President), in the chair.

#### BUSINESS.

The PRESIDENT announced that the Council had unanimously decided to confer the Honorary Fellowship of the Society upon Mr. H. P. Robinson, in recognition of the services rendered by him to photography and to the Society in the past. The announcement was received with hearty applause. It was also announced that the Photographic Society of Ireland had been admitted to affiliation.

Four new members were elected, and nine candidates for membership were nominated.

#### LIGHT IN THE DARK ROOM.

Mr. E. HOWARD FARMER read a paper on "The Illumination of Developing Rooms," in which he gave an account of detailed experiments and measurements which he had made subsequent to those referred to in a previous communication to the Society (in May 1898), and in a paper read before the London and Provincial Photographic Association, and published in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1900 (p. 803). Experiments had been made to ascertain the loss of luminosity occurring with the various light filters in general use, and the actual illuminating power in standard candles of several safe-lights, the results showing that there was an enormous loss of working light in consequence of the general opacity of the different media employed. For instance, with the best ruby glass obtainable, 92.5 per cent. of the light was lost, the intensity of that transmitted from a lamp of two-and-a-half candle power being only .19 candle power; with two thicknesses of green glass and one of orange, the figures were 99.2 per cent. and .025 candle power; and, with two thicknesses of yellow fabric, 96 per cent., and .1 candle power; the useful illuminating power with oil lamps in cases of safe illumination varying from one-sixth to one-twentieth of that given by a single candle. Further experiments with glasses and coloured solutions showed that a solution of potassium bichromate passing the same intensity of light, and apparently the same coloured light, as orange glass, was 250 times safer; and that ruby glass was about the same degree safer, but absorbed ninety-two per cent. of the light passing through it. These differences were measured with an electric arc lamp, in order to place the stopping powers of the liquid filters to actinic rays beyond question; but with oil lamps, owing to the comparative absence of the blue-violet and ultra-violet rays, the differences were less marked. A six per cent. solution of potassium bichromate was practically totally transparent to the red and yellow rays, and almost entirely absorbed the greenish-blue, blue-violet, and ultra-violet rays, so that with it the worker could retain the whole of the useful light and also increase its intensity without fear that the filter would pass the highly actinic rays. The practical outcome of all the experiments was the construction of lanterns giving an illumination of ten standard candles per nine cubic feet of space, one of which was shown. It consisted of two cylindrical glass jars one within the other, both open at the top, the diameter of the inner jar being a quarter of an inch less than that of the outer, and the space between them being filled with a six per cent. solution of potassium bichromate. An incandescent electric lamp, suspended from a wooden disc forming a cover for the jars, was switched on, with the result that the whole of the meeting room was filled with a beautifully soft light. Such a lantern had been in daily use at the Polytechnic for the past fourteen months, where it was placed on a shelf above the developing sink, so that the direct rays did not fall upon the plates, although during the last stages of development the plate could be held in the direct rays and the scale of densities judged with a degree of accuracy and confidence altogether wanting with ordinary lanterns. Orthochromatic plates could be manipulated in the same light by taking certain precautions to shield them as much as possible. At the close of his address, Mr. Farmer developed some plates in the ordinary light of the room by mixing with the developer a quantity of a one per cent. solution of xylidine scarlet to which a little fast yellow had been added, the plates, when fixed, showing an entire freedom from fog.

A brief conversation followed, in which Messrs. Vezey, Chapman Jones, Snowden Ward, Haddon, Bolas, Debenham, Warburg, and others took part, and in reply to which Mr. Howard Farmer said the lantern he had shown was not well adapted for use with gas or oil lamps on account of their heat, but he was pursuing his investigations with the object of finding a film which would take the place of the bichromate filter. A small Wenham lamp might be adapted, but it would be very expensive, and the heat difficulty would be overcome, if a gas flame were placed above a horizontal cell containing the bichromate solution.

Major-General WATERHOUSE said he had lately been experimenting with sulphate of cerium, the use of which as a reducer had been suggested by M. Lumière, and he had been very much impressed by the fact that a spectroscopic examination showed that it had a very dark band of absorption in the yellow, and a narrower band in the green. He suggested that this strong absorptive power in the region where orthochromatic plates were most sensitive might be turned to account in the direction of Mr. Farmer's investigations.

#### COMING EVENTS.

March 20, "A Demonstration of the Heliogravure Process, by Mr. Ignatz

Herbst. March 27, "Some Developers Compared," by Mr. Alfred Watkins.  
 April 3, Lantern Lecture, by Mr. F. P. Cembrano, "Slides Old and New."  
 April 10, "The Municipal Encouragement of Photography," by Mr. Thomas Bedding.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 8.—Mr. Robert Beckett in the chair.  
 Mr. A. J. BROWN showed an extemporised dark-room lamp, made of a stiff ruby-red material, which he had found very useful when away from home for changing plates by in a bedroom. It was conical in shape, something like an extinguisher, and was used with an ordinary night light. Like others, he had used red blotting-paper and other material at a pinch. He also showed a changing bag of an excellent design.

The CHAIRMAN said that, failing even such means as had just been shown, it was perhaps well known that a naked light, placed in the corner of a room and sheltered by one's coat, gave a fairly safe light for plate-changing purposes.

Mr. J. E. HODD sent up for examination a bromide enlargement made some time ago, and thrown aside as not being worth any care in consequence of a harshness caused by wrong exposure. Toned with copper, it resulted in a very fair print, with an apparent reduction of the dense parts and an intensification of the detail in the high lights.

Mr. S. H. FRY asked if there were any suggestions for the modification of the colours resulting from the copper toning. He observed that all the prints so toned had a peculiar dead plum-like colour, which, although pleasing in some instances, is not generally satisfactory.

The CHAIRMAN thought the improvement in the print sent by Mr. Hodd was due simply to the alteration of the colour by the copper toning. In reply to Mr. Fry, he said the resulting colour depended solely on the extent of the toning.

Mr. FRY thought that the toning of the print shown could not be said to be altogether an improvement, because the normal colour of the bromide print was more suited to the particular subject of the photograph. It was pointed out, however, that in its original state the bromide print was useless.

Mr. MACKIE had noticed that Mr. W. B. Ferguson's prints had not the pink tint which characterised some of the results he had since seen, but that they were of a good sepia colour.

The colours were also compared with those given by Eastman's hypo and alum treatment.

Mr. LEWIS MEDLAND showed slides from photographs taken many years ago on a visit to Christiania. There were several of street and market scenes, public buildings, and churches, the rest being views among the hills surrounding the Norwegian capital, and bits from them looking over the picturesque fjord and the islands, which are plentifully dotted about the immediate vicinity of Christiania. The lantern slides were on collodion plates prepared by Mr. Medland. He had cause sometimes to complain of opalescence as the emulsion became older, and wished to know the reason for the trouble.

Mr. MACKIE thought that there were several reasons, all of which he did not know, but one was that the repeated opening of the bottle allowed the solvents to evaporate, with a consequent increase in the proportion of water present to the ether and alcohol. There seemed to be no remedy for it unless one evaporated the emulsion to dryness and redissolved. As an alternative, the old batch might be used in which to make a new emulsion.

**Hackney Photographic Society.**—The Annual General Meeting of this Society was held on the 6th inst., and the report and balance-sheet showed the Society to be still in a very flourishing condition. The following is the result of the election of the new executive:—*President*: Mr. A. Horsley Hinton.—*Council*: Messrs. E. Farmer, W. F. Fenton-Jones, C. T. Fleetwood, F. W. Gosling, E. Puttock, W. Rawlings, J. J. Westcott, L. S. Wilks.—*Curator*: Mr. W. A. Ellington.—*Lanternist*: Mr. H. W. Dunkley.—*Delegates to Affiliation Committee*: Messrs. R. Beckett and W. Rawlings.—*Treasurer*: Mr. W. L. Barker.—*Excursion Secretary*: Mr. S. C. Stean.—*Hon. Secretary*: Mr. Walter Selfe.—*Assistant Secretary*: Mr. A. D. Fort.

**Redhill and District Camera Club.**—March 6.—Demonstration: "Ferguson's Method of Toning Bromide Prints with Copper," by Mr. J. STERRY. Formula used by Mr. Sterry was ten per cent. solution sulphate of copper, 13 parts; ten per cent. solution citrate of potassium, 100 parts; ten per cent. solution ferricyanide of potassium, 11½ parts. By this method a beautiful variety of tones can be obtained, from black to chalk-red; but, as it is not an intensifier but a slight reducer, the development of the print or lantern slide should be carried a little further. Mr. H. SPEZER gave a short lantern lecture on "Snowdon in Winter," which was greatly appreciated. Mr. FRANCIS H. ELLWOOD showed a negative he had recently taken on a Belgian plate nearly twenty years old.

**Bath Photographic Society.**—March 1, Mr. G. Norman in the chair.—Mr. W. MIDDLETON ASHTON (Hon. Secretary) read the report and statement of accounts. The report set forth that eleven lectures or demonstrations had been given at the indoor meetings during the year, this being the largest record of work done in any one session. There were also three excursions arranged and successfully carried out, in addition to those attended by several members of the Society at the Gloucester Convention. The Committee report favourably on the condition of the Society, the improvement referred to last year having been maintained. The attendance had slightly increased, probably owing to the meetings being held at half-past five. After defraying disbursements, there remained a balance in the hands of Treasurer of 15*l.* 14*s.* 7*d.* The CHAIRMAN thought the report was a most satisfactory one, and the balance-sheet spoke for itself. He moved its adoption. Mr. A. T. DAVIES (Keynsham), in seconding, expressed surprise that so much work had been done in the twelve months, it showed great vitality in the Society, and was extremely gratifying. The CHAIRMAN said his two years of service as President had come to a termination; it had been a period in which he had been very unwell

a good part of the time. He, however, did his best, and thanked the members for the post they have honoured him with. He wished to nominate as his successor the Rev. E. A. Purvis. Mr. AUSTIN J. KING had much pleasure in seconding Mr. Purvis as President. They were greatly indebted to Dr. Norman for the work he had undertaken during the past two years. Last year they suffered a shock when Mr. Ashman announced a balance of 11*l.* in hand, and now a further shock occurred in which 15*l.* had to be dealt with; such experiences in societies were quite unexpected. He was sure Mr. Purvis would be an able President, and they could not choose a better leader for the next two years. The Rev. E. A. Purvis then took the chair vacated by Dr. Norman. The following gentlemen were elected by acclamation Vice-Presidents: Colonel Sealy and Dr. Adcock (proposed by Mr. W. P. DICKSON, seconded by Mr. MOWBRAY GREEN). Committee: Dr. Norman, Messrs. George F. Powell, Austin J. King, Aug. F. Perren, Colonel Blathway, Messrs. D. P. Williams, W. P. Dickson, Mowbray Green, and W. Pumphrey, permanent member (proposed by Mr. M. H. SCOTT, seconded by Miss BRUERE). Hon. Secretary and Treasurer: Mr. W. Middleton Ashman (proposed by Mr. GEORGE F. POWELL, seconded by Mr. AUSTIN J. KING).

FORTHCOMING EXHIBITIONS.

1900.  
 March 26 ..... Twentieth Century International, Birmingham.  
 Walter D. Welford, 19, Southampton-buildings,  
 Chancery-lane, London, W.C.  
 ,, 26-31 ..... Photographic Society of Ireland. W. F. Cooper,  
 35, Dawson-street, Dublin.  
 April 3-7 ..... Birkenhead International. C. F. Inston, 25, South  
 John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

Correspondence.

\* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
 \* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

REFLECTOR HAND CAMERAS.

To the EDITORS.

GENTLEMEN,—In your issue of to-day's date is a letter from "R.N.R.," in reply to one appearing in your previous issue from "A.G.B.," in reference to a Reflector Hand Camera, which from the description is practically an exact specification of one of our make, known as the "Gambier Bolton," and seeing that we have extensively advertised this camera for the past twelve months, though not in THE BRITISH JOURNAL OF PHOTOGRAPHY, we are somewhat at a loss to understand why your two correspondents should have experienced any difficulty in obtaining such a camera.—We are, yours, &c.,  
 W. WATSON & SONS.

313, High Holborn, London, March 9, 1900.

[Perhaps "R.N.R." and "A.G.B." will communicate direct with Messrs. Watson & Sons.—Eds.]

RE KODAK V. ELLIOTT.

To the EDITORS.

GENTLEMEN,—Under the above heading various notices have appeared, and, inasmuch as in some instances the question of identity has been put to us, we beg to say that the action has no reference whatever to us.—We are, yours, &c.,  
 ELLIOTT & SON,  
 Barnet, March 12, 1900.

COLOUR PHOTOGRAPHY ON LANTERN SLIDES.

To the EDITORS.

GENTLEMEN,—The lantern slides were only sent as a justification for my statement that I believed that light does impress its colours on the plate, and that it only awaits correct means to prove its power of selection. Considering that the different coloured rays have each its own focus, this seems to me to be a reasonable inference. I see no reason for giving particulars of what is an unfinished experiment, further than to say that the operations were simply developing the negative, fixing and toning the print and all chemicals such as are used at the present time for the purpose.

I confess I should be sorry to see true colour photography become an accomplished fact.—I am, yours, &c.,  
 W. R. O'HARA (Lieut.-Col.).  
 West Lodge, Galway, March 10, 1900.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED :—

J. Davis, 256, Dalton-road, Barrow-in-Furness.—Three photographs of group of Furness Volunteers for South Africa.

T. N. Langton, 539, Attercliffe-road, Sheffield.—Photograph of Serg. Major Donald Duff. Photograph of the Active Service half Company Hallamshire Rifles.

DAVID JONES.—You would not be likely to obtain such chemicals at a local dealer's. Try some such firm as Hopkin & Williams, Hatton-garden, London, or Harrington & Co., Cork.

KARKI.—1 and 2. The firm does remarkably good work, and that is all we know of them. 3. No; not if opportunity is given the apprentice of acquiring a thorough knowledge of photography.

CLEARING ENLARGEMENTS.—R. COLES says: "Is it necessary, in making bromide enlargements, using metol-hydroquinone developer, to clear the prints with acid, as when the ferrous oxalate is used?"—No. That is one of the great advantages of the newer developer.

PHOTO-LITHO PAPER.—LITHO asks if gelatine-coated paper is to be purchased ready for sensitising, or must the user prepare it for himself?—The paper is sold ready to be sensitised. It may be had from Penrose & Co., Upper Baker-street, W.C.; Winston & Sons, Shoe-lane, and others.

GIACOMO.—It is against our rules to give written information of the nature asked for. We have seen the instrument in use many times, possess some most excellent results produced by it, and believe that its practical value is not exaggerated. You would not go far wrong in purchasing one.

VARNISHES, &c.—M. MERRETT asks "if the alcohol given in the formula for making varnishes (as in the ALMANAC) is generally the ordinary methylated spirits of wine?"—Yes. The ordinary methylated spirit, not "finish," will answer every purpose. Its specific gravity should not be more than about .830.

GUM-BICHROMATE.—E. O. S. sends us a piece of gum-bichromate paper he has prepared, saying that he cannot get a picture upon it, as all the coating comes off in the water, and asks the reason.—The trouble is due to there being far too much pigment in the coating, probably three or four times too much. The light cannot penetrate into the film.

KAURI GUM.—J. ATTWELL writes: "Where can I get some Kauri gum for varnish-making? I have tried at several oil shops, but cannot get it; they don't seem to know what it is, many of them."—We do not know where it is sold in small quantities, but probably some of the oil varnish-makers would let you have some. Try Parsons, Long-acre, or Crease, Cow Cross-street.

ADDRESS WANTED.—E. GOODFELLOW asks "for the address of the manufacturers of small ebonised frames (oval and round) with tiny brass rim inside, used for small circular photographs and miniatures."—The frames are supplied by most of the large dealers in photographic fancy goods, such as Marion's and others. We do not know who are the actual manufacturers of them. They are probably made on the Continent.

DEXTRINE FOR MOUNTING.—P. J. CONNOR writes: "I am, as an amateur, tired of having to mix starch every time I want to mount two or three prints. It has occurred to me that dextrine, which will keep good, when mixed, for a long time, would be far more convenient for the purpose. Is there any objection to its use?"—Dextrine is a convenient mountant, but, as met with in commerce, it is almost invariably acid, and therefore might act injuriously on the photographs.

LENS QUERY.—S. B. A. says: "I have two lenses by the same maker, one a *carte*, and the other a cabinet. They are both supposed to have the same ratio, but the smaller one seems to give a better exposed negative, with the same time, than the large one, but the negatives do not seem to have the same brilliancy, even with less exposure. They seem flat?"—Probably the black has worn off the inside of the mount of the *carte* lens; if so, that will account for the difference. Reblack the tube, and see the effect.

OBSCURING GLASS IN STUDIO.—J. & A. S. write: "Last spring and summer we were much troubled with the sun on the roof of the studio, and we expect the same difficulty this year. Can you tell us of anything that will make the glass like ground glass except paint, as that would be difficult to get off for the winter? We do not care to go to the cost of having the present glass replaced by ground."—Make some starch or flour paste, and add some whiting to it, then stipple the glass over with that. This can easily be washed off at the end of the season.

REMOVING SPOTS FROM PRINTS.—A. E. O. asks "the best way to get rid of spots on prints after they have been mounted. The spots in question are caused by dust in the negative or pinhole."—Touch out the pinholes in the negative with water colour, and the white spots, due to dust, on the prints also with water colour.

CAMERA VIGNETTES.—HAYNE. See leading article on another page. Similar results to that forwarded may be obtained by either of the systems described. It was probably done by having a screen the same colour as, or a shade darker than, the background placed between the sitter and the camera. The print is returned as requested.

STUDIO-BUILDING.—X. X. says: "I am about to build a studio at the back of the house. I proposed to build it of wood, covering the opaque portions with zinc. I submitted the plans to the Council, and the surveyor has condemned them. He says that a structure of wood and zinc is not to be allowed, as it is against the bylaws of the Council. What can I do? Is it against the Building Act?"—If it is against the bylaws of the Council, we should not advise you to contest the matter. The better way will be to modify the plans, and bring them in conformity with the regulations. It will save you a deal of bother in the long run.

SPOTS ON PRINTS.—LEICESTER says: "Will you kindly give me your opinion as to cause of enclosed spots all over print? As my customer does not suspect mounts, I have ventured to suggest that it was most probably the bronze printing, which I noticed he has had placed at the bottom of each mount."—The spots may possibly be due to the bronze powder, but the prints generally show signs of fading, as they have turned very yellow. Possibly that may be due to the mounts themselves, or to faulty manipulation on the part of the printer. As you are an analyst, we should advise you to test the mounts to see if they contain any injurious matters.

SITUATION WANTED.—A. D. M. says: "I am twenty years of age, and desire very much to get in a real good studio. I have had working experience of photography since I was thirteen, but not in first-class houses. Could I get a post in some good house to gain more experience at just a living wage, say, 18s. or 17? I am a fair retoucher and operator, and fair printer in C.C. and P.O.P., but not much portrait experience in platinum. I have had a good education."—In reply: We can only suggest that our correspondent should try the effect of an advertisement in our outer columns. We may say, however, that his experience hardly strikes us as sufficient to qualify him for a position in a first-class house.

MARKINGS ON A NEGATIVE.—SPOTS says: "I enclose a negative for your inspection, hoping you can advise me as to the cause of the bluish spots on the film of same; also if there is any means of preventing and remedying them. I have had a great many of my negatives spoiled in this manner; no matter what plates I try, it is always the same. In some cases the spots appear a day or so after washing; in others, many weeks. I had printed about fifty prints from the negative I enclose before the spots appeared."—In reply: Owing to insecure packing, the negative arrived smashed to pieces. However, there were left parts large enough to show the spots complained of. These are clearly silver stains. Moisture has been present between negative and paper during printing, hence the stain. The means of prevention are obvious. For the remedy, see the reply to Jakeman and Carver in last week's JOURNAL.

FADED PRINTS.—COLOUR says: "Enclosed I beg to send you two half prints marked A and B respectively. Specimen A shows the normal colour of fresh prints, and specimen B is a print which originally was about the same colour as A, but which has, as you will now notice, turned a chalky colour. I beg to ask whether you would kindly inform me what, in your opinion, is the most probable cause of the prints thus losing colour? I have thought the change is due to a defect in the paper, but the paper manufacturers maintain that the deterioration may be caused by chemical action resulting through a defect in the mounts."—The print has unmistakably faded. That, we should suspect, is due to its not being perfectly fixed and washed. We do not think that either the paper, or the mount, is at fault. Of course, we could not give any definite opinion as regards the mount without actually testing it—that any analyst will do for you if you cannot do it for yourself.

STUDIO-BUILDING.—A. MCHARRIE says: "1. Sketch shows present building as a shop, &c. It is proposed to raise the side walls of top flat, and convert top story into a studio. Seeing it is only twenty-two feet wide—too short for the studio across to suit the north light—what way would you recommend it should be done? Would a ridge roof thus, A, with glass on each side (east and west) or a one slope leaning roof be best, facing east? Would twenty-five be long enough for studio? How much glass should there be above, and at sides, and what height at eaves and top? 2. Would this style of studio be a suitable one, with the sloping roof facing north at far end of building and a gallery of wood for using the camera in to run out from it, thus; if so, please give sizes. What angle should a roof have?"—1. We should prefer the ridge roof with glass on the east and west sides. Twenty-five feet is a little short for a studio for professional work. Three or four feet longer would be more convenient, particularly in taking groups, &c. Have about five to six feet at the background end opaque, both top and sides, and then, say, about ten feet of glass, that is, supposing the studio is the full width of the building. 2. This form of studio is not to be recommended for portraiture, it is better adapted for copying. *Bolas' Work on Studio Construction*, Marion & Co., will give you much information.

### EX CATHEDRA.

THE new Copyright Bill may at any moment be presented to the House of Lords, but, at the time of writing, it has not been issued by the Queen's Printers. A study of Mr. Bale's paper, however, leads to the supposition that the terms of the Bill will be practically identical with those of the measure brought in last year by Lord Monkswell, which succumbed to an attack of that distressful Parliamentary visitation known as the massacre of the innocents—a fate which, we hope and believe, will overtake the present Bill next August. Last year's Bill was reprinted in the JOURNAL for May 26, 1899; we also give it at page 1008 of the ALMANAC for 1900, so that our readers have two sources from which a knowledge of the text of the measure may be obtained. In connexion with our references to the subject during the past weeks, we understand that the Committee of the Photographic Copyright Union purpose reprinting our remarks of March 2 and March 9, and circulating them in the form of a leaflet amongst photographers. We also learn, from a letter addressed to us by the Hon. Sec. of the Union, that the Committee, at a recent meeting, passed a vote of thanks to THE BRITISH JOURNAL OF

PHOTOGRAPHY for the attitude it has taken with regard to the projected Copyright Bill. This appreciation of our efforts, we need hardly say, causes us the liveliest gratification.

\* \* \*

IN another part of this week's JOURNAL an esteemed correspondent, a professional photographer, quotes figures to prove how hardly compulsory registration, with the attendant necessity of paying a shilling for each photograph it is sought to protect, would press on business men. We can quite conceive of cases where this enforced disbursement of registration fees, as contemplated by the St. John's Wood Bill, would make all the difference, in small businesses, between a tangible profit and a deplorably small one. The promoters of this meanly conceived Bill were probably ignorant of the fact that professional photographers' businesses are chiefly small ones, and cannot stand the financial strain which compulsory registration would put upon them. There would be less room for objection to the compulsory registration clause if all photographs registered within the six months were worth the outlay of a shilling for that purpose; but our readers thoroughly well know that the time specified is a ridiculously short period in which to expect a negative to mature in value.

\* \* \*

LAST week a meeting of the Traill Taylor Memorial Committee was held in London. The business included the election of some members of committee in place of those compulsorily retired. A statement of accounts was submitted by the Honorary Secretary and Treasurer, Mr. Everitt, and this was duly passed by the Committee. The expenses of administering the Memorial Fund are very slight, the cost of the medal and charges for printing and postages constituting practically the whole of the outlay. A sum of over two hundred pounds stands to the credit of the fund. It was decided to ask Mr. Frederic E. Ives to deliver the next lecture in November. If Mr. Ives accepts, as it is hoped he will, his subject will in all probability be colour photography. It will be remembered that previous Memorial lecturers have been Mr. T. R. Dallmeyer, F.R.A.S., who chose "Focometry" for his subject, and Major-General Waterhouse, who read an exhaustive and suggestive paper on "Teachings of the Daguerreotype." To those distinguished

men Mr. Ives would be a worthy successor, and he might be depended upon to make his lecture a valuable and informative one.

\* \* \*

WE observe with interest that photographic record work has attracted the sympathetic notice of American photographers. At the Franklin Institute recently it formed the subject of a discussion opened by Professor C. F. Himes, who, after applauding English efforts in this direction, made the erroneous if excusable statement that the National Photographic Record Association was "recognised by Parliament." Officially speaking, this, we believe, is not the case. Professor Himes suggested that the Franklin Institute, at whose meeting he was speaking, should take up record work, the main purpose of which, in his opinion, should be to make a complete, systematic, practical pictorial record of scientific and industrial facts of the day as they occur. "We make scientific and industrial history as rapidly as civil history, and should be, at least, equally careful for its preservation, for, unless human nature changes, the end of the twentieth century will want to know as much and as minutely about the beginning of it as we do now about that of the century just closing. We must now be satisfied with drawings of that period, often crude, and always limited in numbers; they can expect from us no less than the increased facilities for pictorial representation of to-day entitle them to."

\* \* \*

PROFESSOR HIMES made the further suggestion that provision should be made for stereoscopic pictures in the records. It is not, he pointed out, a question whether most or many persons are accustomed to or even can use the stereoscope, but simply as to whether such pictures have possibilities for representation and record that other pictures have not. Where position in space or form is to be represented, the value of such pictures is too well known to be discussed, but to emphasise the statement he submitted a stereograph of a series of sparks of a Holtz machine. Either single picture presented simply a bundle of interlacing lines; both combined in the stereoscope exhibited lines of definite shape, separated and located in space. So, in a single picture by the Röntgen rays, there is nothing to locate an object, but by two such pictures, stereoscopically related, the object at once assumes its proper position. We certainly agree with Professor Himes that stereoscopic record photographs are to be preferred to monocular productions, and we hope that, if the Franklin Institute takes the suggested work in hand, due provision will be made for this method of handing down to posterity photographic records of things which time and change will not let live. For initiating record work the Franklin Institute has the advantage of great powers of organization, and we shall be interested in watching if the idea takes root in America so firmly as it appears to be doing in this country.

\* \* \*

WE receive each month—and, indeed, always look forward to its appearance on our table—a copy of the *Photographer*, a monthly journal of jottings. This little paper is now in the fifteenth year of its age, and it is issued by Messrs. George Mason & Co., of 120–124, Buchanan-street, Glasgow. In a chatty manner it condenses the month's leading features in practical photography, as they are talked or written about,

and we very often come across little items of interest in the *Photographer* which have escaped our notice in running through our weekly batch of publications, which we number by scores. Mr. George Mason is responsible for the editorial work of our contemporary, the March number of which contains about seventeen pages of catalogue matter, eight of them being set aside for a list of accessories and furniture, lenses, shutters, cameras, and other photographic apparatus included in the spring stock-taking sale.

\* \* \*

THE lack of interest in the work of photographic societies shown by the members is a topic of constant recurrence in Great Britain. Apparently in far-off Madras, where we should have supposed the comparative absence of distracting causes would have conduced to enthusiasm in photographic work, the same trouble exists. The last number of the local Society's *Journal* draws a gloomy picture of the condition of affairs. It states that the Society has a large credit balance at the bankers and a good number of members, but that there is little or no interest shown by the members in the Society. "At the annual meeting, out of fourteen members resident in Madras, only two, in addition to four on the Committee, were present. During the whole of last year the monthly meetings were very poorly attended, and in the month of June there is the following entry in the minute book: "Monthly meeting held June 1899, only two members were present, the President and Honorary Secretary. No meeting was held in consequence." The number of members present at these meetings varied throughout the year from two to seven. During the hot-weather months it is not expected that many will be present, but through this last cold weather the same lack of interest has been shown. It was decided at the meeting held last month to have demonstrations at every monthly meeting, and for this purpose to employ a paid demonstrator and editor. According to the arrangement, post cards were sent to members, informing them that a demonstration on "The Camera" would be given by Major Van-Geysel, I.M.S. When the evening arrived, however, only four members on the Committee were present, and in consequence no demonstration was given." This is deplorable reading. Generally speaking, the interest of the public in photography is not on the wane, and such lassitude as that shown by the members of the Madras Society is hard to account for.

\* \* \*

THE use of the electric light is so considerable in photography, that it may interest many among our readers to learn of the inclusion in its numerous applications of one for the cure of some of the ills to which the flesh is heir. At a hospital in Chicago there is an electric-light bath, which is essentially a large wooden box, the walls and top of which are lined with mirrors and studded with incandescent lamps. The interior horizontal dimensions of the cabinet are  $3\frac{1}{2} \times 4\frac{1}{2}$  feet, with a height of about seven feet. The bottom, side walls, and the ceilings are lined with rectangular plate-glass mirrors, between which are narrow wooden strips with porcelain sockets for the incandescent lamps. In the lower half of the cabinet there are sixty lamps, and in the upper there are thirty-six. The cabinet is carefully insulated to prevent the radiation of heat. The door of the cabinet is in two parts, the lower one being lined with mirrors on the inside, and the top one formed of clear glass. The temperature varies from  $110^{\circ}$  to  $140^{\circ}$  F., and

according to the source of our information, the electric light bath is used for the treatment of nervous diseases, Bright's Disease, and fatty degeneration of the heart. There are only two similar baths in the United States. The interest attaching to the matter would be increased if it could be clearly stated how the rays from electrical incandescence operated in curing such a great variety of diseases.

#### THE USE OF MIRRORS IN PHOTOGRAPHY.

IN many instances in photography, owing to the peculiar nature of the subject, much may be done with the aid of mirrors to produce satisfactory results that otherwise would be almost impossible of accomplishment. A very general belief exists that mirrors are only of use in instances where a certain class of negatives is required for one or other of our photo-mechanical processes. No doubt, they are of great assistance to the process worker, and any one desirous of making direct reversed negatives for single transfer carbon work, but they cover a much wider field in the hands of an all-round photographer.

It is well known that exception has been taken to the use of any ordinary mirrors in photography, simply by reason of the fact that a mirror silvered at the back like we find all ordinary glass mirrors to be in common households, is certain to yield double images, one of these images being yielded by the silver surface of the back, and the other from the plain surface of the glass; hence, for the purposes of photography, specially constructed mirrors are employed; these may be of what is termed a double-surface form—that is, both the back and the front of the glass are silvered, though why such an expedient as silvering both surfaces should be resorted to it is difficult to see, for in reality only one surface is actually required. All surface-silvered mirrors are delicate tools to handle and work with, and, when they get out of order, they are liable to give trouble when used for photography.

Although it is quite true that an ordinary household mirror, which is merely silvered at the back, is liable to yield double images, these old-fashioned forms of mirrors were employed with much success many years ago—in fact, long before the advent of gratings in process negative-making, and it may surprise some of our modern workers to be told that no less an authority than the late J. Traill Taylor specially advocated their employment in portraiture, pointing out that, in many instances where this class of photography was being conducted in such situations as private rooms and the like, the system of working by reflection was greatly superior to a direct method of lighting. When using a mirror for this kind of work, it is pointed out that the double image of a person in front of a mirror is only visible when the angle composed of the incident and reflected ray is obtuse, and that such a condition need not be in force when using a mirror for taking a portrait in an ordinary sitting room.

We believe it was the late Mr. J. Traill Taylor who first drew attention to the means whereby an ordinary mirror could be employed for portraiture without yielding any double image, and, if we mistake not, his method of using a common mirror was very simple, and consisted in placing it upon a table close to any ordinary window and then arranging the sitter about a yard from it, and so seated as to present to the observer's eye a perfect profile. If such an image is very carefully inspected, the observer keeping so near the sitter as just

affords an uninterrupted view of the mirror, a solid image without any appearance of doubling will be apparent, and, when a camera is brought upon the scene, and a plate exposed in the ordinary way, the negative of the reflected figure, even when examined by a magnifying glass, will show nothing wrong. Of course, negatives produced in this manner are reversed, but, in many instances this is desirable, especially, as pointed out, for carbon printing.

There are certainly numerous instances where an ordinary household mirror would not by any means be the most useful to employ by reason of having to so pose the article as to show particular portions or points of the object. Large mirrors, specially prepared for photographic purposes, then become very expensive tools to acquire, and, no doubt, but few of the ordinary run of amateurs would be found willing to incur the cost of same. There is, however, another expedient, viz., the employment of black mirrors, and these any one can, with a little trouble, so rig up himself as to enable a very large field of operations being conducted. In floral photography, for instance, they are invaluable, and it is, perhaps, letting the cat out of the bag to make public their use in this particular class of photography, for it is just one of the good things that some of the old practical workers have managed to keep up their sleeves. Then, again, in cloud photography, the employment of a black mirror for this purpose will come as a revelation to those who have never seen the beautiful effects of the sky as reflected from the surface of a black mirror, and the ease with which splendid negatives are obtained of them. Of the innumerable classes of articles which are specially amenable to treatment by means of a mirror there is no need to speak particularly, suffice it to say that such articles as caskets, vases, and inlaid work of every description are at times only possible of being photographed by the aid of a mirror, and instances will be met with, such as where an open book has to be photographed lying flat, or nearly so, and in which all the printed matter has to be reproduced so as to be easily readable, in which, were it not for employing a mirror, it would be almost impossible.

Process workers know the immense advantages conferred by a good mirror, and, probably owing to such working, so that a wider angle can be transmitted therewith than is possible with prisms, generally prefer them on that account.

To the great body of amateur workers, however, the use of mirrors in photography may be said to be unknown, and, doubtless, the cost of a really perfect mirror, as supplied for high-class process work, would deter many from adopting them in their work. This latter objection, however, need not prevent any enthusiast from undertaking much interesting work, even among the class of subjects, such as clouds and floral photography, previously referred to, for a serviceable mirror may be made by any one without incurring much expense, after the following plan:—

In providing a mirror, it stands to reason the surface of the glass employed must not only be free from flaws, but likewise, if perfect definition is to be acquired in photographing by its means, its surface must be absolutely flat. To obtain this, there is no necessity for any one who merely intends experimenting in such as cloud photography, and on other subjects where extreme fineness of definition is not required, going to the expense of having a large sheet of glass specially ground and polished, for in most households or second-hand furniture shops an old mirror can generally be found, the

surface of which is quite true enough and free from flaws, which, on removing the silver compound from the back, by means of dilute nitric acid and a coarse or woollen cloth, will permit of its being converted into a very serviceable black mirror. To do which, on the back surface being rendered free from any silver deposit, let it be carefully coated with Bates's black varnish or a good sample of Brunswick black, which will produce a very serviceable article.

In using mirrors of this description, unlike those in which the back is coated with silver, the active reflection would appear to be from the front surface of the glass only, the light on passing through to the back becoming absorbed by the dark pigment, so that there is no trouble as a rule from double images when such mirrors are employed. The exposure to a sensitive plate, when some subjects of a non-actinic colour are being photographed, may require to be considerably longer with a black mirror than would be the case with an ordinary silver mirror, but the most perfect definition is capable of attainment. When dealing, however, with light objects, such as clouds, &c., the exposure, even with the black mirror, becomes very rapid.

Flower studies in every variety of colour are most beautifully rendered, and to those who have never experimented in this special branch of photography there lies a wide field for delightful occupation and study.

In using a mirror of any description, of course, the resulting negatives are reversed. Professionals, of course, easily overcome this difficulty, but to the general run of amateurs the printing of such negatives by means of carbon is, in point of fact, most desirable, and, should any one unacquainted with this delightful process of printing take to it, he will never regret doing so, for it is certainly one of the most beautiful and permanent processes we possess.

**Home-made Papier Maché.**—Long before the days of the popularity of celluloid, *papier mâché* had a reputation, and was of much use in photography for, among other things, the marking of dishes, &c., at once light, durable, and, when well japanned, impervious to water. *Papier mâché* in bulk is an excellent material for repairing and filling in cracks in utensils, repairing woodwork, and, on occasion, forming a substitute for wood for small articles; it is lighter than wood, and as plastic as clay. It is easy to make, may be kept in a damp place, or covered with wet blotting-paper for several days. An ounce of paper torn into shreds (old newspapers will answer) is soaked in hot water for some hours, and stirred about with the hand till it forms a perfect pulp; the water is squeezed out till the mass of pulp weighs about a quarter of a pound, then add to it half of a quarter of a pint of hot glue, and work all well together. To this add and well amalgamate about three or four ounces of plaster of Paris. The mass will stiffen in a little while, and must be kept well worked till homogeneous, and another quantity of hot glue added equal in quantity to the first, and the whole vigorously mingled. It must then be tried as to its consistency; a little pressed with the thumb on to a smooth board should stick closely; if it does not, add a little more glue; it must be sticky. If it should be too lumpy, or get hard before use, it may be hammered into proper consistence again.

**Becquerel Rays.**—The study of bodies emitting rays somewhat similar to Röntgen radiations, and termed, after their first investigator, Becquerel rays, continues to excite much interest. We have on several occasions brought before our readers accounts of the work done by M. and Mdme. Curie, and there have recently been read at the Paris Academy papers by these investigators, and by M. Eugène Demarçay and M. Becquerel himself. The latter chemist

obtained some nitrate of polonium, the new radio-active metal, and found that, when excited by a magnet, the effects, as exhibited on a photographic plate, were almost the opposite of those obtained with radium, another of the Curies' discoveries. M. Becquerel finds the radium rays resemble the cathode rays to a certain extent, but not entirely. Thorium also has been found to be radio-active, more so than the metal uranium itself, though less so than radium and polonium. These substances all render the platino-cyanide screen fluorescent, though less so than the Röntgen rays.

**The Action of Gelatine on Copper.**—A very curious reaction between gelatine and copper is described in the *Journal of the Russian Chemical Society*, which may possibly be proved to have a bearing on the copper process of toning bromide prints. Mr. Alexander P. Lidoff, in the course of some experiments in another direction, discovered that an alkaline solution of gelatine, after acting upon a piece of copper fringe placed on it, had taken up 3.54 per cent. of copper. It is thus possible that in Mr. Fergusson's process the copper once deposited may be held by the gelatine itself in combination as well as by virtue of its simple precipitation or substitution.

**The Purification of Water.**—Permanganate of potassium is well known for its use for this purpose, the retention of the pink colouration being a sign of the precipitation of the organic matter originally present. The drawback to the process is the fact that concurrently with the precipitation of the manganese is the liberation of the alkali of the salt in it of calcium or potassium. M. A. Tixier, in the *French Journal of Pharmacy*, proposes to get rid of this defect by the use of a mixture of aluminium and of barium permanganates in solution. The solution he used at a strength of 35° B., which contained 290 grains of permanganic acid per litre, and 7 per cent. of alumina. It is added to the water to be purified till a permanent pink colour is produced. After standing for twenty-four hours, it is fit for use, when passed through a carbon or other filter.

**Albumen and Gelatine.**—At one time in the history of photography the exact composition of albumen formed a subject of perennial interest, and it was attempted to be shown by some writers that the want of permanency in albumenised paper prints was due to the sulphur which formed an integral part of the albumen, as shown by analysis. The advent of gelatine was hailed as getting rid of this source of danger; but such could not be the case. Take, for example, some recent examinations of gelatine by Herr Carl Thore Mörner; he finds it to contain 0.2 per cent. of sulphur present in the gelatine, but not as an impurity. With regard to albumen, Herr A. A. Panormoff finds it by no means the definite chemical compound that some have believed it to be. He states that different birds' eggs contain different kinds of albumen, and he proposes to name each egg albumen according to its characteristics. Thus hen egg albumen easily crystallised from ammonium sulphate solution he proposes to term albumin, and the more soluble albumen albumin. In other cases, to the form which is least soluble in the ammonium sulphate solution he gives a name which is formed by adding the termination "in" to the zoological name of the bird, the more soluble albumens being similarly designated by words ending in "inin" and "inidin" in the order of increasing solubility. Thus the amorphous albumen of pigeon's egg is columbin, and the more soluble crystalline albumen is columbinin.

**Cloud Negatives.**—About the time of the equinoxes—vernal and autumnal—there is usually to be seen a greater variety of cloud effects than at any other period of the year. Therefore the present is an excellent time for securing a stock of cloud negatives for future use. Why we call special attention to this subject just now is that probably many outdoor workers have by them some unexposed plates, left over from last season, that they would not care to risk the use of in the field or far from home. Now, such plates,

though they may have somewhat deteriorated by keeping, may well be utilised for taking stock cloud negatives upon. In fact, in the majority of cases they will answer quite as well for this purpose as freshly made ones. Hence our timely hint that supposed useless plates may be put to a profitable use.

### JOTTINGS.

It is many years since the late Mortimer Collins charmed us with his musical "Summer Song," drawing his inspiration from the sparkling life of the Upper Thames as it is lived when the days are long and sunny and the river is fringed with the greenest and leafiest ribbons from Nature's loom. A scrap from one of the verses—

"Pleasant it is in a boat to glide  
On a river whose ripples to ocean haste,  
With indolent fingers fretting the tide,  
And an indolent arm round a darling waist,"

was jingling through my head a week or two back when I spent an afternoon taking photographs of the flooded river near our village. But it was neither the time nor the place for the interesting sentimentalisms of which Mortimer Collins so neatly sings. Under grey skies and flanked by bare, black trees, the swollen river raced down between the locks, and at the weirs there was a sullen roar such as might have come from the beat of the angry seas on a rock-bound coast in winter. The Thames was out for miles, and the flood mark of 1894 stood not more than a few inches from the face of the violent stream. The one or two boats I saw out did not glide along, they were simply swept down the river, and their occupants had other work to do than fretting the tide with their fingers or curling their arms round ladies' waists. The Thames in full flood gives no opportunities for the gentle philanderings that are permissible in June, when, to again quote Mortimer Collins (who, by the way, was one of the most polished writers of *vers de société* of his time),

"The river's swift ripples flow tardier far"  
than in flood time.

BUT now the river has fallen to its normal level, and steals lazily under the bridge without boiling into fresh-water foam as it meets the arches. Faint spots of pale green are seen on the dark branches of the trees, and in the backwaters busy hands are furbishing up the house boats. Spring is near. The floods and the vast lakes which covered miles of the flat land have gone, but my photographs remain to remind me of the thorough-going and remorseless manner in which the risen waters efface landmarks that are of daily interest and importance to the surrounding population. Submerged towing paths; main roads cut off for leagues; dwelling-houses, familiar hostelries, and snug farm-houses formed into the geographical expressions of islands, and approachable only by express punt; wayside meadows converted into sailing lakes; trees and other objects sticking up here and there, apparently out of limitless sheets of glass—these and many other phenomena gave one the chance of making photographs of the Thames in aspects not familiar to the summer visitor. Opportunist work in photography is always exciting and interesting, and I must say that I enjoyed the little task of making a few exposures on these flood subjects. The time may come when the Thames near our village will never be flooded, for, a mile or two above us, an enormous reservoir and eight miles of aqueduct are being constructed, so that the inhabitants of East London may always have a plentiful supply of drinking water drawn from the Thames. If those thirsty people take all our flood water, my photographs will be additionally interesting to me, and will constitute an imperishable record of the last of the local inundations. But it remains to be ascertained if the aqueduct "intake" would diminish to a measurable extent the heavy floods which the Upper Thames has just felt.

THE word "record" in the preceding paragraph reminds me of a note I made to mention a little point that occurred to me in connexion with the National Photographic Record Association. There

is no question that, under the enthusiastic guidance of Sir Benjamin Stone, good and useful work is being done in collecting photographs of historical buildings and other subjects, which students of the next century may be glad to inspect at the British Museum. It would be a pity if that work were not assured of continuance, for, as time goes on, the effacing hand of the public improver seems to move with increasing power and celerity, and landmarks disappear with a rapidity that is shocking to those who look with a reverential eye on the material manifestations of age or antiquity. As a case in point, the many thousands of readers of this JOURNAL who visited its old office in York-street, Covent Garden, between the years 1864 and 1898, may be interested to know that the street has been continued across Catherine-street into Drury-lane by the simple plan of demolishing all the houses between those two thoroughfares. The work has been in progress some time, but it seemed to be completed in a night. So, distant readers of Dickens's *Bleak House* should be concerned to learn that the burial ground where "Jo" pointed out to the veiled Lady Dedlock the grave of his benefactor ("'E was very good to me, 'e wos") has been replaced by the smooth wooden pavement of a new street, which virtually starts at the old office of the JOURNAL.

SUCH are the changes that are made in the noiseless flight of time! To return to the National Photographic Record Association: In the interest of the work which it has in hand, it is desirable to know if the Association is really an association in anything more than name. Are its members made by election, and is the executive constitutionally chosen? Have arrangements been provided for continuity of administration? What is the subscription to the Association? Where are its offices? Failing Sir Benjamin Stone and Mr. Scamell, who will carry on the work? I ask these questions in no hostile spirit, but because I feel that upon the answers that can be given to them hinges the vital matter of the Association's future. If it is a constitutionally organized body, and continuity of existence and management have been assured, well and good; if not, the sooner matters are put on such a basis the better for the continued success of the scheme to further "record" photography. Some years ago there was a very good society for photographing ancient buildings, but it quietly and unobservedly dropped out of existence, mainly, I fear, because of the imperfections of its constitution. I do not wish to see such a fate overtake the National Photographic Record Association, and that is why I am directing attention to the matter.

MY keenness on photographic record work this month is, no doubt, due to the glamour of the historical associations with which I may describe myself as being now in permanent touch, and amidst which much of my photographic work is necessarily done. For, across the moor that bounds our village, the proud towers of Windsor (never so proud as now!) soar above the tree-tops, and in the immediate foreground the eye falls on the old house which includes some parts of the original mansion in which King John slept the night before he signed Magna Charta. Almost within stone's throw of this house lies the quiet mead on which he met the grim company of Barons who were to wring from an unwilling monarch some of the most cherished liberties of our race. And, if these beautiful prospects do not suffice to stimulate the mind to carry itself back to the remote and stirring past, a turn of the head will lead the gaze to an old grey stone on the river's bank which bears these words: "The ancient stone above the inscription is raised upon this pedestal exactly over the spot where it formerly stood, inscribed 'God preserve ye City of London.' 1285." From mediævalism and the middle ages, to which these dates and scenes waft you back in imagination, it needs some very powerful agency—such as the prosaic-looking camera at your side—to recall you. For nothing is so soothing to the tired mind as to turn back the hand of time a few centuries, and live a while amongst the silent ghosts of the dusty, shadowy past.

TONING formulæ for developed bromide prints have been plentiful enough these last fourteen years, but few of them have survived the test of constant practice. Uranium, with which at one time I

made many experiments, gives a pleasing range of red and brown colours, but the deposit is not sufficiently stable to resist atmospheric and other influences. The image, in fact, is very prone to fade or change colour. I have not tried Mr. Fergusson's plan of toning the picture with a copper compound, as described in the *JOURNAL* of Jan. 12 (p. 30); but, chemically regarded, it seems to be one that should give a reasonably permanent deposit. I have seen some very effectively toned prints produced by this method. At the Birmingham Exhibition one of Mr. Wellington's admired Leaderesque landscapes, having a "standard brown carbon" colour, was toned according to Mr. Fergusson's plan, and I have rarely seen a bromide print more artistically tinted. When so able a worker as Mr. Wellington speaks in terms of approval of copper toning, photographers generally may take it that there is "something in it," and I therefore recommend my readers to follow so excellent a lead.

LADYSMITH DAY, March 1, is, I suppose, burnt deeply into the minds of all of us. There are many things by which I shall always remember the day, for it was full of notable happenings. While the loyal tumult was rising in the streets, I spent an hour or so studying Mr. Craig Annan's delightful photographs in Russell-square, in company with two of the most distinguished portrait photographers of the time. A *verbatim* report of the comments made on Mr. Annan's work would, no doubt, make good reading. Such things, however, are not to be. What I wish more particularly to refer to here was the fact that one of my friends, who admittedly stands at the head of his profession, passed all the time he could spare in London at the picture galleries studying the masterpieces of portraiture, ancient and modern. If I wrote a thick book, I do not think I could give the young portrait photographer, anxious to succeed and produce good work, a more valuable hint than this, namely, to constantly seek inspiration from great paintings. Going from one subject to another, I am glad to hear that, in June, we are to have, at 66 Russell-square, a one-man show of Dr. Emerson's masterly photographs. These beautiful works, so full of the placid charm which distinguishes East Anglian life and landscape, will, I am sure, come as a revelation to many who only know a great photographer, and one of the most gifted of men, through the medium of his books, which, in themselves, have assured their author an imperishable reputation.

COSMOS.

#### AMERICAN PHOTOGRAPHIC CRITICISM.

MR. F. HOLLAND DAY, whose photographic work, in most parts admirable, is much appreciated in this country, supplies Mr. Sadakichi Hartmann with an opportunity of contributing to the March number of the *Photographic Times* (New York), a highly laudatory criticism, some extracts from which may interest those of our readers who are unaware of the extreme lengths to which this sort of thing is just now being carried in the United States. Mr. Day's portraits, according to his admirer, are "plastic psychological syntheses of the persons represented." But the article is crowded with many other equally good things, probably seriously written—and seriously taken in Boston and New York. Says Mr. Hartmann:—

"Mr. F. H. Day's photographic art is an art full of delicacy, refinement, and subtlety, an art full of deep thought and charm, full of dreamy fascinations. This is as much as to say that it is not the kind of work to please everybody. It appeals rather to the intellectual and the refined—to those, in a word, who can understand and can feel—such as those who love and appreciate Mr. Day's work; their support is enough to establish an artist's reputation, and that in a manner far preferable to the notoriety achieved by much of the transient, garish work of the day. I know of no photographer who can drape a figure more pictorially or adorn a man's or a woman's hair with flowers in a more picturesque manner. He has proved in a rapid succession of admirable pictures what possibilities lie in decoration. His decorative feeling, however, is not complete in itself or affected by nothing beyond itself. It is dependent on many external incongruities, as dramatic effect, poetical sentimentalism, æsthetic emotion, and at times even commonplace story-telling.

"He strives to render our modern life more harmonious. No easy task, truly, in this age of ours, when everything tends towards the effacement of character, when uniformity of dress is almost universal, when the levelling of the classes is every day causing our personality to disappear more and more. A risky task, too, and one requiring a rare gift

of perception for its thorough accomplishment; for it is really a fine and fertile subject of study for an artist, conscious of his mission—an age like our own, full of elegancies and refinements of every kind, and instilled with a feverish activity, throbbing perpetually throughout the civilised world, with its thirst for the joys of the moment, its love of pleasure and luxury, its craving for a life crowded with the greatest possible variety of sensations. Mere talent for arrangement does not suffice, and neither does it suffice Mr. Day. He is a psychologist, ever on the alert, ever seeking for this—to grasp and to express in material form the individual characteristics of his subject. What do I care for the blood flowing beneath the skin, for the network of swelling and throbbing veins? What matters the sight of the straining muscles full of life, if the invisible part, the mystery of this living being, be absent from the picture, if I cannot enter into communication with its spirit? I care not how brightly, how truly, the eyes may shine, if I know nothing of the thought, the fancy, animating them. Even a flatness, or the projection of a bone, or the irregularity of a line, a deformity even, gives evidence of some habitual trait which, if at times contradictory, is, nevertheless, always full of interest.

"As I said before, Mr. Day's art is one of delicacy and subtle refinement. To prove this, examine carefully the figures he so delights in. His subjects are intensely alike with the inner life, they seem heedless of all that might tear them from their own secret dreamings. They make no attempt at futile agitation, but are content with the thoughtful gestures of repose, the special poses and attitudes of pensive grace, in which the artist has fixed them. Look, for instance, at his portrait of Miss Ben Yusuf. How well he has caught her habit, her ordinary way of being, 'all her little ways.' One feels at once that the artist has photographed her with his heart, if such a thing can be said. The portrait thus conceived becomes a plastic psychological synthesis of the person represented." [According to the published reproduction, this is a very ordinary photograph of a tastefully dressed young lady leaning against the door of a room.—Eds. *B. J. P.*]

"We find that all his scrupulously studied figure compositions have a setting of their own and a special atmosphere. Mr. Day will have none of that strict exactitude the importance of which is so greatly exaggerated by most photographers. Imagination has too strong a hold on him for that; hence the air of harmony pervading his pictures—a skilful harmony, perhaps somewhat pedantic and affected at times, but generally deep and concentrated, substantial and mellow, expressing exactly what he wishes to express, adding merely enough to transfigure, magnify, and generalise reality.

"The decorative side of Mr. Day's work can, in my estimation, be hardly overvalued. It is this which impels him to those subtle effects of light and shade, and those surprising arrangements of costumes and accessories, giving to each of his figures just those surroundings which are proper to that particular subject, which give such an irresistible charm.

"Mr. Day is fond of strange and wayward fancies. He likes to strike rich chords, but muffled, as it were, by the mist of his dreams. What delicate poems can be found among his studies after the nude—those graceful, youthful forms showing in calm repose on a background of some idyllic landscape! They appear in the twilight air, in which he likes to envelop them, like lovely figures of the past, telling of glories that have faded long ago. They are nearly always broad in treatment, without a trace of coarseness.

"He has always lived the life of an æsthetic, who appears to all, at the first glance, as an extraordinary extravagant personality, one that excites immediate curiosity. Strange stories, both astonishing and ridiculous, are told about him, and he in no way objects to them. In serious dignity, he applies more of his imagination, for instance, to his mounting of prints than to his artistic productions themselves. To pose is a necessity to him, as it is only when he believes himself something out of the ordinary that he can accomplish good work, which is always an endeavour to realise something out of the ordinary.

"Many anecdotes are circulated about him. Once a stranger visited him, and, knocking at the door, heard a most cheerful 'come in,' but, entering, found to his great astonishment nobody present. He looked around everywhere, but could find no trace of Mr. Day; then suddenly he heard a clucking sound, he looked up and saw Mr. Day sitting on a shelf right under the ceiling, wrapped in an Oriental costume, smoking a water pipe! There exist also dozens of variations of the curious theme, how he made his 'Christ studies.' He left Boston with a whole troop of male and female models, accompanied by a waggon load of costumes, a wooden cross, and other paraphernalia, for some secluded country spot in the vicinity of the modern Athens. Out there he went

at once to work, had the cross erected on the top of that hill, built a sepulchre, and prepared for a long stay. Then began the rehearsing of his company, and the sacred tragedy was played more than a hundred times on the top of that hill, while curious farmers on their waggons with their entire families, came from far and near to gaze at the strange spectacle. There is still some doubt in the profession whether he posed himself for the Saviour or not."

We hope Mr. Holland Day's head will not be turned by the extravagant praise to which he is subjected in the foregoing appreciation. Great praise is undoubtedly due to him for the daring and unconventional photographs he produces with such persistence and ability, but the qualities "read in" to them by his gushing admirer are not obvious to persons of less excited imaginations, so that it is probable Mr. Hartmann's florid exaggerations may have the effect of attracting no inconsiderable amount of ridicule as well as sympathetic curiosity towards the photographic work of Mr. Day.

#### PUBLIC ART CONGRESS AND EXHIBITION—PARIS, 1900.

THE city of Paris, through its Municipal Council, has undertaken the organization of the Second International Congress of Public Art. An International Exhibition of corresponding works of Public Art is organized in connexion with the Congress. The Exhibition will be open, at least, during the months of July and August; the sessions of the Congress will be held during the first part of August.

The programme of the Congress comprises those questions which deal with the creation and protection of the artistic aspect of cities and the beauty of country sites. These questions are divided into three series:—

1. Historical Questions.—Concerning the preservation, restoration, mutilation, or destruction (a) of groups of public buildings created in ancient, modern, and contemporary periods with a view to the artistic aspect of cities; (b) of groups of monuments, edifices, works of art, gardens, plantations of trees, &c., which contribute to make up the artistic aspect; (c) of country sites universally admired for the beauty of the works of nature, and consecrated by history, legends, and the habits of the people.

2. Technical Questions.—Concerning the principles of aesthetics applied to cities, the conditions of such application, the processes of preserving and restoring the exterior parts of monuments, edifices, houses, decorative works of painting and sculpture, &c.

3. Administrative Questions.—Concerning laws, regulations, and all other administrative means for creating and protecting the artistic aspect of cities and the beauty of country sites.

The Exhibition will have the same general divisions as the Congress. The Historical Section will exhibit, by means of reductions in relief, drawings, paintings, and photographs, the more interesting examples of preservation, restoration, mutilation, and destruction of entire groups of public buildings, places, and city streets, which present an artistic aspect, and country sites renowned for their beauty. Such examples, so far as possible, should be accompanied by parallel representations of the state of the groups before and after their restoration, mutilation, or destruction. The Organizing Committee especially invites municipalities and associations to have drawn up for this section graphic maps and tableaux, showing the results of their action or the progress of vandalism in their city and country.

The Technical Section will exhibit, in the same manner, the best types of ancient, modern, and contemporary application of the principles of aesthetics to cities: monuments, houses, statues, fountains, stands, public clocks, posters, signs, lamps, gratings, tree, shrub and flower plantations, squares and gardens, specimens of the various processes for preserving and restoring the exterior parts of monuments, houses, and decorative works of painting and sculpture.

The Administrative Section will exhibit various documents, laws, decisions, regulations relating to the creation and protection of the artistic aspect of cities and the beauty of country sites; publications, reviews, journals, and books in which the questions of the programme of the Congress are treated; and, either by the original or in reproduction; posters, placards, notices, &c., and all other curious documents—ancient, modern, and contemporary—relating to the public supervision and protection of monuments, public art works, inscriptions of highways, public places and monuments, &c., which may be found in archives, libraries, museums, and private collections.

The Secretary of the Congress, to whom communications should be addressed, is M. Marius Vachon, Hôtel-de-Ville, Paris.

#### EXPOSURE: THE WATKINS SYSTEM.

At the meeting of the Doncaster Camera Club on March 12, a lecture on "Exposure: the Watkins System" was read by the President of the Club, Mr. G. T. B. Woodley.

The lecturer commenced by explaining that four influences govern exposure, which are subject to variation, viz., Speed of Plate, Opening of Lens, Subject, and Light, and the reason why such a thing as correct exposure was necessary lay in the limitations of the sensitive plate.

If a plate were exposed in different parts to varying amounts of light, a scale of varying densities would be obtained, and for a plate to be correctly exposed the highest light must not make a greater impression on the plate than the minimum indicated, otherwise the familiar grey appearance of over-exposure would result. On the other hand, the exposure must be sufficient for the darker details of the subject to make some impression, or the familiar "clear glass in shadow" of under-exposure would be evident. The quality of a plate depends upon the distance between the minimum and maximum range of exposure, and not upon the speed; a poor-quality plate permits of very little variation in exposure without getting under or over-exposure.

In 1873 Vogel (followed later by Scott, Hurter & Driffield, and others) brought out tables of rough estimates of the value of light at different hours of the day and at different seasons of the year. In 1887 Burton published rough estimates of exposure required for different subjects; these two tables were practically the base of all the slide calculators such as (Ilford, Actinograph, Cadett's, Phillips, &c.) on the market. With these calculators the variation of the light from the average has to be estimated by the human eye, which is notoriously ill adapted for the purpose.

Actinometers had been used by a few advanced photographers for many years, from which the relative value of light is ascertained by the time a strip of sensitive paper takes to darken to a standard tint, and, since Abney adopted bromide paper instead of chloride paper for these instruments, their readings had been reliable even in comparing the dim light of an interior with the bright sunshine outside.

Mr. Watkins invented his exposure meter in 1890, and several attempts had been made prior to this time to utilise the reading of the actinometer by the aid of slide rules; but the mistake had been made of using Burton's subject classification, and although the outdoor light was tested by actinometer, any variation for woods, interiors, &c., became a matter of estimation. By the Watkins system the light actually falling on the subject is tested, the system is therefore essentially different from the older methods and does not use the same tables.

Of the factors named, only light, plate, and diaphragm need be considered in most cases; it is only when the reflecting capacity of the subject varies largely that subject need be considered.

The audience were here reminded that, although plates by two different makers might be marked with exactly the same H & D speed numbers, the speed of the plates might be different, owing to want of uniformity in the standard of light and developer used by the makers; Mr. Watkins therefore tests all plates monthly or oftener, and issues a "speed card" suitable for use with his meters.

The actinometer takes into consideration all classes of lighting and makes allowance for light obstructed in any way, as the sensitive paper is only acted upon by the light actually falling upon it; this is why street scenes (being bounded on each side by high buildings) do not receive so much light as an open landscape, and therefore require longer exposure. In tables, a variation of at least 1 to 100 would have to be estimated by the eye alone.

All objects of an average colour, such as those met with in every-day life, were classified under one subject number, and it was only in cases of exceptional variation in reflecting capacity of the subject, such as in sky, sea, or white objects—snow, or very dark or non-actinic objects—that variation need be made in the subject number.

Distance makes no difference in exposure except when the subject is so close as to necessitate the extension of the camera more than usual, thereby altering the focal value of the diaphragm, or when (as frequently happens in this country) the atmosphere is charged with haze, which reflects a large amount of light on the subject.

The lecturer showed the advantage of the slide-rule system combined with the actinometer, and explained that, when once the instrument is set for plate and stop, the exposure can be read off against the actinometer time without further setting. Although apparently complicated, he considered the original system of having a separate pointer for each factor was the simplest in the end, as each value is marked down with the pointer as found, and when plate and diaphragm values are set they often remain unaltered through a day's work.

In photographing interior work he had introduced the system of exposing the meter at the same time as the plate, inserting such a stop in the lens as would make the camera exposure equal to the tinting of the actinometer to the standard tint. This should be further amplified by the use of a tint which takes only one-quarter the standard time to tint, and still further by observing that the actinometer paper commences to show signs of darkening exactly in one-sixteenth of the time required to colour to the standard tint, thus larger stops and quicker plates might be used by adopting either of these modified methods for interior work.

In pinhole work the system was equally applicable, as Mr. Watkins had published in his exposure book comparative values of different-sized needle holes with ordinary diaphragm numbers; therefore, if a No. 10 needle were used, and the opening named *f*-35, the pinhole was sixty times less than the actual diaphragm, *f*-35, and required one minute instead of one second, which would be indicated on the meter for *f*-35.

In hand-camera work the lecturer had found great comfort and convenience resulting from the use of the hand-camera calculator, which told him that views under trees were capable of a snap-shot exposure when the eye decided that they were not; it was also useful in well-lighted places for determining the proper speed of shutter for any particular stop.

In conclusion, the lecturer remarks that he only dealt with the tools of our science, and, because a man uses over or under-exposure to obtain a particular artistic effect, let him not despise methods giving a definite standard, which he may follow or not as the mood seizes him.

The lecture was illustrated in a very complete and interesting manner by a number of slides, and was greatly appreciated by the members present.

#### PER-SALTS AS REDUCERS.

[Translated from the *Bull. de la Soc. Franc. de Photographie*.]

IN reducing negatives, an effect the opposite of that produced by persulphate of ammonium is sometimes desired, *i.e.*, an increase in the contrasts. This is, indeed, the effect most usually obtained when plates or paper prints are reduced, and it is of particular service when an over-exposed and over-developed negative is in question. Reducers commonly used may be divided into two classes, according to their capability of acting in one or two solutions. Those of the second class consist of one solution which converts the silver into a compound soluble in thiosulphate of soda, and of another consisting of the fixing bath, precipitation, or other chemical reactions, preventing the incorporation of the two reagents in a single solution. Such is the copper chloride and thiosulphate reducer.

The first class includes those in which this oxidising agent and the solvent of the product of its action can be kept in one and the same solution. Such is Farmer's reducer of ferricyanide of potassium and thiosulphate.

The two-solution process is less convenient in practice, because the progress of reduction cannot be watched; and, although Farmer's reducer possesses distinct advantages over copper chloride, the facts that the mixed solution acts irregularly unless kept constantly in motion, and, moreover, soon loses its reducing power, are against it. The former fact—its irregular action—prevents the course of the reduction being readily watched, because every time the negative is removed from the bath the solution must be washed off, or markings will appear.

We have therefore made a number of experiments with a view to obtaining a single-solution reducer, and commenced the examination of a number of per-salts of various metals.

*Ferric Salts.*—Ferric salts, especially the nitrate and sulphate, act as oxidisers of the silver film in neutral solution, according to the equation—

But this reaction cannot be applied in practice, for the reason that the negatives treated with it acquire a deposit of oxide of iron or insoluble basic salt when they are washed to remove the excess of iron salt, and the gelatine, although transparent, remains stained light yellow. We found that this defect of the reducer could be remedied or avoided by the use of a bath of weak acid—such as an organic acid—after reduction or by adding citric acid or citrate or lactate of ammonia to the ferric solution, but this addition, besides complicating the process, introduces a serious disadvantage—the colour of the silver image changes during reduction, and takes on a yellow tint distinctly different from its original colour.

We have made comparative tests on a series of other per-salts, of which the following is an account:—

*Salts of Manganese Peroxide.*—We examined the action of those salts of peroxide of manganese which can be dissolved in water and can be kept without alteration. Only certain salts of organic acids possess these properties. We prepared these compounds by the action of aqueous

solutions of the various acids or a strong solution of potassium permanganate. Hydrated peroxide of manganese is precipitated, and dissolves in an excess of the cold solution of the acid. The brown solutions thus obtained with citric, tartaric, and lactic acids reduce the image, but the solutions do not keep unchanged, and, further, stain the gelatine yellow and alter the colour of the silver deposit. They do not, therefore, possess much practical interest as reducers.

*Salts of Peroxide of Titanium.*—When titanous acid,  $\text{T}_2\text{O}_3$ , is treated with hydrogen peroxide, titanium peroxide,  $\text{NO}_3$ , is produced, which is soluble in various acid solutions forming the salts of peroxide of titanium. Those salts, the acids of which form soluble silver salts, act more or less as reducers. Among these, titanium sulphate acts fairly energetically as a reducer.

Its action is rather curious. The gelatine film bearing the image is detached in thin films, in proportion to the action of the solution, without the underlying gelatine being in any way affected. The reduction seems to be due not to simple solution of silver, but also to removal of the film itself. The action is most apparent in the most transparent portions, a very perceptible relief being produced, and the fine details being eaten away.

*Mercuric Salts.*—Among the salts of this metal, mercuric nitrate is alone capable of being used for the reduction of silver images.

It is a salt melting at  $6^\circ \text{C}$ ., and is therefore liquid at the ordinary temperature of the air. A dilute solution of it is necessary in order to diminish its action on gelatine; 10 c. c. of the liquid salt in 200 c. c. of water is a suitable strength, and a solution made in this proportion rapidly reduces the silver image. The colour of the deposit does not show any particular change until the plate is washed, when a very appreciable yellowing takes place, a fact which rules the nitrate out of court as a practical reducer.

Other mercuric salts, when used in the same way, react with the silver of the image to produce insoluble mercury salts, which give the film the white and opaque appearance familiar in the case of bichloride of mercury.

In addition to the salts of the metals enumerated above, we have experimented with a number of others containing the metal in the higher stages of oxidation. Chromic salts, chromates, arseniates, vanadates, tungstates, and others all gave negative results. The best results came from cerium salts, and particularly from ceric sulphate.

*Ceric Salts.*—Those per-salts of cerium, the electro-negative radicle, which gives a soluble silver salt, such as the sulphate or nitrate, can be used as reducers, and act very rapidly without giving rise to any of the evils inseparable from the use of ferric salts. The sulphate obtainable in commerce is the best, the nitrate becoming rapidly reduced in aqueous solution. Neutral ceric sulphate, it must be noted, precipitates in presence of much water, but, if a little sulphuric acid be added to the solution, an acid salt results which has no distinctive action on gelatine even in strong solution. This salt can be used in concentrated solution, the exact strength merely determining its rapidity of action. Its ready solubility in water, the good keeping properties of the solution when acidulated with sulphuric acid, its rapidity and uniformity of action up to the exhaustion of the solution, make this reducer an extremely convenient reagent. It can be used for bromide prints without the danger of yellowing the whites.

The salt is best kept in a ten per cent. solution to which 4 c. c. of sulphuric acid per 100 c. c. is added. This acid solution does not act on gelatine, since it goes to form a feebly acid salt of cerium. This ten per cent. solution acts vigorously, and yet does not remove fine details in the shadows in preference to other parts of the negative as does the well-known ferricyanide and thiosulphate reducer. Its rapidity of action is easily controlled by simple dilution. A very rapid reducer, which acts more on the opaque portions of the negative than on the shadows, is produced by making a five per cent. solution of ceric sulphate.

*General Conclusions.*—We may thus conclude that, with the exception of ceric salts, none of the per-salts of the metals present any decided advantages as reducers of the silver image; that ceric sulphate possesses certain points which render it superior to Farmer's reducer, *viz.*, its preservation in a single solution, and others referred to above.

As regards the chemical reactions which take place when these various per-salts act on a silver image, they evidently consist of solution of the silver by a part of the acid of salt in proportion as this salt has been reduced according to an equation such as we have given above for ferric salts. In all probability this reaction takes place in every case when the heat of formation of the per-salt is less than the heat of the formation of the silver salt. It is thus possible to understand why certain per-salts reduce whilst others, united to the same electro-negative radicle, do not.

LUMIÈRE FRÈRES ET SEYEWETZ.

#### DEVELOPING TRAYS.

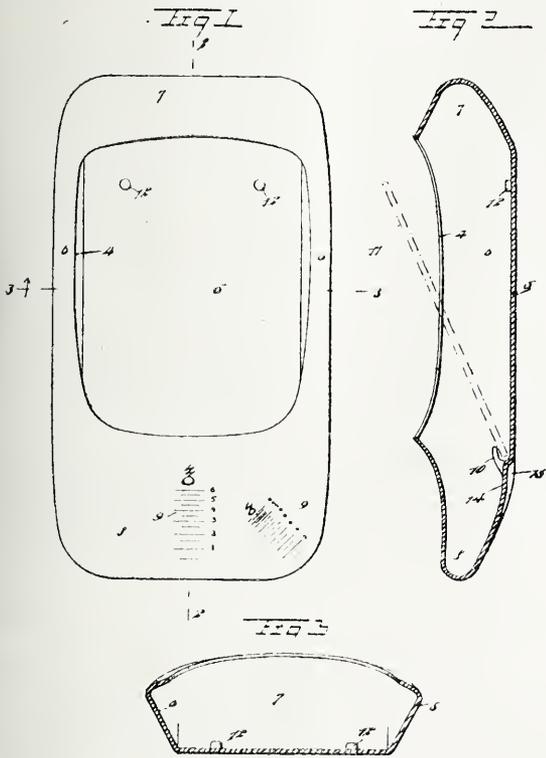

[Patent No. 7611 of 1899.]

THE invention of Messrs. Sheppard and Leech.

The tray is formed of glass, so that the whole structure is transparent, and is shaped with an opening, 4, in its top, which opening is of less area than the bottom, 5, of the tray, which arrangement is produced by ex-

ending the sides, 6, outwardly and upwardly, and thence inwardly, to form a partial top overhanging the bottom of the tray, to prevent the spilling out of the solution. The inwardly extending top of the tray forms at each end a cup, these cups being respectively designated 7 and 8, in one or the other of which the solution will be contained when the tray is placed on end; for example, when in the position shown in fig. 2. The top of the tray at the point of the cup, 8, is formed with two or any number of graduations, 9, thereon, by which graduations the quantity of the solution placed in the tray may be determined, it being understood that for this purpose the tray should be held in the vertical position shown in fig. 2, thus causing the solution to settle in the cup, 8.

The bottom of the tray is provided with two spurs, 10, adapted to hold the edge of the plate, and at the opposite end of the tray slight projections, 12, are formed on the bottom, so that the plate when rested in the tray will bear on these projections, and thus be held out of contact with the bottom of the tray. The opening, 4, in the top of the tray is so shaped that the plate may be introduced into the tray to be engaged by the spurs, 10, and to bear on the projections, 12, and this opening is also tapered slightly toward the cup, 8, so that, when the tray is canted forward slightly from the position shown in fig. 2, and the plate, 11,

is thrown outward as the view shows, the side edges of the plate will engage the sides of the opening, 4, and the plate will be prevented from falling completely out of the tray. This construction enables the plate to be freely examined during the process of development. At the end of the tray, beneath the cup, 8, the bottom of the tray is formed with a raised portion, 14, which is broken by two downwardly extending ribs, 15, which ribs run longitudinally with the tray, and each describe a like curve which merges into the bottom surface of the tray. Each end of the tray is curved upward in the form of a rocker, thus permitting the tray, when placed on a table or other level surface, to be pitched or rocked longitudinally, for the purpose of effectually washing the plate with the solution. The ribs, 15, permit the tray to move easily in this pitching movement, while, at the same time, the raised portion, 14, serves, when the tray is in horizontal position, to throw all of the solution in the vicinity of the plate, causing the plate to be effectually washed, and avoiding the retaining of any of the solution at points of the tray where it will serve no useful purpose. The plate is introduced into the tray by moving the plate longitudinally towards the spurs, 10, and in a line inclined with reference to the bottom of the tray, so that one end edge of the plate is engaged with the spurs, whereupon the plate may be dropped through the opening, 4, upon the projections, 12. The removal of the plate is effected by a reversal of this operation.

PHOTO-MECHANICAL PRINTING SURFACES.

[Patent No. 16,944, of 1899.]

THE invention of Herr E. Rolffs, of Siegfeld, who says: I have solved the problem of producing roller surfaces by photography. I take a negative or a diapositive made upon translucent film paper, and transmit the

same to the roller by pressure. The translucent film paper is provided with a net consisting of cross or longitudinal lines.

The roller to be treated is first covered with a substance sensible to the action of light, as, for instance, chrome gelatine. The negative is pressed upon the roller, the adhesion being increased by an oily substance introduced between the negative and the roller. The roller then is presented to the action of the light, brought into the dark room, the negative and the oily substance is removed, the roller is washed and then etched in usual manner.

The etched picture consists of engraved points or lines, which are determined by a net corresponding to the net previously applied to the translucent film paper. When a net of longitudinal lines is not employed, but one consisting of cross lines, care has to be taken that the lines of the picture do not run parallel to the blades of the ductor, but inclined to the same.

By means of this arrangement it is possible to prevent any engagement of the ductor into the lines of the drawing, whereby the picture during a short time completely would be destroyed.

From the aforesaid it will be seen that when the translucent film paper containing the negative or the diapositive is arranged in a certain manner upon the roller, the picture can be transmitted to the roller by photography, and rendered visible to the eye when etched.

PHOTOGRAPHIC EXHIBITION AT STRATFORD.

THE landscape of the east of London, as viewed from the windows of a carriage on the Great Eastern Railway, on a journey from Liverpool-street to Stratford, is not calculated to inspire the pen of the poet or to excite the enthusiasm of the photographer in search of the picturesque. The ugly factory buildings, the squalid dwellings, the overhanging smoke, and the canals, whose green slime forms almost the only verdant spots to be seen, all tell of lives of evil, and even for a fierce struggle for existence. Amid such surroundings one would hardly expect to find the æsthetic side of photography much in appreciation; nevertheless, we found on our visit to the Seventh Annual Exhibition of the Photographic Section of the Great Eastern Railway Mechanics Institute, on Wednesday, the 14th inst., a collection of photographs which would be creditable to a society with far higher pretensions to importance.

The Exhibition was held in the Lecture Hall of the Institute, and it was as well arranged as the circumstances would seem to permit. It was divided into the usual classes and there was also a class for engineering subjects. The landscapes, seascapes, and river scenery were, on the whole, good, that is to say, the average was a good one. There were few pictures which stood out from the rest, but, on the other hand, there was an absence of work which proclaimed the hand of the novice. As a rule, the mounting and framing were in good taste, and this applies to all the exhibits. In portraiture, &c., the work was distinctly over the general average in a society class. In architecture the section had done well, and, judging from the number of entries in the class compared to the whole number, this branch is a popular one. This is, no doubt, due to the predilections of the photographic instructor to the Institute, Mr. H. W. Bennett, F.R.P.S. We were surprised to find that an equal interest does not appear to be taken in engineering subjects. Situated as the Institute is, in the midst of the vast engineering works of one of our greatest railways, the importance of this branch of photography would seem to have no chance of failing to be recognised.

It is only human, however, to prefer to pursue one's hobby away from the spot upon which the daily bread is earned, and, in neglecting the opportunities which the members of this Institute have open to them they are, perhaps, only following a natural law. We have nothing to say against the quality of the photographs shown in this class, but we were disappointed at there being so few. Some of them were particularly interesting to us, particularly a series illustrating the various stages in the construction of the locomotive (No. 1900) intended for the forthcoming Paris Exhibition. The engine is not yet finished, and the series, therefore, is incomplete; but, when complete, it will form a record—perhaps a unique record—the value of which can hardly be over-estimated. We would remind the members that the making of pretty pictures by photography is not the most valuable use to make of it. The pictorial side of photography is a pleasant one to follow; but the greatest value of photography is in recording facts, and the members have the every-day opportunity of recording facts which though, perhaps, not very interesting from their familiarity to their own circle, are of interest outside it, and the records may become of the greatest importance when in the nature of things our present methods will become methods of the past. We would point out, too, that workshop life, though prosaic enough looked at generally, frequently presents opportunities for pictorial treatment. The Royal Photographic Society's medal was awarded a short time since for one of a series of pictures taken in a gas works.

The members' lantern slides were good, and the Open Class of fair average quality. The Judges were Messrs. F. Seyton Scott and H. Wilmer, F.R.P.S., in the General Classes, and Mr. J. Holden in the Engineering Class.

THE AWARDS.

Members' Classes.

- Class A (Landscape).—Silver medal, J. K. Ayling; bronze medal C. W. Harris.
- Class B (Architecture).—Silver medal, J. K. Ayling.
- Class C (Seascape and River Scenery).—Bronze medal, J. K. Ayling.
- Class D (Portraiture, &c.).—Silver medal, C. W. Harris.
- Class E (Instantaneous)—No award.
- Class F (Engineering Subjects).—Silver medal, A. Woolford.
- Class G (Lantern Slides).—Silver medal, C. S. Scott.

Open Class.

Silver medal, C. W. Walker; bronze medal, W. E. Inston and M. D. Kerr.

Our Editorial Table.

THE SANDERSON HAND CAMERA.

Manufactured and sold by George Houghton & Son, 89, High Holborn, W.C.

It would be hard to mention a desirable movement which the Sanderson Hand Camera does not possess. Available, as the illustrations show, either in the hand or on a stand, it permits of lenses of very great focal length being used, or, by a baseboard adjustment, the front of the instrument may be brought as near as two inches to the focal plane. For use as a hand camera (fig. 1): The front is rigidly fixed in an upright position, and it can then be drawn out and focussed, an engraved

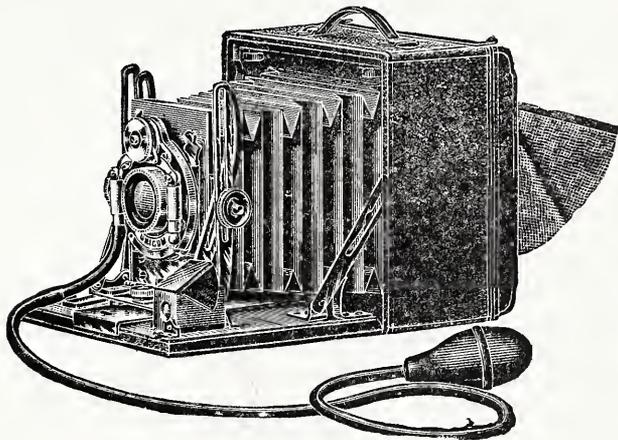

FIG. 1.

scale being provided for the purpose. For use as a stand camera (fig. 2): By raising the front, it is freed from the rigid supports provided for hand-camera work, and the universal movement is at once obtained by means of the slotted arms. The great rise of front which is then obtainable is of special advantage for architectural work in confined spaces, and does away entirely with the tilting of the camera and the necessity of swinging the back. The extension (fifteen inches in the quarter-plate size) is produced by means of the travelling frame in con-

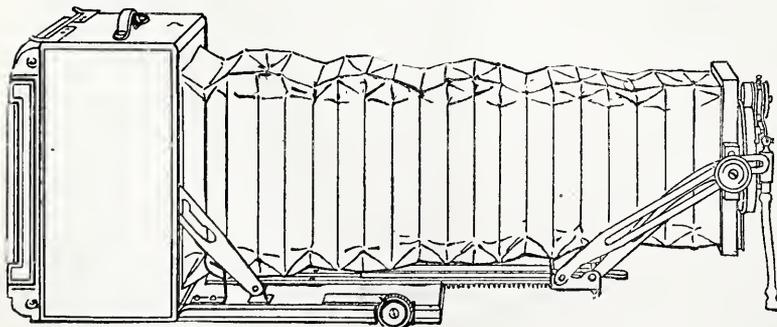

FIG. 2.

junction with the slotted arms (fig. 2), sufficient to use the single combination of a doublet lens or for copying to the same size. To describe the instrument fully: The camera is of polished mahogany, covered externally with fine grain leather. It is fitted with removable focussing screen with spring hood, reversing back, rack and pinion, and engraved focussing scale. The lens is of doublet form, with iris diaphragms, and working at *f*-8. The shutter is the "Bausch and Lomb Umicum," working between the lenses, and giving a varying exposure of from one second to 100th part of a second, either by hand or pneumatic

release. Time or ball exposures are also obtainable, the shutter in the latter case remaining open as long as the ball is pressed. The finder of the brilliant form, and shows the image the correct way up without distortion. The double dark slides supplied with the quarter-plate and 5x4 cameras are of solid pattern with vulcanite shutters. Eastm cartridge roll-holders can be easily adapted to the cameras, fitting in the same groove as the slides, and being in perfect register with the. We have carefully examined a quarter-plate pattern, and, in virtue of universality of movement, have no hesitation in pronouncing it perfectly adapted to meet every requirement for hand or stand work.

LUMIÈRE'S CERIUM REDUCER.

Sold by L. Gaumont & Co., 25, Cecil-court, Charing Cross-road, W.C.

On a previous page we give the translation of an article by Messrs. Lumière, dealing with the per-salts of cerium for reducing purpose. Messrs. Gaumont have been good enough to send us some of the solution to test, and an accompanying circular points out the respects in which it is claimed that the cerium solution is superior to older and better-known methods of attacking the deposit of a too-intense negative:—

It is usually in the presence of the two following conditions that negative requires to be reduced or weakened:—

1. The negative has been under-exposed and over-developed.
2. The negative has been over-exposed as well as over-developed.

In the first case the image must be reduced without any loss of the already insufficient detail in the clear parts, and the use of persulphate of ammonia is particularly suitable. But the second case is different for there is need to increase contrast, and in consequence to act on the whole image, especially on the clearest parts. The combination of ferric cyanide of potassium and hyposulphite of soda, employed almost exclusively up to the present, attains this result, but presents the drawback of producing markings and irregularities, if the negative is not carefully washed each time it is examined during the operation. This mixture also changes very rapidly, and can only be prepared at the moment of use; moreover, its results are not good in the case of bromide papers. We have recognised that the use of the ceric salts does not present these drawbacks in any shape, and gives an action sure and regular, whether it be a negative or a bromide paper print to be reduced. The solution keeps without alteration, and can be employed right up to exhaustion.

The new reducer can be used as follows:—

For an over-exposed negative (in which contrast is to be heightened) take equal parts of this solution and of water. Plunge in the negative, dry, and observe the action carefully, as it is very energetic. When the point wished has been reached, finish off with a complete washing.

For a negative slightly under over-exposed and over-developed, plunge the plate, previously wetted, in—

Concentrated solution .....	1 part,
Distilled water .....	9 parts,

and when the desired effect is obtained wash as before. Any variation of these formulæ may be made according to the depth of contrast desired.

In the case of bromide paper prints, the first solution in equal parts must never be used, and the second (1 to 9 of water) should be considered as the strongest permissible, but may be weakened considerably.

The solution sent us was of the colour of amber, and we tested it with reducing powers with a negative having the characteristics of slight over-exposure and over-development—perhaps the most common kind of defective negative produced, and one therefore of a sort likely to properly test the peculiar qualities of the cerium reducer. We found the solution to act quickly; it converted the negative into a bright, harmonious image without staining it or selectively attacking it. If we may judge by our trials, the new reducer will be found distinctly useful to photographers.

THE "JOHANNESBURG" CHLORIDE OF GOLD.

Prepared and sold by C. E. Elliott, 36, Jewin-street, E.C.

THE name applied to this brand of the principal reagent that is employed in the toning of silver prints, in view of contemporary military history in South Africa, is a singularly happy one. The crystals of the salt are of a brown colour, thus distinguishing the Johannesburg chloride from other varieties of the precious chemical. Practical trial of the Johannesburg chloride as a constituent of the toning bath satisfies us that it is an excellent preparation for the purpose. The tubes are guaranteed to contain the full weight of fifteen grains of chloride, and they are retailed at 1s. 8d. each, or 19s. the dozen.

MESSRS. H. & W. GREEN, of the "Crown" Photographic Manufactory Rotherham, send us a large number of samples of new mounts for the season. These are effective and tasteful in design, and they include the Rococo embossed, neutral-tinted Bristol mounts, fancy-border mounts, Oriental tissues, waterproof packing for P.O.P., and other specialities likely to be appreciated by photographers.

## Studio Gossip.

MESSRS. ELLIOTT & SON, of Barnet, announce that, on and after March 31, the Barnet Studio plate will be issued under a new name and label, and will be known as the Barnet Medium plate. Samples of the Medium plate will be sent to professional photographers on application.

THE PHILADELPHIA PHOTOGRAPHIC SALON, 1900.—The Pennsylvania Academy of the Fine Arts announce that, under joint management with the Photographic Society of Philadelphia, the Philadelphia Photographic Salon for 1900 (third year) will be held in the Galleries of the Academy from October 1 to November 18, 1900. This preliminary notice will be followed, in due course, by a full circular, with all details, entry forms, &c.

We learn with interest that Mr. M. S. Berger (of Messrs. Berger & Co.) has three relatives at the front. A younger brother, belonging to the 1st Gordon Highlanders, was severely wounded in the charge of the Highland Brigade at Agersfontein when General Wauchope was killed; another brother is on the medical staff of Colonel Plumer's Rhodesian Regiment; and a nephew in the Royal Volunteers, only eighteen, but standing six feet four in his stockings, was in the armoured train catastrophe at Chieveley, and was rescued by Mr. Inston Churchill.

## News and Notes.

At the Röntgen Society's Ordinary General Meeting, on Thursday, April 5, 1900, at Hanover-square, a paper will be read by Dr. Norris Wolfenden and Dr. Forbes Ross on "The Influence of the X Rays upon the Growth and Development of Micro-organisms."

WE are pleased to learn that Mr. Henry Speyer's khaki lantern lecture on "Round about the Matterhorn" at Reigate, on Tuesday, March 13, realised a handsome sum of 40*l.*, which will be handed over to the War Fund. We heartily congratulate all concerned on the very great success of their efforts.

OUR bright and helpful contemporary, *The Junior Photographer* for April, will have a supplement in the form of a pictorial post card, given away with each copy. The Editor has sent us half a dozen of these pictorial post cards, which we are glad to have. The picture is entitled, *Bad News from the Front*. It represents an old man consoling his wife who may be supposed to be crying over having bad news of her soldier boy.

THE PERMANGANATE REDUCER.—Mr. W. N. Jennings, of Philadelphia, has carried out some experiments with this reducer, and has arrived at a formula which is somewhat different from the published one: A, Permanganate of potassium, twenty per cent. solution; B, sulphuric acid, twenty per cent. solution, 1/2 drachm; C, 1 drachm; water, 8 ounces. This reducing solution has one great merit, its cheapness; it is many times cheaper than any other. Very much over-exposed but thin, negatives, intensified with mercury and ammonia, and then reduced, although having a decided sepia tone, have the printing quality of perfectly exposed and developed negatives. If there is too much permanganate and too little sulphuric acid, a deep stain is produced.

TRAIL TAYLOR MEMORIAL.—At a meeting of the Committee, on the 14th inst., the Hon. Secretary presented a statement of account showing that 3*l.* 11*s.* had been invested in New Zealand three-and-a-half per cent. Stock in the name of the Trustees. He also reported an expenditure of 25*l.* 2*s.* 3*d.*, and cash balance in hand 10*l.* 11*s.* 10*d.* According to the provision of the trust deed it was decided by lot that the following members of the Committee retire: Messrs. T. Bedding, P. Everitt, H. Snowden Ward, and Sir Henry Trueman Wood, as town members, and Messrs. W. I. Chadwick, M. J. Harding, H. P. Robinson, and A. Werner, as country members. The following gentlemen were then elected to the Committee: Messrs. T. E. Freshwater, S. H. Fry, J. V. Hyde, and J. A. Sinclair, as town members, and Messrs. T. Bromwich, J. J. Croall, A. F. Mowll, and C. R. Rowe, as country members.

A RADIOMETER for measuring the heat radiation of the stars has been tested at the Yerkes Observatory. The instrument is the outcome of the work of Mr. E. F. Nichols, of Dartmouth College. It consisted of a suspension system formed of two mica discs, each two mm. in diameter, blackened on the face, and supported by a light cross arm on either side of a thin glass staff, hung by an exceedingly fine quartz fibre in a partial vacuum. Both vanes were exposed to the radiation of the sky at the focus of a silvered glass mirror of twenty-four inches aperture, fed with light by a siderostat outside. The rays entered the radiometer through a small window made of fluorite. With the apparatus so arranged, a deflection of 0.1 mm. would be given by a candle fifteen miles distant, neglecting loss by reflection and atmospheric absorption. The results obtained showed that stellar heat radiation was distinctly detectable.

ORTOL.—At a recent meeting of the Photographic Society of Philadelphia, Mr. Caspar W. Miller, Chairman of the Technical Committee, made the following statement in reference to ortol: "As you know, ortol is, or at least was when it was first brought out, a light almost white or light grey, circular, finely crystalline powder, and it is so described in all the text-books that I have been able to find, and it used to be that until within about six months. Now, ortol is a perfectly white mass, composed of small round globules very much resembling sand or small hailstones. This is not the only difference. It used to be very soluble, like pyro, in cold water; it is now very much less soluble, about as much so as sulphite of soda. It now smells of sulphurous acid, which it did not, and ought not to, smell of. They now crystallise ortol with sulphate of soda, and charge you for pure ortol. I thought I was paying too much for sulphite of soda, so I wrote to the New York agents and asked them why it was; whether the sample I had bought was adulterated, and whether they were manufacturing a new compound. They said they knew nothing about it, but would write to Germany, where the stuff was made. Here the matter rests."

EFFECT OF LIGHT ON CHEMICALS.—A contemporary states that an interesting phenomenon has been observed by Wilhelm Marckwald in connexion with the change of colour undergone by certain bodies upon exposure to light, without being otherwise altered in composition or structure. The anhydrous chloride of quinoquinoline, upon exposure to light, changes from a yellow colour to an intense green, returning to its original state when heated to 90° C., or if kept in the dark for a few days at the ordinary temperature. This change of colour is brought about in a few seconds by exposure to bright sunlight, and in a few minutes by diffused daylight; it is chiefly due to the more refrangible rays of the spectrum. No effect has been observed with the X rays. A similar action has been observed with the body known as  $\beta$ -tetrachloro- $\alpha$ -ketonaphthalene, which crystallises from its solutions, forming colourless and transparent crystals. These, when powdered and exposed to the light, change to amethyst colour; the large crystals, upon exposure, show a reddish-violet colour in one direction. These changes do not appear to be connected with a chemical or crystalline modification, and, by fusion, a non-sensitive modification may be obtained, which slowly returns to the sensitive form. To these phenomena the experimenter gives the name of phototropy.

ROCHDALE PHOTOGRAPHIC SOCIETY'S ANNUAL EXHIBITION.—Under the auspices of the Rochdale and District Photographic Society there was a small but capital Exhibition of Photographic Pictures in the Temperance Hall, Smith-street, Rochdale, on Thursday, Friday, and Saturday of last week. It is the second of its kind, and is more ambitious than the first venture, there being three open classes this year, as well as classes for members only. Some of the best-known photographers sent exhibits, and several of the pictures on view had previously won gold and silver medals. Local photographers were well represented in the open competitions as well as in those for members. Over 200 pretty and interesting pictures were on view. The efforts of the Committee, who had made the arrangements, and of Mr. R. Turner (Hon. Secretary of the Exhibition), have proved very successful from an artistic point of view. There were six classes, and in each of them the standard of the work was very creditable. In the Members' Class for Landscape, Seascape, or River Scenery, the bronze medal was won by Mr. J. A. Jackson, of Littleborough, and a certificate was awarded to Mr. J. A. Grindrod, of Rochdale. Mr. Ernest E. Ashworth, of Smallbridge, carried off the medal in the Members' Class for Architectural Photography (interior or exterior), the subject being the interior of All Saints' Church, Hamer, Rochdale. Mr. George Smith took the certificate with a picture of the entrance to Whalley Abbey. The Members' Class for Hand-camera Work (set of six prints, any size or subject) did not evoke very keen competition, and the bronze medal was withheld. The certificate was gained by Mr. G. Smith with a very pretty set. The winners in the open classes were: Landscape, Seascape, or River Scenery, Messrs. R. Walker, silver medal, A. J. Loughton, silver medal, and Percy Handcock, bronze medal; Hand-camera Work (set of six prints), Messrs. William E. Inston, silver medal, and J. D. Murray, bronze medal.

A KHAKI LANTERN SHOW.—To the Croydon Camera Club belongs, we believe, the credit of being the first, and so far, the only, Society to describe a lantern entertainment as a Khaki one. Anyhow, the Club is to be congratulated upon having secured a complete success on Wednesday, the 14th inst., when the large Public Hall in Croydon was crowded with an audience which was both distinguished and enthusiastic. Indeed, the would-be attendance was so great that a fortnight before the eventful evening the sale of all seats under 3*s.* was stopped. The programme, for which we understand the President (Mr. Hector Maclean) was responsible, seemed to exactly hit off the wants of the assemblage. Thus, the scene of war was illustrated by picked slides contributed by G. W. Wilson & Co. and Donald Currie & Co. Types of the Army and Navy were lent by W. Gregory & Co. The members, including Messrs. Beales and Bender, showed local C.I.V.'s. The actual operations at the front were graphically brought to sight by a telling series of tele-photo and other hand-camera pictures, taken by Mr. Henry C. Shelley, and specially prepared for the occasion by Mr. Francis T. Beeson. These were placed at the Club's service by the courtesy of "The King," who, we understand, will now be pleased to loan the above to other societies. They are well worth having. Kodak (Limited) also sent some war subjects, which were splendid examples of technical achievement, and in many cases exceedingly interesting in subject-matter. There were the usual martial songs, &c., about which we need say nothing. After the collection on behalf of the A.M.B., four tambourines, each of which had a photograph or sketch upon the under side, were put up to auction, and fetched 10*l.* The chief hit of the evening was, however, the bioscope, which was worked by Mr. Charles Urban himself. It ran for half an hour, and provoked an amount of enthusiasm which rivalled the plaudits that greeted Baden Powell and "Bobs" earlier in the evening. To particularise the films shown is not possible. Those who contemplate arranging for a bioscope at any similar lantern show can see what it is like by visiting the London Hippodrome, where it is used every night. Including 13 guineas collected and 10*l.* obtained by the sale of tambourines, the net profits will probably reach not far short of 100*l.*, the whole of which will go to Tommy Atkins and his children.

## Commercial Intelligence.

THE City Sale and Exchange, of 54, Lime-street, and 81, Aldersgate-street, London, E.C., send us their eight-page list of cameras, lenses, shutters, and other photographic apparatus.

MESSRS. WELLINGTON & WARD, of Elstree, ask us to state that they will have much pleasure in supplying all dealers with a selection of choice show-cards if they will apply direct.

THE AUSTIN-EDWARDS MONTHLY FILM-NEGATIVE COMPETITION.—The prize camera for the current month has been awarded to Mr. W. B. Green, Gladstone-road, Watford, for his negative, *A Winter Scene*.

In the United States the metric system has made such progress that the Government of that country is contemplating its compulsory adoption by all contractors and others having business dealings with the State.

We are informed that the firm of Perken, Son, & Co., of 99, Hatton-garden, London, has been registered as a Limited Liability Company under the title of "Perken, Son, & Co., Limited." As this course has been taken for purely family reasons, no shares have been, or will be, offered to the public.

"THE WITCHERY OF KODAKERY."—From one of our American contemporaries, *Outing*, we clip the following eloquent example of American advertising: "The subtle charm of art, the invigorating influence of active recreation, the joys of delving in the mysteries of chemistry and unveiling its photographic secrets, all or any one of these delights are in store for the Kodaker. In them is the witchery of Kodakery."

We are informed that the photographic businesses hitherto carried on by the late David H. Hogg, in Montreal and Toronto, and more recently by Mrs. Hogg, in the name of David H. Hogg have been transferred to Mr. J. G. Ramsey, who will carry on said business under the name and style of the D. H. Hogg Company, but in which businesses Mrs. Hogg, and the estate of the late David H. Hogg have no further interest or responsibility.

THE WARWICK COMPETITIONS.—The following is the list of awards of the Warwick Competition for March:—10l. prize, Mr. W. Mitchell, Meadow Cottage, Selkirk, N.B., two prints of *Birds Feeding*; 5l. prize, Rev. A. H. Blake, St. Thomas Home, Basingstoke, *The Castaway*; 1l. prizes, Mr. C. M. Balguy, Weyhill, Andover, *Head of an Old Salt*; Mr. W. Bellerby, 8, Burton-terrace, York, *Church of St. Sebald, Nurnburg*; Mr. R. Clapperton, photographer, Selkirk, N.B., *On the Way to the Fields*; Mr. W. U. Clarke, Bridge House, Teddington, Middlesex, *Oak-carved Panel*; Miss G. Evans, The Spring, Kenilworth, *A Snow Scene*; Mr. F. W. Fielder, Foxenden, Dene-road, Guildford, *Draped Figure of Girl with Light*; Mr. A. E. Horne, the Glen, Queenstown, Ireland, *Sunshine and Snow*; Mr. F. Ingham, Winton House, Sale, *Pensive Thoughts*; Mr. J. Kearney, jun., 47, Dale-street, Liverpool, *February Fill Dyke*; Mr. E. Reed, 56, St. John's-road, Liverpool, *Winter, Raincliffe Woods*; Mr. G. H. Schafer, 35, Laitwood-road, Balham, S.W., *Muddy February*; Mr. P. J. Slater, Sawtry, Peterborough, *The Slide*; Mr. W. T. Stokes, Ivydean, Grove-avenue, Moseley, Birmingham, *Bridge, Malvern Hall*; Mr. J. Thomas, 29, Llanover-street, Abercarn, near Newport, *Duckling are Fond of Water*; Mr. A. Thomson, Mounts Bay Hotel, Penzance, *Fresh Fish! Fresh Fish!*; Mr. W. H. Tomkinson, 81, Dale-street, Liverpool, *Frosty Morning*; Miss A. Tomlinson, Fishbourne, Chichester, *A Study in Black and White*; Mr. C. S. Tyler, Earls Colne, Essex, *Morning News*; Mr. J. Welsh, 9, Mountain View, Whitehaven, *Stereoscopic View of Snowy Ghyll*; Mr. G. Young, 2, Six Houses, Ashington, *The Forge*.

THE First Annual General Meeting of Kodak (Limited) was held on Wednesday last at Winchester House, Old Broad-street, E.C., Sir James Pender, Bart., M.P. (the Chairman), presiding. The Chairman said: I have much pleasure in coming before you to move the approval and adoption of the Directors' report and the very satisfactory statement of accounts which have been presented. As this is the first annual meeting of the Company, some comparison may be expected between the promises of the prospectus and the performance, as shown by the accounts. In that prospectus we gave expression to our belief that the sales would continue to increase, and that the trade would expand, and you will all agree with me that the results have amply justified our expectations. It was shown that the profits for the previous year, after allowing for a preference dividend of six per cent., were equal to a dividend of sixteen per cent. on the ordinary shares, with a surplus of nearly 50,000l. We have for 1899 paid a dividend of ten per cent., and we propose to pay a bonus of five per cent., amounting in all to fifteen per cent., on the ordinary shares, while the surplus profits carried forward by the associated Companies amount to 151,846l. Instead of the revenue for 1899 being only five times the sum required to pay the preference dividend, it has been nearly ten times. It may be interesting to you to carry on the comparison of recent years' profits of the several businesses, which was instituted in the prospectus, and referred to at the statutory meeting. The combined profits for 1895 were 49,000l.; for 1896, 122,000l.; for 1897, 185,000l.; for 1898, 243,000l.; and, for 1899, 335,000l. Remarkable as these figures are, the Directors have every reason to believe that the businesses will continue to progress, and, so far, the returns for January and February of this year show satisfactory increases over those of the corresponding period of last year. The accounts of all the Companies have been audited by Messrs. Price, Waterhouse, & Co., and they have accordingly certified the joint account. I will now proceed to take such items of the combined balance-sheet as seem to require reference. The sum of £1,616,900 on the debtor side has included in it the value at par of shares held by shareholders in the Eastman Kodak Company other than Kodak, Limited. Sundry creditors stand at 40,602l., whilst, on the other side, sundry debtors, after providing proper provision for doubtful debts, amount to 69,494l. The reserve account (Paris) refers to a reserve which, under French law, has to be made out of the profits of each year's business of every French company. The item "To interim dividend, December 31, 1899, amount outstanding 10,479l.," represents part of dividend due to be paid on and after January 1, 1900, and speaks for itself. The first item under the entry "To surplus account" shows the earnings of the Companies from November 21, the date of the purchase contract, to the end of the year 1898, after writing off balance of American goodwill purchase account; and the second item is the profit for the year 1899, amounting to 335,919l. making total profits for the period to December 31, 1899, of 345,778l. Lower down, among the dividends paid, the item of 2060l., dividend to shareholders of Eastman Photographic Materials Company, Ltd., represents interest up to January 20, 1899 (the date of the completion of the purchase), and payable under the contract with that Company. On the other side of the balance-sheet, the goodwill and patents figure at 613,086l.; and I would draw your attention to the fact that, upon the basis of last year's profits, these assets are valued at a sum less than two years' earnings.

In connexion with the item of 304,834l. and 20,455l. "land, buildings, plant, machinery, furniture," &c., it should be understood that these amounts are arrived at after making liberal allowance for depreciation, a sum of nearly 14,000l. having been applied for this purpose in respect of the year 1899. Stocks on hand are valued at cost. The item of 69,494l., owing by sundry debtors, &c., has been arrived at after a liberal reserve has been made for doubtful debts. Railway investments speak for themselves; they are all high-class securities. I now turn to the item, "Investments in sundry photographic materials manufacturing companies, 421,280l." It represents in the main the Eastman Kodak Company's investment in the General Aristo Company, which is a combination of all the principal gelatine and collodion sensitised paper business of the United States, including the paper business of the Eastman Kodak Company, the consideration for the latter being the sum of 1,727,000 dollars, say 356,000l., one-half being in seven per cent. preferred shares, and the balance in common shares, the Eastman Kodak Company agreeing to manufacture its papers for the Aristo Company at cost. The purchase price for the Eastman Kodak Company's paper business was so arranged that its dividends on stock in the General Aristo Company are estimated to more than equal the amount it would have made by the manufacture of paper on its own account. As part of this transaction the Eastman Kodak Company were also allowed to purchase 150,000 dollars of preferred stock and 100,000 dollars of common stock for 150,000 dollars, making the total holding of Aristo Company shares equal to 1,977,000 dollars (408,000l.). The sole agency for the entire output of the Aristo Company is now in the hands of the Eastman Kodak Company upon terms which, while favourable to the Aristo Company, produce a handsome profit to the Eastman Kodak Company. Kodak (Limited) has the right at any time within three years to acquire all the shares in the General Aristo Company, paying for the same in shares of Kodak (Limited), the basis of exchange being equality of returns. This transaction having been initiated in America, your Directors, in a matter of such importance, deputed one of their number (Mr. A. S. Statham) to proceed to America to make an independent investigation and consult with the Board of the Eastman Kodak Company, and the business was not concluded until he had fully reported to us on the whole subject. The results have fully justified the action of two Companies. The surplus profits carried forward in Europe and America include investments in sound securities by way of reserve of 71,808l., and this reserve is now being increased to upwards of 100,000l. We have made application for a large slice of the new "Khaki" loan, and we only hope we may be fortunate enough to secure it. Our policy is to build up a good reserve, after providing a large cash working capital, for extensions of business and factories. Our assets are of a most substantial nature, and free from debentures and mortgages, or encumbrances of any description, and all preliminary expenses have been paid out of profits. The old members of the Eastman Photographic Materials Company, Ltd., will be glad to know that their vendor shares have been admitted to quotation on the Stock Exchange. As regards our trade, sales have greatly increased, and the business has been greatly extended. At the statutory meeting I announced the opening of a branch at Brussels, and since then we have established depots in Vienna and St. Petersburg. A separate company has been established under the Canadian laws, with head-quarters in Toronto, to exploit the business in Canada, and other plans are being matured for farther extensions. The efficiently equipped factories at Rochester continue to supply us with improved film and most attractive lines of new goods. The future of Kodak business seems brighter than it has ever been. Although the name of Kodak, Ltd., is only a year old, it would be a mistake to conclude that the business associated with the Company is of a short period of growth, for the increase of the industry has been steady and regularly progressive for twenty years. Kodak, Ltd., not only concerns itself with Kodaks, but covers the whole field of photography, and caters for both amateurs and professionals. We are rapidly extending over the whole world, and this with our continued improvements, which make the practice of the art easier and cheaper, is likely to lead to a volume of business, the extent of which can hardly be estimated at the present time. I now move that the report and accounts be approved and adopted. Mr. George Eastman seconded the motion, which was unanimously adopted. A bonus of five per cent. was declared on the ordinary shares, making a total distribution for the year of fifteen per cent. Sir James Pender and Mr. A. Statham (the retiring Directors) were re-elected, and Messrs. Price, Waterhouse, & Co., were reappointed Auditors.

## Patent News.

THE following applications for Patents were made between March 5 and March 10, 1900:—

SHUTTER.—No. 4134. "Improvement in Photographic Shutter." Complete specification. A. WOLLENSAK.

REPRODUCTIONS OF TILES.—No. 4276. "Improvements relating to the Process of Photographic Reproductions of Glazed Coloured Tiles and other analogous articles." F. C. SHARDLOW.

PLATE-LIFTER.—No. 4298. "An Improved Lifting Device or Attachment for Photographic Developing Dishes and other vessels." B. A. SPAULL.

CHANGING BOXES.—No. 4306. "Improvements in Change Boxes for Pictures, Photographs, Negatives, and the like." Complete specification. H. A. PÉRAUT.

CINEMATOGRAPHY.—No. 4434. "Improvements in Cinematographic Apparatus." C. RALEIGH.

PRINTING FRAMES.—"Improvements in Photographic Copying Frames for Negative Films." R. CARLS.

STANDS.—No. 4574. "Improvements in Stands for Photographic Cameras." Complete specification. E. M. M. SMITH.

## MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
3	Bradford Photo. Society	Members' Slide Night. Criticised by P. E. Newstead.
3	Kingston-on-Thames	Intensification. W. E. Price.
7	Birmingham Photo. Society	Odds and Ends. C. S. Baynton.
7	Hackney	How a Lens is Made. C. P. Goerz.
7	Isle of Thanet	A Practical Lesson in Outdoor Photography. A. Horsley Hinton.
7	Leeds Photo. Society	Some Possibilities of Photography. E. J. Wall.
7	Royal Photographic Society	Some Developers Compared. Alfred Watkins.
8	Borough Polytechnic	Lantern Night.
8	Croydon Camera Club	Tenth Annual Dinner.
8	Southsea	Committee Meeting to Arrange Summer Programme and Excursions.
9	Ashton-under-Lyne	Exhibition of Cameras.
9	Leigh	Plates and Papers for Pictorial Work. A. Horsley Hinton.
9	Liverpool Amateur	The Norfolk Broads. J. Sirett Brown.
9	London and Provincial	Paper by Mr. Haddon.
9	Oldham	A Practical Lesson in Outdoor Photography. Reader, J. Chadwick.
9	Croydon Microscopical	Prize Slides.
9	Southport	Exhibition of Competition Slides. Members only.
9	West London	Beginners' Meeting: Finishing Prints. J. Brown.
9	Whitby	Composition. F. Wasley.
1	Liverpool Amateur	Excursion: Little Ness and Burton. Leader, C. F. Depree.
1	Southport	Public Exhibition of Competition Slides.

### ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 20,—Photo-mechanical Meeting,—Mr. H. Snowden Ward in the chair. PHOTOGRAVURE.

Mr. IGNATZ HERBST exhibited a large number of very fine photogravure prints, both in monochrome and in colours, most of them being about 36 x 24 inches in size, and all of them produced by his own firm in London. He also showed the negatives and transparencies used for the production of the plates, and gave a short talk with reference to the difficulties which had been overcome in order to make the business a commercial success in this country. At first he had had to employ collodion emulsion for the negatives, as no English firm was able to make evenly coated dry plates of such large size, but one London establishment had lately succeeded in producing satisfactory orthochromatic dry plates of the requisite dimensions, and he was now using them. For the transparencies he preferred carbon tissue, which was cheap and easily handled, and with which retouching was facilitated. In order to ensure uniformity in the etching solutions, the perchloride was purchased by tons at a time, and the solution was found to work better if made up some considerable period before it was used. Photogravure was quite useless, as a commercial process, without skilful and artistic work on the plate, and it was in this particular that the method was essentially not a mechanical one. The coloured prints were produced at one operation, the plate being inked up with all the colours by a sponging process, as many as half a dozen men being engaged on a plate, each taking a different colour. The time occupied in inking the plate for one of the large prints exhibited was said to have been about two hours for each print. Mr. Herbst has a most intimate knowledge of this branch of photo-mechanical work, and he and his colleague, Mr. Reichs, very kindly offered to answer, without reservation, any questions upon the subject which might be put to them, an offer of which several members availed themselves in the course of the informal conversation which followed Mr. Herbst's introductory remarks.

The Rev. F. C. LAMBERT said that some years ago he experimented with the process, and endeavoured to apply inks locally, but he invariably found that in wiping the plate the inks were shifted and smeared.

Mr. REICHS said the inks were of the same character as those used in copper-plate printing, and were applied with a dabber or stump, or other suitable appliance, and wiped off first with muslin and then with the hand. No stencils were used to assist in inking, and successful work could only be done by men possessing some artistic taste and training, and then only after long practice.

Mr. W. GAMBLE, without in any way detracting from the satisfactory nature of Mr. Herbst's results, remarked that the process had been in use ever since the days of Bartolozzi and Morland, who got very fine results by means of multiple inking. Great credit was due to Mr. Herbst for having made the method a commercial success, and his prints were certainly far superior to those of the old etchers.

Mr. HERBST admitted that the process was not new, but claimed to have brought it to a higher degree of perfection than had previously been known in this country; he was unable, however, to find suitable workmen in England, and had to get them from the Continent. A great deal depended upon the etching of the plate. For colour work the etching must be much deeper than for monochrome; but, if the plates were properly etched, each part of the picture would take up the right quantity of ink, and any number of prints of uniform character could be produced. The publishers were prepared to pay a fair price for good work, and he was satisfied if a plate produced six prints a day, although double that number could be obtained if necessary. The life of a plate varied from 2000 to 5000 impressions, according to the nature of the subject and the ability of the printers; in the hands of some printers a plate would be spoiled after twenty-five prints had been made.

Major-General WATERHOUSE had seen photogravure printing in colours at Paris, but one man did all the inking, and only about two prints could be made in a day.

Mr. J. C. WARBURG did not deny that photogravure was an artistic process, but he did not think that its artistic character was enhanced by retouching; in fact, he was of the contrary opinion. He asked whether differences of tone and colour were produced by the use of more ink, or inks of different colour, or more than one inking.

Mr. HERBST said the plate was etched deeper in the deeper shadows, and consequently held more ink; in certain parts of a picture different inks would be blended to produce a particular tone of colour. With regard to retouching, photogravure would be quite useless without it, and an untouched picture would not be marketable.

Mr. WALLACE CROWDY said a certain amount of mezzotint work was essential, especially in the colour process. Differences of tone or colour were produced not only by differences of ink, but the plate was, in the first instance, made suitable for the end in view by a certain amount of hand engraving or retouching, which was a most delicate process. In his opinion, photogravure was essentially an artistic method, and the best plate in the world would not produce a satisfactory result in the hands of an unskilful printer.

The Rev. F. C. LAMBERT asked what method of etching was adopted by Mr. Herbst.

Mr. REICHS replied that the perchloride solution was used in three strengths, 40°, 37°, and 36° Beaumé, and sometimes 33°. He did not favour the one-solution method, either with or without dilution.

Mr. LAMBERT next started the evergreen subject of devils, their cause and cure, with the usual inconclusive result. They were attributed to bad copper, impure bitumen, peculiar atmospheric conditions, and other causes, but no infallible remedy was suggested.

### COMING EVENTS.

March 27, Mr. Alfred Watkins, "Some Developers Compared." April 3, the last Lantern Evening of the session, "Slides Old and New," by Mr. F. P. Cembrano. April 10, "The Municipal Encouragement of Photography," by Mr. Thomas Bedding.

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 15,—Mr. Wilfred Emery in the chair.

Mr. R. BECKETT show an example of copying from an old and yellow albumen print. The resulting negative was printed on Gravura paper, the quality of the production being very good, original and copy were passed round.

Mr. S. H. FRY, referring to copper toning, said that he doubted whether the best results were obtained if the bromide print to be toned were fixed in the ordinary way. Better results would be secured if there were a trace of ferricyanide in the fixing bath, for this reason. In the bulk of the prints he had seen which had been toned with copper there was a tendency to a pink deposit all over which, in the whites, was particularly noticeable. This was probably due to silver imperfectly removed by the hypo, or an excess of silver in the hypo. He therefore recommended a final fixing in clean hypo solution to which had been added some ferricyanide.

Mr. ERNEST HUMAN read a paper upon

### ORTOL,

which he endeavoured to prove to be the ideal developer. Extreme latitude of exposure, ability to give hard or soft results, absence of tendency to cause chemical fog, continued use without deterioration and discolouration, absence of staining proclivities, inexpensiveness, and independence of caustic alkali, have been stated as the attributes of the ideal developer, and all these the lecturer claimed for ortol. It worked well with any brand of plates, films, and bromide papers. In action it greatly resembled pyrogallol without the stain of the latter, the image appearing perhaps a little quicker, whilst the effects of modifying the composition agree very closely with those of pyro. He then gave the maker's formulae, and, in commenting thereon, said a word of warning about the undue increase of sodium sulphite, which, with ortol acted as a retarding agent. Mr. Human made up his solutions in three parts, as follows:—

- |                                 |                         |
|---------------------------------|-------------------------|
| (1) Water .....                 | 80 ounces.              |
| Pot. metabisulphite .....       | $\frac{3}{4}$ ounce.    |
| Ortol .....                     | 1 $\frac{1}{2}$ ounces. |
| (2) Water .....                 | 80 ounces.              |
| Soda sulphite .....             | 14 "                    |
| (3) Water .....                 | 80 "                    |
| Soda carbonate (crystals) ..... | 10 "                    |

With the developer in this form, the sulphite can at will be left out, although, as a rule, equal parts of the three solutions are taken, with bromide as required. Without sulphite the mixed solution has not the same keeping powers; but the lecturer had used it even after three days. Hypo in certain proportions acts as an accelerator, and a few drops of a five per cent. solution may be used to this end. Mr. Human passed round some plates developed with the old solution, which quite satisfied him, although it is true the time of development was prolonged. He also passed round two negatives, one of which, by accident, received an exposure of 40 seconds, instead of  $\frac{1}{15}$  second, which was given to the other. The properly exposed plate was developed normally. The other was put in a solution some three months old, which had been repeatedly used, and with every satisfaction. Bromide prints, illustrating the claim for latitude in exposure, were also passed round. The following remarks were concerning the continuing action of ortol under a stream of water. A half-developed plate, placed under the tap for a few minutes, will be found ready for fixing. This power, Mr. Human thought would be of much use in times of pressure of work. Ortol could also be used for simultaneous development and fixing.

Slight over-exposure is essential, and a plate which develops quickly. In conclusion, Mr. Human said that ortol had superseded all other developers for practical purposes in this work.

Mr. R. BECKETT confessed a great liking for ortol, which he had used very largely.

Mr. W. D. WELFORD said it was not so sensitive to fluctuations of temperature as was hydroquinone, and was very much like pyro. A point which had not been alluded to was the speed with which work could be turned out. He had noticed it especially when dealing with large quantities, and found that 45 or 50 seconds was ample for a magnificent negative. No other developer was, he believed, so quick.

Mr. A. MACKIE criticised the practice of making up three solutions as recommended by the lecturer, for the reason that directly he used sulphite he weakened his developer.

Mr. WELFORD said that the solution was nearly saturated at the strength given. Water alone had not the retarding or slowing action of the sulphite solution.

PHOTOGRAPHIC CLUB.

MARCH 14,—Mr. E. W. Foxlee in the chair.

The CHAIRMAN showed a couple of negatives developed respectively with some old used kachin solution and some freshly mixed solution for comparison. The new solution gave a finished negative in five minutes, while the old used solution took eighteen minutes. The latter solution gave an image slightly thinner than did the new solution, but with just as much detail, and he thought four or five minutes longer would have shown that the developing properties of such old solutions had not deteriorated except in the direction of speed. The old solution was a long time making a start, but, when the image once showed itself, things went quicker than one would imagine.

Mr. A. MACKIE, after examining the specimens, remarked that the only effect of age seemed to be to increase the time of development. There was no difference in the scale between one and the other. It must be remembered that the developer was not only old, but had been used several times. In such a case the accumulation of bromide must be taken into account.

A discussion ensued on this point regarding the action of bromide.

It was pointed out by Mr. MACKIE that bromide with a pyro-ammonia developer, for instance, gave increased contrast. With kachin it seemed to exert only a slowing action, as there was no more contrast in the one negative than the other.

Mr. J. W. MASON mentioned some recent experiences with ferrous oxalate as a developer. Finding that a normal developer was a long time in bringing up density, he modified the developer with the addition of more iron, but eventually found a muddy deposit result from the continued addition of iron. He wished to know what was the limit to the quantity of iron allowable in the solution.

It was pointed out that neither the oxalate of potash, nor the sulphate of iron, was the reducing agent, but the combination of the two—ferrous oxalate, and that the excess of iron added was thrown down as ferrous oxalate. It was useless to add the iron to such an extent.

Goldsmiths' Institute Camera Club.—March 15.—Mr. DONALD A. NIGHTINGALE gave a demonstration of the value, for special purposes, of some recent introductions in Velox paper. After a description of the various precautions necessary for successful work with all the Velox papers, the method of printing on the sensitised post card was practically shown. Prints were also made on double-weight Velox, and the new process for obtaining colours by direct development with kachin received considerable attention. Some remarkably good colour effects were obtained, and other specimens by the same process were submitted for inspection. In reply to questions as to whether uniformity of results was possible in cases of modified development, Mr. NIGHTINGALE stated that, where the production of a number of uniform prints was desirable, the most satisfactory method consisted in developing the whole of the exposures at once in a large dish containing, say, one pint of developer. There is no risk of uneven development, since, as in toning P.O.P., the process occupies from five to ten minutes.

North Middlesex Photographic Society.—February 12, Mr. F. M. Ainsley in the chair.—A discussion took place on the following question "Which is the best method of producing large prints, enlargements from small negatives or large negatives?" Mr. MUMMERY opened by upholding the case for large negatives. He said that there was generally better quality to be found in large direct work than in enlargements, and it was really economical, as more care was generally taken in all the operations, so there was much less waste. Mr. H. W. BENNETT, on the other hand, said that better results could be got by making enlarged negatives. All large lenses, even of the best makers, fell far short of smaller ones of the same class in quality. Consequently, better technical results could be got in small negatives, and many things easily taken with a small camera with a lens working at f-8 or f-11, became impossible, if attempted in large sizes, owing to the necessity of stopping down considerably with large lenses.

FORTHCOMING EXHIBITIONS.

1900.	
March 26 .....	Twentieth Century International, Birmingham. Walter D. Welford, 19, Southampton-buildings, Chancery-lane, London, W.C.
„ 26-31 .....	Photographic Society of Ireland. W. F. Cooper, 35, Dawson-street, Dublin.
April 3-7 .....	Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibition should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

Correspondence.

\* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given. \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

THE COPYRIGHT BILL.

To the EDITORS.

GENTLEMEN,—I have read Mr. Bale's address on the proposed Copyright Amendment Act, and the eulogiums on it by other members of the Society of Arts, with amazement. It looks nothing short of an impudent attempt to legalise things so that publishers may reap where they have not sown, with the blessing of British law on their hoary crown; that they may safely use for their own profit the work of the despised photographer without even a "collie will ye lick." And these people prate of piracies, themselves sighing for letters of marque! How is it that Messrs. Bale, Scrutton, and East pose as our guardian cherubs? I am not aware that photographers are dissatisfied with the present state of the law, or admit the right of publishers or painters to constitute themselves our benefactors, and, no doubt, most of us would be grateful if these gentlemen would confine their attention to their own affairs. We cannot believe that this surprising solicitude for our welfare is purely philanthropic. Mr. East says eminent photographers have been consulted. Who are they? But I object to distinctions being drawn in law between one member and another of a profession. Under this Bill all using paint, however abortive and painful the result, are classed as painters. Failure to be eminent is condoned. If Mr. East can be so generous with his less gifted brethren, neither will eminent photographers, whoever they are, betray their own kind, even though tempted with the prospect of hobnobbing with eminent artists.

I beg leave to doubt if the gentlemen aforesaid at all represent the general opinion of painters regarding the compulsory registration of photographs. I cannot see what benefit painters would derive from it, and neither can they. We object to no part of the Bill really framed in their favour. Why should painters interfere with us? Without doubt, the proposal emanates from, and is in the interests of, publishers, and in their interests only. Photographers have become indispensable to them, and have a new and unexpected value, a sort of unearned increment, which they feel would be better in their pockets than in ours. Mean time the whip of the law keeps the "wretch in order." It is no fault of ours that magazine publishers have discovered a new source of profit in our humble productions. We regret it. It is a deplorable fluke and an altogether inadequate recompense for the ruin of our legitimate business by process work. Our intention has been, in making negatives, to publish copies of them by our own methods, which are incomparably more beautiful than any mechanical process.

The reasons given for altering the law do not bear inspection. (1) Photographs of paintings are made in Jersey and hawked about the mainland at a low figure, to the hurt of publishers who have paid for the copyright, and the law provides no practicable means of stopping it. I hope the part of the Bill amending this will pass, and that the knavish firms who copy paintings, without authority, by means of photography, and sell photographic prints, shall be laid by the heels forthwith. This should be extended to prints in ink by process blocks from photographs. A photograph compared with a painting is of little value. Still, it's our pet ewe, and all we have. What's not worth asking is not worth taking. Every publisher of a newspaper or magazine, sold in shops, or hawked or peddled about the country, should be easily punished if he cannot show that the originals of his photo-illustrations were taken by himself, his "special artist," an amateur friend, or have been purchased for the purpose from some obscure practical photographer. (2) Painters are poor and neglected till just before they die, when they become famous, therefore their widows should be consoled with thirty years of copyright. Photographers, on the other hand, create a great sensation, from an early age, and are so run upon that they amass wealth to such a degree that their widows do not require any post-mortem consideration. (3) A would-be publisher of a photograph cannot at present tell whether it is copyright or not. Every publisher knows that the copyright of a photograph is vested in the photographer. Let the publisher apply to the maker of the photograph as he does to the maker of a painting. It is only necessary to register when the copyright is infringed, the idea being to save the question of ownership being disputed in court, and to confine the action solely to proof of infringement.

The call for compulsory registration is a very slim proceeding. Publishers know that, if in palmier days we might have registered, we cannot

ford it now. For instance, take a view photographer with 1500 negatives. 1s. 6d. each, postages, and 3000 prints, would cost 190l.—about 20 years' wages of such a business. But I have hopes that, if the matter is well managed for us, the Lords will not agree to compulsory registration. If they do, there are means of avoiding it, and yet making the use of our work for process blocks impossible. Of this I may write again, though not in your next.—I am, yours, &c.,  
BLACKING BOX.  
March 13, 1900.

PLATE BACKING AND SENSITIVENESS.

To the EDITORS.

GENTLEMEN,—Will you permit me to make a few remarks upon an article in a recent number of THE BRITISH JOURNAL OF PHOTOGRAPHY upon "Plate Backing and Sensitiveness." The writer of the article herein stated that, in his experiments, the resultant negatives of backed and unbacked plates were absolutely identical.

A short time ago I showed before a London and Provincial meeting negatives and prints therefrom, the plates having been partly backed. There was no doubt about the slowing of the backed portion—not great, but still there. The writer of the article must be a bold man, and a trustful one to boot, to believe he got identical exposures under the conditions therein set forth. The slowing is not of a very pronounced character, and in the comparing of one negative with another might easily escape detection. Let the writer do as I did, back part of a plate, expose it upon an evenly lighted subject—there is no need for a sensitometer—he will then see the difference.

There is another point that seems to have escaped his notice. One must not forget that the backing does not really slow the plate, but simply absorbs the light which has passed through the glass, which otherwise would be reflected back to the film, thus giving increased action where unbacked, so that, if you use yellow light—or, at least, light poor in the violet rays—to start with, you ought not to expect much further action upon the film after it has passed twice through the green glass. I myself used in my experiments magnesium or daylight.

Backing with a white pigment just as distinctly, perhaps in a slightly higher degree, shows acceleration. I have been lately trying coating paper with a composition somewhat like that used for the "—graphs" with the addition of zinc oxide. There is no doubt that it increased the exposure—that is, with a given exposure there is an increased deposit of silver, upon development, where the plate has been backed with the white backing. Of course, such a plate would be used only upon occasion. There are times when even this small increment of density may be of value. I have not yet hit upon the best proportions to use. The conditions required are that it shall be easily pressed into contact and as easily removed, leaving none attached to the glass. Variations of temperature and the hygroscopic properties of the composition make this rather awkward to lay down hard-and-fast lines.—I am, yours, &c.,  
17 Albert-road, Walthamstow, March 13, 1900. ALF. J. BROWN.

[We shall be referring to this subject next week.—EDS.]

PHOTOGRAPHY AT THE PARIS EXHIBITION.

To the EDITORS.

GENTLEMEN,—I was astonished at the knowledge of the different parties knowing all about the charges to be made during Exhibition time here, as printed in THE BRITISH JOURNAL OF PHOTOGRAPHY, while here nothing definite could be learned. Now I can give you in full the rules, as published a few days ago.

1. The use, during the Exhibition, of hand cameras is free, but under conditions as expressed in Notes 3 and 4.
2. The use of camera with tripod is only allowed until one p.m., and is subject to a permit delivered by the Commissaire Général, and subject to a fee.

The permit is given for one day, or from the time of opening of the Exhibition. In the first instance the operator receives a special ticket, which costs twenty-five francs (1l.) per camera. The ticket is obliterated at the entrance.

In the second instance the season ticket is a card with the photograph of the operator. This ticket costs 1000 francs per camera (40l.).

The payment of above dues does not dispense the operator or his helps from the regular admission fee of the grounds.

3. Nothing can be photographed without written permission from exhibitors. Permission must also be obtained from foreign representatives, &c., to reproduce their respective palaces and pavilions. The Administration of the Exhibition declines all responsibility for reproductions taken.
4. The operators must in no way interfere with the free circulation, and must submit to orders of the agents of the Administration.

The faculty to photograph remains submitted to all rules which may hereafter be issued in the interest of good order and police.

This is all at present, and if I have not translated the paper word for word, the sense of it is fully given and exact.—I am, yours, &c.,  
Asnières (Seine), March 13, 1900. A. LÉVY.

REFLECTOR HAND CAMERAS.

To the EDITORS.

GENTLEMEN,—Referring to Messrs. Watson & Sons' letter which appears in last week's issue of your JOURNAL, in which it is stated that the Gambier Bolton camera is practically an exact specification of the camera I described in my letter of March 2, will you permit me to point out that this statement is incorrect. If Messrs. Watson & Sons will refer to my letter of March 2, they will find that I specified a shutter capable of giving exposures as long as one-tenth of a second, and that the camera itself should be of the box pattern, and by box pattern I meant a camera in which the bellows, front panel, and lens is absolutely enclosed, the front of the box simply having a circular aperture cut out to admit of the free passage of light to the lens. The shutter fitted to Messrs. Watson & Sons' camera will not, I believe, permit of lower exposures than one-twenty-fifth of a second, and, as far as I can recollect from an inspection I made of the Gambier Bolton camera some time ago, the front has to be opened and the back dropped before an exposure can be made.

In conclusion, I may say that since the date of my last letter I have been in communication with a London firm who are shortly bringing out such a camera as I described, though they intend fitting a behind lens roller-blind shutter, giving various speeds, from one-tenth up to one-three-hundredth part of a second. I am informed that this camera is to be small and compact.—I am, yours, &c.,  
R. N. R.

THE METRIC SYSTEM.

To the EDITORS.

GENTLEMEN,—In the welcome number of the BRITISH JOURNAL OF PHOTOGRAPHY of to-day, "Free Lance" says: "I don't think that what I wrote about the metric system was really read by," &c. The fact is that my letter (see February 2) was written long before "Free Lance" ever thought about writing what he knew or better did not know about the metric system and its use in France. If by what I said in my letter, which he at least read, I suppose, proves to the hilt of his contention that he is right, he is easily satisfied, I dare say. If, however, he would give us some facts and not empty words, he could prove something to others' contention. On January 19, he says: "All this agitation in favour of the metric system," &c., and then goes on speaking about kilos and pounds. On March 16, line 14, he says: "for a pound is no part of the metric system." What does all that mean except that "Free Lance" does not know very well the subject he has undertaken to talk of? He seems to ignore the origin of the kilo, or else he would not say that a pound is no part of the metric system.

The metric system is not exactly the metre, but a certain measure, call it what you like, which is divided into 10, 100, 1000, or more parts which are easily divided, multiplied, &c. It is always funny to hear a foreigner, be he English or French, discuss things from the other country of which he knows nothing about, and these words of "Free Lance" seemed so out of the way that I did not consider them worth an answer, but since he insists let him explain them. Here they are: *In the very home of the metric system, the metric system as a system is practically non-existent, at any rate, for domestic purposes.* What does that mean? Please let us know what is the system used here. By here I do not mean Asnières but France, the same as "Free Lance" probably means England when he writes; however, his notes bear no date, no place, and are anonymous, but, if he had a place or city, he would not mean that special city (sarcastically or not).

Referring now to his problem I find that 160 grammes to 2000 means at a glance 1 gramme in 125, now if 70 grains in 20 ounces mean 3½ grains in 1 ounce, how about 1 grain. It is, of course, 1 grain dividing the ounce into 7 parts multiplied by 2. Then is it troy or avoirdupois. This example does not seem a happy one to have been chosen by "Free Lance." I hope that when "Free Lance" has studied the origin of the kilo and its subdivisions he will no more say they are no part of the metric system.  
A. LÉVY.

Asnières (Seine), March 16, 1900.

Answers to Correspondents.

- \*\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street, Strand, London, W.C. Inattention to this ensures delay.
- \*\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \*\* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

A. J. Ashbolt, 10, Exmoor-road, Southampton.—Photograph of group of Southampton Football Club, full cup team.

- J. W. Dale**, Wellington House, Victoria-road, West Hartlepool.—*Photograph of the Mayor of West Hartlepool. Photograph of the Mayoress of West Hartlepool.*
- T. E. Innes**, 108, Wellington-road, Heaton Chapel, near Stockport.—*Photograph of Heaton Chapel Reform Club. Photograph of Heaton Chapel. Photograph of Heaton Moor Conservative Club. Three photographs of Heaton Moor-road, Heaton Moor.*
- DARK VIGNETTES.**—**S. A. and C. BIGGS.** See leading article in our last issue.
- E. H. ORANGE.**—In all probability, if you lay the facts before the local Superintendent of Police where the person complained of resides, you will succeed in obtaining a return of the money and negatives. We regret to have your complaint.
- ADDRESS WANTED.**—**C. R. C.** asks: "Can you give me the address of E. Cheron (I believe somewhere in Paris) who makes the E.C. ferrotype dry plates in cut sizes?"—In reply: We do not know the full address, but a letter addressed simply "Paris" would, no doubt, be duly delivered.
- ESK.**—We should not expect the developer to keep indefinitely in the one solution. If you use it made up as separate solutions, we should expect it to be powerful enough for your purposes, the proportion of alkali to reducing agent being very great. Try the latter suggestion, which, we think, will get you over your difficulty.
- SILVER WIRE.**—**WET PLATE** writes: "Where can I get pure silver wire, such as is used for the corners of the carriers of dark slides for the wet-collodion process? A jeweller got me some, but it stains the corners of the plates."—Pure silver wire may be obtained from most refiners. It may, we know, be obtained at Johnson & Matthay's, Hatton Garden.
- SECOND-HAND LENS.**—**J. R. J.** The large lens mentioned would be suitable for your requirements, and seems remarkably cheap at the price asked for it. There is, of course, a certain amount of risk in purchasing second-hand apparatus. We should advise you to have the lens sent to the maker whose name it bears for verification before paying the amount.
- DARK ROOM.**—**W. CONWAY.** The room you describe as your dark room is certainly very inconvenient for working in, but many amateurs would like to have it. Some of the rooms they have, perforce, to be content with are far less convenient than yours. Though somewhat inconvenient, there is no reason why the best of negatives should not be developed in it.
- TEST FOR HYPO.**—**HYPO** writes: "I have to wash some negatives of prints by repeated changes of water. I am anxious to know if all hypo is out of both. Is there not some chemical which, when put in the last washing, will show whether hypo is present or not?"—Tests for the presence of hyposulphites will be found on pp. 975 and 976 of the ALMANAC for 1899, both of which are very delicate.
- PRESS FOR COLLOTYPE WORK.**—**TYRO.** A typographic press will do quite well for colotype printing, but we should recommend you to have a proper colotype press, as you have to purchase a press. Being specially made for the purpose, they are more convenient in use than the ordinary Albion presses. Colotype presses are supplied by Penrose & Co., Winstone & Sons, and others.
- COPYRIGHT.**—**G. A. B.** says: "I have received one of the Queen's boxes of chocolate from a friend at the front, and have been asked by several friends for photographs of same; and, as the box is copyright, I would like to know if I would be infringing the copyright by supplying them with photographs?"—In reply: The design is probably registered. By reproducing it, you would render yourself liable to be proceeded against.
- STEREOSCOPIC PHOTOGRAPHY.**—**M. M. LAKIVI** says: "I shall be much obliged by your informing me where I can get stereoscopic transparencies on glass and paper, and coloured stereoscopic photographic slides?"—In reply: Messrs. Lévy, Rue Louis le Grand, Paris, supply transparencies. Paper slides are obtainable from Messrs. Underwood & Underwood, Red Lion-square, London; Messrs. Catherall & Prichard, 326, Camden-road, London; and Messrs. Seaman & Sons, Chesterfield. We do not know the source of the coloured slides.
- ADDRESS WANTED.**—**SUBSCRIBER** says: "On reading your notice respecting acetylene, you give the name of Mr. G. F. Thompson (Consulting Engineer), Lombard Chambers, Brixeth-street, London, E.C., as the publisher of a book on this gas. I wrote there, but my letter has been returned, not known. You would do me a great favour by giving me his address in your next, as I wish to obtain his book."—In reply: It is not surprising that our correspondent's letter was returned to him. Mr. Thompson's address is Liverpool, not London.
- BLINDS FOR STUDIO.**—**HANTS** says: "My studio is lighted both on the south and north sides. I sometimes, though rarely, want to work with the south light, therefore do not wish to block it out permanently. At present I have black blinds and curtains on that side, but they look very funeral-like, and, moreover, are worn out. Can you suggest anything of a more pleasant colour that would answer the same purpose?"—A dark green will be very agreeable to the eye, and answer the purpose quite as well as black, provided the curtains and blinds are of a tolerably thick material, so as to stop out the light.
- SURFACE ON BROMIDE ENLARGEMENTS.**—**STRUGGLER** says: "In looking at some bromide enlargements the other day, I noticed that either before or after working up the surface had been treated with a coat of some gummy substance, which, to my mind, considerably improved it, taking away the rather deadly dullness of the ordinary bromide print. Could you tell me what preparation that was, and how applied?"—Without seeing one of the pictures, it is impossible to suggest what it was coated with. It is not usual to coat bromide pictures with anything. Of course, they may be varnished with any of the paper varnishes. If you send us a specimen to see, we may very possibly enlighten you.
- PAINT FOR BACKGROUNDS.**—**BACKGROUND** asks for the name of the washable water paint or distemper that is so much in use by background painters and the best place to obtain it.—First paint the background with ordinary oil colour, the tint desired. Then flat it. The flattening is the same as the paint, except that the oil is omitted, it being simply mixed with turpentine and a little gold size. If you cannot mix the paint a flattening yourself, any oilman will make it up for you.
- SENSITIVENESS OF BITUMEN.**—**E. X. P. T.** asks: "Is there any difference in the quality of sensitiveness of bitumen of Judea? I have bought some at an oil shop that seems to be quite insensitive."—The sensitiveness of light of bitumen varies with different samples. Sometimes what is so at oil shops as bitumen is common pitch. Better get some from a dealer in photographic materials; you will then obtain a suitable kind. Messrs. Mawson & Swan supply a kind specially prepared for photographic purposes.
- REFLECTING LIGHT IN STUDIO.**—**OPERATOR** says: "Our studio has an unobstructed light from the sky, both top and side. What I wish to know is, whether a reflector, placed outside, will throw any more light into than will be beneficial by shortening the exposure?"—As there is an unobstructed skylight all round, there will be no practical advantage from a reflector; in fact, it would at times create difficulties. The camera might be different if the studio were surrounded by buildings that cut off some of the direct light.
- STEREOSCOPIC PORTRAITS.**—**HAMPSHIRE** writes: "I wish to try and introduce stereoscopic portraiture in my business. Will you please advise me as to the best lenses to get for studio work? R.R.'s would, I think, be too slow, particularly with children."—The most suitable lenses would be a pair of *carte-de-visite* lenses of about six inches equivalent focus, or a pair of stereoscopic portrait lenses, such as are supplied by Dallmeyer and others. The former will enable the camera to be placed a little further from the sitter than the latter, but both will be good.
- REVERSING MIRROR.**—**INVERTED** writes: "Kindly tell me at what angle a reversing mirror, for taking reversed negatives, should be placed with regard to the lens; also whether it should be before or behind?"—The mirror should be at an angle of 45° to the lens. It is usual to fix the mirror in front of the lens, though in some of the larger houses on the Continent it is placed behind. In the latter position, being inside the camera, it is the better protected from injury. Practically, one position is as good as the other so far as results are concerned.
- LENS FOR DIFFUSION OF FOCUS.**—**S. MINTON** writes: "I have been told that the front lens of a portrait combination, Petzval form, can be used for taking portraits with diffusion of focus. I have one about three and a half inches in diameter. Will you please tell me how it can be used for the purpose?"—Remove the back combination, and screw the front one in its place, convex surface towards the focussing screen. With its full aperture the lens will yield much "diffusion;" but, as its aperture is reduced by stops, the image will become proportionately sharper and sharper.
- INTENSIFYING VARNISHED NEGATIVE.**—**T. BARNARD** asks: "Is there any known way of intensifying a negative that has been varnished?"—Nothing can be done in the way of intensifying it so long as it is in its varnished state. The varnish must be removed first. This may be done by soaking it in strong methylated spirit—that is, supposing it is a spirit varnish—for an hour or so, then gently rubbing it with cotton wool. This treatment may have to be repeated two or three times to free the film from it, and it must all be got off, or stains will result. When the varnish is removed, the negative may be intensified by any of the well-known methods.
- BLINDS FOR STUDIO.**—**PYRO** asks us to advise him as to the best material for sufficiently subduing the sun's rays in a studio. "Ordinary white calico is not thick enough, do you know of any material with a texture similar to tissue paper, which there is nothing to beat that I know of? But the bars holding the glass are iron, and it is difficult to attach frames with tissue stretched on. When a photographer is busy he cannot be getting a ladder and lifting frames down as the light fluctuates. Could you also tell me if there is any tissue paper manufactured that remains white for a reasonable time? The paper I have used turns yellow in day or two."—Tracing linen, which may be had from any of the dealers in artists' materials, answers the purpose admirably. It may be strained on light wood frames, and these hinged to stout laths fixed to the ridges and eaves of the studio. Then, by means of cords, they may be adjusted at any angle, according to the light.
- SHADOWLESS PHOTOGRAPHY.**—**P. P. P.** says: "As 'shadowless' photography seems much used in advertising, can you inform me how it is done, or recommend a work which deals fully with the subject, or school, or polytechnic, where this particular branch is taught? Have read the article in the current number of the ALMANAC, which seems feasible enough for botanical specimens and similar subjects, but how to arrange the components of machinery, and things of like nature, showing them in perspective one above another, without the slightest sign of shadow or reflection, as shown in enclosed rough print, is puzzling to me. Have spent a great deal of time experimenting, but cannot succeed satisfactorily, my failures far exceeding my successes, which latter are only attained by an expenditure of much time and labour."—The article referred to is very explicit, and you will see from it that Messrs. Sharp & Hitchmough supply an apparatus specially for photographing objects by a vertical light, which would be suitable for such objects as are shown in the photograph sent. Messrs. Dallmeyer also supply an apparatus for a similar purpose. In photographing machinery and the like, the shadows are softened by the judicious use of reflectors. There is no work published on the subject; but any expert photographer would, no doubt, give you instructions in it.

### EX CATHEDRÁ.

THE preliminary announcement of the Fifteenth Annual Meeting of the Photographic Convention of the United Kingdom has been issued. The meeting will be held at Newcastle-on-Tyne, in the week July 9-14 next, under the presidency of Mr. Thomas Bedding, F.R.P.S., Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY. The Grand Assembly Rooms have been engaged by the Council for the meeting. The members will be officially welcomed to the city by the Mayor of Newcastle-on-Tyne, Mr. Riley Lord, who will be supported by an influential Reception Committee, the officers and members of the Newcastle and Northern Counties Photographic Association and neighbouring photographic societies. A most attractive programme of excursions has been arranged, including Hexham ("The Heart of all England"), the Roman Wall, Durham, Alnwick, Hulne Abbey, &c., &c. An afternoon reception will be held at that picturesque spot, Jesmond Dene, by Mr. G. B. Bainbridge, J.P., President of the Newcastle and Northern Counties Photographic Association. Short excursions will also be arranged to the many places of interest in and around the city, and permission, where necessary, will be obtained for

members to take photographs of its many historical churches, public buildings, &c. Papers, demonstrations, lantern exhibitions, &c., will be given during the meeting. The usual trade exhibition will be held. The entire ground floor suite of the Grand Assembly Rooms has been secured, and it is anticipated that an unusually interesting display of apparatus, pictures, &c., will be on view. The official reception and annual dinner will be held in the upper suite, so that on these occasions the entire building (which is lighted throughout by electricity) will be at the disposal of the members. Further information as to hotels, time of trains, trams, Tyne steamboat service, plans of Newcastle, Jesmond Dene, &c., will be given in the official programme, which will shortly be issued.

\* \* \*

AN unknown friend has been good enough to send us some excellent views of Jesmond Dene and Durham, which will be visited by the Convention. These and the other beautiful places mentioned in the previous paragraph will furnish very fine opportunities for photographic work amidst picturesque and historical surroundings. The detailed arrangements for the week are practically complete, Mr. F. A. Bridge, the General Honorary Secretary and Treasurer, having already visited Newcastle-on-Tyne and conferred with the local Committee on the subject. This body is entering so heartily into the matter, that the remarkable attendance of forty was present at the last meeting to discuss preliminary details. The local Honorary Secretary, Mr. William Thompson; the famous pictorial photographer, Mr. Edgar G. Lee; the highly esteemed Mr. J. Pattison Gibson, of Hexham; and the President of the Newcastle Photographic Association, Mr. Bainbridge, amongst many others, are taking the liveliest interest in the forthcoming visit of the Convention, the members of which may look forward to a well-arranged week. All the signs point to a successful meeting, and it is to be hoped that a very large attendance of members will take advantage of the earnest efforts which thus early the good people of Newcastle-on-Tyne are making to ensure that the 1900 Convention will be pleasant and profitable to all interested in it.

\* \* \*

THE Executive Committee of the Affiliation of Photographic Societies are calling another meeting of the Conference of

Judges to consider certain suggested modifications in the rules and recommendations adopted in 1895, and we are asked to announce that any person who has acted in the capacity of a Judge at an exhibition having open classes is invited to attend. The conference will take place at 66, Russell-square, on Wednesday, April 11, at seven p.m. Copies of the rules now in force and of the suggested modifications may be obtained, by those who do not receive them in the ordinary course, on application to Mr. A. W. W. Bartlett, Secretary. The following are the proposed rules: 1. The Judges' decision shall be final. 2. The Judges shall have full power to withhold any award. 3. The Judges shall have power to exclude all persons from the room while judging. 4. The Judges' expenses shall be paid. 5. It shall be stated in the prospectus that the awards are placed "in the hands of the Judges," or "at the discretion of the Judges." 6. The Judges shall not adjudicate upon pictures exhibited as produced with wares of special trading firms. 7. Where there is a champion class, pictures which have previously taken awards in open classes shall be exhibited in the champion class only. 8. An award shall be made to one picture only, whether it is in print, lantern slide, or other form. 9. There shall be no distinction between amateur and professional.

\* \* \*

FURTHER proposed rules are: 10. No production of any kind whatever from the same negative shall receive more than one award, except as defined in rule 7. This includes lantern slides, enlargements, &c. 11. No award shall be made to a lantern slide until it has been projected on the screen. 12. It shall be stated on the entry form to what extent the work sent for competition is that of the exhibitor. 13. That the names of those who have consented to act as Judges shall be printed in the prospectus of the Exhibition. 14. No award shall take the form of a money prize. The following are the proposed recommendations: 15. The names of the competitors should be withheld from the Judges. 16. The Judges should have power to give extra awards where they may think fit. 17. In order to enhance the value of awards, their number should be limited. 18. The Exhibition Committee should not accept offers of awards from trading firms. 19. The number of awards should be kept as small as possible. 20. No exhibit at the same Exhibition should receive more than one award. Upon the foregoing proposed rules and recommendations, as well as upon some suggestions that have been made to the Committee, considerable discussion may be expected. In the last five years the growth of feeling in favour of the abolition of medals at exhibitions has been very marked, and we may expect this fact to have some influence in the deliberations of the Conference of Judges next month.

\* \* \*

LANTERNISTS, and others interested in optical projection, should acquaint themselves with the new by-laws of the London County Council, which have been approved by the Home Secretary, governing the public exhibition of flash and search lights. Apparently drawn up in the interests of the traffic and inhabitants of the greatest and most crowded city in the world, it remains to be seen how far they will secure general approval. They are as follows: No person shall exhibit any flash light so as to be visible from any street and to cause danger to the traffic therein, nor shall any owner or occupier of premises permit or suffer any flash light to be so exhibited

on such premises. The expression "flash light" means and includes any light used for the purpose of illuminating, lighting, or exhibiting any word, letter, model, sign, device or representation in the nature of an advertisement, announcement or direction, which alters suddenly either in intensity, colour, or direction. No person shall exhibit any search light so as to be visible from any street and to cause danger to the traffic therein, nor shall any owner or occupier of premises permit or suffer any search light to be so exhibited on such premises. The expression "search light" means and includes any light exceeding 500-candle power, whether in one lamp or lantern or in a series of lamps or lanterns used together and projected as one concentrated light, and which alters either in intensity, colour, or direction. Any person who shall offend against any of the foregoing by-laws shall be liable for every such offence to a fine not exceeding 5*l.*

\* \* \*

PROFESSOR R. W. WOOD, of Madison, Wisconsin, U.S.A., who recently delivered before the London learned societies a series of deeply interesting lectures on zone plate photography, the photography of sound waves, and his own remarkable process of colour photography with diffraction gratings, has returned to America. Previously to his departure he saw another notable experimenter in colour photography, Professor Lippmann, of Paris. Professor Wood tells us that he was amazed at the progress Lippmann has made in his interference process. "His landscapes are beautiful, the colours being as vivid and as true to nature as in a well-executed colour slide, sometimes superior." Professor Wood judges that Lippmann has a much larger percentage of successes than formerly. With regard to Professor Wood's process, we trust that those British experimentalists who are qualified for the work will not neglect to give it early attention. Of the four pure spectrum colour processes, if we may so term them, now before us, Professor Wood's most readily admits of the multiplication of copies, and deserves special notice on that account.

\* \* \*

MESSRS. C. ARTHUR PEARSON'S *Royal Magazine* for April strongly appeals to the notice of the devotees of stereoscopic photography. Its first article, "Following a War with the Camera," is illustrated by the halves of binocular photographs taken by Messrs. Underwood & Underwood during the late Spanish-American War. The writer of the article pays a great compliment to Messrs. Underwood for their enterprise and courage in securing these and other war stereographs. Another feature of the *Royal* consists of a couple of pages of British military stereographs, which are excellent. The publishers of the *Magazine* supply a stereoscope for viewing these photographs for two shillings. We have so often advocated stereoscopic photography for purposes of book-illustration that it is needless for us to repeat our ideas on the matter. It is enough to say that we are pleased to see binocular work so largely drawn upon by the conductors of a popular magazine like the *Royal*.

\* \* \*

WE learn from Messrs. Underwood & Underwood that their stereoscopic photographer is at work on the South African battlefields, and, though, like most other correspondents and photographers, he has met with great difficulty in his progress, a large set of war stereographs will result from his efforts. The Queen's forthcoming visit to Ireland will also furnish Messrs.

Underwood with the opportunity of procuring a set of stereographs illustrating scenes in the sister Isle while the Sovereign is there. There appears to be no limit to the energy of this house in making stereographic records of current events and remote parts of the globe, over most habitable parts of which their operators appear to have travelled. Of course, Messrs. Underwood stand in no need of commendation from us, whose interest in the subject of stereography *per se* is our excuse for these references. The fact that a single house has built up a vast business in binocular work shows that this branch of photography is greatly appreciated by the general public, and causes us some surprise that it is not taken up with greater spirit by professional and amateur photographers.

\* \* \*

THE new Copyright (Artistic) Bill has at last been issued. We reprint elsewhere the essential parts of the Bill, which this week was to be read a second time in the House of Lords, and referred to a select committee, consisting of the Lord Chancellor, the Earl of Selborne, Viscount Knutsford, and Lords Balfour, Hatherton, Monkswell, Thring, Farrer, Welby, Davey, and Avebury. The new Bill differs in many vital respects from the measure which was introduced to the Lords last year, and which, in the reasonable apprehension, following upon the meeting held last month at the Society of Arts, that it was to be brought up again this year, has been so severely criticised in our pages during the past few weeks. Lord Monkswell's new Bill proposes to give copyright in photographs for life and thirty years afterwards; is entirely silent on the subject of registration, compulsory or otherwise; defines photography as "artistic work;" provides that the owner of a negative shall be deemed to be the author; simplifies the "valuable consideration" clause, and in other respects, at the first glance, is distinctly sympathetic towards photography—as sympathetic, indeed, as the Act of 1862. But that the Bill in its present form will pass is premature to expect, for, as a result of its reference to a select committee, it may possibly assume a far less objectionable shape. We shall follow its career through Parliament with interest; in the mean while it is satisfactory to know that the Bill on another page, which bears Lord Monkswell's name on its back, does not, so far as we are able to interpret its provisions, attempt to treat photography in the penalising, spolliative, and degrading manner which the notorious St. John's Wood Bill, that we have so often denounced, manifestly intended to do.

#### EARLY DRY PLATES AND PLATE BACKING.

As evidenced by letters we have received regarding our remarks on this subject a short time ago, some little elaboration of what we then wrote is likely to be of interest to our readers. We will deal first with what we may term the historical part of our subject, as referred to by Col. Mitchell. *En passant*, we may say that it is quite refreshing to hear from a "wet-plate man;" so vast have been the strides made by photography in the past two decades that there is already quite an archaic flavour about references to the old days of silver baths and collodion. As our article had no accurately historical aspect, we did not deem it necessary to particularise by name the plates we referred to. But Col. Mitchell is quite right; the plates indicated were, to speak exactly, urano-bromide emul-

slon process plates, as invented by Colonel Stuart Wortley, and we can further bear testimony to their excellence, as testified by our correspondent. They were a collodion emulsion plate, and at the time had a great run, though eventually every plate of the kind was virtually extinguished by the advent of the gelatino-bromide plate. The film of these uranum plates was thin, and so the protection of a backing was a necessity. It may here be worth noting, as an historical reminiscence, that the details of the process were made public by Colonel Stuart Wortley at the first meeting of the Dry Plate Club, the President of which was no less a dignitary than the Archbishop of York.

But as regards to their being "the best, if not the only workable, dry plates placed upon the market prior to the advent of gelatino-bromide plates," we can scarcely give our adhesion to that opinion. Collodio-albumen plates had been many years in use and purchasable in open market, but even presuming that plates of comparative rapidity were meant, collodio-albumen being very slow, we might point out that, prior to the Wortley plate, there were, as a reference to the advertisement columns of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1871 and 1872 would show, many makes of acknowledged repute. Thus in these pages may be seen advertisements of "Pollitt's Dry Plates," "Russell's Rapid Dry Plates," "The Liverpool Dry Plate Company's Plates." In addition to these may be mentioned a plate of the highest quality, which already at that time had enjoyed for years a high reputation and large sale—the "Hill Norris Dry Collodion Plates." It is a fortunate thing that what we have written has given an opportunity of bringing to the notice of the modern votaries of photography that "there were giants in those days."

It was fairly well recognised in those days that reflection at the back of the plate formed a source of evil which was termed indifferently, even by experts, "blurring," or "halation," though at the present time the latter term is practically exclusively used. Still, the cause of halation was, and had been for years, a constant subject of discussion in the pages of this JOURNAL, and the matter was brought to a focus, as it were, by Sir W. Abney (Major Abney then), in a paper read before the Royal Photographic Society, in which he clearly proved the cause of halation, and gave a mathematical formula for its extent dependent upon the thickness of the plate, a method which has been of considerable use in gauging star magnitudes on dry plates.

With regard to the use of dark-paper backing for wet plates to avoid this defect, we may say that, not only have we used it for the purpose, but have also successfully employed black American cloth, temporarily attached (after previously wiping the plate) with glycerine. With regard to the slowing of plates by backing, our experiments are conclusive and not to be gainsaid. Mr. A. J. Brown saw in the plates he had taken evidences of slowing, but which were slight. "Dirt" was said by Lord Palmerston "to be matter in the wrong place;" the unbacked portion of Mr. Brown's plates simply had light in the wrong place, which might easily deceive as to its true meaning.

If our correspondent had had as much experience as we have in the ways of experts in manufacturing, when legal tests were being made, the British legal standard of comparison for illumination, the "Standard candle," he would give his opinion far more modestly in regard to the value of the source of illumination we adopted. "A naked gas flame" (protected goes

without saying) "burning at a constant pressure" cannot be used as a general standard of comparison; but, as a particular standard on a particular occasion, it can be trusted to one-hundredth per cent. "Daylight" and "magnesium" are unscientific and untrustworthy standards.

---

**Embryonic Heart Movements.**—Professor G. Farro contributes to the *Bulletin della Soc. Fot. Italiana* an interesting paper detailing his experiments in the registration of the movements of the heart of an embryo chick, three days after the formation of the same. The egg, kept at a constant temperature, was placed on the stage of a microscope, and sunlight projected through it by means of a heliostat. The image formed by the objective is sent by a prism into a camera at the same time as the image of a Koenig tuning fork vibrating at a constant rate on to a sheet of bromide, moving at a constant rate behind a fixed slit. The illustration is interesting and conclusive as to the regularity of the movement, and the author suggests that there is here a new field opened up by the aid of photography in embryology.

---

**Gallic Acid in Developers.**—Dr. Lüppo-Cramer, of Charlottenburg, has been experimenting with the addition of gallic acid to certain developers, and he finds that two and a half per cent. added to a metol-potash developer slows it so much that the mixture acted exactly like a slow developer, the high lights appearing first, then the half-tones, and finally the shadows, and that the negative, when compared with one developed with metol without the gallic acid, showed a somewhat browner colour but quite sufficient printing density, whilst that developed with metol alone was thin and useless. Subsequent experiments proved that the image partly consisted of oxidation products of the gallic acid, but these were not sufficient to account for the whole of the increase in density, and that the gallic acid certainly increased the developing power. With pyrogallol, hydroquinone, and para-amidophenol, gallic acid acts merely as a very powerful restrainer, and, in the case of hydroquinone, so strongly as to almost prevent development at all; with amidol, whilst slowing the developer, it increased the density-giving powers. The strong colouring matters formed in alkaline gallic acid solution, which cannot be prevented by enormous additions of sulphite, preclude any practical use being made of it. There is an interesting point in connexion with this experiment, and that is, although gallic acid will reduce precipitated silver bromide instantly to the metallic state, it is unable to act as a developer on emulsified silver bromide.

---

**To the North Pole.**—We read that the *Windward*, the vessel presented by Mr. Alfred C. Harmsworth, in May 1898, to the Arctic explorer, Capt. R. E. Peary, is to be rebuilt and re-engined at a cost of forty thousand dollars, this expense being borne by the Peary Arctic Club. The Committee of Commerce of the United States Senate has reported a bill granting a register to the vessel, which is English-built. The register is sought that its enterprising owner and his American friends may have the patriotic reward of carrying the "Stars and Stripes" in an American ship to the North Pole. Nearly every country has had the same ambition, and it will be interesting to see which, if any, will be the first to reach the goal. In all recent expeditions photography has been a feature, and we know that in all future ones it will not be neglected.

---

**The National Gallery.**—The Annual Report of the Director of the National Gallery (Sir E. J. Poynter), for 1899, issued last week, contains some interesting details. From it we see that during the year the Gallery has acquired five fresh works, including two fine Rembrandts, purchased by the Trustees from Lord Saumarez for 15,050*l.* A special grant for this purpose had to be obtained from the Treasury, and it was only granted upon condition that the Trustees should forego the annual grant for 1899–1900, estimated at

5000*l.* The Government certainly cannot be charged with over-liberality in the sum annually granted for the acquisition of fresh pictures for our national collection. If it were not for private donations, this country would fare badly by comparison with some Continental ones. Not the least interesting part of the Report, as showing how art is appreciated in our capital, is the number that visits the National Gallery. It shows that during the year 1899, on the free days, the Gallery in Trafalgar-square was visited by 420,272 persons, giving a daily average of 2040. In addition to this number the Gallery was visited, on the thirty-one Sundays it was open, by 35,226 people, or an average of 1136 per day. The number of visitors on students' days, when the admission is sixpence, shows a marked increase on that of 1898. At the Gallery of British Art, the Tate Gallery, at Millbank, there were, on the free days, 177,420 visitors, giving a daily average of 857. On the thirty-one Sunday afternoons this Gallery was open it was visited by 36,726 persons, an average of 1184 daily. It is noteworthy that the Sunday admissions to the Trafalgar-square collection were but a little more than half the number of the week-day average; whereas, at the Millbank Gallery, it was nearly fifty per cent. more. This would tend to show that the Sunday visitors have a preference for British art over that to be seen in the older building. The Sunday opening, during the summer months, of the national collections of pictures gives photographic *employés* who are engaged during the week the opportunity of seeing and studying the works of the finest masters, old and modern; but it may be a question as to how many really avail themselves of it.

---

**Enlargements versus Direct Negatives.**—We notice, from the report of a recent meeting of the North London Photographic Society, that the oft-discussed theme, "Direct Large Pictures versus Enlargements from Small Negatives," was once more to the fore. This question has formed a fruitful topic for discussion before the different photographic societies during the last three or four decades, and will, doubtless, continue to do so, for, as a matter of fact, both systems may be the better, according to circumstances. It is generally conceded that there is a charm or a certain something about a print from a direct large negative that is not obtainable in an enlargement from a small one. But that does not hold good in all cases. Take, for example, a portrait 15×12. If that be taken direct with a suitable lens for the purpose, which, as we have pointed out on previous occasions, should not be less than twice the focal length at least of the longest dimension of the plate, namely, thirty inches, it will be to most people more pleasing than an enlargement from a small negative. But, on the other hand, if it be taken with a lens such as is too often used for the purpose, which, though it will cover that size plate according to the catalogue of its maker, is of, say, only eighteen or so inches focus, the case will be different. Here the camera has to be approached so close to the sitter that the perspective, though true, is violent, and the picture, though technically excellent, will be very unpleasing. Here an enlargement from a small negative, made with a lens of double the focal length of the plate, will be the better, notwithstanding that it may lack the special charm of a direct picture. We merely allude to these facts to show that, in considering the question of enlargements *versus* direct pictures, so much must necessarily depend upon conditions.

---

THERE is one thing that materially militates against enlargements in the eyes of some, and that is the coarseness of the grain in the original negative. This, in the case of some extra-rapid plates, especially when they are under-exposed and forced in the development, becomes very conspicuous in the enlargements, and gives quite a different appearance from that seen in a direct print. This may to an extent be greatly ameliorated in making the enlargement by putting the lens slightly, very slightly, out of focus. That, if judiciously done, will not materially affect the general sharpness of the picture, while it will greatly avoid the granularity. We were, some time ago, shown several enlargements made from old 10×8 wax-paper negatives to about double their size in which this system

followed. The result was that the granularity seemed to be less apparent than it was in the direct prints from them, though the general sharpness of the pictures did not seem to be impaired in the slightest. This may be a useful hint to those making enlargements from very granular negatives.

**Photogravure in Practice.**—At the last Photo-mechanical Meeting of the Royal Photographic Society the topic of the evening was photogravure, and Mr. Ignatz Herbst, who brought the subject forward, remarked that photogravure was quite useless as a commercial process without skilful and artistic work on the plate, and was in this particular that the method was essentially not a mechanical one. A speaker, however, expressed the opinion that he did not think that the artistic character of the process was enhanced by retouching; in fact, he was of the contrary opinion. That opinion, we know, is not, we know, be endorsed by any one who has to do with commercial photogravure. Even the best photogravure plates that are probably require a certain amount of very skilful hand work to render their prints from them marketable. That hand work must be done by a skilful engraver, and one who can thoroughly carry out the artist's idea as to how his painting should be translated into monochrome. The publisher and those for whom he caters have also to be satisfied, for it must be borne in mind that in the market photogravures are not looked upon in the light of photographs, but as engravings, and the closer they are made to resemble them the greater is their commercial success. Those who purchase photogravures could not have them if they could obtain good line or mezzotint engravings of the same subjects, even if they had to pay a somewhat higher price for them. But, alas! they are not obtainable. The line and mezzotint engravers have died off, and there are no new ones to take their place. This is not altogether surprising, when it is considered that a photogravure plate can be produced in a much shorter time than by the older methods.

WITH regard to the printing from the plates in colour, it will be remembered that some weeks ago we mentioned that we saw this work being done in a Continental house some time ago, and that a man could only produce from two to three impressions per day. At a meeting General Waterhouse also mentioned that he had witnessed, in Paris, colour printing, and there only two impressions a day were obtainable. Mr. Herbst said that, with the large prints he showed, half a dozen men were engaged at the same time in inking up a plate, and that the work took a couple of hours; so it will be seen that colour printing from intaglio plates is necessarily a slow process. One of the speakers (the Rev. F. C. Lambert) said that, when he endeavoured to apply the ink locally, he invariably found that, in wiping the plate, the ink was shifted and smeared. Now, it is just this condition that enables the skilful printer to render the tints, which he could not well otherwise do, and he takes full advantage of it. Colour printing from intaglio plates requires great care and artistic skill in order to obtain the best results. We regret to hear from Mr. Herbst's colleague, Mr. Reichs, that he could not get suitable men for the work in this country, and that, therefore, he had to get them from the Continent.

**ABOLISHING THE DARK ROOM.**

It was with much pleasure I read a paper on the above subject by Mr. Howard Farmer at page 803 of THE BRITISH JOURNAL OF PHOTOGRAPHY for 1900.

Seeing, however, that the actual dyes, or other agents, found by Mr. Farmer to yield the brightest safe light are not stated in that article, I forthwith got my tin lamp altered so that glass tanks could be slid into grooves in place of coloured glasses on two sides of the lamp, and got two caps fitted so as to exclude all light except what passed through the solutions in the tanks. The lamp being ready, I procured at a very cheap rate all the aniline dyes sold in the bazaar, both here and in Bombay at the chemists' and colour shops, and commenced a long series of experiments to find out the best thing to use as a light filter. Being

a medical man, I had in hand several drugs and chemicals yielding coloured solutions, and these I tried also. Of course, I tried, among a heap of other things, the thirty-grain solution of quinine (suggested by Mr. E. Dunmore in your annual), both singly and in combination with various yellow and other dyes. The results of each experiment were tabulated, and they occupy several sheets of foolscap paper. To describe all the things which proved utterly useless would occupy much space, and would be of no interest to the readers of the JOURNAL. I will merely state that the very best results were obtained with eosine in combination with metanil yellow. I need hardly mention that the object of the experiments was not merely to discover what articles gave a safe light, because a safe light was found to be given by almost every dye and chemical which was capable of producing orange or ruby solutions. The object in view was to find an absolutely safe and yet a brilliant light of the palest yellow colour possible, because the paler the yellow the brighter and more pleasant the light is, and the redder the light the worse it is in every way. It was considerations of this kind that made me prefer eosine to aurine, erythrosine, and many other dyes, which give, in very dilute solutions, a redder colour than eosine, and which are, notwithstanding, very much less efficient, weight for weight, if used simply in solution.

If you prepare three solutions, say, of aurine, erythrosine, and eosine, each containing three grains in twenty-four ounces of water, the last-mentioned will be found to be out-and-out the best as a light filter, though the eosine solution was the palest red of the three. I mention this to show that it would be useless to add anything to the formulæ below given to make the light just a little redder. The feeling exists among many, especially beginners, that a dark room is no use unless it be dark, and the light never safe enough unless it be ruby or red, or, at least, deep orange; but all that is changed now, thanks to Mr. Farmer's discovery, and now we must say that a dark room is no use unless it be brilliantly lighted, and the light of no use unless it be of a pale yellow or lemon colour. Some will, no doubt, say, "Oh, let us add a little more eosine, at all events." And to this let me answer, "Please, don't," because the brightness of the light would suffer thereby.

After finding out that eosine and metanil yellow were the best things to use, I tried these in combination in several proportions, and the formulæ below given show, as far as I at present know, the best proportions to give the brightest light compatible with absolute safety:—

1.
 

Eosine .....	1 grain.
Metanil yellow .....	12 grains.
Water .....	48 ounces.

This solution is absolutely safe for rapid plates developed at one-and-a-half feet distance from the flame of a stearine carriage candle.

2.
 

Eosine .....	$\frac{1}{2}$ grain.
Metanil yellow .....	6 grains.
Water .....	48 ounces.

This is perfectly safe for ordinary plates at one-and-a-half feet distance from the flame for commencing development.

3.
 

Eosine.....	$\frac{1}{4}$ grain.
Metanil yellow .....	3 grains.
Water ..	48 ounces.

This is suitable for all bromide papers developed at one foot distance, and for ordinary plates at two feet distance.

The last formula gives quite a glare of beautiful and brilliant light, and experienced photographers, who know the use of the broad of their backs to shield a naked plate from any prolonged direct light, and who commence development either at a suitable distance or on one side of the lamp, will find this formula quite safe enough for all purposes, excluding, of course, orthochromatic plates. I have often developed very rapid plates with formula No. 3 without any trace of fog resulting, but with such plates a little care of the kind above indicated will be found necessary with that formula.

I ought to mention that many kinds of eosine are to be found in the shops. They all have one peculiarity, viz., that if you put an eosine solution of any strength in a tumbler or bottle, and let sunshine or lamp light fall on it, there will be seen on that side of the vessel where the light impinges, as also on the surface of the fluid, a bright green or bluish-green colour, or fluorescence, though the fluid itself is either a ruby, an orange, or yellow colour according to its strength. Some eosines show this fluorescence more than others, and that sample which shows the most will be found the best for use as a light filter.

Again, some eosines are yellow in very dilute solutions, and some, not yellow, but pink or red. That sample which in very dilute solutions is the least pink and the most yellow, and in strong solutions the purest ruby instead of red, will be found the best to use.

As for metanil yellow, which like many useful things comes from Germany, this also comes in a great variety from places like the Badische Anilin and Soda factory. The one I prefer for its bright and clear orange solutions, containing absolutely no turbidity, is of the quality marked on the packets as No. B.K.H. 74. There are two or three metanil yellows which yield deeper orange or golden yellow solutions, but, as they show a slight turbidity with cold water, I rejected them, because the light would vary as the sediment fell to the bottom. Nothing that yields the faintest turbidity in cold water should be employed as a light filter.

Possibly in some of the smaller towns eosine may not be procurable, in which case it should be ordered out by post, and in the mean while the following formula used:—

Caramel .....	8 grains.
Metanil yellow .....	12 „
Water .....	48 ounces.

This can be used at one foot distance for ordinary plates, and at one-and-a-half feet distance for rapid plates. For bromide papers this solution should be diluted to double its bulk with water. It will be understood from the above that I do not recommend this caramel (or burnt sugar) formula if eosine can be procured, as the eosine formulæ I have offered above give a much more brilliant and pleasant light.

K. B. COOPER,

March 6, 1900.

Assistant Surgeon, Ahmedabad.

#### A CAUSE OF UNSHARPNESS IN HAND-CAMERA PICTURES.

AN unsuspected cause of lack of sharpness in some hand-camera negatives has just come under our notice. The facts are these: The camera is one of the fixed-focus type, or, we should say, rather one in which the focussing is done by scale, and with a rigid, not bellows, body. The lens is one with a wide aperture,  $f\cdot5\cdot6$ , and is beyond reproach. When the apparatus was used last season, it was all that could be desired, but, when recently taken into use again, all the negatives proved to be unsharp—palpably out of focus—and it was found, by trial, necessary to rack the camera within about the twentieth of an inch of the normal point, according to the scale, to get a sharp negative, that is, when the lens was worked with its full aperture. A week or so later things went wrong again, or, perhaps it would be more correct to say, got right again as they were originally, for it was found that it was necessary to adjust the focus to the exact point on the scale in order to get a sharp picture. The explanation, when the cause was found, is simple. It is this: During the winter months the apparatus was stowed away in a lumber-room at the top of the house, that was not particularly dry, and which never had a fire in it; consequently the wood in the camera had become expanded sufficiently to throw the lens out of its sharpest focus. But after the apparatus had been in use out of doors on a few dry, sunny days, and was kept when not in use in a room in which a fire was generally burning, the wood contracted to its original dimensions.

We call special attention to this case because it may serve to illustrate what may occur in others. Many of the cheaper kinds of hand cameras are made of anything but the best seasoned wood. As a rule, they are constructed with the grain of the wood running at right angles to the length of the camera—the direction of its greatest expansion and contraction. Now, it can readily be conceived that such a camera is very likely to show a variation if it is carried for several hours in a hot burning sun, or is subjected to an hour or two's rain—conditions that all hand cameras are at times subjected to. It should be mentioned, however, that the slight variation, due to the expansion and contraction of the wood, is only appreciable when lenses of wide aperture are employed; with those of smaller aperture it is quite a negligible quantity.

#### REDUCING OVER-PRINTED PROOFS.

WE notice in the report of one of the London societies, the London and Provincial, that a bromide enlargement that was worthless on account of an ill-timed exposure was shown after it had been toned with copper. The producer said that the result "was a very fair print, with an apparent reduction of the dense parts and an intensification of the details in the high lights." One speaker expressed the opinion that the

improvement in the picture was due simply to the alteration of colour by the copper toning. Another gentleman said that the toning of the print shown could not be said to be altogether an improvement, much as the normal colour of a bromide enlargement was more suitable for the subject of the photograph. Now we are frequently asked, through the Answers column, for a method of reducing over-printed proofs. There are several ways by which pictures printed too darkly may be reduced, but the practical question arises as to whether, except as an experiment, the result when attained is worth the time and trouble expended upon it; in other words, "Is the game worth the candle?" We say, No.

It is an easy matter to make a fresh print from a negative if found, when taken from the frame, to be too light or too dark, and the trouble in doing it is infinitely less than any after-treatment when the picture is finished to make it presentable. The same also applies to enlargements. It takes less time to make a fresh one than to attempt to reduce an ill-timed or over-exposed one. Again, as to cost, it will be found in practice, if time is of any value, that it is far more economical to make fresh pictures than to expend time on attempting to reduce under or over-timed ones. Even if the attempt is more or less successful, the colour of some of the pictures is invariably different from that at first, at in the first instance, while with some methods its permanence is not at all doubtful. The practice with professional printers is, when a picture is under or over-printed, to at once throw it amongst the waste. The same also the custom with professional enlargers, and they, of course, follow this practice as a matter of economy. Still, the different methods of reducing or intensifying faulty prints or enlargements are exceedingly interesting to the experimentalist.

#### PHOTOGRAPHING AT THE PARIS EXHIBITION.

FOR once the regulations made with regard to taking photographs in an exhibition seem to give pretty general satisfaction. In a recent issue we gave, on the authority of the *Moniteur de la Photographie*, what they will be at the forthcoming Exhibition in Paris. Since then—Tuesday March 12—the Minister of Commerce has issued authoritative regulations under which photographs may be taken within the precincts of the Exhibition, and they differ somewhat from those published in the *Moniteur*. They are these: The use of hand cameras will be permitted at all times free of charge or restriction, but the use of apparatus standing on a tripod will only be allowed up to one o'clock in the day. In addition, this class of photographers must obtain a written permission from the Commissioner-General, and pay a fee, which has been fixed at twenty-five francs for one day, or a thousand francs for the period of the Exhibition. Photographers will, however, be subject to the following regulations: "No exhibit may be photographed without the written authorisation of the exhibitor. The interested persons must obtain from the Foreign Commissioners-General or Concessional Administrators of the Exhibition against all claims."

We mentioned just now that the regulations give pretty general satisfaction, and so they undoubtedly do so far as the unrestricted use of hand cameras throughout the day is concerned. Twenty-five francs a day, however, may not be too much for professional photographers using large apparatus to pay; but that sum—equal to one pound English—will certainly deter many amateurs from using a small stand camera, particularly as the day's use does not extend beyond one o'clock. We imagine, however, that amateurs will be thankful for the free use of hand cameras at all times without let or hindrance.

By the way, there seems to have been some little friction amongst the Selection Committee of the Salon with regard to the reception number to be given certain pictures, for we read that one of its members—M. Benjamin Constant, a well-known artist—has sent in his resignation to the body through his disagreement with his *confrères* on that subject.

#### SIMILI-PLATINE PAPER.

UNDER this name M. Van Loo recently introduced before the Association Belge a paper which might be considered a modification of Nicol's kallitype. The sensitising solution is composed of—

Ferric oxalate .....	15 grammes.
Oxalic acid .....	3 „
Silver nitrate .....	3 „
Water .....	100 c. c.

is quantity is sufficient to sensitise a dozen sheets of paper 50 x 60. The paper is printed exactly like platinotype—that is, till the image distinctly visible only, and it is then developed by immersion in—

Borax .....	60 grammes.
Sodium tartrate .....	60 „
Water .....	1000 c. c.

Increase contrast and obtain pure whites, a few drops of a five per cent. solution of potassium bichromate should be added to the above. After development, which takes five or six minutes, the print should be well washed in running water, and then toned in—

Potassium chloro-platinate .....	1 gramme.
Citric acid .....	10 grammes.
Salt .....	10 „
Water .....	1000 c. c.

the desired tone is obtained, and the print should then be immersed five minutes in a two per cent. solution of ammonia, and washed.

THE NEW COPYRIGHT BILL.

The following is the text of the new Copyright (Artistic) Bill, introduced to the House of Lords by Lord Monkswell.

PART I.

1. This Act may be cited for all purposes as the Artistic Copyright Act, 1900.
2. This Act shall come into operation on the first day of January, next ensuing hundred and one.
3. The author of any artistic work to which this Act applies, wherever made, whether he is or is not a subject of Her Majesty, shall be entitled throughout Her Majesty's dominions to the copyright of such work for a term beginning with the making thereof, and lasting for the life of the author, and thirty years after the end of the year in which he dies, and no longer.
4. The copyright in an artistic work and right of ownership shall be personal property: they may be vested in the same or different persons, and shall be deemed to be distinct properties for the purposes of assignment, devolution at law, and otherwise.
5. The owner for the time being of the copyright in any artistic work to which this Act applies shall not, nor shall his representatives or assignees, exercise any privileges conferred by such right without the consent of the owner for the time being of the work itself, or of his representatives or assignees of such last-mentioned owner.
6. The owner of the copyright in artistic work or of the right of possession of such work may assign his right wholly or partially, or may grant any interest therein, but such assignment or grant shall not be valid unless it is in writing, signed by the owner of the right in respect of which it is granted.

INFRINGEMENT OF COPYRIGHT.

7. If any person infringes any right conferred by this Act in respect of the copyright in an artistic work, the owner of such right may maintain an action for damages, and for an injunction, or either of such remedies.

SUMMARY REMEDIES.

8. If any person commits any of the following offences—
  - (1.) Sell or lets for hire, or exposes, offers, or keeps for sale or hire any pirated artistic work;
  - (2.) Distributes or exhibits in public any pirated artistic work;
  - (3.) Imports into any part of Her Majesty's dominions, or from or between any part of Her Majesty's dominions, any pirated artistic work;
 he shall, unless he proves to the satisfaction of the court that he did not know and could not with reasonable care have ascertained that the work was pirated, be liable to a penalty not exceeding five pounds for every copy of work dealt with in contravention of this section, and also to forfeit the copies of the work so pirated to the owner of the copyright, provided that the whole penalties inflicted on any one offender in respect of the same transaction shall not exceed fifty pounds.
9. A court of summary jurisdiction upon the application of the owner of the copyright in any artistic work, or of the owner for the time being of such work, may act as follows:—
  - (1.) If satisfied by evidence that there is reasonable ground for believing that pirated copies of such work are being hawked, carried about, sold, or offered for sale, may by order authorise a constable to seize such copies without warrant and to bring them before the court, and the court, on proof that the copies are pirated, may order them to be destroyed or to be delivered up to the owner of the copyright, or of the work as aforesaid, if he makes application for that delivery.
  - (2.) If satisfied that there is reasonable ground for believing that pirated copies of any artistic work are to be found in any house, shop, or other place within its jurisdiction, may by order authorise any

constable to search for such copies in such shop, house, or place between sunrise and sunset, and to seize and bring before the court any copies reasonably suspected of being such copies as aforesaid, and the court, on proof that such copies are pirated, may order the same to be destroyed or to be delivered up to the owner of the copyright or of the work as aforesaid, if he makes application for their delivery.

10. If any person hawks, carries about, sells, or offers for sale any pirated copy of any artistic work the subject of copyright under this Act, every such pirated copy may be seized by any constable, without warrant, on the request in writing of the apparent owner of the copyright in such work, or of the owner of such work, or of his agent thereto authorised in writing, and at the risk of such owner.

On seizure of any such copies, they shall be conveyed by such constable before a court of summary jurisdiction, and on proof that they are pirated copies shall be forfeited or destroyed, or otherwise dealt with as the court may think fit.

11. All penalties under this Act shall be recovered summarily, but no proceedings shall be instituted for the recovery of a penalty after the expiration of six months from the date of the offence in respect of which the penalty is imposed.

12. Where any penalty is directed to be recovered summarily, or act or thing authorised to be done by or in a court of summary jurisdiction, such act or thing may be done—

- (a.) In England, Wales, or Ireland, by or in a court of summary jurisdiction as defined by the Interpretation Act, 1889;
- (b.) In Scotland by or in any court having jurisdiction under the Summary Jurisdiction (Scotland) Acts;
- (c.) In the Channel Islands, the Isle of Man, or any British possession, by or in the court, or by justices or magistrates who exercise jurisdiction in the like cases to those in which the Summary Jurisdiction Acts are applicable.

13. Where proceedings for any penalty under this Act are instituted by the owner of the copyright, or of the owner for the time being of such work, the penalty shall be paid to such owner by way of compensation for the injury he has sustained, and any pirated copies shall be forfeited and delivered up to the owner on his application. In any other case the penalty shall be applied in the manner provided by the Acts under which the penalty is inflicted, and pirated copies shall be destroyed.

14. The owner of any artistic work, although he is not the owner of the copyright, may in the case of the infringement of the copyright in such work, or of any offence being committed under this Act in respect of any artistic work, institute the same proceedings in respect of such infringement or offence as if he were the owner of the copyright.

PART II.—APPLICATION OF ACT, DEFINITIONS, AND EXCEPTIONAL PROVISIONS.

15. This Act shall not apply to the artistic works following:—
  - (1.) Books as defined by the Literary Copyright Act, 1900, or
  - (2.) Designs as defined by the Patents, Designs, and Trade Marks Act, 1883, or
  - (3.) Engravings, prints or photographs, copies of artistic works in which copyright is subsisting, and which copies are not authorised to be made by the owners of the copyright in the works of which they are copies.
 Save as aforesaid for the purposes of this Act the expression "artistic work" means:—
  - (1.) Any work of painting, drawing, or sculpture, and
  - (2.) Any engraving, etching, print, lithograph, woodcut, photograph, or other work of art, produced by any process, mechanical or otherwise, by which impressions or representations of such works can be taken or multiplied, and
  - (3.) Any plastic work relative to geography, topography, architecture, or science in general, and
  - (4.) Any production in the literary, scientific, or artistic domain which can be published by any mode of impression or reproduction.

16. The expression "engravings and prints" as used in this Act includes "etchings, lithographs, woodcuts, and other artistic work not being photographs produced by any process, mechanical or otherwise, by which impressions or representations of artistic works can be multiplied."

"Author" means the painter, sculptor, engraver, or maker of an artistic work, and includes the personal representatives of the author.

"Owner" means the person for the time being entitled to the possession of an artistic work, and includes the personal representatives of the owner.

"Pirated artistic work" means any work produced without the authority duly given of the owner of the copyright in such work.

"Copyright" in respect of an artistic work means the exclusive right to reproduce such work, or any material part thereof, in any form, in any material, or for any purpose, or to authorise another person to reproduce such work or any material part thereof.

"Action" includes any proceeding in a superior court analogous to an action in England.

SPECIAL PROVISIONS.

17. The following regulations shall be made with respect to engravings and prints :—

(1.) The engraver or other person who makes the plate or other instrument by which copies of an artistic work are multiplied shall be deemed to be the author of the engraving or print, and entitled to copyright in the copies produced by such plate or instrument until and unless such copyright has been assigned as provided by this Act, or vested by devolution in law or death in some other person, and the owner of the copyright in such engraving or print may, subject to any arrangement he has made to the contrary, exercise all the privileges attached to his copyright without the consent of any other person.

(2.) The delivery of the instrument by which an engraving or print is produced shall not, in the absence of a written assignment, as provided by this Act, operate as an assignment of copyright.

18. The following regulations shall be made with respect to photographs :—

(1.) The owner for the time being of the negative shall be deemed to be the author, and an assignment of the copyright may be made either by delivery of the negative or by the assignment of the copyright in writing.

(2.) Where a photograph is made of any person for valuable consideration, the owner of the copyright shall not, during the life of the person photographed, be entitled to sell or exhibit, without his consent, copies of his photograph, but, save as aforesaid, the owner of the copyright in a photograph may deal with his right of copyright without the consent of the owner of the photograph, or of any copy thereof.

19. When the author of an engraving, print, or photograph, is a member of the firm or body of persons, the author, for the purposes of this Act, shall be such member of the firm or body as they may select.

20. Nothing in this Act shall prejudice the right of any person to copy or use any artistic work in which there is no copyright, or to represent any scene or object, notwithstanding there may be copyright in some representation of such scene or object.

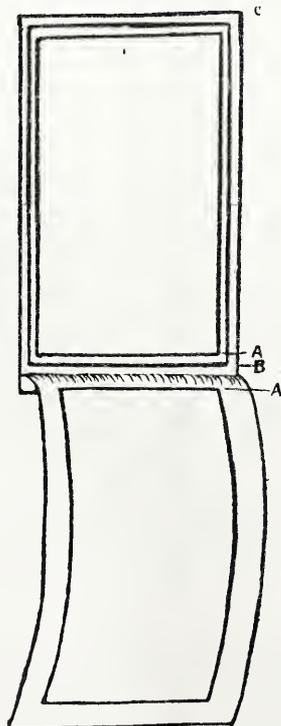

21. Copyright under this Act shall not subsist in any profane, libellous, or indecent artistic work.

22. Part II. of the Literary Copyright Act, 1900, relating to international law, shall apply to any artistic work to which this Act applies in the same manner in all respects as if such part were re-enacted in this Act and artistic work were included in the definition of book.

23. This Act shall apply to any artistic work made before or after the commencement of this Act.

A PHOTOGRAPHIC MOUNT.

Mr. T. H. RADFORD suggests the use of a mount which consists of two cardboards the same size, fastened together on one end, the bottom board

having two or more lines printed on, also being gummed from the inside line, A, to the outside edge, c, on drawing. The top cardboard is cut out in the middle, the same size as the inside line, A, on the bottom board.

The photographs, or pictures, are to be cut to the same size as line B on drawing.

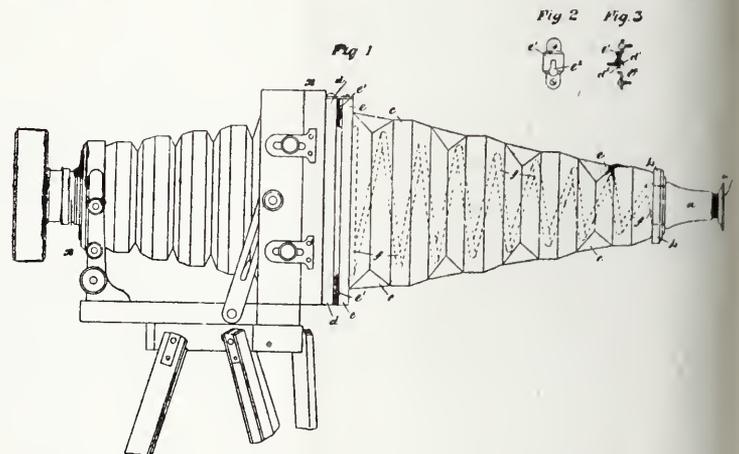

Mr. Radford recommends in mounting, to draw a wet brush over the gummed parts on the bottom board, then place the photographs, or pictures, according to line B on drawing. Press the front board down over the top; the mounting is then complete.

ERECTING THE IMAGE IN FOCUSING.

MR. F. W. SAXBY proposes to do this in the following manner—the description is taken from his patent specification :—

The picture, as represented on the ground glass or focal plane of a camera in reverse, is "erected" so as to be seen as it exists by the employment of a short-focus reversing glass, which in one form is in binocular arrangement, and in another form as a monocular glass. Further, there is used in connexion with a camera—that is, the back of a camera—an extensible and collapsible covering which excludes the light, and, at the outer end of this covering, the said short-focus glass or glasses is or are applied. When these articles or attachments are applied to the back of the camera, and the photographer looks through the glasses, the image appearing on the glass or focal plane will be seen as ordinarily seen by the eye, and not in reverse. Preferably, the reversing glass will be a magnifying glass as well, so that the image can be most carefully examined and scrutinised during the act of focussing, and the best composition and effect accurately obtained.

In one form or arrangement, the glass or glasses, as the case may be, is or are supported in an end plate or board, say, detachably; and between this plate or board and the back of the camera a covering or flexible material, such as a bellows formation or cloth, will be provided, so as to enclose the space between the telescope glass and the back of the camera, and keep out extraneous light. The distance between the

glasses and the back of the camera may be assured, or rendered constant, by folding or extensible arms, levers, or spiral wire spring, or the like, which also support the backboard or plate and telescope.

The short-focus reversing glass is marked *a*, and, by its reversing nature, the object thrown on to the screen, or focal plane, of the camera, in viewing the object prior to taking the photograph, is seen the right way up, and not in reverse, as it appears without the glass. And this glass, *a*, is detachably fixed in the plate, *b* (say, by screw threads on its end), which is fitted on to the outer end of the closed collapsible case, *c*, the front end of the case being fixed on to the frame, *d*, of the ordinary ground-glass screen of the camera, which is of the ordinary kind, and generally designated *x*. The glass, *a*, is kept firm, standing out from the back of the camera in the position shown in the drawing, by means of the spiral spring, *f*, inside *c*, fixed to the frame, *e*, and board, *b*, when expanded, or it may be held out by any equivalent means.

This spring, *f*, supports the glass sufficiently firmly out in the position shown, and at the same time allows of slight lateral movement, being elastic, when the eyepiece, *a*<sup>1</sup>, of the glass, *a*, is touched by the user's face in being looked through, so that the camera itself is not shaken or disturbed.

The spring, *f*, of course, allows of the case, *c*, being collapsible for close storage by pressing the parts, *b* and *e*, towards one another, and locking them together in any suitable known way.

It is well known that, if the subject to be photographed were thrown on to the screen, *d*, as seen by the eye naturally, instead of upside down, as is now always done, the subject could be better arranged, and better or more artistic and satisfactory pictures could be produced; and it is well known that this has been a long-felt want of photographers. It is, however, also well known that this end could be easily effected by using lenses in the camera which would make the subject appear the right side up; but there are against this certain well-known technical and scientific

objections, which render the use of this method of accomplishing the object impossible—that is, more objectionable than the reversed image as now exists. Consequently this method is never employed. By the invention the object is attained by the employment of the case, *c*, closely fitting—*i.e.*, light-tight—to the ground-glass screen, *d*, and having at its outer end the short-focus reversing glass, *a*, by which the image of the subject thrown on to the screen in reverse by the lenses of the camera, is again reversed or “erected” by the reversing glass, and is seen as normally seen by the eye, and, furthermore, the case, *c*, being made of collapsible bag form, such as the kind of collapsible material used on the front of cameras, and, like photographic apparatus, it can be collapsed, and occupies little space when off the camera.

To connect this apparatus with, and disconnect it from, the camera, the front wood frame, *e*, is provided with fastening plates, *e*<sup>1</sup> (see figs. 2 and 3), having slots, *c*<sup>2</sup>, in them which fit over the heads of screws, *d*<sup>1</sup>, having plain shoulders, *d*<sup>2</sup>, on them, and which screw into the back of the screen frame, *d*, one of said fastenings being used at each corner. By this attachment the whole apparatus, consisting of frames, *e*, collapsing chamber, *c*, back frame, *d*, and reversing glass, *a*, can be lifted on and off, collapsed, and stowed away, or applied and extended, very quickly, and will take little space when closed.

### FLASHLIGHT PHOTOGRAPHY.

ON Monday, March 19, a lecture was given, under the auspices of the Derby Photographic Society, by Mr. Councillor W. W. Winter, the well-known photographer, of Midland-road, Derby. The chair was taken by Mr. C. B. Keene, and there was an unusually large attendance, including a number of ladies. The Chairman briefly introduced Mr. Winter, who at once proceeded with his lecture, the subject being, “Flashlight Photography.” He said that, in the days of wet-plate photography, the absence of the sun during certain days of winter rendered it almost impossible to pursue photography with good results. Professional photographers owed a great deal to amateurs for many inventions that had facilitated their business very materially, particularly the introduction of the dry plate. Naturally the modern photographer was unable to appreciate, in comparison with the pioneers of photography, all the improvements in what might truly be termed the most popular of all arts and sciences of the present day. The lecturer then went on to describe the early methods of taking photographs by artificial light, and said the second method which was introduced was one which was more under control, but not sufficiently reliable to become popular—he referred to the magnesium ribbon worked through a lamp. Its weak point was a want of continuity. Passing on, he referred to the invention of Mr. Slingsby, of Lincoln, who was an enthusiast in the direction of artificial lighting. There were a number of lamps in the market at the time, but there was no way of managing them, and Mr. Slingsby invented the apparatus which they saw before them. After a while ordinary gas was used, and an expensive arrangement was floated upon the market in the shape of a huge gas-burner, consisting of a large cluster of gas-jets, perhaps 100. This was set up in the midst of a reflector with a looking-glass back, and in front was a blue glass, very necessary, especially for the sitter, in consequence of the heat given off. This and other methods had been superseded by the introduction of the electric light. Flashlight photography was very useful, but it took too long to fill the lamps and make it a commercial success. Speaking of the work done by the members of the Derby Photographic Society, Mr. Winter said he must confess that he had been greatly charmed by much of it done by both ladies and gentlemen. Having spoken of the various ways in which flashlight photography might be found useful, he went on to warn his audience of the various dangers which were ever present in manipulating the lamps, and pointed out in what manner they were to be avoided and the best results obtained. During his lecture Mr. Winter related some amusing incidents which had occurred in connexion with local photography, and dealt with the technical part of his subject in a very lucid and highly interesting manner. He demonstrated his remarks by experiments, &c., and at the end of his lecture answered a number of questions put by members of the Society.

Mr. W. R. Bland moved a very cordial vote of thanks to Mr. Winter for his great kindness in delivering such an able and valuable lecture. He had been particularly struck with the very genial manner in which Mr. Winter had dealt with his subject, and by the very winning and cordial manner in which he had, so to speak, come down to the amateurs' level. He had told them everything about the difficulties which arose in the flashlight system, and had also gracefully acknowledged the benefits which amateur experiments in photography had conferred upon the profession generally. Mr. Winter had gained a name which was known all the world over, and he had gained it by doing things thoroughly. Amateur photographers, if they desired to succeed, must follow his example, and never be satisfied with anything but the very best productions. He also desired to couple with the motion a vote of thanks to Mr. Winter's assistants, who had also been at great trouble in carrying out the necessary arrangements.

The motion was seconded by Mr. Dawson and carried with applause, and Mr. Councillor Winter suitably responded.

At the close of the proceedings those present were formed into a group and a very successful flashlight photograph was taken.

### THE TWENTIETH CENTURY INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

IN connexion with the Twentieth Century Engineering and General Trades Exhibition at Bingley Hall, Birmingham, Mr. Walter D. Welford has organized a very large and comprehensive display of photographs. For the various medals, &c., offered, over 150 amateurs and professionals competed, and about 600 pictures are hung. The exhibition was opened on Monday last by The Right Hon. The Lord Mayor of Birmingham, the judging of the photographs, however, was completed on Friday last, thus giving Mr. Welford the opportunity of getting the award lists into the hands of the competitors before the exhibition opened, which is at all times a commendable feature.

The photographs occupy the whole of a very long and spacious gallery, and are entirely by themselves. The gallery is nicely decorated and made comfortable with seats, &c., and will doubtless prove a great attraction. Last year there were too many pictures (over 900), but possibly the selective power of the manager has helped in the present great improvement. For, although the walls are still well filled, a better arrangement has been possible altogether, and, moreover, the elimination of some of the very poor pictures gives a higher tone to the rest. The work shown is certainly of a high standard, and in some of the classes the Judges must have had considerable trouble in coming to a decision. In addition to British work there are examples from America, France, Switzerland, and Turkey. The fair sex is strongly and numerously represented, and there are pictures by ladies that, doubtless, ran the male workers rather closely.

Mr. Welford is somewhat disappointed at the result of his efforts on behalf of professionals and employees, the special classes arranged for them certainly not meeting with the support they deserved, although the competition for negative working-up met with fair recognition, chiefly by lady retouchers, however. The class for trade work, photographs taken for business and advertising purposes is, however, quite a failure. Mr. Welford rather humorously states that if this class had been open to amateurs as well it would have been a success, which is rather hard on—well, we cannot say which.

As last year, the division for amateurs who have not previously gained an award at an open exhibition is particularly strong, the Judges themselves remarking upon this point, and this not only in number but in quality.

The Judges were Messrs. Harold Baker, R. Child Bayley, and A. Horsley Hinton, and their awards are embodied in the following notes:—

**THE CHAMPION CLASS.**—Honours again fell to Scotland, Edinburgh winning both the gold and silver-gilt medals. There is no Champion Class of the usual stamp, but the Judges select the best four pictures exhibited, quite irrespective of class, and these four are afterwards debarred from taking other awards except the special prizes. The winner of the premier award, Mr. Jas. Burns, of Edinburgh, is comparatively a new exhibitor, and is to be congratulated upon his success. His picture, representing a girl on the sea shore, entitled *The Wind Bloweth from the Sea*, which gains the gold medal, is a clever piece of work, but one is somewhat in doubt whether, after all, it is not a lucky snap-shot, rather than an earnest attempt at a well-thought-out subject. Still, it is good, and deserves the award. The silver-gilt medal was awarded to Mr. Alex. Allan, of Edinburgh, for figure and doorway study in strong sunlight. It is somewhat suggestive of Demachy and Craig Annan, but is, nevertheless, a very delicate rendering of a difficult subject. The silver medal was gained by Mr. Francis A. Bolton, of Oakamoor, for *Looking Westward*, one of those peaceful, low toned subjects, with a powerful sky. Mr. George Whitehouse, Birmingham, gained the diploma for *A Gleam of Sunshine*, a picture of the birch and bracken school, but without either birch or bracken, the strong feature of which is the soft lighting.

**LANDSCAPE.**—A very good representative class, with work by Messrs. Rawkins, Dubreuil, Hallier, Cowen, Bolton, Terras, Greatbach, Boetto, Revilliod, Fraser, Page Croft, &c. Silver-gilt medal to Mr. J. Page Croft, Birmingham, for *Within the Dale*; silver medal to Mr. Hugh Lewis, Birmingham, for *Through Mists and Snows*; bronze medal Mr. Ralph R. Rawkins, for *The Sentinels*; and diploma to Mr. Harold Burkinshaw, Belper, for *A Derbyshire Lane*. The class comprises some 90 frames from 40 exhibitors.

**SEASCAPE.**—A somewhat small class as usual, with 35 pictures from 25 exhibitors. Silver-gilt medal, Mr. Graystone Bird, Bath, for *Joe's Ship*; bronze medal, Mr. Francis A. Bolton, Oakamoor, for *Low Tide*; and diploma, Mr. W. H. Rogers, Croydon, for *A Bit of Holland*, the gold medal picture of the recent South London Society's Exhibition.

**PORTRAITURE AND FIGURES.**—A very large class of nearly 200 pictures, and one containing some excellent work by no less than 50 exhibitors. Silver-gilt medal, Mr. Jas. Auld, Edinburgh, *Portrait of a Girl*; bronze

medal, Mr. C. Skelton Tyler, Earls Colne, *Morning News*; and diploma, Mr. Heath J. Haviland, London, *Constance*. Amongst other good pictures we may mention those by Eleanor R. Grey, Miss Weil, Mr. Jas. F. Armitage, Jeanie A. Welford, Mr. H. W. R. Child, Mrs. Girdlestone, Mrs. Shawcross, Mr. J. Page Croft, and Mr. Jas. Burns.

**ARCHITECTURE.**—Rather a small collection, but containing excellent work. Silver-gilt medal, Mr. Sydney Alf. Pilcher, Gloucester, *Crypt, Gloucester*; bronze medal, Mr. W. T. Greatbach, Birmingham, *The Miller's Workshop*; and diploma, Mr. Ralph R. Rawkins, London, *A Canal Lock*. There is but little to choose between these pictures.

**SPECIAL** for amateurs who have not previously gained an award at an open exhibition. This is the biggest class in the Exhibition, and in spite of its being practically for novices, there is but little mediocrity. Silver-gilt medal, Mr. Alex Allan, jun., Glasgow, *Sunshine and Shadow*; bronze medal, Mr. J. Greenway, Birmingham, *Hawthorns*; and diploma, Mr. Sparham Camp, Sheffield, *St. Luke's Chapel, Norwich Cathedral*. Excellent work is also shown by Messrs. C. F. Gare, A. H. Robinson, Fred E. Slater, Aubrey C. Peach, Edgar W. Taylor, Max Mossel, Albert Haynes, H. A. Norman, and others.

**HAND-CAMERA WORK.**—Silver-gilt medal, Mr. J. Kearney, jun., Liverpool; bronze medal, Mr. H. W. R. Child, London; diploma, Mr. J. Greenway, Birmingham.

**INSTANTANEOUS.**—Silver-gilt medal, Mr. Ralph R. Rawkins, London; bronze medal, Mr. Fred Spalding, Chelmsford; and diploma, Mr. Walter Kilbey, Richmond.

**FLOWERS AND FRUIT.**—Mr. John M. Whitehead, of Alva, again wins his place, and secures the silver-gilt medal; Mr. William Howell, of London, taking the bronze; and Mrs. Caleb Keene, the diploma.

**COMBINATION PRINTING.**—Silver medal, Mr. Albert O. Forrest, Pontypridd; bronze medal, Mr. Francis Fielding, Blackburn; diploma withheld.

**NEGATIVE WORKING UP.**—In this class a damaged negative had to be retouched, and a print in each state shown. Miss E. A. Briggs, Manchester, gained the silver-gilt medal and diploma; and Miss Dora W. Phillput, Bath, the bronze medal and diploma. The competition in this class was decidedly keen.

**TRADE WORK** for business and advertising purposes.—Silver-gilt medal with diploma, Mr. Jas. W. Tattersall, Accrington; bronze medal and diploma withheld.

**ANIMALS.**—Silver medal, Mr. Chas. E. Walmesley, Ambleside, *Study of Cattle*; bronze medal, Mr. Geo. B. Cowen, Ramsey, *Strayed*.

**SPECIAL PRIZES.**—The *Amateur Photographer* medal for best work by a lady, Miss G. F. M. Hopkins, Oxford; *Photography* silver medal, Mr. Jas. Burns, Edinburgh; hand camera for largest exhibit, Mr. J. Page Croft, Birmingham; "Tella" prize, value 2l. 2s., Mr. H. Dunning, Usk; and Manager's prize, value 1l. 1s., for best bromide print, Mr. Jas. Burns, Edinburgh.

The Gallery is well lit in the daytime, and also at night by electric light, and the photographic section will certainly prove an attraction to the general show.

## Our Editorial Table.

**MESSRS. JOHN J. GRIFFIN & SONS, LIMITED**, of 20-26, Sardinia-street Lincoln's-Inn-fields, W.C., have sent us a specimen copy of a new show-card for advertising "Velox," which they forward gratis to all dealers who stock the paper. The card is strikingly effective in design. Upon a black ground a singularly delicate print on the favourite paper is mounted, and the word "Velox" is stamped in bold silver gilt letters. As a show-card it perfectly "fills the bill."

**MESSRS. A. E. STALEY & Co.**, of 35, Aldermanbury, E.C., have sent us a copy of their new catalogue, a neatly printed and produced little book which gives particulars of the Ray and Korona cameras, Bausch and Lomb shutters, ray filters and microscopes, and other photographic apparatus for which Messrs. Staley are agents. The specimen half-tone illustrations in the book are capital, and the catalogue is one which dealers and others should possess.

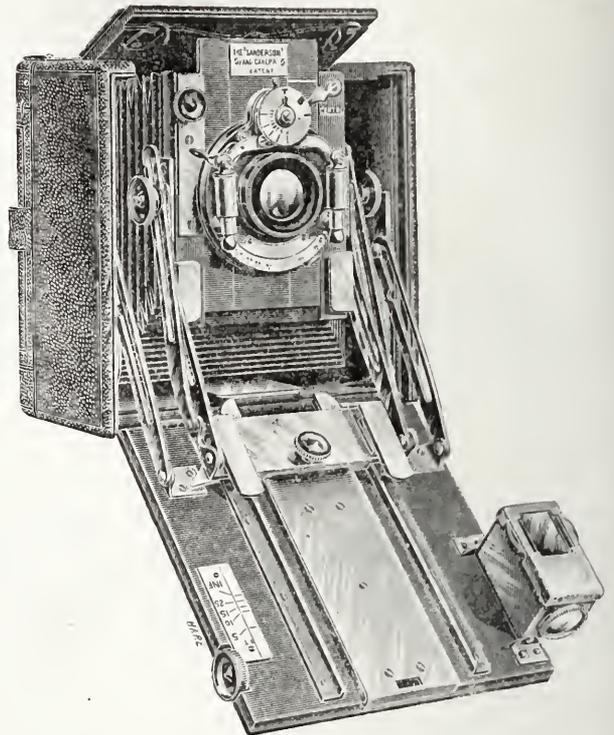

**THE Liverpool Artistic and Enlarging Company**, of 21, Kensington, Liverpool, have submitted to us several specimens of the enlargements with which they supply photographers at low charges. Taking the latter point into consideration, the quality of the work deserves to be commended.

### THE SANDERSON HAND CAMERA.

Manufactured and sold by George Houghton & Son, 88 and 89, High Holborn, W.C.

In our notice last week of the new Sanderson hand camera space could not be found for a lengthy reference to a most valuable new movement which it possesses. The illustration shows the baseboard dropped out of the way when used with a wide-angle lens. This movement allows of wide-angle lenses of three inches, or even shorter focus, being used. It

does not complicate the camera in any way, and simply entails making the side struts supporting the folding baseboard a little longer than usual. When opening the camera for use, the baseboard falls naturally into the normal position, *i.e.*, at right angles to the back, and, should the wide angle movement be necessary, all that is required is to press in the

side struts and allow the baseboard to fall into the position shown in the illustration. Before doing this, however, the lens and front should be drawn forward on to the folding baseboard, and, after dropping the front, the lens can then be brought into the correct position by means of the universal swing front.

### BIBLIOTHÈQUE PHOTOGRAPHIQUE.

Reproduction des Gravures, Dessins, Plans, Manuscrits. PAR A. COURRÈGES.

Manuel Pratique de Photographie au Charbon. PAR EDOUARD BELIN.  
Gauthier-Villars, Paris.

**M. GAUTHIER-VILLARS** has added these two small volumes to the series of the *Bibliothèque Photographique*. The first is dedicated to M. Courrèges to his son, and gives, in a simple form, the necessary conditions to be observed in the copying of engravings, drawings, plans, manuscripts, &c. The second volume is a guide to carbon printing, by M. Ed. Belin. It gives the reader a succinct account of the process, from the preparation of the tissue to the production of the finished print, whether upon paper or other types of final support. A special chapter is devoted to the recent modifications of carbon photography, known as the Artigue and gum-bichromate processes.

**THE "Gem" Dry Plate Co.**, of Willesden Green, N.W., send us a copy of their sheet almanac for 1900. Besides a calendar, there are formulæ for development, intensifying, reducing, &c. The almanac should be found useful for reference in dry-plate work.

**THE "Special Rapid"** is the distinctive name of a new plate of this season's manufacture which the Warwick Dry Plate Company, of Warwick, are just introducing to the photographic public. The plate is intended for studio use, and the characteristic qualities of the image it yields appear to well adapt it for that purpose. Our trial negatives, developed with a metal solution, gave soft, fine-grained deposits, with ample density, and we should judge that excellent portrait results would be obtained on the Warwick Special Rapid plates.

**MESSRS. G. W. Wilson, Limited**, of 2, St. Swithin's Street, Aberdeen, send us their illustrated catalogue of lantern slides of South Africa. The quality of a Wilson lantern slide has passed into proverb: there is nothing better of the kind extant. The present list contains over twenty half-tone reproductions of views taken in South Africa, and indicates that the entire series, which is exceedingly large and comprehensive, is of very great interest. It is to be noted that the series was only completed in 1899, so that it has been brought right up to date. We advise all interested in the illustration of South Africa, by means of optical projection, to send for this list of Messrs. Wilson's lantern slides.

## Studio Gossip.

THE Paris Exposition will not be ready for public inauguration on Easter Sunday, April 15. Many of the buildings will be incomplete, and the Exhibition will be only during the daytime for some time after the official opening. It is thought by May 1 that the Exhibition will be in a fairly satisfactory state.

**THE BRITTLEBANK MEETINGS.**—Mr. Frederick York kindly sends us the following interesting note: "In passing Tottenham Court-road, I noticed that Brittlebank's old premises were being pulled down. I was reminded that twenty years since in his studio a few of the old South London members used to meet and discuss the transition from collodion to gelatine. These informal meetings grew in numbers, and from which emanated the Photographic Club, which located itself at Ashley's Hotel. Many of the earliest of this coterie have passed away (Taylor, S. Fry, Harrison, Kidd, &c.), and others are scattered over the world (Maudsley, Brittlebank, &c.). It is unfortunate that there is no photograph of the old place in existence for Sir Benjamin Stone to have placed it with other memorable buildings in the British Museum."

**PHOTOGRAPHING SUSPECTS.**—At the Glamorgan Assizes on Thursday, during the hearing of a series of cases of hotel robberies at Swansea, it transpired that the chief inspector of the Swansea police force had circulated specially taken photographs of a man arrested in London who was awaiting his trial by the magistrates. In answer to Mr. Justice Bucknill, Mr. Morris, the chief detective, said he knew several instances where a suspect was so photographed; and his Lordship said such a course was absolutely illegal. "Suppose the subject objected, would you use force?" asked his Lordship. "Most certainly," promptly replied the detective, "if my superior officer ordered it." "What's your authority?" continued the Judge. "My only authority is my superior officer," was the reply. His Lordship again pointed to the illegality of such a proceeding as to force a man merely under arrest on suspicion before the official camera.

**SPEAKING AT DERBY ON MARCH 12,** at the distribution of prizes to students of the Municipal Technical College, Sir William Abney, K.C.B., referred to the fact that, at the end of this month, the Department of Science and Art will come to an end. It will be merged in a department to be known as the Board of Education, which is to supervise all kinds of education—elementary, secondary, and technological. He remarked: In the Queen's Speech they were promised that there should be an Education Bill introduced, reorganizing the authorities for secondary education. The introduction of such a Bill marked a great advance in public opinion as to the necessity of local co-ordination of the kind in question. Speaking in his private capacity, and not officially, he hoped that not only would secondary education be under a local authority, which would supervise it and look after its interests, but that all other education would be similarly managed.

**THE PITTSBURGH AMATEUR PHOTOGRAPHERS' SOCIETY** announce that the third annual International Salon and Exhibition will be held in the Carnegie Art Galleries, Pittsburg, U.S.A., from May 17 to 31, 1900. The prospectus states that the Society's purpose in holding its Annual International Salon and Exhibition is manifold, the chief desires being to encourage and recognise the earnest and truly artistic photographic workers to establish a free, permanent, and extensive exhibition of the very best photographic art works of the world, at the Carnegie Art Galleries, of Pittsburg. As heretofore, there will be two separate and distinct divisions or exhibitions, the Salon and General Exhibition. Both divisions will be open to all artistic workers throughout the world. The Salon division will include only such pictures as the Judges may select from the entire collection of pictures entered in either division possessing artistic merit, displaying artistic aim in selection of subject, or other features revealing true works of art. Technical work in the production of these pictures will not receive much consideration. The General Exhibition division will be a separate and distinct Exhibition, and will include photographs of merit, though not of sufficient artistic excellence to entitle them to be hung in the Salon. Special attention will be given to technique and good judgment in the selection and arrangement of subject. It will include all of the better classes of average exhibition work. Pictures from abroad, if delivered not later than April 14, carriage prepaid to the following address, will be transported to Pittsburg and returned to London, free of all expense to the exhibitor. Announcements, entry blanks, &c., may be obtained by addressing General Agent of the American Express Company at London, Paris, or Bremen. Duplicate invoice must accompany each parcel of photographs. If photographs are forwarded by mail, address same to Mr. Joseph H. Hunter, Secretary, Pittsburg Amateur Photographers' Society, Pittsburg, Penn'a, U.S.A. Forwarding directions: General Agent American Express Company, 3, Waterloo-place, London, England. To be forwarded to Pittsburg Amateur Photographers' Society (in bond).

## News and Notes.

**PHOTOGRAPHIC CLUB.**—April 4, 1900, at eight o'clock, paper by Mr. W. Thomas.

**ERRATA.**—In our report, last week, of the Stratford Exhibition, there were two typographical errors. In line 7 the sentence "all tell of lives of evil, and even for a fierce struggle for existence," should read, "all tell of lives of toil, and even of a fierce struggle for existence."

**ROYAL PHOTOGRAPHIC SOCIETY.**—Lantern Meeting, Tuesday, April 3, at eight p.m., at 66, Russell-square. Mr. F. P. Cembrano will show "Slides Old and New." The Exhibition by the National Photographic Record Association can be viewed on presentation of visiting card.

**THE COPYRIGHT BUSINESS OF THE UNITED STATES.**—The last report of the Librarian of Congress gives in tabular form the copyright business for the fiscal year of 1898-99. The number of copyright deposits from July 1, 1898, to June 30, 1899, amounted to 59,217, and, as two copies of each were received, it reached 118,434; of this number 59,217, only 5834 were of books proper. There were 4196 articles entered under the term "book" under the copyright law, including circulars, leaflets, charts, &c. There were 5185 newspapers and magazine contributions, 517 dramatic compositions and 9777 numbers of periodicals, 19,973 musical compositions, 1478 maps, 3505 engravings and prints, 1050 chromos and lithographs, and 7695 photographs.

**NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.**—The Annual Dinner of this Society was held at the Holborn Restaurant on Saturday evening last, the 24th inst., the President in the chair. In the course of the evening a silver coffee service was handed to Mr. Mummery (who recently resigned the presidency, which he had held for nearly five years) as a slight token of the appreciation which all the members felt for the services he had rendered to the Society during his time of office. Mr. Mummery, who was received with cheers and the very hearty singing of "He's a jolly good fellow," said that all he had done for the Society he had done with the utmost pleasure, and he looked back upon the time during which he had occupied the chair as a period marked by the most pleasant memories. He had always received the heartiest support from officers and members.

FROM the report of arrangements in connexion with the forthcoming Glasgow International Exhibition, we find that the use of hand cameras will be permitted in the grounds to ordinary visitors, but the right to use stand cameras and sell photographs has been sold to Messrs. T. & R. Annan. The fact that the right to use hand cameras has been reserved to the public is something to be thankful for, and the members of the Glasgow associations who have worked to this end must congratulate themselves on this victory against the ever-increasing tendency to restrictions in such exhibitions. Probably the like concession granted in connexion with the Paris Exhibition was not without its weight with the managers. Neither is it likely that the Exhibition will suffer from this concession, but rather the reverse, as each print made from negatives taken will be a kind of free advertisement of all the beauties and "fairies" to be seen after passing the turnstiles.

**AFFILIATION OF PHOTOGRAPHIC SOCIETIES.**—At a meeting of the Executive Committee, held at 66, Russell-square, on Wednesday, March 14, 1900, Mr. H. Snowden Ward in the chair, the Secretary reported the inability of Mr. W. Thomas to accept a seat on the Committee. His place was filled by the appointment of Mr. H. Vivian Hyde, both on the Executive Committee and the Slide Division Committee. Arrangements for new lectures and slides were considered, details of which will be announced in due course. Proofs of the *Affiliation Annual* were submitted and approved. It was agreed to procure a small set of slides illustrative of Tinworth's work, to be accompanied by a short paper upon his life. A proposal from the Hackney Society in favour of an attempt being made to secure cheap fares on railways for photographers was discussed. It was decided to inform the Hackney Society that any resolution they might formulate upon the subject would be put forward. It was resolved to call a conference of Judges at an early date, and to invite any person who had acted as a Judge at any exhibition having an open class. Certain modifications in the rules at present in force were made, which will be submitted to the Conference.

## Commercial Intelligence.

MR. J. M. THOMSON, F.S.M.C., B.O.A., has entered the service of Messrs. J. Barker & Co., of Kensington, to have charge of the optical and photographic department.

**KODAK, LIMITED.**—The Directors have declared an interim dividend on the Company's preference issue for the quarter ending March 31, 1900, at the rate of six per cent. per annum, and on the ordinary shares at the rate of ten per cent. per annum for the same period, which dividends will be payable on or after the 1st proximo.

THE International Advertisers' Exhibition, to be held this year at the Crystal Palace from April 28 to May 26, will cover every department of advertising. It is to be divided into nine classes, including posters and show-cards, decorative panels, lithographed book and music covers, pictorial programmes and admission cards, decorated tinware, colour printing processes and machinery in motion, and original designs for posters.

MESSRS. G. MENGEL & Co., of 23, Moorfields, E.C., write: *Re* your issue of Friday, March 16, 1900. Among the addresses wanted, E. Goodiellow wishes to know where he can get small photograph frames with tiny brass rims inside, as supplied by Marion and others. We supply all descriptions of brass rims, &c., for photographing purposes, but only in a wholesale way. If E. Goodiellow is a wholesale buyer, perhaps you will put him in communication with us.

MESSRS. A. E. STALEY & Co., of 35, Aldermanbury, announce a list of new reduced prices for Ray and Korona cameras, in conjunction with the Camera Combined, as follows: Koronas, 5×4, in case, with three slides, lens, time and instantaneous iris shutter, each 45s.; with rapid rectilinear, each 57s. 6d. Ray cameras, 5×4, covered in morocco, on mahogany, in case, with three slides, time and instantaneous shutter, each 45s.; with rapid rectilinear lens, each 60s.

WE are informed that the business of Messrs. Thorn & Hodile, of Westminster and Camberwell, is being converted into a limited company, having, in the course of four years, developed from the manufacture and sale of small acetylene generators for magic-lantern purposes to the supply of installations

for public and private lighting of whole villages with acetylene. The growth of the undertaking has rendered necessary the proposed change in the business, and the lighting of country houses, churches, and villages presents a field for the use of capital which is both interesting and promising.

THE Gem Dry Plate Company, Limited, of 92, Villiers-road, Willesden Green, N.W., announce a free offer for Easter, 1900, of a box of Gem plates. The following are the conditions: 1. The sizes offered are quarter-plates one dozen, and half-plates half a dozen. The speed required must be named, also if the plates are for hand cameras. 2. Applicants must be *bond-fide* amateurs, applying before April 10, and the plates are to be for their own individual use only. 3. If the plates are to be sent by post, the cost of postage, 3d., must be remitted in stamps. 4. The Company reserve to themselves the right to refuse any application.

## Patent News.

THE following applications for Patents were made between March 12 and March 17, 1900:—

DAYLIGHT CHANGING.—No. 4704. "Improvements in or relating to Photographic Apparatus for 'Daylight' Changing and for 'Daylight' Development." W. WATSON.

LAMP AND DRYER.—No. 4776. "'Kleptos' Combined Photographic Lamp and Dryer (for Photographic Developing, Printing, and Drying)." T. L. ROGERS.

EXPOSURE METERS.—No. 4898. "Improvements in Apparatus for Calculating Photographic Exposures." G. F. WYNNE.

DARK-ROOM LAMPS.—No. 4975. "Improvements in Photographers' Dark-room Lamps." F. W. BRANSON.

OPTICAL PROJECTION.—No. 5076. "Improvements in the Means of Viewing the Enlarged Pictures obtained by Optical Projection." J. E. THORNTON and C. F. S. ROTHWELL.

SHUTTERS.—No. 5096. "An Improved Photographic Shutter." S. D. MCKELLIN.

FILM-CHANGING.—No. 5120. "Improvements in Means for Changing Film in connexion with Photographic Cameras." Complete specification. C. BECK and W. BECK.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
2.....	Bradford Photo. Society .....	{ Summer and Winter Visits to the English Lakes. Dr. Llewellyn Morgan.
2 .....	Glasgow and West of Scotland .....	{ Demonstration: Carbon and Ozotype Printing. William Goodwin.
2.....	Southampton .....	Prize Slides.
2.....	South London .....	Annual Meeting.
2.....	Stafford Photo. Society.....	{ A Practical Lesson in Outdoor Photography. Reader, G. Wray.
3.....	Redhill and District .....	{ Demonstration: Iron Printing Process for Architects and Engineers. J. R. Gotz.
3.....	Royal Photographic Society .....	{ Slides Old and New. F. P. Cembrano.
4.....	Borough Polytechnic .....	{ A Trip to Ireland. Charles H. Oakden, F.R.P.S.
4.....	Edinburgh Photo. Society .....	Paper Manufacture. J. Edington Aitken.
4.....	Photographic Club .....	Paper by W. Thomas.
4.....	Southsea .....	{ Orthochromatic Photography. E. Sanger Shepherd.
4.....	Woodford .....	Lecture. H. W. Bennett, F.R.P.S.
5.....	Darwen .....	Lecture: Outdoor Photography.
5.....	London and Provincial .....	{ Discussion on Toning of Chloride Paper. Opened by J. E. Hodd.
5.....	Röntgen Society .....	{ The Influence of the X Rays upon the Growth and Development of Micro-organisms. Dr. Norris Wolfenden and Dr. Forbes Ross.
5.....	Tunbridge Wells .....	{ Pictorial Treatment of Lantern Slides. J. A. Hodges, F.R.P.S.
6.....	West London.....	{ Demonstration: Platinotype. A. C. Beard.

### ROYAL PHOTOGRAPHIC SOCIETY.

MARCH 27,—Technical Meeting,—Mr. Chapman Jones, F.I.C., F.C.S., in the chair.

#### OBJECTS OF INTEREST.

Mr. E. CLIFTON showed a dark-room lamp for use with any ordinary illuminant, the front consisting of a glass dipping bath containing a solution of bichromate of potash, as suggested by Mr. Howard Farmer at a recent meeting of the Society. For the purpose of demonstrating the lamp, an incandescent electric light was adapted to it, and a degree of illumination resulted which one would have expected to be altogether impossible in a developing room; but Mr. Clifton said, corroborating Mr. Howard Farmer,

that the most sensitive plates could be subjected to it without risk of fog. Mr. Howard Farmer used a thickness of three-eighths of an inch of a six per cent. solution of bichromate, but the dipping bath attached to Mr. Clifton's lamp measured more than an inch from front to back, and a weaker solution of bichromate could therefore be utilised.

Mr. A. A. K. TALLENT showed a photo-spectroscopic camera, provided with a prism having a grating on its hypotenuse. He explained its construction by means of a diagram, and submitted it for examination at the close of the proceedings.

#### SOME DEVELOPERS COMPARED.

Mr. ALFRED WATKINS read a paper with the above title, in which he detailed a series of experiments which he had conducted with pyrogallic acid, metol, ortol, adurol, hydroquinone, kachin, and glycin, each developer containing 4 grains of the developing salt, 12 grains sodium sulphite, and 24 grains sodium carbonate to the ounce of water. No bromide was used, in view of the fact, pointed out by Messrs. Hurter & Driffield, that, although the addition of bromide to the developer under certain circumstances practically alters the speed of plates, this alteration is gradually lost as development proceeds, and that, to secure a change, the plate must be taken out at a comparatively early stage of development. The first experiments were summarised in a table giving the time of appearance of the image, the total time of development required to attain a standard development factor of about 0.75, and the multiplying factor deduced from these trials; and from this table it appeared that, of the single developers, pyro stood first, being closely followed by metol and ortol, all the others taking about double the time to do the same work. A mixture of equal parts of metol and hydroquinone was superior to all the single developers in efficiency, the image appearing almost as quickly as with metol alone, while the multiplying factor was the average of the two, and the total time of development shorter than with either separately. Mr. Watkins was of opinion that any similar mixture of two developers would have a corresponding advantage. He had failed to find any evidence in support of the popular belief that certain developers yielded greater density than others. A succeeding series of slides showed a comparison of hydroquinone and metol, and illustrated the fact that, although the latter was ahead during the first four minutes of development, by the end of the fifth minute the hydroquinone had got exactly level, and at the sixth gave a negative denser in all its gradations than that developed with metol. The difference of speed shown by three brands of plates with six of the developers mentioned (adurool being omitted) was insignificant, and the fog with all of them was about equal. It was found that the fog developed upon unexposed plates continued to increase in density, until at 150 minutes the film was practically opaque. After discussing the keeping qualities of the various developers, their power of searching out detail, and the colour of the deposit, Mr. Watkins summed up the differences found upon testing them (unrestrained) on equal terms as follows: Appearance of image, multiplying factor, and total energy, wide differences; effect on speed, very slight and doubtful difference; searching out detail, fogging propensity, and ultimate density power, no difference. Leaving pyro out of the question, the mixture of hydroquinone and metol had more energy than any single developer tried, and the multiplying factor was convenient.

Mr. W. B. FERGUSON, Q.C., said he used a mixed pyro and metol developer, and found that the time of appearance of the image was more or less independent of the quantity of metol present. With two grains of pyro to the ounce the image would appear in about thirty-five seconds, and this would be reduced to ten seconds by the addition of one grain of metol; but the addition of two or three grains of metol made no further alteration.

Mr. WATKINS said that was due to the pyro. Of all the developers he had tried, only two—pyro and amidol—produced an image in the same time at whatever dilution they were used, but, with all the others, the time of the appearance of the image varied in proportion to the dilution.

The Rev. F. C. LAMBERT asked whether the multiplying factor remained constant within certain limits of temperature.

Mr. WATKINS said that it was not influenced by temperature between 45° and 70° F.

The CHAIRMAN, referring to the question of staining, expressed the opinion that the sulphite in the developer had a protective action only for a certain time, and that eight grains per ounce, the quantity used by Mr. Watkins, was altogether insufficient. The quantity of sulphite necessary depended upon the amount of alkali to be used and the period of development, and not upon the pyro; under ordinary circumstances, nothing less than fifteen grains to the ounce of water could be regarded as satisfactory when using carbonate of soda as the alkali.

Mr. TILFORD showed some negatives which had been exposed for identical periods, and developed with a variety of substances according to the maker's formulae, and which were practically alike in density and gradation and detail.

After some remarks by Messrs. SPILLER and WARBURG, Mr. WATKINS replied, and a hearty vote of thanks was given to him for his valuable communication.

#### COMING EVENTS.

On April 3, Mr. F. P. Cembrano will give the last lantern lecture of the session, and exhibit "Slides Old and New;" and at the Ordinary Meeting on April 10, Mr. Thomas Bedding will read a paper on "The Municipal Encouragement of Photography."

### LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 22,—Mr. Herbert C. Rapson in the chair.

Mr. A. MACKIE passed round some negatives chosen at random from a number developed with ortol during the past year or more. They were done with the soda-carbonate and sulphite formula, but he had abandoned this, and now used carbonate of potash in ten per cent. solution, and so also with the ortol, not, of course, omitting the metabisulphite. His normal developer was 2 grains of ortol and 6 of potash per ounce. The quality of negative obtained with this was better than that previously secured, although he did not suggest that the same quality could not be otherwise obtained. He had also tried

ortol-potash developer without sulphite for bromide paper, and one peculiarity which was noticed was that ortol had a tendency to stain, not the gelatine, but the paper, as the back of the print was of the same tint as the lights on the front. In daylight the tint was very pleasing, a faint salmon tint. The deposit was not pure black, for which it was perhaps better.

Mr. F. C. KELLOW had noticed that ortol stained the celluloid of rollable film in the same manner. If the gelatine film were stripped, this would be seen.

Mr. MACKIE mentioned that, at a meeting the night before, Mr. Sanger Shepherd incidentally had particularly warned photographers not to use hydroquinone for the development of orthochromatic plates, but developers which cause the image to flash up generally, like metol, amidol, &c., instead. The reason given was that hydroquinone developed those parts first which had been acted upon by the blue rays. This would account for the fact that hydroquinone brought out the image in "jumps," so to speak. If kept long enough, the other parts catch up, it was true, but for colour work time of development was an important factor.

The CHAIRMAN, alluding to the pleasing tones which Mr. Mackie found resulted from the use of ortol with bromide paper, questioned whether the stain was a permanent one. He recalled the fact that he had printed a negative on white and on mauve albumenised paper, and at first preferred the mauve print; but in three weeks the mauve tint had turned yellow, and he was forced to admit a preference for the white paper. The same might occur with the ortol-developed bromide prints.

Mr. MACKIE could not speak on this point. He drew attention, however, to the differences in the appearance of samples of ortol which he had seen. Some were in the form of distinct crystals, other was like powder, which hung in loose lumps. He also read a note in our issue of last week, in which an American user of ortol had commented upon the same matter.

Mr. ERNEST HUMAN showed a hand camera fitted for compact metal plate-holders, which was examined in detail by those present.

North Middlesex Photographic Society.—March 19, Mr. J. A. Meen in the chair.—Mr. J. MacIntosh gave a lecture on

ISOCHROMATIC PHOTOGRAPHY.

He described the method of finding a suitable screen. Slips of cardboard were to be coated thickly with the following pigments: brilliant blue, emerald green, chrome yellow, vermilion, and white, the colours being toned down with either black or white until they gave equal depth of shadow when tested with the photometer as set forth by Sir William Abney. Thus, yellow, white, and vermilion would require the admixture of black, and the blue and green, white. These colours, if photographed with a suitable screen, would all come out of equal depth in the negative, an isochromatic plate being used. A screen could be made by coating microscopic glass (because of its thinness) with collodion, stained with brilliant yellow on one side and fuchsine (very pale) on the other. This, if of proper depth, would give the result aimed at above. He passed round a screen made with naphthol yellow and aurine, with which the specimens shown were taken. It increased the exposure fifty times. Such a deep screen was not necessary for landscape work, but was excellent for oil paintings, &c. A point to bear in mind was that you should differentiate between the luminosity and the contrasts of colours. Thus, if a picture consisted of, say, three colours of equal luminosity, they would come out with the correct screen, as referred to above, of one depth only in the negative, which would not appear correct, and the screen should be altered until the colour most striking to the eye was given prominence. The plates he used for the experiments were Lumière's panchromatic. Another point he mentioned was that a screen stained with picric acid was useful for photographing light clouds against a blue sky, as the blue was cut out very sharply.

Richmond Camera Club.—March 12.—A lecture was given by Mr. HAROLD MANN on the subject of

GOthic ARCHITECTURE.

Mr. MANN showed the transition from Norman to Perpendicular, and his remarks were admirably illustrated by over 150 excellent slides, made by Mr. T. Coysb.

MARCH 19.—A lecture on

TECHNICAL CONTROL FOR PICTORIAL RESULTS,

by Mr. W. Thomas, was read. The lecture was illustrated by numerous slides, many of which were very good. The writer's literary style was, however, somewhat involved, so that it was difficult for the audience to reap the full benefit of Mr. Thomas's advice.

Newcastle-on-Tyne and Northern Counties Photographic Association.—The above Society some time ago concluded an arrangement with Mr. J. Craig Annan, whereby the exhibition of that gentleman's work, which has lately been on show in London, should be transferred from there to Newcastle-on-Tyne for exhibition by the Newcastle Society. This Exhibition took place on Thursday, Friday, and Saturday last, and proved an unqualified success. It was held in the Grand Assembly Rooms, and was visited by a large number of people who availed themselves of the Society's invitation. Mr. Craig Annan came through from Glasgow, and was entertained to dinner by the Association on Thursday night. The novel idea was carried out of having the dinner served in the fine exhibition room itself, surrounded by Mr. Annan's pictures, and the pleasure of the occasion was much increased by this means. Mr. J. Pattison Gibson presided. In proposing the toast of "Our Guest," Mr. Walter S. Corder said, on behalf of local photographers, he tendered the warmest of north-country welcomes to Mr. Annan, who, he said, was one of the foremost photographers of our time. His work had won their respect and admiration, for in it they had something more than mere technical excellence. Through it all there ran a strong individuality, which was the mark of the true artist; in short, Mr. Annan showed that it was possible to so impress a photograph with such individuality as to fulfil one of the definitions of art as

being "nature seen through a temperament." His works were an encouragement to all who were trying to give to their photographs artistic value. In his reply, Mr. Annan thanked the members present for the very cordial welcome they had given him. Art in his estimation was a sentiment, not a science, and it was only by keen observation of everything beautiful that progress could be made. Whilst good pictures should be studiously sought after and observed, the photographer should not confine himself to that branch of art alone for his education, but should carefully examine, and, as far as possible, endeavour to surround himself, with beautiful examples of furniture, china, metal and wood work; in fact, no example of fine craftsmanship should be allowed to escape observation. Mr. Annan then gave his audience some practical advice as to framing photographs, the selection of suitable mounts, and much other interesting advice. The whole proceedings of the evening were marked by great success. The pictures on exhibition have been so lately described in connexion with their exhibition in London that it is unnecessary to detail them here. During the time they have been on exhibition in Newcastle, they have proved a source of interest to a large number of visitors.

Blairstown and District Photographic Association.—At the monthly meeting on Tuesday it was decided to hold an open photographic Exhibition early next year, and it was remitted to the Executive to make the necessary arrangements. The success of the last Exhibition was such that the Association will require a special effort if they mean to surpass it. We would draw the attention of exhibitors to the extreme punctuality with which the last Exhibition was carried out, and we are assured that no effort will be wanting at the coming Exhibition to maintain this desirable reputation. Arrangements are in progress for the purchase of an enlarging lantern for the use of members. A background is also to be added to the accessories available to members.

FORTHCOMING EXHIBITIONS.

- 1900.
- March 30, 31 ..... Photographic Society of Ireland. W. F. Cooper, 35, Dawson-street, Dublin.
- April 3-7 ..... Birkenhead International. C. F. Inston, 25, South John-street, Liverpool.

Those who desire to send photographs to the above Exhibitions should write for prospectuses to the Hon. Secretaries, whose addresses are given in the second column above. The dates mentioned are those at which the Exhibitions open.

Correspondence.

- \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

PLATE-BACKING AND SENSITIVENESS.

To the EDITORS.

GENTLEMEN,—In your article on "Plate-backing and Sensitiveness" in the JOURNAL of March 9, you refer to plate-backing as no new invention, and state "There were backed dry plates upon the market as far back as almost a quarter of a century ago." You also speak of plates being backed by some kind of dark paper in the old wet-plate work, and further remark that the dry plates referred to were backed by a red pigment. You do not tell us what dry plates these were, though you give us to understand they were not gelatino bromide plates. Probably you refer to the uranium dry plates introduced about that time by Colonel Stuart Wortley. These plates were, as you say, backed by a red pigment, which was easily removed by a wetted sponge before development. Though not as sensitive as gelatino-bromide plates, they were capable of yielding excellent results when properly manipulated. I took a number of negatives with these plates, some of which I have by me now, and they are but little, if at all, inferior in detail or printing qualities to the gelatine plates of the present day, though they are quite a different colour. I have often wondered why, in the numerous references to early dry-plate work which have appeared from time to time, no mention has been made of these plates. As far as my recollection goes, they were the best, if not the only workable, dry plates placed upon the market prior to the advent of gelatino-bromide plates.

Within my experience of wet-plate photography, I have no recollection of any kind of backing being applied for the purpose of preventing or reducing halation. Red blotting-paper was often used to absorb the moisture at the back of the plate when placed in the dark slide after removal from the silver bath, and it is just possible the blotting-paper may have had some slight effect in reducing halation; but it was certainly not placed there for that purpose or with that intention.

The cause of halation was little known or understood by the majority of photographers in those days, and, although the effect of it was so apparent in nearly all photographs of interiors, I don't believe that one photographer in a hundred had any idea that backing the plate would prevent it. The remedy was sought in another direction. For instance, in taking the interior of a church, the east window was covered over on the outside with canvas, or some such material, and, after the necessary exposure was given to the interior, the canvas was removed and a shorter exposure given to the window. The operation was troublesome, but it was often resorted to, and the result was a perfect rendering of the window without, I need hardly say, any sign of halation. I believe there is a doubt in the minds of many photographers of the present day as to whether anything is gained by backing plates to prevent halation. With the plates I use, and have used for several years, I have not been troubled with halation either in landscape work or interiors, except in a very few instances, and have therefore found no necessity for using backed plates.

—I am, yours, &c.,

THOS. MITCHELL.

Newport, March 17, 1900.

### THE ARTISTIC COPYRIGHT BILL.

To the EDITORS.

GENTLEMEN,—I have just received a copy of THE BRITISH JOURNAL OF PHOTOGRAPHY for March 9, in which I am reported as having said, at a recent meeting of the Society of Arts, "that photography was introduced into the Artistic Copyright Bill as an afterthought." Might I refer you to the correction which appears in that Society's *Journal* for March 2, which explains that the Copyright Bill referred to was the previous one, and not the one at present under discussion.—I am, yours, &c.,

ALFRED EAST.

2, Spencer-street, Victoria-street, S.W., March 14, 1900.

[The following is the note in the *Journal* of the Society of Arts to which Mr. East refers: ARTISTIC COPYRIGHT.—Mr. Alfred East, A.R.A., wishes to make it clear that, in his remarks in the discussion on Mr. Edwin Bal's paper on "Artistic Copyright," he stated that photography was introduced as an after-thought into the previous Copyright Bill, not, as he is reported, into the Bill now under discussion.—EDS.]

### DEXTRINE AS A MOUNTANT.

To the EDITORS.

GENTLEMEN,—Your late remarks respecting dextrine as a mountant, in answer to a correspondent, inform me of the reason why dextrine is not in favour. I had seen its use objected to, but had never seen any reason stated; for my part, I have used dextrine for special purposes for at least twenty years, and have found no cause for discontinuing it, but have no doubt that the difference in opinions is from differences in the samples of dextrine used and in the manner of using it. If a good brown dextrine is dissolved with the aid of a hot-water bath in about equal parts of methylated spirit and water, a capital mountant results, which is best used cold, and which on account of the spirit, as I suppose, does not cockle the mounts and is always ready for use, and does not turn sour, as the large percentage of spirit arrests fermentation or mildew. For mounting large prints for framing, putting prints into scrap albums on Christmas mounts, which are often quite thin, &c., this mountant works satisfactorily, and dries readily; but, if made with water only or if white dextrine is attempted to be dissolved in the spirit and water, trouble will follow. The above solution of brown dextrine, mixed with Venetian red or burnt sienna, makes a good plate backing. There is nothing new in this, as I published the formula some twenty years ago; a sample of suitable dextrine enclosed, also print of Mr. Smart's portrait taken some fifteen years back, of which about 1800 have been supplied mounted with dextrine.—Yours, &c.,

E. WILLIAMS.

Highgate, Hawkhurst.

[We will take an early opportunity of trying the sample of dextrine kindly sent us by Mr. Williams; the print enclosed is in perfect preservation.—EDS.]

### THE METRIC SYSTEM.

To the EDITORS.

GENTLEMEN,—Mr. Lévy says in last week's issue his "letter (see February 2) was written long before 'Free Lance' ever thought about writing . . . about the metric system and its use in France." This February 2 letter actually says "I have read with much pleasure 'Free Lance's' dissertations as regards the metric system." So much for Mr. L.'s veracity.

This letter of his seems to be without meaning, except to say I do not

know what I am talking about. To prove his position he suggests that pound is a legal French weight, and part of the metrical system of weights. This is absurd. The metric system was adopted in France almost a century ago within a year; but it was not till forty years afterwards that it was made compulsory. M. Lévy knows, or, if he does not, he ought to know, that the pound is not, and was not, a legally recognised quantity in the metrical system. As proof, I refer him to the metrical tables in a work in chemistry or physics, published in this country or in France, let Mr. Lévy in reply give his proof that a pound is a legally recognised quantity.

The fact is, for all ordinary purposes of life a decimal system of subdivision of weights and measures is a failure. In 1821 the U.S. Government rejected it as unsuitable to practical life, J. Quincy Adams having drawn up a report against it. The French people have discovered the same thing, and, according to M. Lévy, they don't ask for 12 grammes of coffee if they want a quarter of a pound; no, they ask for a quarter of a pound and get it, but that is not by the metric system, the metric system implies decimal subdivision, and that is impractical in daily life.

FREE LANCE.

To the EDITORS.

GENTLEMEN,—But for M. Lévy's letter in your *JOURNAL* of to-day, I should not have troubled you again on the above subject, but there seems to me to be a misunderstanding between him and "Free Lance," which perhaps, I may remove.

"Free Lance" is quite right as to the British pound having no representative in the metric system, but it is quite unnecessary that it should have one; it is quite certain that our friends across the Channel can buy and sell just as conveniently as ourselves; more, it is evident that everybody who has tried the metric system prefers it, and that is the case even with English workmen who have been taken abroad to execute work. There is no charm in the British pound; it owes its exact determination to the Commission, who were directed to make new standards when those of the Exchequer were destroyed in the fire which burnt the old Houses of Parliament. The old standard was a troy pound, and the Parliament, in accordance with the recommendation of the Commission, declared a certain piece of platinum to be the future standard pound *avoirdupois*. This pound had been made, as nearly as the available evidence would allow, equal to 7000 grains of the old troy pound (5760 grains). The sole authority for this, as well as our yard, is 18 and 19 Vic., cap. lxxii., passed in 1855.

But the French word for a pound is *livre*. Now, Napoleon, in 1812, sanctioned the use of a *livre* of 500 grammes as part of what was called the *Système Usuel*, and the use of this was not forbidden in France till 1837. It is quite probable that the use of the word "livre" is common among the people in France, but it does not mean the old *livre* of the Monarchy nor the English pound, but the *livre* of the *Système Usuel* or half kilo, and in that case M. Lévy is quite correct in saying that it is part of the metric system.—I am, yours, &c.,

J. F. T.

### EXPOSURE BY THE WATKINS' SYSTEM.

To the EDITORS.

GENTLEMEN,—Will you kindly correct a misunderstanding which has inadvertently crept into your report of the above lecture, probably through some omission on my part. The author of the lecture is Mr. Alfred Watkins, of Hereford, the inventor of the well-known exposure meter, who lent it to me. I simply read it and showed the accompanying slides. It is only right that I should ask you to kindly make this correction in your next issue.—I am, yours, &c.,

G. T. B. WOODLEY (President).

Doncaster Camera Club, March 23, 1900.

### INTENSIFICATION AND REDUCTION.

To the EDITORS.

GENTLEMEN,—Referring to the admirably compiled paper on the above subject, read before the Sutton Photographic Club by Mr. J. H. Baldock, F.C.S., and appearing in a recent issue, it may be of service to add yet another method of so-called "reduction," which is not so well known as it deserves to be. The procedure is simple in the extreme, the over-dense negative being taken direct from the fixing bath, and placed where the air can get at it. In mild cases, fifteen minutes' exposure to the atmosphere is sufficient to tone down the excessive density of the high lights. In extreme cases the treatment may run into hours, but, however long or short the time may be, the reduction proceeds on precisely the same lines as the ammonium-persulphate method, *i.e.*, high lights first, deepest shadows last to be affected, until the desired result is

ained. In prolonged treatment it will be necessary to occasionally immerse the plate for a few minutes in the fixing bath in order to prevent drying.

If you, Sir, or some of your scientific readers would furnish us with reasons why the atmosphere affects a fixed, but unwashed, negative in this manner, it would, doubtless, interest others besides yours, &c.,  
 Pontypridd, March 20, 1900.  
 ALBERT O. FORREST.

## REFLECTOR HAND CAMERAS.

To the EDITORS.

GENTLEMEN,—My letter regarding a hand and stand reflector camera, which you were good enough to publish in THE BRITISH JOURNAL OF PHOTOGRAPHY of the 2nd inst., had its effect.

Messrs. — wrote that they saw no great difficulty, but it could not be carried out with their present form of shutter. Mr. —, in a letter of the 15th inst., says: "I have considered carefully your letter, and we come to the conclusion that what you describe is quite within our power to make, provided the price would not be too much. But, with so many alterations, we could not undertake to make such an instrument for less than 15*l.* If you desire to have us make one for you, we would do so with pleasure. We would require a sketch and written description."

Don't you think that short-sighted on the part of the maker, and hardly fair on the proposer, who makes a suggestion, not with the idea of gaining a royalty, but for what it may be worth *pro bono publico* or *pro bono fabri*? Suppose I were to send that 15*l.*, with the sketch and specifications—by the way, if I were successful in drawing out these, I could deserve a prize for ingenuity, for I have never had a reflector camera in my hands, nor any closer model than the Kodak genus—what would happen?

The maker would make me my camera, for which he would be amply paid for the extra trouble, and at the same time he would make one or two others, and, if they found a ready sale, within a year he would put the market much improved ones, probably at about a third of the price.

No, that is not good enough for me, and, failing to get such a camera anywhere, I should prefer to wait till the idea germinates, and in the mean time scrape along as before.

My suggestion, shortly summed up, amounts to this: A compact box reflector camera, but capable of extension without appreciable increase in bulk, and only a slight one of a few ounces in weight—much less than a loaded magazine form. The reflecting arrangement would not be indispensable when the camera was extended.

I am writing to Messrs. Watson & Co., as you suggest, but I was well acquainted with their advertisement in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC. Their camera may fulfil "R. N. R.'s" requirements, but they cannot have read my letter; their employment of a long-focus lens, in the first place, would militate against my proposal.

The Continental manufacturers' designs are mostly too complicated and clumsy, but that seems to show that they are groping their way in the direction indicated, and that my idea is more or less practical, and ought to bring profit to the manufacturer who worked it out properly.—I am, yours, &c.,  
 A. G. B.

## NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.

To the EDITORS.

GENTLEMEN,—In last week's JOURNAL our mutual friend "Cosmos" wishes to know details as to the working of the Record Association. I regret that my father, Mr. George Scamell (the Hon. Secretary), is at present in Italy for a holiday, and cannot therefore promptly give the information desired.

On p. 591 of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC is given a list of the officers. Membership is open to all, the qualification being (1) contribution of photographs to the number of six approved prints for the year; or (2) a subscription of not less than ten shillings per annum. I am sure the Council will welcome any hard workers, such as will help to ensure a continuance of the good work, either active photographers who will contribute prints, or men who can and will work in other directions, such as bringing the Association to the notice of the many who would be of service to it, if only they were once introduced to, and interested in, its mission.

At present it has no "home" of its own, meetings having been held at St. Pancras Grand Hotel and 66, Russell-square. Any prints forwarded to the latter address, or to 21, Avenue-road, Highgate, London, N., addressed to the Hon. Secretary, will be duly acknowledged with thanks. I enclose a copy of the rules and by-laws.—I am, yours, &c.,  
 120, Crouch-hill, N., March 27, 1900.  
 EDGAR SCAMELL.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY," 24 Wellington-street, Strand, London, W.C. Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to Messrs. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

### PHOTOGRAPHS REGISTERED:—

A. J. Ashbolt, 10, Exmoor-road, Southampton.—Photograph of A. Turner, footballer.

G. Deuney, 21, St. Sidwell-street, Exeter.—Photograph of the Rev. — Weeks, Rector of Majeking.

TAFFY; "SCUMY TYPE;" AMERICAN; PHOS; and others. In our next.

J. KENNERELL.—We are very much obliged to you for your letter, which it would, perhaps, be inadvisable to publish. Nevertheless, we will retain for reference.

DARK VIGNETTES.—J. W. D. says: "Please inform me if the enclosed is correct for the above, as I have never seen any."—It is something like them, but is a very poor example. It is very much under-exposed, and does not show so much figure as is generally included.

VESSEL FOR WASHING PRINTS.—AMATEUR (Leeds).—A zinc tray, such as you employ in carbon printing, is not suitable for fixing and washing silver prints in. It may, however, be used if the surface of the metal be protected by some impervious material, such as Aspinall's or similar enamel.

PATENT QUESTION.—G. H. RHODES writes regarding apparatus for producing buttons with photographs on the face of them. "If I bought one of these machines, should I be infringing any patents in England? because some of the buttons sold here are stamped as being patented."—In reply: The use of the machine would involve no infringement.

PLATINUM PRINTING.—BEAUCHAMP asks: "Can you tell us what is at fault with enclosed platinum prints? All our printing lately has turned out like it."—It seems very much as if the trouble was caused by scum on the developer. If that is not the cause, we would suggest that you send one or two examples to the makers of the paper and ask their opinion.

RESIDUES.—G. CONHEAD. The gold wastes may be added to the silver wastes, and reduced together, but it is very much better to keep them separate. If they are reduced together, a "parting assay" has to be made of the resulting metal, to ascertain the proportion of gold it contains, which is often too small to be taken into account when it is diffused through a large quantity of the baser metal.

THINNING ENAMEL COLLODION.—C. BRIGDON. The collodion, which has become thick from the evaporation of the solvents, may be thinned with ether and alcohol. It was probably made with equal parts of each; but, as there is little doubt that a larger proportion of the former has evaporated than the latter, more of that should be added than of the spirit—say, two parts of ether to one of alcohol.

THE WATKINS SYSTEMS.—EXPOSURE writes: "Is Watkins' method of exposure and timing development published in book form? if so, where can it be purchased and price?"—In reply: Mr. Watkins has not gathered his many useful papers into book form. The simplest way in which our correspondent could ascertain which papers or articles Mr. Watkins would recommend to the student would be to inquire of him at Imperial Mills, Hereford.

PHOTOGRAPHING A TABLET.—AJAX says: "I want to photograph a plaster-cast of an inscribed tablet. The inscription is in relief. Circumstances oblige me to photograph it out of doors. I can arrange that the light shall fall on one side, or full front, or I can place it in the shade. Which would be best?"—Place the tablet so that it is illuminated by a fairly strong side light, so that a shadow is cast from the relief inscription. That will give prominence to the lettering.

FORM OF STUDIO.—T. W. ASTON.—Considering the space available and the surrounding buildings, we should advise you to have the lean-to form of studio, built against the back of the house. You will then get a studio nearly thirty feet long, with an unobstructed north-west light, and be well shielded from the sun during the greater portion of the day. The arrangement of blinds, as shown in Sketch 2, is quite right, but we should recommend them to be of a light green or blue colour in preference to white.

**AGREEMENT.**—A. Z. We have read the copy of agreement, and we should say you would be very unwise to sign it without due consideration. It seems one-sided, and all in favour of the employer. As at present worded, amongst other things, he can discharge you at a fortnight's notice, and you will be prohibited from starting business or entering the service of another photographer within a radius of a hundred miles. Taking it altogether, we never read such an unreasonable agreement before.

**LENS FOR STUDIO.**—CRANION writes: "I propose making use of a very short studio, say, about fifteen feet. Can you recommend me a lens that will take both full-length and cabinet heads? Also where I am likely to procure same or second-hand, and about what price should I have to pay for same?"—We know of no cabinet lens that will take a full-length satisfactorily in so short a studio. There are lenses that require only about fourteen feet between sitter and camera; but, of course, they could not be employed in a studio only fifteen feet long. Get a catalogue from any of the second-hand dealers, Morley & Copper, Upper-street, N., or Sands & Hunter, Cranbourne-street, W.

**COPYRIGHT.**—INQUIRER writes: "1. A picture is given away with a weekly periodical, I copy this, and obtain some cabinet prints from the negative, not for sale, but just to give away to my friends; do I render myself liable in any way whatever in doing this? 2. I take a lady's portrait in the studio. To whom does the copyright of that portrait, apart from the negative, belong? I am given to understand that the copyright of the negative belongs to the photographer, but that of the photograph itself to the sitter, is this correct?"—In reply: 1. Presumably the picture was copyright; if so, you render yourself liable to an action. 2. If the lady paid you, the copyright is hers; if not, it is yours; in either case the negative belongs to you.

**AN AGENCY QUESTION.**—NOVICE says: "I have lately registered and built an accessory for the studio, and granted to a leading firm of dealers the sole agency on consideration that they push the sale of it—I to supply them at a certain price, they to charge a certain price to other dealers, and another price when sold retail. I want to know if I am at liberty to sell them myself retail at the price decided (that is, the retail price), or if I must hand over the extra profit so made to the sole agents. Nothing has been said about this in our agreement."—It is quite a matter of arrangement. We should say, as you have appointed a firm as your sole agents, you should only supply through them; but, as we have said, it is a matter of arrangement entirely.

**PHOTOGRAPHING ON WOOD.**—C. DIGGINS writes: "Can you enlighten me in making photographs from negatives on wood, the same as an engraver would use? Occasionally I have different articles to photograph to size, and my client wants me to put them on wood. Now, what I have seen appear to be on the wood without any basis, such as collodion gelatine. Now, what I want to know is, how should I prepare the wood to make it sensitive, so as I could print from the negative to the wood instead of paper?"—One of the best methods is by the carbon process, employing a tissue that contains a large amount of pigment in proportion to the gelatine. The powder process may also be employed. There are other methods, but the most successful workers, who do the work commercially, do not, as a rule, publish the methods they employ. Those we have mentioned, however, are used in practice, and yield good results.

**DARK-ROOM ILLUMINATION.**—G. J. SMITH writes: "In the last edition of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, p. 803, there is an article 'Abolishing the Dark Room,' by Mr. E. Howard Farmer—a paper read before the London and Provincial Photographic Association—but I imagine it is much abbreviated; it also refers to a communication to the Royal Photographic Society in May 1898. I should be glad to know where I can obtain the full text of both papers and the price of the same, also where can I obtain the formula of the light filter therein referred to, and the ingredients for the same, and price of former and latter?"—In reply: Mr. Farmer's paper in the ALMANAC is complete. The paper read at the Royal Photographic Society can be had of the Secretary, 66, Russell-square, W.C., for 1s. In this JOURNAL, March 16, a report of another paper also appears. Doubtless a letter to Mr. Farmer, at 309, Regent street, W., would elicit further information.

**SHADOWLESS PHOTOGRAPHY.**—P. P. P. says: "I am greatly obliged by your reply to my query respecting 'shadowless' photography, but the chief point in my letter seems to remain unanswered. If I were asked to produce a photograph of, say, a saucepan with the lid apparently suspended above the saucepan, how could I 'arrange' these, 'showing them in perspective, one above the other, without the slightest sign of shadow or reflection,' as shown in following rough sketch, which is a similar subject to the photograph I sent you? I can understand an egg being made to lie on glass by placing it on a small heap of sand, but to place a saucepan lid on edge is a totally different matter. Even if the saucepan and lid could be placed in position satisfactorily, by looking directly down at them one would get a view thus, or nearly so [sketch]. My difficulty is not taking the photograph in a vertical direction, but arranging and fixing my models in the position required, and showing them in perspective without reflection or shadow."—Suspend the lid by a thread above the saucepan, and illuminate by a nearly direct front light, softening the shadows with a reflector. We again advise you to get a practical photographer to give you some instructions in lighting, as you appear to lack even an elementary knowledge of it.

**STEREOSCOPIC PHOTOGRAPHY.**—WALTER SCOTT says: "I have recently been reading your very interesting and explicit article in the 1900 ALMANAC on 'Stereoscopic Photography.' I have had four years' experience in ordinary work, and have been very successful, but have never tried stereoscopic work, and would like to do so. (1) I would like to project the pictures on a screen from my enlarging lantern, and view them by means of such an apparatus as described by you on p. 665, and used by Mr. Knight. I should only exhibit to two or three friends at once. Please say if you think this would be a success, and if the apparatus described is made commercially; and also (2) if the apparatus in fig. p. 670, can be bought, and where?"—In reply: 1. The system described was successfully tried at a meeting of the Camera Club last year. I cannot say if the apparatus is obtainable, but a letter addressed to J. H. Knight, Farnham, Surrey, would, no doubt, elicit the desired information. 2. So far as we know, it cannot be bought; it is the invention of Sir Howard Grubb, Rathmines, Dublin.

**MARKINGS ON PRINTS.**—E. WILLIAMS writes: "Please oblige by giving me your opinion as to what is wrong with the enclosed prints. They were made in the usual course on —'s paper, toned with a sulphur cyanide and gold bath, fixed in fresh hypo ten minutes, and washed about ten changes of water during a period of thirty-five to forty minutes, all well and separately handled and passed from dish to dish separately, and dried between blotting-paper. The prints were placed in a picture frame in contact with the glass, backed with waxed paper as sample enclosed, secured with back board, and exposed on a stand out of doors, subject to damp, frost, daylight, and sunshine from Christmas until yesterday. Have never seen anything like it before. Some edges of the prints, you may notice, have been protected from light by being overlapped by the next print, and have in such portions remained in good condition. There is one interior print which, curiously, has remained in better condition. Probably this was one of another batch of prints."—The trouble is due to faulty manipulation. Either imperfect fixation or insufficient washing, probably the two combined. The exposure they have been subjected to has hastened the fading, but they would otherwise have faded, sooner or later. The print that has stood evidently received better treatment in its production than the others. Had they received a similar, they would also have been in the same condition.

**LENS QUERIES.**—FOCAL LENGTH asks: "1. What is the diameter of the circle of illumination given by a good half-plate R.R. at full aperture  $f/8$  with an angle of  $75^\circ$ , and, if such a lens were used on a half-plate camera, would its covering power at  $f/8$  be sufficiently good to enable the use of the rising and falling front, without cutting the picture also, with this lens at  $f/8$ , how large a circle would it give free from astigmatism? 2. For general work, do you advise a half-plate or  $5 \times 4$  3. If you advise a half-plate set, and I have a single landscape lens of  $9\frac{1}{4}$ -inch focus, and wished to buy the R.R.  $f/8$ , would such a lens for general work be quite satisfactory, as regards perspective, which had a focus of 8 inches for a half-plate? I shall be much obliged if you will give me your opinion, for some people for the same size plate advise a focus of  $7\frac{1}{2}$ ,  $8\frac{1}{4}$ ,  $8\frac{1}{2}$ , and even 9 inches. I have understood that, provided the focal length is not less than the diagonal of the plate, the perspective will be satisfactory. 4. For general work (when extremes of instantaneous work are not desired), do you advise the euryscopic  $f/8$  or the R.R.  $f/8$ ?"—In reply: 1. The circle of light depends upon the focal length of the lens, and the distance its components are apart. A "half-plate lens" are not of the same focus, and some are freer from astigmatism than others. 2. Half-plate, perhaps; but it is quite a matter of taste. 3. The longer the focus the better it will cover the plate with a large aperture. Yes, the perspective will be satisfactory. 4. The euryscope will, when worked with its full aperture, be the quicker lens. Both forms are good, and, when stopped down to the same ratio, there is not much to choose between them, supposing, of course, they are of equal quality.

**STUDIO-BUILDING.**—ANXIOUS INQUIRER writes: "Will you kindly bear with my ignorance, and help me in my difficulty? I have been working in photography as a business for the past four years. I converted my back yard into a studio. I have worked up a little connexion, and do not wish to leave here. The landlord (my next-door neighbour) has given me the wash-house joining the back yard (as per sketch), which I wish to make into a studio and so secure a side light. I beg to ask if you will kindly (1) give me measurements as to the building of a studio with a north-east light. You will notice I can only make it twelve feet long up to the landlord's workshop, but I can get back in my back yard another twelve feet. My idea was to have two doors to open wide from the present wash-house door, so as to get back with the camera (2) I want to know if the side light will be sufficient. (3) The material it should be built with and probable cost. I don't mind going to 40l. including pulling down, &c. (4) The best position for door to set into the garden from studio. (5) If my ordinary half-plate camera lens R.R. will be quick enough for studio with special rapid plates."—1. The position, as shown in the sketch, is a very awkward one. We should suggest that you have a door in the wash-house, when converted into the studio, so that the camera can be taken into the garden at occasion requires. 2. We think so. 3. Probably the district surveyor will require the structure to be of brickwork and glass. We cannot say the cost. 4. About the centre of the studio. 5. Yes, but a portrait lens would be quicker. We are not quite sure, however, that we fully understand the sketch. If you get Bolas' work on studio-building (Marion & Co.), you will find much that will be useful to you in it.

### NOTICE—GOOD FRIDAY.

*As Good Friday falls next week, THE BRITISH JOURNAL OF PHOTOGRAPHY will be issued a day earlier than usual, namely, on Thursday, April 12. Will our correspondents therefore kindly make a point of addressing their communications to us no later than Tuesday morning, the 10th inst?*

### EX CATHEDRÁ.

Copyright (Artistic) Bill was last week introduced to the House of Lords by Lord Monkswell, who, in moving the second reading, said the Bill had been redrafted by Lord Thring. It differed from that of last year, not only in form but to a considerable extent in substance. Under last year's Bill a longer and shorter term of copyright was proposed for different kinds of artistic work. This Bill swept away this distinction, and gave the longer term for every description of artistic work. Lord Monkswell admitted that this Bill was put before the House in a tentative form. At an earlier stage

of the proceedings Lord Balfour said that on behalf of the Board of Trade he did not propose to offer any objection to the second reading of the Literary Copyright Bill, also introduced by Lord Monkswell, or to the appointment of the Select Committee. That assent, however, must not be taken to imply that it would be convenient at the present time to pass that Bill and the Copyright (Artistic) Bill into law. The Bills were not the same as those which were passed through certain stages last year, and which were then sent to various colonies for their observations, and it would be obviously undesirable that Bills which differed from those which had been sent to the colonies should make rapid progress through Parliament until a full opportunity had been given to have answers received from the Colonial Governments.

\* \* \*

FROM the quoted remarks of Lords Balfour and Monkswell it is fairly certain that the Artistic Copyright Bill stands very little chance of passing into law this session. As it appears in our pages last week, it must not be looked upon as having assumed final form; and, when it has reached that shape, there is an official pledge that the Imperial Colonies shall have a voice in the matter. All this takes time, and it is hardly probable that three months, in the present state of National affairs, will suffice to obtain Colonial opinion on an amended Bill and pass it through both Houses of Parliament. Meanwhile we imagine that photographers, by their representatives, will endeavour to be heard by the Select Committee to which the Bill has been referred. The Committee of the Photographic Copyright Union and the Copyright Committee of the Royal Photographic Society have, we understand, formed a joint committee, with a view to taking concerted action in the matter. We may safely conclude that the progress of the Bill will be jealously watched, and that no effort will be wanting to exclude from it the harsh and hostile photographic—or rather anti-photographic—clauses which disfigured last year's Bill.

\* \* \*

We referred last week to the stereoscopic photographs of military subjects appearing in the *Royal Magazine* for April.

The veteran photographer, Mr. H. N. King, of 4, Avenue-road, Shepherd's Bush, W., tells us that the pictures were made from his negatives; at the same time he has submitted to us a large and interesting series of stereographs, having very great present interest, when the war in South Africa is the one subject uppermost in men's minds. These binocular views represent various types, home and colonial, of khaki-clad warriors, royal personages and equipages, and many other groupings which will appeal to the imagination and the patriotism of the people at large. Mr. King, who has lately executed a great deal of binocular work, supplies transparencies as well as slides, and we are pleased to give publicity to the fact that the war has recently kept his camera in constant use.

\* \* \*

OUR contemporary, *Country Life*, announces a photographic competition, flowers being the objects towards which entrants are invited to point their cameras. We have much pleasure in giving full details of the competition on another page, as we consider that the photography of flowers is a branch of work which deserves to be encouraged. It lays a tax on great technical skill, and at the same time leads the mind to study some of Nature's most interesting and beautiful productions. *Country Life* is an elegant journal, which appeals to people who live in and love the country, and the editor states that he is always glad to see photographs from amateurs and others upon matters pertaining to country life in any of its aspects. The number before us contains several well-printed reproductions of photographs of the Duchess of Newcastle's hunters. They are from the skilful hand of Mr. Thomas Fall, of Baker-street, and the characteristic points and beauties of the animals are shown to perfection.

\* \* \*

THE important case of the Thornton-Pickard Manufacturing Company *versus* Thornton was tried by Mr. Justice Kekewich on Tuesday last, occupying nearly the whole of the day. Briefly, the action was brought to restrain Mr. J. E. Thornton from engaging in the manufacture of films at Altrincham or elsewhere, on the ground that when, some few years ago, he sold his business to the plaintiff Company, he covenanted not to engage in a similar business or the manufacture, among other things, of photographic "appliances." One of the points for the Judge to decide was whether celluloid films could be termed "appliances." The evidence of Messrs. Andrew Pringle and Chapman Jones tended to show that, in photography, the word "appliances" had a comprehensive meaning, and could be taken to refer to anything used in the production of a photograph. In the course of his judgment, his Lordship made it clear that he regarded films as appliances, but he decided the case in favour of the defendant, Mr. Thornton, on the ground that the clause of the agreement which formed the cause of the action was too wide and prohibitive. A large number of witnesses had been subpoenaed, but, in addition to Messrs. Pringle and Jones, only Mr. Pickard, Mr. Thornton, and Mr. Rothwell were called. The effect of the judgment will be that Mr. J. E. Thornton will proceed with the manufacture of celluloid films at Altrincham, in which place the Thornton-Pickard Company will also continue to produce their well-known shutters, cameras, &c. As impartial observers of the

affair, we should say it is feasible that the two businesses could be carried on side by side without clashing to any appreciable extent.

\* \* \*

WE have much pleasure in drawing attention to the fact that, under the auspices of the Croydon Microscopical and Natural History Club, a lecture will be held at the Public Hall, Croydon, on Tuesday, April 24, at eight p.m. precisely, with Dr. Chisholm Williams, F.R.C.S., &c., and Dr. F. S. Pepper, M.A., &c., will deal with the subject of "Röntgen or X-Ray in Peace and War." The whole subject will be thoroughly demonstrated, many beautiful electrical and other experiments performed, upwards of 100 limelight views of the actual possibilities of the new light will be shown, and its great value to surgeons in time of peace and war. The nett proceeds will be devoted to the X-Ray Department of the City Orthopaedic Hospital, Hatton-garden. Tickets, 1s. each, may be obtained of Messrs. Roffey & Clark, High-street; from Mr. Pusey, the Hall; or from the Hon. Sec., at 11, Park Hill-rise. It is hoped there will be a good attendance of members and their friends on this special occasion.

\* \* \*

WE are requested by the Secretary to the Royal Commission for the Paris Exhibition to announce that the Congress of Photography will be held in Paris from July 23 to July 27. Any further particulars may be had by applying to the Organizing Secretary, M. Pector, rue Lincoln, 9, Paris. We have already given an outline of the proceedings which will engage the attention of the Congress. The sizes and thicknesses of photographic plates is one of the subjects that will probably be brought before it, and we understand that in connexion with the British plate and camera-makers will take joint action with a view to put the Congress in possession of their ideas on this important matter.

\* \* \*

AT a recent meeting of the Photographic Society of Philadelphia, Mr. F. E. Ives submitted some interesting criticisms of Professor R. W. Wood's diffraction colour photographs. In his opinion, one of the principal defects of the process was the crudeness of the colouring. Theoretically, the diffraction light diffracts, or it does not diffract (there is no half way about it); consequently one would naturally expect that with a diffraction print you would get simply red or green or blue light, and not mixtures of these colours, two and two, or three and three, &c. That is what one would expect from examination of the theory; but Mr. Ives pointed out that it sometimes happens that in photographic processes we realise conditions which do not appear to quite sustain the theory. Sometimes we get results which we would never prophesy if we based our opinions entirely upon theoretical considerations; so Professor Wood hopes that in practice, by modifying his method of procedure, he will get gradations in the images. He thinks that Mr. Ives has made some advance in that direction, and he has shown Mr. Ives some prints to show his advance. The results, in the opinion of the latter gentleman, are better than those first shown, but still the colours are crude in comparison with the colouring of the kromskop images.

## VIGNETTED NEGATIVES.

MOST photographers who are particular as to the excellence and uniformity of the portraits they issue are fully aware that the extra price charged for vignettes does not mean so much extra profit, particularly when the printing is entrusted, as it often is, to careless printers or inexperienced girls and apprentices, on account of the great waste entailed. With this fact before us it becomes somewhat a source of wonderment that the negatives themselves are not vignetted in the first instance. If they were, the prints could be made with no more trouble or waste than fully printed ones, and, what is more, they would be uniform so far as the vignetting is concerned.

In the *pre-carte-de-visite* days, when, perhaps, only one or two prints were required from a negative, the present system of vignetting became adopted, and it has generally been followed ever since, notwithstanding that the prints are now usually ordered by the dozen. When only a print or two per negative are required, the present method is, perhaps, the simplest, but in the case of dozens it is a different matter. In establishments, however, where uniformity of results is a desideratum, the waste is considerable, even when the printing is done by careful hands. Therefore, as we have just said, it is a little surprising that no attention seems to have been paid in late years given to the vignetting of the negatives. That it may easily be done by the operator, who, when he takes the portrait, is the best judge as to how much of the figure should be included in the finished picture.

The first vignetted portraits produced were Daguerreotypes, and they were taken direct in the camera. Not only were Daguerreotypes made, but glass positives were also produced in the same style. The different methods by which these pictures were produced are equally applicable to negatives, and these also were produced in the early days. We shall here describe some of the methods, and it will be seen that they are all very simple, though some of them actually formed the subject for patents many years ago.

Here is a method that was in vogue in the late forties and early fifties: A mask was placed in the camera, with an opening including as much of the figure as was desired—of course, out of the focus of the lens. After exposure a reverse of this mask was put in front of the plate, which was then exposed a second or two to diffuse light. If this second exposure were omitted, it is manifest that the vignette would have a dark or black margin. Another method was to interpose between the sitter and the camera a white, or very light, screen, with an opening with serrated edges through which the figure was seen; the result was a perfectly vignetted picture. Sometimes the screen was suspended and set swinging during the exposure. A modification of this system was to pose the sitter before a light background, and then have a half-screen, of a slightly darker tint than the background, placed between the sitter and the camera, so as to shade off as much of the figure as was deemed necessary. Sometimes this screen was loaded with cloud effects, which greatly enhanced the picture. This system was also in vogue in the Daguerreotype days.

Here is an early method of making vignetted negatives: A mask with a serrated opening is placed in the camera between the plate and the lens—of course, well out of its focus, and the exposure made in the usual way. After the exposure has been made this mask is removed—slid out of the camera, and a reverse of it slid in and a second exposure made—this time to a white screen.

About 1864 the late Mr. Napoleon Sarony took out a provisional protection for this system of producing vignettes in the camera, but the patent was not completed, probably because Mr. Sarony found that the idea was by no means new. It is well to note, however, that Mr. Sarony mentioned that the second exposure might be made, with the lens in focus, to a light screen, on which were some hatched lines on scrollwork.

Another method of making vignetted negatives was published by the late Mr. Adam Salomon in the very early seventies. It was this: He took a piece of ground glass, the same size as the focussing screen, upon which it was placed, and, while focussing, on it he roughly sketched with pencil an outline of so much of the figure as he wished in the finished picture. The exposure was then made in the usual way. The exposed plate was then taken into the dark room; here a mask, roughly corresponding to the sketch on the ground glass, was cut out of black paper, and used to shield the exposed portion of the negative while it received a brief exposure to a weak white light from a small window in the dark room, a piece of cotton-wool being used during the time to soften the vignetting.

The method we described a few weeks back for producing vignettes with dark margins, by the interposition of a screen between the sitter and the camera, is equally as applicable to the production of those with white ones, by simply using a white or light screen instead of a dark one. Indeed, the screen may be dark on one side and light on the other; thus one screen will serve for both styles of picture; or, if grey or tinted margins be desired, the screen may be of a more or less intermediate colour.

We have not here described all the methods by which vignetted negatives may be produced, but we have indicated enough to enable any photographer to adapt or modify any of those referred to to his particular requirements. On a future occasion we may have something more to say on methods of vignetting.

**Material Nature of Radium Radiation.**—The rays emitted by this newly discovered body possess exceptional interest from their resemblance—with a difference—to Röntgen Rays. They, as we have before pointed out, act upon a photographic plate, yet differ in regard to their penetrative power with regard to several substances transparent to the older rays. The exact nature of the radiation whose discovery we owe to Röntgen is still matter of discussion, but they are understood, on the whole, as conditions of ether. Radium, on the contrary, as far as recent investigations have pointed out, owes its action to the efflux from it of material particles. Naturally the first objection that would arise as against this is that the emitting body would, in case of the hypothesis being proved correct, gradually become lighter in weight by the loss of substance. But M. Curie has shown that the charges carried off are so feeble that some millions of years would be required to remove one milligramme of radium in the case even of the most intense radiation that has yet been noticed. An article in a recent number of the *Revue Générale de Science*, as quoted in the *Chemical News*, describes some of the most recent investigations of M. and Mme. Curie, in which, by means of a series of intricate and most delicate experiments, they have obtained evidence which is almost conclusive as to the materialist theory of the radiations from the new metal. It would be foreign to the needs of these pages to describe them, they being mostly of an electric or magnetic nature, but we may say that the paths of the particles have been determined and opaque objects have been placed in the paths of their trajectories, and the particles in one path filtered out, as it were, from those in another. It is, however, of sufficient interest, as connected with photography, to place here on record.

**To Ignite a Gas Jet without Exploding the Generator.**—The laboratory experiment of making hydrogen gas and igniting it at a burner has little interest for photographic readers, but with acetylene experiments on a small scale the same difficulty would arise as with hydrogen, *i.e.*, the possibility of producing an explosion if all the air be not expelled. Mr. C. G. Hopkins, in the *Journal of the American Chemical Society*, describes a method of avoiding all danger in the experiment. The usual instruction is, "When the gas is coming off freely, light the jet." Too frequently an explosion follows the application of the light. Mr. Hopkins recommends a test tube to be filled with the issuing gas, the tube then to be ignited at its mouth, and in its lighted state transferred to the issuing gas. If the gas is explosive, it would explode in the test tube, but, if the tube can be carried still aflame to the jet, the gas will be safe, and will light at the generator orifice.

**Photographic Search for an Intra-Mercurial Planet.**—Professor W. H. Pickering, in the *Harvard Observatory Circular*, describes a method which he has devised, and will carry out in the next Eclipse Expedition. The plan is founded on the fact that "the faintness of a star that may be photographed with a given instrument against a *bright* background of the sky depends within certain limits directly on the focal length of the lens, and is independent of its aperture." In a previous circular he had shown that "three minutes after the pole star first becomes visible to the naked eye in the evening, the sky surrounding it is of about the same photographic intensity as that of the sky near the sun during a total solar eclipse." He uses a photographic lens of 3 in. aperture, and 11 ft. 4 in. focus, its field being sufficient to include four 10 × 8 plates. Exposing for one minute to the region of the pole, within three minutes of its having become visible, the light of the sky fogged the plate slightly, but not sufficiently to obliterate the star images. Four such instruments will be employed, and the expectation is that, if there be any planet, it would in the same way as the pole star impress its image, notwithstanding what might be termed the faint sky glare.

**New Mode of Fireproofing.**—The U. S. Consul at Freiburg has been describing a new industry that has been started there—a method of making materials fireproof at a slight cost. We have often drawn attention to the premiums required for photographic studios, and any practical method for decreasing fire risks ought to have an effect in reducing rates, which we have before stated to be unjustifiably heavy. The new method treats goods quickly, and in the case of woven fabrics, such, say, as studio curtains and the like, the treatment does not interfere with their texture, fibre, colour, or weight, and the extra cost is slight. Consul Liefeld experimented with materials treated with the new method, and found that even a lighted candle failed to ignite them, it merely charred them. He then poured kerosene oil upon the articles and set fire to it. The fabric was simply charred where the flame travelled, but did not burn. A piece of wood enwrapped with some of the fireproof fabric, and placed for a few moments on the red-hot coals of an anthracite furnace, was found to be uninjured except where the coals had touched it. The only disadvantage of this new material seems to be that it is only of use for indoor purposes, as rain would dissolve away the protective material, but this would be quite immaterial in photographic apartments. The cost is stated not to exceed three half-pence per square yard of material, and the increase of weight to be only about a pound for every fifty square yards.

**INFLUENCE OF X RAYS ON SELENIUM.**—M. Perreau has lately made a number of researches as to the effect produced by X rays upon selenium, and has presented his results to the Académie des Sciences. He finds that selenium, which is sensitive to light, is also affected by this form of radiation. The experiments were carried out with a selenium cell made up in the usual way with brass strips  $\frac{1}{10}$  mm. thick, separated by strips of parchment paper of  $\frac{1}{10}$  mm. The cell, contained in a zinc box and covered by a sheet of aluminium, was placed in circuit with a Daniell element, a resistance box, and a galvanometer. The resistance of the selenium was found to be 40,000 ohms in the dark, and, when exposed to diffused daylight or to a gas burner at a distance of 1½ metres, this fell rapidly to 33,000 ohms, coming back to its original value in the dark.

## THE PHOTOGRAPHER'S YEAR.

APRIL.

"WHEN that April with his showers sweet  
The drought of March has pierced to the root,  
And bathed every vein in such liquor,  
Of which virtue engendered is the flower;  
When Zephyrus also with his sweet breath  
Inspired hath in every holt and heath  
The tender crops, and the young sun  
Hath in the Ram his course run,  
And small birds make melody,  
That sleep all night with open eye,  
So pricketh them and nature in their courage,  
That folk long to go on pilgrimages,

\* \* \* \* \*

And specially from every shire's end  
Of England, to Canterbury they Wend,  
The holy blissful martyr for to seek,  
That hath helped them when they were sick."

Slightly altered to rid some of the words of their archaic form and endings, these, the opening lines of the prologue to the "Canterbury Tales" give the first reference to April in modern English. They are the placidly laudatory ones, general in tone, that would be expected from Chaucer as a Londoner bred and born. Much like the Londoner of to-day, his knowledge of the country was probably rather vague, more in the abstract than the reality of close and loving observation. It has nothing, for instance, of Blackmore's love, as shown in his very first description in *Lorna Doone* of the opening of a Devonshire spring. No that we would begrudge the former his lack of this particular knowledge and description if it were to be gained, as it probably would, at the expense of the priceless picture of the

"Nine and twenty in a company  
Of sundry folk by adventure befallen,  
In fellowship, and pilgrims were they all  
That toward Canterbury would ride,"

whom he came across in "The Tabard Inn in Southwark." The country between the Tabard and the objective point of the pilgrimage—the tomb of the canonised Becket at Canterbury—is much the same to-day as it was then, and we can enjoy it at our leisure; but the vivid and visible description of the pilgrims, representative figures of the English life of six centuries back, we emphatically cannot afford to be without. Would there had been a photographer amongst them! How inestimably valuable would his prints be to-day, although taken by a fourteenth century process, of the knight, squire, yeoman, clerk, shipman, doctor, miller, reeve, and the rest. Alas! it was out of the question, and we have to come much further down the stream of time before the photographer presents himself. Our philosophical consolation must be found in evoking hopefully forward rather than regretfully backward, and believing that our posterity will be more blessed than we are in this respect. Sir Benjamin Stone will possibly be regarded in the twentieth century as the photographic Chaucer of the twentieth, and his shade, let us trust, gain an appropriate and a pleasing reward in being conscious of the fact. Those of most of the rest of us will, I doubt, regard instead the dead-sea fruit reward of having, when the opportunity was also ours, seen too much in the utilitarian view of the American who asked, Why he should think of his posterity? What had it ever done for him?

Returning, however, to our more practical object, the photographic sequence of the months, April must without hesitation be regarded now as in the time of Chaucer, as a month of showers. Here we are on travelled ground, as such pictures as *Sunshine after Rain*, *A Passing Shower*, and so on, prove. Working conditions are very different to those of March. The light passing through air well washed of all impurities can hardly be better in quality. The great drawback is, that as yet there is no photographable foliage. The thin, hazy cloud of green over tree and hedge is very pleasant in its suggestion of the fuller life so near at hand; but, however scientifically conscientious the lens in its rendering, the result upon the plate is a blur, and not faint colour. No can sentiment be worked in a homeopathic fashion into the constitution of any emulsion, to help matters out. As the result of observation, and failure, the workers who have gained the best typical results in April have turned to the broad masses of light and shade that suggest the characteristic coming or passing shower. This is advanced work. Watching a shadow and a gleam of sunlight as they pass over the face of the earth, and arresting them in a second at the exact point in their course at which their value tells to greatest advantage, must be regarded

as rising to the greater heights of photographic art and practice. Watching shadows is of necessity bound up in also watching the clouds by which they are produced. He who would have April pictures must introduce clouds into them; and the additional truth will soon be borne in upon him that pictures taken in any other month, to be at their natural best, must also have clouds, not the smoked-glass or cotton-wool clouds. There are many ridiculous things in photographic practice: the cast-iron posing of the studio, modelling a face, or smoothing out its expressive wrinkles, deliberately throwing the focus out of tune with the view to gaining a so-called "impressionist" picture, may be quoted as some instances. But these are trivial compared with the colossal assurance of competing with the Almighty in making and arranging clouds. To ignore the clouds altogether is bad enough, but to complacently substitute home-made smudges is intolerable. The idea of a stock of clouds ready for use is as palpable an absurdity, from any rational point of view, as regarding the painted canvas and pasteboard accessories of a stage sky and landscape as real. The reason that we placidly accept the only too orthodox order of things, and fail to detect the lack of fit between the artificial sky printed in from one of such negatives and the earthly scene spread below it is that, looking so infrequently at the sky, we know next to nothing of clouds.

We rarely notice clouds except it be when turning a look towards them in the effort at deciding whether it would be wise to take an umbrella or not. It is natural perhaps. We are of the earth, very earthy, and clouds lack so markedly the personal human element we find so all-important in conferring piquancy and interest in life generally. A landscape much nearer to us, and interesting in proportion, will soon pall if deficient in the same element or its suggestion. The chimneys of the hall rising in the distance beyond the trees in the park add immensely to the value of the picture, the distant figure walking along it to the interest of a road. If we could expect a man to step out from behind an outlying spur of a mountain of cloud and start climbing it, or take the long, clearly defined cloud road stretching away to the west, we would be ready enough to turn our eyes upwards. A balloon occasionally entering into or emerging from a mass of cloud would have the same effect. Even when the rare reference is made to clouds, as often as not it will be a comparison of their shapes with such human products as towers, castles, and city walls. The painted clouds around the setting sun we certainly do look at and enjoy, but it is the enjoyment of colour more than their shape and form. We always have clouds with us, and plenty of them—as carriers of rain too plentifully oftentimes. It is a case of "nothing pay, nothing value." How grateful, on the other hand, to a dweller under cloudless skies must be occasional clouds, not merely in their coolness and suggestion of desired rain, but as relief to the soul from the ever blue and brilliant heavens above. Still, spite of their normal presence and the absence of a human touch about them, they are well worth studying, if only as giving so much added value to a picture. They are worth photographing, and photographing truly, dovetailed in to make a perfect and symmetrical whole. It is so easy to do too. A tilt of the camera and a duly shortened exposure upon an extra plate will give the exact sky we ought to have for the particular picture, and, if we can rise to admitting that clouds, cloud lights, and cloud shadows as arranged by nature are correct, it would be well worth while comparing a picture with its true sky with the same in which the most suitable sky from the stock of cloud negatives has been printed in. The difference to a right-thinking mind should settle the question and correct practice at once.

Outside of clouds and their effects, it would be rather hard to find much readily and strikingly photographable in April. The month is fuller in faint, but pleasing promise than anything else; and where here and there, as in the wealth of fruit blossom, that promise rises to a higher and more distinct note, the camera is not the instrument to catch and preserve it. The lovely pink and white of apple blossom is for the painter, and not the photographer. The angler can, perhaps, be caught, for this is his first—rational—month of going abroad; and in certain favourable positions he is worth catching. But the absence of foliage again in the setting of the picture detracts sadly from its value, and, if he can be taken to greater advantage from this point of view, later on it would be wiser to let him bide a while, for he makes no typical figure in April. It is too early, too, for picnicking parties and their pictorial possibilities, the weather being as yet too cold and variable for any lengthened rambling. Indoors we cannot stay with so much, if fugitive, brightness outside. Besides, April indoors is the month of spring cleaning, emphatically a non-artistic, non-photographable, and non-everything else, that means comfort and pleasure, process. The short walk in the invigorating and mind-quickening freshness, which is a very marked quality in the month, may have a high

kind of negative value in pointing out the natural limits of photographic work. There are so many things we would like to take and cannot, that a fitting respect for the higher domain of the artist and painter is gained, for by a telling and suggestive seasonal touch they can convey budding nature and renewed life. This will prove in its fuller development a solid item of education, and contribute much to added pleasure, if only in looking over, and analysing, the wealth of illustration presented so lavishly nowadays in periodicals and magazines. It might ultimately even rise to so judicious a selection of suitable material for working upon as would compel the approbation and valuable help of the artists, that as a class we have hitherto been at war with, and rob the writings of a Pennell of the edge of their bite.

#### THE CONVENTION AND NEWCASTLE.

THE Convention, for the first time in its history, has chosen the recognised northern metropolis for its temporary place of meeting; that they (the Conventioners) are to be congratulated upon their choice goes without saying.

Though not a native of Tyneside, I lived so many years in the "canny town" that I became inoculated with many of the ideas and idiosyncrasies of the inhabitants thereabouts, chief of which was the sentiment, indigenous to every native breast, that there's "nee pleyce like Newcassel!" This sentiment is very real and very general, and takes hold of one very genuinely. You can imagine, therefore, the shock it is to me, when sometimes speaking of "Newcassel," some greenhead thinks I am referring to a trumpery place, which happens to be of the same name, in the Black Country!

Conventioners can take it from me, that from the point of view of the photographer (their view in fact) the sentiment above elaborated is particularly the case.

Newcastle (and district) has been from earliest days to the front in all matters pertaining to the art of photography. Where would the world be but for Mawson's collodion? What about the good old "Swan" plate of years gone by, and the many experiments conducted under the shadow, so to speak, of the old castle, which led up to the carbon process of to-day?

It was my good fortune, I think, to have come into contact with some of the old, and many of the new, men of the north, at a time when it was in the power of any town to distinguish itself by thorough, earnest, and enthusiastic work, in that newer photography which grew up with the introduction of the modern dry plate. Newcastle, as I knew it first turned out excellent work as times went, Mendelssohn, W. & D. Downing, P. M. Laws, and Ed. Sawyer, being the principal artists. My own ambition, after many years smouldering, was fired by actual association with the apparatus then in vogue. The outfit I bought was—for men were sitting on the fence at the time in such matters—a curious blend of the wet and dry, but with it I struggled on, and the main idea in men's minds being technique, persevered until the operations of taking and developing a negative were thoroughly mastered.

There was a restless spirit abroad, which impelled a small coterie of us to be continually at work in the various directions of plate-making, drop-shutter work, and the various printing processes, enlargements, copying, and the rest of it. At this time I became acquainted with the late Mr. Auty, whose earnest, thorough style of working did a great deal later on to foster in the northern amateur's brain a desire for excellence. Further on, when Secretary of the Newcastle Society, I made friends with the veteran, J. P. Gibson, the *doyen* of Northumbrian photographers; Thomas Galloway, the oldest northern photographer, still active and enthusiastic; the late Edgar Goold, whose fine and large wet-collodion work was at once the envy and admiration of his compatriots; Mr. P. M. Laws; Mr. W. Parry, whose reputation and name as a marine and engineering photographer has gone to the four corners of the earth; the younger Goold, who succeeded his father, and appears to have begun where his father left off, bringing to the work scientific and well-trained knowledge, and the skill of the intelligent draughtsman. Mr. W. D. Welford comes from coaly Tyne, and, although I cannot claim his acquaintance, everybody else knows him. E. G. Lee, younger, perhaps, than any of us, but a giant amongst medallists. Lyd Sawyer was a host in himself.

There was quite a band of enthusiasts, genuine hard workers, and the exhibition lists of a few years back testify to the power of the Novocastrian contingent to annex awards. Most of the lesser-known amateurs were just as keen; J. G. Sinclair's *Peep at Derwentwater* will be remembered. Mr. Bulmer, in a quiet way—far too quiet—turned out hundreds of fine picturesque bits of wonderful excellence; Mr. A. Campbell Swinton, then, as now, an earnest and up-to-date experimentalist. Mr. Galloway produced admirable photographs of the impressionist type, long before the days of the "Society Split," and the Salon. It would be easy to add to the list, which has, furthermore, been added to by newer men since my time; there is no reason to doubt that the old spirit is still alive and active.

To account for this enthusiasm in large measure was the prolific

picturesqueness and interest of the country as regards the ancient and mediæval. The antiquarians were strong, and very much to the front, and some four members were also members of the Antiquarian Society, while one of our amateurs had, in quiet excursions and pilgrimages along the line of the "wall," and so on, accumulated hundreds, literally hundreds, of little quarter-plate views of local scenery, architectural bits of old and modern interest, enough to make a "lantern-slide man" green with envy.

It is this characteristic scenery of which I should like to say a word. The Newcastle native looks round on his city and his country with a good deal of pride, satisfaction, and contentment; he knows there is no better place, for business or pleasure, in the country or out of it. I know the feeling well, but it is very possible for a first visitor to be disappointed or disillusioned; or, at the least, fail to work up any special pleasure over the "High Level," or the Cathedral, or even the magnificent thoroughfares. When the late genial editor of this JOURNAL was there in 1887, I did my best to show off the features of the old city in which we took most pride, but I rather fancy he enjoyed a stroll through "Jesmond Dene" most of all. The local committee may be trusted to make the best arrangements possible for visitors in the way of excursions; my experience is, however, that these somewhat cut-and-dried functions are rarely adapted to serious photography; others prefer to go "on their own," as the saying goes, and there are a few who stay over the official limit of days. To such, let me say, that at Alnwick one finds oneself in the very heart of the county's history, the grand old castle, the quaint township, the quiet picturesque river, the drive further on (by permission) to the ruins of Alnwick and Hulne Abbeys—such a day is to be remembered. In order to see the beauties of the Upper Tyne, nothing could be better than a run over to Chollerford, some six miles beyond Hexham; here a day could be put in, in order to inspect the very interesting relics of the Roman occupation in Britain; thanks to the owner of "The Chesters," close by Chollerford, we see here, in the Park that is, and occupying some five acres, the remains of one of the largest of the Roman stations on the line of the Wall. Returning over the bridge, we can stroll up the river-side towards Hexham, and get a variety of subjects. I believe I ran great risks as a trespasser when I went there, but I landed safely with a full bag.

It would be a pity to miss the trip down the Tyne, and, landing at Jarrow, the old church of the Venerable Bede, with its Saxon tower, and, in the chancel, what is said to be Bede's chair—don't be sceptical about this, but take it on trust, for what is life without imagination? On the other side of the river we can see Shields—

"A mass of houses—not a town,  
On heaps of cinders squatted down  
Close to the river's oozy edge,"

as the poet says—dirty but picturesque. If visiting Durham, stand a few moments by Bede's tomb in the lady chapel of the Cathedral, and, if it can be managed, by all means go to Chester-le-Street, *en route*, and mainly to Finchale Abbey—ruins certainly, but not so ruinous, and full of marvellous beauty and charm. Then we may mention Hexham, Rothbury, Bamburgh (famous for its castle, and reminiscent of Grace Darling), Bellingham, and Hareshaw Linn, Warkworth, "of less historic fame than Alnwick, but in itself a more pleasing object of study," says Mr. Freeman; this is a matter of opinion, but there is no question that the place is worth visiting. In short, leaving scores of other routes and districts unnamed, is there not some reason in the belief of the Northumbrian that his is a canny town and county?

J. PIKE.

### THE METRIC SYSTEM.

In the course of a paper lately read to the Society of Chemical Industry, and printed in its *Journal*, Dr. W. S. Squire discusses some objections recently urged to the metric system, and points out that there are many curious coincidences which have been urged in defence of the British weights and measures and as an argument against the metric system, but, with one exception, they are mere rough approximations; and even this exception, like the rest of them, was not the result of design, but of mere accident. Sixteen years ago, says Dr. Squire, Sir F. Bramwell called attention to some of them. For example, a sheet of water one inch thick and of the extent of one acre weighs 100 tons approximately (really 101 tons). A piece of boiler plate, one inch thick and a foot square, weighs 40 lbs. approximately. Steel weighs rather more, and cast iron less. Again, a bar of iron one foot long and five-eighths of an inch in diameter weighs one pound, approximately (really a little more). I myself might add several others, and I will mention first the most remarkable of all, viz., that a cubic foot of water weighs 1000 ounces, this time exactly; but this, curious as it is, was quite undesigned. Then, again, a cubic inch of water weighs nearly 250 grains (really 252.458), a square foot of lead one inch thick weighs 60 lbs. very nearly, as the result of the specific gravity of lead being very nearly fifty per cent. more than that of wrought iron. Again, a pipe or vessel ten inches in diameter and a yard long holds 10 gallons (really 10.2).

If we turn to money (with which, however, we are not concerned to-night), we find that eight guineas per cwt. is eighteen pence per lb. This, like the cubic foot of water, is exact. I may also call your attention to

the other coincidences of this character, which, however, cannot be put to the credit of British weights and measures, as they are in the domain of geometry. The area of a circle is four-fifths of a square of its diameter (really a little less), and the contents of a sphere is half that of a cube of the same diameter (really a little more). Of course, this is only an approximation, but it is quite near enough for people who rely on these purely accidental coincidences for their calculations. It would be strange, indeed if a few coincidences did not occur here and there among the multiplicity of objects and dimensions which have to be dealt with in life, but that any one should seriously rely on them as a basis for calculation is stranger still. They do very well as "Bauer-egeln," and are fit only for rule-of-thumbists.

It can scarcely have occurred to those persons who have preached the cult of coincidence as a basis for happy-go-lucky calculations, and are using it as an argument against the introduction of the metric system, that they have thereby provided the very strongest argument for its adoption.

If a system of weights and measures is good in direct proportion to the number of coincidences to which it gives rise, what about the metric system? It teems with coincidences. It consists of coincidences and nothing else. It was intended to be so. A cubic decimetre of water measures a litre, and weighs a kilogramme. A square metre of water, one millimetre thick, measures a litre, and weighs a kilogramme. If we wish to know the weight of a sheet of anything one metre square and one millimetre thick, its weight in kilogrammes is expressed by its specific gravity, &c. All this is exact; there is here no question of approximation. How does the five-eighths of an inch bar of iron compare with this? The nearest approach is afforded by the British gallon of water, which weighs 10 lbs.; but then comes in that terrible 277.274 cubic inches as its cubic capacity. I need not enlarge on the beauties of the metric system, which coincides everywhere with mathematical precision. I have said enough to show that the argument of coincidences is a very sharp two-edged sword to play with.
