Seated beside the President—whom I recognise from your admirable portrait of him—my eyes light with pleasure on the face of the worthy secretary—long may he continue in that office, as it will be a very difficult business to get a successor capable of filling his shoes. Just behind him, and forming an appropriate centrepiece, I see that grand old man, John Stuart, and right glad I am to see him again amongst the "bright band." Kindly, "couthie," and in every sense a man, I trust that he may long be spared to go out and in amongst us. Near by is Godfrey Bingley, of Leeds, who will always live in my memory as the beau-ideal of helpfulness. Well I remember how when first I joined the Convention, he unostentatiously but helpfully smoothed the rough places, and made me, an utter stranger, feel very much at home. May he long continue a conventioner, and the creator of those exquisite lantern slides associated with his name. But what is wrong with the Crooke of Edinburgh? Is he frightened that the President will fail at the critical moment of exposure that he gazes so earnestly towards the central group, or is it merely a desire to be portrayed in profile. He's one of the good ones, and is always ready—but, then, what conventioner is not?—to assist in making the annual gathering a success to everyone. The serious face beside him of Harold Baker gives no indication of the wealth of fun concealed behind the pincenez; but one or two may remember a fusillade of pease which disturbed the serenity of a certain official group. Away near the other side of the picture, supporting a column, is the "hail fellow, well met," of the Convention, Snowden Ward. He seems to "know everyone, and everyone seems to know him." He suffers from the disadvantage of a talented better half, which to some extent throws his own abilities into the background; but we could not afford to do without Mrs. Ward, or who would reply for "The Ladies"? Near the outside right of a picture is a prominent man, a veteran whose personality I remember well, but whose name at the moment escapes me. I looked in vain for a black-bearded face which you, Mr. Editor, may know, but I can't fix it.*

Others I might mention, but, no, no. I wait and trust to meet them, in the flesh, shall I say, as I have always hoped, next year?—I am yours, etc.,

A. SCOR.

[* The face is there, minus the beard; look again, friend!—Eds. B. J. P.]

CHEMISTS AND PHOTOGRAPHERS.

To the Editors.

Gentlemen,—Please allow me to vigorously protest against the unfair competition we poor wretched photographers have to contend with. I refer more particularly to photographic chemists. I as a professional can only get my 10 per cent., although I do a good bit of dealing. My clients come to me and ask me to get cameras, lenses, etc., for them. Naturally, I do not refuse; but what is the result? After all my time and trouble and paying carriage I get 10 per cent., whilst my dealer gets his 33 per cent. Now comes the hard part. This same dealer develops and prints amateur's negatives, enlarges, and when there is anything special on takes negatives and sells them all below my prices, and why? Of course, he can afford to do so. Sirs, this is not an isolated case. Finally, Mr. Editor, who are these people who do this work? Why amateur (so-called) photographers, whom, I assert, are not qualified in many cases to undertake the work. I should like to hear what others have to say on the subject.—Yours faithfully,

C. S.

IRRITANT POISONING BY PHOTOGRAPHY.

To the Editors.

Gentlemen,—I began to write my experience in reply to your correspondent, "C." but seeing he omitted in his list both bichromate of potass and metol, I thought I would wait to see if anyone had a similar experience apart from either of these. Some years ago I worked a good deal with bichromate, and then probably from it there was developed a skin eruption. After discontinuing its use and a course of arsenic treatment, it disappeared, I may say, entirely. About nine months since I began to use metol for development of negatives, when almost immediately appeared the old eruption, though I think in a rather worse form. As I read of its tendency I took the precaution to have a tap of running water near, into which I placed my fingers after each immersion in the metol solution, but this did not prevent its action. I accordingly gave up its use, good though it is in some cases; and now as to cure. I washed affected parts daily in Calvert's carbolic soap and then anointed them with vaseline occasionally after washing, applying sulpholine lotion, to be bought at any chemist, with the result, the eruption is practically gone again. I think this, with other experiences, recorded in your last, proves that metol decidedly, with some, produces the eruption, and the only course is to avoid it or similar compounds. "C." included in his list mercurial intensifier. It is probable with some it may have a like result. Though I have used it for years as occasion required, in my

case it seems it did not cause any eruption, or it would have appeared in the interval of some years between the use of bichro. and metol. I question if bichro. affects much unless pretty constantly used.—Yours,
OLD PROFESSIONAL.

DOING THE REST.

To the Editors.

Gentlemen.—I should like to say a word re. your interesting article "Doing the Rest," in last issue. Practically, it is asked, why does not the professional "do the rest" for amateurs? I reply, often because it does not pay. The amateur dealer, so-called, has helped to this condition of things. Two cases in point have recently come to my notice. 1. A lady amateur called with a bull's-eye Kodak film and asked if it could be developed. I replied, "Certainly, Madame." "But what is your charge?" she asked. "The same as the Kodak Company, 3s." "Oh," she replied; "that is too much. I only paid 1s. in B——." "Well, Madame, it will pay you best to post them there." 2. A gentleman brought a packet of twenty Frena films, the small size, to be developed, and inquired the charge. "The same as the Frena makers," and produced their list, 4s. "Oh, that is too much; I only paid 1s. 8d. in such a town." I replied, "they cannot be done properly at the price."

Now this, I believe, is the crux of the whole thing. Amateurs conclude, because chemicals cost so much, and so much is needed to develop so many, therefore the price should be so much. Allowing little or no margin for use of plant or brains, the result is that those who value their brains prefer to use them better than "doing the rest," unless the customers are prepared to pay a fair price. The amateur dealer of the chemist class often allows a junior assistant, with no photographic training, to develop, and most often he puts a dozen ½-plates in a dish at once, and treats them all alike, and no wonder if half are spoilt. Though I have not tried, I believe it would pay better to do the cabinet part at 1s. than to develop twenty Frena films at 1s. 8d.—Yours,
P. W.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

FORMULA WANTED.—H. WEST asks: "Please give me formula for gumming stamp photos."—In reply: A solution of gum acacia, to which a little glycerine has been added, is as good as anything. Dextrine may also be used, but as most of the commercial samples are acid, it is not to be recommended, as it may have an injurious action on the photographs.

THOS. DUNKERTON.—(1) We expect you will have to have a brick foundation. (2) We do not think putting the structure on wheels will exempt you at all. The building bye-laws vary so much in different localities that we cannot give an opinion; what would be allowed in some would not be in others. We should advise you to consult a surveyor in the neighbourhood who is familiar with the bye-laws of the town council.

BOOK WANTED.—M. KING asks: "Would you kindly inform me the best

book I could obtain on working up enlargements?"—In reply: So far as we are aware, there is no book wholly devoted to finishing enlargements published. Johnson's book on the "Art of Retouching, Finishing, and Colouring Photographs" will give you much information on the subject. It may be had through any of the dealers.

COPYRIGHT.—"J. B." writes: "I have been called to copy an engraving from a very valuable oil painting that has lately been exhibited in Birmingham. Would you please inform me if I can make an enlargement and exhibit the same, not for sale, but just as a specimen of work?"—In reply: Certainly not, if the engraving is copyright—and most likely it is. The fact that the copy is not for sale makes no difference.

LENS QUERY.—"BURTON" writes: "I have a lens offered me, which bears following inscription, 'R. O. J. A. Vorm Emil Busch. Busch's Portrait Aplanat, No. 4. Foc. 14in.' (1) Is this a reliable maker, and can first-class work be done with same? (2) Is it a quick lens? (3) What distance would be required for full-length cabinet? It is quite new."—In reply: (1) We have had no experience with the lenses named, so cannot speak as to their merits, but the house of Busch has a good name. (2) As we do not know the aperture, we cannot say. (3) About 20ft. between the lens and the sitter.

STUDIO BUILDING.—"PROPER ANGLE" writes: "Would either of the enclosed plans make a really satisfactory studio for general work? Which is the most practical? I should like to avoid, if possible, an outside screen. Would you kindly suggest any improvement? The studio is to be built over ground-floor offices. They are corner premises, very solid timber and plaster walls, but the addition must be iron outside. As this looks rather ugly, I do not want it higher than necessary on the south side, which runs up a street."—In reply: Either design is good, and it is quite a matter of opinion as to which is the best. Some prefer one form and some the other. On the whole, we should rather prefer the design marked "B" ourselves.

DEVELOPING ALPINE EXPOSURES.—J. B. R. S. writes: "I have noticed in old numbers of the JOURNAL letters giving the exact exposures of successful Alpine negatives, but an equally important point is the treatment of such negatives during development. Could you, or any of your correspondents, instruct me as to the best method of developing negatives having dark trees and chalets in the foreground and bright snow mountains in the distance?"—In reply: The only instruction we can give is to begin with a very dilute developer, so as to get out all detail before the negative acquires density. When all detail is out, finish off with a stronger solution. That is the way to deal with subjects having strong contrasts.

FOGGED NEGATIVE.—COLONEL GUBBINS writes: "I enclose a negative, which please return in the envelope sent herewith. Will you kindly tell me the cause of the fog on it? Also of the row of dots? I thought it an ordinary case at first, but the fog extends over the part protected by the rebate (this shows very clearly if the negative be put on a sheet of white paper), so it could not have been caused in the camera. I think that the two defects point to a fault in the manufacture."—In reply: It is difficult to account for the fog, but it has all the appearance of having been caused by light. The spots rather appear to be due to the film, but they may be caused by some mechanical impurity in the developer. We can, however, give no definite opinion on the point.

IDENTITY OF PROCESS.—"SALOPIAN" writes: "The plate sent herewith is an old photo, taken probably about 1870, and most likely at Shrewsbury. Can you tell me what process it is, and whether there is any possibility of restoring it? As the portrait of a deceased member of my wife's family, it is of considerable interest to us, and as an old specimen it may be of value. I enclose stamps for its return."—In reply: The picture is a Daguerreotype, but it has been ruined by careless handling and fingering. The image is almost all destroyed, and cannot be restored. You surely could not have read the articles on the subject that appeared in our issues for July 25th and August 15th, or you would not have sent the picture packed as it was. It has been returned, as desired.

STUDIO BUILDING.—"LIGHT" asks: "I am having a new studio built with east light; could not have north because there is a high church that stops the light, and the owner of the property is having a high hoarding erected to preserve his ancient light. What I want to know is whether the boards (which will be much higher than the studio light) will make any difference to the light, and would it be better to colour the boards or leave them natural colour? All the glazing is ground glass. The hoarding runs north to south, and studio is at right angle, and uninterrupted in the front by any building, but of course the sun will be on my side of the boards all day."—In reply: If the studio has an east light, and you work with that, and that is uninterrupted, we do not see that the hoarding will interfere at all, whatever colour it may be.

DRY MOUNTING.—"MOUNTING" writes: "Three weeks ago there was a note in 'Ex Cathedra' on mounting prints flat; that suggested to me coating the prints after dry with a plaster similar to that used in ordinary medical sticking plaster, and then after that has set, mounting the prints by applying heat from a flat-iron, or any other means. I inquired of a chemist what the nature of the plaster was, and he told me that lead was used in making same. That I

suppose would be injurious to a photograph; but perhaps a plaster could be made that would have the same sticky nature without anything injurious in its composition, and would also be cheap."—In reply: We do not think the lead plaster would be found suitable for the purpose, even if the lead had no injurious action on the pictures. Why not get some of the material mentioned in the article you quote? It is said by the makers to be harmless.

LENS QUERIES.—"IBEX" writes: "(1) Is it the short focus of a lens, or bad quality, which makes the hands appear abnormally large? I use a portrait lens of cheap make (City Sale and Exchange), 8 $\frac{1}{2}$ in. focus, working at f/4, and find this defect in results. (2) Would a Cooke lens, series 3, of 7 $\frac{1}{2}$ in. focus, working at f/6.5, or an Optimus Euroscope, of 8 $\frac{1}{2}$ in. focus, at f/6, be better than my present lens for portraiture? (3) Would either the Cooke or Optimus Euroscope be equal to a medium-quality portrait lens? (4) And which would be the best for portraiture of the two above-mentioned lenses?"—In reply: (1) If a short-focus lens be brought very close to the sitter the more prominent portions will appear abnormally large. (2) The longer the focus of the lens the less will be apparent distorting, because the sitter will be further away. (3) Both have a smaller aperture than the usual portrait lens, and consequently are slower in action. (4) The one with the longest focus.

FERROTYPE WORK.—"BEGINNER" writes: "Would you please explain cause of failures re ferro plates herewith? I have tried all ways of exposing, and timed developing and fixing in proportion to exposure, etc., but do what I will, this objectionable creamy appearance will not disappear unless the plates are developed about four or five seconds, then blank plates naturally follow, as under-developed. Is it essential to gauge exposure and time developing and fixing to a fraction of a second? It is a new departure to me, but persevere as I will I cannot get a clean result. My solutions are made up as per formulæ on box of plates. Might I ask some of your readers to write me, and give some information of their experience, and how better results may be obtained? I would return postage to them for any reliable hints on ferrotype work. The book I have, although by a great authority, is no blessed good. The exposures mentioned are miles out of the way; in fact, the camera I got last Friday is a farce. The affair has already cost me £9, and I have not got a decent negative with it yet. I may add, although the camera is perfectly new, and arrived here last Friday, it was sent to be repaired the day it arrived, and has travelled there and back every day since. I wonder people are allowed to sell such rubbish. It is a case of send cash first, and then you are nicely done. None of the faults for which the camera was sent to repair are caused by the railway company—it is rotten work. If I sent the camera back we all know what follows. The camera seems to work right now, but I cannot get on with the exposing, developing, and fixing."—In reply: "As a matter of course, in the ferrotype, as in every other process, the proper exposure is essential. So is proper development. You must not expect that the mere purchasing of the apparatus will enable you to produce perfect results with a few trials. We judge you are quite ignorant of photography, because you say you have not been able to get a decent negative. The ferrotype is not a negative process, but one for taking positives. We notice that all the examples sent are not focussed at all. We should advise you to get someone to give you a little practical instruction in the use of the apparatus."

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

Compressed Acetylene. As our readers are no doubt aware, the strictest supervision is exercised by Government, and, indeed, by railway companies also, over explosive materials. The former lay down rules as to what may and may not be permitted to be manufactured and dealt with, while the latter have stringent rules as to the carrying of explosives and dangerous goods. Such as they undertake to carry at all can only be sent at certain times, and the rates are very high. Among them are several of the materials used in photography—nitric acid, pyroxyline, etc. Many interesting particulars in regard to other substances are to be found in the annual reports issued by his Majesty's Inspectors of Explosives, and published by Messrs. Eyre and Spottiswoode. In the recently issued report for 1901 there will be found in Appendix F an order by the Secretary of State regarding acetylene. For the future it is not, when compressed into certain porous substances, to be treated as hitherto, as a prohibited explosive. Whether the removal of the prohibition will tend to further developments in the manner of using it cannot be foreseen; but that the use of it for an illuminant is only in its infancy we feel assured. The absurd restrictions with which ignorant and timorous officialdom surrounded its manufacture, storage, and use are one by one being removed. Railway trains travelling at the fearful rate of twenty miles an hour were once considered highly dangerous, and, similarly, we hope to

see acetylene gas robbed of the public fear of its danger, and take a high place among domestic and technical illumination.

* * *

A New Fireproof Substance.

One great cause for the high rates charged for insuring some photographic studios is the inflammable nature of so many of the erections used for photographic work, wood being the chief constituent of the building. There is, however, a possibility that all this may be changed, and that a studio can be built which would be actually indestructible by fire by the use of a newly-invented material called uralite. This new material is mainly composed of asbestos, and it can be cut with a knife or saw. The latter, we may say, is no novelty; some of our readers may remember the interest felt at the Bath Convention upon seeing the famous Bath stone cut, not with a chisel and mallet, but with an ordinary hand-saw. It can be painted, framed, polished, and glued, like wood, and can also be veneered. Further, it will not split when a nail is driven through it. The principal ingredient in its manufacture is, as we have said, asbestos. This material is cleaned and afterwards mixed with chalk and water as a hardening agent to make a pulp like paper pulp. The mass is rolled into sheets, first, and to secure its stability, a small quantity of silicate of soda is added. The sheets thus formed are cut into sizes, and put aside to dry, leaving fibrous asbestos boards. These are again steeped in silicate and dried, and afterwards placed in a bath of bicarbonate of soda and again dried, a coating of silicate being then deposited upon the fibres of the asbestos, with finally a driving off of 75 per cent. of water. The final result is a hard slab, indestructible by fire, and possessing the qualities above described. It should be a most valuable material for studio-building.

* * *

A Suggestion about Ordnance Maps.

Apropos of the new Ordnance maps on the scale of four miles to an inch, a specimen of which has just been issued by the Ordnance Survey, a correspondent sends us a suggestion, which we may place on record. The new map, by the way, is spoken of in the highest terms by our scientific contemporary, "Nature." "The technical production," this journal writes, "leaves nothing to be desired, and we confidently place this map before any other in the world on the same scale for beauty of finish, accuracy of execution, and sound judgment in the selection of features and names." The names and general detail are printed in black, railways in a strong black line, county boundaries in a dotted line, roads in three classes in brown, rivers, etc., in blue, the surface relief

being cleverly represented by half-tone reproductions of washes in colour. Our correspondent's suggestion is that, instead of the usual map-drawing, the details should be purely photographic, and made by two or more successive reproductions superposedly printed in one or more colours from negatives taken from raised models. Each colour might have its own type of subject. The result would be, if the model were properly illuminated, a striking representation of the actual appearance of the mapped area. Something of this sort has already been done, but our correspondent's first suggestion we believe to be quite novel. It is that the whole model should be photographed in one colour on a small scale, and that the print should be in the form of a stereoscopic view and examined in a stereoscope. The whole area would then be so vividly represented to the eye that it would almost immediately and permanently be impressed upon the brain.

* * *

A New Hardening Solution.

The use of alum and chrome alum as hardening agents, both in negative and positive work is universal, and till the introduction of formalin we may safely say that there were practically no other hardening substances used. Of the two, chrome alum, which, by the bye, has no aluminium in it, was considered the better, its action on gelatine being to raise the melting and setting point from eight to ten degrees. So far as we are aware, there has been no systematic investigation of the tanning effect of these two alums, and the statement that they did harden having been made, it was accepted, and passed on from writer to writer, till it has become axiomatic. Professor R. Namias, who is well known for his photographic research, has been examining the action of the alums, and he has found that chrome alum has really very little effect, and this, he says, is due to the acid character of the salt, and that if it be mixed with excess of solution of ammonia and heated till there is only a slight precipitate of chromium hydroxide left, its tanning action is so increased that a 20 per cent. solution will, after one hour's action, prevent even a 2 per cent. solution of hydrochloric acid from causing the gelatine to swell, and that after twelve hours the gelatine has lost its suppleness. As the result of his experiments, he suggests the use of the following mixture, and states that its action is so great that a negative film after treatment by it will not expand when treated with hydrofluoric acid for stripping, and, further, gelatine thus treated has not the characteristic green colouration given by chrome alum. A 10 per cent. solution of chrome alum, neutralised with ammonia so that some of the chromium hydroxide is left in suspension is to be mixed with a 10 per cent. solution of ordinary alum and then boiled for some time. About 1893 Dr. Stolze suggested for tanning gelatine-chloride papers a solution of chrome alum which had been rendered distinctly alkaline with ammonia, his reason being that the gelatine was less likely to be stained by this than by the ordinary solution, and that it did not make the film acid; but he did not state that it rendered it harder, though he recognised that the alkaline solution was equally as effective in this direction as the acid.

* * *

Electricity and Photographic Films and Plates.

Plates and films, when developed, sometimes show markings that their users are quite unable to account for, and can in no way attribute them to anything in connection with their own manipulation; neither are those we refer to.

At a recent meeting of the London and Provincial Photographic Association some rollable film negatives were shown with curious branch-like markings upon them. Others have also, at times, met with similar defects. One of the members present was, however, able to give a correct explanation of their origin when he said that they were caused by electric sparks, due to stripping the film from its glass support after it had been coated. Now, celluloid, collodion, and its congenitors are very electrical substances when in a dry condition, and a slight friction will generate electricity. If we take a glass plate coated with plain collodion, that has become perfectly dry, and strip off the film, we shall find it in a highly electrical condition when first stripped. It will curl up and adhere to anything that is close to it at the time. If the surface is large, and the film is pulled away suddenly, an audible "crack" will be heard, and in the dark a spark will sometimes be seen. If the collodion supported a highly sensitive emulsion, of course, this sparking would affect the film more or less. Such effects, however, cannot be detected when the film is examined, any more than can that caused by its being fogged by light. It is not all rollable films, however, that are made on glass plates. Those made by coating the finished celluloid film may be expected to be free from this defect. There is another trouble that sometimes arises through electricity with plates, as well as films. Some dark slides are fitted with ebonite shutters. Ebonite is also a highly electrical substance, and slight friction on it, when it and the atmosphere is dry, will generate electricity. When these shutters are used the light is trapped with velvet, and if, when this is abnormally dry and the atmosphere also in that state, the shutter be quickly withdrawn or closed, electricity is generated, and a spark may be produced and the light from it affect the plate. When using these shutters in warm and dry weather it is always well to withdraw or replace them very slowly; then no harmful result will follow.

* * *

Misplaced View-Finders.

The letter from a correspondent, that we published last week, details a trouble that many have met with when relying on the finders as fitted to their cameras. Our correspondent found a remedy in his case—though only after negatives had been marred—by "driving a nail in the body of the finder." In this case the remedy, though practical, would not be a desirable one to adopt with a costly apparatus. View-finders are more often than not placed in the axis of the lens, more especially in the cheaper forms of cameras. Consequently, the picture as seen on them does not coincide with that found on the negative when developed, which too frequently leads to disappointment, the subject found on the negative, as regards composition, being quite different from that shown by the finder. This is especially likely to be the case with those finders that are hinged, through the hinges not being properly fixed. They may be right when used horizontally, but just the reverse when turned vertically. If purchasers of cameras were to test their finders before using them, by, sav. placing them at a window and comparing the image as seen on the ground glass with that shown on the finder when that is in an alternately vertical and horizontal position, any discrepancy is easily rectified. A small slip of thin cardboard, or thick paper, at one end or other of the fitting will usually do the needful. There is another point in connection with finders, which often applies, not only to the cheaper forms of cameras, but to some of the more costly ones, namely, that the angle of view shown by the finder does not coincide with that obtained in the negative. It may be more, or it may be less, as the case may be. This, however, is

of minor importance when it is fully realised, as it is easier to make mental note of the discrepancy and to allow for it when fixing on the point of view from which the picture is taken. Adapting a finder, or finders, to a camera that includes exactly the same angle as the lens, and at the same time is precisely in its axis when the camera is used either horizontally or vertically—requires greater time and care than can be bestowed on cameras that are sold for one or two pounds. Purchasers of new cameras, whatever price may be paid for them, would do well if they spent an hour or so, and a few plates or films, with them in a "full dress rehearsal" before taking them on a tour away from home. If this were always done, much disappointment would often be avoided.

* * *

Wood Engraving versus Process Blocks.

This is a question that has often been discussed, both *pro* and *con*. The subject was again dealt with in a leader in the "Standard" of Saturday last, and in a letter from a correspondent, who asks questions if the pictures in the illustrated papers of to-day are equal to those of times past. The correspondent quotes illustrations of great events, such as the opening of the late Exhibition of 1857, as compared with those of the late Coronation at Westminster Abbey, and questions if in this class of illustration we have advanced at all. He asks, "Will it be possible fifty years hence for anyone to take up any of these pictures, and say, from the features there presented, that was the Primate or that was the Bishop of London, and so on?" In conclusion, the writer says, "Comparing the old with the new, it seems, in my humble judgment, that the old was better." We must confess there is some ground for this criticism, for we happen to have by us an old cheap work entitled "The Crystal Palace and its Contents," published in 1852. The blocks, we are told, were old ones, that had been used in one of the illustrated papers the year before. The work was printed by Bradbury and Evans, and we must say the illustrations are superior to the pictures in many of the best papers of the late ceremony at Westminster Abbey. Of course, they are printed from hand-engraved wood blocks by good artists, and the paper that the pictures are on is of what may be termed of very common quality, and would be quite useless for modern process blocks. In its leader, the "Standard" very forcibly points out that the old style would not fulfil modern requirements of illustrated journalism, either as regards cost of production and in the time required for producing wood blocks, mentioning that now, for a sovereign, it is possible to obtain a half-tone block that half a generation back would have cost eight or ten, or even more, on wood, and adds that there might still be a chance for wood-engraving, which, as an art, is almost extinct in England, if the public were content with less for their money. That is so; it is simply a question of demand and supply. The public demand for their sixpence a large number of pages, containing, perhaps, nearly a hundred pictures, and these can only be supplied by process blocks, from photographs made from wash-drawings, or from nature. It is true that from good process blocks, and careful printing by good machines, and on suitable paper, excellent results are produced, but it is questionable if they are, artistically, as good as used to be produced from engraved wood blocks. Be that as it may, the present style of illustration gives ample work for photography and its allied processes.

BOTANICAL PHOTOGRAPHY.

JUDGING from our annual photographic exhibitions, both in London and the provinces, but little attention has been given in England to recording photographically the various phenomena of plant life; and this opinion is certainly strengthened by an examination of most of the photographic illustrations reproduced in the weekly and monthly journals devoted to horticultural matters. Certainly, many of the photographs reproduced by those journals are beautiful examples of landscape work, showing us charming leafy vistas and quiet old-world gardens, in which we would gladly wander for the rest of our days, forgetful of the hideous rush and struggle for existence in this prosaic twentieth century. For these landscape and garden photographs we have nothing but praise, for they tell how truly and steadily increasing is the progress of artistic photography. But when we turn to the majority of the photographs of individual trees, plants, fruits, and flowers—alack, what a falling off is there! The peaches and grapes have lost their exquisite bloom in the developing dish; the flowers have grown stiff and rigid, as if aware that their delicate tints are not going to be too faithfully rendered; while the trees look mournful and depressed; all have lost, to a greater or lesser degree, their natural grace and individuality.

The reason for this contrast between the photograph of a garden and a photograph of one of its inhabitants is not far to seek; the photographer, in nine cases out of ten, has not thoroughly realised that plant life and human life are really very near akin to one another. Each tree, plant, and flower has its own peculiar characteristic shape, colour, mode of growth, and mode of life every bit as much as a human being, and unless that fact is fully realized and careful attention paid to the correct delineation of those characteristic traits, the photographer will produce but a poor, if not utterly false, idea of the original.

The successful portrait photographer gains his reputation from studying, at least, the elements of facial anatomy, by mixing with his fellow-men and closely observing those little traits of expression, gesture, pose, and effects of light and shade which give individuality and distinction to each sitter. The same method and principles must be applied, if really life-like and characteristic photographs of plant life are to be obtained. The would-be exponent of plant portraiture must be prepared to go forth into the fields, lanes, and forests, to tramp over moorland and marsh, and climb the mountain side at all hours of the day, watching the daily life of the plants, and the effects that varying atmospheric conditions have upon them. He must bring to his aid a genuine love for the wonders of plant life, so that the delicate spiral of a vine tendril and the exquisite bloom on a fruit may have the same joy and significance for him as the gracefully curling lock of hair and delicate flesh tints have for the portrayer of human beauty.

Few trees are more difficult to really satisfactorily portray photographically than pine and yew trees; and yet they have beauties peculiarly their own, which can be found in no other trees. On the other hand, few trees are more susceptible to atmospheric conditions, and the varying play of light and shade, than the different species of pines. Out on the hill-side, as we rest beneath their shelter through the warm, star-lit, summer night, the branches form a delicate tracery against the deep indigo sky, and gently stirred by the soft west wind, ever and anon whisper some peaceful lullaby. An hour before the dawn we throw off our plaids or rugs, and climb to a spur from which we may watch the sun rise and send its first rays across

the sky to kiss the summit of the mountain. In the grey dawn, the clump of Scotch pines under whose shelter we spent the night stand out like dusty sentinels, keeping watch above the glen. Grey gives place to a pinkish hue in the East, and the highest point of the mountain is touched with the rosy glow of approaching dawn. With all possible speed, we set up our camera and focus the pines, still sombre amongst the dark shadows. All is ready, and almost breathlessly we wait and watch that eastern light, which is momentarily growing stronger. Broad beams of rosy light, swift heralds of the approaching sun, stream out across the sky, bathing the mountain tops in exquisite hues. Suddenly, as if some magic wand had touched them, the pine trees stand out against the eastern sky, each branch and trunk transformed to burnished silver. As rapidly as possible, we make our exposures, and if we keep cool and steady may be able to make three or four ere this wonderful effect, the greeting of the pine trees to the rising sun, has passed. It lasts but a few minutes, just as the sun begins to rise above the horizon, and is gone until the morrow. Ten minutes later, at the most, the silvery glow has vanished from the trunks of the pines.

As quickly as possible, we descend to the valley, where many of the flowers and trees are still asleep, with the sparkling dew-drops upon their foliage. Look at that half-opened rose, with a splendid tear of dew scintillating with the colours of a priceless pearl upon its expanding petals; it will make a far more beautiful and characteristic photograph now than at high noon, when its petals will have lost their fresh bloom and crisp curl, and the tear-drop vanished for ever. Good old "John-go-to-bed-at-noon" is very wide awake at this early hour, and even though but a humble species of dandelion has a beauty all his own, with his big yellow head and cool green leaves all silvery with the dew. In a couple of hours his head will begin to droop, the big golden disc will gradually contract, and "John" will sleep. So while he is fresh and wide awake we will photograph him.

After breakfast we stroll out into the garden, to smoke a pipe and watch the bees at work amongst the flowers. The warmth of the sun is making some of the unopened flower-buds of the poppies rapidly expand, and here is a chance of obtaining a photographic record of an interesting phenomenon. We set up our faithful camera and focus a group of poppy buds that are beginning to expand. Our first exposure will give us a record of the sepals just breaking away from the base of the petals. A few minutes later the sepals have parted sufficiently to give us just a peep of the tightly-folded petals within, and we promptly expose another plate. And thus, with a little care and watchfulness, we obtain a record of the first separating of the sepals, until they fall to the ground, and the petals unfold and expand in the warm morning sunshine. The whole operation will have barely taken an hour, and we are the richer by a most interesting series of photographs.

An hour before noon the wild roses are generally at their best, some of the dainty blossoms having expanded to their fullest, while others still coyly arch their half-opened petals, as if reluctant to part from the golden wealth of pollen to the lusty bees. They will not bear transference from the hedge to the studio, these delicate pink and white children of the lanes, and, therefore, to gain a photograph of them at their best we must wander forth and seek them in their native environment.

All day long the pretty pink flowers of the red campion are wide awake, with their petals fully expanded; but if we want to photograph its cousin, the delicate-scented white campion, we must wait until the sun has nearly set. Then, too, we shall be able to get a good photograph

of the evening primrose, which also sleeps all day, and only expands its yellow petals as the shades of evening approach. The grand old oaks, elms, beeches, look their best in the soft yellow light of the sunset hour; at mid-day their foliage is more sombre and heavy, except, of course, in the spring, when they are just unfolding their dainty young leaves.

Fruits require the greatest care and attention to successfully photograph; they must be carefully selected, handled as lightly and as little as possible, and photographed as soon after being gathered as circumstances will permit. Grapes, peaches, plums, and all fruit, depending on their delicate bloom for their most perfect condition, are probably amongst the most difficult subjects to render in a faithful and characteristic manner. The greatest attention must be given to the lighting, so that the delicate transitions of colour and form are seen at their best. Fruits with glossy skins, like some apples and pears, will be found rather troublesome, and require a more subdued mode of lighting, as their skins are apt to reflect back any strong beams of light, and hard patches of light will appear in the photograph.

Where it is desirable, for scientific reasons, to isolate a single plant growing in a field, or in any situation where it is closely surrounded by other plants, a piece of greyish, washable canvas background will be found most useful. It should be mounted on two light iron rods, pointed at one end, so that they can be easily pushed into the ground; and in this way the background can always be placed in the most suitable position, and a good photograph obtained without in any way disarranging the natural position of the plant. Two or three such backgrounds of varying tints, all made to slip on the one pair of iron rods, can be easily rolled up together and carried, and will be found most useful when at work in the fields and lanes. They can be slipped behind sprays of flowers, foliage, or fruit growing on the hedge-rows; and if we have with us a faithful and interested companion, one of these backgrounds can be held up as a screen, to cut down the too strong light that may be falling on one side or on the top of our subject.

Of course, in this branch of photography the use of the isochromatic plate is imperative, if the colour values of the flowers, fruits, and foliage are to be anything like correctly rendered. Where a very full exposure is possible, in the rich golden light of the sunset, wonderfully orthochromatic effects can be obtained by the use of a slow plate and careful development.

It is important not to force development under any circumstances, no matter what plate has been used, and the developer with which the worker finds he can obtain the greatest amount of gradation and freedom from chemical fog is the one which must be used.

To be able to mount with each herbarium specimen a photograph showing the plant in its natural environment, and giving as nearly as possible the correct colour values, will make our collection of botanical specimens of the greatest possible interest and value. Once really earnestly taken up, the photographic study of plant life will be found of the most intense and absorbing interest, and we venture to say will never be dropped until the worker has grown too feeble with age to rock a developing dish or focus a lens.

PATENTS in Germany.—In 1900 there were 1,565 patents taken out for electrical inventions in Germany. For telegraphs and telephones the patents numbered 283; for primary batteries and accumulators, 203; thermopile, cables, and distributing system, 368; motors and distribution accessories, 199; meters, etc., 149; lighting, 250; auxiliary apparatus, 58; heating and cooking, 50.

PHOTOGRAPHERS AND THE DIVINATORY ARTS.

WONDER what stern readers of the BRITISH JOURNAL OF PHOTOGRAPHY have thought when preparing to devour their weekly fare, and finding in their menu what at first sight must have appeared an unpalatable dish, under the rubric of "Photography and Palmistry," and how many have stared and then wondered if, by a printer's error, some of the matter belonging to the Proceedings of the Psychological Research Society had not got transposed into this matter-of-fact organ of a rational art science? No doubt, a large number of the gentle, suave section of the devotees of the camera must have shuddered at so unexpected a reference, made, without any warning, by hardened Editors, whose concern of sensitiveness must be limited to one of films, and have meekly asked to themselves what photography and photographers may have in common with palmistry? The answer may be two-fold, and must be guided entirely by the writer's intention: Nothing, if by Palmistry the writer merely intended to refer to the rather diverting, and to-day fashionable, inoffensive pastime obtainable in most of the best-behaved réunions; but a very great deal if his reference were taken in the sense of a *minomer*, and intended to refer to the combined arts of chiromancy and chiromony, forming to-day a synthetical, exact science, capable of surprising revelations of the inner man, *Anthropometry* being purely and simply a branch of the above, and, therefore, capable of rendering immense services to everyone in general, and to Portrait Photographers in particular.

It is evident that the photographic friend introduced by the Editor must have held this view, and that, moved with a justifiable desire to ascertain all the peculiarities of his sitter's personality, but being totally or insufficiently versed in the secret of the art of Divination, he sought the aid of the man "who does the rest," while you wait. Every science, trade, or profession can produce a goodly number of these helpers (?), arrayed with more or less self-granted honours, diplomas, medals, and the rest, but this particular branch of the occult may reasonably be considered a very good second in the professional race of humbug champions, with a variety of favourites, not only hailing from the proverbial "Sheffield," but also genuine wizards direct from Egypt-by-Bow, real Hindoos, prophets, born in the vicinity of Kennington, or self-styled French Professors, natives and direct from the Ville Lumière, with lots of knowledge, and an Irish accent; one and all in great demand; possessing secret and wonderful formulæ, dosed with double occult occultism's essence; very dark in appearance, but warranted to give results free from fog, and crisp details, from deepest shadows to purest high-lights.

L'embarras du choix makes a choice difficult, and our friend may be, perhaps, free from blame, if the adepts of his choice proved rather ignorant in the application of their "profession," yet if incapables in bringing out details with clear perfection, they have at least given undeniable proof of talent in the fixing and reducing process of their clients' precious metal, and all with a good degree of permanence in the client's memory. I would not affirm that if good fortune had led this friend to a diviner with less honour and more science that the desired result would have been obtained, but there would have been, at least, an immediate saving of time and fees, and an addition to commonsense knowledge, for on principle, whatever the nature of a research, it is necessary that an experiment be carried on in a rational way, else failure must be the only possible result. What kind of rebuff would the tyro in our art science be likely to receive from any serious advanced worker, if, when seeking his help in the initiation of how to reveal the unseen, he made some ridiculous condition, such as, for example, the refusal

of a developing agent of any sort, and insist to go in straight for the hypo tub, and when coming out with a blank, declared the whole game to be a perfect fraud?

Extraordinary as this metaphor may seem, the researcher referred to in "Photography and Palmistry" did as bad, if not worse. First, he starts on his errand equipped with certain photographs, presumably on best glossy P.O.P., extra enamelled, portraying the hand of a third party, ignoring, or failing to ascertain, that his material was unfit for the edifice. For, if the human hand may permit or give any reliable disclosure, it is only on condition that the lines, marks, and signs shown thereon, and not only therein, are read and considered sub-junctively with the texture, temperament, colour, and complexion, which in their synthetical sense are the key to the individuality, and a centre from which all other indications radiate. Can all this be shown in any graphic reproduction, including the most sharp P.O.P. print? Then again, a single sign or mark is fully admitted to be nothing more than a meagre indication, a presumption, but by no means ever a certainty, until fully corroborated elsewhere. Again, "la main, comme l'écriture, n'a pas de sexe," even anatomically; thus the hand of many a man of the psychic type (conical shape) would appear, specially in a photograph, much more like that of a woman, than the latter's, if of the type known as elementary (square, thick, relatively heavy hand), and it must stand to common sense, that a great many indications, really favourable in a woman's, should be considered as so many unfavourable signs in that of a man's.

I could offer a long string of considerents, but the above would probably be considered quite enough to demonstrate the necessity for our friend to endeavour to do better the next time, and also to bear in mind that if divination is at all possible, it is so only within limits, and that it is no more rationable to expect any useful or dependent revelations and indications from a photograph than from the time-honoured tooth or lock of hair taken by the croyant to the fortune-teller, and that, in his reported endeavour, he received the only result likely to be ever derived, viz., a relief of an over-burden of ready cash. That the human hand is capable of revealing not only a fair amount of fairly accurate facts, and more specially past events, but positively certain indications as regards the owner's personality, dispositions, aptitudes, character, and tendencies, is beyond reasonable denial; proofs of this are not only many, but as plentiful as the proverbial blackberries, only much more easily and quickly obtained. A mere glance, rapid as the shortest exposure, may sometimes be quite sufficient to tell one all one may need to know of another. The finer divination belongs to chiromancy, and is obtained by the aid of lines, marks, signs, etc., not only within the palm, but over the whole of the hand, front, side, and back; certainly a difference, and perhaps can we assign to this the explanation why the name of palmist is applied to a large number of would-be occultists, taken as a derivation of palm—palmed—palming. "They palmed the trick that lost the game." (Prior.)

To presume that the number of these helpers (?) is less than formerly, and that the craze for palmistry is not so rife as of former years, is an erroneous idea. A perusal of the advertising columns of the daily and weekly fashionable press will soon dispel this view, for not only has the number very much increased, but is still growing. The assertion that professors of palmistry have been prosecuted is not quite correct, for, in reality, the reading of the hand could not possibly be treated as illegal, being in operation in the office of every European Government, but so-called palmists generally cumulate, and are not only readers of the hand, but readers in crystal, readers in cards, manufacturers of charms; not only diviners in all branches, but clairvoyants and fortune-tellers, and that is where

the law wisely steps in. Erroneous also, the time-honoured, but exploded theory that the lines of the hand may only be regarded as a consequence involved in the necessary apparatus of opening and closing the fist (sic). We all know that constant action generally tells tales—it does so on the bellows of our camera, also on our trousers, specially at the portion covering the knee, but the human frame does not seem indicted in this ruling, otherwise the hands of persons following the same craft or trade, using the same kind of tools, and doing the same manipulations, would, perforce, offer if not exactly identical marking, at least a very great similarity of lines, etc. But it is not so. Then, again, the hand of the penman, the artist, and any other calling demanding the production, more from the brain than from the hand, would leave the latter almost virgin of rays, or, at least, with much fewer lines than should appear in the hand of a mechanic, so that the facts, the undeniable facts, that it is quite the contrary, that brain workers display a much greater number of lines, in and on the hands, than the labourer or average mechanic, should be sufficient answer to this fallacy! Lord or peasant, artisan or poet, journalist or tinker, there does not exist, the world over, two pairs of hands alike, and similarity is only found with geniality, never properly with profession, calling, or trade. At part with this error is the reference to apes. Will the writer give me a single instance in which the hand of an ape is, or can be, more marked than that of a human being? Although the ape is the nearest approach to man, and an animal fairly supplied with brain and thinking qualities, to brain power, quality, and action are the lines and the marks of the hands attributed and undoubtedly due.

The suggestion advanced, that the modern West End diviner gains more information by the study of character (physiognomy) than by that of the hand is paying these "professors" an undeserved and unnecessary compliment, the former being much more difficult in its application and far less reliable than the latter; the facial organs being mobile, and therefore easy of control, the hand free from possible dissimulation, hence the invaluable help it may give to all seriously concerned in the study of the individuality of man, amongst whom is the Portraitist. Every text book wisely recommends the student desiring to progress in the fascinating but oftentimes difficult, thankless study of portraiture photography, to carefully observe the personality of the sitter, and give a pose congenial to the personality; but these, probably from a number of causes, omit to explain how the student is to gain this precious knowledge that must open the door to success! The amateur, usually practising with some good friends, using the word good in its fullest intent, may have ample opportunity to do so, ditto with the painter, crayonist, etc.; but where is the over-criticised studio operator, who seldom has greater opportunity than exchanging a few words in about as many seconds with the sitter he is expected to accurately portray? A small, very small, knowledge of the hand could provide all the necessary. The full study is neither suggested nor necessary to his practical needs. The knowledge of chiromancy, and past or future events in the life of his sitter, concern him not, but individuality does, and the elements of chiromancy (the study of the form of this organ) give all that. A mere glance at one's hand may often tell him more than a close scrutiny of one's face. Modern painters are well cognisant of this fact, nor is this organ scantily treated by them to-day, as of yore—it has a meaning, a signification. The stern and matter-of-fact Government officials in every large country have at last recognised that it is so, and practically apply the science, with excellent results. Why not the portraitist? A few hours' serious study would do it; it is so simple, so easy, and yet so ignored!

GEORGES D'ARMORIC.

A FORECAST OF THE BRITISH ASSOCIATION.

[Abridged from "The Times."]

THE last Belfast meeting was, in one respect at least, one of the most memorable in the history of the Association. The President of the meeting was the late Professor Tyndall, and his address roused the greatest excitement, and even consternation, not only in scientific, but in religious circles. It dealt mainly with the supposed conflict, if not between science and religion, between science and the Church. Its concluding words were especially memorable, and one phrase in particular may be said to have become a literary commonplace. Speaking of the human mind turning to the mystery from which it had emerged, seeking so to fashion it as to give unity of thought and faith, Professor Tyndall concluded:—"Here, however, I touch upon a theme too great for me to handle, but which will assuredly be handled by the loftiest minds when you and I like streaks of morning cloud, shall have melted into the infinite azure of the past." It is interesting to note that the President of the second Belfast meeting is Professor Tyndall's successor at the Royal Institution, Professor James Dewar, F.R.S., whose distinction as a chemist is known to all, and whose success in the liquefaction of gases has been almost sensational. Professor Dewar is not in the least likely to emulate his famous predecessor, so far as the subject of his address is concerned. He will keep to his own special subject of chemistry, and will probably trace the progress in physical chemistry through the schools of Boyle, Black, Andrews, and Thomson, pointing out what it has led up to in our own day.

The attendance at the Belfast meeting of 1874 numbered 1,950, a number rather below the average, and not likely to be much exceeded at the meeting which begins on Wednesday, September 10th. For the following particulars as to the work of the several sections, we are indebted to the courtesy of the sectional presidents and recorders.

The general programme of Section A (Mathematical and Physical Science), the president of which is Professor John Purser, has not yet been definitely arranged. Professor Purser's address will be in the main biographical, giving an account of the Irish school of mathematicians and physicists in the last century (not living). He will refer to the two Lloyds, Bartholomew and Humphrey, to Dr. Romney Robinson, Lord Rosse, Rowan Hamilton, McCullagh, Bishop Graves, Dr. Jellett, Sir Andrew Hart, Samuel Haughton, Michael and William Roberts, Townsend, Casey, George FitzGerald, Preston, Andrews, and James Thomson. There is this year to be a department of Astronomy and Cosmical Physics, under the presidency of Professor Schuster. To this department communications on the work done on Eros and on Nova Persei will be made, and it is hoped that some stellar photographs from Yerkes will be exhibited. Some points in the nebular theory will probably come up for discussion, and the subject of seismology will be brought prominently forward. In the section itself Lord Rayleigh will probably raise the question of the conservation of weight in chemical reaction; Professor Tronton may be able to show his experiments on the magnetic field due to the motion of a charged condenser; Professor Martin will communicate some results in electrical oscillation and some experimental work done by students under his direction; while Dr. Larmor will have something to say on the temperature of radiant energy. Mr. Petavel has promised a paper on radiation experiments, with a view to the construction of a more trustworthy standard of light, and will also, in conjunction with Captain Bruce-Kingsmill, consider the question of a high pressure gauge for artillery.

Section B (Chemistry) will be presided over by Professor Edward Divers, F.R.S., the subject of whose address will be

August 29, 1902.]

The Atomic Theory: What it has become in the course of a century." Referring as little as possible to the structural constitution of the matter, Professor Divers proposes to treat this subject in a comprehensive and somewhat novel manner, which will not, however, it is expected, be found uncongenial by modern thinkers. The most important papers in Section B are "The constitution of the Diazo-derivatives," by Dr. G. T. Morgan, and "On reduced derivatives of benzene," by Dr. A. W. Crossley. The first of these is a *résumé* of our knowledge of the subject, and a criticism of our views upon it. Other papers are "The alkylation of the sugars," by Professor P. Purdie and Dr. Irvine; "The synthetic action of enzymes," and "On glucosides," by Dr. E. F. Armstrong; "The colour of opidine-containing compounds," by Miss Ida Smedley; and "The action of distilled water on lead," by Dr. F. Clowes, of the London County Council. Professor D. Vorländer, of Halle, and Professor E. Knoevenagel, of Heidelberg, are to attend as guests of the section.

Dr. Cannan will preside over Section F (Economic Science and Statistics). The staple of his address will probably be the thesis that economic theory is useful in regard to practical questions, such as protection, housing, and other municipal enterprises (especially those connected with locomotion), the Post Office, and various means of raising revenue. He will maintain that better knowledge of economic theory would obviate the necessity of many costly experiments and much painful experience. In order to make this clear, Dr. Cannan will probably have to begin his address with a brief sketch of what he takes "economic theory" to mean. As in other sections, the general work of the branch will largely deal with Irish subjects. Mr. Benjamin Allen is expected to deal with the effect of the adoption of free trade on Ireland, the Rev. Professor Finlay with rent in Ireland, Mr. Lloyd Paterson will trace the history of the linen industry, while the Right Hon. Horace Plunkett will discuss technical instruction and industrial development. The effect of factory legislation is the subject of the work of a committee which will make a lengthy interim report, and Miss Hutchins (Regulation of Home Work) has promised a paper on her work, as has Miss Harrison (Administration of the Factory and Workshops Act in Workshops) on hers. Other papers are on miscellaneous subjects, including central and local administration, which will be dealt with by Mr. P. Ashley; Indian prices, by Professor T. Morison; the Survival of Domestic Industries, by Dr. Cunningham; Municipal Trading, by the Hon. R. Porter (director of the U.S.A. eleventh census); and the Position of Economics and the Applied Sciences in the University training of men intended for a commercial life, which will be discussed by Dr. W. R. Scott. Dr. Alexander will contribute a paper on industrial superannuation; this, with Professor S. Chapman's paper on the regulation of wages on the basis of prices and profits, together with the report and papers on factory legislation, will give labour questions a fair share of attention. There will be a paper by Mr. Ashley on municipal policy and state control. Specially interesting at the present time should be papers by Dr. Ginsburg on Shipping Combines; Professor Graham, on Trusts; and Judge Shaw, on Preferential Tariffs. Papers are also expected from Professor S. J. Chapman, Professor Gonner, and Mr. A. B. Clark (of Edinburgh).

Professor John Perry, F.R.S., who presides over Section G (Engineering), will have something very incisive to say in his address on the Training of Engineers. He does not think that German methods are at all suited for English boys, and he affirms, moreover, that such methods are unpractical. Being of opinion that the great technical colleges of England suffer because their pupils have had no good general education, he

will urge that an endeavour should be made to instil into all boys—whatever profession they intend to enter—(1) A knowledge of English, as distinct from classical, subjects; (2) the power to compute—to achieve this the present methods employed in the teaching of mathematics must be completely revised; (3) a knowledge of the methods of study in experimental science. Professor Perry will contend that the average boy is not stupid, and that what is needed is a radical change in our educational systems. The great technical colleges themselves need reforming; for one thing every teacher at an engineering college, whatever his subject, ought to have engineering experience, and many more and better-paid teachers are required. Among other points that will come under discussion are whether workshop experience ought to come before, or after, or during an engineering college course, and the reforms due to foreign competition going on in engineering-shop management and methods. In the general work of the section, Professor Hele-Shaw is expected to present an important report embodying the result of the deliberations of the Road Traction Committee, while the report of the Screw Gauge Committee is likely to conclude a prolonged discussion of an important point of detail in small mechanisms. Among the papers that have been promised are the following:—"The combustion of bituminous coal," by Mr. W. H. Boots; "Water power in Ireland," by Mr. F. J. Dick; "The Belfast water supply," by Mr. L. L. Macassey; "Exhibition of electrical apparatus," by Mr. M. B. Field; "Recent progress in large gas engines," by Mr. H. A. Humphrey; "The importance of minor details in engineering work," by Mr. L. Holroyd Smith; and "Direct reducing levelling staff," by Mr. G. W. Herdman. Papers on some electrical subject have been promised by Mr. P. McMahon and Mr. F. Holden, and Mr. J. E. Knigsbury will discuss some aspect of telephony.

Professor W. D. Halliburton, F.R.S., the president of Section I (Physiology), will take as the subject of his address, "The present position of chemical physiology." This is the first occasion in the comparatively short history of this section on which the chair has been occupied by one whose research work has been identified with the application of chemistry to the solution of physiological and pathological problems; and as would, perhaps, have been anticipated, Professor Halliburton will dwell upon the recent great advances in this branch of science. These are due to a growing *rapprochement* between chemists and physiologists. Physiological chemistry, as it is sometimes called, is yearly becoming a more exact science, as is shown by our increasing knowledge of the constitution of such substances as the starches and sugars, uric acid, and the purine compounds. The constitution of albuminous substances which are the main constituents of living material, and are found nowhere else, is not yet revealed, but earnest investigators in many countries are paving the way to this final conquest of organic chemistry. Another striking instance of the progress of chemical physiology is seen in the application of physical chemistry to the investigation of physiological questions; the modern doctrine of solutions, of ions and electrolytes, has produced quite a revolution in the ideas of physiologists in connection with the important processes of osmosis and secretion. Among the other subjects that will be considered are the views of the modern vitalist; the usefulness of bold theorizing as exemplified by the work of Ehrlich in connection with the subject of immunity, and of bold experimentation as exemplified by the work of Pawlow on digestion; and the extension of chemical methods in the elucidation of the nature of nervous activity. In the general work of the section, Mr. Barcroft has a paper on the estimation of small quantities of uria, Professor Halliburton and Dr. F. W. Mott, F.R.S., will discuss nerve regeneration, Dr. W. Page May will deal with the morphology

of the camel's brain, Dr. W. A. Osborne (recorder) and Mr. S. Zobel will consider the Hydrolysis of Glycogen, Dr. John Turner will discuss some new features in the structure of the human cerebral cortex, and Professor E. A. Schäfer, F.R.S., will contribute papers on the paths of conduction for volitional impulses, and the functions of pituitary body.

As Professor H. E. Armstrong, F.R.S., may justly be said to be the originator of the new Section L (Educational Science), his address may be expected to be one of unusual interest, and the reforms which he will probably advocate will be somewhat drastic. The address will be devoted largely to a discussion of the educational outlook. Professor Armstrong will consider the deficiencies of the present curriculum and the directions in which it needs reform, and will also deal with the question of the training of teachers, which is of such importance to the future of education. Following the practice of last year, a definite programme has been arranged for the section, so that a number of important subjects may be debated. The first two days will be mainly devoted to the discussion of Irish educational problems. Dr. W. J. M. Starkie, Resident Commissioner of National Education, will deal with recent reforms of Irish education, primary and secondary, with a view to their co-ordination. A debate on intermediate education in Ireland will be opened by Mr. R. M. Jones, M.A., of the Academical Institution, Belfast, and another on the introduction of practical instruction into Irish national schools, by Mr. W. Mayhorne Heller, B.Sc., Head Organiser of Science Instruction, Dublin, and recorder of the section. In a debate on technical instruction in relation to industrial development in Ireland, the Right Hon. Horace Plunkett, Vice-President of the Board of Agriculture and Technical Instruction, has promised to take part. More general debates later in the meeting will be on the training of teachers, about which Professor Withers and Miss Walter will have something to say, and the teaching of English, in which Mr. P. T. Hartog and Canon Lyttelton will take part. Dr. Kimmins will discuss the subjects to be taught as "science," and the order in which they should be taken, and papers on educational experiments have also been promised. Reports will be presented on the teaching of mathematics, the teaching of science in elementary schools, the conditions of health essential to the carrying on of the work of instruction in schools, and on examinations. For the Tuesday afternoon a joint discussion with Section G, on the training of engineers, has been arranged. The Friday evening discourse will be by Professor J. J. Thomson, F.R.S., on Becquerel rays and radio-activity, and that on Monday evening will be by Professor W. F. R. Weldon, F.R.S., on the subject of inheritance. The lecture to working men on Saturday evening will be by Professor Miall, F.R.S., and will deal with gnats and mosquitoes.

TECHNICAL Education.—A return recently issued shows that the amount spent on technical education in England and Wales by local authorities during 1900-1, exclusive of the sums allocated to intermediate and technical education under the Welsh Intermediate Education Act, was £1,051,422 0s. 9d. The amount raised by loan on the security of the local rate under the Technical Instructions Acts was £152,833 14s. 4d. The amount of the residue received under the Local Taxation (Customs and Excise) Act by councils of counties and county boroughs in England (excepting Monmouth County) for 1900-1 was £924,359 19s. 10d., of which £863,846 11s. 5d. was appropriated to educational purposes, and £60,513 8s. 5d. to relief of rates, the latter sum including £32,711 9s. 2d., devoted by the London County Council to the relief of rates. The amount of residue paid to the county and borough councils in Wales and Monmouth was £44,358 5s. 10d., the whole of which was devoted to intermediate and technical education, chiefly under the intermediate Education Act. The various councils are making grants out of rates under the Technical Instruction Acts, and the total amount expended on technical education under these Acts during the year was £44,791 4s. 9d.

THE TONING OF BROMIDE AND CHLORO-BROMIDE PAPERS.

A TREATISE on bromide paper and its uses a year or two ago would probably not have broached the subject of producing various colours with it, or, at any rate, would merely have treated the subject in a perfunctory manner; a great deal of attention is now, however, being paid to the various methods, and much valuable information regarding them is to be gathered from the recent work of Franz Loescher, "Vergrössern und Kopieren auf Bromsilberpapier." Theoretically, there are three ways of producing an ultimate warm tone: (1) by using a special emulsion for the paper, such as "Alpha" emulsion; (2) by sulphur toning; (3) by producing a chemical deposit of various metals and their salts upon the reduced silver image. The first may be passed over as being out of the range of the practical worker. For the second, a direct or indirect means may be employed; thus a warm bath may be used as follows:—

Sodium thiosulphate	150 gms.
Alum	15 gms.
Hot water	1000 c.c.m.

This bath, according to Loescher, should be kept a day before use, and used warm; toning takes up to half-an-hour, according to the colour desired. A similar method, advocated, we believe, by Dr. Wilson, is to bleach the prints in a solution of mercuric chloride and lead nitrate, wash well, and then treat with a 30 per cent. solution of ammonium hydrosulphide.

For red tones the following is recommended:—

I.—Lead nitrate	1 gram.
Pot. ferricyanide	3 grams.
Water (distilled)	50 c.c.m.

II.—A 1 per cent. solution of uranium nitrate.

III.—A 20 per cent. solution of citric acid.

IV.—A 1 per cent. solution of ammonium chloride.

Take 25 c.c.m. of I., 100 c.c.m. of II., 100 c.c.m. of III., and 20 c.c.m. of IV. By omitting No. IV. brown tones will be obtained.

Various red and sepia tones will result with the following bath:—

I.—A ½ per cent. solution of copper sulphate.

Concentrated ammonium carbonate solution is added to this till the precipitate formed is redissolved.

II.—Pot. ferricyanide	12 grams.
Water	700 c.c.m.

Add solution II. to I., shake, and then add more carbonate solution till clear.

The following is a convenient bath for blue tones:—

Ferrous sulphate	1 gram.
Ferric chloride	1 gram.
Water	20 c.c.m.

This follows after a preliminary immersion in a uranium bath. If blue tones are to be got without uranium, another method is offered. Make up the following:—

I.—Lead nitrate	1 gram.
Pot. ferricyanide	3 grams.
Water (distilled)	50 c.c.m.
II.—Ferric chloride	1 gram.
Water	50 c.c.m.
III.—Citric acid	10 grams.
Water	50 c.c.m.

For use take two parts each of Nos. I. and II., and three parts of No. III.

A bath for giving violet tones is the last, and is made up in the following manner:—

A.—Ferric oxalate.....	1 gram.
Pot. ferricyanide	1 gram.
Water	2000 c.c.m.
B.—Copper chloride	1 gram.
Water	100 c.c.m.

To both solutions ammonium carbonate is added till the precipitates formed are redissolved. The print is placed first in A till it has acquired a Berlin blue colour; it is next placed in B till the desired colour is arrived at, and then well washed. Too long immersion tends to produce red tones.

In all the methods the prints are to be well washed after fixing before treatment with the toning solutions.

T. THORNE BAKER.

THE GLUE AND GELATINE INDUSTRY.*

[Reprinted from the "Pharmaceutical Journal."]

GLUE, which constitutes a weighty factor in the animal organism, is found principally in the cartilaginous material, bones and skin of most animals. Technically, it is divided into three classes—bone glue, leather glue, and skin glue. In its preparation, the raw material is first submitted to a process of division into very small pieces, either in a stamping machine, or in a mill, very similar in construction to the ordinary flour mill. In this process very careful attention must be given to the temperature of the material. It must not be allowed to get too high, or the product will acquire a very foul and disagreeable odour; the quality of the finished product being, moreover, otherwise injured, in that it loses in tenacity, though the chemical changes that occur in the heating of the substance have not yet been fully cleared up. The ground-up bones (*Knock enmehl*) still contain fatty matter which must first be carefully removed, for which there are various processes, the selection of which depends upon whether the fat is to be utilised or not. The older process consisted of heating the mass in kettles provided with a double or false bottom, which prevents the bony material from coming in contact with the directly heated bottom, and thus getting burned. The fat, on heating, melts and assembles on the surface, from which it is skimmed off as it arises. The difficulty with this method of getting rid of the fat is that it takes up a great deal of time, and does not do the work completely, as the residual fat injures the quality of the glue. A better process is that in which the vacuum pan is brought into play. The kettle is made air-tight, and is connected with an air-pump, which enables the boiling process to proceed under rarified air, and, of course, under a much lower temperature. A good deal of time is also gained by it. By far the best process, however, is removal of the fat by benzol in closed iron cylinders. The benzol being recovered by distillation, the cost of the substance cuts but little figure in the process. When the process of defatting is over, there are other impurities or foreign substances that must be removed, the mineral ingredients of the bone substance—calcium, phosphorus, etc. The most convenient agent for this purpose is hydrochloric acid. This is added to the defatted mass and left in contact therewith, from forty-eight to seventy-two hours, according to circumstances. At the end of this time the cartilaginous material is freely washed with water, and becomes what is technically called "crude" or "raw" glue (German, *Rohleim*). The washing is a very particular process, and must be most

carefully done, as the slightest residue of acid will interfere with the clarification of the finished product. A slight remnant of calcium phosphate gives the glue a milky appearance, which is unsightly, but does not injure the quality of the product in the least. To tell the truth about it, baryta, or white lead, is often added to poor glue produced by other chemical methods, by some manufacturers, in order to give their product the appearance of having been prepared by the benzol process. The crude glue now passes to the boiling apparatus in caldrons provided with perforated bottoms. On long-continued boiling, the water, holding glue in solution, gradually separates from the cartilaginous matter (technically called, in German, *Leimwasser*, or glue-water), and, from time to time, is drawn off by faucets, arranged for this purpose. At first the draw-off is very thin, and contains but little glue, but as the boiling proceeds it gets richer and richer in glue, until finally it arrives at a point when it must be transferred to the evaporating pans for solidification. Of late years, evaporation has been carried on, as in the earlier defatting process, in vacuum pans, on account of the advantages thus gained (lower temperature, rapidity, etc.). Evaporation is continued until the gelatinous content of the material in the pans has reached 45 per cent. The pans are now disconnected and removed to the pouring room, where their contents are emptied out into shallow forms provided with glass bottoms. These are arranged in sets, in such a way that an air-space is left around each to facilitate evaporation and solidification. The air is kept in constant motion by ventilators driven, usually, nowadays, by electrical apparatus. Sometimes the glue, instead of being poured into large shallow pans or forms, is poured into deep moulds, and is allowed to solidify in blocks of the consistency of cold jelly, which are afterwards cut by machinery into slices of the desired thickness. The drawback to this process is that it cannot be practised in all kinds of weather—not with the same convenience, at least. When the material has reached a certain degree of solidity it is removed from the glass-bottomed forms and placed into trays with bottoms of wire netting. These are then put on an endless carrier and passed into a series (three or four) of closed compartments, each succeeding one of which is heated a few degrees higher than the one just left. When the space or compartment is reached, whose temperature is deemed most suitable for the material (which depends entirely upon its percentage of residual water), it is taken off the carrier and left in the chamber for a length of time, also dependent upon its hardness. The glue is thus gradually dried, passing from one room to another until it is thoroughly exsiccated. The temperature of the first drying room is 30 deg. C. (86 deg. F.), and it increases by spaces of 10 deg. C. (60 deg. F.). It usually requires about one month to complete the drying process and deliver the glue ready for market.

GELATINE.

Gelatine is nothing more than an especially pure glue, obtained from bone-glue by means of sulphurous acid, and its manufacture is in no wise to be distinguished from that of glue. As raw material the parings and clippings of the shoe factories and shops, odds and ends from tanneries, old leather (boots, shoes, belts, scraps from book-binderies, etc.), calves' trotters, heads, etc., are also used. America carries on this manufacture on a very large scale, there being several very large gelatine factories that are supplied with raw material by the gigantic abattoirs of that country. The raw product is first submitted to a process technically called "liming," in which the material is acted upon by dilute milk of lime. This process is a long one, lasting from fifteen to twenty days for the thinnest and lightest leather parings, to thirty, or even forty, days for beef hides. The milk of lime arrests decay,

* Translated from the "Drogisten Zeitung" (Vienna) for the "National Druggist."

decomposes the products of fermentation, dissolves the fleshy matter, saponifies the fats, and, finally, loosens up the cartilaginous matter. The lime, together with the saponified fats and other products, is now removed by thorough washing, best with running water. The further handling of the material is, in general, the same as that already described in the manufacture of glue, with the exception that the process for getting rid of the mineral contents of the raw material is dispensed with. The first drawing of the glue-water yields the best glue, the second an inferior sort, while the third is almost destitute of adhesive property. It can only be used by adding to it a portion of the first or best sort. The solutions must all be more or less refined, according to the uses for which the glue is intended. To this end the liquid is first brought to a boil, and then cast into blocks, which are cut into slices and dried. This is what is called "cabinet-makers' glue."

By-Products.

We now come to the by-products. The fat is usually sold to the soap makers, by whom it is converted either by the hot or cold process into soap (after having, as a usual thing, some palm oil or stearine added to it). The better class of these fats are also used for the manufacture of stearic acid, which plays a considerable part in the manufacture of candles. When so used, they are first saponified with lime, then hot dilute sulphuric acid is added. This converts the lime to a sulphate (plaster of Paris), which is thrown down by elainic acid, and the stearic acid thus left free. The next by-product of the glue factory is phosphorus, of which the crude material carries a high percentage. The glue residue is first carbonified, and then treated with sulphuric acid, which produces calcium phosphate. This is mingled with coal, packed in retorts, hermetically sealed, and brought to a white heat. Phosphorus is distilled off, and is caught under water. A third by-product of the industry is bone-black, or animal charcoal. A good article of bone-black is of a deep, intense, matt-black, and plays a very prominent part in the arts and industries, especially in the manufacture of colours. It has the characteristic property of absorbing from other substances colouring matter, lime, and salts, and hence it is used in the decolorisation of oils. It is also used as filtering material in sugar refineries, as it removes all traces of colour and leaves the sugar of a snowy whiteness. Another use of bone-black is in the preparation of blackings. After the fats and gelatine are extracted from bones, the latter are very brittle, but still contain some calcium phosphate and about two per cent. of nitrogen, and possess considerable value as a fertiliser. Formerly farmers used to cover their land with coarsely-powdered bone. It was, however, made plain that in this condition the material had but little fertilising value. Now they are ground to meal or very small bits by a machine especially devised for the purpose, which not only comminutes the material, but sorts out the product. Bone meal has great fertilising value, the utility of which is further much increased when it is made soluble in water. This is done by submitting it to the action of sulphuric acid and converting it into superphosphate. In conclusion, we would remark that it is an interesting fact that every particle of the seemingly worthless residue of the slaughter-houses has been, by chemical skill, converted into substances of value in the arts and industries. Absolutely nothing is lost, but all made valuable. Even with the by-products cited by us, we have not yet reached the end, and might follow the residues of the soap and candle factories, and show how glycerine is got from them. This, however, belongs to another article, and we will leave it for that time.

ERNST PAUL REHFELD.

THE INVISIBILITY OF TRANSPARENT OBJECTS.

[Reprinted from "The Physical Review."]

A TRANSPARENT body, no matter what its shape, disappears when immersed in a medium of the same refractive index and dispersion. Could a transparent solid substance be found, whose refractive index and dispersion were the same as those of air, it would be absolutely invisible. We can find a solid, the refractive index of which is equal to that of air for light of a certain wave-length, but unfortunately it is not a transparent substance. If it were, we should have an example of a solid absolutely invisible when illuminated with monochromatic light. The dispersion curves of some of the aniline dyes cross the line of unit refractive index for certain wave-lengths, but the point of crossing is in the immediate vicinity of the absorption band. Cases of this nature will be discussed more fully under another heading.

The disappearance of a transparent substance when immersed in a medium of identical optical properties is usually illustrated by dipping a glass rod into Canada balsam, but the disappearance is not complete, for the dispersion of the glass and the liquid are not the same. A better fluid is a solution of chloral hydrate in glycerine, which is quite colourless. The glycerine is to be heated and the crystals added until the refractive index is of the required value. The hot liquid will dissolve a most astonishing amount of the chloral, ten or fifteen times its bulk, if I remember right, and only a very small amount should be placed in the beaker to start with. This solution has almost exactly the same dispersion as glass, and finely powdered glass stirred up in it becomes perfectly transparent without showing a trace of Christiansen's colours. A glass rod disappears completely when dipped into it, and when withdrawn presents a curious aspect, for the end appears to melt and run freely in drops.

Lord Rayleigh, in his article on optics in the "Encyclopædia Britannica," points out that perfectly transparent objects are only visible in virtue of non-uniform illumination, and that in uniform illumination they would become absolutely invisible.

A condition approaching uniform illumination might, he says, be attained on a top of a monument in a dense fog. I have recently devised a method by which uniform illumination can be very easily obtained and the disappearance of transparent objects when illuminated by it illustrated. The method in brief is to place the object within a hollow globe, the interior surface of which is painted with Balmain's luminous paint, and view the interior through a small hole.

The apparatus can be made in a few minutes in the following manner:—A quantity of Canada balsam is boiled down, until a drop placed on cold glass solidifies. The Balmain paint, in the form of a dry powder, is stirred into the hot balsam until the whole has the consistency of thick paint. Two glass evaporating dishes of equal size are carefully cleaned and warmed and coated on the outside with the hot mixture, which can be flowed over the glass, and by the dexterous manipulation of a small Bunsen flame made to cover the entire outer surface. I first tried painting the inside of a copper sphere with the commercial paint, but the surface was unsatisfactory and could not be easily cleaned. Probably two perfectly plain hemispherical finger-bowls could be used instead of the evaporating dishes. As soon as the coating has become hard, a small hole is cut through it, to enable the interior to be viewed. If the lips of the dishes are placed together, the interior can be seen through the small opening, but in this case the line of junction, which is always more or less dark, comes opposite the aperture, which is a disadvantageous arrangement.

If the inner surfaces be exposed to bright daylight, sun, or electric light, and the apparatus taken into a dark room, a

crystal ball or the cut glass stopper of a decanter placed inside, it will be found to be quite invisible when viewed through the small aperture. A uniform blue glow fills the interior of the ball, and only the most careful scrutiny reveals the presence of a solid object within it. One or two of the side facets of the stopper may appear if they happen to reflect or show by refraction any portion of the line of junction of the two hemispheres.

PROF. R. W. WOOD.

PRISMS AND PLATES FOR SHOWING DICHROMATISM.

[Reprinted from "The Physical Review."]

THE usual method of showing dichromatism, or the change in the tint of the transmitted light, with increasing thickness of the absorbing medium, is to superpose two or more stained films or strips of suitably tinted glass. The method has a disadvantage in that it does not demonstrate very clearly the cause of the change of colour. As is well known, the change is due to the fact that the coefficient of absorption is greater for one absorbed region than for some other. If the medium be given the form of an acute prism, and a source of light be viewed through it, the transmitted colours are separated, and the change in the intensities of each can be followed, as the thickness increases by moving the eye from the refracting edge towards the base.

I have made prisms of this nature in the following way: A quantity of Canada balsam is boiled down until it will harden on cooling, and a quantity of brilliant green is dissolved in it. The dye must not be added to the balsam until it has cooled almost to the point of becoming thick, otherwise it will be decomposed and a very muddy green result. The amount of the dye should be such that a layer of the liquid 1.5 cm. thick appears blood red. Thin layers appear blue, and if a prism be made of this mixture it will show a blue-red dichromatism. A green-red dichromatism is much more striking, and the requisite green colour can be produced by the addition of a quantity of naphthol yellow. This makes a beautiful dichromatic medium. A small hollow prism made of two strips of plate glass mounted together with wooden sides, in which grooves have been cut, is warmed and filled with the mixture. As soon as the balsam is hard, a small quantity of melted sealing wax is poured on top of it, which materially increases the strength of the prism. A lamp flame viewed through this prism is separated into a red image and a green image, and as the eye is moved along towards the base the green image fades rapidly away, while the red one scarcely changes at all.

If a broad flame be used, the overlapping portions of the two images will be seen to be coloured yellow, secondary yellow due to the mixture of red and green light on the retina. The thickness of the prism at the point where this yellow is purest is the critical thickness, or the thickness at which the change from red to green takes place. If we consider the colour change as a subjective phenomenon, there are three distinct colours seen with different thicknesses of this medium, green, yellow, and red. This can be shown better by making the balsam solution of the dye much stronger, and pressing it out between plates of glass. It is easy to prepare in this way plates very slightly prismatic, which are red along one side, yellow in the middle, and green along the other side. The yellow is always a little puzzling, especially if a flame is the source of light looked at. The lack of achromatism in the eye causes the yellow image to have red or green borders, the effect being difficult to describe. In the case of one of my plates, the colour of the transmitted light is almost exactly that of the sodium flame, and yet a sodium flame is absolutely invisible through it.

The dependence of the colour on the original composition of

the light is also well shown by these plates, some of them appearing red by lamplight and bright green by daylight, a phenomenon exhibited by the well-known Alexandrite crystals.

I have a prism which I made several years ago which is dichromatic by lamplight, but not by daylight, which illustrates well that dichromatism depends on the relative intensities of the different parts of the spectrum of the light used, as well as on the different absorption coefficients. If I remember rightly, this prism was made of malachite green.

The prisms should be made about 4 cm. long, and 2 cm. thick at the base.

PROF. R. W. WOOD.

LECTURE ROOM DEMONSTRATIONS OF ASTIGMATISM AND OF DISTORTION.

[Reprinted from "The Physical Review."]

THE astigmatism of a lens for an oblique pencil of rays may be shown subjectively by looking obliquely through a magnifying glass at the rulings on a piece of cross-section paper. The lens may be adjusted to show one set of rulings distinctly, when, upon moving the lens nearer to or farther from the paper, the other set of rulings will become distinct. The conditions necessary to bring out the astigmatism in a striking manner are that a narrow pencil of rays be employed, passing through a small portion of the lens, and that the field angle be narrow. This is substantially realised in the above use of the magnifying glass, inasmuch as the pencil of rays from any given point in the sheet of paper is delimited by the pupil of the observer's eye, and inasmuch as the field angle where the eye is fixed upon a given point of the paper is determined by the extent of the region of distinct vision, that is by the size of the yellow spot in the retina of the eye.

The astigmatism of a lens for an oblique pencil of rays may be shown objectively by projecting on the screen an image of a cross-ruled transparent plate, the projecting lens being turned so that its axis makes an angle of twenty or thirty degrees with the optical axis of the lantern. Under these conditions the vertical or horizontal lines may be sharply focussed at will, and if the lines are very fine; it may easily be that the one set of lines is rendered invisible by blurring, when the other set of lines is sharply in focus. A small portion only of the plate should be used, the remainder being cut off by a diaphragm; and the lantern should be adjusted so that the light from the condenser may be focussed as it passes through the projecting lens.

The error of a lens known as distortion, an error which is exhibited to a marked degree by the so-called view lens of the amateur photographer, may be demonstrated by means of the projection lantern, and the principle of rectilinear lens may be shown. In this connection it should be remembered that the distortion produced by a simple lens or by a simple achromatic doublet is very small except when a stop or diaphragm is used at some distance in front of the lens to improve the definition. Instead of a diaphragm, it is more convenient to adjust the lamp in the lantern so that the condenser lenses focus the light in front of or behind the projecting lens, as may be desired, the position of this focus corresponding to the position of a diaphragm or stop. To show this error as large a field angle as possible must be used.

A large cross-ruled transparent plate is placed in the lantern, and projected by means of a simple biconvex lens. If the lamp is adjusted until the focus of the condensing lenses lies, approximately, in the plane of the projecting lens, and the projecting lens is adjusted to give the sharpest possible image on the screen, the image shows little or no distortion. If the lamp is adjusted as that the condensing lenses focus the light

some distance in front of the projecting lens, and the projecting lens is adjusted to give the sharpest possible image on the screen, the image is distorted, the lines being concave on the side towards the centre of the field. If the lamp is adjusted so that the condensing lenses focus the light some distance beyond the projecting lens, and the projecting lens is adjusted to give the sharpest possible image on the screen, the image is distorted, the lines being convex on the side towards the centre of the field.

In the symmetrical orthoscopic or rectilinear doublet the diaphragm or stop is midway between the lenses of the doublet, that is, in front of one lens and behind the other, and the distortion of one lens is opposite to that of the other. The distortion is thus compensated.

W. S. FRANKLIN.

THIS WAY TO THE LUNATIC ASYLUM.

My friend Smith departed in high spirits for the annual club outing.

"We're sure to have a jolly time," he said, as I bade him farewell at the station; "you have no idea how fraternal people are. The chaffing and joking are endless, and everybody's temper is literally angelic."

But when he came back, alas and alack—as the classics have it—he had a weary little twinkle in his eye. I met him that evening, and he immediately buttonholed me.

"Why did——?" he began.

"What was the field meeting like?" I interrupted.

"Oh ripping! But, I say, do you know why did——?"

"Have you got many negatives?"

"Yes, lots. But have you heard this: Why did——?"

"Don't ask me why did the owl 'owl.'"

"No, no; these are quite new. Why did Photop-ake?"

"Of course, I give it up."

"Because she saw Glissoline on Ethelbert Henry. Ha, ha!"

"What a rotten one! Where did you pick it up?"

"Composed it myself. But here's a better one: What would you do if you got too fond of Käse-bier? Why, of course, you'd have to stick to Adam's Yale."

"Oh, lor'! They can't have stuck to it at the field meeting, if that's the kind of giddy jest they bandied about."

"My dear fellow, that's nothing to some of them."

"Well, let's have a few samples."

"Let me see. Oh, yes. What was Photographic Salon?"

"How do you expect me to know what the young lady was on? Tell me at once."

"Eastman's Brownie."

"What? Sal was on Eastman's Brownie?"

"Eastman's Brown knee, don't you understand?"

"My sainted grandmother!"

"And can you explain: Why did Gambier Bolton?"

"No, I can't."

"Because they made Waterhouse stop."

"Spare me!"

"No, I will not spare you. Look here. Why is Burroughes Wellcome? Because he can always make develo purr. What was it that Lancaster? The secret is only by Hydroki-none. What was it that the Cadett? A slice off a Velox. How was Lamb-ert? By seeing Gly-cin. How much does Solio? More than Cooke Lens. Where did they washer? In Eastman spools. What gave the studio window pane? To see the roller blind. Why is it that the camera bellows? Because it's just been punished fo'cussing. Where did——?"

"Halt! I can't endure any more." And I wrenched myself free and fled home.

That night sleep did not visit my eyelids for many hours. I had caught the disease, and lay tossing upon my couch inventing fresh conundrums (or should it be conundra?), to outvie those of my friend; and, *en passant*, I may mention that he is my friend no longer.

"Why were W. and D. Downey?" I pondered. "No; I have it! Why weren't W. and D. Downey? Because sometimes Bros. Moulton. (Ho, ho! good one, that!) Let me see. How do you know he has Vevers? Obviously by his tungstate. Why did Hyposulphite? Because he saw the plate box. (Um, um; that's rather feeble.) How does Wainwright? So badly that he really Autotype. Why wasn't Shardlow? Because the P.A.J. was a Wellborne Piper. (That one has a trifling fault; it's Cockney.) To proceed: Why did he refuse the Jewell? Because you might expose two seconds. (Rather smart, that!) Why did the dark-room sink? Under the weight of an extra photo-gram. Why did the roll-holder? To prevent her falling on the dark slide."

Eh, me! but I was weary before I fell asleep. Next morning in my bath I made my last riddle, and swore a solemn oath to make no more. It was: What are photographic riddles? And the answer simply is: Bausch!

WARD MUIR.

THE THEORY AND PRACTICE OF INTENSIFICATION. PART II

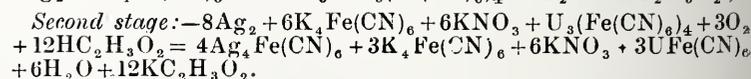

THE FERRICYANIDE INTENSIFIERS.

When metallic silver is brought into contact with an aqueous solution of a salt of hydroferricyanic acid, it acts as a reducing agent, removing portion of the acid from the salt, and converting it into a ferrocyanide. Upon this reaction are based the existing processes of photographic intensification by means of ferricyanide solutions.

The intensification, as was mentioned in my former article, may be either direct or indirect. In the former case, the ferricyanide bath is itself the true intensifier, but in the latter the action of the salt on the image is not an intensifying one—despite the fact that ferrocyanides are still produced—but has merely the effect of converting the silver film into a state capable of being readily intensified by after treatment in a solution of a chromate, sulphide, or other suitable salt.

In direct intensification it is customary to make use of a bath containing uranium ferricyanide as the active constituent, whilst in indirect lead ferricyanide is the salt employed. The combining proportions of the constituents of uranium ferricyanide have not been exactly determined, but seeing that hydroferricyanic acid is tribasic, there is reason to suppose that the composition of the salt is accurately represented by the formula $U^3(Fe(CN)_6)_3$.

On the assumption that such is the case, the reduction of the uranium compound by silver may take place in accordance with the second of the following equations, the final products of the reaction being a mixture (or perhaps a double salt) of the ferrocyanides of silver and uranium, constituting the image, and potassium nitrate and acetate, which pass into solution:—

Uranium ferricyanide is first formed by the double decomposition of uranyl nitrate and potassium ferricyanide, and the remainder of the latter salt is converted into ferrocyanide. Part of the ferrocyanide is then, in its turn, decomposed, and silver ferrocyanide is formed in its place, while the uranium salt is reduced to ferrocyanide at the same time.

In practice it is usual to acidify the uranium bath by the addition of acetic acid, as a safeguard against the staining of the film during the operations of intensification. The addition of the acid is also to be recommended, on account of the circumstance that an acidified solution has less solvent action on the products of intensification than one which is neutral or markedly alkaline.

Before employing the uranium bath the plate to be intensified should always receive a few minutes' soaking, either in water alone or preferably in a very weak aqueous solution of acetic acid, say, one part by volume of the acid to seventy parts of water.

In effecting the double decomposition, it is customary to add the solution of potassium ferricyanide by degrees to the bath containing the acidified uranyl nitrate solution, after a few minutes' treatment of the plate in the latter, and this plan has its advantages, as it is possible by its means to obtain the maximum intensifying effect of the bath by taking the simple precaution to add no more ferricyanide solution than is necessary to effect the conversion of the image into uranium and silver ferrocyanides. When an intensifying bath containing an excess of ferricyanide is made use of, a certain percentage of silver ferricyanide, a comparatively soluble salt, is always formed along with the ferrocyanides, and by the continued action of the bath this salt is partly dissolved, the result being, of course, a partial reduction of the density of the image.

As to the strength of the solutions that should be employed in these operations there is considerable diversity of opinion. Generally speaking, a bath containing from two to three grains per fluid ounce of mixed solution of each of the salts employed will be found efficacious. If a stronger bath is required, the percentage of uranyl nitrate should be increased in preference to that of the ferricyanide.

It is, unfortunately, impossible to estimate otherwise than roughly the amount of ferricyanide required to produce the maximum degree of intensification, because the weight of the silver constituting the image after the operations of development and fixing are completed cannot be determined, and without its weight to guide us, we cannot say what the weight of the intensification products will be. The quantity of acetic acid which ought to be added to the bath is also variously stated, some writers recommending the addition of two volumes of acid to every ninety-eight volumes of water employed, and others again no less than seven times as much. Speaking from my own personal experience, I have found a four per cent. solution to give very satisfactory results.

The ferrocyanides obtained by the action of the uranium bath differ much in appearance. Silver ferrocyanide is a white compound which is said to assume a blue colour on exposure to air, a circumstance which serves to explain the rich deep hues exhibited by a negative which has received a treatment of some hours' duration in the intensifying bath. Uranium ferrocyanide, on the other hand, is a compound of a fine brownish-red colour, inclining to orange in its lighter, and to crimson in its darker, tints. It is a very non-actinic colour, too much so, indeed, to be entirely satisfactory as regards the facilities which it affords for rapidity of transmission of light in the process of printing. The slow printing qualities of the negatives intensified by its means, is, however, the only serious objection that can be urged against the use of the uranium ferricyanide bath, which in other respects is a valuable photographic adjunct, and is perhaps the only intensifier upon which entire reliance can be placed.

The increase of density (*i.e.*, weight per unit volume) produced by the action of the uranium bath is very considerable, being no less than 646.21 parts by weight for every four molecules (861.28 parts) of metallic silver present. There is also a large increase in the volume, the amount of which I am, however, unable to state, as the value for the specific gravity of uranium ferrocyanide necessary to make the calculation has not apparently been determined.

The process of indirect intensification with the ferricyanide bath has next to be described. The chemical reactions involved in the process are, in all respects similar to those which we have just been considering, the only difference being in the composition and appearance of the deposit forming the latent image produced by the decomposition. Its two constituents, ferrocyanide of silver and ferrocyanide of lead, being both colourless bodies, are not, truly speaking, intensification products, but rather what may be styled—using the expression in a purely photographic sense—products of reduction. The solution of lead ferricyanide employed in the treatment of the plate is usually prepared by double decomposition, the salts selected for this purpose being potassium ferricyanide and nitrate of lead. The formation of the compound is represented by the following equation:—

It will be seen that, besides the ferricyanide, a large percentage of potassium nitrate is formed. It is not necessary that this should be withdrawn from the solution before employing the bath, as the salt does not appear to exercise any injurious action upon the reduction products.

The equation representing the conversion of the image into lead and silver ferrocyanides may be written thus:—

If the bath is too strong in ferricyanide in proportion to the amount of silver present in the image to be intensified, some ferricyanide of silver will be formed, in a manner quite analogous to the behaviour of the uranium bath acting under like conditions. Assuming what in actual operations is never likely to occur—*viz.*, that all the silver is converted into ferricyanide, the action may be represented thus:—

Hence it is inadvisable to employ a highly concentrated solution, particularly when a very weak image, poor in silver, is to receive intensification.

As a matter of fact, lead ferricyanide is only sparingly soluble in water alone; but, as in the process of direct intensification, it is usual to add acetic acid to the solution, and this has the effect of increasing the solubility of the salt.

For the production of lead ferricyanide, theory requires the presence of rather more than sixty-six parts by weight of potassium ferricyanide for every hundred parts of lead nitrate employed. In practice, notwithstanding, the addition of a considerable excess of the former salt, is generally recommended, and this, no doubt, together with the acetic acid present, tends to increase the solubility of the lead compound.

The following standard formula, which will be familiar to most photographic readers, may be taken as a fair representative of its class:—

Uranyl nitrate, 100 grains.
Potassium ferricyanide, 150 grains.
Acetic acid, one fluid drachm.
Water, five fluid ounces.

As to the time that will be required to effect the necessary reduction of the image in the bath, no definite rules can be given. All depends upon the degree of intensification which is sought to be imparted. In the case of a very weak image it may be necessary to prolong the action until the whole of the silver is converted into ferrocyanide, and entire bleaching ensues. Usually, however, notwithstanding the statements to the contrary that are to be met with in certain photographic text books, an immersion such as will produce a decided but merely superficial whitening of the image will be sufficient to give the effect desired.

In order to remove the last traces of soluble ferricyanide, the film after treatment must be well washed in running water, for at least twenty minutes. Upon the thoroughness of this washing the success of the subsequent intensifying operations very largely depends.

For intensifying purposes a solution of ammonium sulphide is usually recommended. As the commercial salt, however, consists of a mixture of sulphhydrate and sulphides, and is, besides, a very unstable compound, better and more certain results are obtained by the use of sodium sulphide. The following equation exhibits the decomposition of the reduction products, representing the image when treated with a solution of this reagent:—

The sulphide acts upon the mixture of ferrocyanides, converting them into insoluble sulphides, and sodium ferrocyanide is simultaneously produced, and passes into solution. The intensification products, silver and lead sulphides, are both dark-coloured bodies. Owing to the predominance of the lead compounds in the mixture forming the image, the hue produced is usually a deep gray or grayish-black.

The increase of density represented by the conversion of four molecules of silver into silver sulphide is obtained by subtracting the number 861.28 (*i.e.*, eight times the atomic weight of silver), from 989.20 (four times the molecular weight of the sulphide), when we have as remainder, 127.72. To this, however, in order to find the total increase, must be added twelve times the molecular weight of lead sulphide, and thus we have:—

$$127.72 + (238.41 \times 12) = 2988.64.$$

This, it will be observed, is more than three times 861.28, the density of the original image.

In regard to the increase of molecular volume, the atomic volume of metallic silver is 10.2, which, multiplied by 8, gives us 81.6. The molecular volume of four molecules of silver sulphide is found by multiplying 989.20 by the reciprocal of the specific gravity. The specific gravity of the sulphide when formed artificially is stated to be 6.85, therefore:—

$$989.20 \times 14598 = 144.40.$$

The specific gravity of lead sulphide in the condition in which it is obtained in the reaction is 6.92, the reciprocal of which is .1445. Multiplying the molecular weight of a single molecule, 238.41 by 12 to obtain the molecular weight of the twelve molecules of sulphide produced, and this in its turn by the reciprocal, we have as product, 413.40.

The increase of volume is therefore:—

$$144.40 + 413.40 - 81.6 = 476.20.$$

It will be seen that this increase is no less than 5.8 times the original volume of the silver in the image, a sufficiently striking result.

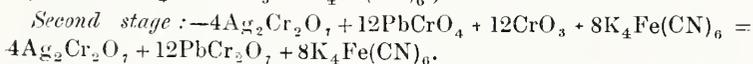

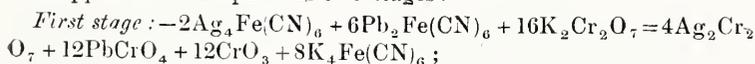

It is really immaterial what strength of sodium sulphide solution is employed in the intensifying operations, provided always that it is not too dilute. A bath containing from twenty-five to thirty grains of the salt to each fluid ounce of water will be found to answer well, and may be recommended for use.

The chromate bath next requires notice. Unlike the sulphide bath, this gives an image of a very warm quality of tone, somewhat similar to that obtained with uranium ferricyanide. The deposit is composed of a mixture of the chromates of silver and lead, these compounds being produced by the action of a solution of an alkaline chromate upon the mixture of ferrocyanides obtained by the preliminary treatment in the lead ferricyanide bath. In preparing the solution, either the normal potassium chromate (K_2CrO_4), or potassium bichromate ($K_2C_2O_7$) may be employed. The latter is the salt usually recommended, but the former, for reasons which will presently be given, is to be preferred whenever it is obtainable.

The following is the equation representing the change produced by the action of a solution of the normal salt:—

With a solution of bichromate, the action is rather more complicated, and appears to take place in two stages:—

In the first stage, the products of the double decomposition are silver bichromate, normal lead chromate, chromium trioxide, and potassium ferrocyanide. The two last-mentioned compounds dissolve in the water present. In the second stage, the solution of chromium trioxide attacks the lead salt, converting it into the red bichromate, $PbCr_2O_7$. As to this secondary action, however, the fact must be mentioned that the conversion of the normal chromate into bichromate takes place so slowly, that, for all practical purposes, the products of intensification may be regarded as consisting merely of silver bichromate and normal lead chromate.

Normal silver chromate is a dark red salt, which is insoluble in water. Silver bichromate resembles the normal chromate in colour, but differs from it in solubility, being attacked in the presence of excess of water and partially dissolved. Owing to this circumstance, it is not possible to estimate with accuracy the degree of density that will be obtained when a bath of potassium bichromate is employed. It is better, therefore, always to use the yellow chromate in the preparation of the solutions that are intended for intensifying purposes.

The colour of the image after intensification is orange or orange-yellow, this being attributable to the large percentage of lead chromate produced.

The increase of density due to the conversion of four molecules of silver into normal chromate may be found by subtracting 861.28 from 1,326.44, that is, 531.61 (the molecular weight of the chromate), multiplied by 4. This gives 465.16 for the silver salt alone. The molecular weight of lead chromate is 322.68, and 12 molecules of the salt are produced in the reaction. Multiplying these figures together, we get 3,872.16, and we have then for the total increase of density, $3872.16 + 465.16 = 4337.32$, which is equivalent to rather more than five times the original density.

The increase in molecular volume produced by the reaction can also be calculated, as the specific gravities of the two chromates have been determined. As before, we have 81.6 for the atomic volume of four molecules of silver. The specific gravity of silver chromate is 5.77, and that of lead chromate is 5.65. Multiplying the molecular weights by the reciprocals of the respective specific gravities, and the products in their turn by the number of molecules, we have:—

$$\text{Volume of } 4Ag_2CrO_4 = 331.61 \times 1733 \times 4 = 229.87$$

$$\text{Volume of } 12PbCrO_4 = 322.68 \times 17699 \times 12 = 685.33$$

Therefore, the total increase of volume is:—

$$229.87 + 685.33 - 81.6 = 833.60$$

The primary and final volumes are thus in ratio of the numbers one to eleven.

A solution containing 25 grains of normal potassium chromate per fluid ounce is recommended for intensifying purposes. The following may be used as a substitute, and gives equally good results:—

Caustic potash, 67 grains.

Potassium bichromate, 175 grains.

Water bichromate, 10 fluid ounces.

MATTHEW WILSON.

THE UNIVERSAL EXPOSITION AT SAINT LOUIS, 1904. DEPARTMENT OF LIBERAL ARTS.

CIRCULAR No. 5.—Photography, Its Processes and Products.

Event to be Celebrated.—The anniversary of that important historic event, the acquisition of the Louisiana territory, will be celebrated in St. Louis by a Universal Exposition, embracing exhibits gathered from every field of human endeavour, both at home and abroad, which will illustrate, to the fullest practicable extent, the developments of a century in art, science, and the industries.

International in Scope.—The national and international scope and character of the Exposition is fully set forth in the organic act of March 3, 1901, in the following terms:—

Act of Congress.—“Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That an exhibit of arts, industries, manufactures, and products of the soil, mine, forest, and sea, shall be inaugurated, etc. The President shall be authorised to make proclamation of the same. And he shall, in behalf of the Government and the people, invite foreign nations to take part in the said Exposition and to appoint representatives thereto.”

President's Proclamation.—It is also voiced in the proclamation of the President of the United States, issued August 20, 1901, under the above authority of Congress, who, in the name of the Government and the people of the United States, invited all of the nations of the earth to take part, “By appointing such representatives and sending such exhibits to the Exposition as will serve to fitly illustrate their resources, their industries, and their progress in civilisation.”

Fifteen Million Dollars for Buildings, etc.—That this Exposition will be of unusually large proportions is evidenced by the fact that the citizens and City of St. Louis have contributed ten million dollars (10,000,000.00 dols.) and the United States Government five million dollars (5,000,000.00 dols.), a total of fifteen million dollars (15,000,000.00 dols.), all of which will be used in the preparation of grounds, erection of buildings, and kindred expenses pertaining to installation.

Government and States Allotment.—In addition to this amount, there has been appropriated 1,308,000.00 dols. for a Government building and exhibits; 1,000,000.00 dols. by the State of Missouri, and amounts ranging from 20,000.00 dols. to 250,000.00 dols. by the several States and territories of the Union, all for the collection and installation of their respective exhibits.

Site.—The Exposition will occupy a beautiful site, covering about 1,000 acres in area, in and adjacent to Forest Park in the central-western part of the city.

Date of Opening.—The opening date has been fixed on April 30, 1904, and the closing date on December 1 following.

Buildings Designed by a Commission of Architects.—At the inception of the work, the designing of the building and the embellishment of the grounds was assigned to a commission composed of some of the leading architects and landscape engineers in the United States, and the results will undoubtedly be such as to win the enthusiastic admiration of all visitors.

Inner Courts.—By means of colonnades and inner courts they have made special provision for shade and coolness throughout the exhibit buildings.

Area of Liberal Arts Palace.—The Department of Liberal Arts will occupy an entire building, covering an area of about 400,000 square feet, and all exhibits will be on the main floor.

Architects.—The Liberal Arts Palace was designed by Barnett, Haynes, and Barnett, an architectural firm of established repute in St. Louis. It is the most easterly of the main exhibit buildings, and is near the United States Government building.

Estimated Cost.—It will be built of staff, at an estimated cost of 500,000.00 dols. Although following the prevailing style of architecture of the Exposition—the Renaissance—it adheres very closely to classic lines.

The architects describe the structure as designed in the following terms:—

Style of Architecture.—“The style of architecture is a severe treatment of the French Renaissance for the exterior facades. In fact, the treatment embodies rather a feeling of the classic than of the Renaissance. It has been the endeavour of the architects to depend largely on sculpture in the decoration of the building, refraining from the over-use of stereotyped architectural ornamentation.

Main Facade.—“The main facade will be 750 feet long, and will be made interesting by the use of a centre pavilion and of two end pavilions. The centre pavilion is brought somewhat above the connected buildings which unite it with the pavilions on either side. Each of the three pavilions, on the fronts, forms an elegant entrance to the building.

On the main facade there are three entrances, and on the 525-foot facades are two entrances, one in each of the end pavilions.

Main Entrance.—The main entrance will be in the form of a hemicycle with circular colonnades. The ceiling of this hemicycle will be frescoed on a background of old gold. The decorations and ornaments will be brought out in relief. The plan is conspicuous for the perfect simplicity of its arrangement and the practicability of its exhibit spaces. The ten main entrances of the building intersect the exact centres of the exhibit spaces, the axial lines of these entrances running through the centres of the exhibit spaces from east to west and from north to south.

Exterior Treatment.—“One of the most beautiful treatments of the exterior will be the broad allegorical processional frieze on the interior walls of the exterior loggias. These mural paintings will be executed on a background of old gold.

Light and Ventilation.—“The building is to be constructed without interior columns, the exhibit space being spanned in one truss. The internal court can, if necessary, be used as an overflow exhibit space. The exhibit space is adapted to any kind of exhibit, and the building will be ventilated and lighted by an abundance of windows, both in the exterior walls and in the clearstory.

“The court of the Liberal Arts Palace will be carried out in the Italian school of architecture, and will be enclosed by colonnades embellished with rare statues and beautiful arabesques. The cloisters formed by these colonnades will afford cool promenades for the visitors to the Fair.

“It is the intention of the architects to have this court laid out with flower beds and to install hanging gardens at the attic story line. In these gardens there will be groups of statuary by reproductions from antiques. In the centre of the court will be a beautiful basin of water, in whose limpid depths will be reflected the gardens and the classic lines of the colonnade. This basin is surrounded by balustrades and approached by broad flights of steps. In the angles of the court there will be Italian fountains enriched with statuary. The gardens will furnish visitors a delightful place for resting and for sight-seeing.

“The inner walls of the court entrances will be decorated with mural paintings in the style of Alma Tadema.

“These courts will be one of the charming features of the Exposition, and when illuminated at night with glistening cascades, flowers, and fountains, will form an enchanting picture.”

Attractive Exhibits Desired.—Diligent efforts will be made to fill this building with attractive and interesting exhibits of products and processes of the highest types of the various arts and industries of to-day from all parts of the world, and at the same time illustrate their evolution by showing some of the products and processes of the earlier days.

Co-operation Requested.—Your earnest co-operation is solicited, and you are cordially invited to submit plans and specifications for exhibit space in this department in one or more of the groups of the following classification:—

Field Covered by Liberal Arts.—Group 15.—Typography—Various Printing Processes; Equipment, processes and products.

Group 16.—Photography—Equipment, processes and products.

Group 17.—Books and Publications—Book Binding; Equipment and products.

Group 18.—Maps and Apparatus for Geography, Cosmography, Topography.

Group 19.—Instruments of Precision, Philosophical Apparatus, etc.; Coins and Medals; Equipment, processes and products.

Group 20.—Medicine and Surgery.

Group 21.—Musical Instruments—Materials, processes and products.

Group 22.—Theatrical Appliances and Equipment.

Group 23.—Chemical and Pharmaceutical Arts—Equipment, processes and products.

Group 24.—Manufacture of Paper—Raw materials, equipment, processes and products.

Group 25.—Civil and Military Engineering.

Group 26.—Models, Plans, and Designs for Public Works.

Group 27.—Architectural Engineering.

Each of the above groups is divided into several classes.

Photography.—Group 16, relating to Photography, its processes and products, is further described in the following pages:—

GROUP 16.—Equipment, Processes, and Products.

Class 54.—Materials, instruments, and apparatus of photography, equipment of photographic studios.

Class 55.—Negative and positive photography on glass, paper, wood, cloth, films, enamel, etc. Photogravure in intaglio and in relief; photocollography, photolithography—stereoscopic prints. Enlarged and

micrographic photographs. Colour photography. Direct, indirect, and photo-colour printing. Scientific and other applications of photography. Artistic photography as applied to portraiture, landscapes, etc.

This group embraces the equipment, processes, and products of photography in all its branches.

Attractive Surroundings.—Photography will here find an attractive home, amid congenial surroundings, filled with displays of the graphic arts, music, the drama, civil engineering, architecture, etc.

Artistic Photography in Art Palace.—Special provisions will be made for the display of selected high-grade examples of artistic photography.

Admission Through National Jury.—Admission to this class will be confined strictly to such art work in photography as may satisfactorily pass the critical inspection of the National Jury of Selection of the Department of Art.

The pictures from United States exhibitors, which are thus admitted, shall be hung in the United States section of the Art Building, to such extent as the room available will permit.

Foreign Exhibits Subject to Foreign Rules.—The pictures from foreign exhibitors will be admitted under similar rules, but must also, in all cases, conform to the rules of the respective foreign sections to which they belong, as to whether they can be hung in the foreign sections of art or not.

Special Place in Liberal Art Palace.—A suitable, attractive space will be specially prepared in the Liberal Arts Palace, where pictures selected in accordance with the above rules, and other high-grade work, may be properly displayed, in case they do not find suitable space in the Art Building.

Display of Highest Order Expected.—Under this system there should be gathered such a fine array of artistic photographs as will merit the admiration of art connoisseurs, and win the plaudits of artists of the older schools of the brush and pencil.

Aid of Photographic Fraternity Desired.—The very large number of professional and amateur photographers in all parts of the world, who are daily producing pictures of a high order, will doubtless gladly lend their aid in gathering a most interesting and valuable display of their work.

Colour Photography.—The latest developments in colour photography in all its phases should be freely treated, as also the scientific applications of photography to astronomy, surveying, etc.

The photo processes also afford a fine field from which to gather attractive exhibits.

Cameras and Other Appliances.—All classes of cameras and their appliances will find a suitable place in this group.

Historical Exhibits Desired.—It would also be very gratifying to have examples of the work done, and the cameras used by Wedgewood and Davy, Niepce and Daguerre, and others of the earlier workers, to show the progressive steps of this wonderfully fascinating art.

The specific mention of certain features of the several classes are simply suggestions which can readily be amplified by similar treatment of every item in the classification.

Rules Must be Carefully Considered.—The Rules and Regulations of the Exposition accompanying each application blank should be carefully considered before filling out requests for allotments of space. These must in all cases, conform strictly to said rules and regulations.

Make Exhibits Attractive.—In the preparation of exhibits, it should be borne in mind that the best interests of the exhibitor, the visitor, and the Exposition, require that no effort should be spared to make the exhibit attractive in its arrangement and in its movement, and special processes should be shown whenever it is practicable.

Quality Rather than Quantity Desired.—While as liberal allowances of space will be made as are found to be practicable, exhibitors should restrict themselves to as few well-selected examples of their products as permissible with due regard to the creditable display of the best features of their work, rather than attempt to make an exhibit attractive through its magnitude.

Space and Power Free of Charge.—There will be no charge for space occupied by exhibits, and a limited amount of power for the operation of mechanical devices to illustrate processes of special interest will be furnished to exhibitors gratuitously.

Any further information desired will be promptly furnished on application.

ROYAL Cornwall Polytechnic Exhibition.—The following are the awards in the photographic section:—First Silver Medals: J. H. Coath, J. C. Burrow, and H. Speyer. Second Silver Medals: H. T. Jessop, J. R. Gotz, and Rev. H. H. Mills. First Bronze Medals: J. B. Hawke, J. P. Milnes, W. A. Clark, W. Lidger, W. M. Martin, Annie Blamey, F. Martin-Duncan, R. R. Beard, J. C. Douglas, W. Fleet, Autotype Company, and G. Bird. Second Bronze Medals: C. J. King and Rev. G. E. Hermon.

THE ILLINGWORTH COMPETITIONS.

Messrs. Thomas Illingworth and Co., Ltd., of Willesden Junction, write:—"We shall be much obliged if you can find space in your valuable JOURNAL to mention that our £100 Carbon Printing Competition, which closed on August 1st, has been a great success. It is the first competition held for carbon workers, and over 800 prints were submitted by the leading professional and amateur photographers. The prints were of very excellent quality, and the judges, Messrs. Thomas Bedding and R. Child-Bayley, had the greatest difficulty in adjudging the awards. Appended is a list of the winners:—

List of winners in Illingworth's competition:—Class A. (for small prints by double transfer).—*1, G. W. Morgan (Aberdeen), £14 12s.; 2, Carine Cadby (Kent), £3 3s.; 3, A. V. Kenah (Blackheath), £2. Class B. (for large prints by double transfer).—*1, J. Moffat (Edinburgh), £17 15s.; *2, N. S. Kay (Bolton), £7 5s.; 3, W. R. Lathbury (Bristol), £2. Class C. (for small prints by single transfer).—*1, James Patrick (Edinburgh), £14 12s.; 2, J. Longton (Southwell), £3 3s.; *3, J. Moffat (Edinburgh), £4. Class D. (for large prints by single transfer).—*1, Valentine and Son (Dundee), £17 15s.; *2, Gunn and Stuart (Richmond), £7 5s.; 3, William Clayden (Plymouth), £2. Class E. (for prints on Illingworth's special "gravure" tissue).—*1, R. Fellows Willson (Bond Street, London), £12 10s. *Are professional photographers, and prize includes £2 special award to the working printer."

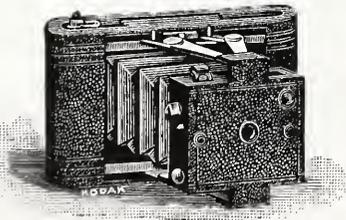

YORKSHIRE UNION OF ARTISTS.

The fifteenth annual Exhibition will be held at the City Art Gallery, Leeds, and will include an international invitation exhibition of pictorial photographs. The exhibition will be opened on Tuesday, October 14th, 1902, and closed on Saturday, January 3rd, 1903. Mr. F. G. Issott, of 62, Compton Road, Harehills, Leeds, writes: "I beg to invite your attention to the enclosed circulars which give particulars of the forthcoming international exhibition of pictorial photography to be exhibited in conjunction with an exhibition of paintings, water-colour drawings, etc., submitted by Yorkshire artists to be held as above. I believe this is the first occasion on which any society of painters has thus far recognised the artistic possibilities of photography as to welcome it to an exhibition side by side with paintings. The exhibition will include work submitted by the Yorkshire Union of Artists, Leeds and Yorkshire Architectural Society, and a thoroughly representative collection of modern pictorial photography by well-known workers in Great Britain, France, Germany, and America, and will be held in one of the finest and best appointed galleries in the United Kingdom. Apart from the members of the Yorkshire and Northern Societies interested in photography, science, art and architecture, the exhibition will be visited by a large and varied section of the art-loving public."

New Apparatus, &c.

The No. 0 Folding Pocket Kodak. Manufactured and sold by Kodak, Ltd., 43, Clerkenwell Road, London, E.C.

The latest addition to the numerous family of Kodak Cameras will not, it is safe to say, be less popular than its relations. It takes photographs 2 1/4 in. by 1 1/2 in., and as it only measures, when closed, 3 1/4 in. by 1 1/2 in., it may easily be carried in the pocket. It weighs about 10 1/2 oz. The front of the instrument is extended by means of the well-known lazy-tongs movement, and the back is non-detachable—it folds

back after a small nickelled catch is disengaged. This simple little improvement is to be very widely appreciated. The Bijou Kodak is constructed of wood and aluminium, and is covered with fine-grain leather. The other features of the camera include the Kodak over-set rotary shutter: three stops; finder; and, of course, the instrument takes spools of roll-film. Compact of form, convenient to hold or carry, and exceedingly simple to use, the No. 0 Folding Pocket Kodak is excellent value for its cost (26s.), and is sure to make its way in popular esteem.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

August.	Name of Society.	Subject.
30.....	Birmingham Photographic	{ Half-day excursion to Welford-on-Avon. Leader, Mr. H. Wilmot.

1.....	Southampton Camera Club	Print Competition—Architecture.
2.....	Rotherham Photographic	The Life and Work of George Tinworth.
3.....	North Middlesex Photographic	Eighth Lantern Slide Competition.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

August 21st.—Mr. H. C. Rapson in the chair. Mr. Brown passed round two wet-plate negatives made in 1852, and remarked on the splendid condition they were in after all these years. These negatives led to a discussion on the superior brilliance of the wet plates over the gelatine negatives. Mr. T. E. Freshwater said he had seen a number of similar negatives made some years ago, over which a curious stain has appeared, and the entire negatives seem more dense than they were originally, and the same good quality print cannot now be obtained as when the negatives were first made.

Mr. A. L. Henderson remarked that there was no reason why an iron or pyro developed plate, if properly fixed and washed and then varnished, should not keep almost indefinitely.

Mr. Henderson asked why should a gelatine plate, intensified with bi-chloride of mercury, become insoluble, even in boiling water, and after it has been reblacked with ammonia or any alkali it should become soluble again.

Mr. S. H. Fry said he had noticed the same thing, but he had still found it insoluble after the reblacking.

The hon. secretary, in announcing the Association's forthcoming competitions and awards, said that the committee had decided that the pictorial competition will be held on the first open night in December, and the pictures must come in a week before. The exact date would be announced later.

The last date for receiving papers for the Henderson award is September 18th, and the decision would be made at a general meeting on October 11th.

The hon. secretary wished it to be made clear that the committee would not take the responsibility of going over all the papers read outside the Society, in the event of any of the papers read before the Association not being accepted, if such papers are not placed before the committee on or before the date given.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

AUGUST 20TH.—

Mr. F. P. Bayne gave a lantern lecture on "Notes on Photographing Natural History Subjects in the Field." Numerous slides of birds' nests, with eggs or young birds, were shown, photographed in their natural positions. Birds, insects, and moths were also shown, and the methods by which the results were obtained were explained.

In the Cobham and Leatherhead outing, on Bank Holiday, Mr. Seaborne and Mr. Mummy were respectively placed first and second.

SOUTHAMPTON CAMERA CLUB.

The members of the above Club met on the 18th inst., under the presidency of Mr. G. Vivian, when an extremely interesting and instructive developing demonstration took place. Six plates had been exposed to the same object, with carefully-adjusted time, under precisely similar conditions. Development was carried out by various members, and a very good set of negatives was produced. The different kinds of developer used were pyro-ammonia, hydroquinone, rodinal, pyro-potash, and cristallos.

The negative obtained with pyro-ammonia was considered to have the advantage of the others, which, however, were all of a good workable character, especially that produced with hydroquinone, which was almost equal to the pyro-ammonia one.

Arrangements were then made for an outing on the 23rd inst. to Shawford, that most enchanting hunting-ground for photographers.

"BEFORE I leave the melodrama of Mont Blanc let me mention another item. In the shops where they sell picture postcards they are now exhibiting several photographs of a particularly gruesome kind. The photographs illustrate the process of bringing the dead down the mountain side. Anything more ghastly it would be difficult to imagine. Everybody who is going up Mont Blanc must see these pictures before he starts. The guides have halted half-way down to be photographed. Some of them have posed themselves; others are smoking pipes. The bodies, wrapped up, are lying on the ground, with the ropes attached to them by which they are being dragged on their awful journey. After this, I am sure you will agree with me that the Chamionards do not look upon Alpine tragedies as likely to injure their business. The guide Blanc, with his frost-bites, his wounds, and his bandages, is already on sale in the shop windows."—"Dagonet" in "The Referee."

New Books.

The Beginners' Guide to Photography. 139 pp. Price, 6d. London: Published by Perken, Son, and Co., Ltd., 99, Hatton Garden, E.C. This very old friend is now in its eighth edition and seventieth thousand—an eloquent tribute to its practical value. The author, "A Fellow of the Chemical Society"—(times out of number we have found ourselves wondering whose identity is thus concealed)—knows his subject thoroughly, and has the rare gift of being able to write down to the intellectual level of the beginner. He deals with the principal branches of photography in a lucid manner, and gives some useful hints on the choice of apparatus.

P.O.P. By A. Horsley Hinton. 134 pp. Price, 1s. London: Published by Hazell, Watson, and Viney, 52, Long Acre, W.C. The author has evidently been at great pains to compile a mass of information relating to the manipulation of printing-out papers, but the book, we think, would have gained by condensation. It consists of eight chapters, the headings of which are as follows:—Introduction, and Paper Described; Printing the Paper; Toning the Print; Variations in Toning; Combined Baths, Fixing, and Washing; Drying the Prints, and Preparation for Mounting; Developing P.O.P. Prints; Collodion Papers—Rapid Printing, etc. "P.O.P." should meet the needs of the beginner, who finds much fascination and mysticism in formulæ. The instructions are given minutely and with a wealth of words that is characteristic of Mr. Hinton, whose reputation, however, can hardly be advanced by such an obvious piece of "bookmaking" as "P.O.P." appears to us to be. Still, it is fair to admit that compilations of a florid kind find much favour with certain classes of readers.

Commercial & Legal Intelligence

MESSRS. H. AND W. GREEN, Rotherham, write: "A Mr. J. Menhinick, in your issue of August 15th, asks about a German mount. If he will send a sample, we shall be pleased to supply him."

THE Imperial Dry Plate Company, Ltd., Cricklewood, London, N.W., write:—"In spite of the large additions to premises and plant which we made in the Spring of 1900, the demand for Imperial plates has again grown beyond our present power of production. To prevent a shortage on the larger and more important sizes, we have for the present stopped making plates smaller than $\frac{1}{4}$ -plate size. We hope to be able to overtake the demand in a few weeks' time, and to supply the small plates by the middle of September. Meantime we are again extending our factory to prevent any delay in execution of orders next year. As we cannot supply small plates, it is impossible for amateurs to enter Class 3 in our Competition; we therefore propose to hold this class over until next year, making the closing date for receiving entries July 31st, 1903, and increasing the prizes from £26 16s. to £50, to be allotted as follows:—One prize of £5 5s.; one prize of £3 3s.; five prizes of £2 2s.; twelve prizes of £1 1s.; thirty-seven prizes of £10s.; total, £50."

RE Frederick Thomas James Morris, 137, White Ladies Road, Clifton, photographer.—The first meeting of the creditors interested under this failure took place at the offices of the Official Receiver for the Bristol District, on August 21st, before the Official Receiver. The summary of accounts showed liabilities amounting to £232 0s. 1d., and assets estimated to produce £235 2s. 2d.; but preferential claims absorbed £56, thus leaving a deficiency of £52 17s. 11d. The Official Receiver's observations were as follows:—The debtor states that he began business as a photographer and stationer eleven years ago, with a capital of £250 or £300 in cash and photographic accessories. He admits that from the commencement he has made practically nothing out of the concern, and that his drawings for personal requirements have only been about £40 per annum. He attributes his insolvency to "keen competition, and the electric trams carrying people past the premises." It is evident from an examination of his stock that it is not likely to realise more than half his estimate, and that he ought to have written off a considerable amount for depreciation some years ago. He has kept a careful record of his receipts and expenditure and ledger accounts with his creditors and debtors, but has never prepared a statement of his liabilities and assets. With the exception of a liability of £20 lent the debtor in the year 1893, and £17 17s. due for undrainable rent, the bulk of the indebtedness is for goods supplied during the past twelve months. Mr. Darley stated that a substantial offer had been made for the lease of the premises and fixtures.

MESSRS. F. YORK AND SON, 67, Lancaster Road, Notting Hill, London, W., have issued their thirty-third annual supplemental catalogue of photographic optical lantern slides, lecture sets, etc., for the season 1902-1903. Messrs. York remark: "From the commencement of our business, the trade quickly appreciated the value of the productions which we introduced. Many leading exhibitors adopted them, and our business was gradually extended from England to all parts of the world, for the reason, we believe, that we have endeavoured to study the wishes of dealers, to conduct our business in accordance with their views, and to spare no expense or efforts to make the best possible productions. We beg to acknowledge the many favours we have received, and to state that we are at all times happy to accept suggestions and carry them out as perfectly as possible. We now submit our thirty-third annual supplemental catalogue, which contains many valuable additions." The catalogue lists the following series:—"Pharaohland. Cairo to Second Cataract." "Pekin: Its Environs, and Forbidden City." "The British Empire in the Twentieth Century." "Wonders of the World." "Con-

stantinople." "Klondyke, and White Pass." "Oxford and Its Colleges—In Chronological Order." "H.M. Men-of-War." "Gas-Making." "Coronation Street Decorations." "Dominion Day at Canada Arch." "Review of Indian Troops by the Prince of Wales." "Return of Lord Kitchener: Passing through Hyde Park." "Coronation Procession." "Coronation Decorations." "The Royal Tour to the British Colonies." "Wit hRoyalty through Canada." "Celebrities."

RE William Henry Parkinson, 115, Newton Street, Bradford, photographer.—The above-named debtor appeared for his public examination at the Bradford Bankruptcy Court, on August 21st, before the Registrar. This debtor was up to 1896 an artist, being in the employment, as principal artist, of a Mr. Ledgard. He then entered into business on his own account, as an artist and photographer, in George Street, Bradford, with £50 capital. In 1892 he removed to Newton Street, his capital by that time having doubled. In 1893 he purchased the freehold for £600, borrowing the whole of the purchase money. His business was at that time prosperous, and he made a comfortable living until two years ago. His turnover then amounted to about £16 a week, but had since, owing mainly, the debtor said, to competition, fallen off by one-half. The principal loss was attributed, however, to depreciation in the value of his property. He filed his petition on creditors beginning to press him, particularly his second mortgagee, who advanced him £650 in August, 1901. The gross liabilities amounted to £1,831, of which £614 was expected to rank for dividend. The assets were estimated at £503, leaving a deficiency of £111. Replying to the Official Receiver (Mr. Binns), the debtor said that, after going to Newton Street, he erected a large gallery in connection with his premises there, for the purpose of doing exhibition work and ordinary work. The Official Receiver: What do you value the property in Newton Street at? Debtor: About £1,200 or £1,300. Would there be any surplus if sold out by auction now?—No. How was it you got so much as £650 lent upon a second mortgage?—It was on the condition that I took Mr. Louis Firth as an assistant, to be paid £3 per week, that his mother lent me the £650. Have you given as much attention to your business during the last three years as formerly?—No, I have not. Is it partly owing to that neglect that your present position has been brought about?—Yes. Have you had dealings with any money-lenders?—Yes. With whom?—With Wolf: I borrowed £100 from him. How much did you receive?—I signed a promissory note for £150. I paid £100, and then I had to pay £50 in a lump sum, which I could not do, and had to re-borrow. I signed again for £150, and got £50. So that you have really got £150, and signed for £300?—Yes, I have paid £190. On the application of Mr. Firth, the examination was closed.

THE extraordinary extent to which photography has become popular amongst all classes during the last decade is evidenced by the enormous capital which large companies have laid out in the manufacture of cameras, plates, papers, and other supplies, so as to render the pursuit less difficult for both professionals and amateurs. Before the introduction of dry plates and ready-sensitised papers, only professionals could, as a rule, undertake photography, which then necessitated the use of wet plates and required considerable chemical knowledge on the part of its exponents. Thanks to the great advance that scientists have brought about, photography, certainly in its essential processes, is now reduced to simplicity, and can without hesitation be taken up by amateurs, who no longer need to fear the intricate methods of other days. The expansion of the wholesale drug business carried on by Sharland and Co., Ltd., at their warehouse in Willeston Street, has rendered it necessary that they should take separate premises in a leading thoroughfare for their photographic supply business, which of late years has very much increased in importance. They have accordingly opened a photographic supply depot in a shop in the "New Zealand Times" Company's building on Lambton quay. The shop has handsome fittings of polished cedar and plate glass, designed by Messrs. Crichton and McKay, architects, and constructed by Messrs. Mainland and Barr. A dark-room is fitted up in one corner of the shop. At this establishment Sharland and Co., who carry a very large stock of photographic supplies, and have always catered for the wants of photographers in the very best manner, have on sale cameras, dry plate, printing papers, mounts, and sundries. The company are sole agents for "Velox" paper, "Planiscope" lenses, "Hypax" hypo destroyer, developing "Cartols," "Mabor" limes for limelight production, the celebrated Goerz anastigmat lenses, and the "Southern Cross R.R." lens. The following cameras are held in large variety:—Rochester Optical Company's "Premo," Watson's, Houghton's, Lancaster's, Miller's "Adelphi" (hand), Eastman's Kodak, Talbot and Eamer's "Miral" (hand), Busch's (hand film), and "Alvista" (panoramic). In addition to those already mentioned, the company has for sale lenses by such well-known makers as Taylor, Taylor and Hobson, Cooke, Watson, Ross, Beck-Steinheil, and Busch. They stock Ilford P.O.P., Wellington and Ward P.C.P., and bromide, and Eastman's bromide papers. The company also make a speciality of mounts, a large assortment of which is carried, representing almost every size and shape used for the mounting of portraits, views, groups, etc. Magic lanterns and microscopes, and parts for them, are another feature. Sharland and Co. have a large connection throughout New Zealand, and they do an extensive postal business. They will shortly issue a new illustrated price list, and any photographer at a distance desiring a copy of it can have one posted to him on application.—"The New Zealand Times."

THE committee of the Hospital for Sick Children, of which the Duke of Fife is president, have made Mr. F. W. Speaight an honorary life governor of the hospital in recognition of his "great and invaluable services" in having designed the Imperial Coronation Bazaar, by which a sum of nearly £25,000 was raised.

News and Notes.

MR. MULLINS, of Ryde, had the honour of sittings from their Majesties the King and Queen and Princess Victoria of Wales, on board the Royal yacht, on Tuesday, 19th inst.

THE Board of Agriculture have made arrangements with the Postmaster General, whereby pocket editions of small-scale Ordnance Survey maps for certain districts will be kept for sale to the public over the counter at head post-offices in some towns in those districts in which there are no agents for the sale of such maps. It is proposed to introduce this system, in the first instance, as an experiment, at the head post-offices in the following towns:—Scarborough, Rochdale, Burton-on-Trent, Scutport, West Hartlepool, South Shields, Luton, Worthing, Pury St Edmunds, Huntingdon, Stafford, Macclesfield, Crewe, Stockport, Ilkley, Richmond (Yorkshire), Driffield, Sittingbourne, Cromer, Ilardvno, Weymouth, Littlehampton, Greenock, Blairgowrie, and Pitlochry. Ordnance Survey maps can at present be ordered through most head post-offices from the depot at Southampton, on prepayment of the postage, but under the new arrangement, which will come into operation at once, copies of small-scale pocket-maps of the districts round the above selected towns will be supplied to the public at the head post-offices in those towns, on application, without any charge beyond the price of the maps.—"The Standard."

JAPANESE Prints.—Mr. Arthur Morrison delivered a lecture on Saturday, in the upper hall at the Whitechapel Art Gallery, on Japanese prints and paintings. He dwelt on the Chinese influence, and drew on a blackboard some of the signs which represent, not letters, but ideas—as "mountain," "horse." They have been conventionalised so that they can be written by the simple, and Chinese and Japanese can make themselves understood, though they know not a spoken word in common. Mr. Morrison said that his task was a difficult one, because the art of Japan was extremely conventional. The painter of a picture of a woman aimed less at making a likeness than at suggesting something of the grace of all the women in the world. On the other hand, the Japanese object very strongly to the average European portrait, deeming it grotesque and deliberately ugly. Mr. Morrison explained the process of colour printing, and showed a design by Hokusai, which had not been destroyed in the engraving, because the "Old Man mad on Painting" died before he could indicate the colour scheme. With regard to some of the painters, he made assertions which were a little difficult to accept, though they were obviously the result of the minutest study. He held that important pictures were often painted in anywhere from five minutes to half-an-hour. He mentioned that the oldest painting now in Japan was the work of a Korean priest, dating from the Seventh Century. Then he told how Moronobu revived the idea of depicting scenes of common life and obtained at once a host of followers. To begin with, the prints were done in black and white. Then they were occasionally coloured by hand. After a time the idea of colour-printing occurred to certain artists, and results were obtained which have never been equalled in the history of art. At first no more than two colours were used, but it would puzzle most people to decide how many blocks go to the making of a print after Haranobu. Mr. Morrison touched lightly on the work of the artists of the popular school, and explained that their work was done for the people—a sort of equivalent of the latter-day halfpenny evening paper. He told the story of Hokusai and of how he painted the monster picture, his pupils attending with buckets of paint, in order to flabbergast those who had said that he could only work in miniature. Then he dwelt on the lamentable falling off which followed the death of Toyokuni and the introduction of aniline dyes. Afterwards Mr. Morrison descended to the room where the loan collection of prints is exhibited, and commented on most of the examples.—"The Morning Post."

THE British Academy.—Last January we published the petition presented to the King for the incorporation of the British Academy for the Promotion of Historical, Philosophical, and Philological Studies, and the names of the distinguished signatories, fifty-one in number. These were contained in the "London Gazette" of January 14th, and it was announced that the petition had been referred to a committee of the Privy Council. His Majesty has now been pleased, acting upon the advice of this committee, to accede to the petition and to grant to the British Academy a Royal Charter. This states that the Academy aims at the promotion of the study of moral and political sciences, including history, philosophy, law, politics and economics, archæology, and philology. Of the original fifty-one petitioners, who, according to the draft charter, were to be the first Fellows of the Academy and to elect a president and council from among their own number, three have died—Lord Acton, Mr. S. R. Gardiner, and the Rev. A. B. Davidson. On the other hand the name of Lord Rosebery has been added to the list, so the following forty-nine gentlemen now become the first Fellows of the British Academy:—The Earl of Rosebery; Viscount Dillon, President of the Society of Antiquaries; Lord Reay, President of the Royal Asiatic Society; Mr. Arthur Balfour, M.P.; Mr. John Morley, M.P.; Mr. James Bryce, M.P.; Mr. Lecky, M.P.; Sir William Anson, M.P., Warden of All Souls College, Oxford; Sir Frederick Pollock, Corpus Professor of Jurisprudence in the University of Oxford; Sir Edward Maunde Thompson, Director and Principal Librarian, British Museum; Sir Henry Churchill Maxwell-Lyte, Deputy Keeper of the Public Records; Sir Courtenay Ilbert; Sir Richard Jebb, M.P.; Regius Professor of Greek

in the University of Cambridge; Dr. Monro, Provost of Oriel College and Vice-Chancellor of the University of Oxford; Dr. A. W. Ward, Master of Peterhouse and Vice-Chancellor of the University of Cambridge; Dr. Edward Caird, Master of Balliol College, Oxford; Dr. H. F. Pelham, President of Trinity College and Camden Professor of Ancient History in the University of Oxford; Dr. John Rhys, Principal of Jesus College and Professor of Celtic in the University of Oxford; the Rev. George Salmon, D.D., Provost of Trinity College, Dublin; Professor J. B. Bury, Regius Professor of Greek in the University of Dublin; Professor S. H. Butcher, Professor of Greek in the University of Edinburgh; Professor Ingram Bywater, Regius Professor of Greek in the University of Oxford; Professor E. B. Cowell, Professor of Sanscrit in the University of Cambridge; the Rev. William Cunningham, D.D.; Professor Rhys Davids, Professor of Pali in University College, London; Professor Albert Dicey, K.C., Vinerian Professor of English Law in the University of Oxford; the Rev. Canon S. R. Driver, D.D., Regius Professor of Hebrew in the University of Oxford; Professor Robinson Ellis, Corpus Professor of Latin in the University of Oxford; Mr. Arthur John Evans, Keeper of the Ashmolean Museum, Oxford; the Rev. A. M. Fairbairn, D.D., Principal of Mansfield College, Oxford; the Rev. Robert Flint, D.D., Professor of Divinity in the University of Edinburgh; Mr. J. G. Frazer; Mr. Israel Gollancz, University Lecturer in English in the University of Cambridge; Mr. Thomas Hodgkin; Mr. S. H. Hodgson; Professor T. E. Holland, K.C., Professor of International Law and Diplomacy in the University of Oxford; Professor F. W. Maitland, Downing Professor of English Law in the University of Cambridge; Professor Alfred Marshall, Professor of Political Economy in the University of Cambridge; the Rev. J. E. B. Mayor, Professor of Latin in the University of Cambridge; Dr. J. A. H. Murray; Professor W. M. Ramsay, Professor of Humanity in the University of Aberdeen; the Rev. Canon William Sanday, D.D., Lady Margaret Professor of Divinity in the University of Oxford; the Rev. W. W. Skeat, Erlington and Bosworth Professor of Anglo-Saxon in the University of Cambridge; Mr. Leslie Stephen; Mr. Whitley Stokes; the Rev. H. B. Swete, D.D., Regius Professor of Divinity in the University of Cambridge; the Rev. H. F. Tozer; Professor Robert Yelverton Tyrrell, Professor of Ancient History in the University of Dublin; and Professor James Ward, Professor of Mental Philosophy in the University of Cambridge.—"The Times."

FLASHLIGHT Pictures with Kodak Cameras.—The invention of the flashlight apparatus renders the taking of photographs at night easy with such a camera as the No. 1A Folding Pocket Kodak. The requisites are:—The Kodak; the flashlight apparatus; 1oz. of flash powder. The flashlight apparatus consists of a specially-constructed spirit-lamp, having in front of it a little tray upon which is poured a teaspoonful of flashlight powder. A rubber tube, attached to a blowpipe in the flame of the lamp, conveys a blast of air from the bulb held in the hand, and serves to project the powder into the flame of the lamp when it is desired to take a picture. As soon as the powder touches the flame it flashes up an intense white light, sufficiently strong to make a picture instantaneously. Many interiors can be taken with the flashlight that are impracticable by daylight, either by reason of a lack of illumination, or because there are windows in the direct line of view which cannot be darkened sufficiently to prevent the blurring of the picture. Pictures are taken so quickly that groups of people round a dinner-table or card-table can be taken as clear and sharp as if they were in the open sunlight. This enables the photographer to obtain souvenirs of many occasions which could not otherwise be easily secured. *Photographing a Room.*—The camera should be prepared for time exposure, as directed on page 20 of this manual, and placed on some level support or where it will take in the view of the room desired. *Preparation of the Flashlight.*—The light should always be placed 2ft. behind and 2ft. to 3ft. to one side of the camera. If placed in front, or on a line with front of Kodak, the flash would shine upon the lens and fog the picture. It should be placed at one side as well as behind, so as to throw a shadow and give a little relief in the lighting. The lamp should be at the same height or a little higher than the camera. The support upon which the lamp is placed should not project far enough in front of it to cast a shadow in front of the Kodak. A piece of cardboard a foot square placed under the lamp will prevent any powder from the flash doing damage. A sheet of white cardboard set up behind the flash-lamp will act as a reflector and increase the strength of the picture. *Taking the Picture.*—Having the camera and lamp both in position, load and light the lamp according to the directions furnished with it, pouring upon the tray the required quantity of the powder; then set the shutter open, stand at arm's length, and press the bulb. There will be a bright flash, which will instantly impress the picture on the sensitive film. Then push the lever to close the shutter, and turn a fresh section of film into place with the key, ready for another picture. *The Powder.*—The amount of powder required to light a room varies with the distance of the object farthest from the camera, and the colour of the walls and hangings. When more than one tea-spoonful is to be used, all the powder should be poured in one pile on the tray. *Table.*—For 10ft. distance and light walls and hangings use 1 even teaspoonful; for 10ft. distance and dark walls and hangings use 2 even teaspoonfuls; for 15ft. distance and light walls and hangings use 2 even teaspoonfuls; for 15ft. distance and dark walls and hangings, use 3 even teaspoonfuls; for 25ft. distance and light walls and hangings use 3 even teaspoonfuls; for 25ft. distance and dark walls and hangings use 4 even teaspoonfuls. *To Make a Portrait.*—Place the sitter in a chair partly facing the camera (which should be at the height of an ordinary table) and turn the face slightly towards the camera. The proper distance from the camera to the subject can be ascertained by looking at the image in the finder. For a

three-quarter picture this will be 8ft., and for a full figure 10ft. The lamp should be on the side of the camera, away from the face; that is, the sitter should not face the lamp. The lamp should not be placed higher than the head of the sitter. *To Make a Group.*—Arrange the chairs in the form of an arc, facing the camera, so that each chair will be exactly the same distance from the camera. Half the persons composing the group should be seated, and the rest should stand behind the chairs. If the group is large, any number of chairs may be used, but if any of the subjects should be seated on the floor, care should be taken that the limbs are not extended towards the camera, because the perspective would be too violent. *Backgrounds.*—In making single portraits or groups, care should be taken to have a suitable background against which the figures will show in relief; a light background is better than a dark one, and often a single figure or two will show up well against a lace curtain. For larger groups a medium light wall will be suitable. The finder on the camera will aid the operator to compose the group so as to get the best effect. In order to make the image visible in the finder, the room will have to be well lighted with ordinary lamp-light, which may be left on while the picture is being made, provided none of the lights are placed so that they show in the finder.—From "Picture-Taking with the 1A Folding Pocket Kodak."

Correspondence.

BACKGROUNDS.

To the Editors.

Gentlemen, — Referring to Mr. Baldock's illustrations of, and article upon the influence of, backgrounds, it has struck me that it would be interesting to know precisely the effect on the density of the image by the substitution of a black for a white background. Of course, this would be a matter for experts in their measurements, and would require some sort of standard for the tint of the subject photographed and for the backgrounds used, as well as the area of each respectively. It was common knowledge in wet-plate days that more density was gained by photographing in front of a dark screen than in front of a white one, but the explanation seemed then to lie in the fact that the free silver from the whole surface of the plate was, when mixed in the developer, reducible on a smaller area, with a black background, and therefore became a thicker deposit. This explanation would not be applicable with the alkaline developer, and the reason of increased deposit, if proved, would have to be sought for elsewhere.—Yours truly,

SENEX.

August 22nd, 1902.

THE GOERZ LECTURES.

To the Editors.

Gentlemen,—Would you be good enough to announce in an early issue of your paper that I shall this season have three lectures to place at the disposal of photographic societies.

They are called respectively "The Photographic Lens," "What can be done with a Hand Camera," and "How a Lens is Made." They are illustrated by a number of lantern slides varying in number from 50 to 100. The first is a new lecture this season, and deals exclusively with the work of the photographic lens.—Thanking you in anticipation, I am, dears Sirs, yours faithfully,

C. P. GOERZ.

4 and 5, Holborn Circus,

London, E.C., August 26th, 1902.

THE PROBLEM OF PORTRAITURE IN COLOURS.

To the Editors.

Gentlemen,—The pessimistic article under the above heading in your last issue calls for an antidote, as it might act as a deterrent on some who would otherwise be inclined to attempt portraiture in colours.

As to the colour screens, carefully worked glass is quite unnecessary, for if the screens are placed in contact or close to the sensitive plate, then an ordinary dry plate on glass, free from flaws, can be freed from the silver salts and stained and successfully used.

The making of three negatives exactly similar is an easy task, if the time development system, suggested by Mr. Alfred Watkins be adopted, and why this should be rendered difficult by the use of coloured screens, necessitating different exposures, all of which would be the so-called "correct exposure," I cannot see. Your contributor seems to imagine that it is difficult for the average professional photographer to gauge different exposures and to be ignorant of the science of developing.

As regards the studio, I am certainly opposed to the view of Mr. Kenah, nor can I for one moment grasp why "we should have to make a fresh adjustment of our apparatus, on account of the peculiarities of the light in the studio." May I ask what are the particular peculiarities to which allusion is made? Assuming that the average professional photographer keeps his glass clean, the only effect, if it were not coloured, would be a suppression or absorption of the troublesome ultra-violet rays and a little loss of general intensity, and actual spectrum composition would not be altered.

What is the particular disadvantage in working with the lens at full aperture, and thus obtaining an out-of-focus background? As a rule, large apertures are generally considered desirable in a studio.

In Dr. Mieth's case, the total exposure was $5\frac{1}{2}$ seconds; assuming that work in the studio required an increase of six times, would 33 seconds be impracticable?

If one can reproduce colours correctly, there should be no greater difficulty in reproducing greys, and it is an open question whether greys do predominate in sitters of the present day.

As regards the positive work, Mr. Kenah seems to totally ignore the possibility of obtaining prints on paper by any other means than the half-tone process. Possibly, he has not heard of the trichromatic carbon tissues of Hoffmann. Personally, I see no difficulty in preparing similar tissues, and it might be possible to use the transparent trichromatic ink powders of Messrs. Fleming or else the synthetic colour powders of Hazura and Heuza. Further, with the new process, for such portraiture in colours would be to the public, there would be no difficulty in using opal glass, ivory, or celluloid as support instead of paper, and these would fetch a higher price.

I am convinced that no photo-mechanical process would be accepted by the public, except perhaps photogravure. The cheapening of illustrated literature and universality of three-colour illustrations, execrable though they be, would deter the average sitter from paying even half-a-crown for a dozen C.D.V. prints, though perfect in their colour rendering.

As regards the McDonough-Joly process, this is certainly not the process for the professional, notwithstanding the advantage of one negative and a brief exposure. Far better results are likely to be secured by using the stained and superimposed film process on celluloid or ivory.

I think that "hasty and ill-advised" statements, such as Mr. Arthur V. Kenah's, are decidedly to be deplored.—I am, yours, etc.,

E. J. WALL.

DRIVEL.

To the Editors.

Gentlemen,—Drivel is an expressive word, which well expresses a mental process, closely akin in derivation to dribble; the concrete simile of the inconsequent dribbling of an infant is closely paralleled in the abstract by the mental dribbling of many writers in photographic journals.

The "oily polloi" in the republic of photography are often swayed by the blatant oratory of some dogmatic demagogue, and are content to allow such an one to form their opinions. There is too great a tendency to chatter, too little writing that is educative. The majority of the papers to which the photographic babe turns for maternal sustenance seem content to "suckle fools and chronicle small beer," without attempting to train their progeny.

It is saddening to read an article crowded with petty details as to bicycle lamps, bicycle tyres, the improvisation of a dark room by blocking out the actinic light from a bath-room window, etc., etc., *ad nauseam*, and when one finds such an article under a name which is deservedly held in high repute, in matters affecting photographic chemistry, "drivel" is not too forceful a term by which to designate such puerilities. One reads criticisms—so-called—of pictorial photography which tend to shake one's faith in the value of honest criticism, so illogical and contradictory are they.

Shrieking diatribes are penned which simulate the inconsequent

scribblings of an hysterical woman, in their false premises and unfounded assertions, products of an ill-balanced brain, for which the writer is hardly to be held responsible. Yet such vapourings are published, an act which flatters the scribe and furnishes cheap copy for the editor, but "degrades the high lights" of photographic journalism. One reads with increasing disgust that type of paragraph which gives minute instructions upon "the uses of a piece of string"; why not with an equal amount of logic give detailed instructions upon "the use and advantages of soap in the morning tub?"

Valuable as such information may be to the crassly ignorant, who among the readers of our photographic papers is so devoid of plain mother-wit as to need instruction on such a technical point (?) point.

In conclusion, let us hope that in the immediate future there will be an increase of virile writing in the photographic Press, typical of a man in his prime and an absence of the emasculated type which one always associates with physical and mental senility.—I am, yours,
ANTI-DRIVEL.

H. T. Lloyd, 26, Earl Street, Coventry. Photograph of portion of Godiva Procession.
A. Miller, Barrhill Road, Old Cumnock, Ayr. Two photographs of Lord Bute.
"A. LEARNER."—Good results are obtainable with the system mentioned.
G. R. (Corfu).—It is, we believe, a Berlin company, with branches in England and America.

CAMERA.—(1) The address, we believe, is Great Windmill Street, London, W. (2) We have not kept particulars of the publications; any large bookseller would obtain them for you.

OLD NEGATIVES.—"NEGATIVES" says: "Having several gross of old negatives to dispose of, we shall esteem it a favour if you can give us the name of anyone in the London district who purchases same."—In reply: We do not know of anyone who purchases such things. Old negatives are generally looked upon as being valueless, as they are not worth cleaning off for the glass they are on.

SUNSET PICTURES.—"YOUNG Pro" says: "During this month I shall be touring along the coast, and am very anxious to secure a good sunset negative by the seaside. I should therefore be obliged to you if you will kindly instruct me how to do so."—In reply: Space is too limited in this column to give such full instructions as are often desired. We should, however, suggest that orthochromatic plates, backed, be employed, and with a colour screen as occasion may require. Care must be taken that the sun does not enter the lens.

COPYRIGHT QUERY.—DAVIES AND SON write: "May we ask you to be kind enough to let us know whether a Mr. — has copyrighted certain views of Aberayron and neighbourhood? We beg you to be so kind as to supply us with this information as soon as possible."—In reply: The only way by which we could answer this question would be by searching the register at Stationers' Hall. Our time is, of course, much too fully occupied for us to do this. The register is open to any to make a search.

PURCHASE OF BUSINESS.—"UNCERTAIN" says: "I should feel obliged if you would give me some information on the following subjects:—I am about to buy a business (photographing). (1) If, after my buying a business, with all fittings, can the creditors of the seller lay any claim on the business or stock? (2) If a seven years' agreement, written out by the landlord, and stamped at Somerset House by me, be binding?"—In reply: (1) No; unless a fraudulent sale can be established. (2) Yes. But it will be well for you to thoroughly consider the terms of the agreement before signing.

BURNISHING.—"BURNISHER" says: "I have just bought a photo-burnisher, one with steel bar heated by gas. I believe the prints have to be lubricated before burnishing. I should be glad of formula for lubricant, and also the heat required. Do prints require much

pressure? Any information on the subject would be most welcome."—In reply: Rub the prints over with a solution of Castile soap in alcohol (about a grain or two to the ounce). The bar should be quite as hot, or a little hotter, than the hand can bear. A good pressure is required to get a good polish.

UNSATISFACTORY VIEW.—"INCLINE" writes: "Enclosed is a photograph of a very steep incline. The weight of the empty tub is drawn up by the full one going down, with a man at the top to regulate speed. The photo gives the impression of a very gentle slope instead of being steep. The lens used was a wide angle Zeiss Anastigmat. Kindly say, if you can, what is the cause."—In reply: Evidently the camera was not level at the time the photograph was taken. It would have been better if the camera were further back and a lens of longer focus used. Also if less foreground had been included.

CAMERA WANTED.—"BEGINNER" writes: "I have a fine ¼-plate Anastigmat lens, and I want a good hand and stand camera. I prefer the folding type, but would be guided by you. What should be considered essential in the camera, and what type would be best? I think I prefer separate slides to magazines, unless the latter were best. If you can give me advice, I shall be obliged."—In reply: It is quite a matter of choice as to whether you have a camera with slides or a magazine one. Some prefer one form and some the other. There are plenty of good ones of both types now on the market, and we should advise you to get the catalogues of the leading makers and make a selection from them. It is against our rule to recommend any particular maker's goods.

MAKING P.O.P.—J. B. says: "I am making my own P.O.P., but cannot avoid small bubbles; in fact, quite 50 per cent. of the sheets are rendered useless from this trouble. It is the usual gelatino chloride formula, and the heat I have been working at has been 120deg. The room I have worked in has been about 70deg., and the room in which I have stored my Baryta paper has been about 65deg. Can you tell me how to avoid this? I enclose two pieces for your inspection. I have been most careful in floating it, and do not think the cause lies in this."—In reply: The defects are clearly due to either air bubbles on the surface of the emulsion when the paper is floated, or they get imprisoned between at the time it is floated. The remedy is to see that neither happens. It is simply a question of care.

FAULTY LIGHTING.—"AMSET" says: "I want to photograph an object, of which I send you an unsatisfactory photo. How should I proceed? The centre plaque, with the objects on it, is covered with a very convex glass—made of very inferior glass. I am not allowed to remove the cover glass. I have tried direct side light, but as I only get one side illuminated, the result is very unsatisfactory. The enclosed print shows where the light has been reflected back from the cover glass. I tried also photographing in a room very dimly lighted, but I got such a faint image of the bronze mount that the photo is useless. I shall be obliged for any hint you can give me."—In reply: It is simply a question of judiciously lighting the subject, and there are no set rules for doing that. It is merely a matter of skill and judgment; to avoid the reflections, bearing in mind that the angle of reflection equals the angle of incidence. Probably the faint image of the bronze mount, when the photograph was taken in the room, was due to under-exposure. We should advise you to try with an isochromatic plate, backed, and with a yellow screen.

* * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published early in December next. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The edition for 1903 will be increased to 25,000 copies, a large number of which are already ordered.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1903. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances

will be recorded, and wherever practicable new features of an informative nature will be added.

Secretaries of societies will oblige us by promptly forwarding lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, etc. Those firms who wish to take advantage of this feature should communicate with us not later than October 31.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRA.

Incandescent Bulb Risks. A few weeks ago we called attention to the danger incurred by placing electric glow lamps in too close proximity to textile fabrics. A case of accident has since been reported which shows, in a most conclusive manner how real is the danger to which we referred. In this case a number of 16-candle power lamps, of the familiar pattern, were enveloped in raw cotton, and very shortly after the current was switched on and the lamps lighted the material began to smoke. When a draught of air was purposely admitted to see what further would happen, the cotton at once burst into flame. From an examination of the bulbs, it would seem that the heat from the incandescent filaments, not being able to radiate into space as it would have done had the lamps been left uncovered, accumulated until it was sufficient to soften the thin glass, which caved in, and became hot enough, by its nearness to the filament, to fire the cotton. The careful man will profit by this experience; but it is easy to predict that others will plead that they know the danger, and are not in the habit of placing lamps where they will do mischief. But now that it is such a common practice to use these lamps in connection with leads which can be shortened or lengthened at will, a lamp can easily by accident be brought into dangerous company. When such a lamp is covered with coloured varnish, as is often the case, for use in a photographer's dark room, the dangers incurred by ignition of surroundings are proportionately increased.

* * *

A Finger Shield. An advance sample of a very useful little implement has just reached our hands, and we have put it to one or two tests, from which it has come out in a satisfactory manner. It consists of a

corrugated rubber finger stall, which will be presently put upon the market at the modest price of one penny. Its primary object is to protect the fingers of readers in public libraries, and elsewhere, whose duty—or pleasure!—involves the turning over of many soiled leaves of books and journals. It is the unfortunate practice of many to wet the finger in order to get a better grip of the paper, and it is not inconceivable that by such means the infection of certain diseases may be carried from one person to another. As we happened to have some reference work on hand, we put on this new finger stall, and found that it gripped the leaves well, and proved to be a very cleanly thing in use. We shall certainly continue to use it whenever we have such work in hand. We think, too, that it will be especially useful to those who have much handling of glass, as in plate-making factories, for a finger covered in this way has a much better hold of the material, while risk of cutting the flesh with a sharp edge is altogether avoided. India-rubber finger stalls for dabbing in chemical solutions are, of course, as old as the hills, but here we have one with a roughened surface, which enables us to get a clinging hold upon slippery materials.

* * *

Portable Buildings.

There is to be seen, for a few weeks, on a piece of vacant land at the back of the Imperial Institute, South Kensington, a portable wooden house, containing four spacious rooms, which should be visited by all photographers, whether amateur or professional, who may require a portable studio or an extension of the premises which they already devote to their work. This house has been erected as a specimen of Silbiger's transportable and transformable system of building, and when we explain that the erection was put up in a few days by inexperienced hands, and without the use of tools, it will be seen that the method has much to recommend it. The sole necessity is a piece of levelled ground upon which the house can be erected. Every part of the building is interchangeable, so that when once the framework is set up, doors, windows, or blank panels can be fitted, in any position required. The partitions separating the rooms can also be varied to suit any needs, so that a room can be made smaller or larger with very little trouble, and its doors and windows shifted at pleasure. We can imagine no better system than this for the professional who wishes to extend his workshop area by the provision of extra enlarging rooms, or apartments devoted to any other purpose, or for the amateur photographer who desires to keep his photographic operations distinct from his dwelling-house, without going to the serious expense of a brick and mortar building. We are informed that buildings of any length and up to 30ft. in width can be constructed by this method. A large house can be converted by means of a few extra pieces into several smaller houses, or a large hall into several rooms, and *vice versa*. Factories have been erected in France, Russia, Germany, and Austria on this principle, as well as in more distant parts of the world. A prospectus which has been handed to us gives a number of half-tone blocks of these portable houses, applied to a number of different purposes, such as bungalows, field hospitals, barracks, chapels, and the like. The houses are perfectly weatherproof, and can be made fireproof, and even guarded against the encroachments of those terrible white ants, which, in various parts of the world, are so destructive to ordinary woodwork. The builders are Messrs. Farquharson, of 85, Gracechurch Street, E.C.

* * *

P.O.P.

"Imitation," we learn, "is the sincerest form of flattery," but it is certain that it is more often prompted by the love of filthy lucre. Every

trader knows well enough that, as soon as he hits upon a thing which succeeds with the public, a number of imitations are at once thrown upon the market. It is the same in the publishing business, and here is an example. Some time ago a journal was published with the unique title "M. A. P.," meaning "Mainly About People." Another one is now launched on the sea of public approval called "P. O. P.," having the much-strained sub-title of "Point on People." It at once suggests a community stuck over with pins, or lightning conductors, but there is another suggestion with regard to it which will possibly occur to photographers. It may be a fortuitous accident, but the fact remains that by adopting this title, the proprietors get a kind of vicarious advertisement through thousands of packets of "P. O. P." which are sent broadcast to professional and amateur photographers, and appear in our own and other pages. If this result has been foreseen it is an exceedingly smart piece of business, but it is not original. Many years ago, when the well-known hostelry at the bottom of Tottenham Court Road was in the course of erection, it occurred to the proprietor thereof to give the place a bold and mystic advertisement by posting all over London a picture of an enormous horseshoe. There were no letters or other indication of what it referred to, nothing but this big horseshoe staring one in the face from every hoarding. And at that time of day pictorial posting was in its infancy, so that this picture was actually aggressive. Everyone was asking what this mural decoration might mean, and the sharp proprietor of one of the minor theatres thought that it would be a good notion to take advantage of the common curiosity. So, with the help of a ready writer, he started a big melodrama with the title "The Horseshoe." We never saw it, nor can we call to mind whether or not it was a big success, but the vicarious nature of the advertisement was undoubted. Of course, the Simon Pure of Tottenham Court Road had no redress for the cream thus skimmed off his milk, and in the more recent case the makers of P. O. P. cannot complain. After all, they may get a little reflected advertisement from the title of the paper which apparently hopes to obtain the same from them.

* * *

Light from Aluminium.

Magnesium has done yeoman service for photography in furnishing operators with the means of lighting up dark places which could hardly have been photographed without its aid. Coal and other mines hundreds of yards below the light of day, caves deep down in the bosom of the earth, inscriptions in rock-cut temples, and many other hidden things have been made plain by means of the flash light. It was pointed out some years ago that Aluminium might answer the same purpose as magnesium for this particular service, but the latter metal has retained its place in the affection of photographers. But that aluminium is capable of furnishing a white light of extraordinary brilliance and splendour has long been known to visitors to the Crystal Palace firework displays, in which Messrs. Brock have been using it with wonderful effect. On the night of the Shah of Persia's reception at Sydenham, some hundred-weights of the metal must have been employed, judging from the marvellous blaze of silvery light in which the grounds were enveloped. It would be impossible to exaggerate the beauty of the scene when feathery streamers of Aluminium fire rose up in every direction, and when the water temples seemed to be flowing with liquid silver. This was quite a new item in the programme. Fireworks which, we trust, will be repeated. The metal used for firework purposes is

such impalpable powder that it flies about as a fine dust when handled, and settles upon the clothes, and is therefore very different in condition to the far coarser magnesium powder commonly used by photographers. It clings to the fingers, and covers them with a coating like silver, and the very fineness of the particles causes them to cling together in clots. It is therefore evident that the ordinary flash-light apparatus employed for magnesium would not answer for aluminium, unless the latter were mixed with some substance which would separate the tiny spangles of the metal, and so enable them to mix freely with air, and burn. Lycopodium, or powdered resin, would, no doubt, answer the purpose well, but we doubt whether the metal so adulterated would give the brilliant flash associated with magnesium. Aluminium should, however, be very useful in places where a time exposure is allowable, and it will be found that by mixing it with certain ingredients it will burn well and quietly in a thin paper case. We have tried a few experiments with it, and find that a very brilliant light is obtainable by mixing one part of aluminium with an equal weight of saltpetre and barium nitrate, together with one-third part of dextrine, and one-sixth of sulphur. These quantities are approximate, and no doubt as good or better results may be obtained by additions to or subtractions from the formula here given. A couple of turns of thin paper round a pencil, with the edge fixed down with starch, makes a suitable case for the composition, but of course if a big illumination is wanted the size of the case must be proportionately increased. The mixture gives off, when ignited, very little smoke, and this is an advantage not possessed by many of the pyrotechnic compounds which have been employed for lighting up dark interiors.

* * *

Monotyping. There are many persons who never seem satisfied with the ordinary ways of doing things, but, with a restlessness peculiar to them, must find out new methods. Such a trait, under proper control, is extremely useful to humanity at large, for from it springs the inventive faculty; but when this desire for change is applied to anything and everything it may be voted a nuisance. The other day we had to chronicle a new process of oil-painting, in which brushes were dispensed with, and the soft paint was made up into sticks, to be rubbed against the canvas. What can be the object of such a procedure unless it be notoriety, and a very ephemeral and worthless one, for the contriver thereof? And now there is brought forward another new process—if it can be dignified by such a respectable word, called “monotyping,” which its advocates speak of in hushed tones, as a new means of artistic expression. It is described and illustrated in the current number of the “Studio.” Professor Von Herkomer seems to have discovered this comparatively new thing, for he writes: “When I visited America in 1885 I was shown by an American artist a form of work, at that time quite new, of painting on a copper plate with printing ink, and then ‘blotting’ it off on the paper by means of a printing press. I found it a fascinating kind of work, so suggestive and expressive without labour, that I felt a regret that the plate should only yield one impression.” We will now give a rough outline of the method adopted in monotyping, the chief advantage of which process seems to be that the picture is done at one sitting, for the work must be completed while the plate is wet. If need be, however, the necessary softness of pigment can be retained by immersing the plate in water. A smooth, polished plate of copper is covered with a thin coating of oil paint, which must not be too oily. (As we under-

stand it, the plate must be rolled up with an oily ink in the same way that a collotype is treated.) “The picture is then worked out of this, with thumb and finger, brushes or rags, and bits of wood or twisted paper for taking out the high-lights.” In other words, you wipe off the greasy pigment when you want your high-lights, tickle it with a brush for your half-tones, and leave it untouched for the shadows. Then, passing this plate through a press, with a piece of Japanese paper above it, you secure your one, and only, impression, which gives the precious process its name—“monotype.” The illustrations to the article from which we have quoted are not bad, but they would be much better if executed by ordinary methods and with common tools. What advantages this new and extremely dirty method possesses we fail to see, but we are quite alive to its drawbacks when compared with more legitimate ways of going to work. Why not at once draw on a lithographic stone, and secure those exquisite gradations of tone which the grain of the mineral secures, while, at the same time, any reasonable number of copies can be had from the one drawing? Why choose a method by which the original drawing is reversed? In a word, why not use pencil, crayon, brush, or any other of the ordinary tools of the artist procurable at the shops, and use them in the way which experience has long ago prescribed? Echo answers, “Why not?”

* * *

Submarine Photography. A certain coroner was lately alleged to have remarked that he never believed the newspapers, that they were full of falsehoods, and that if he was presented with a sovereign for every lie which had been printed with regard to himself he would be able to retire into private life. We read this sad pronouncement, and, after thanking the gods that we are not as other journals are, we turned to a fresh page, and came upon a paragraph which at once rivetted our attention, while still the coroner’s warning words seemed to creep in through the rivet-holes. The paragraph was headed, “Submarine Snapshotting,” and it opened with the astounding statement that the said submarine snapshotting was likely to become a popular pastime. Visions were immediately conjured up, in a perhaps too fertile brain, of visitors to Margate, Ramsgate, Sandgate, and all the other gates donning bathing costumes, or doing without them, diving beneath the surface of the briny ocean with cameras in their hands, and snapshotting one another, posed as mermen and mermaids amid the rocks below. But we were too precipitate. The pastime has not yet arrived at the popular stage; it is only going to. At present it is more in the academical condition, for we read on further that “A well-known scientist, who began by investigating the animal life of the waters, has become an enthusiastic sea-bottom camerist.” We must pause to congratulate this gentleman, whose inherent modesty prevents his name being revealed, on attaining to the dignity of this remarkable title. Some men are proud of being made a C.B. or an F.R.S. or a D.C.L.; but here is a man who excels all in being able to place after his name the majestic title, “Sea-bottom camerist.” We learn, further, that he has lately published some of his remarkable photographs of submarine scenery, and we can only express our regret that the name of the publisher is withheld from us. He uses, we are told, a hand camera, enclosed in a tight copper box, having a plate-glass window, and it is mounted on a cast-iron tripod. “When is a hand camera not a hand camera?” is the conundrum that we are inclined to ask, the obvious answer being, “When it is fixed to a cast-iron tripod.” We presume that the S.B. camerist also carries

with him a steam or hydraulic crane to lift this cast-iron concern in and out of the water; but we are not told so. We are, however, informed that suitable mechanism is provided to expose and change the plates. The difficulty with regard to water pressure at a depth of from 20ft. to 30ft. is surmounted by squeezing air into the apparatus from a rubber ball! We are next told that light fades rapidly in these depths, daylight exposures being impracticable at a depth of 25ft. In order to meet this difficulty, daylight is altogether dispensed with, and magnesium powder is burnt in oxygen "in a suitable glass globe." The wonderful account closes with the remark that "by this powerful illumination instantaneous exposures are made, with interesting results." The paragraph is disappointing, because it follows the fortunes of the instrument rather than those of the sea-bottom camerist. We want to know what becomes of him while the picture is being taken. Does he go down with the cast-iron work, and share the oxygen with the magnesium lamp, or breathe some of the air out of the rubber ball; or does he merely focus the camera, and set the shutter and so on from a boat thirty feet above? In either case, the man is a positive genius.

* * *

Sundials. It is difficult to realise the condition of things when watches and clocks were unknown, and when people had to depend upon sundials—"the wayfarer's time-tellers," as they have been called, when they wanted to find out the time of day. Such dials may still be seen in old gardens and on the southern porches, or the towers, of old churches, and some of these are so quaint and picturesque in appearance that a collection of photographs of them would be a very good object for anyone who travels much about the country to aim at securing. Many of our old dials bear quaint inscriptions, either in Latin or English, most of them referring to the quick flight of time, and the necessity for looking towards another life. Not a few bear an obvious pun, which has no doubt been a source of hilarity to many a generation of rustics. This hoary and oft-repeated jest consists of the words, "We must—" the rest of the sentence being represented by the dial; i.e., "We must 'die all.'" There is a fine sundial in the Temple, London, with the motto, "Shadows we are, and like shadows depart." In the garden form of time-keeper, the dial lies horizontally, and is often supported upon a most picturesque stand or pedestal, and in some cases they are placed on the bases of ancient churchyard crosses. A notable example of a garden sundial stood on the grass at Clements' Inn up to the time that the Law Courts were built. The pedestal consisted of the life-size figure of a stooping negro. We wonder what has become of that statuesque nigger? Sundials are not correct time-keepers—or, rather, we should say that a dial gives the actual clock time only upon four days of the year—and sometimes it is as much as sixteen minutes out in its reckoning. So that the motto which stands on a certain old dial in Yorkshire, "Who dares to say the sun speaks false," is open to question. It falls to the lot of some of us to pass at intervals by one of these old dials, and instinctively we each time compare it with our watch. Seldom do we find the two timekeepers in agreement, and we know well enough that this is because the solar day varies in length, while the twenty-four hours ticked out by a clock do not vary. In other words, the sundial gives the "apparent" time, while the watch gives "mean" time. A new form of sundial has lately been invented by Major-General Oliver, C.M.G., which is a great improvement upon the old model, in that it gives the actual time as denoted

by a watch. It has none of the picturesque setting, or the old-world appearance of those ancient dials to which we have called attention, but it is interesting by reason of its novelty, and the way in which an apparently very difficult problem has been solved. We know that in the ordinary sundial the time is indicated by the shadow on a straight edge. In the new instrument, which is called the "mean time sundial," the shadow is given by a curved surface, so that as the position of the sun is slightly higher or lower than the normal, the discrepancy is made up by the curvature of the object which casts the shadow. We should think that very few persons are dependent, in these days of cheap clocks and watches, upon the sun as a timekeeper, and if any such there be, they have, in this year of endless wet and gloom, our sincere sympathy. We must also condole with General Oliver for the fates being against him in this matter, but we have at the same time a very high opinion of his ingenious sundial. It is being made by Messrs. Negretti and Zambra.

ON NATURALNESS.

In those early and unsophisticated days when photography first came into existence, the new art was hailed with delight by many who saw in it a promising means whereby man might be led closer to Nature by a nearer contemplation of what they anticipated would be exact and literal renderings of whatever was placed before the camera, free from the flattery and conventional falsehood of Art. Disillusionment followed fast on their dream, however, for it was soon perceived that the absolutely unsympathetic and cruelly candid truth of the lens was an even worse exaggeration, though in a contrary direction. The photographer, as the person most interested, found himself involved from the very beginning in an energetic conflict with this undiplomatic and undiscerning directness, and forced to devise means and methods by which it might be, if not overcome, at least kept within bounds, and turned to his own purposes. The studio worker took eager advantage of the introduction of retouching to render his negatives more acceptable to his patron's vanity; the landscape man, by careful choice of lighting and position, and all the useful wrinkles that experience taught him, endeavoured with similar intentions, though in a different manner, to circumvent his camera's inconvenient exactness of portraying the things presented to it.

And, certainly, a great measure of success rewarded their labours. Portraits were produced possessing a beauty and delicacy of modelling scarcely dreamed of outside the range of miniature-painting, and flattering the sitters to their hearts' content. And photography in other directions than portraiture seemed equally happy. We are too apt to forget in our pride at the latter-day perfection of our results what really fine work was turned out by many of the pioneers of camera craft. It will often give a wholesome snub to our vanity if we pay a little more attention to such early productions, and will serve in some respects to enhance our appreciation of the general truth of the wise king's dictum, that under the sun is nothing new.

But every movement carries its own recoil; no sooner does the pendulum swing one way than gravitation inflexibly insists on the reverse action. The very anxiety of the photographer to escape from the barren truthfulness which his camera would of itself prefer led by degrees to grave faults of a different kind. Over-elaboration became the order of the day. The primal simplicity of the studio portrait soon disappeared in favour of

September 5, 1902.]

abundance of superfluous ornament in backgrounds and accessories; a too great fondness for retouching was evident; the whole work displayed a worrying neatness and attention to trivial details of finish, which repelled rather than attracted. While, perhaps, seen at its worst in the domain of portraiture, similar defects were by no means lacking in other directions. The same want of naturalness, to give the fault a name, was noticeable in the landscape work of that period, although there was certainly, at the same time, much to admire and commend. The photographers of the day were, on the whole, much more concerned in producing what they called good photographs than with any anxiety of mind regarding the artistic side of the subject in its broadest sense.

Then, in the fulness of time, came the pictorial movement, the credit of which no wise man would desire to admit to any one school or clique. It was unquestionably a general progression, rendered inevitable by time and evolution. Since its inception the general advance of photographic work in all those qualities which tend to give lasting pleasure has been marked and phenomenal. As was only to be expected, however, in the nature of things, features good in themselves and tending to artistic progress have been here and there overdone and pushed to the verge of eccentricity, so that it might be said that some of these later products of the camera were even more lacking in naturalness than the over-elaborated works that preceded them.

Naturalness is, like most abstract qualities, difficult of definition. It is much easier to say what it is not than what it is. It is essentially something that belongs to the whole effect created by any composition rather than to any individual part or parts of it. We may take up a photograph of a laughing child and say, approvingly, "How charmingly natural!" without probably analysing very deeply the complex aggregation of perceptions and suggestions which have led us to that conclusion. If questioned, we should most likely argue as follows: In the first place, the pose and attitude are free and unstilted, reminding us by their easy and careless grace of other lovable home fairies that, maybe, we know of; then, the expression, in this case most important of all, is full of happy child life and character, and absolute unconsciousness of studio surroundings; finally, we no doubt feel in a lesser degree, for it would not be true art if it struck us at first glance, how all the accessories of the photograph and details of production and finish are quietly and successfully in harmony, forming altogether by well-attuned combination the pleasing picture which we take up so appreciatively.

A photographer, whose name is a household word in the Midlands, tells the following amusing story against himself. He had to take a certain little five-year-old maiden one afternoon—a morsel of femininity who truly deserved to be called a "pickle" if ever child did. And whether it were that his customary skill had for the time deserted him or that his tiny sitter had assumed extra perversity for his especial benefit, certain it was that he could by no means bring to her face the expression that he wanted, nor effectually chase away what was now an offended pout and then a gaze of dismal apprehension. And so it came to pass that he dispatched the resulting proofs with a philosophical expectation of either a re-sitting or a small order. Judge, therefore, of his surprise when, a few days later, the little girl's mother came, full of commendation of what our friend had made up his mind was really the worst proof. "I am perfectly delighted with this," she beamingly exclaimed. "It is so very natural." "I am glad you

think so, madam," replied its producer. "Yes, indeed," said the lady; "it is just exactly how she looked when I caught her spilling the ink over the carpet yesterday."

We will not spoil this deliciously naive anecdote by forcibly joining some far-fetched moral to it. It does seem to point out pretty plainly, however, that naturalness takes to itself many forms, and does not always appear in the guise we expect, nor under those conditions by which we seek to attain it. It comes unsought. To strive for it too carefully and painfully is one of the surest ways of missing it. How many a fine landscape have we seen spoilt by the obvious effort and labour for an effect which simply and unrestrainedly expressed would have been perfection. And, again, how often at our exhibitions pictures in every way satisfactory are killed, and have their chances ruined, through unfortunately obtrusive framing—yet another instance of that fussiness and care which, though rightly directed, err by excess, and defeat their own object.

How, then, shall we attain this elusive quality of naturalness, which may not be sought after and resents pursuit? In the beginning, we must avoid and shun all that common-sense tells us is unnatural, and contrary to the evident rules of beauty and simplicity. Then, we must be natural ourselves, "for who knoweth the things of a man but the spirit of man which is in him?" We cannot appreciate and interpret the finer shades and nuances of human expression, nor the ever-changing moods of inanimate Nature, unless we attune ourselves in sympathy with them. In addition, we must, while aiming at perfect mastery of all those mechanical details of our art which constitute good technique, yet try to keep ourselves oblivious of them in the actual execution of our work. This sounds contradictory, perhaps, but it is not so in reality. It is simply the crystallisation of the principle that excess of attention to any one point will lead to its own undoing. The methods and means of the photographer—he, at least, who wishes to produce natural and pleasing work—should always occupy a very subordinate place in his mind, as compared with the intention and motive which shape and fashion, or should do, every picture he is responsible for. And with so many difficulties to overcome and pitfalls to avoid, he is well deserving of the satisfaction he is bound to feel, when he can contemplate his creations, and know of a surety that unnaturalness and affectation are absent.

PHOTOGRAPHIC WORKERS AT WORK.

MESSRS. J. J. GRIFFIN AND SONS (LIMITED), AT THEIR PHOTOGRAPHIC WORKS, EAST MOLESEY.

SOME of the present generation of photographers may be inclined to the opinion that the house of J. J. Griffin and Sons (Ltd.), is a comparatively new one in the photographic world. That, however, is not the case, for, as a matter of fact, it is one of the very oldest now existing. We have before us as we write a catalogue of Daguerreotype and photographic requisites, as supplied by John Joseph Griffin, F.C.S., the founder of the house, 10, Finsbury Square, bearing date 1853. As it may be interesting to some of our readers to know what the early workers had to pay for their materials, we just give two or three quotations from the list. Pyrogullic acid is quoted at 16s. per ounce, or sixty grains for 2s. 6d.; bromide of potassium, 2s. 6d. an ounce; hyposulphite of soda, 2d. an ounce, or 1s. 4d. per lb. Daguerreotype plates, which the user had to prepare and sensitise at the time of using, are quoted, for the quarter-plate size, at 11s. per dozen; the half-plate, £1 5s.; and the whole-plate at £2 5s. the dozen. High as these prices may seem to us now, we are told that at that time Griffin's was

one of the cheapest houses in the trade. It is not, however, with the house as it existed half a century ago that we are at present interested, but rather as it is now.

A few days ago we received an invitation from the Messrs. Griffin to visit their photographic works at East Molesey, and we availed ourselves of it. Arriving at the Hampton Court Station, accompanied by Mr. F. H. Ibbetson, the manager of the photographic department, a pleasant drive of a mile or so brought us to the works. Photographic works generally are not particularly notable for their outward architectural beauty, and those of Messrs. Griffin and Sons are no exception to the rule. They are designed for utility and not for outside show.

We were first shown into a room where the specimen prints of the different papers, as used on the show cards, are produced. Here are kept albums of trials of every batch of paper that is made, whether the well-known P.O.P.'s, carbona, glycia, or the Climax ready sensitised albumen papers. Each page contains a finished print, a piece of paper merely exposed to the light to just tint it as a test as to the evenness of the coating,

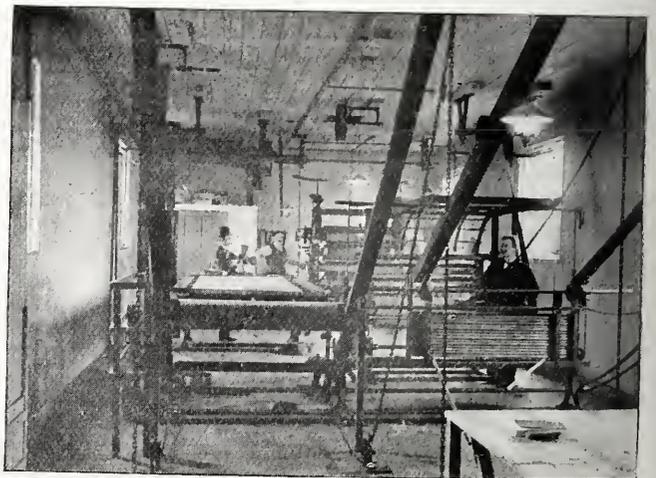

and a yellow envelope containing pieces of the unexposed paper to prove the keeping qualities of every batch. All these trials are numbered according to the numbers on the packets as put on the market, and can be quickly referred to at any future time. From here we went into a building devoted to the making of the emulsions. This was fitted with convenient tanks, heated by steam, to contain the emulsion jars. In the basement of this building is the ice store, a large quantity of ice being necessary in hot weather.

Next we visited the coating rooms, of which there are two, the one above the other. These rooms are two hundred feet long, and of proportionate width. They are furnished with the most recent coating machinery, and this has been further improved upon by the Messrs. Griffin. In the lower room is also a machine for putting a baryta coating on raw paper. Both rooms are lighted by incandescent electric lamps, so that there are no fumes of gas to act injuriously on the paper. The paper, as it is coated—and it can be coated up to 45in. wide—is automatically festooned as it passes to the top of the room.

It then travels on chains slowly to the end of the room, and when it arrives there the rods upon which it hangs are caught on a turn-table and the paper comes back on the other side of the room to the reeling-up machine, and by the time it gets there it is dry and ready to be reeled. During its passage the position of the paper on the rods is being continually changed automatically, so as to avoid unequal drying.

The ventilating and drying arrangements are very complete, and no expense seems to have been spared to make them so. The air is drawn in on one side of the room by large fans, and drawn off on the other. As the air is drawn in it passes over steam pipes, so that it can be heated when necessary, which is not the case during hot weather. By means of sliding doors the air, as it enters, can be distributed to different parts of the room at will; the same with the exhaust—it may be drawn off from different directions. In addition to this arrangement, there are smaller fans, actuated by electric motors in different parts of the room, that keep the air in a continual state of agitation, which greatly facilitates the drying. At the time of our visit the coating of a mile and a quarter of carbona paper had just been finished, and we were told that two such batches could be dealt with in each room per day. The arrangements

in the upper room are similar to those in the lower one, and off this is the cutting room. Here are four costly machines. One is used for trimming the edges off the paper as it is unreeled. Another is a slitting machine, which first cuts the paper in strips of the desired width, and then cuts them transversely to the length required, ready for packing. This machine is adjustable to cut any sizes that may be required,

and works automatically. There is also a guillotine machine for cutting the paper into large sheets. These machines are all driven by power. In this room we noticed a very fine large calendering machine with polished steel and compressed paper rolls for calendering paper up to about 4ft. wide. A large proportion of this elaborate machinery was supplied by the well-known firm of Hirsch, of Frankfort-a-Main. It may be mentioned that all the entrances to the different rooms are fitted with "light locks" so that there is no danger of light being admitted as the workpeople pass in or out.

The next place visited was the manager's office and the laboratory adjoining. This was most conveniently equipped, and that is not at all surprising, seeing that laboratory fitting is a speciality in the general business of the Messrs. Griffin. We now pass to the engine and boiler house. Here we find a 40-horse-power engine at work for driving the different machinery. In this room is also a dynamo for generating the electricity for lighting the premises, and for the motors for driving the smaller ventilating fans, etc. The boiler, which is larger than is needed for the engine, also supplies the steam for heating purposes. The water supply for the entire works is spring water obtained from a deep well. Close to the engine room is a smaller one, in which is a still, heated by steam, from which water is continually distilling for making the emulsions, silver solutions, and other purposes for which distilled water is required.

The last room we visited was where the well-known "Climax" albumenised paper is sensitised. Here there are three rows—six in each—of large deep porcelain trays, the full size of the sheet of paper. The floating of the paper is done by girls, who are very expert at the work. After sensitising, the paper is hung up to dry under a canopy of muslin, so as to avoid all contact with dust should there happen to be any in the room. This room, like all the others, is heated by steam pipes when heat is required, for it is essential, in order to obtain a uniform sensitised paper, that the sensitising be done under uniform conditions. In addition to what we have described, there are the packing rooms, mechanics' workshop, etc., but these call for no special notice.

On leaving Messrs. Griffin's works we came away with the impression that they were amongst the most complete and convenient that it has been our pleasure to visit.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

[The following notes are abstracted from the P.P.A. Handbook No. 3, which was issued to members a few days ago.—Ed. B.J.P.]

FOREWORDS.

THE Professional Photographers' Association is the one and only representative body of its kind throughout the British Empire. Its objects are, to improve the status of those who practise photography as a profession; to defend their interests; to assist them by advice; to afford them opportunities for meeting and discussing matters pertaining to the advancement of the craft; and to employ all legitimate means of upholding the rights and dignities of the profession.

In the first year of its existence it has received the active support of between five and six hundred members, and has earned commendation from all parts of the world. Besides its legislative sphere, the Association has its social uses, and it also aims at constituting itself the authoritative governing body of British professional photographers throughout the world.

A vast field of work lies before the Association, in the furtherance of whose objects it is hoped that it will secure the active membership of the many thousands of photographers who have not yet joined.

Officers and Committee of the Professional Photographers' Association.

President.—William Grove.

Past President.—Thomas Bedding, F.R.P.S.

Vice-Presidents.—H. Walter Barnett, W. Crooke, Ernest Elliott.

Committee:

London.—F. A. Bridge, H. J. Dalby, Alfred Ellis, H. Edmonds Hull, M. Jacolette, A. Mackie, Edgar Scamell, G. V. Simmons, Lang Sims, T. C. Turner.

Country.—W. Barry (Hull), H. A. Chapman (Swansea), W. Gill (Colchester), Frank Moffatt (Edinburgh), G. W. Morgan (Aberdeen), H. C. Spink (Brighton), W. D. Valentine, J.P. (Dundee), G. Watmough Webster (Chester), H. J. Whitlock (Birmingham), Alfred Werner (Dublin).

Hon. Treasurer.—William Grove, 63a, Baker Street, London, W.

Hon. Secretary.—Alfred Ellis, 51, Baker Street, London, W.

Hon. Solicitor.—P. E. Marshall, Esq., 62, Lincoln's Inn Fields, London, W.C.

Auditors.—S. H. Fry, 12, South Villas, Camden Square, N.W.; M. B. Barraud, 54, Clarence Street, Kingston-on-Thames.

Bankers.—National Provincial Bank of England.

NOTICES TO MEMBERS.

All communications for the P.P.A. should be addressed to the Honorary Secretary, 51, Baker Street, London, W.

Members will greatly oblige by addressing their communications thus:—

Professional Photographers' Association.

ALFRED ELLIS, Hon. Sec.,

51, Baker Street,

London, W.,

to distinguish them from the business letters of Alfred Ellis and Walery.

Members are reminded that their annual subscription became due on July 1st, 1902.

Members are advised, wherever practicable, to become dealers in photographic materials, in order to obviate the unfair competition they are subjected to by shopkeepers, and others, who are not photographers, undertaking the production of portraits, enlargements, etc., which legitimately fall within the sphere of professional photographic work.

*** Members desiring legal advice must make application to the Hon. Secretary, Mr. Alfred Ellis, 51, Baker Street, W., who will place the matter before the committee. Application for advice may, however, be made direct to the Association's Hon. Solicitor, Mr. P. E. Marshall, 62, Lincoln's Inn Fields, W.C., but in such cases the Association accepts no responsibility.

*** It is suggested by the committee that, on their cards, note headings, invoices, and business stationery, members should print the words, "Member of the Professional Photographers' Association."

FIRE INSURANCE.

In accordance with instructions from the general meeting of the members held on February 7th, the committee have made arrangements with the Fine Art and General Insurance Co., Ltd., of 90, Cannon Street, London, E.C., by which any member may transfer his present policy to this company, and obtain a reduction of 20 per cent. on the premiums hitherto paid. To secure this concession, it will be necessary for the member to forward his policy to the Hon. Secretary, Mr. Alfred Ellis, 51, Baker Street, W. A charge note for the premium will then be

sent, holding the insured covered for a period of thirty days to enable the new policy to be prepared.

In cases where the member has not been previously insured, or requires a new policy, it will be necessary to have an accompanying proposal form completed, when the insurance company will allow a discount of 20 per cent. off their usual rates.

COPYRIGHT.

The committee, during the past year, having had many applications for advice on copyright matters, make the following suggestions for the guidance of members:—

1. Important.—A copyright photograph is one taken at the photographer's own expense, and for which he does not receive payment or other stipulated consideration. It is recommended that in all cases, distinction should be made in members' books between photographs that are charged for, and those for which no charge is made.

2. Registration.—Every copyright photograph should be registered by the proprietor delivering or sending by post prepaid to the Registrar, Copyright Office, Stationers' Hall, London, E.C., a signed memorandum of such copyright, with a fee of one shilling. Special forms, one penny each, containing full instructions of how to register a photograph, can be obtained on application at Stationers' Hall.

3. Necessity of Registration.—No proprietor of a copyright is entitled to the benefit of the Act until registration, and no action can be maintained or any penalty recovered in respect of any infringement before registration. In registering, the name of the actual photographer should be inserted as author.

4. Transfer of Negatives.—In all cases where a negative of a photograph is transferred for the first time by the owner to any other person, the copyright will cease to exist, unless at or before the time of such transfer an agreement in writing be signed by the transferee reserving the copyright to the owner, or by the owner transferring the copyright to the transferee as may be the intention of the parties. A member purchasing a business or another photographer's negatives should be careful to see that the copyrights are properly assigned and registered in his own name.

5. Reproductions.—Members are advised not to give permission for their copyright photographs to be reproduced until they have full particulars of the size and style of the proposed reproduction, and to formulate their charges accordingly. For example: A newspaper should pay a fee of not less than 10s. 6d. for half-tone black-and-white reproduction not exceeding 6in. x 4in., when printed with letterpress in one issue of the paper; but if it is printed as an inset the fee should be at least one guinea. If printed in colours, collotype, or photogravure, it should be a still higher fee. If the photograph is to be reproduced for advertising purposes, a higher fee should be charged than for newspaper work. In all cases, the permission should be in writing, and state the amount of fee to be paid, the process by which the photograph is to be reproduced (whether in black-and-white or colours), the limit size, and the purpose for which the reproduction is to be used.

THE Zoological Photographic Club has vacancies for one or two members. Subscription to May 31st next, 2s. 6d. The hon. secretary is Mr. Chas. Louis Hett, Springfield, Brigg.

We have received from Messrs. O. Sichel and Co., of 52, Bunhill Row, E.C., a price-list of photographic mounts manufactured by the A. M. Collins Manufacturing Company, U.S.A. Some of the mounts catalogued are well worthy the attention of up-to-date professionals, and we recommend them to write for an illustrated price-list of these American productions.

PHOTOGRAPHIC SUPPLIES IN FOREIGN COUNTRIES.

[Reprint of an American Advance Sheet of Consular Reports.]

It is the general impression that the United States leads the world in advertising. This may be true of many lines, but we are certainly behind in the advertising of photographic supplies. Some two years ago I organised an amateur photographic club, which counts five nationalities among its members. This has brought me in close touch with many interested in the art, and I am pleased to find that American photographic appliances have an exceptionally good reputation among foreigners. American manufacturers have reached a more satisfactory solution of the problem of a practical combined hand-and-stand camera than their foreign competitors, and two lines of American sensitised paper are recognised as very superior by advanced workers throughout the world. Our plates and films have a universal reputation for excellence, but owing to the very high prices asked for plates, the latter cannot compete abroad with those of foreign manufacture. A good reliable English plate can be bought for half the money asked for the American article. With this exception, we can hold our own in price. In quality we are not excelled, and in several lines not equalled. We have the material, but lack the enterprise to push our goods abroad. Among the thousands upon thousands of amateurs throughout the world the demand is very large, and it is astonishing to find our makers behind the English, German, and French in catering to this demand.

Setting aside for the moment the subject of foreign advertising, we are without a single photographic publication in America carrying sufficient advertising to make the publication of special interest to foreign dealers on the look-out for photographic supplies. Other lines of American industry have trade journals that are widely patronised by the manufacturers, but the home photographic trade goes almost unrepresented. England possesses, in "The British Journal of Photography Almanac," an annual publication which dealers and enthusiastic amateurs are glad to get. The number for this year (1902) is a bulky volume of 1,550 pages. Of these, 1,010 full pages are devoted to the advertisements of 245 advertisers. As many of the advertisers are general agents representing several manufacturers, there are probably four or five hundred different makers represented. I believe this publication to be one of the most valuable advertising mediums in the world. With the "Journal Almanac" in his hand, a foreign dealer is in close touch with the English supply trade. He finds there every novelty in his line, and as the leading manufacturers occupy enough space to cover briefly their whole field (several firms utilise upward of thirty pages each, and one well-known house fills sixty-five pages), the dealer has before him abridged catalogues of practically every maker in Great Britain.

Now let us see what the United States has to offer in this line. We have several very good photographic annuals, so far as the quality of the reading matter is concerned. Two of these are before me, and I find that in illustrations and general make-up they are in advance of the British annual referred to above. They have a comparatively large foreign circulation, and are much appreciated for the good things they contain, but they lack the most valuable feature of all—representative advertising. The 1900 issue of "The American Annual of Photography," which is the largest of our annuals, contains 489 pages. Of these, 119 pages are devoted to advertisements, and the seventy advertisers represented seem, as a rule, content with a mere uninteresting address card. The publishers, who control a large photographic supply-house, occupy most of the space. Foreign dealers obtain something even from this poor advertising array, but very little as compared with "The

GRADUATED LIGHT FILTERS.

[Abstract of a Paper read before the Royal Photographic Society and reprinted from the "Photographic Journal."]

ONE of the earliest attempts to correct the erroneous representation, to which I have referred, is to coat the whole of the negative with a stained varnish, and afterwards remove the varnish from those portions, such as the sky of the negative, which are of greatest density, and in this way to effect a certain amount of compensation or equalisation, but it cannot be said that the method is a satisfactory one.

Later, attempts were made to attain the desired end by forms of lens shutters, so devised as to give a greater exposure to the foreground of the picture than to that of the sky portion. A flap shutter opening and closing from the top is one of the simplest of these devices; for, if slowly opened and closed, a much greater proportion of the light from the foreground of the subject falls upon the sensitive plate (Fig. 1).

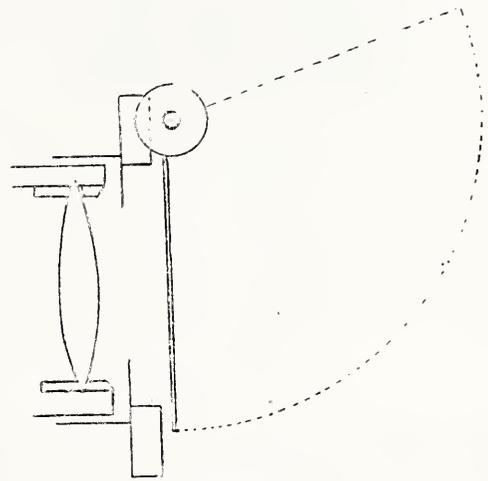

Fig. 1

With such a shutter, however, it is extremely difficult to forecast what result will be obtained, with any degree of certainty.

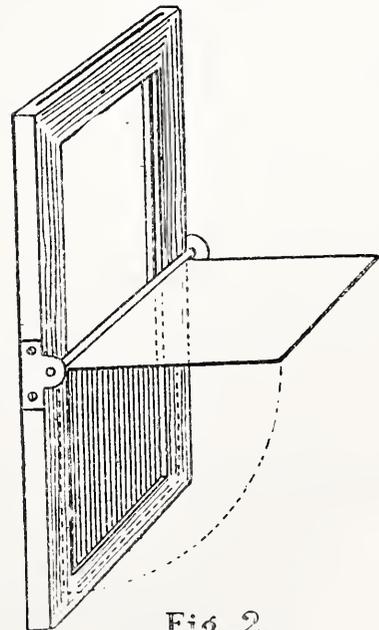

Fig. 2.

Fig. 2 represents a later form of shutter—a combination of the flap and simple drop shutter. In this shutter the flap is gradually opened, and on reaching its highest point, a drop shutter falls over the lens, completing the exposure. Both of these shutters give gradually decreased exposure towards the

British Almanac." The fault is not with the publishers. They offer a brighter setting for advertisements than their foreign contemporaries, and the advertising rates are no higher. It is our manufacturers who are at fault. If it were only possible to convince them of this and induce them to join in building up an American advertising medium like "The British Almanac," our foreign trade in photographic supplies would increase greatly. I may appear to be over-confident on this point, but I have given the subject much study for the past six years, and feel sure of my position. I have seen considerable orders for miscellaneous photographic supplies go to English manufacturers merely from the fact that the "Almanac" placed before the dealer a complete review of the latest novelties in the entire photographic line. Nothing could be learned about American goods without waiting for three months for catalogues, only then to find, perhaps, that the wrong manufacturers had been applied to, and that certain desired goods could only be obtained from other makers.

Our manufacturers could not do better than to look the field over carefully, select one or more of our photographic magazines and their annuals, and give such publications their hearty support. Let them advertise with illustrations and descriptive matter their most popular lines. The foreign dealer and amateur will, without great delay, find out the journals containing the most advertising, and these publications will soon be in possession of a circulation sufficiently large to make the trifling sum which the manufacturer has expended a splendid investment. Photographic societies are in existence now throughout the world, and they subscribe to the leading photographic papers, American, English, and German. Amateurs vie with one another in obtaining the best apparatus and latest photographic novelties; thus the advertising pages are of exceptional interest. Manufacturers should, therefore, value photographic journals for the quality of their circulation rather than the mere number of copies each may issue.

In foreign advertising American manufacturers apparently take but little interest. I find in the "Tokyo Shashin Geppo" (Photographic Journal) 4 German, 2 English, and 2 French advertisers represented; and in the "Shashin Shimpo" (Photographic News) 9 English, 5 German, 2 French, and 1 American. The charge for space in either of these journals is about 4.00dols. half page, and 7.00dols. a full page for English text. An equal space with Japanese text is given gratis. A large discount is made for two or more insertions, and no charge is made for Japanese translations.

Three or four of our largest manufacturers are heavy purchasers of expensive space in our home magazines, but only the kodak cameras are well advertised in Europe. A small part of the appropriation for American advertising, if expended in foreign journals, would introduce our goods abroad and lay the foundation of a valuable trade. We have many good things in the photographic line. We should let the world know it.

JAMES W. DAVIDSON, Consul.

Tamsui, April 10, 1902.

MR. W. E. DUNMORE, auctioneer and valuer, expert in photographic and optical goods, of 33, Gerrard Street, Shaftesbury Avenue, London, W., writes:—"I have felt for some considerable time that there was an opening for an auctioneer confined to the photographic and optical trade. I have fitted up a large mart at 33, Gerrard Street, capable of accommodating 150 to 200 people, and shall hold auctions of photographic and optical goods periodically. It is my desire to cater principally for the amateur photographers. Having this in view, I have arranged for the auctions to take place in the evening, to give my clients an opportunity of visiting me after business hours. Another special feature is that I offer to sell photographic goods for the amateur free of cost, on the understanding that the money realised shall be expended in photographic or optical goods from my retail stock. I am also willing to accept commissions to bid for any given lot without making any charge should the intended buyer not be in a position to visit the mart."

sky portion of the negative, but, in order to give greater control, Colonel Durnford devised a very pretty contrivance, which effected its object, but was, unfortunately, complicated and awkward for transport.

In principle this shutter, which I now pass round, is excellent. The front portion of the lens supports, as you see, a flap shutter with a serrated edge. This flap can be made to stand at certain different angles by an adjusting piece. In addition to the flap shutter there is a drop shutter, as in Fig. 2; but working not immediately in front of the lens behind the flap, but at the diaphragm slot. Instead of the drop shutter having an opening equivalent to the aperture of the lens only, it has an additional opening in the form of a slit parallel with the line of drop (Fig. 3).

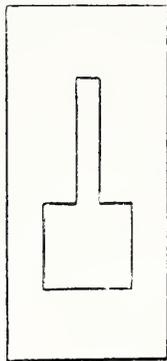

Fig. 3.

In operation the flap shutter is raised to its highest point, and the drop shutter until the larger opening is opposite the lens opening. The image is then examined on the ground glass focussing screen, and the flap with the serrated edge moved up and down until the line of the serrated edge corresponds to the horizon of the picture, and the flap is set in this position by means of the small quadrant. On closing the flap shutter the whole arrangement is ready for exposure. On releasing the trigger the serrated flap opens until it reaches the predetermined point, and up to this point, the larger opening of the drop shutter being opposite the lens—the full effective aperture of the lens is in use. From this point, however, to

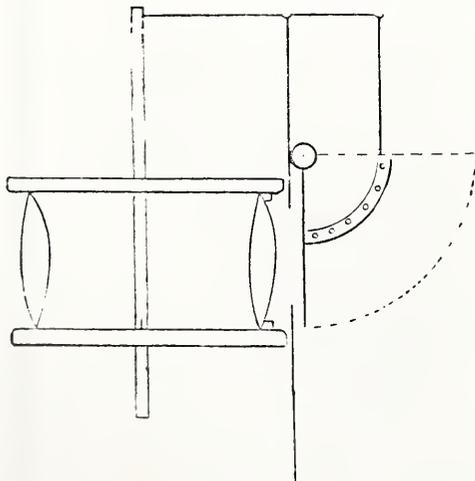

Fig. 4.

the end of the exposure, the slit portion of the drop shutter corresponding to a smaller sized stop, is in action; and, further, although the shutter moves with an uniform motion, the portion of light from the sky which reaches the plate is, relatively,

enormously reduced (Fig. 4). This shutter then certainly works well, and it does not seem to be capable of very much improvement, so far as its principle is concerned, but the mechanical construction is ugly and inconvenient, and I propose to show you a means by which the same result can be obtained in a much simpler manner.

You know that some ten or twelve years ago saw the introduction of what was then known as an isochromatic screen, or more correctly, a light filter, and since that time all photographers have felt the increasing necessity for the use of light filters as constant companions, in order to secure the best results. The first light filters were made of yellow glass of very imperfect quality; this yellow glass was made by stirring up a pot of molten glass with a wooden rod. A certain amount of carbon became mechanically mixed with the glass, and gave a yellow colour which was, however, anything but a pure yellow, and far from the most suitable yellow for a light filter. A piece of this glass ground and polished on both sides was placed either before or behind the lens, or against the diaphragm—it does not matter appreciably where it is placed—either of these positions, or immediately in front of the sensitive plate will answer equally well.

A better device was the use of a glass tank filled with colour liquid, as quite a number of different absorptions could be obtained with this liquid filter, by varying the absorption of the liquid used. Liquid filters are, however, subject to many ills—leakages, unevenness, and the effects of changes on temperature rendering them very unsatisfactory for practical use.

Later, filters were made from worked glass, coated with gelatine, stained with a suitable permanent dye—the film being protected by a cover glass fixed to it with Canada balsam. This form of filter has quite superseded all others, as its advantages are enormous. There are now a very large number of aniline dyes of proved permanency, which may be used for light filter work; and, by combining two or more coloured films, and by variation in the strength of the dye, it is possible to make light filters of any predetermined absorption.

To return to the question of graduated exposure to the foreground and sky, it occurred to me the simplest method of effecting graduated exposure would be the use of a graduated light filter in front of the lens combination. The first filters

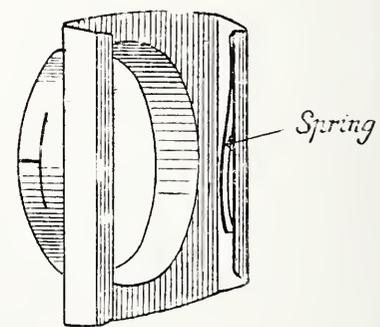

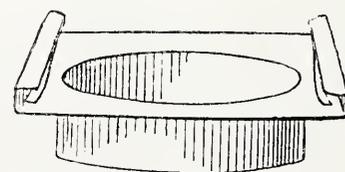

Fig. 5.

I made were simply coloured gelatine cast upon a glass plate in wedge form. By varying the amount of colour in the gelatine

varying steepness of gradation can be secured. Some of these filters were made in Indian ink, and in others I used a similar combination of yellow dyes to those used in the preparation of the Cadett Gilvus filter. The most suitable form of fitting for attaching the filter to the lens is represented in Fig. 5.

It consists of a brass disc turned over at two opposite sides, so as to form two grooves attached to a tube of suitable size to fit the hood of the lens. The grooves are furnished with springs to hold the glass against the brass platen. After using such an arrangement for some time, it occurred to me that it might be desirable, in many cases, to alter the scale of gradation from the straight line given by the wedge-shaped casting. If we represent the relative amount of light transmitted by the different parts of the filter, by varying the height of a line drawn above the base line, as in Fig. 6, I can better explain

Fig. 6.

what I mean. In order to experiment with different curves, the filters were made by printing in carbon transparency tissue under a rotating sector in which suitable shaped apertures had previously been cut. This is a very useful method of translating the curved line drawing into a photographic scale of opacities. Fig. 7 represents the arrangement used. A light

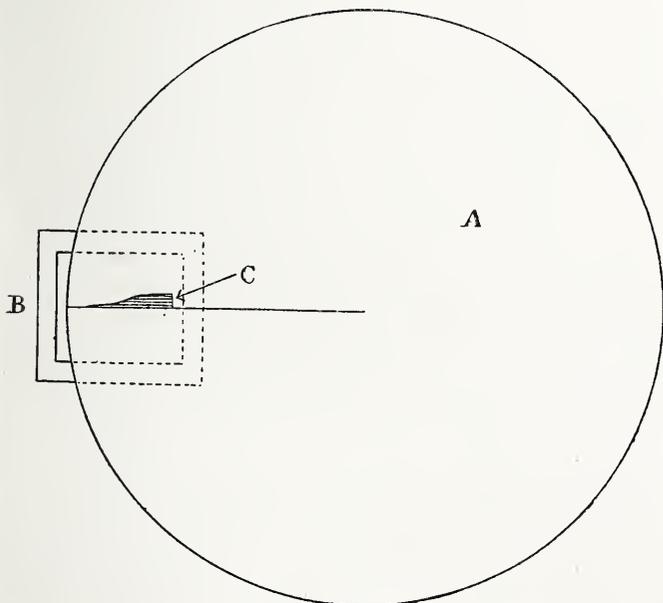

Fig. 7.

opaque sector A is so mounted as to revolve immediately in front of the printing frame B, containing the pieces of sensitive carbon tissue. An opening, corresponding to the required curve of opacities, is cut in the sector, A and C, and the whole is exposed to the light from an electric arc—the sector A being rapidly rotated by an electric motor.

After considerable experiment, I have found that a filter corresponding in opacity to the curve given in Fig. 8 is per-

Fig. 8.

haps the most useful. The filter is best made of an oblong form,

like Fig. 9, with the maximum change in gradation at about

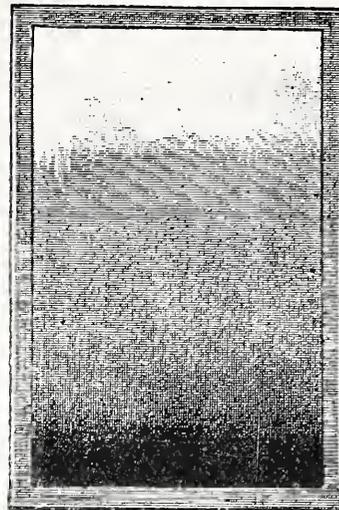

Fig. 9

the centre of the filter. It is then possible to get the maximum change in gradation to correspond with the maximum change of light in landscape, by observing the effect upon the ground glass whilst moving the filter up and down in its mount (Fig. 5).

E. SANGER SHEPHERD.

UREA IN THE DEVELOPER.

In the June number of the "Journal," there is an abstract of a paper by Dr. R. A. Reiss on "Urine as a Developer for Photographic Plates," published in the May number of the "Revue Suisse de Photographie." In this paper Dr. Reiss claims to have discovered that urea is a developer of the photographic image, not perhaps alone, but in combination with an alkali, as in the case of most other developers. As this statement was contrary to my own experience, I thought it worth while investigating.

In my first paper on thio-carbamide reversals (see "Journ. Pho. Soc. India," 1890) I showed that whereas thio-carbamide, or sulpho-urea, with alkali gives off ammonia and darkens and reduces the silver haloids; and a strong solution of it is capable of darkening a gelatine plate in the dark even without alkali; carbamide, or urea, in ten per cent. solution does not visibly darken a gelatine dry plate film, even with alkali, nor darken or reduce the silver haloids in the absence of light. The experiments on which these statements were based were carried out with freshly precipitated, well washed haloids, and had there been any tendency to reduction by the alkaline urea, it could not have escaped notice, because the reducing effect caused by the addition of eikonogen to the alkaline urea solution is recorded. The addition of urea to the ordinary eikonogen developer for negatives gave only a normal result, and seemed to have no practical effect worth noticing or following up.

Trying again the same sample of urea as was used twelve years ago, with ordinary English dry plates, it was found that a mixture of it and carbonate of potash in the proportions given by Dr. Reiss had absolutely no developing power at all. The same result was obtained with a fresh sample of "pure urea" (synthetic), the plate being left in the solution for two days without showing a trace of an image. Urine was also tried with negative results when used alone, but the simple addition of some pyro-sulphite solution without alkali developed an image.

These results led me to suspect that the developed images obtained by Dr. Reiss with his alkaline solutions of urea were not due to the urea, but to some ingredient of the emulsion on the plates he used. On looking up his paper, I found that he had used for all his experiments Mercier's "Intensive" plates, a quite special brand of French manufacture, containing *emétique** (tartar emetic?), eserine (phytostigmine), and morphine, some of them substances of strongly sensitising and accelerating power, while others are retarders, as explained in M. Mercier's paper on the subject ("Bull. Soc. Franc. Phot.," 1900, p. 227). It fortunately happened that I had two of these plates which were given me last year at the Glasgow Exhibition. On trying the urea with them the explanation became evident that Dr. Reiss' results, even on these plates, were not due to the urea at all, and could be obtained without it by means of a simple alkaline solution. The two plates were exposed, and then cut in half, giving four exposed pieces.

No. 1 was immersed in a two per cent. solution of pure urea. There was no trace of an image after twenty hours' immersion, pyro-sulphite added did not bring up the image, but the addition of a solution of carbonates of potash and soda brought it out at once.

No. 2. The same two per cent. solution of urea was used, but with the addition of the solution of mixed carbonates in the usual proportions for pyro development. This immediately gave an image, weak, but full of detail.

No. 3. A solution of mixed carbonates, diluted to the same strength as in No. 2, was used alone, without any urea. This brought out a thin image almost identical with No. 2.

No. 4. To the above mixed carbonate solution (No. 3) some pyro-sulphite was added, and the remaining piece developed readily up to normal density.

The results Nos. 2 and 3, taken in connection with the fact that the alkaline solutions of urea showed no developing power on ordinary English plates, tend to prove that the production of the image in these cases was mainly, if not entirely, due to the action of the alkali and the sensitising alkaloids or other substances included in the French emulsion. Dr. Reiss seems to have confined his trials to these plates, and not to have checked them with ordinary plates or the simple silver haloid salts.

Further trials with pure silver bromide quite confirmed my earlier observations that urea is not a reducing or developing agent. Silver bromide exposed to light and then immersed in solution containing five per cent. each of carbonate of potash and of urea showed no reducing action, and although it was darkened in a mixture of pyro-sulphite solution with a ten per cent. solution of urea, it was equally darkened in the pyro-sulphite alone without the urea.

Further tests with exposed dry plates showed in the same way that no development was produced in a ten per cent. solution of urea, nor with a mixture of ten per cent. solutions of carbonate of potash and urea, but with the pyro-sulphite solution and ten per cent. urea in equal parts, a good dense image was developed. Other trials with ordinary dry plates showed that the action of the urea was that of a weak alkali; if it were present in considerable proportion with the pyro-sulphite, it gave a dense image as above, but more dilute solutions developed very slowly, and gave poor images, compared to those in which a mixture of carbonate of potash and urea and pyro-sulphite was used. It may be noted that the solution of pyro-sulphite

and urea did not discolour so much as the ordinary developer with mixed carbonates.

As regards the use suggested by Dr. Reiss of urine in making up developing solutions, except for special investigations such as these Dr. Reiss is engaged on, it is not only unpleasant, but so complex and uncertain in its composition that it is not likely to give uniform results, and any advantage it might give could no doubt be obtained with urea, if further trials should show that this substance has any value as an adjunct to the developer. It may be found useful in bringing up a weak, well-detailed image for subsequent strengthening with a stronger developer. At any rate, the results I have obtained seem to show that it certainly cannot be considered as a new developing agent, and can only be of use as a weak alkali.

MAJOR-GENERAL J. WATERHOUSE, I.S.C.

A ROYAL UNDERSTUDY: THE CORONATION THROUGH FRENCH EYES:—KING ALPHONSE I.

[Reprinted from the "Daily Express, August 28, 1902.]

I saw the King crowned in the Abbey. It was a very great and noble scene; but perhaps you have read about it in the papers. They all had something to say.

Yesterday I saw the second crowning of the King—at the Alhambra Music Hall. Only it wasn't the real King, but a French gentleman. He looked as if he were called Alphonse. And the Abbey was not the real Abbey, but French lath and plaster; and the peeresses were fair Parisiennes, who were quite pretty, but—well, they didn't take up the sitting room of the dowagers. It was a bioscope representation of the Coronation that the Warwick Trading Company arranged near Paris, and, believe me, it teemed with quiet fun.

They had not done this thing better in France; but no doubt they did their best.

I am so afraid of appearing disrespectful to our good King, whose most loyal subject I am, that I will call the gentleman who took his part King Alphonse I. He had that appearance.

The bioscoped Coronation opens amid grand gesticulations. The Archbishop shrugs his shoulders triumphantly, as who would say, "It is magnifique! It is better than the real thing! Also I myself am very beautiful!" He glances proudly at four empty thrones grouped together. Of course, in our Coronation there were only three—two placed on high in the centre of the choir, and one, the chair which held the stone of Scone, near the altar. But these details do not matter in France.

The transepts of the Abbey are, as you know, broad arms. To the right sat the peers; to the left the peeresses. Also, they were seated some thirty in a row, while behind them was a gallery for the Commons. In the coronation of King Alphonse I. the peeresses are sitting in a gallery that holds eight in a row to the right of the thrones. They smile; they are happy. Are they not well dressed? What would you?

ANNOYING WIGS.

Enter Alphonse I. Behind him follow the officers of the household, in costumes that would have delighted the White Rabbit and brought a smile to the face of even the Walrus and the Carpenter. They wear several yards of horsehair wig, that stray all over their faces. It is annoying; but they are brave Frenchmen. They would die rather than scratch their noses. A bas les Anglais, who are merely aristocrats after all. Alphonse I. is introduced to the Warwick Trading Company. He is very pleased to see them, and bows to their representative, who is working the bioscope. Through him he smiles upon the Alhambra. But suddenly two trumpeters, arrayed after the manner of French jockeys, rush in and blow a fanfare under his nose. He is discomfited, but calm. There is a general disposition to cry, "Vive"—something or other.

Alphonse takes off his robe and appears in the uniform of a French Colonel. The Archbishop beckons him. He kneels. He kisses a book. A Horsehair flourishes a two-foot quill. He signs the book. There is no ink, but the intention is enough. Sensation!

* According to Wurtz's "Dictionnaire de Chimie," several double tartarates of antimony and other metals are known under this name.

September 5, 1902.]

Enter more Horsehairs carrying canopy. Alphonse sits down nervously on the edge of his chair. He is not accustomed to this sort of thing. It is a torture to him. Poor Alphonse! A bas le British Institution.

ARCHBISHOP IN A HURRY.

The Archbishop is very quick on his feet. There is no time for delay, for something may go wrong with the machine at any moment. He partially anoints Alphonse, who rises while a huge sword is tied to his side. Again a robe is placed on the King. The Archbishop makes quick passes in the air. Horsehairs hurry up carrying the galia on cushions in a manner suggestive of ices.

The Archbishop seizes the crown, and displays it to the Warwick Trading Company. Alphonse I. is crowned amid tumult, in which the trumpeters again rush in and the peeresses clap on their coronets—which is just what they didn't in Westminster. But what matter? Vive la France! Vive Alphonse I.! Vive everybody!

The new monarch is led up to the higher throne to be effusively embraced by the Archbishop, while the Horsehairs bow so low that they look like Shetland ponies. The Queen appears and sits beside him. Poor Queen, she is never crowned at all, and seems to feel the dignity. Another moment and darkness. The films have run out.

Have I been too critical? If so, I apologise. The house enjoys the show thoroughly, and it was an enterprising scheme—even for the scope.

B. F. R.

THE ROYAL CORNWALL POLYTECHNIC SOCIETY'S EXHIBITION AT FALMOUTH.

THE sixty-eight exhibition was opened on Tuesday, August 26th, by the president, Sir William Preece, K.C.B., F.R.S. There was a large and fashionable attendance, the large hall being packed to excess. The principal feature of the exhibition was electricity, and scarcely anyone can handle that subject better than Sir William. In his speech he referred in very high terms to the photographic section, under the management of Mr. W. Brooks. He specially mentioned the examples of the gum bichromate process by Mr. J. R. Gotz, of London, also the beautiful work of Mr. J. H. Coath, of Liskeard, and the beautiful Alpine pictures of Mr. H. Speyer, and Mr. Brooks's exhibits, of about twenty examples, which were not in competition, he being one of the judges. The exhibition was then declared open.

Photographic Section.—The judges of the photographic section congratulate the society on the unprecedented success of the department. It has broken the record, and the available space has been strained to the utmost, and although the pictures in many cases have been packed so closely, not one picture has been overlooked by the judges.

Professional Section.—In the catalogue, Miss Gertrude Boynes sends an effective picture, "Wild Heather at Thurlestone." Mr. J. H. Coath, of Liskeard (an old exhibitor), is again well represented. He has about thirty frames, and great is the variety of his subjects. For a large picture (730), "Is He Coming?" he has been awarded a first silver medal. The other pictures in his collection are well worth careful study, especially his studies of cats, dogs, etc. Mr. W. Brooks, of Reigate, sends a collection, which includes a picture of the imperial crown of England (full size photograph from the original), that was used at the Coronation of King Edward VII. Mr. Brooks' (one of the judges) works are entered "Not for Competition." A second silver medal has been awarded to Mr. H. Trevor Jessop, for a picture of a child and dog (757), "Quite Weedy." John C. Douglas sends some very artistic productions (765), "Breakers." A first bronze medal is awarded. He also has a very effective picture of an old fisherman, "Uncle Ephraim." Mr. F. H. Tim's enlargement of Truro Cathedral is a little too weak to be effective. Mr. H. Evans's "Gathering in the Hay" is meritorious. Mr. E. Argall, of Truro, is represented by three portraits, printed in platinum, showing careful work, but are spoiled somewhat by being mounted on white mounts. The same artist sends two enlargements. Mr. J. C. Burrows, of Camborne, is again to the front with some of his mine pictures of large size. Although taken at a great depth below the surface, he has managed the artificial light so perfectly that one is impressed that the photographs seem to have been taken by daylight. There is an entire absence of any violent contrasts, as generally seen in this class of work. The judges have awarded him the first silver medal for 771, "Half a Mile Deep in Cook's Kitchen Mine." He also has two others of the same order. Mr. Walter Fleet has been awarded a first bronze medal for a picture of the genre order, 774, "A Practical Lesson." Another picture by the same artist is admirable, "The Umbrella Mender." All his exhibits show skill and good composition. Mr. W. Moore sends two frames of geological subjects. The Autotype Company, of

New Oxford Street, London, is well represented by specimens of their well-known work, which need no description. For a charming interior subject of Winchester Cathedral a first bronze medal has been awarded. Their exhibit also contains some excellent portraits.

Mr. Graystone Bird sends two charming little studies, the best of which is No. 778, "Good Morning," which takes a first bronze medal. A large composite group (T. B. Hawke) of naval officers of H.M.S. shows an immense amount of work in getting together, and is extremely effective; the group was awarded first bronze medal. Mr. P. Garland contributes some pleasing subjects. J. P. Milnes has been awarded first bronze medal for 798, "Study of a Child's Head," which is tender in treatment, and very artistic. Mr. C. M. Wane is again a contributor with some good work. Mr. J. R. Gotz, of Shaftesbury Avenue, London, sends some of the finest examples by the gum bichromate process. 809, "Burnham Beeches, Spring," has been awarded a second silver medal. It plainly shows what the process is capable of in the skilled hands of Mr. Gotz. He also has another picture equally fine, "A Cottage, Aldbury Park." Mr. V. L. Paul is represented by three specimens of his work. Mrs. Bainsmith sends about thirty examples of her work, portraits several lack force, and are somewhat flat, and others are hard. Some of the poses are good, but the judges hope in future to see an improvement.

B. Lyons sends two examples, which show careful work. Mr. C. J. King contributes three examples of flower subjects. To No. 850 has been awarded a second bronze medal, "Narcissi, Double White."

Amateur Section.—First in the list are the beautiful works of Henry Speyer, of Alpine fame. His pictures are perfect gems, and it is difficult to say which is his best; but 854 takes first silver medal; his other five are equally good. W. Wainwright is represented by one picture study of trees in winter; Wm. Howell by four examples of his work. Mr. A. J. Anderson forwards some half-a-dozen, evidently printed by the gum bichromate, which are very poor. C. E. Story shows four pictures, Italian subjects. John H. Rowe sends a frame of twelve small pictures. C. H. Dymond shows ten pictures. Bernard Mitchell's and Mr. Dan Dunlop's pictures show careful work. W. A. Clark receives first bronze medal for No. 908, "In the Choir, Southwell," which is a little gem. T. Lee Lloyd shows one small picture (910), "Within and Without," which is fairly good, but uninteresting. A. W. Gill is represented by some Alpine views, the Matterhorn, etc., which are of considerable merit. W. Lidgley shows about a dozen flower studies, of a very high order, which would be difficult to beat. (920) "Primrose-Coloured Daffodil," a charming little study, takes a first bronze medal. It is a pity they are not printed in a permanent process, such as carbon or platinum, instead of P.O.P. Rev. G. E. Hermon secures a second bronze medal for a capital enlargement for 935, "On the River Fowey." C. Coath, a youth, sends two frames, which show great merit. Mr. F. Martin Duncan sends examples of microscopic work of a very high order; he sends also a very fine production (970), "Octopus Vulgaris," the rendering being faultless, and the judges have awarded a first bronze medal. Mr. W. M. Martin takes first bronze for his interesting work (938), radiograph "Incubation of Pigeon's Eggs," which is very interesting. He also shows a large series of radiographs of fishes, etc., subjects which have been done over and over again for years past. R. B. Moss, J. P. Padwick, and W. Leader show good examples. Mrs. Annie Blamey has greatly improved in her work since the last exhibition; to her series of hand camera pictures of one dozen goes a first bronze medal. Rev. H. Holroyd Mills sends a most interesting series of bird pictures, nests, etc.; also telephoto work of birds in their haunts on the rocks. He has evidently spent a lot of time in the work he has done to his collection; has been awarded a special second silver medal.

Photographic Appliances.—Mr. A. Gregory sends rather a rough contrivance for taking stereographs of X-Ray subjects. Mr. Thomas Thorp, of Manchester, again contributes some of his exquisite diffraction gratings, done concave in form and silvered, and a very fine prism mounted grating, used in the construction of the new form of spectroscope, which is fully exemplified by the spectroscopic camera, sent by Messrs. Penrose, of London, which, in the opinion of the judges, had a great future before it, and to those who go in for colour rendering will find it an invaluable instrument. Messrs. Penrose and Co. have put the price exceedingly low, so that it may be within the reach of all. They have also kindly sent two specimens of Lippman colour photography process, being the first seen in Cornwall. They have also sent a set of Klein's colour filters, and some specimens of colour half-tone process, which are of great interest and very instructive. Mr. R. R. Beard the judges are very pleased to see contribute again. He sends three forms of hand feed arc lamps, the workmanship of which is perfect, solid, and substantial. To No. 1.001 has been awarded a first bronze medal. He also sends two portable rheostats for 240 volt circuit. Messrs. Sanders and Crowhurst, of London, send a frame of lantern slides of birds, and also a series of Westminster Abbey, etc. Unfortunately, the same firm sent a camera, which arrived two days after the exhibition opened, and was thereby excluded from exhibition; this camera had several new features in it.

The exhibition in all departments has been a great success. The

president of Thursday lectured to a crowded audience on wireless telegraphy. Mr. W. Brooks during the exhibition was kept busy explaining Tallent's spectroscopic camera, sent by Messrs. Penrose, which we noticed was marked sold. The Autotype Company sent some examples of materials used in the carbon process, which also kept Mr. Brooks on the go, explaining the simple working of the process. In the professional section many of the pictures were sold. Some were selected as prizes in the Art Union.

THE CAMBRIDGE CONVENTION: FINAL MEETING OF THE LOCAL COMMITTEE.

THE Cambridge General Committee, who so successfully organised the 1902 Photographic Convention of the United Kingdom at Cambridge, met last week, at the residence of Mr. C. S. Addison, Market Hill, to conclude business. The president of the committee (Mr. F. H. Sanderson) occupied the chair, and there were also present: Mr. H. A. Chapman (hon. sec.), Dr. Bansall, Messrs. Tams, C. S. Addison, E. Field, J. Johnson, F. J. Stoakley, E. S. Peck, W. F. Bird, Sowdon, and T. B. Hunt.

The hon. sec. presented the balance sheet, showing receipts amounting to £156 6s., and expenditure £158 18s. 9d., leaving a deficiency of £2 13s. 9d. Mr. Chapman informed the committee that, with the exception of the Bury excursion, on which there was a slight loss, the excursions had been run at a small profit. The deficiency on the dinner was small. He thought, taking into consideration the unexpected expenses they had had to meet, they had come out very well, and that the loss was small under the circumstances. Mr. Bridge, the general secretary, had complimented the local committee on the manner in which they had organised the gathering. The chairman endorsed Mr. Chapman's remarks. It was a source of great gratification to find the deficiency so small, and he would be delighted to make himself responsible for the deficiency. It had been a great ambition of his to get the Photographic Convention to visit Cambridge. They had had adverse circumstances to contend with, but he thought they had every reason to congratulate themselves upon the result. There was no doubt the visitors considered the gathering a very great success. The committee had received nothing but praise from them. The excursions gave the members of the Convention the utmost satisfaction. The hon. secretary remarked that before they accepted the chairman's generous offer to make himself responsible for the deficiency, he would like to point out that Mr. Sanderson's name was already in the subscription list for three guineas. Mr. Addison observed that it was not the fault of the local committee that there was a deficiency. It was the fault of the Convention, and he thought the loss should be borne by the council. After more discussion, three members offered subscriptions, and the meeting accepted Mr. Sanderson's offer to make himself responsible for the remainder. It was resolved that a donation of £1 5s. (already provided for in the balance sheet) be made to the Ely Cathedral Fund, and on the motion of Mr. Peck, seconded by Mr. Sowdon, the balance sheet was adopted. Mr. Field proposed, Mr. Hunt seconded, and it was agreed, to leave outstanding matters in the hands of the chairman and hon. secretary to wind up.

Mr. Bird proposed a hearty vote of thanks to the chairman for his unwearying efforts on behalf of the Convention. Twelve months ago, he said, he had the pleasure of proposing the election of Mr. Sanderson as president of the committee, and he wished all the things he had done had been equally successful. The chairman had done all he could to make the Convention a success, had worked hard, and certainly with effect. To him their best thanks were due. Dr. Bansall seconded the proposition, which was carried unanimously. The chairman, in returning thanks, assured the meeting it had been a great gratification to him to do what he could in the matter. He hoped they would all have pleasant recollections of the Convention, and of the many friendships they had formed. He was certain many Cambridge friends visiting the Photographic Convention, wherever it might in future be held, would be heartily welcomed, for he was sure their efforts had been very much appreciated. The chairman moved a vote of thanks to the hon. sec. He said the meeting thanked him as chairman, but he had had nothing like the work to do Mr. Chapman had. The success of the Convention was in a very large measure due to Mr. Chapman's tact, ability, and energy. Personally, he should owe Mr. Chapman a debt of gratitude to the last day of his life. The motion, which was seconded by Mr. Johnson, was carried unanimously. Mr. Chapman returned thanks, and said that though there had been a lot of work, it had afforded him the greatest pleasure. At the Convention he met many delightful men, and formed friendships which he hoped would never be broken. He was specially indebted to Mr. Bird, Mr. Stoakley, Mr. Addison, and Dr. Bansall for their assistance. Thanks were also voted to Sir Robert Ball (president of the Convention), Mr. J. W. Clark, Registrar of the University, Dr. James, the

Dean of Ely, Mr. H. I. Hankin (ex-Mayor of St. Ives), Canon Scott (Lavenham), the vicar of Long Melford, Dr. Mann, Mr. F. Dewberry Mus. B., Messrs. G. E. Foster, Jos. Reed, W. F. Bird, Trench Smith, C. S. Addison, and Tyndall. After a few words of thanks from the chairman to the committee for their hearty co-operation and support the meeting concluded.

CORONATION PHOTOGRAPHY "AT HOME."

[FROM A CORRESPONDENT.]

PHOTOGRAPHY has played an important, if unseen, part throughout the Coronation period. An especial staff had to be utilised one afternoon at the Richmond Post Office, to send and receive telegrams in connection with photographing the peers and peeresses in their Coronation robes, by Mr. Byrne. Approximately, some three hundred telegrams were sent and received. More than one hundred of the specially invited guests of the King and Queen, at the Abbey, in their Coronation robes, sat to Mr. Byrne. The portraits were all taken "At Home," in the sitters' own residences, and in many cases receptions of friends were held by the sitters while the sittings were proceeding. In some cases as many as fifty friends were present.

The photographs of Lord and Lady Muncaster, by their request, were taken in the garden, on the terrace connected with the house, in Carlton Gardens, the garden itself being separated from the road by only some iron railings. The roads were up, and some two hundred workmen and other spectators, admiring, silent, and well-behaved, were interested witnesses of some twenty different portraits, separately and grouped, being perpetuated.

On Coronation Day some thirty peers and peeresses were subjects, and although several operators, with different carriages were employed, it was extremely difficult to proceed through the crowded streets from one place to another. The matter was successfully negotiated by leaving the night before Coronation Day sets of apparatus and plates at the residences of the principal sitters, Lord Rothschild's, in Piccadilly, Lady Hillingdon's, at Camelford House, and other places. The sittings on Coronation Day commenced at 6.30 a.m., before going to the Abbey, and they practically lasted until dark. On the return from the Abbey many of the peeresses were much fatigued, but came up in even more gallant style "to face the photographic music" than the men.

An especial dispensation no doubt had been obtained, for right through Sunday graceful women and handsome men took their places, in what, after some years have passed may be considered historical portraits.

The robes, as worn, were a greatly improved edition on those at first designed. The alterations in the Lord Chamberlain's department not only greatly improved them, but put them in the best of taste, and, in fact, rendered them most becoming to the wearers. Mistakes will always occur. The peer's surcoat, a species of old-fashioned long under-waistcoat, was to be worn "de rigueur." The surcoat was of rich velvet, trimmed with ermine, of the same colour as the outer robe; it was extremely heavy wearing—hot, trying, and expensive. On reconsideration by the official department, the surcoat was found to be a useless appanage, and an order was issued rendering its use optional. The surcoats had, however, all been bought by them.

Many of the pages attending at the Abbey made picturesque and excellent photographs in their old-fashioned costumes, with their quaint three-cornered hats. Jewels galore! Such a feast of precious stones, family heirlooms, as never seen except on such a rare occasion.

The diamonds in the Rue de la Paix and Bond Street pale before such magnificence, and the jewels possessed the doubly added charm of having human setting off, upon the persons of such fair wearers. Priceless pearls were those of Lady Rothschild—as large as plums, and Emily, Lady Amptill, and Lady Clanwilliam's were of the utmost magnificence. Lady North's tiara, ear-rings, and necklet, of the finest water diamonds, would presumably vie with any in the world. Pure drops of dew they appeared. Lady Dufferin and Ava had some very beautiful gems, and the Stanhope heirlooms were superb. Many of the peeresses are presenting these "At Home" photographs, printed in one of the permanent processes, to each tenant on their estates. Countess Howe's robes were cut in the style of the Elizabethan period, very wide, short, with stomacher. Lady Sarah Wilson, after being "under fire" at Mafeking, had again to face cannon of another description, in the shape of the camera and lens. Some of the robes had been worn at many previous coronations. Most carefully preserved had they been, and the colour of the old robes was very beautiful, being mellowed with age. No vivid colour was here; of course, all the stiffening had perished. Lord Coventry's robe was traceable back to 1642, veritably a good old age. How long before that it had been in existence it would be difficult to say.

The coronets in connection with these old robes are very beautiful, all the bands of metal work, wrought by hand, either in gold or other valuable metals, and beautifully chased. How different from the modern cast ones. Of course, the weight is great. Mr. Byrne, how-

ever, considers the old robes, however beautiful in colour, not so adapted for draping and making beautiful rich folds.

An amusing contretemps occurred with the sitting of a certain Lord, high in the land. A telegram was received by Mr. Byrne from him, "Cannot sit at noon; hard up." On inquiry at his Lordship's to know what it meant, it turned out to be that he was "laid up."

Coronation Day, for the purpose of photographing, was, indeed, a difficult one. On several occasions, to get from one place to another, when cabs were unprocurable and not allowed in the cordon, Mr. Byrne requisitioned the first empty carriage and pair he could find, the coachman of which did not seem over busy. A little *douceur* made it thus possible to get, under difficult circumstances, to the next engagement in time.

Coronation portraits are truly regal, the length of robe, when brought round in front of the figure, giving the effect of height to the subject. On many occasions the peers were captured by force by the peeresses to undergo their Coronation photographic christening. The peer's robes were first brought up into the room, the peer then called, and with strong persuasion, and no means of escape, usually capitulated gracefully. On one or two occasions, however, they took to flight. The number and success of these "At Home" photographs, not one of which was taken in a studio, but all in ordinary rooms, demonstrates how entirely independent photography is of such an adjunct. Good work can be done in practically any room, and the most pleasing results obtained rapidly, and in all the comforts of home, without climbing innumerable stairs, in mounting to the tops of houses, let alone the going to and fro, frequently in evening dress. There is no reason for such discomfort and trouble, as is evident by all the Royal photographs, including those of the King and Queen, photographed by Mr. Byrne, being all taken in ordinary rooms.

PRACTICAL NOTES AND HINTS CONCERNING "SULPHITE," "METABISULPHITE," ETC., ETC.

I.

THE use of sulphur dioxide (SO₂) either in the form of a sulphite, metaspulphite, or aqueous solution (i.e., "sulphurous acid") is now very generally recommended, and widely adopted in the making up of many developers. It therefore behoves the intelligent photographer to have some general knowledge as to why this is done, how it should be done, difficulties likely to arise, etc. The following notes have been brought together with the idea of putting before the reader such information as he is likely to require from time to time, so that he may advisedly take out this page and put it in his cuttings book. To further facilitate ready reference, the subject matter has been divided up into numerous subsections, such as History, Impurities, Tests, Ases, etc.

HISTORY.

Its use in our present connection appears first to have been suggested by Berkeley in 1880. He seems to recommend that an 8-grain soda sulphite per ounce (water) be made up and used for the preliminary soaking—developer compounding—and washing after developing, and before fixing. Watkin and Chapman Jones subsequently pointed out that the quantity of sulphite should vary with the quantity of solution, and not simply with the quantity of the developing agent, e.g., pyrogallol acid, etc.

CHEMISTRY.

If we burn sulphur in air (i.e., oxygen and nitrogen) the sulphur and oxygen combine, yielding a pungent gas (sulphur dioxide—Thus S 20 SO₂). This gas is formed when we light an ordinary sulphur match. The gas combines with the moisture in the nasal membranes, and produces a pungent, stinging sensation and suffocation in the throat. When sulphur dioxide or sulphurous anhydride is dissolved in water it is supposed to form an acid called sulphurous acid, or hydrogen sulphite (SO₂ H₂O H₂SO₃). This readily takes up more oxygen, and becomes sulphuric acid, or hydrogen sulphate (H₂SO₄).

Now, sulphurous acid is dibasic, that is, we can replace one or both of the hydrogen atoms. If one only is replaced, the salt is an acid salt. If both are replaced, we get a neutral or normal salt.

Thus Na HSO₃ is acid sodium sulphite, i.e., soda bisulphite, and Na₂ SO₃ normal or neutral sodium sulphite. If we cause more SO₂ to combine with the neutral sulphite we get the now familiar metabisulphite, i.e., Na₂ SO₃ SO₂, or Na₂ S₂ O₅—formerly known as pyrosulphite (N.B.—Nothing to do with the photographer's "pyro" in this connection). The normal sulphate crystallises with 7 molecules of water, i.e., as a heptahydrate, i.e., Na₂ SO₄ 7 H₂ O. Thus its mol. weight, 252, contains 126 (or just 50 per cent.) water of constitution.

PREPARATION.

Into a solution of sodium carbonate a stream of SO₂ gas is passed until saturation is reached. The solution is then allowed to crystallise out, and yields the acid sulphate or bi-sulphate of soda, .H Na SO₄.

If, however, we divide into two equal parts our carbonate solution, then saturate one moiety with SO₂ gas, and then add the unsaturated solution to it, and allow to crystallise, we get the neutral or normal sulphite, Na₂ SO₃. If into a hot and strong solution of caustic soda (Na HO, sodium hydrate), is passed SO₂ gas to saturation, then the crystals yielded are the metabisulphite or pyrosulphite salt.

IMPURITIES.

From the above-given mode of preparation it is easy to see that in the normal sulphite an excess of carbonate is likely, and in the meta salt an excess of very loosely combined SO₂ is probable. Experience shows that these conditions frequently occur. Freshly-prepared meta salt often strongly smells of SO₂, and the normal sulphite is frequently strongly alkaline to litmus.

Now, it very conveniently falls out that we can employ one defect to counteract the other. Used as a preservative, the sulphite should be slightly acid in solution, so that the SO₂ may be readily available. Some writers recommend the addition of dilute sulphuric acid for this purpose. Others recommend citric acid. But it is preferable to add the acid meta salt until the solution shows a slightly acid reaction.

But these do not end our troubles. The normal sulphite is itself liable to change on keeping. The changes are twofold, (1) in dry, warm air the glossy crystals effloresce, i.e., become covered with a white powder. This is due to their parting with some of the water of crystallisation; (2) in damp air the clear crystals also become coated with a white powder, but in this case oxidation has taken place, and soda sulphate has been formed.

The former change is the less harmful. The crystals should be put into small bottles, and the bottles filled up to the top, a sound cork inserted, and the cork and bottle neck dipped in melted wax or paraffin. Preserving the crystals in ether has been suggested, but the cost is hardly justified for photographic purposes. Commercial samples vary considerably. They should not contain more than 2 per cent. of carbonate or sulphate.

In practice it is a good plan to clean away any surface powder by placing the crystals on a bit of muslin stretched over the mouth of a dish, and then put under the cold water spray for a moment. The crystals are then thrown on to dry blotting paper, dried, and weighed.

N.B.—These impurities have a practical bearing. The presence of sulphate is by some authorities regarded as a restrainer. An excess of acid in the meta salts implies the addition of enough alkali before the developer will begin working properly. An unknown excess of carbonate disturbs our calculation in the addition of alkali.

PROPERTIES.

Solubility.—Soda sulphite, 100 pints water at 32 degrees Fahr. dissolve 14 pints sulphite.

100 pints water at 68 degrees Fahr. dissolve 25 pints sulphite.

100 pints water at 100 degrees Fahr. dissolve 50 pints sulphite.

100 pints glycerine at 60 degrees Fahr. dissolve 4 pints sulphite.

Insoluble in alcohol.

PROPERTIES (Sulphites).

The crystals should not smell of sulphurous acid (SO₂). They should completely dissolve in strong, pure, cold hydrochloric acid, and Ba NO₃ S₂ should not produce any ppt. in this solution. Aqueous solution should be feebly alkaline, and show but slight effervescence when powdered citric acid is added.

Has a reducing action with Au Cl₃, H₂ Cr O₄, Fe₂ Cl₆.

Has oxidising action with nascent H, SH₂, Sn Cl₄.

PHOTOGRAPHIC USES.

As preservative with pyro-metal, etc.; as accelerator with amidol-synthol, etc. In intensification with mercuric chloride. For fixing prints by dissolving silver chloride-bromide, albumenate, etc.

FUNCTIONS.

Primarily the object aimed at is preserving in entire condition the developing agent, i.e., pyro, metol, etc. This the SO₂ does by itself by taking up the oxygen dissolved in the water or adjoining air, and so preserving the pyro, etc. Consequently the pyro being prevented from oxidising, remains a more or less colourless solution. Thus secondarily the sulphite is a stain preventer, i.e., by preventing the developer becoming a dark-coloured fluid, which thus would stain gelatine, paper, or fingers. Hence the advisability, when clean and stainless negatives or slides are required, of using a sulphate solution for washing the plate after developing and before fixing, and also of the addition of sulphite to the hydro-fixing bath.

Note, furthermore, that in the case of several of the newer developing agents, e.g., amidol, synthol, etc., the sulphite is not only a preserver, but seems to afford also the accelerating functions that a few years ago we usually assigned to the alkali (i.e., ammonia, carbonates, or caustic alkalis). And seeing that a sulphite solution of pure sodium sulphite, which has but a very feeble alkaline reaction, has marked accelerating functions, it would seem that alkalinity is

not—as often so supposed—equivalent to functional activity in this sense.

RELATIVE PRESERVING VALUES.

We have then practically three preparations to select from, viz., aqueous solution of SO₂, or sulphurous acid of commerce; the normal sodium sulphate, and the metabisulphite. To compare their relative preserving powers we must dissect their chemical formulæ, and ascertain what percentage of SO₂ they contain. This we can most conveniently see in tabular form:—

	Mol. weight.	SO ₂ contained.	SO ₂ percentage.
Sulphurous acid	—	—	about 12 per cent.
Variable strength ...	—	—	—
Sodium normal sulphite			
Na ₂ SO ₃ 7H ₂ O, i.e.,			
Na ₂ O, SO ₂ , 7H ₂ O.....	252	64	25.4
S. metabisulphite,			
Na ₂ S ₂ O ₅ , or Na ₂ O,			
2SO ₂	190	128	67.4 ...

It will be seen that the meta salt has rather more than two and a half times as much SO₂ as has the sulphite.

Sulphurous acid presents no advantages. At 65 degrees Fahr. and normal pressure, 100 parts water contains about 12 parts SO₂. Diminution of pressure or increase of temperature reduces this quantity; and normally the aqueous solution is slowly deteriorating.

It must, however, be kept in mind that the meta salt is acid, and therefore for alkaline development we require to add extra alkali to neutralise this acidity. For various reasons (see impurities, etc.) it seems that a strong balance of advantages is with the meta salt as a preservative. It is not, however, apparently a desirable substitute for the sulphite when used alone as an accelerator.

REV. F. C. LAMBERT, M.A.

New Apparatus, &c.

Kalona: A New Self-toning Paper. Manufactured and sold by Ilford, Limited, Ilford, London, E.

Most, if not all, the self-toning papers at present on the market yield prints of which the surfaces are non-glossy or matted, in virtue of the special system of preparation adopted by the manufacturers; but with that shrewd appreciation of the needs of vast numbers of photographers which has always characterised the Ilford House, the company have come forward with a self-toning printing paper, the surface of which is glazed, and as the appended instructions point out will "give prints of enamelled surface by squeegeeing down on plain glass in the usual way." We suppose that so long as photography itself exists the taste of the individual will range itself upon the side of either "matt" or "glossy" surfaces, and while this difference of taste remains a force we have nothing but commendation for the technical skill and commercial enterprise which allow the photographer to avail himself of the privilege of a choice. Coming to "Kalona," the latest claimant for public favour: at least one morning this week proved bright and rainless, so we had the opportunity of preparing a few trial prints. Kalona prints quickly, and from negatives of fair density gives vigorous reddish-brown images. It will be noticed that in the "toning" formula printed below, ammonium sulphocyanide is a constituent. By way of experiment, in our trial, sodium acetate was substituted for the ammonium compound, with the result that the colour of the fixed and washed images very closely matched that of some specimen prints which Messrs. Ilford have kindly handed us for inspection. These prints have all the appearance of gold-toned images, and the colour is what may be roughly described as a purplish brown of a distinctly pleasing character. Save in the instance referred to the annexed instructions were scrupulously followed in our trials of Kalona; and as illustrative of the expeditiousness of the process, most excellent fixed and washed prints were placed on our breakfast-table on the morning of our trials of the paper. Besides being a quick printer and yielding images of great colourific beauty and refinement, Kalona strikes us as possessing the most valuable of all features in a printing surface: that of giving uniformity of tone. Indeed, we were strongly impressed by the remarkable evenness of our own results. Kalona enters the market at an opportune moment, and we recommend it to our readers as a good thing worth trying and worth using. Here are the makers' instructions:

WORKING INSTRUCTIONS.

Print as for P.O.P.

Immerse prints, without washing, in the following bath:—

Alum (powdered)	1½ ozs.
Ammonium Sulphocyanide	20 grains
Water	20 ozs.

This bath can be used for about 50 half-plate prints.

Keep prints moving for 5 minutes.

Wash for 10 minutes in several changes.

Fix in hypo 3 ozs. Water 20 ozs.

Wash for 2 hours in running water, or many changes.

Follow these instructions exactly and the batch of prints will be uniform in tone.

For convenience the following stock solutions may be prepared:—

No. 1. Alum (powdered)	8 ozs.
Water	100 ozs.
No. 2. Ammonium Sulphocyanide	100 grains.
Water	10 ozs.

Mix 18 ozs. No. 1 with 2 ozs. No. 2.

Mount with starch paste in the usual way. This paper will also give prints of enamelled surface by squeegeeing down on plain glass in the usual way.

Commercial & Legal Intelligence

Six Months for a Canvasser.—At the Handsworth Police Court, on Friday last, Frederick Bickmore, alias Fred Miller, of no fixed abode, was again brought up on charges of obtaining money by false pretences from various persons. He pleaded guilty. The evidence given at the previous hearing was repeated, showing that the prisoner called on numerous persons in Handsworth, West Bromwich, and Birmingham, and represented himself as the agent of Mr. Hall, a Handsworth photographer. He took orders for portraits and received 6d. or 2s. 6d. on account. When his dupes presented themselves at the photographer's, they were told that the prisoner had no authority to take orders for Mr. Ball. John Albert Ball, photographer, of 33, Albert Road, Handsworth, stated that the prisoner had applied to him for employment as agent, but he refused. Prisoner then asked for some specimen photos to show his friends, and witness gave them to him. He had not authorised the prisoner to receive payments for him, nor had the defendant paid any over to him. Detective-Sergeant Myatt, who arrested the prisoner on the 21st inst., produced a receipt-book showing that the prisoner had victimised over 100 people. Prisoner was sentenced to three months' hard labour for each of the two cases which were proved, making six months in all.

RE the Sensitised Paper Manufacturing Syndicate, Ltd.—A winding-up order having been obtained against this syndicate, meetings of the creditors and shareholders were held at the Board of Trade Offices, Lincoln's Inn, on Monday last, before Mr. H. M. Winearle, Assistant Official Receiver. A statement of affairs was lodged, showing unsecured claims £916 19s. 9d., and assets, consisting of unpaid calls (£907), estimated to realise £607. The chairman stated that the syndicate was registered in June, 1900, for the purpose of acquiring from the Electrical Inkless Printing Syndicate, Ltd., the exclusive license for England and Wales to use an invention for the manufacture of a special paper for printing purposes called sensitised paper, on which printing could be done without ink, upon the application of an electric current. The nominal capital of the company was £100,000, divided into £1 shares, but only seven shares to the signatories were actually allotted. The company was to acquire the license mentioned in consideration of £8,000 payable in cash and £60,000 in fully-paid shares. The company, however, never commenced business, and the agreement was never carried out; nor was an agreement with Mr. F. L. Sanderson for the lease of certain paper mills. No steps were taken to obtain working capital, and beyond the purchase of a small quantity of machinery nothing was done towards the manufacture of the sensitised paper. A brief discussion followed, and the proceedings, in the absence of a quorum at either meeting, were formally adjourned for a week.

PHOTOGRAPHY and the Australian Immigration Act.—The "Immigration Restriction Act" became law at the end of 1901, and provided that no person shall be allowed to land in Australia who, "when asked to do so by an officer (the word officer being defined as meaning an officer specially appointed or any Customs officer), fails to write out at dictation, and sign in the presence of the officer, a passage of fifty words in length in an (*sic*) European language directed by the officer." If this means anything, it means that any Customs officer can confront any person on board any ship and ask him to write out fifty words in any European language which the officer chooses to direct: if the stranger is obviously a Frenchman, he can be asked to write his dictation in Turkish. There are additional clauses providing for the rejection of undesirable, but the first clause is widely embracing enough for all purposes. The only exemptions are Australians who have been away and are returning to their native shore, ambassadors, soldiers and men of the Royal Navy, and crews of trading vessels during their stay in port. Any other persons found at large in Australia contrary to the provisions of the Act can be sentenced to six months' imprisonment, or fined £50. Regulations have been issued under the Act, whereby residents of Australia leaving home are advised to be photographed in four different positions before leaving, so that they may be identified when they wish to return. It would be awkward if the Australian eleven and the Federal Premier returning from England should be shut out of their own country if they had altered from their photographs.—"The Times."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

S-pt.	Name of Society	Subject
5	Croydon Natural History	Lantern slide trial night
5	Ashton-under-Lyne Photo	Ramble to Mottram. Leader, Mr. H. Hall
6	Brentford Photographic	West Drayton and District.
6	North Middlesex Photographic	<i>The Origin and Development of Land-cape Painting.</i> Mr. H. A. Mummery.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AUGUST 23RD.—Mr. T. K. Grant in the chair.

Mr. Walter D. Welford gave an interesting account of the experiences of the party which formed his Photographic Camp on the River Avon a few weeks ago. The chat was illustrated by lantern-slide views of camping incidents and the surrounding country. The camping party enjoyed some ten days' stay on Glover's Island, near Evesham. The company was primarily a photographic one, and a good deal of camera-work was therefore done. Both ladies and gentlemen took part, and although few in number, it seemed that the time was spent none the less pleasantly on that account. Those who have tasted of the pleasures and pains of camp life will, of course, need no telling of the necessarily rough-and-ready manner of living; but Mr. Welford's party seem to have been well cared for, if one may judge by the roomy tent accommodation, the sound boarded floors, the piano, and so forth. Excursions had been arranged to the places of interest in the locality. That these were patronised, the photographs shown allow of no doubt, but Mr. Welford said that there was no mistaking the kindly feeling for the camp and its living, and the party was not anxious to leave it. Evesham furnished a number of opportunities for the photographic members of the camp. Stratford, near by, also came in for a goodly share of attention, and Mr. Welford was able to show pictures of Shakspeare's house, Ann Hathaway's cottage, the Shakspeare Memorial and the Memorial Theatre. The church, and many bits along the stream. All the views were hand-camera pictures, and amongst them were bits at Fladbury Weir and Mill, Chadbury Weir, Cleeve Mill, and Hardington.

Following this series, Mr. Welford showed a few portrait studies by Mrs. Welford, which drew forth very appreciative applause from the company present.

WEST SURREY PHOTOGRAPHIC SOCIETY.

The glycerine method of developing Platinotype prints was the subject of a demonstration last week by Mr. W. T. Marriott, which was remarkably well attended and very happily given. The want of control, the lecturer said, had been the drawback hitherto with Platinotype printing, but by the use of glycerine and oxalate solutions and their various combinations with bichloride of mercury he was able, as he showed the meeting, to control the development of his picture and restrain or act on portions of it and get such effects as, more or less artistically, he wanted to obtain. And so, too, with colours. He showed sepias, black, brown, and yellow tones produced at will, and said the work had now become quite a pleasure and a fuller means of expression of one's self and ideas in that beautiful and still unrivalled Platinotype process he could not wish for. The demonstration was excellently given, with cheerful variations, and very well received, and followed by a unanimous vote of thanks.

THE Hackney Photographic Society will hold its fourteenth annual exhibition at the Morley Hall, Triangle, Hackney, on Wednesday, Thursday, and Friday, November 12th, 13th, and 14th, 1902. The exhibition will be opened at 7 p.m. on Wednesday, and at 2 p.m. on Thursday and Friday. The judges will be Messrs. Reginald W. Craigie, A. Horsley Hinton, and Rev. F. C. Lambert, M.A. Mr. Alexander Mackie has kindly consented to arrange the pictures for hanging. The following classes are open:—(F) Portraiture and figure studies; (G) Landscape, seascape, and river subjects; (H) Architecture; (I) Still life, animals, scientific, and any subject not included in F.G.H.; (J) Stereoscopic (sets of four); (K) Lantern slides (sets of four). One silver and one bronze medal will be awarded in each class, with the exception of Class B, in which there will be one gold centre, one silver, and one bronze. A gold medal is offered for the best picture in members' classes (A to D), and also a gold medal for the best picture in the open classes (F to I). Certificates will be awarded at the judges' discretion. A silver medal is offered for the best trade exhibit, and a bronze medal for the most useful photographic novelty exhibited, either by the trade or any amateur. Exhibits will be collected free of charge from the R.P.S. and Salon Exhibitions. The entry form must be returned to the hon. secretary, Mr. Walter Selfe, 70, Paragon Road, Hackney, N.E., on or before October 25th, 1902.

News and Notes.

STARS BY DAYLIGHT.—“Are the stars visible to ordinary sight in the daytime?” asks Mr. E. Walter Maunder in “Knowledge.” “There is a widespread tradition that they are; that if an observer places himself at the bottom of any deep shaft—as of a mine, a well, or a factory chimney—which may shut off scattered light and reduce the area of sky illumination acting on the retina, he will be able to discern the brighter stars without difficulty. The tradition is one of a respectable antiquity, for Aristotle refers to persons seeing stars in daylight when looking out from caverns or subterranean reservoirs, and Pliny ascribes to deep wells a similar power of rendering visible the stars the light of which would otherwise be lost in the overpowering splendour of the solar rays. The tradition, well founded or not, has often been adopted for literary effect. It seems almost sacrilegious to hint that no star known to astronomers could have shone down unceasingly upon poor Stephen Blackpool during his seven days and nights of agony at the bottom of the Old Hell Shaft; that at best he could only have caught a glimpse of it for a few minutes in each twenty-four hours as it passed across the zenith. Dickens, indeed, does not absolutely say that Stephen watched the star by daylight; it is only a natural inference from his description. But is the tradition true? Of course, everyone knows that Venus from time to time may be seen even at high noon; but then Venus at her brightest is many times over brighter than Sirius. Then, again, the assistance of a telescope enables the brighter stars to be discerned at midday; but the telescope not only directs the eye and greatly limits the area from which the skylight reaches the observer, but it enormously increases the brightness of the star relative to that sky illumination. The naked-eye observation of true stars in full sunlight stands in quite a different category. Humboldt, who was much interested in the question, repeatedly tried the experiment in mines, both in Siberia and in America, and not only failed himself ever to detect a star, but never came across anyone who had succeeded. Much more recently an American astronomer set up a tube for the express purpose of seeing the Pleiades by daylight, also with no effect. It has been supposed that Flamsteed, the first Astronomer Royal, sank a well at Greenwich Observatory for the purpose of observing Gamma Draconis, the zenith star of Greenwich, in this manner. The existence of the well is undoubted, though Sir George Airy, the late Astronomer Royal, was unable to find it; but Flamsteed marks it on more than one of his plans of the Observatory, and there is a drawing extant of the well itself, showing the spiral staircase that ran down it. But its purpose seems to have been, not to have furnished the means of observing the star with the naked eye, but to enable the observer to measure as accurately as possible the distance of the star from the true zenith at the moment of transit.”

THE Kodak is *the* rage this year. Whole families go about armed with them. You sometimes see father and mother and all the boys and all the girls presenting their Kodaks at the same object. At Clarens, on Lake Lemane, I came suddenly upon a priest who was kodaking the scenery, and several other reverend gentlemen were gathered around him giving him hints. All the French officers out with the autumn manœuvres carry Kodaks. As they snapshot the village maidens, the photographing is evidently not for military purposes. In many of the museums and galleries and collections of curiosities they make you leave your Kodak at the “sticks and umbrellas” counter, but I have seen them carried into churches and used while service was being celebrated. The kodaker does not seem quite able to draw the line for himself as to when and where it is permissible to “snap.” The etiquette of kodaking has yet to be written. The Paris authorities take away your Kodak before they permit you to enter a public building. I saw twenty-seven Kodaks hanging up by the gates of Père Lachaise. The kodaking mania obtains to such an extent this year that in many places you see people formed up in line waiting their turn to photograph a local specialty. Many amateur photographers, tired of scenery, peasantry, and ecclesiastical buildings, have taken to photographing each other in a variety of attitudes. The uses to which the Kodak may be put by a domesticated amateur was strikingly illustrated one hot afternoon in the garden at Chamonix. A charming French family had taken possession of a little green lawn. The family consisted of papa, mamma, and the baby, and a typical French nurse, all buxomness and cap-strings. I sat under a shady tree, and watched a little domestic comedy of kodaking with the greatest interest. Papa was young and handsome, mamma was young and pretty, and baby was about a year old. First of all papa photographed mamma, who posed for him prettily with a red sunshade and a smile. Then mamma took the baby, and after an effort which lasted a quarter of an hour to make baby turn his head in the proper direction, papa photographed mother and child. Then papa was put in a chair and spruced himself up and mamma proceeded to take a snapshot of *him*. Then mamma sat down and took the baby on her knee, and papa knelt down by her side and held the baby's hand, and the nurse photographed the group. And then occurred a little scene of sweet simplicity that carried me far back into the history of the human race, and made me fancy for a moment that the garden was not in Chamonix, but on the banks of the Euphrates, and that its name was Eden.—[Was Eden on the

Euphrates?—EDITOR.]—For, papa having carefully arranged his Kodak, mamma sat down and proceeded to give baby his five o'clock tea, and thus, amid the smiles of a gardener who was at work, a waiter who was in the hotel doorway, and a couple of ladies at an upper window, papa snapshotted his wife and child. The scene was perfect in its innocence, and its simplicity. It was an idyll of the Kodak. It was just what might have happened had there been no serpent in Eden and Adam had had a Kodak and snapshotted Mamma Eve with little Abel.—“Dagonet” in “The Referee.”

THE annual report of the proceedings in the Cambridge Observatory for the year ended May 24th last has been published. The weather was, on the whole, rather unfavourable for meridian work, since, of the 100 nights on which observations were made, only seventy-nine could be called clear. Notwithstanding this, fair progress was made with the determination of the places of the 2798 Zodiacal stars in Sir David Gill's Catalogue, and a very few circum-polar stars, re-observed at the request of Dr. Stechert, of Hamburg, on which four nights were spent in July. To these ends 3,315 observations were recorded. The observations for Nadir Point were 54; for Level and Collimation 24. A fresh determination of the intervals of the transit wires was made at the beginning of 1902, from the 138 available observations of Polaris taken during the previous year. The result closely agrees with previous determinations. All the right ascension observations are reduced to centre wire. The instrumental corrections are applied, the time of true transit obtained, and the clock corrections and rates calculated up to May 3rd; and the true apparent right ascensions obtained up to April 18th. The reductions to mean Equinox at the beginning of the year are almost completed up to February 27th. The declination observations are reduced as far as apparent Zenith distance up to May 2nd; the true North Polar distance is obtained up to April 1st; and the reductions to mean Equinox at the beginning of the year are brought up to February 27th. In January began the observations for stellar parallax, which will be the principal work of the Sheepshanks photographic equatorial. A first working list includes some twenty objects of individual interest, and a region of the Milky Way (about R.A. 20h. 15m., Decl. plus 37deg.), which contains eight Wolf-Rayet stars, several variables of long period, and the Nova of 1600 (P Cygni). A preliminary search in the southern part of this region for stars of large parallax has been made by Professor Kapteyn. The weather this year has been peculiarly unfavourable for parallax work. The efficiency of the electric control to the driving clock has until lately been impaired by the very uncertain action of the relay. A new form of relay has been made and presented to the observatory by Captain E. T. Dixon, R.H.A. Much time has been spent on the commencement of the reduction of the photographs of Eros made in co-operation with about fifty observatories of the northern hemisphere during the winter 1900-1 for a new determination of the Solar Parallax. As an experiment, fifty-two exposures made on November 9th and 10th, 1900, were measured and reduced, with the aid of a special ephemeris, which was very kindly computed for the purpose by Professor E. Millosevich. In response to requests made to Professor W. W. Campbell, director of the Lick Observatory, Mt. Hamilton, U.S.A., and to Professor F. P. Leavenworth, director of the observatory of the University of Minnesota, Minneapolis, U.S.A., measures of photographs made at these observatories were kindly communicated, and have been reduced in combination with the Cambridge measures. The results of this preliminary and experimental reduction were very satisfactory and it is now proposed to extend the trial to a larger series of Cambridge plates. The work will be greatly facilitated by the readiness with which M. Loewy, president of the Eros Commission of the Paris International Conference, 1900, consented to publish the new ephemeris of Eros, computed under his direction, in the rectangular co-ordinates from which is required, as well as in the more useful form of planetary ephemeris. Observations of *a* Persei have been carefully discussed for determination of velocity in the line of light, and a note summarising the results was communicated to the Royal Astronomical Society. Considerable time was devoted in the autumn to the study of the material obtained in Sumatra in the total eclipse of the sun in May, 1901, and a preliminary report on the observations was communicated to the Royal Society and the Royal Astronomical Society.

* * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A *Contents Bill* is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * NOTICE TO ADVERTISERS.—A *Revised Tariff* for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

Correspondence.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* * We do not undertake responsibility for the opinions expressed by our correspondents.

A CONUNDRUM.

To the Editors.

Gentlemen,—Here is a conundrum for your readers. What Shakespearean character does the “Photographic Convention of the United Kingdom represent?” If you cannot guess it, the solution will be given in your next. H. A. L.

THE LANTERN SLIDE EXCHANGE CLUB.

To the Editors.

Gentlemen,—The above club is now making preparations to start its work for the fourteenth year. There are some vacancies through removals, etc. May I be allowed to state in your columns that if any fairly good workers wish to join such a club I shall be happy to send them particulars. Subscription is 1s. a year.—Yours faithfully,

J. S. HAWKER, Secretary.

Mutley House, Plymouth.

THE R.P.S. EXHIBITION.

To the Editors.

Gentlemen,—Permit me to remind your readers that unpacked exhibits for the pictorial, scientific, and technical sections must be delivered at the New Gallery, 121, Regent Street, not later than 8 p.m. on Friday, September 12th. Exhibits sent by carrier must arrive not later than Thursday, September 11th. Copies of the prospectus and entry form may be obtained on application to the undersigned.—Yours faithfully,

A. W. W. BARTLETT, Secretary.

August 30th, 1902.

HEALTHY PHOTOGRAPHY.

To the Editors.

Gentlemen,—I have many films and plates to develop for amateurs. I find it best to use a harmless, and, as far as possible, a stainless developer. This I find in adurol. I generally use the maker's formula, and never find any skin trouble, such as your correspondent refers to. It develops quickly, and the colour of deposit is good.

I have had forty-two years of photography and have always avoided using chemicals which injure health. One of your correspondents asks how to remove the stains of pyro. I think the best thing is a strong solution of citric acid. It also removes the stain of permanganate of potash and many others.

A stained negative can often be cleaned by taking off the varnish with methylated spirit, and then soaking it in fresh hypo, four ounces to the pint, for an hour or more.—Yours faithfully,

A. SEELEY.

Studio, Hindhead.

THE PROBLEM OF PORTRAITURE IN COLOURS.

To the Editors.

Gentlemen,—In reply to Mr. Wall's criticism of my recent article which you were so kind as to publish, concerning “Portraiture in Colours,” I wish, before going into technical details, to express my regret that Mr. Wall should consider it necessary to describe my writing as “pessimistic, hasty, and ill-advised.” The two last qualifications are especially objectionable to me, and I cannot help feeling that your correspondent has behaved in an ungentlemanly fashion towards me. I believe I am entitled to my opinions as much as Mr. Wall is to his, and because I express mine in a signed article, that is no reason for anyone to wax wrath thereon. My essay was necessarily very incomplete, and was written for the guidance of the rank and file alone of professional photographers, and Mr. Wall's antidote—as he is pleased to call it—in no way makes me regret my effort—rather I wish most emphatically to remark that “Quod scripsi.

scripsi." And now for Mr. Wall's technical pointers. It is a very difficult matter to make large screens of even density, and from my experience I consider small screens on optically worked glass preferable. They are then available for different size work, are easily placed in position, and are not so readily damaged.

Mr. Wall should recollect that everyone does not endorse Mr. Watkin's method of development; and so again it is, I think, a matter of personal equation. I cannot enter into a discussion on the studio question here, as I have not the space, nor can I speak from actual experience, but only from a personal theoretical hypothesis. You see, I am perfectly frank. I think, though, that 33 secs. is quite an impractical exposure for ordinary work. As regards the predominance of greys, this is, in my opinion, the weak spot in three-colour work, but, like nearly everything else in this process, it is largely a matter of personal judgment when one gets to details. I am quite aware that the carbon process has been used for positive work, but I have never yet had the good fortune to see one really fine specimen by this process. I, however, hope for a great advancement if Messrs. Fleming's new transparent ink powders are used. This particular point is though a little speculative just at present. My views and Mr. Wall's on the acceptability of photo-mechanical three-colour printing by the public are so diametrically opposed that I will not discuss them here. Mr. Wall speaks very emphatically concerning the McDonough-Joly process, and yet does not mention the conversion method adopted by Messrs. Sampolo and Brousseau. Neither did I, for the simple reason that I had already passed my boundary line of space, and had to draw up. And yet this method is quite a pretty problem, and is capable of some most interesting mathematical speculative exercises.

I, however, must now state that I absolutely refuse to answer any more criticisms on my article, in the correspondence pages of this Journal, and I can only regret that I have offended Mr. Wall, for whose experience and writings I have a great respect.—Apologising for encroaching so much on your valuable space, I am, gentlemen, yours, etc.,

A. V. KENAH.
2, Eliot Hill, Blackheath, S.E.

THE IMPERIAL DRY PLATE COMPANY, LIMITED.

To the Editors.

Gentlemen,—We shall be obliged if you will find room for the following letters in your Correspondence columns next week.—Thanking you in anticipation, we are, yours faithfully,

THE IMPERIAL DRY PLATE CO., LTD.

Cricklewood, London, N.W.
August 29th, 1902.

[COPY.]

The Imperial Plate Co.,

Gentlemen,—We are receiving reports from both amateurs and professional sources that the Imperial Plate Co. is to be Americanised.

We do not usually attach any importance to reports of this nature, but noting the increased frequency of the rumour, we think you should be given the opportunity of setting all doubts at rest.—Yours faithfully,

DREW AND CO.

August 23rd, 1902.

[COPY.]

Messrs. Drew and Co.,

227, Borough High Street, S.E.

Dear Sirs,—We are in receipt of yours of the 23rd inst., and thank you for bringing the rumour to our notice.

We may tell you definitely that it is untrue. There have not been any negotiations, as far as concerns this company, which remains under the same control as hitherto.

We shall be pleased to know whether you will allow us to publish this correspondence in the photographic journals, as we feel that a statement affecting us so materially should have a wide and public contradiction.—Yours faithfully,

THE IMPERIAL DRY PLATE CO., LTD.

Cricklewood, London, N.W.
August 28th, 1902.

"BIBBY'S QUARTERLY" AND THE PHOTOGRAPHIC PROFESSION.

To the Editors.

Gentlemen,—Some time ago you admitted into your correspondence

column a series of letters sent in by one of your readers reflecting on a letter of mine, copied and addressed to a number of the best photographers. I am not too old to learn, and I have now decided upon publishing the names of my photographic contributors, as you will see, if you refer to any council member. I have now addressed the enclosed letter to the same photographers, to whom my former letter was sent, and perhaps you may think it worth while to publish same for the benefit of all and sundry. A copy of my current quarterly accompanies this letter, and I shall be glad should you see any other faults in it, from the photographer's point of view, if you will kindly point out the same in your columns.—Sincerely,

J. BIBBY.

(Copy of Letter sent to a Selection of the Best Photographers.)

Dear Sir,—Some considerable time ago we sent you the current copy of our "Bibby's Quarterly," and enclosed a letter asking if, at any time, you had any suitable photos for brightening up our LITERARY SUPPLEMENT—we do not want cattle pictures—you would let us see prints, we would pay 2s. on acceptance, and 10s. 6d. on reproduction, but without *photographer's name*.

We find, however, that there is some objection amongst photographers against the publication of their work without their name appearing under the photograph, and as we have no wish to go against the wishes of our contributors, we are now altering our terms, and will pay 10s. 6d. for each photograph accepted and published, giving under each photo the name of artist, as we have done in the literary section of the current number.

Kindly note that we only want photographs for our *literary supplement*, and that our next number will be the Christmas one.—We are, your obedient servants,

JNO. BIBBY.

Exchange Chambers, Liverpool.

August 29th, 1902.

"A CASE FOR THE P.P.A.?"

To the Editors.

Gentlemen,—Last week I had the misfortune to lose my wife, and since that time I have received advertising matter of every description with every post. I enclose one of the kind I refer to, which offers a 24 by 19 enlargement for 8s. 6d., usual price one guinea. Is this a case for the P.P.A.?—Yours truly,

J. L. BROWN.

St. Bernard's Bank, Knott End, Fleetwood.

August 27th, 1902.

[We append the circulars sent by our correspondent, who does not appear to be a member of the P.P.A. Why does he not join that body and bring his case before the committee?—Eds. B.J.P.]

Dear Sir,—We trust you will not consider we are taking a liberty in offering you our sincere condolence on your recent bereavement. Knowing, however, the value placed on a life-like portrait of one who has departed, we beg to mention that we execute life-size portraits, enlarged from any photo (no matter how old or faded), and skilfully painted in oils, water colours, or black and white, at most moderate prices. We have made this branch a speciality in our business, and have received thousands of testimonials, every one of which proves appreciation of our work.—Apologising for troubling you at such a time, and assuring our best care and attention to your kind commands, we beg to remain, yours obediently,

ELITE PORTRAIT COMPANY.

267, High Holborn, W.C. (next door to the Inns of Court Hotel).

August 25th, 1902.

Important Notice.—To introduce our work to you we will make a black and white permanent enlargement, from any photo, no matter how old or faded, artistically mounted, measuring 24 by 19 inches, and will send it, together with original, carriage paid, to your address for 8s. 6d. complete (usual price one guinea). No money required until picture is received and approved by you. This offer is available for 14 days only. Send photograph, with your name and address, to the Elite Portrait Company, 267, High Holborn, London, W.C. Numerous testimonials. Price list for larger sizes, oil paintings, etc., post free on application.

Answers to Correspondents.

- * * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C."* Inattention to this ensures delay.
- * * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.*

PHOTOGRAPHS REGISTERED:—

- E. Kelley, 26, Queen Street, Newton Abbot. *Two photographs of the Rt. Revd. W. Vaughan.*
- W. Harrison, Holly Bank, Onchan, Isle-of-Man. *Two photographs of King and Queen's visit to Ramsey.*
- J. A. Stelling, 60, Peckham Road, S.E. *Two photographs of Dr. J. L. Campbell.*
- F. W. Harrison, Holly Bank, Onchan, Isle-of-Man. *Photographs of King and Queen's visit to Douglas.*
- G. A. May, Buxton Road, Bakewell. *Photograph of the Duke of Rutland.*
- E. Hamilton-Toovey, 36, Royal Parade, Jersey. *Photograph of Sir. W. Laurier and two others. Photograph of Sir. W. and Lady Laurier and others. Photograph of Sir. W. Laurier.*
- J. E. Reeves, 48, Hermit Road, Canning Town. *Photograph of West Ham United Football Team. Photograph of W. Linward. Photograph of J. Bigden.*
- B. G. Brock, 237, Wellingborough Road, Northampton. *Photograph of the late W. Taylor.*
- R. Leak, 60, South Parade, Bradford. *Photograph of Coronation Fete.*
- T. W. Steven, 3, James Morrison Street, Glasgow. *Photograph entitled "Lizzie Crew."*

H. TRESS.—The initials probably stand for "J. F. Shew."

PYRO.—Write to Mr. Reginald Craigie, The Camera Club, Charing Cross Road, London, W.C.

SECTIONAL OR PORTABLE.—Your second letter did not arrive till after the answer to the first one was in type; hence the reply appeared, as it did, with your name attached.

ADDRESSES WANTED.—"COLLOTYPE" writes: "Could you kindly give me the names and addresses of the Collotype firms in Paris?"—In reply: We are sorry we do not know the names and addresses of Collotype firms in Paris. There are many Collotype firms in England, and we do not think you will get better work from France than is produced in this country.

HALF-TONE WORK.—"PROCESS" writes: "I wish to make myself acquainted with that branch of photography which deals with the reproduction of pictures from photographs, in the manner similar to the sample I enclose. Can you advise me as to what book or books to read up for this purpose, and is there any place in London where I could get practical teaching?"—In reply: A good work on the subject is "Half-Tone Process: On Zinc and Copper," by Verfasser. We should advise you to join the L.C.C. Technical School, Bolt Court, Fleet Street, E.C., for practical instruction.

BOOKS WANTED.—H. B. writes: "Would you kindly inform me which are the standard and most reliable books on (1) stereoscopic photography, (2) portrait photography, (3) general photography?"—In reply: (1) The "Stereoscope and Stereoscopic Photography," from the French of F. Drouin; or the article in the Almanac for 1900, which fully deals with the subject. (2) "The Studio and What to Do in It," H. P. Robinson. (3) "Instruction in Photography," Abney. On pp. 682-3 of the Almanac you will find a list of the principal works published on photography.

MOUNTING, ETC.—"OLD SUBSCRIBER" asks for the best method for mounting glass enamelled prints on card mounts; and mountant. "I find using warm liquid glue leaves marks when dry. What I desire to use is an adherent that does not spoil the appearance of the enamel surface."—In reply: Most of the large dealers supply an impervious paper, which, when used according to the directions given with it, enables the prints to be mounted on ordinary mounts, with any mountant, without their losing the gloss. You cannot do better than obtain some of that.

FLASHLIGHT PHOTOGRAPHY.—"TIPPERARY BOY" writes: "Will you kindly give me some little hint as to taking flashlight photographs? I intend to photograph a cave close to here. Would you recommend flashlight candles; if so, what exposure on Imperial flashlight plate?"—In reply: The flashlight candles will be very good for the purpose; but we can give no idea as to the exposure, as that must depend upon the number of lights used, their disposition, the size of the cave, the aperture of the lens, etc. Your best way will be to make one or two experimental exposures.

MOUNTING PRINTS.—J. P. S. writes: "I have purchased a considerable quantity of "mounts" from a certain German firm, but cannot get the prints to adhere. I have written to the firm, stating this fact, and they replied, advising me to use gelatine instead of starch, which for thirty years I have found effective, satisfactory, and efficient. Can you kindly advise me as to the best system?"—In reply: If the prints will not adhere with starch—though we should have thought they would, if it were used thick enough—you cannot do better than employ gelatine, as the makers of the mounts recommend. The one mountant is as good as the other, provided the gelatine is free from acid.

FLASHLIGHT PHOTOGRAPHY.—"FLASHLIGHT" writes:—"Could you tell me what is the best flash lamp made for taking 12 by 10 groups at night; for instance, dinner parties, suppers, balls, etc., and the best lens to use for such work?"—In reply: There are so many flash lamps in the market, all of which are claimed as being the best. Better consult the Almanac. You will there, in the catalogues of the different makers, be able to judge which will answer your purpose best. It is a fixed rule with us not to recommend any particular maker's goods. A rapid rectilinear or a lens of the anastigmat type that works with a large aperture is best for the purpose.

PHOTOGRAPHY AS A PROFESSION.—F. B. writes: "I am eighteen years of age, and am about to enter the photographic profession. Would you kindly inform me the best branches of the business to learn that would give me the greater remuneration after my apprenticeship, if I am skilled in such departments?"—In reply: This is a very difficult question to answer, seeing that the photographic labour market is now very much overstocked, and the future outlook is by no means hopeful. Possibly the manufacture of photographic materials offers the greatest prospect. We should advise you to seriously consider whether it will be worth your while to enter the photographic ranks at all.

COLLOTYPE.—W. R. writes: "Could you give me your advice about setting up plant for doing Collotype work? This would chiefly consist of pictorial postcards and view-books. What machinery would be required? How could I learn the process, and at what cost would I be able to put down the plant? If it could be done reasonably, I have no doubt I could make a good thing out of it. Of course, there would probably be the motive power to supply, but this could easily be done by electricity, which can conveniently be put in in this town."—In reply: We should advise you to write to Messrs. Penrose and Co., Farringdon Road, E.C., for their price-list of Collotype appliances; from that you will learn the cost of such as will suit your requirements. With regard to your learning the process, you cannot do better than join the L.C.C. Technical School, Bolt Court, E.C., unless you take private tuition.

MOUNTING PRINTS.—E. B. P. writes: "I have mounted a number of photographs in an album. Round some of these I have ruled lines with Pelican drawing ink. The prints are of various sizes, and it therefore follows that the lines round some of the smaller prints must come in contact with the face of the larger prints when the album is closed. It did not occur to me at first that the ink is a chemical compound and might therefore be harmful to the prints. Can you tell me whether there is any risk in using the ink, or whether the chemicals employed are harmless; and, in the event of there being a doubt as to the safety of this ink, can you tell me what would be safe to use? Would the liquid Indian inks sold by artists' dealers be safe, or are risky chemicals employed in their manufacture?"—In reply: Not knowing the composition of the ink named, we are quite unable to say whether it would act injuriously on the print or not. Indian ink, however, may be relied upon as being harmless.

LENS QUERIES.—"LENS" asks: "(1) Whether a Busch rapid aplanat, f/8, angle 75deg., is superior in every way to the ordinary good make rapid rectilinear lens. I cannot afford the higher-priced anastigmats. (2) Can same be used with a larger stop for general work than the rectilinear, and has it a flatter field? (3) Would you recommend this lens in preference to purchasing an ordinary good rectilinear lens. (4) Would the said Busch lens be more rapid with same stop in comparison with the rectilinear? (5) Can I be sure of obtaining this year's "B. J. P." Almanac through Smith's Bookstall?"—In reply: (1) As we have frequently said before, it is quite against our rule to pass an opinion on the comparative merits of different makers' goods. (2) Much will depend upon the quality of what you term "a good make rapid rectilinear." (3) See Answer (1). (4) No; each would have the same rapidity. (5) We cannot say. Better make inquiry at the bookstall. It was out of print as soon as it was published. Possibly Smith's may have a copy left.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published early in December next. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The edition for 1903 will be increased to 25,000 copies, a large number of which are already ordered.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1903. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will

be recorded, and wherever practicable new features of an informative nature will be added.

Secretaries of societies will oblige us by promptly forwarding lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, etc. Those firms who wish to take advantage of this feature should communicate with us not later than October 31.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRA.

A Time-Honoured "Par."

The "three-colour process," whether in lithography or in the ingenious Joly system, has rather taken the wind out of the sails of the newspaper paragraphists, who, in intervals of about eighteen months, have for the last thirty years announced the solution of the problem of photographing in natural colours; but he is irrepressible—we might almost say eternal. This is what he has last told us in the columns of the "Daily Chronicle" in a letter from its Geneva correspondent:—"A Swiss amateur photographer, M. Adolphe Gartner, residing at Berne" (it is best to be particular as to details) "has discovered the secret of colour photography, after a number of years of experiments. The inventor takes his photographs on glass porcelain and paper, and in any colour, the best results, however, being obtained from blue, red, and yellow. His productions on glass are veritable pictures, being true to nature in every detail. The secret lies in the 'bath,' and in the developing process, for the photographs are taken with an ordinary camera." This is very circumstantial. It is well, for example, to know that it is not in the fixing solution, nor the varnishing that the secret method comes in.

* * *

Camphor Subs and Photography.

The connection between camphor and photography is not, at first sight, obvious; yet we are credibly informed that the requirements of photographic technics have been such as to influence the market price of that interesting product. It is true that the native method of obtaining it, which involves the cutting down of the camphor tree, must lead to its gradual extermination, and consequent rise in price, yet if the information conveyed to us be correct, the amount of camphor (which is a vegetable pro-

duct of comparatively limited production) required in the manufacture of celluloid is so extensive that it has raised the price above what it averaged in the days when celluloid was a commercial product of no great importance. What it means nowadays in photography our readers do not need to be told. There are, of course, other and minor uses to which camphor is applied; for example, in the making of varnishes the addition of camphor aids in the solubility of certain resins, and again it possesses the remarkable property of greatly increasing the amount of bichloride of mercury that can be dissolved in spirit of wine. This, however, would not be of practical use in intensifying, as the camphor would be thrown down upon the addition of water, and fill the liquid with flocks. This substance possesses considerable chemical interest, and forms one of the list of vegetable bodies which chemists are trying to replace by artificially-formed substitutes. According to "La Nature," practical success has attended the experiments, and M. E. Callemberg, of Lank-on-Rhine, is now making on commercial lines pure hydrochlorate of terebinth, or artificial camphor. A curious property of this new product is its power of dissolving gun-cotton when dissolved in nitro-glycerine, though we imagine that there is little danger of the time-honoured collodion being displaced by this novel gun-cotton solution.

* * *

Other Uses of Collodion.

As we have just said, there is little danger of the solution of gun-cotton known to photographers as collodion, being replaced by a nitro-glycerine-and-artificial-camphor solution. All old wet-plate workers are familiar with the tough membranous-looking substance produced when a collodion-coated plate is soaked in water, but few of them are aware that the same product is made in a different manner and spun into an artificial silk, and on such a scale that there is a large manufactory devoted entirely to its production. There is, however, a possibility that preparation of gun-cotton in its turn may be displaced, for, as explained in an article in the "Lancet," an important step has been taken in the production of synthetic silk. *En passant*, our readers may be reminded that a collodion made from silk has been proposed—a solution in either ammoniacal solution of cupric oxide or of nickel oxide; it is not precipitated therefrom by alkaline salts, sugar, nor gum. What has been produced by synthesis is not actually silk, but the constituent to which it owes most of its properties—the sericine, or rather its derivative by hydrolisis sericine, that has been made. Sericine constitutes about 70 per cent. of the natural article. Speaking of the replacement of the natural article by artificially-produced substitutes, the "Lancet" humorously remarks, "It is just possible that in the near future it will be no uncommon experience to hear in the shops a customer precise in his demand for either the synthetic or natural article in accordance with his choice."

* * *

American Import Duties on Works of Art.

Many of our readers are possibly unaware that there is a heavy customs duty on works of art as they enter the United States from Europe. For example, if, say, a photogravure picture enters America it has to pay, whatever its value, an *ad valorem* duty upon it which is pretty high, and, what is worse for Europeans, it may be copied without let or hindrance, as there is no copyright in America, unless the work is actually produced there—that is to say, the photogravure is printed there. Now, when paintings of great value are

imported the import duty becomes a very serious item. We read in the "Daily Telegraph" that an organisation of wealthy art lovers is in progress of formation to secure the repeal of the customs tax on pictures. Mr. C. T. Yerkes, speaking recently on the subject, is reported to have mentioned the name of Mr. Pierpoint Morgan, and said that both of them have valuable paintings stored in Europe, which they will not import into America because of the duty exacted by the United States. It is pretty well known through the daily Press that wealthy Americans have, of late years, been purchasing paintings here at almost fabulous prices, and that a proposal has been made for prohibiting the best pictures here from leaving the country, as is the case in some Continental countries. Until that is done, many at home will desire that the American customs tax will remain unrepealed. When it is considered that the import duty is so very high, it must be a very considerable addition to the price actually paid for the pictures, and thus restrain purchases, except by veritable millionaires. Until there is some legislation for prohibiting the works of old masters from leaving this country that does not possess many of them, it is to be hoped that the United States duty will remain as it is.

* * *

The Dark-room Bench.

In too many cases we are afraid the dark-room bench is anything but what it ought to be, and we have found it ere now moist with developer stains, which too readily adhere to the hands, or the bottoms of measures, and even sometimes we have seen a fine crop of hypo crystals showing. If covered with linoleum, they are for a time decent in appearance, but the damp and the alkaline solutions soon attack the structure of the linoleum, and it will rub up to a fine powder, which has a happy knack of adhering to everything. Zinc is readily attacked by spilt fixing solution, and soon becomes riddled with holes. Lead is the only satisfactory metal to use as a covering, but any metal is apt to try the strength of dishes and measures. Common paint, or even bath enamel, will not stand repeated and long soakings with alkaline splashes. M. Clerc in "La Photographie Française," one of the best of our French contemporaries, now states that, having experimented for several years in the chemical laboratories of the Faculté des Sciences de Paris, he has finally adopted the following treatment with every satisfaction; the following solutions must be prepared:—

A.

Sulphate of copper	125 g.
Chlorate of potash	75 g.
Bichromate of potash	50 g.
Water to	1000 cc.

B.

Aniline hydrochloride	150 g.
Water to.....	1000 cc.

The solutions should be heated to boiling point, and A. is liberally brushed over the bench and allowed to dry, and then B. is applied and allowed to dry. A crop of crystals will appear as soon as the wood is dry, and these must be brushed off, and again successive coats of A. and B. applied as before. This treatment gives a deep greenish colouration to the wood, and if treated with boiled linseed oil or a thick paste of hard paraffin and vaseline, it will be quite impervious to water. The whole operation will only take about four hours, and it should be left for this time to dry thoroughly before use.

Collodion Negatives and Their Stability.

At one of the recent meetings of the London and Provincial Photographic Association some negatives by the wet collodion process were shown that were said to have been made in 1852. If this date be correct these negatives were made when the wet collodion process or negatives was, commercially, almost in embryo, for it was not until two or three years later that it came into general use for negatives, although it did for glass positives. Supposing the date to be correct, these negatives were probably developed with pyrogallic acid, for it was not till some years after that iron was used for the purpose, though it was the universal developer for positives. The majority of the pyro-developed negatives were very dense, and took a long time to print, not because they were retained, as many of the pyro-developed gelatine ones are, because the shadows were represented by clear glass. The long printing was necessary by reason of the density of the image itself; great density then being considered an essential to a good negative. Mention was made by one of the members of some collodion negatives he had seen, over which a curious stain has appeared, and the negatives seemed denser than they were originally, and the same good quality of prints was got from them as when they were first made. We have seen many hundreds of negatives that were made in the early days of the process, but have not seen any that have become stained. It is quite conceivable, however, that if they were fixed, or incompletely fixed, with hypo, and insufficiently washed, they might, possibly, become deteriorated, though we have never seen any example. The majority of collodion negatives produced by professionals were then, as now, fixed with cyanide. Its action was quicker, and it was more quickly washed out of the film than is the case with the hyposulphite of soda. It has, at times, been asserted that collodion negatives become denser with age, but we very much question if this is the fact. The image of a wet collodion negative, developed with iron, is different from that in a gelatine one. It consists of metallic silver only in a thin film of quite inert material, and, if that is varnished, the air can have no access to the metal to alter its colour or its condition. By comparison with modern gelatine negatives, the old collodion ones do seem very dense, and many may surmise that they were not made so in the first instance, or they would never have yielded good prints. They certainly, many of them, will not on gelatine papers, and that may have given rise to the supposition. But it must be borne in mind that they were not made for these papers, but for albumen—the only paper then in vogue—and that was strongly salted and also strongly sensitised to suit them—very different conditions from those existing in the present day P.O.P.'s.

UPON DRYING NEGATIVES AND DRYING MARKS.

THAT a few remarks on this topic will not be out of place could be proved, if it were necessary, by an incident that occurred not very long ago at a meeting of the L.P.P.A., when a discussion took place as to whether a negative was darker or lighter when wet than when dry. There was by no means a unanimity of opinion on the subject. The question of negatives wet and negatives dry was evidently too simple a one to engage the attention of the bulk of those engaged in more important investigations. Yet the drying of negatives being a necessity, it were well to be acquainted with all its possible vagaries. As a concrete example, we may refer to a mistake that no old wet-plate workers are likely to make, though it is by no means uncommon among amateurs—the setting a wet negative to dry, or even to rest, for a moment upon a shelf or ledge not free from dust. The surface tension of the liquid causes particles of the dust to be carried up and deposited all over the surface, to leave spots, roughness, or smears sufficient to considerably mar its perfection. This is one of many common causes of spoiled negatives, and we will briefly allude to others following the course of its progress from developer to drying rack.

Before a negative is put up to dry it must, of course, first be washed. If it be not sufficiently washed, one of two things will follow: either the hypo will dry in visible flat crystals, injuring the film where they form, or else the hypo left in will cause the film to remain soft, and eventually lead to its darkening or staining and to the causing of stains upon the paper when put out to print. These markings on the negative may not appear at first, but are bound to show sooner or later; if later, then the negative may probably be ruined beyond recall. Hence proper drying involves proper washing.

Before a plate is put up to dry there are several points to be attended to, and where (as ought always to be the case) the negative is intended to be afterwards varnished they are of prime importance. In the first case, it is to be observed that a negative placed upright in a trough to be washed may remain without injury for ten times as long a period as would be permissible if it were placed horizontally under a tap from a water-main. Virtually, all tap water contains a greater or less proportion of suspended particles, and these, as the tap water flows over the plate, are deposited on the film, in the case of the horizontally placed, but pass over without adhering to those vertically disposed in a trough. This very simple matter is little known, but the deposited particles are painfully evident when the plate comes to be varnished. A piece of flannel tied over the tap forms an excellent filter. Then, again, now that backed plates are so much used, it will be observed in the case of a backing composed of a powder pigment such as sienna, lamp-black, etc., rather than a soluble substance such as caramel, the powder is very apt to deposit a thin adherent film, either in the developer or the fixing, and before the plate is put up to dry this must be carefully removed by gentle friction with a pad of cotton wool, or otherwise the dried negative will have a film stained in places where the untouched deposited pigment lay, but clear in patches where any handling of the film had taken place, and so removed the coloured surface stain. We have here the explanation of many an undiscovered cause of stained negatives. There is, further, to be considered the kind of water available for the washing. Some waters contain a large amount of dissolved solids, such, for example, as carbonate of calcium, hence when the negative is dry the dissolved matter remains in or upon the surface of the film, and leads to the forma-

It was announced, last week, that a new comet has been discovered by Mr. C. D. Perrine, the Assistant Astronomer at the Lick Observatory, Mount Hamilton, California. The comet is only of the ninth magnitude, and is situated in the Constellation of Perseus, its R.A. and N. Dec., at fifteen minutes after noon, Greenwich time, being: R.A. 3hr. 17min. 0sec., decl. 34 degrees, 38 seconds. It is thus visible practically throughout the whole night in this latitude, being low down in the north-east at sunset, and crossing the meridian 17 degrees south of the zenith about half past four in the morning. Since the announcement of its discovery the comet has been photographed at the Royal Observatory, Greenwich. The observations there confirm the reported faintness of the object, and comparison with the figures given with the observation at Lick shows that it is moving in the direction of decreasing right ascension at the rate of rather more than a minute of time, and northward about 2 minutes of arc per day. Although the comet is so long visible after dark, it is so feeble in light—being only of the ninth magnitude—that it can only be seen telescopically, and can only be photographed by suitable astronomical appliances. Hence there is no chance of the new comet being photographed with ordinary apparatus.

tion of mottled or other drying marks. When this state of the water is known the negatives should have a final washing with distilled or rain water. Especially is such a treatment indicated in the case of certain popular films. They have such a repellent surface as though they had been subjected to the action of formaline vapour, that they should always, before putting in the drying rack, be blotted with fluffless porous paper, to remove the surface moisture which otherwise would dry in clots or patches, and lead to irremediably stained negatives. An exception to this principle of action occurs with rollable films, with which it is desirable to add to, instead of taking from, the final washing water. Such films should be immersed for a time in a 1 or 2 per cent. solution of glycerine in distilled water. When dried after this treatment they remain limp and comparatively flat, instead of drying up into quills, as they do if not so treated, causing infinite trouble to print from.

Coming now to the actual drying itself, so long as the plates are kept free from dust or from standing on dusty supports, there is little to be said, beyond giving the caution that it must be regularly done. For example, if a negative, before taking from the rack, prove to be nearly, but not quite, dry, it must be replaced to finish drying, and on no account be heated at the fire to expedite the operation, as such treatment would inevitably result in a dark patch, the last quickly-dried portion coming up decidedly darker than the rest. Further, if the whole film be surface-dry only, the result of finishing it off before the fire will be to produce an insensible partial melting, all the margins of the various objects especially losing their crispness and becoming surrounded by a decidedly marked outline. This aspect of the subject leads to a consideration of the print we first mentioned. Is the negative denser or paler when dried than when wet? Unless under exceptional circumstances the negative upon drying becomes darker, and when varnished the opacity is slightly reduced. We may conclude by referring to a very interesting aspect of this point. Negatives are occasionally marked by splashes of water from the sink, for example, or through raindrops being carelessly allowed to fall upon them. When dry these marks are light, with dark margins, and if present in quantity appear to irretrievably ruin the negative. Yet such is not the case. A complete cure is usually brought about by soaking the maculate plate in water for some time. The effect is remarkable; every trace of the spots will have vanished, and the negative is restored to its pristine excellence.

DISCURSIVE NOTES ON ALBUMENISED PAPER.

At some of the recent meetings of one of the London Societies the merits of albumenised paper has come under discussion, and the reason why it is so little used by amateurs now. There can be no question that gelatine papers have, during the past few years, very largely supplanted albumen, not only amongst amateurs, but amongst professionals as well, though many of the latter who use it freely admit that prints on albumen paper are superior to those on gelatine, still they do not employ it. On the other hand, some professionals still use it for their general work, but many of those purchase the paper ready sensitised for the reason that it saves the trouble of sensitising, and also that it keeps longer than that of home sensitising, both before and after printing, as the latter only remains good, as ordinarily kept, for a day or two in hot weather.

There are, however, some professional photographers

with whom trouble is a secondary consideration to the quality of their productions, who still continue to sensitise their own paper, and there is no question that for some tones, such, for example, as the purples, the paper of home sensitising is preferable to that purchased ready sensitised. Paper of home sensitising also tones more readily than as a rule, do those purchased ready sensitised, though it should be mentioned that there are exceptions even to that rule, for some of them do tone as readily—or nearly so—as the others. Even with the paper of home sensitising the deep rich purple blacks that were so much in vogue some thirty years ago, and which are much sought after by some now, are not easily obtainable, even with negatives of vigorous character, and the paper is sensitised on a strong silver solution—the essentials for securing these tones. It may therefore be as well to explain the reason why.

At the time to which we refer the papers were, comparatively, but slightly albumenised. The albumen was then, often, diluted with water. Now in the commercial papers it is used undiluted, and, more often than not, concentrated by evaporation, or dried albumen is added to it so as to obtain the highest possible gloss. Furthermore, with these papers they are not so highly salted as were those of the old type, which require a stronger silver solution for their sensitising than is required, or even desirable, now. It may be explained that with these thickly albumenised papers the image is mostly confined to the albumen, whereas with the less highly glazed ones it was, to an extent, in the paper itself.

Having pointed out the difference between the albumen papers of the olden times and those of the present day, we will now consider the working of what is, commercially, available now, as we must deal with them as we find them on the market, for no one nowadays thinks of albumenising his own. First the sensitising of them by the user. On this point we are often consulted by printers, whose only experience in their work has been with gelatine papers, when they have taken an engagement where albumen paper is used, and it is sensitised on the premises. It used to be said that the sensitising bath should contain from seven to eight times the amount of nitrate of silver that the paper contained chloride, supposing that be chloride of ammonium or an equivalent in other chlorides. Now, as nearly the whole, if not actually the whole, of albumen papers obtainable at the present time are prepared on the Continent, the user has no means of learning the proportion of chloride it contains—or what chloride it is. For this reason he had best sensitise the paper according to the formula supplied with it by the makers. If, when the paper has been sensitised according to that formula, and dried, it be kept between sheets of blotting paper that has been moistened with a solution of carbonate of soda, and dried, as first suggested by the late Mr. William Bedford, it will keep for a week or more without deterioration. All home sensitised albumen papers require to be toned the day, or the day after, they are printed, otherwise the whites will suffer. This is one of the drawbacks of it as compared with the ready sensitised papers.

We will now consider the ready sensitised papers. It was said, at the meetings above referred to, that there was a difficulty in amateurs getting the paper, as many of the dealers did not stock it, because it did not keep as other papers did. Well, it certainly does not keep so well as bromide, or even gelatine P. O. P.'s do, but still it keeps for a long time, and some brands keep for a much longer time than others. We surmise that the reason it is often not stocked by some dealers is because they have but little

demand for it as compared with the demand for gelatine papers. We have just mentioned that the whole, or nearly the whole, of the paper is albumenised abroad, and we may add that much of it is now sensitised there. But there are many firms that sensitise it here, and from them it may be had either in small, or large, quantities, with the assurance of having it freshly prepared. There is one advantage in the ready sensitised paper, beyond their keeping qualities, that may be referred to here. It yields prints of greater vigour from weak negatives than does that of home sensitising, which makes it better for the class of negative that is now so generally made.

All these papers are strongly acid, as citric, or other organic acid, is the preservative, and it is this that confers the greater vigour in the prints from these negatives. This acid retards the toning, and unless it is removed the toning will proceed but slowly, and then often not beyond the red, or red brown stage without mealiness. It is a good plan with these papers, when the silver has been washed out prior to toning, to pass the prints through a very dilute solution of common washing soda, and then give them another rinse in water. They will then tone more readily, and take a deeper tint than they would otherwise do. If the prints were always treated in this way we should hear less of the difficulty in toning ready sensitised papers, though some, it should be mentioned, do not require that treatment. Albumen paper is not yet extinct amongst the better class of professionals, or the more artistic amateurs, for there is no question that the results upon it are far more artistic than are those on the garish gelatine P.O.P. papers, to say nothing of their probable greater stability when carefully produced.

A PHOTOGRAPHIC HERO.

MARK SURTEES is a photographer, and Mr. Charles Marriott has made him the hero of "Love with Honour." The story opens in the bedroom occupied by Mark and his fellow-assistant, Hermann Fischer, and it is the dawn of the day which releases Mark from his apprenticeship to a provincial photographer named Rangeworthy. During his apprenticeship Mark has been imbibing other ideas than those which appertain to photography; he has come to the conclusion that "our ideas of happiness are all wrong," that "the art of living consists in doing without;" and his resolve is fixed on demonstrating the "folly of civilisation," and on preaching the "gospel of bread, water, and the blue sky."

During the days of Mark's apprenticeship the interest on the thirteen hundred pounds left him by his father has been paid to Rangeworthy as compensation for his tuition in taking negatives, retouching, and finishing enlargements; but now that his indentures had expired he proposed to utilise that forty pounds a year in another way. It would find him in food and shelter while he tramped the country and learnt from Nature at first hand.

As a preliminary to diverting the interest on his capital to new uses, Mark sought an interview with Anthony Pembroke, lawyer and guardian. It was to this worthy man Mark owed his apprenticeship to Rangeworthy; Pembroke had been guided in his choice by "Mark's fondness for pictures and his own general desire for a gentlemanly occupation." Pembroke held exalted notions of photography as "a profession nearly allied to the Fine Arts," and when visited by his youthful client he, without waiting for an expression of Mark's intentions, effusively called for a bottle of his best port that he might drink success to "Mark Surtees, photographer." But his respect for photography as a profession was either only skin deep or

merely inspired by admiration for his own wisdom in selecting that occupation for his client, for, on Mark protesting that he did not think he had any real vocation for photography, Mr. Pembroke ejaculated: "Vocation? Fiddlesticks!" It was all very well to talk of vocation in connection with the Church or the Law. "But photography? Pooh! Who needs a vocation for shoemaking?"

Despite his lawyer's sudden depreciation of the profession "nearly allied to the Fine Arts," Mark stuck to his guns. "The fact is," he said, "I have come to consider photography, as it is practised, rather a sham. My work, though it isn't work, really, makes me feel artificial, almost dishonest." So Mark wins his way, and henceforth Pembroke will forward to him, in whatever part of the country he may be, his forty pounds a year in quarterly instalments.

But Mark Surtees was not to be so easily released from the thralldom of the camera. For a time all went well, and presently his peregrinations brought him to the lovely village of Charlote, in Somersetshire. Various reasons, chief among which was the unsuspected magnetism of Laura Dampier, prompted a long halt here, and Mark took lodgings with one of the villagers. His forty pounds a year are ample for all the requirements of rural life. Suddenly, however, comes a message from Pembroke of the failure of the mines in which his capital is invested, and Mark is faced with the necessity of seeking a source of income elsewhere.

Photography's opportunity had dawned again. In his perplexity Mark wrote for advice to his old fellow-assistant, Hermann Fischer, now settled in London with a studio of his own. Hermann's reply was an offer of work. Would Mark care to supply him with landscape negatives? There seemed to be a demand for large work in platinum and carbon. Hermann said that his present circumstances did not allow him to offer a very good salary, say, twenty-five shillings a week, but that there was every reason to suppose the thing would grow. If Mark liked the idea he could carry it out without interference to his mode of living. Hermann would, of course, supply apparatus and materials, but he suggested the advisability of Mark finding a fixed headquarters where he could develop his negatives, etc. Mark's reply is interesting not only as showing how accurate Mr. Marriott's knowledge of camera work is, but also as containing hints useful to other photographers than heroes in novels.

"If you are disposed to give me a free hand," he wrote, "I'll not only satisfy you, but enjoy myself into the bargain. If, on the other hand, you want me to do the stale old tricks over again, I may as well say at once that I prefer stone-breaking. I am only just beginning to know how rotten the ordinary landscape photograph is, and I see that the fault is not with the medium, but the method. As a matter of fact, I don't remember that there are any landscape photographs in existence except local 'views' and the faked 'art photographs' of exhibitions. Let us come to an understanding upon that question. With your permission we'll have no trick printing, no stock skies or clouds put in with cotton wool on the negative. I propose an honest photographic record of the thing as it happens. There's a lot of material about here, and I don't think I could do better than exhaust this district first, and so save the expense of hiring conveyances to take my traps about. That brings up the question of tools. I should prefer to work whole-plates with a single landscape lens. I think you will agree with me that this avoids the more aggressive vices of the machine. At any rate, it keeps one from Zolaism and the wide-angle; also the size does away with the temptation to enlarge. If you'll take my advice, you won't print anything bigger than you can get direct from the negative, and stick to

platinum and carbon. Let me know what you think; write at once, as I am anxious to get to work; the more I think of the idea the better I like it. Terms you offer will suit me very well."

Waiving the question as to how far Laura Dampier was the unconscious cause of the desire to "exhaust" that district first, we have now to think of Mark Surtees as hard at work at Charlote in amassing negatives giving a "photographic record of the thing as it happens." Here is an outline of his methods:—

"After a feverish hunt for subjects, ending in failure, he had finally escaped from the obsession of the picturesque, and settled down to a pursuit of conditions rather than of things. He lay in wait for hours to catch the right mood of the weather; a silhouette of pine tops, while all else was drowned in pale vapour; a drift of shadow against the hillside; the delicate veining of light and shade in a distance—little problems overlooked by a hundred for one who responded."

That Mr. Marriott's knowledge of photographic craft is not a matter of mere cramming is evident from the delightful manner in which he uses the art as a storehouse of metaphors by which to help his story along. Mark was watched at his work by Mrs. Winscombe, the widow with whom he had taken lodgings, and who was more keenly interested in Laura Dampier than Mark knew.

"That is beautiful," said Mrs. Winscombe suddenly, as Mark, with brown, dripping fingers, held up a negative in the doorway, scowling the while.

"Is it?" he laughed; "I call it beastly flat."

"Oh, I don't mean the picture, but what you said about over-exposure. The plate is dull and flat because the camera has looked too long on what you were taking, isn't it? Don't you think that explains why folks don't get a very clear idea of what is always before their eyes? I should like to know whether the opposite is true; when a picture is under-exposed are the dark parts very dark and the light parts very light?"

"Yes; the contrasts are exaggerated."

"Do I tire you?" asked Mrs. Winscombe, twisting her apron nervously.

"By no means; you interest me."

"Well, isn't an under-exposed negative exactly like a hasty judgment? If one waited a little while, one would be able to make excuses for people because one would understand."

"One could fill in the half-tones, so to speak," said Mark, falling into the trap.

"I suppose that is what I mean," she answered; then, smiling in an embarrassed way, she added, "I cannot abide that you should misjudge one that I love."

Of course, Mrs. Winscombe was thinking of Laura Dampier. Her woman's instinct had taught her that these two were mated for each other. But Mark had not thought of Laura in that light. How should he? Although his father had been a clergyman of the Church of England, yet he was a mere photographer, and Laura was the daughter of an officer of aristocratic connections. So Mark went on with his photographic work, and allowed destiny to mould the events which were in the end to bring Laura to his side.

By and by Mark moved on from Charlote to another district, to the estuary of the Severn, in fact, and the photographic reader of his story will find something to arrest him in Mark's method of regarding the subjects he found there for his camera.

"There was not only that he set out to do, the purpled ribbons of river, the sleek sand, the faint hills; but full in his eyes, above little thickets isled in vapour, the breast-like eminence topped by Newbury Church. This eastern view must be caught quickly, before the sun shouldered up from his

ambush behind the tump; and Mark thanked his foresight in arranging backed plates overnight. It was all a matter of vivid sky line, and here the photograph, like the sonnet, is 'a moment's monument.'

"The tone problems of the river bed were for leisurely consideration, and Mark selected his points of view with fastidious care. After exposing half a dozen plates, he decided to wait until sun and mist allowed an outline of the hermit's island—or, rather, peninsula—far away down-stream on the opposite shore. While he waited he mentally licked his lips over the subject; broad flat reaches of half-toned mud and flashing pools, narrowing up to one exquisite inch of conflict where water-line, cloud, and point came together."

But how, the utilitarian reader will be asking—how does all this pan out from the commercial side? Given a man with Mark's temperament, this was an ideal life for him, no doubt; but Hermann, the practical man at the other end—what of him? Mark himself thinks he would like to know, and when he visits his old chum's studio in London for the purpose of finding out, this is how Hermann greets him, after placing in his hand a delicately got up oblong folio containing exquisite reproductions of his own photographs:—

"I'm not an oversanguine person, as you know, but, unless I am mistaken, the thing is going to pay hand over fist; it has caught on like beeswax. Without exaggeration, I believe Watters and Pike are willing to give us a commission to do the whole country in the same series. All they stipulate is that the negatives shall not be used for any other purpose. The two dozen they have used I selected out of what you sent me; I have already done very good business with single prints, and it was this that put the idea into my head. People don't care to frame photographs for their walls, but they are glad to have a book for the drawing-room table. I talked it over with Watters and Pike, and they agreed to stand the expense of canvassing and printing a prospectus with reduced specimen plates. They had a thousand subscribed for in a very short time, and went ahead. It's the price, you see; we get the public that won't have the ordinary book of 'views' because everybody has them."

It is not necessary to follow the fortunes of Mark Surtees beyond this point. What must be obvious is that Mr. Marriott has introduced photography into literature. That there are in this story of "Love with Honour" ideas of educational worth to the photographer will be evident from the extracts given above, but the chief value of the book lies in the fact that, for the first time in the history of fiction, the art of the camera has been worthily, and with knowledge, lifted into the realm of imagination.

H. C. SHELLEY.

THE LAW RELATING TO THE SALE OF POISONS.

[Paper read at the Annual Congress of the Royal Institute of Public Health, Exeter, Tuesday, August 26, 1902, and reprinted from the *Pharmaceutical Journal*.]

It has been said that the only true functions of Government were the maintenance of order at home and security abroad. The growth of the power of the State shows that a very liberal interpretation is given to the term "order at home." It is not many hundreds of years since the State was powerless to do anything at home beyond the most crude attempts at the maintenance of the King's peace. The Government of an undeveloped community was not strong enough to interfere in the private quarrels let alone the private commercial relationships of individuals. As civilisation advanced it became the business of the State to protect the lives and property of its subjects, and with that advance came the power to effectively enforce rules governing the conduct of individuals.

During the last century the growth of the power of the State in this direction was exceedingly rapid, and this is seen not only in the amount of domestic legislation but in the increase of administrative interference. We have learnt that the State must assist the higher motives which make men careful as to health, morals, and mental improvement. We now act upon the principle that the physical and moral well-being of the individual are matters within the province of the State. The Government interferes not only to protect those who are unable to protect themselves, such as children against employers or even parents, but has also protected those presumably who could take care of themselves. There is scarcely a commercial transaction or even a private act of the individual to which some rule enforced by Government does not apply. The Sale of Goods Act, Merchandise Marks Act, Sale of Food and Drugs Acts, Weights and Measures Acts, are important examples of the interference of the State in matters apparently only affecting the actual parties to a contract. I may so trust my baker that I consider he is wasting my time and his by weighing my half-quartern loaf, but the State does not leave that matter to the joint discretion of myself and the baker. It orders him to weigh it. If I want to build a house for my own residence on my own land you say I must build it so as to satisfy the local State-created authority that it is a safe house for me to inhabit. If I go into most of the many towns represented at this Congress cannot bargain with the first man I meet for the hire of a cab. However much I may be impressed with the appearance of the man as a safe driver, or of his vehicle as a suitable conveyance, even if I am a coach-builder, I must not trust to my unaided judgment. The State considers my life of too much value to it to allow of my engaging with anybody but a licensed driver, or for anything but a vehicle which has been examined by a public servant and stamped with the mark of his approval. It is not surprising then to find that a State which so nurses its subjects has had something to say about the sale of poisons. The Legislature first dealt with the sale of arsenic by a short Act, passed in 1851, which is still in force. It provides that every sale of "arsenic," which includes arsenious acid and the arsenites, arsenic acid and the arseniates, and all other colourless preparations of arsenic, shall be registered so as to give the date, name, and address of the purchaser, and his occupation, the quantity sold, and the purpose for which it is required. It is not to be sold to a person unknown to the seller, except in the presence of a witness known to both seller and purchaser, and the buyer must be of full age. It has to be coloured with red or indigo unless the purchaser represents that such colouring would render it unfit for the purpose for which it was purchased. Arsenic dispensed in accordance with the prescription of a registered medical man is exempt from the provisions of the Act.

It may be well to mention here two Acts dealing with the sale and use of poisoned grain and the use of poisoned flesh.

The Poisoned Grain Prohibition Act, 1863, prohibited the sale of grain, seed, or meal dipped in or mixed with poison. It also imposed a penalty for wilfully sowing or placing such grain on any ground or exposed place. The selling or use of any solution or material for dressing seed for bona-fide use in agriculture was expressly allowed.

The Poisoned Flesh Prohibition Act, passed a year later, prohibited the use of poisoned flesh, though it allows the occupier of a house or owner of a rick to put down poisoned meat for the destruction of rats or other small vermin, provided the flesh is so placed as to be inaccessible to dogs.

Before 1868 there were numerous attempts at legislation regulating the sale of poisons, instigated largely as the result

of notorious poisoning cases. The Pharmaceutical Society, founded in 1841, and incorporated by Royal Charter in 1843, for the purpose of advancing chemistry and pharmacy, of promoting a uniform system of education for pharmacists, and for the protection of those who carry on the business of a chemist and druggist, produced a draft Bill in 1847. It would have prohibited anyone exercising the business of a chemist and druggist, or dispensing for sale or gain any prescription of a medical man, or using any title implying registration under the Act unless he was a registered chemist. It contained exemptions in favour of qualified medical men, vendors of simple and uncompounded drugs, patent medicines, and horse and cattle medicines. A Bill instituted by Mr. Wakley, the founder of the "Lancet," dealing with the medical profession, was at this time referred to a committee. It contained a clause prohibiting the sale by retail of certain poisons except by licensed chemists and druggists. Nothing came of either of these Bills. In 1850 Mr. Jacob Bell, the founder of the Pharmaceutical Society, obtained a seat in Parliament, and in 1851 introduced a Pharmacy Bill. It did not propose to restrict the selling and dispensing of medicines to registered chemists, but to prevent the use of any title denoting a vendor or dispenser of medicines. It was referred to a Select Committee, and was passed after such alterations as left the business and title of chemist and druggist, and the sale of poisons, open to anyone without restrictions. It, however, secured the protection of the title pharmaceutical chemist.

In 1857 the Government introduced a Bill. Its effect would have been to have repealed the Arsenic Act, and to apply its provisions to a large number of dangerous substances. It also proposed that the purchaser should produce a certificate signed by the clergyman of the parish, medical practitioner, or a justice of the peace, stating that he was known to the person signing the certificate, and that he might be trusted with the poison. Packets containing poisons were to be wrapped in tin-foil as well as paper, and bottles were to have the word "Poison" moulded upon them. Vendors of poisons had to keep them in certain vessels and under lock and key. The fine for infringement was to be £20, and for a second offence the defendant was to be prohibited for ever from selling poisons or carrying on the business of a chemist and druggist. It was referred to a Select Committee of the House of Lords, who, recognising the all-important principle that the training and qualification of the keeper and seller of poisons is essential to the safety of the public, recommended clauses restricting the sale of poisons to medical practitioners or vendors licensed after examination. The examiners were to be authorised to enter and search any shop where poisons were stored, and see that the regulations as to storage were carried out. The Government re-introduced the Bill in the following session, but Lord Palmerston was defeated and resigned before the Bill was discussed. Lord Derby, the succeeding Premier, produced a Bill on very similar lines. It passed the House of Lords, but met with such strong opposition from chemists, headed by the Pharmaceutical Society, that it was withdrawn when in 1858 it reached the Commons.

At the end of 1858 a druggist in Bradford supplied a confectioner with arsenic in mistake for "daff," a sulphate of lime. The confectioner used the arsenic in the manufacture of peppermint lozenges, which were sold in the market. Twenty persons were killed, and over 200 were made seriously ill. A new Bill followed in 1859, introduced into the House of Commons by Mr. Spencer Walpole, Home Secretary. It contained nothing about a purchaser's certificate or examination of the vendor, and the Schedule of Poisons was much reduced. The Bill contained provisions for labelling vessels or packets containing poisons in

stock and when sold, and there was to be an entry of sales. Purchasers were to be of full age, as also the witness, for each sale was to be witnessed. On the order of a magistrate constables could search premises where poisons were sold, and penalties were imposed for breach of the regulations. The Committee of the Commons passed the Bill, but the Government was defeated on the Reform Bill before the third reading of the Sale of Poisons Bill was reached. In 1863 Lord Raynham tried a short Bill, called "A Bill for the Prevention of Accidental Poisoning." This simply proposed regulations as to the packet or vessel containing the poison. It was thrown out on the second reading. In 1860 the United Society of Chemists and Druggists, representing chemists who were not members of the Pharmaceutical Society, was founded, and for the next few years took a prominent part in the production of Pharmacy Bills. There was considerable controversy between the Pharmaceutical Society and the United Society, and a Bill from each Society was submitted to the House of Commons. The essence of the Pharmaceutical Society's Bill was the restriction of the business of a chemist and druggist "in the keeping of open shop for the compounding of prescriptions to registered chemists and the protection of their titles." It did not deal with poisons as such. The United Society's Bill would have imposed a penalty of £5 upon any person not a registered chemist retailing or dispensing drugs or medicines, or employing unregistered assistants in such business, and a penalty of £20 upon anyone selling, except under the conditions of entry in a register, and witnessing, etc., any of the "active poisons" named in the Bill. These were pharmaceutical preparations of aconite, arsenic, atropine, ergot of rye, strychnine, and varatrine. A penalty of £20 was to be inflicted upon any unregistered seller of drugs or medicines who called himself a chemist and druggist. The Schedule contained a list of dangerous drugs, apparently the articles the sale of which was to be restricted to qualified men. The General Medical Council supported the Pharmaceutical Society's Bill, but the Select Committee appointed in 1865 to consider both Bills recommended the principle of restricting the sale of scheduled dangerous drugs to examined and registered men. The proposal of the Pharmaceutical Society to restrict the dispensing of prescriptions to qualified chemists was rejected by the Committee. Both Bills were for the time being abandoned. In 1867 the two societies came to a substantial agreement, and ascertained that Mr. Hardy, the Home Secretary, was not unwilling to support a Bill which would restrict the title of chemist and druggist to those then in business, and those who afterwards passed a satisfactory examination, and prevent the sale of certain scheduled drugs to chemists and druggists so qualified. They abandoned their desire to restrict dispensing to registered chemists. The Bill was introduced into the House of Lords in 1868 by Lord Granville. It was not a Government measure. After considerable discussion in both Houses, and some alterations, the Pharmacy Act, 1868, officially described as "an Act to regulate the Sale of Poisons, and alter and amend the Pharmacy Act, 1852," became law. I think no one will quarrel with the principle laid down in the preamble, which says:—"Whereas it is expedient for the safety of the public that persons keeping open shop for the retailing, dispensing, or compounding of poisons, and persons known as chemists and druggists, should possess a competent practical knowledge of their business . . ."

The first fifteen sections provide:—

- 1.—That no person should use any title implying registration under the Act, or sell or keep open shop for the retailing, dispensing, or compounding of poisons unless
 - (a) He is registered under the Act.

(b) He conforms to the regulations as to keeping, dispensing, and selling poisons which are prescribed by the Pharmaceutical Society with the consent of the Privy Council.

It is sometimes overlooked that a registered chemist, if he keeps open shop and neglects to conform to these regulations, forfeits, for the time being, his right to the title.

- 2.—A definition of the term "poison" within the meaning of the Act, namely, those articles named in the Schedule. Power is given to the Society to recommend to the Privy Council that any article be included in the Schedule, and on the approval of the Privy Council and due notice in the "London Gazette," the article becomes a poison for the purposes of the Act.
- 3.—That the examiners appointed by the Pharmaceutical Society, with the approval of the Privy Council, shall examine all candidates for registration as chemists, and that at such examination any officer appointed by the Privy Council shall be allowed to be present.
- 4.—That a register of those qualified for registration shall be kept.
- 5.—A penalty of £5, recoverable only at the instance of the Pharmaceutical Society by civil proceedings in a County Court—
 - (a) If an unregistered person uses the title or sells a poison, or keeps open shop for the retailing, dispensing, or compounding of poisons.
 - (b) If any person (registered or not) fails to conform with the regulations for the keeping and selling of poisons.
 - (c) If any person (registered or not) compounds any medicine of the British Pharmacopœia except according to the formularies of the Pharmacopœia.

The 16th Section says that none of the foregoing provisions are to apply to—

- 1.—Legally qualified apothecaries (extended by amending Act, 1869, to legally qualified medical practitioners).
- 2.—Veterinary surgeons.
- 3.—The making or dealing with patent medicines.
- 4.—Wholesale dealers in supplying poisons in ordinary course of wholesale dealing.

It also expressly permits the executors of a chemist in business at the time of his death to continue such business so long as the business shall be conducted by a qualified assistant.

Section 17, as amended by the 1869 Act, offences under which are punishable, after summary conviction, by a fine not exceeding £5, provides—

- 1.—That all the scheduled poisons shall be labelled with the name of the article, the word "poison," and the name and address of the seller.
- 2.—The following conditions under which poisons in the first part of the Schedule must be sold:—
 - (a) Only to a person known to the seller or introduced by a person known to the seller.
 - (b) An entry made in a register, showing the date, name, and address of purchaser, name and quantity of poison sold, purpose for which it is required, signature of purchaser, and that of the person introducing purchaser.

None of these restrictions apply to any medicine supplied by a legally qualified medical man to his patient, nor apply to any article when forming part of the ingredients of any medicine dispensed by a person registered under this Act; provided such medicine be labelled with the name and address of the seller, and the ingredients be entered, with the name of the

person to whom it is sold or delivered, in a book to be kept by the seller for that purpose.

I believe there are many medical men who do their own dispensing who are unaware that if the medicine they supply contains poison, they are liable to prosecution by the police, or indeed any informer, unless the foregoing conditions are complied with.

Wholesale dealers in poisons need not comply with the provisions solely applicable to poisons in Part 1 of the Schedule, and need not put the name and address of the seller on the label. The label need only contain the name of the article and the word "poison." It is important to notice that the use of poisons in the arts and manufactures is not interfered with except to the extent of insisting that the article is properly labelled. I suppose tons of cyanide are used in the Midlands yearly without any inconvenient restrictions imposed by the Pharmacy Act.

The following is the list of substances now scheduled as poisons:—

PART 1.

Arsenic, and its preparations.

Aconite, and its preparations.

Alkaloids.—All poisonous vegetable alkaloids and their salts.

Atropine, preparations of.

Cantharides.

Corrosive sublimate.

Cyanides of potassium and all metallic cyanides and the preparations of such articles.

Emetic tartar.

Ergot of rye, and its preparations.

Prussic acid, and its preparations.

Savin, and its oil.

Strychnine, and its preparations.

PART 2.

Almonds, essential oil of (unless deprived of its prussic acid).

Belladonna, and its preparations.

Cantharides, tincture and all vesicating liquid preparations of.

Carbolic acid and homologues, liquid preparations of (containing more than three per cent. of those substances, except any preparation prepared for use as sheep-wash, or for any other purpose in connection with agriculture or horticulture, and contained in a closed vessel, distinctly labelled with the words "poisonous," the name and address of the seller, and a notice of the agricultural or horticultural purpose for which the preparation has been prepared, ought to be deemed poisons within the meaning).

Chloroform.

Chloral hydrate, and its preparations.

Corrosive sublimate, preparations of.

Morphine, preparations of.

Nux vomica, and its preparations.

Opium, and all preparations of opium or of poppies.

Oxalic acid.

Precipitate, red (red oxide of mercury).

Precipitate, white (ammoniated mercury).

Every compound containing a poison within the meaning of the Act when prepared or sold for the destruction of vermin.

In my opinion there is urgent need for adding to the Schedule the mineral acids, and sugar of lead, which are frequent

sources of accident. Medical men present know too the danger from the indiscriminate use by the public of potent drugs such as acetanilide and antipyrin. Surely these substances should be classed as poisons.

The regulations at present in force for the keeping, dispensing and selling of poisons are as follows:—

1.—That in the keeping of poisons each bottle, vessel, box, or package containing a poison be labelled with the name of the article, and also with some distinctive mark indicating that it contains poison.

2.—Also that in the keeping of poisons each poison be kept on one or other of the following systems, viz.:—

(a) In a bottle or vessel tied over, capped, locked, or otherwise secured in a manner different from that in which bottles or vessels containing ordinary articles are secured in the same warehouse, shop, or dispensary; or

(b) In a bottle or vessel rendered distinguishable by touch from the bottles or vessels in which ordinary articles are kept in the same warehouse, shop, or dispensary; or

(c) In a bottle, vessel, box, or package kept in a room or cupboard set apart for dangerous articles.

3.—That in the dispensing and selling of poisons all liniments, embrocations, lotions, and liquid disinfectants containing poison be sent out in bottles rendered distinguishable by touch from ordinary medicine bottles, and that there also be affixed to each such bottle (in addition to the name of the article, and to any particular instructions for its use) a label giving notice that the contents of the bottle are not to be taken internally.

The Pharmacy Acts applicable to Ireland divide the qualified men into two classes—pharmaceutical chemists, who may sell and dispense poisons; and registered druggists, who may sell but not dispense poisons.

A short Pharmacy Act passed in 1898 deals simply with the administration and organisation of the Pharmaceutical Society, and does not touch the subject of this paper.

Legislation for Great Britain dealing with the sale of poisons is practically contained within the Arsenic Act and the Pharmacy Act, 1868. The legislation on this subject stands where it did thirty-four years ago. The 1868 Act, largely the result of compromises, has not been strengthened by subsequent statutes.

There have been many important judicial decisions in reference to cases arising out of the Act. It was not until 1890 that the Courts laid down that when the Act says no unqualified person shall "sell" it means the person who does the physical act of selling, not as in the 17th Section, the person on whose behalf the sale is made. In 1893 it was held that the exemption in favour of patent medicines did not apply to medicines liable to medicine stamp duty as such, but was confined to medicines which were the subject of letters patent.

The leading case, however, is that of the Pharmaceutical Society v. London and Provincial Supply Association 1880. In this case the House of Lords ruled that whereas Sections 1 and 15 of the Act said no person unless registered shall use the title of chemist and druggist, etc., or keep open shop for the sale of poisons, it did not say that no company should do these things. They decided that the word person did not include a corporate body.

There have been many attempts made by the Pharmaceutical Society to secure an amending Act so as to render the 1868 Act efficient; and during the last few years some little agitation for

revision has arisen from outside the Society—an agitation, I believe, actuated by a desire to render easier in the interests of makers and dealers the distribution of certain useful but dangerous preparations. Considering the difficulties which are bound to arise when the Legislature attempts to deal with intricate subjects such as the sale and dispensing of poisons, the administration of the Act which, with the exception of a few police prosecutions under the labelling (17th) Section, has been carried on for over thirty years by and at the expense of the Pharmaceutical Society, has been a marked success. It is an Act which, with a little amendment, can be made to completely fulfil its object, that is, the protection of the public from injury by accidental poisoning, and to make hard the way of the intentional poisoner. The present agitation by makers and sellers of such poisonous substances as insecticides containing deadly poisonous alkaloids, for an alteration in the law which would allow of anyone selling their toxic preparations put up in a very attractive form, has been largely instrumental in the formation of a Committee of the Privy Council to consider the question. Yet it was only in January of this year that a gardener died as the result of drinking by mistake a preparation of nicotine from an old brandy bottle in which it had been supplied to him by the shopkeeper. It was proved that if two tablespoonfuls were swallowed death would result.

It is said by the agitators that the Pharmacy Act is a piece of class legislature—that it provides a monopoly for chemists, who are extortionate people who will only sell these useful preparations at exorbitant profits—that the public have a greater difficulty in obtaining these things than would be the case if they could be obtained of any shopkeeper who chooses to stock them. Of course it would be easier to obtain postage stamps if every shopkeeper sold them, but for the convenience of the department, and therefore of the community, stamps can only be obtained at Post Offices or licensed dealers. Protection from poisoning is not consistent with a system of automatic machines at every street corner for the supply of poisons, and all legislation carries with it some occasional inconvenience, even to the honest citizen. There are over 9,000 chemists in business in Great Britain, many of whom have branch shops, and there cannot be a widespread difficulty in the way of obtaining these articles. Here and there there might be a delay of twenty-four hours, and a slightly increased cost, but is that sufficient reason for tampering with the existing safeguards relating to the sale of poisons?

The monopoly theory will not hold water. I speak from personal experience when I say that but for the distinction it gives the shop of the qualified chemist from the unqualified vendor of drugs, chemists would prefer to be without the business of selling poisons (not dispensing). It is a source of great worry and little profit. If the ordinary member of the public considers how much he spends on poisons during the year, and compares the amount, say, with what his blacklead pencils cost him, he will see that poison selling cannot be a lucrative business for a chemist. I know of no business where competition is keener than the drug trade, and there need be no fear of extortionate profits. Our poison law has worked well, with a minimum of inconvenience to the public. It has been the model for legislation in Ireland and all the Colonies, and the Legislature will do well to consider before weakening in any particular the excellent restrictions at present placed on the sale of poisons.

So far from weakening it, the Act wants strengthening. At present a company consisting of seven or more unqualified men may do as a corporate body what the State would trust none of them as individuals to do. They can call themselves chemists, they can keep chemists' shops, where deadly poisons

are stocked and sold. They do not break the law if they have a hundred such shops where poisons are sold every day, and employ not a single qualified man. True, the unqualified assistant, often a boy, who sells a poison is liable for a debt of £5, recoverable in the County Court, if he happens to have anything that can be distrained upon. They need not conform with the Poison Regulations as to keeping poisons, which are binding on individuals. The Legislature has said that the keeper of the open shop, the person responsible for the control of businesses where deadly poisons are sold must be qualified, and this principle is being violated by companies daily.

I feel sure that gentlemen attending the Congress will appreciate the importance of maintaining the principle which is the very basis of the Pharmacy Act. However important regulations and mechanical contrivances may be as auxiliary aids to the prevention of accidental poisoning, the chief safeguard always must be that the man who stands between the public and dangerous poisons should be one who has the hall-mark of competence, that is, duly qualified by examination. Qualified chemists may keep branches in charge of unqualified men provided the manager is prepared to run the risk. The master breaks no law. There is no necessity for registration of shops where poisons are sold, and to which the regulations apply. The law at present allows anyone to dispense poisons; the chemist, doctor, or company may employ the errand boy to dispense strychnine provided the actual sale of the medicine when dispensed is conducted under the supervision of a qualified man. All these defects are met in a draft Bill prepared by the Pharmaceutical Society. It will make the masters, whether companies or not, responsible for the acts of their servants. They will be responsible for registering their shops, and for providing a qualified manager in each. The company must be controlled by directors who have shown by qualification their competence to keep open chemists' shops. The title of chemist and druggist must only be used by those who have earned the right to use it. The public, when they see the word chemist over a shop, will be able to feel secure that that shop is controlled by a man or men who have satisfied the State of their fitness to conduct such shops.

At present the public need warning that the word chemist over a shop run by a limited company does not necessarily mean that there is a chemist anywhere about the place. Whereas they have the security that if the shop is not owned by a limited company the owner who puts up the word chemist must either be properly qualified, or be running a risk of £5 penalties. They should be warned that the law requires the precautions against accidental poisoning from careless storage to be carried out by Mr. Smith, chemist and druggist, whilst there is no such legal obligation on Smith, Ltd., chemists. I do not intend to do more than mention another aspect of the defects in the present Poison Laws. I think you will agree that if the State, in the public interest, call into being a body of trained and examined persons it is the duty to protect their legitimate interests. The continued existence of such a body depends upon its being afforded proper protection. Apart from the question of public safety, the use by companies of unqualified persons of the title of chemist and druggist, a title which individuals can only obtain the right to use by proving their fitness by examination, is a great injustice to a class of men who deserve better at the hands of the community. The draft Pharmacy Bill is hung up pending the report of the departmental committee, but I hope to see it introduced into Parliament next session. May I ask that it should receive the valuable support which members of this Congress can give it?

W. S. GLYN-JONES.

PHOTOGRAPHING DOMESTIC ANIMALS.

[Reprinted from "Wilson's Photographic Magazine"]

Or the thousands who use the camera few have opportunity for long journeys after the rarer wild animals, and not many can engage in the work with enough time, patience, and accessories to make acceptable pictures of fish. Everyone, however, has chances, and constantly recurring chances, to study and to photograph the domestic animals. Dogs, cats, chickens, horses, cows, sheep, swine—some of these are within reach always, for most of us. While the zest of the hunt, the spice of danger, the long tramps afield, are missing in this work, it has its own difficulties, and its rewards are entirely adequate. The writer has a connection with an advanced and elaborately illustrated magazine dealing with country life, and he has been made very sensible, in the past year, of the great scarcity of good photographs of the familiar animals about us. An endeavour to supply certain pictures has fully brought out the difficulties to be encountered, as well as the attractions of the quest. Let us, then, in no-wise despise the household pets, the street dogs, the cattle of the field, as objects of interest for our cameras, and, indeed, of profit for our pockets, if success is attained.

The "tabby" of the home is the easiest of the subjects, apparently. Endless are the ways in which cats are pictorial; endless are the contrarieties of the felines! Choose that way and place and attitude which most attract you, and try your camera on the puss. She is calm, peaceful, but by no means immobile you will find. Scan closely the lighting—you must, almost, be showing the house cat *in* the house—and make your trials. Make them at home, if you can; for strange cats, like strange babies, are not favourable to strangers at all times.

The bait of food is often suggested for luring these animals, and for securing attention, but I deprecate its use, unless the scene is plainly a feeding scene. A hungry look is not the most attractive aspect, and it is to be your art to show the sitter in a comfortable or an alert or even excited condition. Familiarity and petting will often do better than food, especially if the photographer has that sympathy with animals which they so promptly recognise, and without which he is at a very great disadvantage in the handling of our domestic pets and helpers.

Delightful work can be done with kittens, given the art of handling them. Where several are photographed at once, a very quick light becomes essential. Outdoors on an overcast day, or in places protected from the direct rays of the sun, this work can be done to advantage. Again, take care of the lighting; the most pictorial and satisfactory effects are not had when the camera light is full on the front of the subject. Before me at the moment are three fine pictures of a beautiful white Persian cat, "Zoroaster," by Alfred Klakring, all lighted at an angle to the camera, and so as to bring into relief by shadows the whiteness of the cat's long hair. In focussing for such a picture, look for shadows in the white parts. If you do not have them, the result will hardly be pleasing.

The familiar pets of the home, the useful helpers of the barn-yard and pasture, are anything but easy to photograph. Their very charm of vivacity and alertness is the difficulty. Well do I remember a session had with a splendid and most friendly Scotch collie, who would look at me with rapt attention while my head was under the focussing cloth, only to bound high in the air out of sheer playfulness, when I emerged, all ready to snap the shutter! Many plates were spoiled before we fully agreed. But dogs do acknowledge authority, and will sometimes "stay put." If the alert and active life is to be shown, we must work outdoors, and with quick shutter. The sleeping dog may serve for the slower indoor exposure; and this points the fact that in all this work, whether it be dog or grizzly bear,

a series of pictures of the same subject is most desirable if it can be had, showing the animals in various attitudes.

As some dogs are of large size, it is well to caution the naturalist photographer as to the focal length of his lens and the position of the animal. With an ordinary lens of, say, six to eight inches focus, an astonishing distortion shows if the big dog is posed with head away from the camera. A full or nearly full side-view, or a view with the head towards the camera, will be best. If several dogs are grouped, consider this matter all the more carefully, to avoid a grotesque result.

With the most rapid plates and a focal-plane shutter, we may succeed in catching the dog's picture as he runs at full speed—and thereby will we acquire some astonishing knowledge as to what queer positions four feet can assume. And the point will be emphasised that instantaneous pictures of an animal in motion do not *show* motion at all.

Of the domestic fowls very charming pictures can be made, especially when the soft, fluffy little balls of down that include very young chickens, ducks, and geese are considered. The swimming animals give a particularly fine opportunity, for the reflection of light from the water affords so strong an illumination as to help greatly. Chicks feeding are good subjects for pictures, practice, and patience, and a little child in the composition adds much to its charm, if properly placed.

Very few good photographic pictures of horses are extant, comparatively. It is not because this noble beast, the friend of man, has not attracted the ubiquitous camerist, but because he has baffled, to a great extent, the efforts to picture him. There are, of course, vast numbers of mere photographs of halter-led animals, but these are not much better, from the pictorial standpoint, than photographs of stuffed museum specimens of birds and the like. Yet such work, to show the "points" of the horse, must be done, I suppose, and it will not be amiss to quote the suggestions of an experienced and somewhat artful professional worker, as recently presented in the New York "Tribune":—

"The best results are obtained by placing the horse on a slight incline, so that the fore feet are a trifle higher than the hind feet. This position throws the head up. Then snapping the fingers or making any slight noise will cause the animal to prick up his ears, and at the moment when he is in this position of attention the photographer makes the picture.

"When horses in harness are to be photographed they must be posed on level ground or on a very slight incline. To make them look alive a hat or a card is sometimes tossed up in front of them, and at the moment when they look up the snapshot is made.

"When pictures of horses in action are made we usually place the camera near the ground, and by that means we get the best hoof positions, which cannot be secured when the camera is held or placed at the ordinary height. To make pictures of jumping horses, the same method is employed, and the height of the jump is sometimes exaggerated by placing the camera below the track-level. An excavation is made in the ground for that purpose, and pictures made from there increase the apparent height of hurdles and make a small jump look something remarkable."

The horse in real action is another matter, and we must go after him just as we would any other interesting animal. If he is to be pictured at work, select the point of view past which the horse will come, being most careful that the camera is so placed as to see the animal either broadside or somewhat "head on." Ignorance or neglect of this dictum produces some remarkable results. I am minded of my own attempt, some years ago, to make a photograph of a horse's head from the carriage he was pulling, with a "fixed-focus" camera. The

film on development showed in the distance a diminutive head, but the hindquarters of the horse, occupying very fully the foreground of the photograph, were anything but diminutive!

To secure pictures of a horse in active motion a very quick exposure must be made, and as the human eye cannot follow the complex movements of a horse's feet when trotting, the result, even when successful technically, may be anything but pleasing.

Fine pictures may be made—if the worker is able to compose them—with real working horses as subjects. What is a better exemplification of power than the strain of a good team pulling a loaded waggon up a stiff incline? How the great shoulders reach forward, and the strong legs set themselves surely on the roadway! Or a team ploughing—here is a fine pictorial subject, for it shows both horses and man in action, and, therefore, life-like, and the speed is not so great as to make good work improbable.

I cannot resist the temptation to express a hope that in the photographing of horses, pictures may occasionally be made of "bob-tailed" horses, deprived by silly fashion of their most useful and ornamental caudal appendage; for their photographs are always disgustingly grotesque, and serve well as tracts against this cruel and foolish practice.

Let not the aspiring maker of horse photographs feel any surprise if some of the negatives from which he has hoped much show an entire absence of one leg, the entire tail, or even the head. Be not alarmed; you are only experiencing a demonstration of the fact that a horse's motions in chasing a fly are somewhat quicker than the leaves of the average camera-shutter.

To get pictures of the horse in his most natural and graceful attitudes, one must find him at liberty in a field. Here even the most sober cart-horse shows his joy at the freedom that has long been denied him. Patience and a quick shutter will tend toward fine results in photographs of the many free and unconstrained positions constantly recurring under these conditions. A good hand-camera, or the twin-lens or Reflex boxes, will also help to get good things without an undue use of patience and plates.

J. HORACE M'FARLAND.

SOME MODIFICATIONS OF THE NORMAL PHOTOGRAPH.

[Reprinted from "The Scientific American."]

THE amateur photographer begins with an ordinary camera, becomes dissatisfied and procures a better one, and frequently proceeds in the same manner until he is satisfied that he has secured the best instrument that can be obtained. It cuts the photographic image from the centre to the edge of the plate with fidelity, and he derives great satisfaction in possessing as good a lens as can be made. But before long he learns that a picture photographically perfect lacks a great deal in true artistic feeling and quality, and he begins to remedy the defects of the perfect lens by throwing the plate out of focus, or by using a larger stop, or both, and thus secures to some extent the broad effect that he has learned to admire.

In addition to following out these suggestions he may produce artistic effects in other ways which recommend themselves to the experimenter in photography. One of the simplest methods of obtaining a soft ethereal effect consists in interposing between the lens and the plate a piece of ground glass, glass coated with ground glass substitute, or ground glass celluloid, placed at different distances from the plate, according to the effect desired. A very good scheme is to withdraw the slide from the plate-holder and replace it by a slide of translucent ground glass celluloid, like that shown in one of the illustrations, taking care to exclude the entrance of light by changing the slides under the focusing cloth, the exposure being made through the ground glass celluloid. The resulting picture,

whether portrait or landscape, is soft in outline, and is possessed of mellow lights and shades. The finer details of the photographic image are omitted, and the much-desired breadth is secured. If broader effects are desired a square of finely-ground glass can be placed in the camera within or inside of the reversible back. Of course, the farther the glass or celluloid is removed from the sensitive plate the more details are omitted from the negative. If it is desired to show more of the detail than is possible with a translucent slide of the kind described a thin sheet of crystal glass of the size of the plate may be coated with ground glass substitute and placed in the holder along with the plate, with either the film or coated side out, according to the effect desired. The ground glass celluloid when placed either side out in contact with the sensitive film produces a desirable effect. If it is difficult to get ground glass celluloid a piece of fine, thin tracing paper may be secured by its corners to a thin piece of glass (an old negative glass, thoroughly cleaned, will answer). The effect will be quite broad if the glass side is placed next the sensitive film, and the negative will be very soft if the tissue paper is placed next the sensitive film. These interposed films absorb more or less of the light, and necessitate an increased exposure, but the increase is very slight and can be determined only by experiment in each case. A lantern slide produced from a negative of this kind, if well coloured, appears on the screen more like a painting than a photograph.

Another peculiar effect is secured by placing over the sensitive plate a thickness of fine, thin muslin stretched over a frame of common tin, or thin brass plate, the frame being placed in the holder along with the plate. The muslin should be wet when mounted and secured to the frame by straten or some other adhesive cement. Broader effects may be produced by removing the muslin screen to the reversible back.

Lantern slides printed from ordinary negatives through fine ground glass, or ground glass substitute, lend themselves beautifully to colouring, as they are broader and more like paintings than other coloured slides.

A painter who dislikes to copy an ordinary photograph, on account of the difficulty of omitting detail, will find a copy of a good photograph taken through ground glass or tracing paper much more agreeable to follow than the photo with its many details. Half-tones may also be copied in this way.

This may seem to the ultra-photographer, who takes the greatest interest in sharpness, depth, and multitudinous detail, as a retrograde movement, tending toward the degradation of photography, but the true artist will find use for photographic pictures with reduced detail.

GEO. M. HOPKINS.

TRAVEL in Italy.—Mr. Consul S. J. A. Churchill, in a Report on the Trade of Sicily for 1901, makes the following observations:—"Commercial travellers and others likely to be in Sicily for some days, and likely to travel to Girgenti, Syracuse, Catania, Taormina, and Messina, over the lines of the Sicula Orientale, should provide themselves with a photograph on white paper, and take out a first-class ticket for free circulation on this railway in any direction for one month at a cost of 100 lire (£4). This ticket also serves as a certificate of identity during its term of existence. Travellers who have had the misfortune to have their pockets picked or to have lost their baggage, and to have written home for a remittance, appear to expect that the remittance from Malta or the United Kingdom will be payable by the post-office when the letters which announce these remittances are received. This is not the case. No money order can be cashed until the letter of advice concerning it has been received from the central office at Turin. This, in cases of money orders from the United Kingdom or Malta, may take ten days or more. Therefore, any travellers in a hurry should not choose this means of obtaining a remittance. When the remittance arrives there will be the question of identity. This can easily be got over by any commercial or ordinary travellers spending a good deal of time abroad, especially in Italy, by proceeding to the nearest post-office with two known witnesses and a photograph on white paper, and receiving for a fee of 1 lira a 'Libretto di Ricognizione' (Certificate of Identity), good for the Kingdom of Italy. On payment of a fee of 1 lira, a certificate of identity can be obtained for the whole world."

PHOTOGRAPHIC SURVEY AND RECORD OF SURREY.
(Inaugurated May, 1902.)

OBJECT.—"The work of the Association shall be to preserve, by permanent photographic process, records of antiquities, anthropology, buildings of interest, geology, natural history, passing events of local historical importance, portraits of notable persons, old documents, rare books, prints, maps, and scenery, so as to give a comprehensive survey of what is valuable and representative in the county of Surrey."
-Rule 2.

PRESIDENT:

The Right Hon. Viscount Midleton, Lord Lieutenant, County of Surrey.

VICE-PRESIDENTS.

The Right Hon. C. T. Ritchie, M.P.
H. C. Leigh-Bennett, M.P.
Sir Frederick L. Cook, Bart., F.R.G.S., D.L., M.P.
Charles Ernest Tritton, M.P.
John Burns, M.P., L.C.C.
Percy Melville Thornton, M.P.
R. K. Causton, M.P.
J. Macdona, M.P.
T. J. Macnamara, L.L.D., M.P.
Wm. Keswick, M.P., J.P., D.L.
Edward J. Halsey, C.A., J.P., Chairman Surrey County Council.
Alderman Howarth Barnes, J.P., Mayor of Battersea.
Col. Samuel B. Bevington, V.D., J.P., Mayor of Bermondsey.
W. Scott-Scott, J.P., Mayor of Camberwell.
N. Page, J.P., Mayor of Croydon.
A. F. Asher, J.P., Mayor of Guildford.
C. Burgess, J.P., Mayor of Godalming.
J. White, LL.D., J.P., Mayor of Lambeth.
W. E. St. L. Finny, M.D., J.P., Mayor of Kingston-upon-Thames.
F. Redman, J.P., Mayor of Southwark.

RULES.

- 1.—This Association shall be called "The Photographic Survey and Record of Surrey."
- 2.—The work of the Association shall be to preserve, by permanent photographic process, records of antiquities, anthropology, buildings of interest, geology, natural history, passing events of local or historical importance, portraits of notable persons, old documents, rare books, prints, maps, and scenery, so as to give a comprehensive survey of what is valuable and representative in the county of Surrey.
- 3.—The Association shall consist of photographic and other societies and individual members, with a president and vice-presidents.
- 4.—Societies, or individual candidates, for election as members, shall be proposed by any member or delegate. The election is vested in the council, and the subscription shall be two shillings and sixpence per annum for each delegate sent by a society, and member.
- 5.—The business of the Association shall be transacted by a council, which shall consist of a chairman, local vice-chairman, hon. secretaries (survey and general), hon. treasurer, hon. curator or curators, not more than two delegates from each associated society, and not less than six ordinary members.
- 6.—The annual general meeting shall be held in March, when a report and audited statement of accounts for the year ending December 31st preceding shall be submitted, and the president, vice-presidents, officers, and auditors, and non-delegate members of the council shall be elected for the ensuing year. Voting shall be by ballot. Nominations shall be in writing and signed by at least two members, and shall be in the hands of the hon. general secretary seven clear days before the meeting; but societies shall elect their own delegates.
- 7.—At every general meeting, the chair shall be taken by the president, or failing him, by a vice-president, or if no vice-president be present, the chairman shall be appointed by the meeting.
- 8.—Meetings of the council shall be held quarterly, and at such other times as may be necessary. Five shall form a quorum. The council shall have authority to appoint special committees with power to add to their number.
- 9.—In the event of the death or resignation of any officer or other member of the council, the council shall have power to fill the vacancy, except in the case of a delegate of a society, when that society shall appoint a successor.
- 10.—*Photographs (including lantern slides) shall be approved by the council before acceptance. Prints must be sent in unmounted, or on the regulation mounts.
- 11.—These rules shall be altered only at an annual meeting, or at a special meeting convened for the purpose, and notice of any alteration shall be sent out with the circular convening the meeting fourteen clear days before the date thereof.
- 12.—The general secretary, by direction of the council, or on the written request of not less than ten members, specifying the business,

shall convene a general meeting, not later than four weeks after receipt of such direction or request.

NOTES.

- (a) *The copyright of a photograph remains the property of a contributor, unless specially ceded to the Association.
- (b) A register will be kept by the hon. survey secretary of the names and addresses of contributors who are willing to sell or supply copies of their prints to those applying for them.

COUNCIL:

Chairman: W. Whitaker, B.A., F.R.S., F.G.S.
Local Vice-Chairmen: Hector Maclean, F.G.S., F.R.P.S., President Croydon Camera Club; J. Bulbeck, Vice-President West Surrey Photographic Society.
Hon. Treasurer: W. W. Topley, 3, Marlborough Road, Croydon.
Hon. Curator: L. Stanley Jast, Chief Librarian, Croydon Public Libraries.

Elected Members: W. Watts, M.A., Prof. of Geology, University of Birmingham; J. J. H. Teall, M.A., F.R.S., P.G.S.; Prof. J. W. Judd, C.B., LL.D., F.R.S., F.G.S.; H. Keatley Moore, B.A., B.Mus.; Councillor J. Noaks; G. W. Moore; C. L. Faunthorpe; J. H. Baldock, F.C.S.; A. Roods; G. Clinch, F.G.S.; Alderman F. Foss, J.P.; E. Mawdesley, B.A., LL.B., Town Clerk, Croydon; J. Epps, Junr., F.L.S., President Croydon Nat. Hist. and Scientific Society.

Delegated Members: B. H. Winslow, E. L. Curtis, Norwood Natural Science Society; W. Wood, W. H. Rogers, Thornton Heath Photographic Society; E. Gane Inge, E. W. Eele, Haslemere Nat. Hist. and Micro. Society; E. Salt, H. M. Bennett, Croydon Camera Club; N. F. Roberts, F.G.S., Croydon Nat. Hist. and Scientific Society; R. Hovenden, F.S.A., S. W. Kershaw, M.A., F.S.A., Brit. Arch. Association; M. S. Giuseppi, F.S.A., W. Bruce Bannerman, F.S.A., F.G.S., Surrey Arch. Society; A. C. Haddon, F.R.S. (Pres.), J. Gray, B.Sc., Anthropological Institute; E. A. Martin, F.G.S., Croydon and Norwood Branch Selborne Society; C. Thwaites, Sutton Photographic Club; H. W. Monckton, F.L.S., F.G.S., W. P. D. Stebbing, F.G.S., Geologists' Association; G. R. Beckett, G. Robinson, South Norwood Photographic Society; W. H. Wilshe, West Surrey Photographic Society; R. Quick, M.I.S., Dulwich Scientific and Literary Association; H. G. Quarterman, Society of Architects; F. W. East, Kingston-upon-Thames and District Photographic Society; J. J. Coleman, F. Sears, Clapham Junction Y.M.C.A. Natural Science Circle; W. Coomer, W. J. Wilson, Croydon Y.M.C.A. Camera Club; F. R. Taylor, E. W. M. Wonnacott, Architectural Association Camera and Cycling Club; J. M. Hobson, M.D., B.Sc., Croydon Antiquities Protection Committee.

Hon. Secretaries: Survey, H. D. Gower, 55, Benson Road, Croydon; General, J. M. Hobson, M.D., B.Sc., 1, Morland Road, Croydon.

**PRACTICAL NOTES AND HINTS CONCERNING
"SULPHITE," "METABISULPHITE," ETC., ETC.**

II.

QUANTITY TO BE USED IN PHOTOGRAPHIC DEVELOPER (Sulphite).

This is a practical matter of very considerable importance from various points of view, and upon which somewhat widely different opinions have been expressed. The quantities herein suggested may be taken as representing the average opinion of the leading authorities:—

Pyro-ammonia developer should contain 8 grains per ounce of mixed developer.

Pyro soda requires quite double the quantity, say 20 grains per ounce.

With quinol, i.e., hydrokinone, its presence seems essential, and 20-40 grains per ounce seems the range of reliable opinion. The same proportions apply also in the case of erkonogen.

With amidol the quantity should not exceed 60, or at most 80, grains per ounce.

The above quantities refer to the total quantity of sulphite per ounce of mixed developer in the dish when exposed to the air.

Obviously, these conditions are not quite the same as when a concentrated or stock solution of pyro metol, etc., is required.

In the case of pyro stock solution, rendered slightly acid with nitric or, preferably, citric acid, it will be found that 4oz. sulphite dissolved in 8oz. boiled water, then acidified and added to 1oz. pyro, and then made up 10 fluid ounces (i.e., say 5 grains pyro per dram of solution), will keep a light colour fully six months. Amidol, ortol, and metol require less than one-fourth this quantity of preservative, but one in ten is a convenient proportion. It should be borne in mind that an excess of sulphite is harmful, as it is a solvent of silver bromide, and in excess tends to give fog.

METABISULPHITE AS A PRESERVATIVE.

From the above theoretical considerations we should expect to find the meta salt about two and a half times as efficacious as the normal sulphite, but experience shows that its contained sulphur dioxide is

more readily available. Consequently, in practice, we find that one part of the meta salt is roughly equivalent to four parts of the sulphite.

Thus one ounce of pyro needs four ounces of sulphite in 10 of water, but one ounce of the meta salt seems to act quite as well, if not better.

Doubtless many of the complaints anent the use of the meta salt are due to thoughtlessly substituting one salt for the other in equal quantities. A moment's thought will show that if two developers be made up with equal quantities of sulphite and meta sulphite (the alkali being also the same in both) that the meta solution will be much less active, because already so much of the alkali has been neutralised by the acid meta salt.

TESTS, REACTIONS, AND SIMPLE EXPERIMENTS.

The reader is advised to make himself familiar with the properties of sulphites and sulphates by repeating the following very easily performed experiments:—

SULPHITES.

Use sodium sulphite dissolved in pure water.

(1) Add a few drops of dilute hydrochloric acid. A pungent, nose-stinging gas (SO²) is given off, and suggests the smell of burning sulphur matches.

(2) Cover a few small bits of clean zinc with water, add a few drops of hydrochloric acid. Note that bubbles of (hydrogen) gas are given off. This gas (when pure) has no smell. Now add a few drops of sulphite solution. An evil-smelling (rotten-egg like) gas is given off. This is hydrogen sulphide or sulphuretted hydrogen. Moisten a bit of blotting paper with a solution of lead acetate, and lay this on the mouth of the test tube. The darkening of the paper (by formation of lead sulphide) indicates the presence of sulphuretted hydrogen gas.

(3) To some sulphite solution add a few drops of silver nitrate solution. A white precipitate (silver sulphite) is formed. Divide the milky mixture into two parts. To one part add more sulphite of soda solution. The precipitate dissolves. To the other part add hypo solution (fixing bath). The white silver sulphite also dissolves.

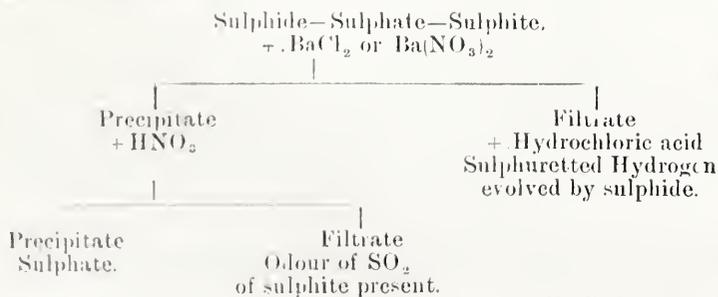

(4) To another portion of sulphite solution add silver nitrate, with shaking, until a permanent precipitate is formed. Now gently heat to boiling, when the precipitate darkens and some metallic silver is thrown down on the inside of the test tube, forming a mirror-like surface.

(5) To a solution of potassium bromide add a few drops of silver nitrate solution. A light yellow precipitate of silver bromide is formed. Fill up the test tube with water and shake well. Allow the precipitate to settle, pour off the clear supernatant fluid, and half fill with water. Shake and divide into two parts. To one part add soda sulphite solution. The silver bromide is dissolved. To the other add clean, fixing bath, hypo solution. The precipitate is dissolved. Compare experiment.

(6) To a solution of sodium sulphite add solution of barium chloride, or, preferably, barium nitrate. A white precipitate of barium sulphite and probably some sulphate is thrown down. Fill up the test tube with water and shake well. Allow precipitate to settle, and pour off the clear liquid. Half fill with clear water, shake, and divide into two parts. To one add either strong hydrochloric acid, or, preferably, dilute nitric acid. This dissolves the sulphite and leaves the sulphate unaffected. Comparison of the two tubes gives a rough idea of the quantities of sulphite and sulphate.

SEPARATION OF SULPHIDE, SULPHATE, AND SULPHITE.

(7) Add barium chloride, or, preferably, nitrate. Sulphates and sulphites are thrown down. Filter. Filtrate contains any sulphides. Test with filtrate with hydrochloric acid. Hydrogen sulphide evolved if sulphide present. Shake the precipitate with pure hydrochloric, or, preferably, nitric acid, dilute. The sulphates are dissolved. Filter. To the filtrate add hydrochloric acid, if it does not already smell of sulphur dioxide. The insoluble precipitate is a sulphate. This experiment is best seen in tabular form.

F. C. LAMBERT.

THE R.P.S. DINNER.

The following gentlemen constitute the organising committee: Mr. Frank Bishop, Dr. Ernest C. Fincham, Mr. Alfred Ellis, Mr. T. E. Freshwater, and Mr. Martin Jaconette.

The following will act as stewards: Mr. James Brown, Mr. Henry E. Davis, Mr. T. Sebastian Davis, Mr. W. E. Dunmore, Dr. A. R. F. Evershed, Mr. John H. Gear, Mr. Thomas K. Grant, Dr. C. F. Grindrod, Mr. Henry E. Hull, Mr. H. Vivian Hyde, Mr. Francis Ince, Mr. C. F. Inston, Mr. Ernest Marriage, Mr. J. C. S. Mummery, Mr. Leslie Selby, Mr. R. Lang Sims, Mr. G. W. Tottum, Mr. T. C. Turner, Mr. H. Snowden Ward.

The annexed circular has been issued to members: Fellows and members of the Society, and members of affiliated societies, are reminded that the Royal Photographic Society's Dinner will be held at the Café Royal, on Monday, September 29th. Those who intend to take part, and have not yet signified their intention to do so, are requested to send an early intimation to the secretary or one of the stewards, stating whether they will be accompanied by any friends. The tickets are half-a-guinea each, exclusive of wine. Final arrangements have to be made very shortly, and it is important that the committee know how many for whom to provide.

The Secretary,
Royal Photographic Society,
66, Russell Square, London, W.C.

September, 1902.

Please send me Tickets for the Royal Photographic Society's Dinner to be held on September 29th, at the Café Royal.

I enclose remittance for

Signed.....

Address.....

THE KODAK COMPANY'S NEW PREMISES.

On Monday last, on the occasion of the official opening of their new showrooms, offices, etc., at 41-43, Clerkenwell Road, E.C., Messrs. Kodak, Limited, had an "at home." The additional premises now forming part of the Kodak headquarters were until recently in the occupation of Messrs. Salmon and Gluckstein, and contain a floor area of some 23,000 square feet. By this acquisition the accommodation placed at the disposal of the firm for extra stockroom and office space for

A CORNER OF THE NEW KODAK RECEPTION ROOM.

present needs, and for future contemplated expansions, has been more than doubled. The frontage of the establishment carries a sign composed of the word "Kodak" in wood letters no less than 17 feet high. The most prominent feature of the interior of the new premises is a handsomely decorated showroom on the first floor. The board-room and the managerial offices are also situated on this floor.

The latest Kodak novelties were demonstrated, together with a full range of Kodak cameras and accessories. An interesting display was also made of bromide enlargements from Kodak photographs. A novelty shown was the Kodak Developing Machine, which is a nickelled metal box, into which the exposed spool is placed. A few

turns of the handle unwind the black paper covering of the film; the developer is now poured in, and the turning of the handle continued until the negatives are developed. Fixing and washing are carried out in the same manner. Demonstrations of the new apparatus were given.

New Apparatus, &c.

Messrs. Erdmann and Schanz, of 116, Bedford Hill, Balham, S.W., are issuing the following stereoscopic slides:—Views of the United Kingdom; royal palaces (interiors and exteriors), London street scenes and principal buildings, Kew Gardens, the Thames, seaside resorts, cathedrals, castles, abbeys, ruins, English, Scotch, and Irish scenery. Views: Foreign; France, Germany, Italy, Monaco, Switzerland, Belgium, Greece, Norway, Sweden, Palestine, Algeria, United States America, West Indies. Views: India and Ceylon. This series includes a large number of type studies, native temples and other buildings, general views, and street scenes. Hoar Frost Scenes. Statuary: Antique and Modern; a series of the principal statues in the Vatican and other noted galleries. Animals (Wild); lions, tigers, elephants, giraffes, zebras, emus, etc., etc. Military types; types of British Regiments, including Grenadier Guards, Royal Horse Guards, Scots Guards, Dragoons, Royal Artillery, Imperial Yeomanry, etc., etc., Australian and New Zealand Regiments, Canadian and West Indian Regiments, French Regiments, etc., etc. Humorous; comic scenes, tableaux vivants and fanciful scenes. Art Studies from Life of the Female Figure. South African War; this series comprises many interesting scenes illustrating the whole of the War. Royal Coronation; a series of scenes of the Coronation Procession, Naval Review and Review of Indian troops. Shipping and Locomotives. Coloured Stereos: this series of hand-painted slides includes flowers, views and tableaux vivants. Messrs. Erdmann and Schanz are also introducing the "Triumph" aluminium stereoscope, with plush-bound and hand-engraved hood, and varnished sycamore shaft. They send this stereoscope on approval to applicants, by parcel post. The instrument is well finished, strong and serviceable, and is of the "Holmes" pattern. The stereoscope and the slides are supplied to the trade.

The Falloroll Camera. Sold by Jonathan Fallowfield, 146, Charing Cross Road, W.C., London.

The "Falloroll," it may be assumed, comes at the end of a long line of new cameras which have been offered to the public during the spring and summer (as we must in courtesy refer to these seasons) of the present year. The principal characteristics of the instrument are thus concisely described in the little handbook which accompanies it:—

"The Falloroll camera is one of the folding type of camera, taking plates or films; the latter can be both put in and taken out in daylight,

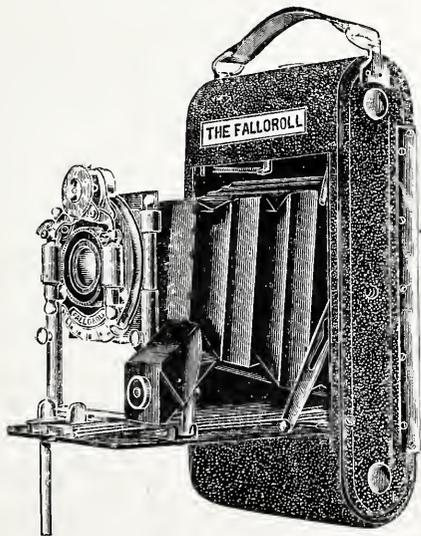

FIG. I.

any make of film may be used in the camera, and by a simple and ingenious arrangement a plate-holder holding two quarter plates can be used with the same back used for films. Fig. II. will show how the plate-holder and the focussing screen may be used. To use the camera press the button on the right-hand side, and this allows the aluminium front baseboard to fall into place. To draw the lens and bellows into position, press the two small handles at the bottom of the lens, at the same time draw the camera front, with lens outwards till the pointer on the left is at the distance (in feet) of the object which you wish to photograph. The clamping is automatic, and directly the pressure on the two handles is released they spring back and hold the front firmly in position. The camera is fitted with a tripod screw hole, and can be used either for portrait or landscape views. It has a reversible finder. The shutter of the Falloroll is of the Unicum pattern, made by the well-known opticians Messrs. Bausch and Lomb. The lens is a rapid rectilinear working at f8 and having Iris diaphragms.

"To load the camera (see Fig. III.) place the film in the space at the top, and in such a way that the reel is working on the two small pivots which work by springs at either side; see that the black paper winds in such a way that the spool is underneath, and bring the end across the two nickel rollers and space, and slip into the slot of the wooden reel

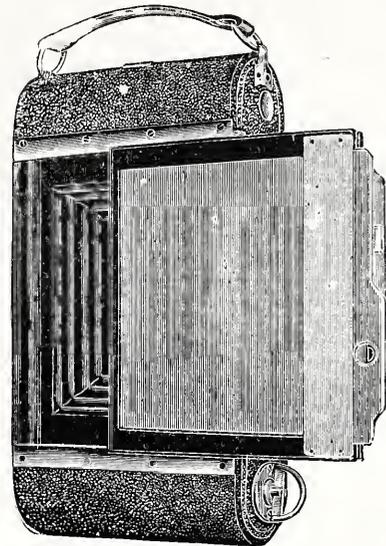

FIG. II.

at the bottom. Then shut the back and wind till a figure appears under the red window (which should be always at the top of the camera). The camera is now ready to take the first picture. Pull out the front and place pointer at the distance marked on metal disc to which the object corresponds."

Nowadays, the difficulty of imparting novelty in design, form, or detail to hand cameras by no means tends to diminish; it may almost be taken as axiomatic that in half a dozen instruments chosen at random the points of resemblance mostly outnumber those of difference. Neverthe-

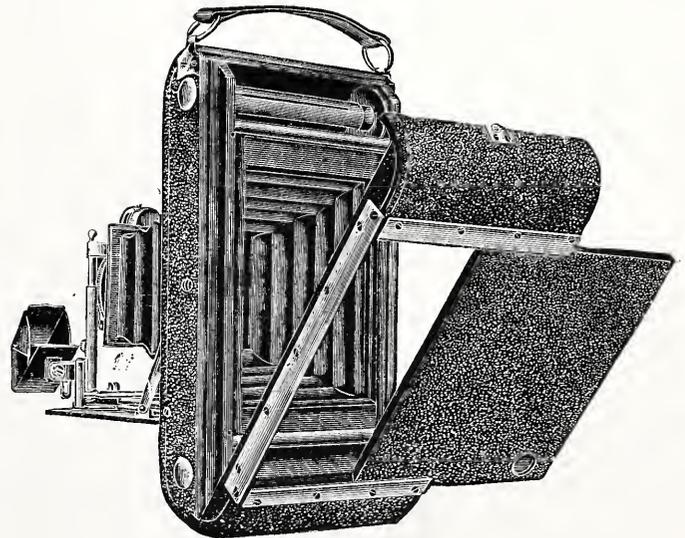

FIG. III.

less, the makers of the Falloroll have quite succeeded in rendering it distinctive in one or two respects. The back, it will be observed, is permanently hinged, and in place of the removable panel either the focussing screen or the double dark slide may be inserted in the focal plane. The method of inserting the spools is shown in Fig. III. From the practical point of view, we can certify that the Falloroll is an easy instrument to work. The other features of the camera are indicated in the above-quoted description. It is beautifully made, with metal baseboard, nickelled fittings, movable finder, and focussing scale. The shutters of the dark slide are of bright metal. The "Falloroll" appeals to a wide circle of modern photographers, with whom it should become a favourite.

MR. RANDOLPH SMITH, of the St. Michael Street Studio, Malton, has been honoured by His Majesty the King accepting from him an album of photographic views of the local Coronation celebrations. The letter received by Mr. Smith is as follows: "The Private Secretary is commanded by the King to thank Mr. Randolph Smith for his letter of the 11th inst., and in reply to say that if he will forward the album of photographic views his Majesty will be pleased to accept it.—30th August, 1902."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
12.....	Croydon Scientific Society	Consideration of Rules for the Portfolio Criticisms.
13.....	Woolwich Photographic	Barking. Leader, Alex. Lees.
13.....	West London Photographic	Richmond Park.
15.....	Southampton Camera Club.....	Demonstration of the "Rotograph" Papers by Mr. W. A. Sims (of the Rotary Photographic Co.)
17.....	Southampton Camera Club.....	Ramble—Beaulieu.
17.....	North Middlesex Photographic	Bromide Enlarging. F. A. Haylett.
17.....	Borough Polytechnic	Monthly Outings Competition.

SOUTHAMPTON CAMERA CLUB.

The members of the above club met on the 1st inst., under the presidency of Mr. G. Vivien, when a print competition took place, the subject being "Architecture."

Some very creditable specimens were submitted for criticism, those contributed by Mr. Cooke being pronounced the winning pair. They were excellent enlargements—one of the Norman portion of Winchester Cathedral (north transept), and the other of the ambulatory at St. Cross, near Winchester.

Mr. Cooke was awarded the club's certificate of merit.

DEVONPORT CAMERA CLUB.

Mr. R. J. Lamb presided over the annual meeting of the Devonport Camera Club, held at the Technical Schools, Devonport, last week. The secretary, Mr. F. B. Langdon, read the committee's 11th annual report, which stated that fourteen general meetings had been held, at which instructions and practical demonstrations had been given on enlarging, lantern-slide making, Christoid films, gaslight papers (exposing with Dawson's densitometer), Wellington films and slow contact paper, improving negatives and prints, colour photography (on which occasion members of Stonehouse Camera Club attended), and the carbon process. The lantern evenings, at which members' friends, including ladies, were cordially invited, were successful, much credit being due to Messrs. J. F. Coombs, W. G. Parkman, and J. Neal for services rendered in manipulating the lantern. It was to be hoped that good work had resulted from the summer outings arranged to Ivybridge, Dousland, and Yelverton, Denham Bridge, and Buckland Abbey. The visit to the ancient abbey, by kind permission of Lady Elliott Drake, and to whose hospitality the club was greatly indebted, was much enjoyed. At the close of the winter session the late president, who was entrusted and had undertaken responsible work in connection with the proposed exhibition, unexpectedly resigned, which necessitated a postponement. The committee, however, trusted that arrangements would be made shortly for holding an exhibition worthy of the town of Devonport, which had reason to be proud of having given to the photographic world one of its earliest pioneers, Robert Hunt, born in Devonport, or "Dock," as it was called in 1807. The club had been affiliated with the Royal Photographic Society for six years, which conferred upon its members the right of attending the meetings of other affiliated societies. The affiliation now comprised 100 societies in Great Britain, Ireland, India, Australia, New Zealand, and South Africa, with an aggregate membership of between 8,000 and 9,000, every member of which received a copy of the Red Book, its production being a permit to photograph in places where otherwise specific permission had to be obtained.

The committee regretted having to record the death of Mr. Jas. A. Boulds, who filled the office of president two years ago, and was an enthusiastic and valued member; also of Messrs. J. B. Foster and T. W. Earl. Consequent upon the frequent changes in a town connected with Government establishments, some useful and earnest members had resigned. The committee, therefore, hoped others who take interest in photography would become members.—The treasurer, Mr. A. J. Catford, reported a balance in hand of £1 1s. 6d., which the Chairman thought was very satisfactory.—Mr. Langdon remarked that it was so, considering that they commenced with an adverse balance.—Mr. R. J. Lamb was re-elected president for the forthcoming year, and the following officers were also elected:—Vice-presidents, Messrs. C. Croydon, J. F. Coombs, W. H. Lethbridge, and J. Trouern Trend; committee, Messrs. A. Tregise, W. H. Mayne, R. Maw, and R. O. Jolliffe; secretary, Mr. A. J. Catford; and treasurer, Mr. F. B. Langdon. Mr. R. G. Lamb and Dr. E. S. Saunders were appointed delegates to the Royal Photographic Society, and Messrs. W. G. Parkman and S. F. J. Heal (assistant) lanternists.

A vote of thanks to the retiring officers was passed.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 4TH.—Mr. T. E. Freshwater in the chair.

Mr. A. L. Henderson showed a photograph, on a cardboard mount, representing some seaside view, and drew attention to the strong discolouration that it had undergone through exposure to the sea air. He believed it to be not an instance of imperfect fixing, as some would suppose, but an effect due entirely to the atmosphere of seaside places. In his experience such prints were common in the coast towns. He proposed to open a discussion on the matter early in October.

The hon. secretary passed round some sample sheets of Mr. H. E. Bullen's sensitised albumenised paper. In reference to a difficulty, recently alluded to, in the getting of blue tones on ready-sensitised albumenised paper, Mr. Bullen expressed his belief that with his paper any such difficulty would be found to disappear.

Mr. Henderson passed round another photograph made by Dr. Grun with his fluid lens in order to test its defining power under severe conditions. The doctor claimed to have made considerable improvements in his lens, and the test shown would probably have demonstrated the fact had particulars of the stop used and the conditions under which the photograph was made been available.

Mr. Henderson then gave a display of slides taken during his recent travels in Spain.

Many of his pictures were of Burgos, the capital of Old Castile, situated on the Arlanzon, one of the small tributaries of the Douro. Its cathedral is one of the finest in Spain, full of richness and beauty, and containing some fourteen chapels. It abounds in a wealth of beautiful carving and ornament, which compels the admiration, even in a country like Spain, where exquisite taste, luxuriance of detail and superbness of design are to be found in the architecture of past centuries almost at every step. Contrary to what he anticipated, Mr. Henderson found that the beggars were not such important features of Spain as had been represented. His photographs in the streets, however, frequently suffered from the unsightly crowds of youths and children who thought it well to monopolise the foregrounds of his compositions. Notwithstanding this little trouble, however, the photographs were all much admired, and especially the interiors, where Mr. Henderson seems to have spent hours and hours days together reproducing the wonderful beauties of the old palaces, cathedrals and churches. Most of the pictures were from stereoscopic pairs, and a number were panoramic in their nature. Many of the palaces are now used as dwellings by the poorest people, and very picturesque are the "bits" to be found in their vicinity.

Cordoba also attracted Mr. Henderson and his camera. Its former magnificence has much decayed. The cathedral is a splendid edifice, and the mosque, fountains, courtyards, city walls and gates yet make very fine subjects for the photographer. Granada, the capital of the last of the Moorish kingdoms, stands in a plain of much beauty at the northern foot of the Sierra Nevada. It is a most interesting place, and Mr. Henderson was much fascinated by its attractions. The mountains in the distance lend also a charm to the place that is refreshing in its variety. The Alhambra, lastly, calls for almost more praise than any of the preceding places. Its handsome pillared courts and mosaics provide infinite opportunities for the picture-maker, and the lecturer availed himself with his usual success of these fine old Moorish glories.

A hearty vote of thanks to Mr. Henderson closed the meeting.

Commercial & Legal Intelligence

WE have received a catalogue of photographic, optical, and electrical goods from Mr. James Henderson, photographic dealer, 164, Union Street, Aberdeen.

RE The Sensitised Paper Manufacturing Syndicate (Limited).—Under the failure of this company adjourned meetings of the creditors and shareholders were held at the London Bankruptcy Court on Monday last before Mr. H. E. Burgess, Assistant Receiver, and it was intimated that the official receiver would continue to act as liquidator under the proceedings.

BRITISH Trade and Foreign Competition.—Lord C. Beresford, M.P., in reply to a correspondent, who asked "In what direction should our natural energies be increased in order to meet successfully the competition of foreign countries?" says:—"It is my opinion that if we wish to compete with foreign countries we must work on the same methods which foreign countries have found so successful. During my mission in China, in 1893, on behalf of the Associated Chambers of Commerce, I found foreign countries made and sent out what the people wanted. Many British firms were only prepared to make and send out what they thought the people ought to want. Foreign countries will accept orders so small that such orders really amount to samples only. British firms rarely take small orders, the reason advanced being that they do not pay. In trade the great effort should be to form new connections, and, with this object in view, orders, no matter how small, should be accepted. Foreign commercial firms make out prices and weights of commodities in the language of the country with which they wish to trade. British commercial firms generally give English currency, and use the English system of weights and measures, the most difficult of all for a foreigner to understand. Foreign commercial agents are obliged to learn the language of the country with which they desire to trade. Many British commercial agents appear to take a pride in knowing no language but their own, and seem to regard those who cannot speak English as people wanting in intelligence. The British trader had formerly a monopoly in many of the trading centres of the world. He is now met by the fiercest and most determined competition in every quarter of the globe. Unless the British commercial classes realise this fact, and compete in a manner suitable to modern requirements, British trade and commerce is bound to decline." Now there is no question that there is a great deal of truth in what the writer says. Take, for example, photographic apparatus. The English market is at the present time being flooded with hand cameras of foreign make—French, German, and American—taking the English quarter-plate, a standard size in this country. But in the countries in which they are made it is not, and a difficulty is often met with abroad in getting plates the size for them. All these cameras are made expressly for the English market, and it shows the enterprise of the foreigner.

News and Notes.

DARWEN Photographic Association.—An exhibition of photographic work will be held in the Belgrave Schools, Darwen, from Thursday, November 13th, to Saturday, November 15th, 1902. The judges will be Messrs. Alex. Keighley, F.R.P.S., and Percy Lund. The following classes are open to all amateurs and professionals:—Class 1.—Landscape, seascape, or river scenery. Class 2.—Portraiture, figure, fruit, flower, or animal studies. Class 3.—Architecture. Class 4.—Best print not above half-plate, mounted or framed, any subject, for those who have never won a prize. Class 5.—Set of four lantern slides. Entrance fee 1s. per set. 6.—Champion Class (First prize, silver medal; second prize, bronze medal).—For best picture, any size or subject, and produced by any process, and sole work of exhibitor. Should the entries exceed 80 an extra gold medal will be awarded. Entry form, with full entrance fee or fees, must reach hon. secretary on or before November 6th, 1902. Exhibits must arrive at Belgrave School, labelled "Photographic Exhibit," not later than November 12th. The hon. secretary is Mr. J. G. Thomas, Fern Cottage, Sough Road, Darwen.

CHLOROPHYLL Formation in Absence of Light.—It was shown by Radais (C. R., 130, 795) that *Algae* can form chlorophyll in the absence of light. Artari, who has recently occupied himself with the same subject, comes to the conclusion that under these conditions the formation of chlorophyll is controlled by the form in which the nitrogenous compounds are provided. Experiments were made with the green *Alga Stichococcus bacillaris*. A culture solution containing cane sugar and the other necessary constituents, except nitrogen, was prepared, and to this was added a nitrogenous compound. It was found that when peptone, asparagin, or ammonium acetate was supplied the *alga* continued to form chlorophyll in the dark, although it was noted that the chromatophores did not remain quite normal. If, however, the nitrogen was added in the form of leucin or potassium nitrate, then the *alga* generally lost the green colour altogether. But the colour could be restored either by placing the culture in the light, or even in the dark if asparagin was substituted as the source of nitrogen.—*Berichte der Deutschen Bot. Gesellschaft*, 20, 201 (From the "Pharmaceutical Journal.")

In the Right Direction.—We are pleased to see a Bill has been introduced into the State Parliament to provide for and regulate the method of advertising in or near public places. We have on several occasions expressed regret that our beautiful harbour and foreshores should be the dumping grounds of the bill-sticker. So we reasonably rejoice that there is a prospect of our pleasure resorts being so protected that they may display their natural beauties undisturbed. The Bill, among other things, enacts that "no person or body corporate shall erect, or cause to be erected, on the foreshores of the harbour of Port Jackson, any hoarding or other structure for the purpose of placing or exhibiting thereon any placard, sign, or advertisement of any kind whatsoever." Advertisements on buildings are also prohibited, as well as on land adjoining foreshores or adjacent to the harbour. Penalties not exceeding £2 and £5 are provided. We would like to see this desirable measure go a step further, and check the present unsightly practice of sailing boats displaying their pink, blue and black pill announcements. We sincerely trust the Bill may pass.—"The Australasian Photographic Review."

THE Goldsmiths' Institute, New Cross, S.E.—Courses of photographic lectures and demonstrations will be given, commencing September 24th and 26th, 1902. On Friday evenings, from 8.30 to 9.30, a six-months' course on practical elementary photography will be given. On Wednesday evenings, from 7.30 to 9.30, a six-months' course on practical advanced photography will be given, including enlarged negative making, retouching and working-up negatives; carbon and gum-bichromate printing; preparation of printing papers; lantern slides by three-colour process; photo-lithography, colotype process blocks, photogravure, etc. Each lecture will be illustrated either by a practical demonstration of the process under consideration, or by specially prepared lantern slides projected by an electric lantern. Students at the above courses will be eligible to sit for the examinations in photography of the City and Guilds of London Institute, held in May, 1903, at their fee of 3s. 6d. The Friday course will prepare for the ordinary grade examination, and the Wednesday course for the honours grade examination. The ordinary grade must be passed first. Practical courses will be given during quarters commencing September 22nd, 1902; January 5th, 1903; and March 30th, 1903; and including individual tuition indoors and outdoors. For ladies—Monday afternoons from 2.30 to 4.30; Monday evenings from 6.30 to 9. For gentlemen—Tuesday afternoons from 2.30 to 4.30; Tuesday evenings from 7 to 9.45. Fees each course—One quarter, 10s. 6d.; two quarters, 17s. 6d.; three quarters, 25s.

PAPERS Read before the Royal Astronomical Society.—I have upon more than one occasion commented here on the insufferable dreariness of certain papers which the Council of the Royal Astronomical Society has selected for reading—or permitted to be read at the ordinary meetings of the Society. That this dreariness is not always necessarily inherent in the papers themselves I have proof in a series of reprints of some of them which have been issued from the Oxford University Observatory, which, being presented in a form admitting of study, become of very real interest. Notably is this the case with one by Mr. Plummer, "On the Accuracy of Photographic Measures," discussing a paper by M. Loewy, in which I venture to think that our very eminent French confrere by no means gets the best of it. Now I have before remarked in these columns upon the irksome and depressing effect of some of Mr. Plummer's oral contributions to the Society's proceedings; but here, where the reader

can peruse it at his leisure, we find a real addition to our knowledge conveyed in a lucid and readable form. The series of reprints of which I am speaking contains also essays by Prof. Turner, including his discussion with Sir David Gill as to the trustworthiness of the late Prof. Pritchard's photographic determination of stellar parallax; an ingenious suggestion for surveying with a camera; on the performance of various object-glasses in photographing stars; and the third paper of a series on stationary meteoric radiant points. Like everything that Prof. Turner puts his pen to, these are all worth reading. Surely the inference from all this is obvious.—F. R. A. S. in the "English Mechanic and World of Science."

THE Late George M. Hopkins.—It is with most profound sorrow that we ("The Scientific American") record the decease on the 17th ult., at Cheshire, Mass., of Mr. George M. Hopkins, so long identified with the "Scientific American" as Associate Editor. It was while enjoying a vacation trolley outing with his wife in this beautiful locality among the Berkshire Mountains that Mr. Hopkins became suddenly ill on the 15th, and despite the best medical treatment, never recovered. His sudden demise will be a great shock to his intimate associates in the "Scientific American." Mr. George M. Hopkins was born in Oakfield, Genesee County, New York, November 21st, 1842, and while a lad went with his father and family to Albion, Orleans County, New York, where he received the usual public school education. He early displayed a liking for mechanics, having a natural ability to discover the reason of things in a mechanical way as they were studied. His father encouraged him to pursue matters to his liking by having him obtain practical information in the workshops at Albion. He early made the acquaintance of Thomas A. Edison, in whose laboratory he worked, and the friendship continued throughout the epoch of the telephone and electric light development, and to the present time. On May 10th, 1876, he became connected with the "Scientific American," beginning his work as an attorney in the Patent Department; it was soon noticed that he evinced a fondness for experimenting in matters connected with physics, especially in a more simple and direct way than was customary. He was encouraged in this work, and from time to time the results were published in the "Scientific American." The experiments were so simple and clear that any boy could understand them. The value of the published experiments was that they were based on actual manufacture of the apparatus and trial before publication. It is needless to add that these many different publications formed the nucleus of Mr. Hopkins' popular book, "Experimental Science," which has been of such assistance to many thousands of students of physics. Some months ago Mr. Hopkins undertook a thorough revision of the book, with a view to bringing it up to date, that many of the remarkable discoveries of the last few years might be included. It is a great gratification to feel that this work was entirely completed, and that the proofs had been thoroughly revised and read by Mr. Hopkins before he started on his vacation several weeks ago. The popularity of the work is shown by the fact that the twenty-third edition has just been published. Of late years he gave particular attention to literary work, editing the special department of "Notes and queries," and contributing to our columns a series of scientific articles which were marked by the clearness and brevity by which his work is easily recognised. Mr. Hopkins possessed in a marked degree the literary qualifications of a scientific writer. To his simplicity and clearness of style, no doubt, was largely due the great popularity of his writings, which attracted and held the interest of the widely diversified classes of readers who were interested in the subjects he discussed and subscribed for his published works. It is certain, moreover, that his directness and purity of style were one expression of the character of the man himself; for our late associate was possessed of sterling traits that won him the invariable respect and admiration of all those with whom he had business relations. His disposition was most kindly, amiable and attractive. He was ever ready to render assistance and freely impart such knowledge as he possessed. Mr. Hopkins occupied his leisure hours with the practice of photography as a stepping-stone for the study of art. He enjoyed painting small pictures as a pastime, using his photographs as a guide.

GERMAN Legislation Against Advertising Disfigurement.—Mr. R. Evans, hon. secretary of the Society for Checking the Abuses of Public Advertising, writes to "The Times": "At this season many thousands of travelling Englishmen are roused to an exasperated consciousness of wrong. They leave home for something more than change of scene. They look for the enjoyment of a certain unspoilt freshness in landscape, for the charm which attaches to the monuments of the past, for the fine effects of architecture, and all the picturesque aspects of the haunts of men. Experience brings its disillusionment. 'Medio de fonte leporum, Surgit anari aliquid.' Year by year the number, the vividness and the size of the intrusive objects that distress the eye increase. The sting of the injury lies in its wantonness. Ten hotel proprietors can kill the beauty of a lakeside town by sticking up monster boards on the sky-line of their establishments; but the effect is to diminish rather than increase the aggregate influx of guests. The place, to quote the brief judgment of the passing tourist, 'is spoilt'; and those whose shortsighted competition does the harm reap no profit. We who have for some years laboured to convince our countrymen that a rational ideal of civilization includes a vigilant regard for aspect, and that no individual should be allowed an unfettered discretion as to the degree in which he practises upon the sight of his fellows, have not hitherto secured a hearing in our own Legislature. But we retain our absolute confidence in the common sense of the nation, and do not doubt that before long the patent defect of our municipal law will be corrected, and powers analogous to those which apply to building, drainage, begging, and so forth will be bestowed on local authorities. The principle has already been recognised in certain private Acts. I desire, by your permission, to offer some account of a stimulating example lately set in Germany—the country to which we so often are told to look for illustrations of the

eminently practical and businesslike temper. An Act to prevent the defacement of scenery was passed in the last session of the Prussian Landtag. It runs as follows:—'With the object of preventing the disfigurement of places remarkable for their natural beauty, the police authorities are empowered to prohibit outside of towns (ausserhalb der geschlossenen Ortschaften) such advertising boards or notices or pictorial devices as disfigure the landscape by means of police regulations issued in accordance with the Law of July 30, 1883. Such regulations may apply to particular areas or spots.' Instructions, we are glad to learn, have now been issued by the central Government to the local authorities for the strict enforcement of the provisions of this salutary measure, and it may be expected that many painfully familiar eyesores on the frequented routes will speedily disappear. There is beauty worth saving in the street as well as on the river or amongst the mountains. But it appears from the proceedings in the Landtag that regulations already exist which are considered adequate for the protection of urban areas. As regards the open country the Prussian Legislature has gone upon the lines which we are anxious to see adopted in English practice. (1) The law is elastic; it places an effective remedy within reach where a grievance exists, but avoids any interference with general usage in the matter of business notices. (2) It sets up no arbitrary distinction between one class of conspicuous signs and another. The sole criterion is disfiguring effect. There is one and the same rule for the big letters on the wall of a building which announces that it is Messrs. So and So's manufactory and for the multitudinous puffs which the same firm sets up along all the highways of travel. (3) The ground of public policy upon which we rely was asserted throughout the debate in strenuous terms. In the report of the committee which submitted the project occurs this paragraph:—'What is needed is the creation of a legal basis. We must do for the country what is already recognised as right for the town. The equitable interest of all who love beautiful nature is in question—tho' to say, of most persons, whatever their nationality may be, who travel for pleasure. Nor can we overlook the pecuniary loss that will accrue if the progress of disfigurement diminishes the profits from the tourist traffic.' In the final debate in the Upper House, Herr Spiritus, the reporter of the committee, developed more fully the doctrine of the higher utility:—'We of the Rhine districts see many hundreds of thousands coming every summer from far and near to seek on the sunny heights, wooded hills, and shady valleys rest and delight. All return strengthened and entranced. . . . It is the same elsewhere. I trust that the conviction will grow that it is the sacred duty of our generation, especially of our public men, to preserve for posterity these beautiful tracts of the Fatherland.' Let me add that the assent of the Diet was by no means perfunctory. All the stock objections, the claims for compensation, for exemption in favour of this or that order of advertising sign, were urged and decisively rejected. The Hessian Legislature has included provisions of a similar character in a statute enacted recently for the protection of public monuments. Such is the way in which the wise and eminently practical people of whose progress so much is said amongst us order their affairs. I confess that I feel some patriotic humiliation in reading that the residents of Folkestone are still struggling in vain to rid themselves of a monster of the same kind as that which S.C.A.P.A. some time ago had the honour of helping to drive from the Dover cliffs. All because a House of Commons which votes thousands of pounds yearly for creating and maintaining pleasant places has not yet empowered local bodies to save the unbought and unpurchasable beauties of nature! Let us hope that the reproach will soon be wiped away. The question is not one of refined sensibilities, but of elementary common sense."

THE Late Sir Frederick Abel.—We regret to learn that Sir F. A. Abel died on Saturday, September 6th, in his 73rd year. According to "The Times," Frederick Augustus Abel was born in London on July 17th, 1827, being the eldest son of J. L. Abel, of Woolwich, and grandson of A. C. A. Abel, Court miniature painter to the Grand Duke of Mecklenburg-Schwerin. Undeterred by warnings that it offered very slight prospects as a career, he determined to adopt chemistry as his profession, and was at once met by the difficulties which confronted everyone of limited means, who, in the early years of Queen Victoria's reign, desired good scientific instruction at moderate expense. The Royal Polytechnic Institution was practically the only available place where the latter requirement was fulfilled, and, accordingly, in 1844, Abel's name was entered as a pupil on its books. But it was not long before he found that no attempt was made at methodical instruction; indeed, he soon began to doubt whether the "professor" had the ability to teach, even if he had had the wish. After spending six months in working through a standard textbook of chemistry according to his own devices, he decided that he had had enough of the Polytechnic Institution, and took his leave, the proud possessor of a testimonial setting forth the skill and minuteness with which his analyses had been conducted, and confidently recommending him to any post where a knowledge of practical chemistry might be required. But, luckily, for him, a scheme for establishing in London a school of chemistry on the lines of Liebig's famous one at Giessen was successfully carried through about this time, and thus he was able to form one of the 26 students on the roll of the Royal College of Chemistry, when its temporary laboratory in George Street, Hanover Square, was opened in the autumn of 1845, under the direction of the famous German chemist, A. W. von Hofmann. At the college he spent some six years, during five of which he was one of Hofmann's assistants, and he only left to succeed Faraday as Professor of Chemistry at the Royal Military Academy. A few years later, in 1854, he was appointed Chemist to the War Office—a position which he filled for 34 years. His official duties naturally led him to devote attention to the study of explosives for military purposes, and thus he became intimately concerned in some of the most important developments that the latter part of last century witnessed

in the manufacture and use of ammunition. When mineral oils came into use as a means of domestic illumination it was soon found necessary to frame regulations for their storage, because some of the constituents of the mixture termed petroleum are so volatile that at ordinary temperatures it may give off inflammable vapours which in certain conditions become explosive. The first Petroleum Act, passed in 1862, defined as dangerous, and placed restrictions on the sale of any petroleum that gave off vapour at a lower temperature than 100 deg. F., but, as it omitted to specify any method of testing the oil, it was practically inoperative. During the next few years Sir Frederick Abel and other chemists investigated the matter, and as a result, in 1868, the second Petroleum Act was passed, legalizing the Abel "open-test" apparatus. In time it was recognised not only that the indications of this instrument were inherently untrustworthy, but that it lent itself to manipulation on the part of an operator who had some motive for not discovering the truth. In 1875, therefore, the whole question was referred to Sir Frederick Abel. He reported that, though the established flashing point of 100 deg. was calculated to afford adequate protection to the public, the method by which it was ascertained was not satisfactory, and at the same time, as an improvement, he brought forward the Abel "close-test" instrument. This was legalised in 1879, and has been the British standard ever since, besides being adopted, with or without modification, by several other countries. The flash-point of a given oil as determined by the new apparatus not being the same as that shown by the old one, it became necessary to fix the relations between the two. To this end a thousand samples of oil were tested by both methods, and it was found that on the average the temperature at which the oil vapour flashed was 27 deg. lower with the close than with the open test. Hence, the flash-point of 73 deg. was adopted as the equivalent of the 100 deg. prescribed under the old system, and has been adhered to ever since. Agitations (it is to be feared not always inspired by pure regard for the public safety) have from time to time been started to effect an alteration, but without success. The first condition for reducing the annual tale of accidents would rather appear to be due attention to common-sense principles of lamp construction and management, such as are embodied in Sir Frederick Abel's reports to the Metropolitan Board of Works and the Chief Inspector of Explosives. In 1885 Sir Frederick Abel rendered valuable service as a member of the Council of the Inventions Exhibition, and on the formation of the Imperial Institute, two years later, he was appointed organising secretary and general director. The duties of this office he continued to perform, in later years receiving no pecuniary reward for his services, until the end of his life, and practically until the end of the existence of the Imperial Institute as an independent entity; for it was only in July last that the Royal Assent was given to an Act, which will probably become operative at the beginning of next year, for the transference of the Institute to the control of the Board of Trade. The tenure of this arduous and difficult position did not prevent him from undertaking a great deal of other scientific and official work. He ceased to be Chemist to the War Office in 1888, but immense labour was involved in the investigations of the Special Committee on Explosives, which lasted till 1891. As a prominent member of the Goldsmiths' Company he took considerable interest in the subjects of technical education and original research, and was instrumental in establishing at the Imperial Institute well-equipped research laboratories in connection with its scientific and technical department.

WHO PHOTOGRAPHED THE CANADIAN ARCH?

To the Editors.

Gentlemen,—I have been requested by some customers of mine, at Wrightington Hall, near Wigan, to try and find out a photographer who took the Canadian Arch on July 7th, about 6.15 a.m. There are three civilians and a policeman in picture, all of whom the photographer took trouble to pose. Unfortunately, they did not at the time ask for his card or address, and it is now particularly required, if it can be procured.—I am, Sirs, yours respectfully,

A. RUDOLPH-DOUGLAS.

23, Upper Dicconson Street, Wigan.

September 3rd, 1902.

A CASE FOR THE P.P.A.?

To the Editors.

Gentlemen,—We have read the letter of your correspondent in this week's issue of the BRITISH JOURNAL, and can only agree with your remarks that Mr. Brown (if he be a photographer, which, judging from his indignation appears a little doubtful), should become a member of the P.P.A., of which the head of our firm has been a member since its foundation.

At the same time, we fail to see that anything has been done which calls for the criticism of the committee of the association. Our work

is all we claim for it, as is borne out by the numerous testimonials we have received. We enclose copies of two from customers whose social standing is, at any rate, a guarantee of their value, and must ask you, in justice to ourselves, to give the same publicity to these testimonials, as you have to the communication of your correspondent, Mr. J. L. Brown.—Yours truly,

ELITE PORTRAIT COMPANY.

267, High Holborn, London, W.C.
September 8th, 1902.

[COPIES.]

The Cloister House, Gloucester.
May 28, 1902.

Canon St. John is much pleased with the portrait, and encloses 8s. 6d. He thinks that other members of the family will want copies when they see his.

(From the Hon. Sir Spencer Ponsonby Fane, P.C., G.C.B.).
Brympton, Yeovil.

September 3, 1902.

The enlarged photograph has arrived, and is very satisfactory. I enclose postal order and stamps for your account, 8s. 6d.
(Signed) S. PONSONBY FANE.

THE THORNTON-PICKARD COMPETITIONS.

To the Editors.

Gentlemen,—As our competition closes on October 1st, may we ask you to be good enough to draw the attention of your readers to that fact in an early issue of your valued paper? At the same time we would ask you to mention that negatives need not accompany prints in the first instance, and will be required afterwards only from prize-winners. Complete prospectus and entry form will be sent post free on application.—Thanking you in anticipation, we are, yours faithfully,

THE THORNTON-PICKARD MANUFACTURING CO., LTD.

Altrincham.

September 5th, 1902.

IRRITANT POISONING BY PHOTOGRAPHY.

To the Editors.

Gentlemen,—I should like to express, through the columns of your paper, my thanks to Professor Grün for his letter contained in your issue of August 15. The lead lotion remedy suggested by him has proved very efficacious in my case. Two days before seeing Professor Grün's letter I was developing "Velox," with the usual solution, containing 7 grains metol in 10 oz. water. I accidentally got a little on the fingers of my left hand. The result has been astonishing. My fingers swelled to twice their normal size, probably owing to their tenderness after former attacks, and the irritation was acute. The lead lotion treatment has certainly cured me, and, what is quite as useful to know, the weak prussic acid solution prevents a recurrence if the affected parts are dipped in it occasionally.—Yours very faithfully,
C.

September 3rd, 1902.

THE PROBLEM OF PORTRAITURE IN COLOURS.

To the Editors.

Gentlemen,—I have most carefully read my letter in your issue of the 29th ult., and I fail to see what has raised Mr. Kenah's ire, nor why he should call it ungentlemanly. I was not aware that it was considered ungentlemanly to call an article pessimistic, any more than to call it excellent, or satirical, or humorous; but I am always willing to learn. As regards the terms, "hasty and ill-advised," this was borrowed from your contributor's article, and, personally, I should have thought it more ungentlemanly to stigmatise all writers about colour photography and advertisers of goods for the same in all the photographic Press, as unworthy of credence, as he does when he cautions your readers against the same.

I was under the impression that any contribution in the pages of the BRITISH JOURNAL was open to criticism, contradiction, or comment; if, however, your contributor's effusions are an exception to this rule, it would be as well that he should append a notice to that effect to them. I endeavour below to justify my criticism, and the use of the terms complained of, for, personally, I consider them hasty, because to me they seem to have been written from a limited or ignorant point of view, and without consideration, and ill-advised, because they might deter "the rank and file of photographers" from trying the process, and this would be deplorable; the whole article seemed pessimistic, because it left me with the impression that there was nothing the professional could attempt, except photomechanical work.

I can assure Mr. Kenah that it takes somewhat more than his article to offend me, but I consider his letter a display of wounded vanity, deserving of the utmost contempt. Whether he chooses to answer my criticism or not, will not disturb my equanimity one jot

or tittle. I, however, claim the right, with your permission, gentlemen, to deal with the subject of portraiture in colours, on the basis that an article has been published in our Journal, and has, therefore, received the imprimatur of being worthy of consideration, and that any reader is entitled to criticise the same, but that the author was A. V. Kenah, or Tom, Dick, or Harry, is to me a matter of the utmost indifference. It is to the rank and file of your readers that my statements are addressed.

With regard to the screens, if these are to be used before, behind, or between the lenses, then they should be preferably of optically worked glass; but as this is expensive, patent plate can be used. I have for the last five years used a special thin and white patent plate, about one-sixteenth of an inch thick; it is wonderfully free from flaws, and when using two pieces cemented together, I have not found that it impairs definition at all. I believe this is made by Pilkington and Co., and costs me, retail, one farthing per square inch. It is possible, and some authorities recommend the use of the filter in contact with, or close in front of, the plate, and then an old negative, freed from the silver, may be stained and used with successful results. A set of whole plate screens thus made, I have repeatedly used for practical work.

As to the making of three similar negatives, I have for three years used the Watkins time development system for colour work, and, therefore, I can recommend this from practical experience.

The question as to the light in the studio came under my notice four years ago, when a test chart was photographed in and outside the studio, and no readjustment of the screens was found necessary. I speak in this case from practical experience, and not from a personal theoretical hypothesis.

We now come to the point, and an important one, of the exposure. Dr. Miethe used screens of his own manufacture, but as he has given the regions of the spectrum which each transmits, even to wave lengths, it should not be difficult to make similar screens. The plates he used were made for him by Perutz, of Munich. These can be obtained commercially, and I fancy Dr. Miethe's screens can be had from Dr. Heseke and Co., of Berlin. The exposure given was $5\frac{1}{2}$ sec. in all, but according to a statement in the September number of the *Photogram*, with which is supplied one of Dr. Miethe's colour supplements, an improvement has been made in the plates, so that the exposure would be reduced to 3 secs., under the above conditions. My estimate as to the increase in exposure in studio is borne out by an editorial comment on the same colour supplement, in the *Bulletin de la Société Française*, for August, for it says:—"Dans l'atelier, les poses sont naturellement plus longues et varient, avec une lumière moyenne, de 15 à 30 secondes." Let us accept, then, an increase of six times, by the improved plates, the exposure is reduced to three seconds, with F/12.5, the aperture used by Dr. Miethe; if we use F/6, the exposure would be only four seconds, which is surely within the range of practical work.

The predominance of greys in sitters is a matter which the rank and file of professionals can answer better than I can.

Hoffman's trichromatic carbon tissues were obtainable commercially nine months ago; I cannot say whether they are now. I do not expect the average professional to experiment, but there are others who might wish to do so, and to them I suggest Fleming's transparent ink powders. The synthetic colour powders of Hazura and Hruza are described in the *Photographische Correspondenz* and Eder's *Jahrbuch*, for 1900 and 1901. I think I cannot look the matter up, for, having but lately moved all "those wretched books," as someone calls them, are muddled in heaps upstairs, and I am as yet unable to manage even one step.

At the last R.P.S. exhibition there were some excellent specimens of superimposed films on opaque supports, and I think three years ago, at the same exhibition, a print on paper was shown, but this was by the gum bichromate process, and I doubt the practical process of this, for professional work.

The McDonough-Joly process I dismiss, because it is only applicable to transparency work, or to paper by a photomechanical process, and to expect operators to learn how to make half-tone negatives, and blocks, and print from them is an absurdity. Besides, I do not think Strephon will appreciate Chloe's portrait, with her lovely blush rose and creamy complexion, streaked with yellow and blue.

When a friend of mine, to whom I sold a camera, calls next week and tells me he cannot pay me because he has been trying a pretty problem and indulging in some most interesting speculative exercises, in the shape of the Sampolo-Brasseur process, I shall promptly put him in the County Court, but I shall try the dodge on my landlord anyhow, the next time he calls for the rent. If it comes off your readers shall know.

Allow me to append the following extract, from the price list of the Lumière N.A. Company. I fancy the statement is in Mons. Lumière's original paper, but am not sure:—"Prints in colour may also be produced on paper, in which case it will be necessary to employ much fainter monochromes than are used for transparencies. The operations generally are of a more delicate nature, and require extremely careful manipulation."

That portraiture in colours on paper is possible I know, that it is

in such a stage as to be taken up by the rank and file now, I doubt; but an enormous step has been made by Dr. Miethe, and I feel that within a short time it will become comparatively general; but there is an old proverb about the early bird.

I must apologise for taking up so much of your space, but the BRITISH JOURNAL has always been open to gentlemanly and polite letter writers, although they do occasionally become prolix.—Yours, etc.,
E. J. WALL.

INTERNATIONAL CONVENTION RELATING TO PATENTS, DESIGNS, AND TRADE MARKS.—IMPORTANT AMENDMENTS.

To the Editors.

Gentlemen,—It will be of considerable interest to manufacturers to know that on the 14th September (instant) amendments of importance will take effect in all the States of the Convention—that is to say, in Belgium, Denmark, France, Italy, Japan, Netherlands, Norway, Portugal, Sweden, Switzerland, Tunis, and United States.

The principal amendments taking effect are as follows:—(a) The priority granted to applicants for patents, designs, or trade marks, in any of the States of the Convention, shall be *twelve months* for patents, and *four months* for designs or trade marks, reckoned from the date of the application in the State in which the applicant is domiciled. (b) The patents applied for in any of the States of the Convention by persons entitled to the privileges thereof shall be independent in duration of patents obtained for the same invention in other States, whether parties to the Convention or not. (c) No patent applied for under the Convention shall incur forfeiture for non-working until the expiration of a minimum period of three years from the date of the application.

The extended period of priority given to applicants under the Convention has been granted in Great Britain since the 1st January, 1902, by the amending Act that came into force on that date.—We are, Sir, your obedient servants,
EDWARD EVANS AND CO.

27, Chancery Lane, London, W.C.

September 9th, 1902.

SOLUTION OF THE CONUNDRUM.

To the Editors.

Gentlemen,—Transpose (you see) U.C. and then you have it.—“Puck.”—Yours, etc.,
H. A. L.

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to “THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C.” Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

T. R. Braybrook, Church Square, West Hartlepool. Photograph of “The Harlequins Coronation Souvenir.”

J. Patrick, 52, Comiston Road, Edinburgh. Photograph of Edinburgh. Photograph of Lady Nairn and Son. Photograph of J. Welsh.

A. WALKER.—The formula that will probably suit you will be found on page 1,069 of the ALMANAC.

OPINION WANTED.—“RETOUCHING” writes: “Will you kindly inform me as to what you think of my retouching?”—In reply: The work is very creditable, and is better than much that is submitted to us. But we can give no opinion as to how the likeness has been retained, as untouched prints were not sent.

FORMULA WANTED.—C. T. writes: “May I trouble you to let me know of a reliable formula for making toning and fixing solution in large quantities for bottling, for retail to amateurs?”—In reply: We presume you mean a combined toning and fixing solution. A good formula for that is given on page 1,077 of the ALMANAC.

RETOUCHING.—L. G. G. writes: “I should esteem it a great favour if you would comment on the enclosed specimens of my retouching, and advise me as to what salary I could command as assistant operator and retoucher? I am also competent of taking a good negative.”—In reply: The retouching may be classed as tolerably good. It is impossible to say the salary you could command simply by seeing two or three specimens. We should say, from what is sent, you could not command a very high salary.

STUDIO CONSTRUCTION.—“PHOTOPHIL” writes: “I should be glad of indications respecting a moderate-sized studio or workroom for copying and photographic reproduction. I can command light all round. The lighting is the chief point.”—In reply: There are so many forms of studio that will answer for copying; indeed, all will answer for the purpose, so long as the object is evenly illuminated.

Perhaps the most convenient to you would be one with a sloping front light, facing the north, as the light from that direction is the most constant. We are assuming that the studio is required for copying only.

NIGHT PHOTOGRAPHY.—“INCANDESCENT LIGHT” writes: “Would you kindly say what number of incandescent burners would be required to obtain a good negative at about two seconds’ exposure, using, say, an Imperial flash-light plate and a good, quick portrait lens with open aperture?”—In reply: Very much will depend upon the distance the lights are placed from the sitter and how they are distributed. If they are placed near the sitter, as they may be when only, say, a bust portrait is desired, fewer will suffice than when a full-length is necessary, and the lights have to be much further away. Again, the mantles deteriorate as they are used. Try from eight to a dozen for a medium distance.

SPOTS ON C.C.—“BROS” writes: “Can you tell us cause of black spots on prints enclosed? They are on — paper. We have used this make for about six or eight months, and up till about three or four months since we have never been troubled with these spots, although there is no change of treatment. Previous to that we used —, and found that excellent; but, somehow, they gave over sending the latter.”—In reply: Beyond saying that the spots appear to be caused by contact with something that has reduced the silver where they are, we can give no decided opinion. We should advise you to send a few examples on to the makers of the paper; they may perhaps be able to tell you more decidedly the cause.

CRACKED FILM.—W. S. B. writes: “I have a 1-1 plate negative, subject of value to me. The glass has got cracked, but the film is undamaged. Fair good negative, but perhaps a little thin. It has been retouched, therefore rubbed over with retouching medium. What is the best and safest way to transfer to another glass? If necessary to remove the retouching medium, please say how? I don’t mind whether it is same size or allowed to expand. Only the latter may make it still thinner, in which case it may not print very brisk.”—In reply: The method of stripping negatives has often been described in the JOURNAL. Briefly, here it is again: Place the negative face upward on another glass, and immerse in a solution of alum, if the negative has not previously been alumed. Rinse and put into water, to which four or five drops per ounce of hydrofluoric acid have been added. In a few minutes the film will have been loosened, and may be floated off on to another glass which has previously been coated with a thin solution of gelatine, and allowed to set. It may then be allowed to dry. The retouching medium had better be removed beforehand.

SPOTS ON PRINTS.—“PERPLEXED” writes: “Please tell me cause of white spots on enclosed platino-bromide prints? They were developed with amidol. Suspecting some foreign substance had got into amidol or sulphate of soda, new stuff was procured from the dealer. Still the bad marks continued to appear. Everything used in making these prints was perfectly clean. The moment the image began to appear these spots became visible, as if they were non-sensitive parts of paper. Do you think impurities in the water may have been the cause? Will you also kindly say cause of spots on enclosed negative developed with pyro and soda?”—In reply: The spots on the prints seem to be due entirely to careless work. Evidently particles of dust or dirt in the solutions are the cause. This is also the cause of the spots on the negative. On that the particles can be distinctly seen. We do not think they come from the water. However, you might put a couple of thicknesses of fine flannel over the water-tap and see if the spots appear then.

* * * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * * NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published early in December next. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The edition for 1903 will be increased to 25,000 copies, a large number of which are already ordered.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1903. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will

be recorded, and wherever practicable new features of an informative nature will be added.

Secretaries of societies will oblige us by promptly forwarding lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, etc. Those firms who wish to take advantage of this feature should communicate with us not later than October 31.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRA.

Another Photographic Competition.

The Parisian journal, the "Figaro," announces another photographic competition. As it enjoys a large circulation, amateur and professional, photographers may think it worth while to enter prints. The selection of subject is restricted to artistic, ancient, and ecclesiastical architecture and decoration. The prints must not be smaller than 9c. by 12c., and must be sent to Monsieur Voisin, Secretary of the "Figaro" Photographic Competition, 26, Rue Drouot, Paris, from whom further particulars may be obtained. Prints will not be accepted after October 5 next.

* * *

The Transparency of Ebonite.

Monsieur Perrigot has made a further communication to the French Academy upon this subject. In his communication of April 20 last he showed that ebonite was transparent, and that the phenomena of so-called black light might be explained by photographic reversal. He has continued his experiments with sheets of ebonite 0.5mm. thick, perfectly polished, using Carbutt films for the impressions. Ebonite apparently acts as a colour screen, and this may be perceived by examining it with a beam of light of great intensity. The rays transmitted are orange-red. Experiments with orthochromatic plates, very sensitive to red and yellow. (Lumière, Series B), gave similar results with much less exposure. Sheets of ebonite 2m.m. thick, although opaque to the eye, still transmitted sufficient light to affect a plate, especially if the sensitiveness extended to the red and yellow. This was ascertained by exposure to sunlight and electric light, and normal results, or reversal, could be obtained, either by using the

plate in its original state, or by giving it preliminary exposure.

* * *

The Decimal System of Weights and Measures.

There is no question, as we have said on previous occasions, that the decimal system of weights and measures will be universally adopted in this country for all purposes. For some time past the metric system has been legal in trade transactions in this country. Here is a further step towards its general adoption, at least in one branch of business. One day last week the following announcement was made by the Liverpool Cotton Association: "On and after the 1st October next trading in 'spot' and 'futures' American cotton in Liverpool will be in hundredth parts of a penny per pound, instead of sixty-fourth parts and on the same date the discount of 1½ per cent. hitherto allowed will be abolished. This important change in terms will result in a lowering of quotations by approximately 4-64ths to 5-64ths or 6-100ths to 7-100ths per pound, being the equivalent of the discount no longer given, the net value thus remaining unaltered. On the same date the weight of the American cotton contract for futures will be altered from 47,200lb. to 48,000lb." This, it is true, is but a small step, inasmuch as the penny is not the decimal part of the £; still, it is a step in the right direction for the decimal system becoming universal.

* * *

New Lenses.

A further interesting development in lens construction has recently appeared in Germany. The calculator of this new instrument is Dr. Harting, one of the leading men at Messrs. Voigtlander and Sons', of Brunswick. The lens is an anastigmatic triplet, with a relative aperture of $f. 4.5$, this intensity being not only attained in the smaller sizes, but throughout the series. It is thus little short of the rapidity of the ordinary portrait lens. The front and back lenses of the combination are both formed of two cemented components, and the middle lens is, apparently, a single biconcave. The combination has been named the "Heliar." Owing to its large aperture, it is specially suitable for very rapid instantaneous work, portraiture, tele-photography, enlarging, and lantern work. Professor Aarland, to whom a specimen of about 14in. focus was submitted, speaks in high terms of its performance, and draws special attention to the good correction for coma. We also see that a patent has been granted to A. H. Rietzechel for a symmetrical combination closely resembling Steinheil's Orthostigmat. Although both components consist of four elements, instead of three, the middle one of the Orthostigmat, a meniscus, has been split into a plano-convex and plano-concave of slightly differing refractive indices. Dr. Hugo Schroeder has also taken out a patent for two unsymmetrical combinations, the components in both cases being of four lenses each. The specification does not, however, give any particulars of the indices of the glass, the radii, and the thicknesses. The relative aperture and the angle included are likewise not specified.

* * *

The Amount of Silver Bromide on a Plate.

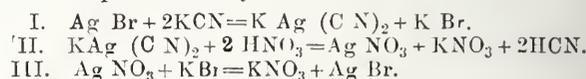

The "Allgemeine Photographen Zeitung" contains a communication from Dr. Bellach, of the Royal Technical High School, Berlin, concerning the determination of the quantity of silver bromide present in the film of a photographic dry-plate, and it is recommended for its simplicity

and approximate correctness. The film is placed in a dish, containing a 5 per cent. solution of cyanide of potassium, for about fifteen minutes, or sufficiently long to convert the whole of the bromide of silver. Place the solution in a beaker, rinse the dish with distilled water, which add to the solution. After warming the same, add nitric acid, which precipitates the silver bromide and liberates hydro-cyanic acid. This should be done with great care. Pure hydro-cyanic acid is one of the deadliest poisons, and even the inhalation of a small quantity of its vapour is fatal. After precipitation of the bromide, pour off the supernatant fluid and filter through a well-dried, double filter-paper, which has previously been weighed. Wash the bromide by pouring hot water through the filter several times. Dry and weigh. The excess above the weight of the filter-paper will indicate the amount of silver bromide. The following result shows that the process is sufficiently accurate:—

Given amount of silver bromide by weight, 0.31 grammes. Amount after decomposition and precipitation, 0.32 grammes.

Two plates, 9c. by 12c., of different make, were tested, and found to contain 0.21 and 0.24 grammes respectively.

The chemical process may be stated as follows:—

The silver may also be recovered by electrolysis from the solution of silver bromide and potassium cyanide. It should then be weighed, and its equivalent of silver bromide found by calculation.

* * *

Tri-chromatic Portraiture. We have recently had the opportunity of communicating with the firm of O. Perutz, of Munich, concerning the colour-sensitive plates prepared by them, according to Dr. Miethe's formula for colour photography. Since we drew attention to the remarkable colour print, which Dr. Miethe published in the "Atelier des Photographen," very considerable interest in the possibilities of tri-chromatic portraiture has been awakened. There can be no doubt that excellent colour photo-mechanical prints may be produced by the photographer who has mastered the three-colour process, provided the light is good when the photographs are made. We have had numerous inquiries upon the subject, and in answer to these we have much pleasure in publishing the further particulars which have been supplied to us by Messrs. Perutz. In our "Ex Cathedra" notes of August 15 we mentioned that we believed the plate sold for these photographs was the "Perorto," but we were misinformed. The plate used for the purpose is the "Perchromo." It is sensitive to blue, green, and red light, and has a speed of about 25 Warnerke. As stated in a previous note upon this subject, it is very important that the three exposures should be correctly timed, according to the sensitiveness of the plate, for the three primary colours. Further particulars upon this point may be gathered from our issue of April 11. But not less important is the fact that the three negatives must be simultaneously developed, with the same solution, for the same length of time, otherwise the negatives will probably vary in density, and produce bad prints. Those who have studied the Hurter and Driffield theory will understand the importance of this precaution. The colour screens prepared by Dr. Miethe may be obtained from Herr Perutz, of Munich. Great care must be used in the dark room and a suitable screen for development may be prepared by thoroughly staining a fixed and well-washed dry plate, first with 1 gramme of

methyl violet dissolved in 400c.c. of water and then with 1 gramme of tartiazin dissolved in 100c.c. of water. Hitherto the most frequent cause of failure has been a disregard of the precaution to develop all three negatives simultaneously for the same length of time. We recently drew attention to another plate, manufactured by Herr Perutz, called the "Perxanto." This is very sensitive to green and yellow, but not to blue. It is an orthochromatic plate, giving a true rendering of colour without the use of a screen. Its speed is about 23 Warnerke.

* * *

Cloud Effects and Stock Cloud Negatives.

These lines will reach the reader at about the time of the Autumnal Equinox, and when many amateurs will be thinking of relinquishing photography—out of doors, at least—for some months, and will be devoting their attention to producing results from the negatives they have secured during the past summer season—or such a photographic summer season as we have had in this country. With gelatine negatives, it is pretty well known that, when taken under ordinary conditions, natural clouds—that is, printable clouds—are not secured in the negative. Therefore the prints appear with white or tinted skies, unless the sky be printed in from a second negative. But how many amateurs have a stock of cloud negatives from which they can select one to suit any particular picture? All that many have are half a dozen, or perhaps a dozen, purchased commercially, from which they select one that the best fits in for the picture, though it may be quite unsuited to the subject. At this time of the year there are to be obtained a greater variety of cloud effects than at any other time, not excepting the Vernal Equinox; yet many amateurs do not embrace the opportunity, much as these cloud negatives might improve their pictures, however small they may be. This is the more surprising, inasmuch as they may generally be obtained without leaving home, and on plates that may have deteriorated by keeping, or at least such as one would not care to take away on a day's outing; old stock may be utilised for the purpose, as the margins are of little moment in cloud negatives. Hence it will be seen that a large stock of cloud negatives may often be secured without any outlay for plates, and only for the small trouble of exposing and developing. One of the chief faults of stock cloud negatives is that they are taken with the camera pointed too much to the zenith, so that the light upon them does not accord with that upon the landscape. That is too often noticeable in some of the so-called "art pictures" seen at some of the exhibitions. Unless the introduced clouds are in unison with the landscapes, they are better omitted. One often sees in pictures of the type just alluded to wild, turbulent skies introduced into serene land or seascapes, and the result is often extremely ludicrous in the eyes of artists. Much of this might be avoided if the photographer had a good stock of negatives to select from, and had judgment to make the selection. Now is the best time of the year to secure such a varied stock, as all kinds of clouds, summer, autumn, and winter, are to be seen about this time of the year. Years ago it used to be said that introduced clouds in lantern slides spoil the picture, but that idea has now been dispelled, particularly when the clouds are printed on the cover glass.

* * *

Dangers in Compounding Flash-lights.

is not available,

The season is now fast approaching when photographers will be requisitioning artificial light to supplement daylight for many purposes. Where electric light "flash-lights" are frequently employed,

and often by those who have no idea of the danger that lurks in many of them, particularly those that contain chlorates. This fact is once more called to mind on reading the report, recently made, by Captain Desborough to the Home Office upon the accident which occurred in the building used for the manufacture of non-explosive ingredients at the factory of Messrs. Pain and Sons, Mitcham, on June 15 last, when two persons were killed. In his report, Captain Desborough says: "The fact of an explosion in a non-danger building must, on the face of it, be evidence of an illegality having been committed." In concluding his report, he says: "To prevent the possibility of a chlorate coming in contact with other ingredients, I have requested Messrs. Pain to take steps to keep all chlorates in a separate store, and to arrange that all the operations of sifting and weighing such chlorates may be carried out in a building into which other chemicals are never brought." The accident that necessitated this report occurred at a firework factory, where it might be supposed that the character of the materials employed were well understood. But that is not always the case with photographers who compound flash-light compositions for their own use from published formulæ. In these formulæ often no special precautions are given, beyond "Pulverise separately and then mix." Whenever we have been asked for formulæ by correspondents we have always impressed upon them the dangerous nature of the manipulations when chlorates are amongst the ingredients. Chlorate of potash, for example, under normal conditions, is a perfectly harmless substance, but when mixed with some others, say some that enter into flash-light compounds, it becomes highly explosive and dangerous, although all the other ingredients may be quite harmless by themselves. The danger only steps in when they are mixed together. In compounding flash-light compounds containing chlorates or oxygen-forming substances, all the ingredients should be dried and pulverised separately and only mixed together at the time of using, and then only in quantities for a single flash, as many of them are liable to go off spontaneously and when least expected. The mixing should always be done on a sheet of paper, with a slip of thin carboard as a spatula, and even then used at arm's length, so that if an accident should happen no great injury will be done to the operator. This is by no means the first time we have called the attention of readers to the great risk there is in compounding flash-light powders by those who are ignorant of the materials with which they are dealing.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for the current month has been awarded to the Rev. Canon Pearce, The Vicarage, Bedlington, R.S.O., for his negative "The Bettmer Alp."

THE Professional Photographers' Association.—There will be a meeting of the General Committee at 51, Baker Street, W., to-night, Friday, at 6 o'clock, at 51, Baker Street, London, W. Business: Fire Insurance Policy; Appointment of Assistant Secretary; Birmingham Branch Formation; Price Cutting, etc.

Borough of Southport.—A Photographic Exhibition will be held in the Atkinson Art Gallery, Southport, from November 24th to December 6th, 1902. The judges will be Messrs. Harold Baker, R. Child Bayley, F.R.P.S., and H. Snowden Ward, F.R.P.S. The following is the Selecting and Hanging Committee:—Councillor F. W. Brown, Chairman Art Gallery Committee; Dr. Baidon, Vice-Chairman Art Gallery Committee; Messrs. D. E. Benson, A.M.I.C.E., C. H. Brown, Willis Brunt, Geo. Cross, J. Noton, and F. W. Teague. The exhibition will be open on Saturday, November 22nd, by a private view, and will continue open daily (Sundays excepted) from Monday, November 24th, to Saturday, December 6th, from 10 a.m. to 10 p.m. Each Monday, Wednesday, and Saturday evening, an exhibition of lantern slides will be given by the Southport Photographic Society. The exhibition will be divided into six sections, namely:—(1) Selected Pictorial Photographs; (2) Scientific Photography; (3) Lantern, Stereoscopic, and Decorative Transparencies; (4) Photo-Mechanical Processes; (5) General Professional Work; (6) Photographic Apparatus and Material. Entry forms can be obtained of Mr. F. W. Teague, Curator, Atkinson Art Gallery, Southport.

ON SOME PHOTOGRAPHIC FETISHES.

It is doubtful whether in all modern social history the survival of so many fetishes can be paralleled by what we see in the every-day practice of photography. The primitive savage, when he hangs a bit of coloured rag round his neck, in the full trust in its efficacy to ward off evil, and in many ways to help him in his daily life, simply discards it or tears it to pieces and jumps upon it when it disappoints him in his expectations; it is not generally taken up and fondled by a neighbour or a rival in his dusky affections. But in photography the discarded beliefs of its early days and the proved uselessness of many of the practices of its adolescence are picked up again and hugged, and metaphorically prayed to by an immense number of its devotees and adherents. Take what is perhaps the most familiar example of all, the experience of the very earliest daguerrotypists. The sitters sat, sweltering in the sun, motionless, and with instructions not to blink, for a period of time not counted by seconds, or fractions of a second, but by actual minutes, until the use of bromine enabled the exposures to be brought within reasonably practical limits. Then wet collodion reduced the minutes to seconds, and gelatino-bromide to fractions of a second. Yet to the very present the full conviction of the need of sunshine and the fatal effect of blinking during exposure survives, and is a fetish whose absurd inefficacy cannot be fully brought home to the public mind. Photographers deride it and explain the falsity of the idea, but what our great-great-grandfathers were taught to believe in is still cherished by a vast proportion of their modern descendants—arguments seem powerless to cause its banishment—and every day the professional has to listen to the praises of the “beautiful day” for photographing, all the while he is silently anathematising the sun for spoiling his outdoor group-lighting or causing his studio-sitters to screw up their eyes through its glare. But, on the other hand, can we truthfully say that he has no fetishes of his own in his own practice? Scarcely. Let us take his management of his lenses. If there is one belief the average photographer holds more strongly than another, it is that a landscape lens must not be used for architectural subjects, and he becomes great on “pincushion and barrel-shaped distortion” when he discusses the question. He would be surprised to learn—indeed, he would most probably be incredulous—upon being told that some of the best architectural photographs, interior and exterior, that have ever been taken are the results of the use of landscape lenses. It is absolutely true, and not a consequence of the introduction of modern improvements, that the so-called landscape lenses—single lenses, simple or cemented, achromatic or non-achromatic—may be used with perfect safety for taking architectural subjects, the only restriction being that a comparatively narrow angle only can be utilised. We say comparatively narrow, but a sufficiently large pictorial angle may be used without the marginal straight lines of the subject losing their rectilinearity in the negative. Bringing the question to a practical issue, it may be said that if a landscape lens be employed with a focus double the length of the longest side of the plate, and its axis be directed to the centre of the plate (that is to say, the camera sliding front is not raised or lowered), curvature of marginal lines would

not be noted. If, however, such a lens with a focus, for example, of eight or ten inches be used to take buildings upon a whole-plate size, we should expect to see bent lines towards the edge of the negative. But even here, in a very large number of the subjects that are likely to be photographed, the limits we have set down would be unnecessarily large. We have before us as we write a 12 by 17 print of a building used as a bank; it was taken for the bank authorities, to show the grandeur of their property, so that it naturally almost fills the plate. Yet, though taken, to our knowledge, with a 16½ in. focus landscape type of lens, and the camera front raised so as to include the chimneys, it would take a most acute observer, armed with a straight-edge or compasses, to detect the slightest deviation from a straight line in even the outside angles of the building. In other words, the supposed need for a rectilinear type of lens in lieu of a landscape is a fetish only. Yet another example of a lens fetish—so-called “depth of focus.” It is not long since we saw in a leading lens manufacturer’s advertisement a lens recommended for its “depth of focus,” which, it was stated, had been brought about by adopting certain materials in its construction, clearly implying that the “depth” was a function in the structure of the lens. Leaving aside the undesirability of the use of the term “depth of focus,” which purists in technology deprecate, we would point out the utterly misleading nature of such a recommendation. If there be an absolutely inexpugnable statement in photographic technics, it is that depth is not a function of any particular form or material of construction of a lens, but is solely governed by the relation of effective aperture to focus. A common spectacle lens working at *f.* 16, for example, would within its area of sharp definition have as much depth as the dearest anastigmat ever produced. The rubbishy lens attached to the lowest grade of hand camera, with paper imitation leather covering, and working with an aperture of about *f.* 12, is equal in depth to its aristocratic anastigmatic neighbour, surrounded with all its glory of real morocco and silver fittings. Indeed, it might be more truly stated that the cheap lens has the most depth, seeing that it cannot be worked with a larger aperture than about *f.* 12, while *f.* 4 or *f.* 5 represents the rapidity of the other type at its quickest when depth is conspicuous by its absence. This rule holds good, whatever the type of lens employed—simple or compound, achromatic or non-achromatic, wide or narrow angle, with or without air lenses—made with Jenn glass or ordinary glass. If we could feel that what we have here written would have some effect in spreading the truth about depth, we should feel we had done real service; but so long as such advertisements, and others, as grossly misleading, like them, continue to be published the depth-of-focus fetish will still be worshipped.

AN Act of Vandalism: Works of Art at Guildhall Slashed about with a Knife.—Indignation was expressed at the Guildhall a few weeks ago owing to the treatment to which two pictures were subjected by an unknown person. One of them was deliberately cut with a knife, and the other was extensively damaged by, apparently, a man’s boot. A strict inquiry made at the time failed to discover the person who had done the damage. This week a third picture has been disgracefully slashed about with a knife. The men employed on the premises were closely questioned, and finally one of them confessed to having done the damage to the third picture, but could give no reason for his act. He has been in the employ of the Corporation for some time, and appears to have conducted himself well. The man has, of course, been suspended, and the City Lands Committee will consider what steps should be taken with regard to the matter, and, further, to discover, if possible, whether there is any connection between the present outrage and the two previous ones.

COPYING.

THE most useful type of all lenses for copying is the anastigmat, which term includes all the newer lenses, which, with a large aperture, possess a flat field. Of the older type of lenses, the old Ross portable symmetrical is one of the best, as it possesses an unusually flat field. As regards the focus of the lens, there is not much to be said, though personally I prefer to use one of as long a focus as possible, as the illumination at the corners is far better than with an extremely short focus lens; the only case in which a long focus is sometimes objectionable is when copying full size, when the necessary extension of camera bellows becomes sometimes too great.

It saves a lot of trouble, if one, before starting work, calculates out the conjugate foci for the lens that is going to be used. In every copy of the "British Journal Almanac" will be found the necessary table giving the conjugate foci for reduction, but it may not do any harm to give the well-known rule. Divide the longer side of the subject by the longer side of the desired reduction, and the result will be the times of reduction; to this add one and multiply by the focus of the lens; the result is the distance between the lens and subject. To find the lesser conjugate focus, or the necessary extension of camera, divide the greater conjugate focus by the times of reduction.

It may happen that only one camera is available, but if there is a choice one of the old-fashioned square bellows type, focussing at the back is to be preferred to the front focussing. In all cases the focussing screen should be ruled with parallel lines in both directions, and I have found it a great convenience to rule these lines at intervals of one inch, and mark also the half and quarter inches by short lines, and further, to commence the numbering of these lines from the centre of the focussing screen, so that if it is required to reduce the copy to a given size one can easily see the measure on the focussing screen.

Above all things, for really critical sharpness, it is highly desirable to cement two microscopic covering glasses to the ground glass, one at the centre, and the other in one corner of the screen. It is necessary to first mark the ground glass with a cross in lead pencil, and then, if the focussing magnifier is set so that this is in focus, one can be quite sure that the image is in focus on the plane of the ground glass. At the risk of telling an oft-told tale, the following is my method of cementing these glasses down:—The focussing screen is removed entirely from the back and warmed over gas or in the oven till hot, then a good-sized drop of Canada balsam is placed in position, the cover glass dropped on to it, and then gently pressed down with a wine cork; if the balsam does not spread to the edge of the cover glass the whole is put into the oven and heated still further and again pressed down. Any balsam exuded should be wiped off, when quite set, with a rag wetted with spirit.

The ideal process for the reproduction of black and white or line work is wet collodion, but equally good results can be obtained on dry plates, when you know how to do it. The only plate that is suitable for this class of work is the slow photo-mechanical plate. Sometimes it happens that for lecture purposes it is required to reduce a diagram to the regulation lantern size, then one can use any of the commercial lantern plates for black tones with equally good results as the photo-mechanical plate.

There are two distinct methods of working, the one to use as large a lens aperture as possible, and develop as long as possible without any deposit showing in the lines; the other to use a small aperture, a blue screen, and develop till extreme density is obtained, regardless of the lines, and then reduce

with Howard Farmer's reducer. Personally, I prefer the former method, and rarely fail to obtain full density with bare glass.

The best developer for this work is undoubtedly one suggested by Lumière, which is without alkali and bromide, and gives extreme density with correct exposure: the formula is:—

Hydroquinone	8 grains.
Sodium sulphite	80 grains.
Formaline	10 grains.
Distilled water to	1oz.

Should it happen that after fixing it is found that there is not quite enough density—and this only occurs with incorrect exposure—it is extremely easy to intensify, and for preference with the potassio-silver cyanide formula.

Pencil drawings sometimes give trouble by a deposit in the lines, though I have found it advantageous to disregard this whilst developing and then reduce. A few months back I believe that at the Photographic Club Mr. A. Mackie suggested placing a piece of fine ground glass over the pencil drawing and copying through this, as it made the pencilling photograph cleaner. This, however, I have not tried.

Blue or ferro-prussiate prints sometimes give a lot of trouble, and the best method of working I have found is to use a slow isochromatic plate and a yellow screen, this being sufficiently deep to make the blue print, when examined visually, look a deep dirty green.

Of all troublesome things to copy, miniatures, or other pictures from which one must not remove the convex glasses with which they are covered, are the worst. It seems that, light them how one will, there is sure to be a reflection. I have got over this trouble to a great extent by hanging tissue paper round the miniature; in fact, placing the same at the bottom of a tunnel of tissue paper; this softens the reflections a good deal. Of course the proper thing to use would be a Nicol prism, but these of reasonable size are not to be picked up every day.

For copying ordinary photographic prints a plate of medium rapidity should be used. Frequently faded prints are brought to be copied, and then we must have recourse to a blue screen. Very pale blue glass may be obtained, but it is easier to make a screen by staining a plate, as will be described hereafter, with methylene blue; only a very pale tint is wanted, and the depth of the screen can be easily varied if aniline dyes are used.

It is almost unnecessary to point out the necessity of insuring the even lighting of any subject to be copied. In a studio this is not difficult, but it is far more difficult in a private house, and it will frequently be found more advantageous to work out of doors. When we come to copy coloured objects, the question of the illuminant is far more important, and it may be considered as an axiom that the more brilliant the illumination the better will be the rendering of the colours, and therefore sunlight is to be chosen, if possible. For old masters, or those old paintings which have become mellowed by time into rich deep browns, sunlight is the only illuminant which will give a satisfactory rendering of the same, assuming, of course, that arc lamps are not to hand, as they usually are not in the majority of cases. For small pictures magnesium ribbon may be used, but for large and deep toned pictures the quantity required is considerable. For small pictures, whether in oil or water-colour, if of the modern schools, and thus brilliant in colouring, successful work may be done with two oil lamps or incandescent gas burners, placed one on each side of the picture, with a dark shade placed on that side of the lights next the camera. For such work I use the largest sheet of Bristol board folded in half, one side being left white to act as a reflector, the other being covered with black needle paper, so as not to reflect light into the lens. If lights are used in this way, whether oil, gas, or magnesium, they

must be placed one on each side of the picture, and as near as possible so as not to be included by the lens; if placed by the side of the lens, far more reflections are caused.

Of course one of the most important questions with regard to the copying of coloured subjects is the question of plates, and for the best rendering the so-called panchromatic plates are the best; these require rather careful handling in the dark room, as most of the ordinary dark room media will fog them.

Next to the plates comes the question of the screens for use with the same. Considerable diversity of opinion exists as to the best place for the screen, but if of optically worked glass it is not of much moment, nor is this important if very thin white patent plate be used, but focussing must be effected with the screen in position. A very convenient way of using the screen is in contact with the plate in the dark slide; if this is done, of course allowance must be made for this in focussing. It can also be placed in the camera back, and not in contact with the plate. If this plan is adopted the simplest way to prepare the screens is to use a useless negative, and remove the silver image by means of hypo and ferridcyanide. It is necessary, of course, to choose a negative on a piece of good glass.

If glass is to be coated with gelatine, a 10 per cent. solution should be made, and it is advisable to use a good emulsion gelatine, such as Heinrich's, Drescher's, or Stoess's; it is as well to add a little carbolic acid, xylol, or thymol to the solution to prevent it from spotting whilst drying. Fifteen minims should be allowed to each square inch, and the solution should be about 100deg. F. for coating. There is no difficulty in coating this quantity, proceeding just as with collodion. It is important to level the glasses for setting, and this can be readily done by placing on a larger slab, which has been levelled by three wedges. The gelatine coating must be allowed to dry completely before staining.

The stains to use may practically be considered as confined to the yellow aniline dyes, and brilliant yellow, uranine, naphthol yellow, auramine green, metanil yellow, acridine yellow, and possibly aurantia, may be chosen from; brilliant yellow will generally be sufficient for all ordinary work if a little erythrosine be obtained. It is immaterial what strength the solutions are, but 1 per cent. is convenient.

The main purpose of the screens is, as is well known, merely to cut the action of the blues, and therefore the deeper the colour of the yellow screen the longer we can expose without the blues being rendered too light. The solution of the dye should be filtered and used at a temperature of from 65deg. to 70deg. F., and the gelatinised glass should be placed in them, and air bubbles looked out for. It will be found that the depth of colouring will vary to some extent with the duration of soaking, but after about ten minutes there is no perceptible increase in tint, so that if a deeper yellow is required it will be advisable to use either two screens, or, what I prefer, to add to the yellow solution a few drops of erythrosine solution, which immediately deepens the colour, though too much must not be used, or the greens will be rendered to dark; this is the effect of orange. One method of working is to use a very deep red screen for, say, three-fourths of the exposure, and then to remove it and continue the exposure without it; but this is quite unnecessary with panchromatic plates, if a deep enough yellow or orange screen be used.

If it is required to cement two screens together, one may use either the thick Canada balsam or dilute it with benzole. Personally, I use ordinary Canada balsam, which has been baked for some time, so that it is quite thick, and then warm the screens well on a hot plate, and then apply the balsam, also warm, and then squeeze into contact. For large screens this is somewhat troublesome, but as long as they are well warmed and kept under pressure they will dry evenly without separating at the edges.

A. D. PRETZL.

ON THINGS IN GENERAL.

I have, at various periods of my life, come into close contact with many interesting persons and things, but in emulation of Oliver Twist I want more. It is too late to interview the Dodo, or the Great Auk, so that I dismiss them from my mind, with a lingering regret. I have talked with a King and a Queen, but I long to have a little conversation with a Shah or a Czar; I think I should prefer a Begum. My desires are not wholly in a regal or imperial direction, for I confess to a weakness in the direction of an expert pickpocket or a skilled burglar: it is evident such professionals do exist, though they do not usually exhibit a nameplate with their business qualifications on their door. In a photographic direction my longings are mainly confined to a being such as signs a letter "Justice"—Heaven save the mark—in this JOURNAL for Aug. 8th. "Justice"—there must be such a being, or the Editors would not have put the letter in—was willing to give a month—four whole weeks—of his valuable services for anyone who would find him a suitable occupation, and he found, or believed he had found, someone who, in return for twenty pounds, would teach him his business, give him thirty shillings a week, and "turn him out a good average hand." A bricklayer will make that much, perhaps, on an average, but I do not think the most enthusiastic workman would expect to learn bricklaying in a month, or even a year. Indeed, when a man has spent years in learning a business, he often enough expects to make his first essay as a paid workman as an improver. Why, in the name of all the commonsense deities (there ought to be, if there is not, a commonsense deity), should photography differ from any other business in this direction passes my weak intellect to discover. Even a seampstress, who is passing rich on fourteen shillings a week, would scarcely go to the length of proposing to teach a girl ignorant of the use of needle and thread how to become a good average hand in a month's time. Mr. Editor, does such a person as "Justice" really exist? Do try to let me have a good view of him some time; I will promise not to snapshot him for Madame Tussaud's use.

To turn from these unsatisfied longings to surroundings of more ordinary life, it is refreshing to experience the light-some touch of the writer who, over the signature of "Georges D'Armoric," plays with the connection between photography and palmistry. I am, however, not quite inclined to accept his dictum: "For, if the human hand may permit or give any reliable disclosure, it is only on condition that the lines, marks, and signs shown thereon, and not only therein, are read and considered subjunctively with the temperament, colour, and complexion, which in their synthetical sense are the key to the individuality, and a centre from which all other indications radiate." I would rather say, propounding the whole from the concrete rather than the abstract, thus viewing it from an objective, and not a subjective, standpoint. The question arises whether the indications are not concentric rather than radiatory, whereby and whereon the thesis is established, everything to the contrary notwithstanding—and if so, why not?

Bravo, J. W. Davidson, Consul! It is a long while since I read an "appreciation" to which I so fully gave in my adhesion as that Consul Davidson writes in the American Consular reports of that wonderful volume the BRITISH JOURNAL OF PHOTOGRAPHY ALMANAC. Interesting as is the reading matter—compact compendium of valuable original matter and condensed compilation of makers' and users' formulæ—the value of the ALMANAC as the practical man's *vade-mecum* and business directory is plainly and logically set forth. With regard to the latter part, the business and telegraphic address pages are

particularly useful. One is apt to forget for the moment the address or the telegraphic code of a firm one is writing to, and the ALMANAC tells us in a moment.

Early this month a querist asked about the use of liquid Indian ink, the Editors informing him that he might use it with safety for making marginal lines round prints in an album, without fear that it would in any way set off on other prints that might be brought into contact with it in closing the leaves. That is all right; but I should like to point out that there are liquid Indian inks and liquid Indian inks. A little while ago, having occasion to draw a series of diagrams, including many circles, I purchased a bottle of this liquid ink, with a first-class maker's name against it. After a while, I found my old dexterity with the use of mathematical instruments seemed deserting me. I could not make the compass pen to work—adjust the screw how I would, the circles were broken and imperfect. Several times this happened, and I could not diagnose the cause till it occurred to me to rub up a stick of ink—the work usually given to the youngest apprentice in an engineer's or an architect's office. This done, everything went on all right. So I would advise "E. B. P." not to put his trust in liquid inks, but to make fresh ink each time he desires to use it, monotonous and time-absorbing as it is.

I notice the publication of the Professional Photographers' Association's observations upon fire insurance policies. That the labours of the Committee have led to the offer of a particular company to take any insurer for twenty per cent. less than he now pays is a great step forward, for the rates that some photographers are charged are simply scandalous. Photography nowadays has not the accompanying risks of twenty or thirty years ago, with its collodion and guncotton, and varnish, alcohol, and ether. The risks are ever so much less, though the premiums in many instances remain unchanged. Photographers should know that in many offices nowadays premiums would be much lower if it were not for the negatives. In case of fire, so much damage could be very soon done by the water, not to speak of the bogus claims rendered easy for the unscrupulous, and such there are in every business or profession. It has been said that a fixed rate should be made for photographic studios and contents: but this is impossible, for several reasons. Before fixing the premium, regard must be had to the personality of the insurer, and this I can assure my readers is a very important factor. Then the question of position is important—whether the premises are detached, or abutting upon others, and whether in a sparsely or thickly built district. The proportion of value of negatives to general stock and the average value attached to them are governing factors in determining the rates to be fixed. Three shillings and sixpence per cent. all round is by no means an uncommon average rate. I may here remind my readers that they should always be careful in making alterations to get the insurance officials to examine them and endorse the policy, otherwise there is the possibility, in case of fire, of the office pleading the clause which causes the policy instantly to lapse if the insurer do anything to increase the fire risks. The introduction of the electric light is one of the things that the policy holder should ask to be examined by the insuring company's officer, as soon as the installation is completed, as he might decline to pass it if certain of their rules with regard to wiring, etc., were not carried out.

The professional photographers of the kingdom should take to heart the Editors' advice in the "We-do-the-rest" article of Aug. 15th. Amateur photography at the present time is a very

big thing, and the amateurs get through an immense quantity of material of one sort or another. Why is not this trade secured by the "pro."? I suppose because in time gone by the local chemist was the main source of supply, and still usually continues to be, though everything has changed in apparatus and materials. No doubt many photographers consider it beneath their dignity to take up the selling of materials, yet why should they, when some of their leading brethren in London and the country now publicly advertise that they have opened photographic goods depôts in connection with their businesses? Following upon this, of course, would come the we-do-the-rest part of the business, which is, indeed, profitable enough. The sooner the uninitiated start dealing the better: someone may begin before him, if he do not, and thus cut the ground from under his feet. The professional photographer is now the proper man to supply photographic goods, whatever may have been the case in the past. It need not compromise his dignity in the slightest degree—besides, "there is money in it," which cannot be truly said of many of the purely photographic businesses in the country.

Some years ago the breeding of a popular strain of dogs was one of my hobbies, and shortly after I had started it a friend said, "Well, I always looked upon you as an honest man; but now I give you up." Is there not a grave risk of a similar pronouncement being applied to those who take up photography, especially from an amateur's standpoint? With regard to the number of good negatives obtained from, say, a hundred plates on a given expedition, the man with the big maximum may be looked upon as an innocent bragger, akin to the chartered libertine of the storytellers, the fish story man. It is not silly boasting of this sort that will bring the amateur photographer into disrepute; it is the lamentably low standard of ethics that so many of them act by. For example, how many cases has not one heard of where one of this stamp goes to a professional photographer, and asks whether he may change his plates in his dark-room, simply to get an entry into a place where he may pick up wrinkles? This, however, is almost venial in comparison with the particular moral obliquity that has of late forced itself into notice. I refer to the would-be private pirate of other people's work. There is rarely a month passes, but there is to be seen a reply to some such query as that on copyright in Aug. 15th, and a somewhat similar one on 1st. In the former case the inquirer writes for "a friend," who has utilised another man's brains by conveying his picture into a pamphlet. He appears to have bodily conveyed the photograph, without any reference to the producer, and now only writes to the Editors to ask if he is safe; when he is experiencing a fear of being sued by the producer of the picture in question. His standard of morals is so low that he evidently would not scruple to rob the author of the fruits of his brain if he could do it with impunity. In the other case, the writer seems actually to be aggrieved because he cannot get to know whether a certain picture is copyright or not, and so he cannot copy it with a mind free from anxiety as to possible legal damages. There is still another case more flagrant than all. There are certain well-known photographic copies of paintings in the National Gallery, which anyone with the most elementary knowledge of photography must be aware could only be produced at the expenditure of considerable time and labour. Yet an inquirer has the presumption to write to the JOURNAL, to ask whether, as the paintings themselves are not copyright, he could not copy these copies? This utter meanness is absolutely appalling—rather than pay a few coppers for another print to the man (or his representative) who has taken such trouble to reproduce some of

the nation's pictorial treasures, this individual would, if he could, by what might be termed a legal quirk, save a penny or twopence by making a copy himself. I can scarcely believe it possible that it is his intention to produce these copies in number for sale. That would be such an example of moral turpitude that would at first sight appear impossible.

FREE LANCE.

THE OPTO-TECHNICAL SECTION OF THE NORTHAMPTON INSTITUTE, CLERKENWELL.

[Abstracted from the Annual Volume of Educational Announcements. The Principal, Dr. R. Mullineux Walmsley, informs us that the evening courses and classes in all technological subjects will commence on Monday next, September 22nd.—Eds. B.J.P.]

OPTICAL AND SCIENTIFIC INSTRUMENTS.

THE lectures in this course are intended for opticians and optical instrument makers who have already had a good training in elementary optical theory. Those who have not had such a training should attend the course on Applied Optics, either simultaneously or as a preliminary course, and only those will be admitted to this more advanced course who can satisfy the head of the department that they are qualified to profit by the instruction.

Laboratory and Calculations Classes, which are an essential part of the course, have been arranged, and all students will be expected to attend them. In addition, instrument makers should attend one evening per week in the workshop.

(a) Measuring Instruments (Four Lectures, from 22nd September to 13th October, 1902).—Measuring machines, dividing engines, and comparators, their construction and use; standards of length; cathetometers; chemical and physical balances, their construction and testing; chronographs for accurate time measurements; compensation for temperature.

(b) Mathematical and Surveying Instruments (Five Lectures, from 20th October to 17th November, 1902).—Simple compasses and miners' dials; prismatic compasses; levels and clinometers; theodolites and sextants; adjustment and testing of surveying instruments; collimation.

(c) Optical Projection Apparatus (Four Lectures, from 24th November to 15th December, 1902).—Construction and mechanical details of various types of optical lanterns; condensers and front lenses; formation of the image; effects of spherical and chromatic aberration and their elimination; projection microscopes. Sources of light; oil, acetylene, oxy-hydrogen, electric, etc.

(d) Telescopes, Opera and Field Glasses (Four Lectures, from 22nd December, 1902, to 26th January, 1903).—Optical principles of terrestrial and astronomical telescopes; use of concave and erecting eye-pieces; object glasses; testing qualities of glass, design and construction of object glasses; centring of lenses; Ramsden's and Huyghen's eye-pieces; micrometer eye-pieces, alt-azimuth and equatorial mountings; determination of the magnifying power of a telescope.

(e) Photographic Apparatus (Five Lectures, from 2nd February to 2nd March, 1903).—Construction of cameras and details of adjustments; single landscape lenses, their design and construction, use and calculation of stops; symmetrical, portrait, rectilinear, and anastigmatic lenses; calculation of lens curves; centring of lenses. Testing of photographic lenses, focal length and depth of focus, covering power, distortion, chromatism, astigmatism, flare spot, etc. Types of diaphragms. Waterhouse, Iris, etc. Construction and testing of time and instantaneous shutters. Telephotography.

(f) Microscopes and Objectives (Six Lectures, from 9th March to 20th April, 1903).—Theory of the compound microscope;

mechanical construction; English and Continental stands; rack-work and fine adjustments; simple and mechanical stages; sub-stage illuminators; construction and use of ordinary and sub-stage condensers, spot lenses, paraboloids, Lieberkuhms, etc.; binocular microscopes; camera lucida and other accessories; micrometers; objectives of low and high power; their design and construction; centring; correction collars; water and homogeneous immersion objectives; interference and diffraction, and their influence on the resolving power of a lens; Abbe's diffraction theory; testing objectives.

(g) Spectrometers and Polarising Apparatus (Three Lectures, from 27th April to 11th May, 1903).—Construction of chemical spectroscopes; spectrometers and goniometers; direct vision and diffraction spectroscopes; testing and adjustment of spectroscopes; tourmalines; Iceland spar, Nical prisms, selenites; construction of microscope and projection polarisopes, and polarimeters; construction and testing of spar, selenites, and other crystals; cutting and mounting specimens, etc.

THE DESIGN OF OPTICAL INSTRUMENTS.

Lecturer: DR. C. V. DRYSDALE.

This course will be open to students who have already satisfactorily passed through the courses in Applied Optics and Optical Instruments, and who have also a thorough working knowledge of algebra and trigonometry. An acquaintance with the elementary principles of the differential and integral calculus will be required later in the course and may be obtained by simultaneous attendance at the class in Advanced Calculations. Other students will be admitted if they can show evidence of preparedness to profit by the course.

TUESDAYS, 7.30 TO 8.30 P.M.

Syllabus.—Theory of Image Formation.—General conditions for colinear relationship between object and image, coaxial systems, conjugate points; classification of optical systems; optical nomenclature and definitions.

Optical Systems.—First Approximation.—Reflection and refraction at a single spherical surface; conjugate positions; optical centre, focal and symmetrical planes, magnification; absolute and reduced distances and curvatures.

Refraction by single thick lens; conjugate positions; magnification; principal focal and symmetrical planes; Listing's nodal points; position of Gauss points in special cases.

General theory of refracting and reflecting systems; determination of the position of the Gauss points in any system.

Chromatic Aberration.—Chromatic aberration of single thin lens; calculation of thin double and triple achromatic combinations; chromatic differences of focal length and magnification in lens systems; effects in optical instruments; apochromatic combinations.

The Five Aberrations.—Brief discussion of von-Seidel's theory; spherical aberration, coma, radial astigmatism, distortion and curvature of field; von-Seidel's and other expressions for the amount of these aberrations and conditions for removal; the sine law, anastigmatic flattening of chromatically corrected images, new achromats.

Path of Light through Refracting System.—Direct method of calculating the course of a ray through a system; application to photographic lenses and microscope objectives.

Aperture and Diffraction.—Definition of aperture effects on brightness of image; interference, calculation of width of bands, diffraction by slit, edge, etc.; diffraction patterns, cornu spiral, Babinet's principle; resolving power of grating; diffraction by circular aperture, limit of resolution of an optical system.

Telescope.—O.G.'s design of object glasses; double and triple combinations, compensation for chromatic and spherical aberration, and coma; mounting object glasses; effects of temperature, moisture, etc.; photo visual lenses.

Oculars.—Positive and negative forms, calculation of magnifying power; conditions for achromatism, etc.; erecting eye-pieces; erection by prisms; calculation of aperture of prismatic glasses; general design.

Photographic Lenses.—Design of simple achromatic and spherically compensated landscape lenses; use and position of stop; distortion, double objectives; principle of spherical correction of entrance and exit pupils; curvature of field condition for flattening, new achromats; anastigmats, Rudolph's principle; illustrations of modern lenses; convertible anastigmats and their design.

Microscope Objectives.—General principles of construction, short historical account of improvements; immersion objectives, aplanatic points of sphere, principle of Amico; resolving power dependence on aperture, Abbe's diffraction theory and recent developments; examples of modern objectives adjusting and testing.

OPTICAL WORKSHOP.

In conjunction with the course of lectures on Optical and Scientific Instruments, an optical workshop has been equipped for practical instruction in the construction of lenses for various purposes, and for giving students an opportunity of actually verifying the principles of lens design given in the lecture course. In optical matters, proof of the advantage of any special design of lens can only be obtained by actually constructing and testing it, and it is therefore hoped that all those who wish to become proficient in practical optics will attend this course. The instruction will be given by a trade glass worker, under the supervision of the Lecturer in Optics, and as soon as some degree of proficiency in lens working has been attained, the students will have opportunities of designing special forms of lenses, and of practically constructing and testing them. The workshop is already equipped with a number of lathes and tools for grinding spherical lenses of various curvatures, and arrangements are being made to instal special machines for lens grinding and polishing.

TUESDAYS, 7.30 TO 9.45 P.M.

Syllabus.—Roughing, turning, grinding, and polishing simple lenses for spectacles, etc.; centring, edging, and fitting spectacle lenses; grinding and polishing of plane and cylindrical lenses and prisms; determination of axes of cylinders and prisms, mounting of lenses.

Use and properties of the different kinds of crown, flint, and Jena glass; workshop tests of glass for uniformity and optical properties; construction of achromatic combinations, centring and cementing surfaces; making and gauging curves of grinding and polishing tools.

Composition and making of cements, polishing waxes, pitch tools, balsam, etc.; washing and grading emery; use of machinery in grinding and polishing plane, spherical, cylindrical, and sphero-cylindrical lenses.

Making the optical parts of various optical instruments, object glasses for telescopes, cameras, microscopes, etc.; positive and negative eye-pieces, micrometer eye-pieces, etc.

The workshop is primarily intended for those students who are simultaneously attending the lecture course, but if other applications are received from students who have had the necessary preliminary training, they will be favourably considered if there be room.

CLASSES IN TECHNICAL OPTICS.—APPLIED OPTICS.

The following course is intended as an introduction to the previous course on Optical Instruments, and should be taken as preparatory to that course by all students who have had no previous training in scientific optics. In conjunction with the course on Visual Optics, it also covers the requirements of the full examination of the Spectacle Makers' Company for the Freedom and Diploma of the Company. Candidates for this examination should take the elementary portion of this course, and also the specific portion of Course No. 5 relating to the instrument they select for special study.

In connection with the lectures there is a course of laboratory work on Tuesday evenings, which it is essential that all students should take up, as, without doing so, they cannot hope to make much progress. Students who have no previous mathematical training should also attend the class on Technical Calculations on Friday evenings.

MONDAYS, 7.30 TO 8.30 P.M.

Syllabus.—Nature of light, its velocity and mode of propagation; determination of velocity; formation of shadows; illumination and its laws; photometry and photometers; explanation of the reflection and refraction of light; reflection of plane waves at plane surfaces; theory of spherical waves and surfaces; measurement of curvature; use of the spherometer, dioptric system of measurement; reflection of plane and spherical waves at plane and curved surfaces; concave and convex mirrors; theory of conjugate foci.

Refraction and its laws, explanation by wave theory; refraction through parallel plates and prisms; definition and determination of the refractive index; determination of the angle and deviation of prisms, degree and dioptric measurement; refraction at spherical surfaces; use of lenses; conjugate foci; determination of the convergence and focal length of lenses; formation of images by lenses and magnification. Types of lenses:—Double, plane, and meniscus; convex and concave, spherical, cylindrical, and sphero-cylindrical lenses; determination of prismatic effects of lenses; axes of prisms and cylinders; optical centre; prismatic equivalent of a decentred lens.

Combinations of lenses in contact and separated; theory of thick lenses and systems of lenses; principal focal and symmetrical planes and nodal points; dispersion and achromatism, decomposition, and recomposition of light; index of dispersion, and its determination; spectrometry; achromatic prisms and lenses, and their forms; calculation of achromatic combinations; elementary theory of optical instruments, camera, telescope, microscope, etc.; spherical aberration and its effects; formation of focal lines; distortion; aplanatic surfaces and lenses and their calculation; focal surface and depth; interference of waves and its applications; production of interference bands by various methods; diffraction and its effects under various conditions; use of gratings.

Elementary theory of polarisation; production of polarised light by simple reflection and refraction; propagation of waves in crystalline media; ordinary and extraordinary refraction; behaviour of Iceland spar; optic and crystallographic axes; positive and negative, uniaxial and biaxial crystals; construction of Nicol's, Foucault's, and other prisms; interference of polarised light; formation of colours, rings, and brushes, etc.; polarising action of solutions and polarimetry; electro-magnetic theory of light; influence of magnets on polarised light, etc.

Throughout the course the practical applications of the subjects referred to will be specially kept in view, and the course is so arranged as to supply the theoretical knowledge required for the previous courses on optical instruments.

VISUAL OPTICS.

Lecturer: DR. E. CLAUDE TAYLOR, M.D., M.S.

In addition to the last-named course, those opticians who intend to present themselves at the examinations of the Spectacle Makers' Company should attend a course on Visual Optics, which will be given on Tuesday evenings at 7 p.m., and will continue throughout the session. The work of this course will be in accordance with the following official syllabus of the Spectacle Makers' Company:—

TUESDAYS, 7 TO 8 P.M.

Syllabus.—General anatomy of the human eye; the course of light passing through the media of the eye alone, and as modified by spherical and cylindrical lenses and prisms. Hypermetropia, myopia, astigmatism, presbyopia.

Instruments commonly used for determining the refraction of the eye; trial lenses, test types, astigmatic chart, the optometer. The principle of the ophthalmoscope; the principles of, and various forms of spectacles.

The whole of the practical work necessary for the examinations of the Spectacle Makers' Company will be given in this course, and in the Optical Laboratory in connection with course 75b.

WORKSHOP CLASSES FOR OPTICIANS.

Instructor: MR. R. J. GAGE.

The objects of this class are to give to opticians the necessary experience and manual dexterity to enable them to fit various lenses and alter and repair frames, and also to make up oculists' prescriptions and test the correctness of the work. Instruction will also be given in repairing simple optical instruments.

WEDNESDAYS, 7.30 TO 9.45 P.M.

Syllabus.—Centring, shanking, and edging simple spherical lenses.

Fitting lenses to frames.

Shaping bridges of frames to measurements and prescriptions.

Adjustment of temples.

Repair of steel and gold frames. Soldering, brazing, and electro-plating. Finishing and burnishing frames.

Fitting and adjustment of *pincers-nez*, including ordinary, cylindrical spring, and spring placquet glasses.

Fixing of unrimmed glasses.

Adjustment of cylindrical, prismatic, and bifocal glasses.

Treatment of pebble lenses. Testing axis of pebbles by pebble tester, etc.

Workshop testing of completed glasses.

Repair of opera and marine glasses. Balsaming and burnishing in lenses.

The complete course for opticians is as follows:—

Lectures on Applied Optics, Mondays, 7.30 to 8.30 p.m.; Optical Laboratory Work, Tuesdays, 8.30 to 9.45 p.m.; Visual Optics, Tuesdays, 7 to 8 p.m.; Optical Workshop, Wednesdays, 7.30 to 9.45 p.m.; Practical Calculations, Fridays, 8.30 to 9.45 p.m.

The following aniline colours are supplied by Messrs. Mawson and Swan, Mosley Street, Newcastle-on-Tyne, put up in small quantities, in corked phials, for the convenience of photographers:—Acridin, orange; alizarine, blue; aniline, blue; aniline, sulphate; auramine; aurantia; aurine; azo, blue; black (Diazo); chrysoidin; cœrulin, bisulphite; Congo, red; coralline, scarlet; coupier, blue; cyanin; cyanosin; diazo, black; echte rot (fast red); eosin; eosin, blue; eosin, yellow; erythrosin; fluorescein; fuschin; gentian, blue; gentian, violet; glycin, red; hæmatoxylin; Hoffman's violet; malachite, green; methylene, blue; methyl, green; methyl, orange; methyl, violet; nigrosin; orange I.; orange IV.; orange methyl; phenylene, blue; quinoline, red; red (Congo); red (glycin); fast red B.; "Echte Rot"; Rose of Alps; rose, Bengal; roseine; scarlet corallin; tartraisin; uranine; violet (gentian); violet (Hoffman); violet, methyl; yellow, acridin; yellow, brilliant; yellow, canary; yellow, eosin; yellow, Martini's; yellow, primrose.

THE BRITISH ASSOCIATION: ABSTRACT OF THE PRESIDENTIAL ADDRESS.

[Delivered at the Belfast Meeting on Wednesday, September 10th, 1902.]

I HAVE thought it might be instructive, and perhaps not uninteresting, to trace briefly in broad outline the development of that branch of study with which my own labours have been recently more intimately connected—a study which I trust I am not too partial in thinking is as full of philosophical interest as of experimental difficulty. The nature of heat and cold must have engaged thinking men from the very earliest dawn of speculation upon the external world; but it will suffice for the present purpose if, disregarding ancient philosophers and even medieval alchemists, we take up the subject where it stood after the great revival of learning, and as it was regarded by the father of the inductive method. That this was an especially attractive subject to Bacon is evident from the frequency with which he recurs to it in his different works, always with lamentation over the inadequacy of the means at disposal for obtaining a considerable degree of cold. Thus in the chapter in the *Natural History*, "*Sylva Sylvarum*," entitled "Experiments in consort touching the production of cold," he says, "The production of cold is a thing very worthy of the inquisition both for the use and the disclosure of causes. For heat and cold are nature's two hands whereby she chiefly worketh, and heat we have in readiness in respect of the fire, but for cold we must stay till it cometh or seek it in deep caves or high mountains, and when all is done we cannot obtain it in any great degree, for furnaces of fire are far hotter than a summer sun, but vaults and hills are not much colder than a winter's frost." The great Robert Boyle was the first experimentalist who followed up Bacon's suggestions. In 1682 Boyle read a paper to the Royal Society on "New Experiments and Observations touching Cold, or an Experimental History of Cold," published two years later in a separate work. This is really a most complete history of everything known about cold up to that date, but its great merit is the inclusion of numerous experiments made by Boyle himself on frigorific mixtures, and the general effects of such upon matter. The whole elaborate investigation cost Boyle immense labour, and he confesses that he "never handled any part of natural philosophy that was so troublesome and full of hardships." After the masterly essay of Boyle, the attention of investigators was chiefly directed to improving thermometrical instruments. The old air thermometer of Galileo being inconvenient to use, the introduction of fluid thermometers greatly aided the inquiry into the action of heat and cold. For a time great difficulty was encountered in selecting proper fixed points on the scales of such instruments, and this stimulated men like Huygens, Newton, Hooke, and Amontons to suggest remedies and to conduct experiments. It must be confessed that great confusion and inaccuracy in temperature observations arose from the variety and crudeness of the instruments. This led Amontons in 1702-3 to contribute two papers to the French Academy which reveal great originality in the handling of the subject, and which, strange to say, are not generally known. The first discourse deals with some new properties of the air and the means of accurately ascertaining the temperature in any climate. He regarded heat as due to a movement of the particles of bodies, though he did not in any way specify the nature of the motion involved; and as the general cause of all terrestrial motion, so that in its absence the earth would be without movement in its smallest parts. In the following year Amontons contributed to the academy a further paper extending the scope of the inquiry. He there pointed out more explicitly that as the degrees of heat in his thermometer are registered by the height of a column of mercury, which the heat is able to sustain by the spring of the air, it follows that the extreme cold of the thermometer will be that which reduces the air to have no power of spring. This, he says, will be a much greater cold than what we call "ver-cold," because experiments have shown that if the spring of the air at boiling-point is 73in., the degree of heat which remains in the air when brought to the freezing-point of water is still very great, for it can still maintain the spring of 51½in. The greatest climatic cold on the scale of units adopted by Amontons is marked 50, and the greatest summer heat 58, the value for boiling water being 73, and the zero being 52 units below the freezing point. Thus Amontons was the first to recognise that the use of air as a thermometer substance led to the inference of the existence of a zero of temperature, and his scale is nothing else than the absolute one we are now so familiar with. It results from Amontons's experiments that the air would have no spring left if it were cooled below the freezing-point of water to about 2½ times the temperature range which separates the boiling-point and the freezing-point. In other words, if we adopt the usual centennial difference between these two points of temperature as 100 degrees, then the zero of Amontons's air thermometer is *minus* 240 degrees. This is a remarkable approximation to our modern value for the same point of *minus* 273 degrees. It is not till Lambert, in his work on "Pyrometrie," published in 1773, repeated Amontons's experiments and endorsed his results that we find any further reference to the absolute scale or the zero of temperature. Lambert's observations were made with the greatest care and refinement, and resulted in correcting the value of the zero of the air scale to *minus*

70 degrees as compared with Amontons's *minus* 240 degrees. Lambert points out that the degree of temperature which is equal to zero is what one may call absolute cold, and that at this temperature the volume of the air would be practically nothing. In other words, the particles of the air would fall together and touch each other and become dense like water; and from this it may be inferred that the gaseous condition is caused by heat. Lambert says that Amontons's discoveries had found few adherents because they were too beautiful and advanced for the time in which he lived. About this time a remarkable observation was made by Professor Braun at Moscow, who, during the severe winter of 1759, succeeded in freezing mercury by the use of a mixture of snow and nitric acid. When we remember that mercury was regarded as quite a peculiar substance possessed of the essential quality of fluidity, we can easily understand the universal interest created by the experiment of Braun. This was accentuated by the observations he made on the temperature given by the mercury thermometer, which appeared to record a temperature as low as *minus* 200deg. C. The experiments were soon repeated by Hutchins at Hudson's Bay, who conducted his work with the aid of suggestions given him by Cavendish and Black. The result of the new observations was to show that the freezing-point of mercury is only *minus* 40deg. C., the errors in former experiments having been due to the great contraction of the mercury in the thermometer in passing into the solid state. From this it followed that the enormous natural and artificial colds which had generally been believed in had no proved existence. Still the possible existence of a zero of temperature very different from that deduced from gas thermometry had the support of such distinguished names as those of Laplace and Lavoisier. In their great memoir on "Heat," after making what they consider reasonable hypotheses as to the relation between specific heat and total heat, they calculate values for the zero which range from 1,500deg. to 3,000deg. below melting ice. On the whole, they regard the absolute zero as being in any case 600deg. below the freezing-point. Lavoisier, in his "Elements of Chemistry," published in 1792, goes further in the direction of indefinitely lowering the zero of temperature when he says, "We are still very far from being able to produce the degree of absolute cold, or total deprivation of heat, being unacquainted with any degree of coldness which we cannot suppose capable of still further augmentation; hence it follows we are incapable of causing the ultimate particles of bodies to approach each other as near as possible, and thus these particles do not touch each other in any state hitherto known." Even as late as the beginning of the 19th century we find Dalton, in his new system of "Chemical Philosophy," giving ten calculations of this value, and adopting finally as the natural zero of temperature *minus* 3,000deg. C. In Black's lectures we find that he takes a very cautious view with regard to the zero of temperature, but, as usual, is admirably clear with regard to its exposition. It is interesting to observe, however, that Black was evidently well acquainted with the work of Amontons, and strongly supports his inference as to the nature of air. The views that Black attributes to Amontons have been generally associated with the name of Lavoisier, who practically admitted similar possibilities as to the nature of air; but it is not likely that in such matters Black would commit any mistake as to the real author of a particular idea, especially in his own department of knowledge. Black's own special contribution to low-temperature studies was his explanation of the interaction of mixtures of ice with salts and acids by applying the doctrine of the latent heat of fluidity of ice to account for the frigorific effect. In a similar way Black explained the origin of the cold produced in Cullen's remarkable experiment of the evaporation of ether under the receiver of an air-pump by pointing out that the latent heat of vaporisation in this case necessitated such a result. Thus, by applying his own discoveries of latent heat, Black gave an intelligent explanation of the cause of all the low-temperature phenomena known in his day. After the gaseous laws had been definitely formulated by Gay-Lussac and Dalton, the question of the absolute zero of temperature, as deduced from the properties of gases, was revived by Clement and Desormes. These distinguished investigators presented a paper on the subject to the French Academy in 1812, which, it appears, was rejected by that body. The authors subsequently elected to publish it in 1819. Relying on what we know now to have been a faulty hypothesis, they deduced from observations on the heating of air rushing into a vacuum the temperature of *minus* 267deg. as that of the absolute zero. The whole question took an entirely new form when Lord Kelvin, in 1848, after the mechanical equivalent of heat had been determined by Joule, drew attention to the great principles underlying Carnot's work on the "Motive Power of Heat," and applied them to an absolute method of temperature measurement, which is completely independent of the properties of any particular substance. The principle was that for a difference of 1deg. on this scale, between the temperatures of the source and refrigerator, a perfect engine should give the same amount of work in every part of the scale. Taking the same fixed points as for the centigrade scale, and making 100 of the new degrees cover that range, it was found that the degrees, not only within that range, but as far beyond as experimental data supplied the means of comparison, differed by only

minute quantities from those of Regnault's air thermometer. The zero of the new scale had to be determined by the consideration that when the refrigerator was at the zero of temperature the perfect engine should give an amount of work equal to the full mechanical equivalent of the heat taken up. This led to a zero of 273deg. below the temperature of freezing water substantially the same as that deduced from a study of the gaseous state. It was a great advance to demonstrate by the application of the laws of thermodynamics not only that the zero of temperature is a reality, but that it must be located at 273deg. below the freezing-point of water. As no one has attempted to impugn the solid foundation of theory and experiment on which Lord Kelvin based his thermodynamic scale, the existence of a definite zero of temperature must be acknowledged as a fundamental scientific fact.

LIQUEFACTION OF GASES AND CONTINUITY OF STATE.

In these speculations, however, chemists were dealing theoretically with temperatures to which they could not make any but the most distant experimental approach. Cullen, the teacher of Black, had indeed shown how to lower temperature by the evaporation of volatile bodies, such as ether, by the aid of the air-pump, and the later experiments of Leslie and Wollaston extended the same principle. Davy and Faraday made the most of the means at command in liquefying the more condensable gases, while at the same time Davy pointed out that they in turn might be utilised to procure greater cold by their rapid reversion into the aeriform state. Still the chemist was sorely hampered by the want of some powerful and accessible agent for the production of temperatures much lower than had ever been attained. That want was supplied by Thilorier, who in 1835 produced liquid carbonic acid in large quantities, and further made the fortunate discovery that the liquid could be frozen into a snow by its own evaporation. Faraday was prompt to take advantage of this new and potent agent. Under exhaustion he lowered his boiling-point from *minus* 78deg. C. to *minus* 110deg. C., and by combining this low temperature with pressure all the gases were liquefied by the year 1844, with the exception of the three elementary gases—hydrogen, nitrogen, and oxygen, and three compound gases—carbonate oxide, marsh gas, and nitric oxide; Andrews some 25 years after the work of Faraday attempted to induce change of state in the uncondensed gases by using much higher pressure than Faraday employed. A very important series of experiments was made by Joule and Kelvin "On the Thermal Effects of Fluids in Motion," about 1862, in which the thermometrical effects of passing gases under compression through porous plugs furnished important data for the study of the mutual action of the gas molecules. No one, however, had attempted to make a complete study of a liquefiable gas throughout wide ranges of temperature. This was accomplished by Andrews in 1869, and his Bakerian Lecture "On the Continuity of the Gaseous and Liquid States of Matter" will always be regarded as an epoch-making investigation. During the course of this research Andrews observed that liquid carbonic acid raised to a temperature of 31deg. C. lost the sharp concave surface of demarcation between the liquid and the gas, the space being now occupied by a homogeneous fluid which exhibited, when the pressure was suddenly diminished or the temperature slightly lowered, a peculiar appearance of moving or flickering striæ, due to great local alterations of density. At temperatures above 31deg. C. the separation into two distinct kinds of matter could not be effected even when the pressure reached 400 atmospheres. This limiting temperature of the change of state from gas to liquid Andrews called the critical temperature. He showed that this temperature is constant, and differs with each substance, and that it is always associated with a definite pressure peculiar to each body. Thus the two constants, critical temperature and pressure, which have been of the greatest importance in subsequent investigations, came to be defined, and a complete experimental proof was given that "the gaseous and liquid states are only distinct stages of the same condition of matter and are capable of passing into one another by a process of continuous change." In 1873 an essay "On the Continuity of the Gaseous and Liquid State," full of new and suggestive ideas, was published by van der Waals, who, recognising the value of Clausius' new conception of the Virial in Dynamics, for a long-continued series of motions, either oscillatory or changing exceedingly slowly with time, applied it to the consideration of the molecular movements of the particles of the gaseous substance, and after much refined investigation, and the fullest experimental calculation available at the time, devised his well-known Equation of Continuity. Its paramount merit is that it is based entirely on a mechanical foundation, and is in no sense empiric; we may therefore look upon it as having a secure foundation in fact, but as being capable of extension and improvement. James Thomson, realising that the straight-line breach of continuous curvature in the Andrews isothermals was untenable to the physical mind, propounded his emendation of the Andrews curves—namely, that they were continuous and of S form. We also owe to James Thomson the conception and execution of a three-dimensional model of Andrews results, which has been of the greatest service in exhibiting the three variables by means of a specific surface afterwards greatly extended and developed by Professor Willard Gibbs. The equation of continuity

developed by van der Waals involved the use of three constants instead of one, as in the old law of Boyle and Charles, the latter being only utilised to express the relation of temperature, pressure, and volume, when the gas is far removed from its point of liquefaction. Of the two new constants one represents the molecular pressure arising from the attraction between the molecules, the other four times the volume of the molecules. Given these constants of a gas, van der Waals showed that his equation not only fitted into the general characters of the isothermals, but also gave the values of the critical temperature, the critical pressure, and the critical volume. In the case of carbonic gas the theoretical results were found to be in remarkable agreement with the experimental values of Andrews. This gave chemists the means of ascertaining the critical constants, provided sufficiently accurate data derived from the study of a few properly distributed isothermals of the gaseous substance were available. Such important data came into the possession of chemists when Amagat published his valuable paper on "The Isothermals of Hydrogen, Nitrogen, Oxygen, Ethylene, etc.," in the year 1880. It now became possible to calculate the critical data with comparative accuracy for the so-called permanent gases oxygen and nitrogen, and this was done by Sarrau in 1882. In the meantime a great impulse had been given to a further attack upon the so-called permanent gases by the suggestive experiments made by Pictet and Cailletet. The static liquefaction of oxygen was effected by Wroblewski in 1883, and thereby the theoretical conclusions derived from van der Waals equation were substantially confirmed. The liquefaction of oxygen and air was achieved through the use of liquid ethylene as a cooling agent, which enabled a temperature of *minus* 140 degrees to be maintained by its steady evaporation *in vacuo*. From this time liquid oxygen and air came to be regarded as the potential cooling agents for future research, commanding, as they did, a temperature of 200 degrees below melting ice. The theoretical side of the question received at the hands of van der Waals a second contribution, which was even more important than his original essay, and that was his novel and ingenious development of what he calls "The Theory of Corresponding States." He defined the corresponding states of two substances as those in which the ratios of the temperature, pressure, and volume to the critical temperature, pressure, and volume respectively were the same for the two substances, and in corresponding states he showed that the three pairs of ratios all coincided. From this a series of remarkable propositions were developed, some new, some proving previous laws that were hitherto only empiric, and some completing and correcting faulty though approximate laws. The most suggestive advance in the improvement of the van der Waals equation has been made by a lady, Mme. Christine Meyer. The idea at the base of this new development may be understood from the following general statement:—Van der Waals brings the van der Waals surfaces for all substances into coincidence at the point where volume, pressure, and temperature are nothing, and then stretches or compresses all the surfaces parallel to the three axes of volume, pressure, and temperature, until their critical points coincide. But on this plan the surfaces do not quite coincide, because the points where the three variables are respectively nothing are not corresponding points. Mme. Meyer's plan is to bring all the critical points first into coincidence, and then to compress or extend all the representative surfaces parallel to the three axes of volume, pressure, and temperature, until the surfaces coincide. In this way, taking 29 different substances, she completely verifies from experiment van der Waal's law of correspondence. The theory of van der Waals has been one of the greatest importance in directing experimental investigation, and in attacking the difficult problems of the liquefaction of the most permanent gases. It is perhaps not too much to say that as a prolific source of knowledge in the department dealing with the continuity of state in matter, it would be necessary to go back to Carnot's cycle to find a proposition of greater importance than the theory of van der Waals and his development of the law of corresponding states. It will be apparent from what has just been said that, thanks to the labours of Andrews, van der Waals, and others, theory had again far outrun experiment. We could calculate the constants and predict some of the simple physical characteristics of liquid oxygen, hydrogen, or nitrogen, with a high degree of confidence long before any one of the three had been obtained in the static liquid condition permitting of the experimental verification of the theory. This was the more tantalising, because, with whatever confidence the chemist may anticipate the substantial corroboration of his theory, he also anticipates with almost equal conviction that, as he approaches more and more nearly to the zero of absolute temperature, he will encounter phenomena compelling modification, revision, and refinement of formulas which fairly covered the facts previously known. Just as nearly seventy years ago chemists were waiting for some means of getting a temperature of 100deg. below melting ice, so ten years ago they were casting about for the means of going 100deg. lower still. The problem was not so much how to produce intense cold as how to save it when produced from being immediately levelled up by the relatively superheated surroundings. It was while puzzling over this mechanical and manipulative difficulty in 1892 that it occurred to me that the principle of an arrangement used nearly twenty years before in some calorimetric experiments, which

was based upon the work of DaLong and Petit on radiation, might be employed with advantage as well to protect cold substances from heat as hot ones from rapid cooling. I therefore tried the effect of keeping liquefied gases in vessels having a double wall, the annular space between being very highly exhausted. Experiments showed that liquid air evaporated at only one-fifth of the rate prevailing when it was placed in a similar unexhausted vessel, owing to the convective transference of heat by the gas particles being enormously reduced by the high vacuum. But, in addition, these vessels lend themselves to an arrangement by which radiant heat can also be cut off. It was found that when the inner walls were coated with a bright deposit of silver the influx of heat was diminished to one-sixth the amount entering without the metallic coating. The total effect of the high vacuum and the silvering is to reduce the ingoing heat to about 3 per cent. The efficiency of such vessels depends upon getting as high a vacuum as possible, and cold is one of the best means of effecting the desired exhaustion. All that is necessary is to fill completely the space that has to be exhausted with an easily condensable vapour, and then to freeze it out in a receptacle attached to the primary vessel that can be sealed off. The advantage of this method is that no air-pump is required, and that theoretically there is no limit to the degree of exhaustion that can be obtained. The action is rapid, provided liquid air is the cooling agent, and vapours like mercury, water, or benzol are employed. It is obvious that when we have to deal with such an exceptionally volatile liquid as hydrogen, the vapour filling may be omitted, because air itself is now an easily condensable vapour. In other words, liquid hydrogen, collected in such vessels with the annular space full of air, immediately solidifies the air, and thereby surrounds itself with a high vacuum. Many combinations of vacuum vessels can be arranged, and the lower the temperature at which we have to operate the more useful they become. Vessels of this kind are now in general use, and in them liquid air has crossed the American continent. Of the various forms, that variety is of special importance which has a spiral tube joining the bottom part of the walls, so that any liquid gas may be drawn off from the interior of such a vessel. In the working of regenerative coils such a device becomes all-important, and such special vessels cannot be dispensed with for the liquefaction of hydrogen. In the early experiments of Pictet and Cailletet, cooling was produced by the sudden expansion of the highly compressed gas preferably at a low temperature. Linde saw that the continuous use of a jet of highly compressed gas, combined with regenerative cooling, must lead to liquefaction on account of what is called the Kelvin-Joule effect; and he succeeded in making a machine, based on this principle, capable of producing liquid air for industrial purposes. These experimenters had proved that, owing to molecular attraction, compressed gases passing through a porous plug or small aperture were lowered in temperature by an amount depending on the difference of pressure and inversely as the square of the absolute temperature. This means that for a steady difference of pressure the cooling is greater, the lower the temperature. The only gas that did not show cooling under such conditions was hydrogen. Instead of being cooled it became actually hotter. The reason for this apparent anomaly in the Kelvin-Joule effect is that every gas has a thermometric point of inversion above which it is heated and below which it is cooled. This inversion point, according to van der Waals, is six and three-quarter times the critical point. The efficiency of the Linde process depends on working with highly compressed gas well below the inversion temperature, and in this respect this point may be said to take the place of the critical one, when in the ordinary way direct liquefaction is being effected by the use of specific liquid cooling agents. The success of both processes depends upon working within a certain temperature range, only the Linde method gives us a much wider range of temperature within which liquefaction can be effected. This is not the case if, instead of depending on getting cooling by the internal work done by the attraction of the gas molecules, we force the compressed gas to do external work as in the well-known air machines of Kirk and Coleman. Both these inventors have pointed out that there is no limit of temperature, short of liquefaction of the gas in use in the circuit, that such machines are not capable of giving. While it is theoretically clear that such machines ought to be capable of maintaining the lowest temperatures, and that with the least expenditure of power, it is a very different matter to overcome the practical difficulties of working such machines under the conditions. Coleman kept a machine delivering air at *minus* 83deg. for hours, but he did not carry his experiments any further. Recently, M. Claude, of Paris, has, however, succeeded in working a machine of this type so efficiently that he has managed to produce one litre of liquid air per horse power expended per hour in the running of the engine. This output is twice as good as that given by the Linde machine, and there is no reason to doubt that the yield will be still further improved. It is clear, therefore, that in the immediate future the production of liquid air and hydrogen will be effected most economically by the use of machines producing cold by the expenditure of mechanical work.

LIQUID HYDROGEN.

Hydrogen is an element of especial interest, because the study of

its properties and chemical relations led great chemists like Faraday, Dumas, Daniell, Graham, and Andrews to entertain the view that if it could ever be brought into the state of liquid or solid it would reveal metallic characters. The only chemist who adopted another view was my distinguished predecessor, Professor Odling. In his "Manual of Chemistry," published in 1861, he pointed out that hydrogen has chlorous as well as basic relations, and that they are as decided, important, and frequent as its other relations. From such considerations he arrived at the conclusion that hydrogen is essentially a neutral or intermediate body, and therefore we should not expect to find liquid or solid hydrogen possess the appearance of a metal. This extraordinary prevision, so characteristic of Odling, was proved to be correct some 37 years after it was made. Another curious anticipation was made by Dumas in a letter addressed to Pictet, in which he says that the metal analogous to hydrogen is magnesium, and that probably both elements have the same atomic volume, so that the density of hydrogen, for this reason, would be about the value elicited by subsequent experiments. Later on, in 1872, when Newlands began to arrange the elements in periodic groups, he regarded hydrogen as the lowest member of the chlorine family; but Mendeleef in his later classification placed hydrogen in the group of the alkaline metals; on the other hand, Dr. Johnstone Stoney classes hydrogen with the alkaline earth metals and magnesium. From this speculative divergency it is clear no definite conclusion could be reached regarding the physical properties of liquid or solid hydrogen, and the only way to arrive at the truth was to prosecute low temperature research until success attended the efforts to produce its liquefaction. This result I definitely obtained in 1898. The case of liquid hydrogen is, in fact, an excellent illustration of the truth already referred to, that no theoretical forecast, however apparently justified by analogy, can be finally accepted as true until confirmed by actual experiment. Liquid hydrogen is a colourless transparent body of extraordinary intrinsic interest. It has a clearly defined surface, is easily seen, drops well, in spite of the fact that its surface tension is only the 35th part of that of water, or about one-fifth that of liquid air, and can be poured easily from vessel to vessel. The liquid does not conduct electricity, and, if anything, is slightly diamagnetic. Compared with an equal volume of liquid air, it requires only one-fifth the quantity of heat for vaporization; on the other hand, its specific heat is ten times that of liquid air or five times that of water. The coefficient of expansion of the fluid is remarkable, being about ten times that of gas; it is by far the lightest liquid known to exist, its density being only one-fourteenth that of water; the lightest liquid previously known was liquid marsh gas, which is six times heavier. The only solid which has so small density as to float upon its surface is a piece of pith wood. It is by far the coldest liquid known. At ordinary atmospheric pressure it boils at minus 252.5deg., or 20.5deg. absolute. The critical point of the liquid is about 29deg. absolute, and the critical pressure not more than 15 atmospheres. The vapour of the hydrogen arising from the liquid has nearly the density of air—that is, it is 14 times that of the gas at the ordinary temperature. Reduction of the pressure by an air-pump brings down the temperature to minus 258deg., when the liquid becomes a solid resembling frozen foam, and this by further exhaustion is cooled to minus 260deg., or 13deg. absolute, which is the lowest steady temperature that has been reached. The solid may also be got in the form of a clear transparent ice, melting at about 15deg. absolute, under a pressure of 55mm., possessing the unique density of one-eleventh that of water. Such cold involves the solidification of every gaseous substance but one that is at present definitely known to the chemist, and so liquid hydrogen introduces the investigator to a world of solid bodies.

THE ABSOLUTE ZERO.

By the evaporation of solid hydrogen under the air pump we can reach within 13deg. or 14deg. of the zero, but there or thereabouts our progress is barred. This gap of 13deg. might seem at first sight insignificant in comparison with the hundreds that have already been conquered. But to win one degree low down the scale is quite a different matter from doing so at higher temperatures; in fact, to annihilate these few remaining degrees would be a far greater achievement than any so far accomplished in low-temperature research. For the difficulty is two-fold, having to do partly with process and partly with material. The application of the methods used in the liquefaction of gases becomes continually harder and more troublesome as the working temperature is reduced; thus, to pass from liquid air to liquid hydrogen—a difference of 60deg.—is, from a thermodynamic point of view, as difficult as to bridge the gap of 150deg. that separates liquid chlorine and liquid air. By the use of a new liquid gas exceeding hydrogen in volatility to the same extent as hydrogen does nitrogen, the investigator might get to within 5deg. of the zero; but even a second hypothetical substance, again exceeding the first one in volatility to an equal extent, would not suffice to bring him quite to the point of his ambition. That the zero will ever be reached by man is extremely improbable. A thermometer introduced into regions outside the uttermost confines of the earth's atmosphere

might approach the absolute zero, provided that its parts were highly transparent to all kinds of radiation, otherwise it would be affected by the radiation of the sun, and would therefore become heated. But supposing all difficulties to be overcome, and the experimenter to be able to reach within a few degrees of the zero, it is by no means certain that he would find the near approach of the death of matter sometimes pictured. Any forecast of the phenomena that would be seen must be based on the assumption that there is continuity between the processes studied at attainable temperatures and those which take place at still lower ones. Is such an assumption justified? It is true that many changes in the properties of substances have been found to vary steadily with the degree of cold to which they are exposed. But it would be rash to take for granted that the changes which have been traced in explored regions continue to the same extent and in the same direction in those which are as yet unexplored. Of such a breakdown low-temperature research has already yielded a direct proof at least in one case. A series of experiments with pure metals showed that their electrical resistance gradually decreases as they are cooled to lower and lower temperatures, in such ratio that it appeared probable that at the zero of absolute temperature they would have no resistance at all and would become perfect conductors of electricity. But with the advent of the more powerful refrigerant liquid hydrogen it became necessary to revise that conclusion. A discrepancy was first observed when a platinum resistance thermometer was used to ascertain the temperature of that liquid boiling under atmospheric and reduced pressure. All known liquids, when forced to evaporate quickly by being placed in the exhausted receiver of an air-pump, undergo a reduction in temperature, but when hydrogen was treated in this way it appeared to be an exception. The resistance thermometer showed no such reduction as was expected, and it became a question whether it was the hydrogen or the thermometer that was behaving abnormally. Ultimately, by the adoption of other thermometrical appliances, the temperature of the hydrogen was proved to be lowered by exhaustion as theory indicated. Hence it was the platinum thermometer which had broken down; in other words, the electrical resistance of the metal employed in its construction was not, at temperatures about minus 250deg. C., decreased by cold in the same proportion as at temperatures about minus 200deg. This being the case, there is no longer any reason to suppose that at the absolute zero platinum would become a perfect conductor of electricity; and in view of the similarity between the behaviour of platinum and that of other pure metals in respect of temperature and conductivity, the presumption is that the same is true of them also. At any rate, the knowledge that in the case of at least one property of matter we have succeeded in attaining a depth of cold sufficient to bring about unexpected change in the law expressing the variation of that property with temperature, is sufficient to show the necessity for extreme caution in extending our inferences regarding the properties of matter near the zero of temperature. A theoretical investigation on the relaxation of "electrons" and atoms has led him to suggest a hypothetical metal having the following remarkable properties—below 1deg. absolute it is a perfect insulator of electricity, at 2deg. it shows noticeable conductivity, and at 6deg. it possesses high conductivity. It may safely be predicted that liquid hydrogen will be the means by which many obscure problems of physics and chemistry will ultimately be solved, so that the liquefaction of the last of the old permanent gases is as pregnant now with future consequences of great scientific moment as was the liquefaction of chlorine in the early years of the last century. The next step towards the absolute zero is to find another gas more volatile than hydrogen, and that we possess in the gas occurring in cleveite, identified by Ramsay as helium, a gas which is widely distributed, like hydrogen, in the sun, stars, and nebulae. A specimen of this gas was subjected by Olszewski to liquid air temperatures, combined with compression and subsequent expansion, following the Cailletet method, and resulted in his being unable to discover any appearance of liquefaction, even in the form of mist. His experiments led him to infer that the boiling-point of the substance is probably below 9deg. absolute. After Lord Rayleigh had found a new source of helium in the gases which are derived from the Bath springs, and liquid hydrogen became available as a cooling-agent, a specimen of helium cooled in liquid hydrogen showed the formation of fluid, but this turned out to be owing to the presence of an unknown admixture of other gases. As a matter of fact, a year before the date of this experiment I had recorded indications of the presence of unknown gases in the spectrum of helium derived from this source. When subsequently such condensable constituents were removed, the purified helium showed no signs of liquefaction, even when compressed to 80 atmospheres, while the tube containing it was surrounded with solid hydrogen. Further, on suddenly expanding, no instantaneous mist appeared. Thus helium was definitely proved to be a much more volatile substance than hydrogen in either the liquid or solid condition. The inference to be drawn from the adiabatic expansion effected under the circumstances is that helium must have touched a temperature of from 9deg. to 10deg. for a short time without showing any signs of liquefaction, and consequently that the

critical point must be still lower. This would force us to anticipate that the boiling-point of the liquid will be about 5deg. absolute, or liquid helium will be four times more volatile than liquid hydrogen, just as liquid hydrogen is four times more volatile than liquid air. Provided the critical point is not below 8deg. absolute, then, from the knowledge of the conditions that are successful in producing a change of state in hydrogen through the use of liquid air, we may safely predict that helium can be liquefied by following similar methods. If, however, the critical point is as low as 6deg. absolute, then it would be almost hopeless to anticipate success by adopting the process that works so well with hydrogen. The present anticipation is that the gas will succumb after being subjected to this process, only, instead of liquid air under exhaustion being used as the primary cooling agent, liquid hydrogen evaporating under similar circumstances must be employed. In this case the resulting liquid would require to be collected in a vacuum vessel, the outer walls of which are immersed in liquid hydrogen. The practical difficulties and the cost of the operation will be very great; but, on the other hand, the descent to a temperature within 5deg. of the zero would open out new vistas of scientific inquiry, which would add immensely to our knowledge of the properties of matter. To command in our laboratories a temperature which would be equivalent to that which a comet might reach at an infinite distance from the sun would, indeed, be a great triumph for science. If the present Royal Institution attack on helium should fail, then we must ultimately succeed by adopting a process based on the mechanical production of cold through the performance of external work. When a turbine can be worked by compressed helium, the whole of the mechanism and circuits being kept surrounded with liquid hydrogen, then we need hardly doubt that the liquefaction will be effected. In all probability gases other than helium will be discovered of greater volatility than hydrogen. It was at the British Association meeting in 1896 that I made the first suggestion of the probable existence of an unknown element which would be found to fill up the gap between argon and helium, and this anticipation was soon taken up by others and ultimately confirmed. Later, in the Bakerian lecture for 1901, I was led to infer that another member of the helium group might exist, having the atomic weight about 2, and this would give us a gas still more volatile, with which the absolute zero might be still more nearly approached. It is to be hoped that some such element or elements may yet be isolated and identified as coronium or nebulium. The chemists of the future will find ample scope for investigation within the apparently limited range of temperature which separates solid hydrogen from the zero. Indeed, great as is the sentimental interest attached to the liquefaction of these refractory gases, the importance of the achievement lies rather in the fact that it opens out new fields of research and enormously widens the horizon of physical science, enabling the natural philosopher to study the properties and behaviour of matter under entirely novel conditions.

THE UPPER AIR AND AURORAS.

The present liquid ocean, neglecting everything for the moment but the water, was at a previous period of the earth's history part of the atmosphere, and its condensation has been brought about by the gradual cooling of the earth's surface. This resulting ocean is subjected to the pressure of the remaining uncondensed gases, and as these are slightly soluble they dissolve to some extent in the fluid. The gases in solution can be taken out by distillation or by exhausting the water, and if we compare their volume with the volume of the water as steam, we should find about 1 volume of air in 60,000 volumes of steam. This would then be about the rough proportion of the relatively permanent gas to condensable gas which existed in the case of the vaporised ocean. Now let us assume the surface of the earth gradually cooled to some 200deg. below the freezing-point; then, after all the present ocean was frozen, and the climate became three times more intense than any arctic frost, a new ocean of liquid air would appear, covering the entire surface of the frozen globe about 35ft. deep. We may now apply the same reasoning to the liquid air ocean that we formerly did to the water one, and this would lead us to anticipate that it might contain in solution some gases that may be far less condensable than the chief constituents of the fluid. In order to separate them we must imitate the method of taking the gases out of water. Assume a sample of liquid air cooled to the low temperature that can be reached by its own evaporation, connected by a pipe to a condenser cooled in liquid hydrogen; then any volatile gases present in solution will distil over with the first portions of the air, and can be pumped off, being uncondensable at the temperature of the condenser. In this way, a gas mixture, containing, of the known gases, free hydrogen, helium, and neon, has been separated from liquid air. The spectroscopic examination of these gases throws new light upon the question of the aurora and the nature of the upper air. According to the old law of Dalton, supported by the modern dynamical theory of gases, each constituent of the atmosphere while acted upon by the force of gravity forms a separate atmosphere, completely independent, except as to temperature, of the others, and the relations between the common temperature and the pressure and altitude for each specific

atmosphere can be definitely expressed. If we assume the altitude and temperature known, then the pressure can be ascertained for the same height in the case of each of the gaseous constituents, and in this way the percentage composition of the atmosphere at that place may be deduced. Suppose we start with a surface atmosphere having the composition of our air, only containing two ten-thousandths of hydrogen, then at 37 miles, if a sample could be procured for analysis, we believe that it would be found to contain 12 per cent. of hydrogen and only 10 per cent. of oxygen. The carbonic acid practically disappears; and by the time we reach 47 miles, where the temperature is minus 132deg., assuming a gradient of 3.2deg. per mile, the nitrogen and oxygen have so thinned out that the only constituent of the upper air which is left is hydrogen. If the gradient of temperature were doubled, the elimination of the nitrogen and oxygen would take place by the time 37 miles was reached, with a temperature of minus 220deg. The permanence of the composition of the air at the highest altitudes, as deduced from the basis of the dynamical theory of gases, has been discussed by Stoney, Bryan, and others. It would appear that there is a consensus of opinion that the rate at which gases like hydrogen and helium could escape from the earth's atmosphere would be excessively slow. Considering that to compensate any such loss the same gases are being supplied by actions taking place in the crust of the earth, we may safely regard them as necessarily permanent constituents of the upper air. The temperature at the elevations we have been discussing would not be sufficient to cause any liquefaction of the nitrogen and oxygen, the pressure being so low. If we assume the mean temperature as about the boiling point of oxygen at atmospheric pressure, then a considerable amount of the carbonic acid must solidify as a mist, if the air from a lower level be cooled to this temperature; and the same result might take place with other gases of relatively small volatility which occur in air. This would explain the clouds that have been seen at an elevation of 50 miles, without assuming the possibility of water vapour being carried up so high.

The whole mass of the air above forty miles is not more than one seven-hundredth part of the total mass of the atmosphere, so that any rain or snow or liquid or solid air, if it did occur, would necessarily be of a very tenuous description. In any case, the dense gases tend to accumulate in the lower strata, and the lighter ones to predominate at the higher altitudes, always assuming that a steady state of equilibrium has been reached. It must be observed, however, that a sample of air taken at an elevation of nine miles has shown no difference in composition from that at the ground, whereas, according to our hypothesis, the oxygen ought to have diminished to 17 per cent., and the carbonic acid should also have become much less. This can only be explained by assuming that a large intermixture of different layers of the atmosphere is still taking place at this elevation. This is confirmed by a study of the motions of clouds about six miles high, which reveals an average velocity of the air currents of some seventy miles an hour; such violent winds must be the means of causing the intermingling of different atmospheric strata. Some clouds, however, during hot and thundery weather, have been seen to reach an elevation of seventeen miles, so that we have direct proof that on occasion the lower layers of atmosphere are carried to a great elevation. The existence of an atmosphere at more than 100 miles above the surface of the earth is revealed to us by the appearance of meteors and fireballs, and when we can take photographs of the spectrum of such apparitions we shall learn a great deal about the composition of the upper air. In the meantime, Pickering's solitary spectrum of a meteor reveals an atmosphere of hydrogen and helium, and so far this is corroborative of the doctrine we have been discussing. It has long been recognised that the aurora is the result of electric discharges within the limits of the earth's atmosphere, but it was difficult to understand why its spectrum should be so entirely different from anything which could be produced artificially by electric discharges through rarefied air at the surface of the earth. If we turn to the question what is the cause of the electric discharges which are generally believed to occasion auroras, but of which little more has hitherto been known than that they are connected with sun spots and solar eruptions, recent studies of electric discharges in high vacua, with which the names of Crookes, Röntgen, Lenard, and J. J. Thomson will always be associated, have opened the way for Arrhenius to suggest a definite and rational answer. He points out that the frequent disturbances which we know to occur in the sun must cause electric discharges in the sun's atmosphere far exceeding any that occur in that of the earth. These will be attended with an ionisation of the gases, and the negative ions will stream away through the outer atmosphere of the sun into the interplanetary space, becoming, as Wilson has shown, nuclei of aggregation of condensable vapours and cosmic dust. The liquid and solid particles thus formed will be of various sizes; the larger will gravitate back to the sun, while those with diameters less than one-and-a-half thousandths of a millimetre, but nevertheless greater than a wave length of light, will, in accordance with Clerk-Maxwell's electro-magnetic theory, be driven away from the sun by the incidence of the solar rays upon them, with velocities which may become enormous, until they meet other celestial bodies, or increase their dimensions by picking up more

cosmic dust or diminish them by evaporation. The earth will catch its share of such particles on the side which is turned towards the sun, and its upper atmosphere will thereby become negatively electrified until the potential of the charge reaches such a point that a discharge occurs, which will be repeated as more charged particles reach the earth. This theory not only accounts for the auroral discharges, and the coincidence of their times of greatest frequency with those of the maxima of sunspots, but also for the minor maxima and minima. The vernal and autumnal maxima occur when the line through the earth and sun has its greatest inclination to the solar equator, so that the earth is more directly exposed to the region of maximum of sunspots, while the 26 days' period corresponds closely with the period of rotation of that part of the solar surface where sunspots are more abundant. J. J. Thomson has pointed out, as a consequence of the Richardson observations, that negative ions will be constantly streaming from the sun merely regarded as a hot body, but this is not inconsistent with the supposition that there will be an excess of this emission in eruptions, and from the regions of sunspots. Arrhenius's theory accounts also, in a way which seems the most satisfactory hitherto enunciated, for the appearances presented by comets. The solid parts of these objects absorb the sun's rays, and as they approach the sun become heated on the side turned towards him until the volatile substances frozen in or upon them are evaporated and diffused in the gaseous state in surrounding space, where they get cooled to the temperature of liquefaction and aggregated in drops about the negative ions. The larger of these drops gravitate towards the sun and form clouds of the coma about the head, while the smaller are driven by the incidence of the sun's light upon them away from the sun and form the tail. The curvature of the tail depends, as Breddichin has shown, on the rate at which the particles are driven, which in turn depends on the size and specific gravity of the particles, and these will vary with the density of the vapour from which they are formed and the frequency of the negative ions which collect them. In any case, Arrhenius's theory is a most suggestive one, not only with reference to auroras and comets, and the solar corona and chromosphere, but also as to the constitution of the photosphere itself.

PROFESSOR JAMES DEWAR, F.R.S.

Exhibition.

CAMBRIDGE.

A PHOTOGRAPHIC exhibition was opened at the Corn Exchange, Cambridge, last Wednesday in connection with the Cambridge and District Horticultural Society.

At the luncheon Mr. F. H. Sanderson, one of the judges, said he thought he might say that the Society were to be congratulated on the show of photographs. Last year the first effort in that direction was made, and he was delighted to know that it was sufficiently successful to warrant the attempt this year. He was pleased to note that two of last year's prize winners were medallists again this year; he was also pleased to see that an open class was inaugurated. If they wanted to encourage photography, his advice was, "Don't confine it to the town." The amateur in the town, he pointed out, was apt to follow the lead of the professionals in the town and be influenced by the show-cases. The professional had absolutely the last chance in the world of producing the best photography. They wanted men to give their whole soul and strength to producing the highest possible article, and they would find in the photographic world the professional did not produce the work of the highest standard, simply because he had to work at a price and gain a livelihood. By having the open class they would get work from all over the country, and they would instil into those who took up photography a love for the finest productions.

Compared with last year, the exhibition showed a great improvement in point of the number and the quality of works sent in. Last year the class for architecture was the smallest; this year it was the reverse, and some of the work was of the highest possible quality. The silver medal was awarded to the Rev. H. R. Campion, of Ely; he also took the cup, accompanied by another silver medal for a photograph of the entrance to Bishop West's Chapel, Ely, which was adjudged the best picture in classes 1 to 4. The bronze medal went to some very fine pictures of Canterbury Cathedral by Mr. T. J. Snowden. Miss E. M. Pope, of Sandy, was highly commended. In the class for portraits and figure studies (always a strong class for local workers) Mr. Alphonso Smith took the silver medal for a set of three pictures, entitled, "An Errand of Mercy," "Sen-Sen," and "The Cobbler." The last-named was decidedly the best of the three; the reason is obvious to one who knows Mr. Smith. Mr. William Moore, a rising and enthusiastic worker who takes particular interest in figure work, took the bronze medal for a picture entitled, "Wrinkles, Old and New," which represented an old man (well-known in the town) reading a contemporary. The posing and the expression were excellent. Mr. Moore is to be congratulated also

on a set of pictures illustrating poaching, bird-nesting, etc. In this class Mr. J. Johnson was highly commended.

The landscape and seascape class was rather weak, and not nearly so good as last year. There were a few good pictures, but none of sufficient merit to warrant the silver medal award. A landscape and a seascape by Miss E. M. Pope gained the bronze medal. Mr. Alphonso Smith was highly commended for two pictures. Mr. A. G. Swannel was also commended.

In the juniors' class, first prize was awarded to Mr. H. S. Clayton for a picture of the May boat races. The second prize was withheld.

The open class was of great interest. Mr. C. E. Walmsley won the gold medal with three excellent studies. The Rev. F. W. Strong won the silver medal for two portraits, of which "Thoughts of Youth" was the finest. A Bristol worker, Mr. W. R. Lathbury, won the bronze medal. Highly commended Mr. F. M. Barkway, and Mr. W. Inston commended. Other good work was shown by Wynnham Shakespeare and W. Page.

Messrs. F. J. Stoakley and W. H. Hall were awarded a special silver medal for some Sanger Sheppard colour slides.

The judging was in the capable hands of Messrs. W. B. Redfern and F. H. Sanderson. The duties of hon. sec. were undertaken by Mr. C. S. Addison, assisted by Messrs. A. J. Mouel and F. Stoakley, whose part in making the exhibition a success was very considerable.

PERSONAL PARS AND NEWS NOTES.

MANY as well as myself must have regretted the disappearance of the column of "Personal Paragraphs" that once used to ornament page 2 of each issue of a certain photographic weekly. Why, I ask, has this popular and truly twentieth-century feature vanished? Has "Lux" ceased to perambulate (note-book in hand) the apartment of Anderton's Hotel, in which certain of the faithful are wont to meet? Does he no longer haunt the purlieus of Tudor Street, Whitefriars, on Thursday nights; has he stopped lurking—a silent listener—in a corner of the smoke-room at 28, Charing Cross Road; can he never now be desecrated in the neighbourhood of Russell Square; in short, is he no more hunting for "copy" in those spots of the metropolis where camera folks most generally do congregate? If not, why not?

One reason, and one only, presents itself as being possibly the true secret. Lux may have become an editor, and is consequently too grand to deign to write mere pars. Such being the case, may I offer myself—Solomon Sage—as a humble substitute?

My idea is not to confine myself to sordid details of a man's ancestors, his researches into chemistry, and such-like dry information. On the contrary, I'd give chatty notes on personal appearance, dress, and habits, etc., with stories of incidents and *bon mots* scattered in between, to flavour the literary hash—I mean, dish. Further, my paragraphs would not be confined to people only.

But in order that you may more clearly grasp my meaning, I have jotted down a selection of sample pars., as follows:—

I saw Mr. Snowden Ward get off a bus outside the door of the "King Lud" the other day. It gratified me to observe that, instead of entering, he went to Slater's next door. He was wearing a brown lounge suit, with a charming green tie. His hat, as usual, was of the soft felt variety. I am in a position to deny the ridiculous *canard* which credits Mr. Ward with having stated that it was possible for amateurs to earn money by press photography.

Mrs. Cadby, I learn, has just placed a permanent order with Messrs. Straker for a large weekly supply of pen-nibs and paper. It is said that her articles on garden photography are all arranged for up to the spring of 1904.

Mr. Holland Day has returned to America. The price of white stock scarves has fallen perceptibly since his departure. Mr. Day took with him some fine '86 platinotype with which to replenish his cellars.

Another American visitor who recently quitted our shores was Mr. Yarnall Abbot. It is whispered that while in London he, conducted by one of our most prominent photographic lights, visited the Zoo, the R.P.S., Romano's, an A.B.C. shop, the Tivoli, Westminster Abbey, and other refined resorts of the metropolis. Mr. Abbot was overheard to pronounce the evening service at the Abbey "real bully," and although the meaning of this cryptic utterance may be somewhat obscure, everyone who met the speaker will agree that it was doubtless said in good part.

The statement that the Eastman Company have added to their enormities by turning pro-Boer is without foundation. P.K. stands.

for pocket-kodak as well as the name of the (late) President of the Transvaal.

A good story is going the rounds at present in which the Rev. F. C. Lambert is the central figure. Mr. Lambert, it seems, called one afternoon at Effingham House, Arundel Street, and on the doorstep encountered Mr. Brown. They entered the lift (beg pardon, the elevator) together, and ascended towards the top floor of the mansion. The lift (realising, perhaps, that it had a clergyman on board), travelled very slowly and sedately. "I thought you advertised that this elevator was the fastest in London?" remarked Mr. Lambert. "So it was," said Mr. Brown, who had had to stand the whole way up. The reverend gentleman's reply, if he made one, is unrecorded.

It is incorrect to suppose that the photographs of lightning exhibited in the Scientific Section at the recent New Gallery show were merely negative prints from certain tree and branch studies at the Salon.

A Parisian correspondent informs me that Mr. Edouard Steichen has organised a new artistic society in that city. The society is a delightfully informal one, holding its meetings (at which members' work is exhibited, criticised, and occasionally even admired) wherever it happens to find itself at the time. Mr. Steichen is, so far, the only member.

I hear a rumour that Dr. Grün is about to set up a portrait studio on each of the stations of the Underground Railway. The eminent optical worker's latest feat was to snapshot a negro in mourning walking through a mist at midnight. The likeness is excellent.

In view of the fact that several more meetings are soon to be held at the Royal Photographic Society's rooms, I am thankful to be able to announce that No. 66, Russell Square has at last been connected by private wire with the nearest ambulance station.

A story having been circulated in the Camera Club to the effect that the price of afternoon tea was to be raised to sixpence, several prominent members are reported to have stated emphatically that they would sooner drink whiskey than submit to such an extortion. The momentary storm has, however, subsided.

There! If those paragraphs won't do, I don't know what will. Should you decide to publish a series such as the above, kindly wire me at once in order that I may buy a suit of armour for street and evening wear. Also purchase fresh bales of paper to cope with the doubled circulation of your journal. Yes; Solomon Sage is your man!

SOLOMON SAGE.

Commercial & Legal Intelligence

PLATINUM Residues.—Messrs. Blundell and Sons, of 199, Wardour Street, Oxford Street, London, ask us to state they treat platinum residues very economically, and give clients best value for all parcels entrusted to them.

ALLEGED Bogus Photograph Company.—At the Westminster Police Court on Monday last Ernest Frewtrell Hopper, aged 27, of High Street, Plumstead, and Charles Davies, aged 46, of Darwin Street, Walworth, were charged on a warrant with conspiring together to obtain money by means of false pretences.—Detective Sergeant Baxter stated that the prisoners were arrested on a warrant granted in January of last year, the allegation being that they obtained various sums of money from domestic servants and others, for orders for photographs. When applications for the orders were made, the parties were told that the money had not been paid in. He arrested prisoner Hopper on Saturday evening, when the accused said: "I suppose you will have Davies." He afterwards added: "He is the instigator of this." The concern was called The International Photograph Company. The accused subsequently said: "I was employed by Davies at a salary of 10s. per week, 15 per cent. commission on all orders, and 7½ per cent. on collections. Davies has been my downfall. I was straight until I met him. Only a week or two ago, we got some money from different people for orders, and divided it equally. We afterwards spent the money. I am glad it has come to this, but for Davies I should not be standing here now. After this I shall get clear, and then start afresh. Davies is a scoundrel, and I shall have the satisfaction of seeing him punished as well as myself."—The Sergeant further stated that he got the prisoner Davies to attend the Rodney Road Police Station by a ruse on Sunday morning. When charged, he said: "It was a genuine business, but one can hardly earn a living at it now."—Davies now expressed astonishment at the action of the police, and said he had been residing at the same address for upwards of twelve years.—Eventually the prisoners were remanded.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sept.	Name of Society.	Subject.
19	Croydon Natural History	<i>Tele-Photography.</i> E. Marriage
20	Ashton-under-Lyne Photo.	{ Ramble to Hartington. Leader, Mr. R. T. Marsland.
20	Brentford Photographic	{ Wraybury to Windsor.
23	Birmingham Photographic	{ Members' Lantern Evening. Chairman Mr. R. Haines, M.A.
24	Borough Polytechnic	{ Annual General Meeting.
24	North Middlesex Photographic	{ Technical Meeting.
25	London and Provincial	{ <i>More Gems from Spain.</i> Mr. A. L. Henderson.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 11TH.—Mr. W. E. Dunmore in the chair.

Mr. W. D. Welford asked whether the experiences of others confirmed what he himself had noticed in the process of intensifying a plate with mercury. If a plate be bleached with mercury and then blackened at once, a certain amount of intensification takes place; but if, after bleaching, the plate is allowed to dry and to remain in the light for a few days, and is then blackened, nearly double the first intensification is obtained. What was the action of the light on the bleached plate that brought about the increased density under the blackening agent.

Mr. A. Haddon suggested that to make the case quite clear and indisputable, a plate should be bleached and divided into three parts. One part should be treated with ammonia at once; another should be placed in the light; and the third should be kept in darkness. The two last might then be treated with the ammonia after a few days, to see, first of all, whether there was a difference between them and the first plate, and secondly whether the increased density was due to exposure to light or to effluxion of time, a point which would be settled by the relative conditions of the two last sections.

Mr. Welford said that he had kept half of a bleached plate covered up for three days while the rest was exposed to daylight, and he found that the latter was blackened more than the protected portion by the alkali.

The Chairman said that he had noticed that after intensification the gelatine of a film negative became quite hard, not brittle, but hard.

Mr. Haddon attributed this to the tanning action of the mercury on the gelatine.

The Chairman added that this phenomenon was peculiar to films so far as he was aware. It was also a fact that films intensified with mercury did not keep so long as glass negatives, and he found it advisable to take what prints he wanted very soon after intensification. The deterioration showed all over the emulsion, which often came quite away from the celluloid.

Mr. Welford said that it was a curious thing that if one did not wash the bleached film properly a deterioration, in which the blackened negative gradually reassumed its bleached form, set in. It was somewhat mysterious, however, that a film treated in exactly the same way as a plate lasted only for weeks, as against months in the case of the plate.

Mr. A. Mackie remarked that the fading of intensified images varied very much. He had come across negatives intensified in 1877 which were perfect, whereas there were plenty of cases of later intensifications which had gone quite wrong. He believed that the first thing to bear in mind was perfect fixing in the first place and to finish with a fresh solution of hyposulphite of soda, so that no silver salt could remain.

A discussion also took place on matters of minor importance, which call for no comment here.

FULHAM CAMERA CLUB.

WITH the object of inaugurating the session of 1902-3 in connection with the Fulham Camera Club, the President (Mr. Arthur C. Baldwin), Vice-President and Council held a successful "At Home" in the large hall of the Conservative Club, Shorrolds Road, on Wednesday evening last week. The programme arranged for the occasion included vocal and instrumental music, the presidential address, and a lantern exhibition.

The President said that it afforded him much pleasure on behalf of the Vice-President, Council, and himself to welcome them all in the name of the Fulham Camera Club. He had no doubt that they had noticed that on their syllabus was their motto, "Lux et umbra." Those of them acquainted with the classics knew exactly what it meant, but on this occasion he took the liberty of giving a more freer translation, and say its "lucky you brought your umbrellas." They had had a letter of regret from the Mayor of that important borough to say that a previous engagement prevented him from attending. He would now proceed to deliver what was set down in the programme as the presidential address, and he had called it "Photography in many lights." On a former occasion two years ago his subject was "shadows," and he would now deal with "lights," and they could take his remarks as "the idle thoughts of an idle photographer." The address proceeded:—

The former treatise that I made treated of photography under the title of "Shadows," and I justified my selection of that title by recourse to Nuttall's dictionary, and once more I appeal to it. I find that photography is "the art of producing pictures of objects on a chemically prepared ground by the action of light," and is derived from one Greek

ord Phos, which means "light," and another "grapho," "to write." shadow is sombre, but I do not recollect that my earlier screed was together of a sombre character, but as photography is a subject of light, I trust that I may be pardoned if on this occasion I treat it in a light manner. A photographer is somewhat of a butcher, because though he may not have much liver (alas! some of us have one too many and are painfully conscious of it), yet he has plenty of lights. High lights, ruby, canary, and day lights, electric, gas, and other artificial lights. It is therefore in several lights that I wish you to glance at photography this evening. I have ascertained that there was a Mr. Maxwell Lyte who figured somewhat prominently in the early days of the science we follow more or less artistically, and he must have treated it in a "Lyte" manner, and as his method was the instantaneous process I will endeavour to follow in his footsteps, and think of Noah and be brief. Dr. Diamond was a pioneer, and from his brilliant setting shed light and lustre on the subject. Photographers use diamonds, but I never heard that the famous doctor ever made cutting remarks, and so I hope I shall not fall into that error either. People are never tired of saying that photography is still in its infancy. I consider that if that is so, it is a very fully developed child. It is, however, sufficiently ancient as to possess the halation of a legendary period, and therefore we will look at it first in a legendary light. The Baptista Porta, who I have no doubt thought no small beer of himself, improved the camera obscura, and since then the camera has not been so obscure an object as it once was. The thin end of the wedge would have been driven in much earlier had the dissolving properties of hypo-sulphate of soda been more widely known during Wedgwood's life, but solutions are not always at hand when most wanted, which is especially felt on a hot day in a stuffy dark room, with the candle curling over towards the ruby glass, your best exposed plate under development—temperature at 80 degrees—and you suddenly remember that there is not a bit of alum in the place, and it is early closing day. Wedgwood was not aware that he could retain the images on his plates which he had coated with a silver solution by means of a fixing agent. There were many people travelling on many lines from different starting places, but it was reserved for Mr. Scott Archer to bring photography on an arrow gauge by his collodion process, and express speed was made in the progress of the art. Photography is like some one or two of our generals in the late war. It has its reverses, but no defeats. First there were wet plates, now there are dry. At one time we have negatives, and then we have positives, and I am positive that although (in speaking) two negatives can make one positive, in photography millions of positives can be made from one negative, which is very transparent, and can be appreciated by the densest among us. I would now consider our subject in a high light, and for that purpose must mount to a photographer's studio—and even here legends abound. When you are gibbeted in the chair, with all the photographer's furniture around you, your gaze is directed on a fixed point, and you see staring you in the face "Cash at time of sitting." The artist invites you to look pleasantly, and how can you, when you know for certain that the money for the fire insurance must be sacrificed to your vanity, and you recollect that your housemaid, in whose care you have left the home, has a mania for resuscitating the fire with the best white rose oil. Another moment and the operator (how suggestive of a surgery) says "moisten the lips please." Another favourite motto is "The eyes may be blinked." At one time it used to be "The eyes may be winked," which of course means the same, but seems to invite an air of sauciness or incredulity on the part of the subject, and so it was abandoned in favour of the former. The President went on to refer to people who aped the manners and habiliments of portrait painters, and converted humanity into graven images all stiff and unnatural, and said, therefore, the loss of them is our gain, for it must be confessed that portraiture of to-day in many well-known instances are triumphs of photography, and show an advancement in the art that brings us nearer to the possession of pictures of our relatives and selves than we could have done had we lived in the time of Kneller, Reynolds, and Gainsborough. It has always been a difficulty to say exactly what high art is, but if it means art in high places then it must be found in a photographer's studio. From high lights to twilights is an easy declension, and it is here that photography has its uses. There is a gradually waning demand for photographic albums, and I think it is due to the many and various sizes of photographs. At one time it used to be only C.D.V. Don't photographers envy the times now gone for ever when they demanded and received 10s. per dozen C.D.V. one positive only, and now some of them are glad to accept an order for 3s. 6d. dozen and a 12 by 10 enlargement thrown in. Then cabinets were introduced, and for many years albums as receptacles for these portraits enjoyed a large sale. Now every photographer has a special size of his own, and it is difficult to get an album to take all these sizes. It has, however, had the effect of adding a charm to room decoration, and increased the sale of frames. However, to return to the album and twilight. How poetic it must be in the soft waning light of early summer evening to sit on a garden seat with your best boy showing him the family portraits—something after this style. That's papa! that's mamma! and that's mamma before she was married. It really was a cabinet, but you see it has been made smaller because papa's rival had been taken with her, and when she became engaged she thought she would be like papa and cut him out too. The poet sang, "The shades of night were falling fast," and that reminds me of photography in a night light. A lady the other day had a small camera given her, and she went into a Southsea dealer's shop for a flash-light apparatus—cheap, of course—and thought she would be able to take the fleet at Spithead. It was a magnificent idea, and showed good "resolution," but I am afraid a victory would not have been gained.

In his further remarks the President went on to give an interesting and humorous sketch of a Photographic Society's meeting, and dealt in

an amusing and witty manner with other features of photographic art. Speaking of photography in a poetic light, he said that poets and photographers had one thing in common, and that was that they gained their inspiration from, and spent some of their best efforts in the admiration of nature. At the conclusion of his address Mr. Baldwin was loudly applauded.

Mr. Lloyd moved a vote of thanks to Mr. Baldwin for his address, and this was carried by acclamation.

In responding, Mr. Baldwin said he might say without any shamefacedness that that meeting was held for a purpose. That club was now entering upon the third year of its existence, and the Council thought it would be a very good idea to lure them there to spend a pleasant evening, but that was only the pleasant side of the camera club. Its real object was to meet together to improve themselves in their own work, and to render mutual help to other members who were engaged in the art which they followed. He went on to speak of the objects of the club, and expressed their indebtedness to the committee of the Conservative Club for allowing them the use of the room for club meetings.

GOLDSMITHS' INSTITUTE CAMERA CLUB.

THE annual general meeting was held on Tuesday evening, the 9th inst, and was well attended by the membership. The question of amalgamation with the Chemical Society, which has been raised by the Institute authorities, was of course discussed at considerable length, it being fully decided that the hon. secs. should lay the views of the members on the subject before the Governors, and on receipt of their reply, call a special general meeting to deal with the matter. It was also decided that the present executive remain in office at any rate until this business is finally disposed of.

The following report detailing the work of the club for the past year, and its present position, was submitted by the hon. secretaries:—

ANNUAL REPORT FOR YEAR ENDING SEPT. 30TH, 1902.

It is to-night for the fourth time our pleasing duty to present our annual report to the members of this club, and to record to the best of our ability the events and progress of the session which has just departed.

The year 1901-2 has been a stirring one in our national history, the lights and shades of triumph and despondency, joy and sadness, alternating with startling and significant rapidity in the minds and hearts of the citizens of our world-wide Empire; and, on a smaller scale and in a more restricted sense the same may be said of the Goldsmiths' Institute Camera Club and its members. However, all's well that ends well, and though the shadows seemed to predominate in the early part of the session, yet we are happy to say that the natural balance has been amply restored, and we end the year with a largely increased membership and a record of much useful photographic work accomplished.

The lectures and demonstrations given during the winter months were most interesting, but we regret to say they were not well patronised by the membership. Indeed, so bad did the attendances become that we were obliged to call a special general meeting on the 16th December last, at which the whole question was fully discussed, and, among other things, a reduction in the number of public fixtures, and a consequent increase in quality agreed upon.

The re-introduction of the weekly meetings, which have been held in Room 42, has proved to the popular taste, at any rate sufficiently so to warrant their continuance in the future.

One of the most successful functions we have ever held as a club took the form of an "At Home" on February the 11th. This being quite a new departure it was embarked upon with some amount of fear and trembling, but we are pleased to be able to report that it went with a "snap" from start to finish, and with music, flashlights, refreshments, and a lantern exhibition, there was not a dull moment from reception to God Save the King. As far as we were able to ascertain the feelings of those present we feel that we may safely say that everyone was delighted, and that there is no doubt whatever that this ought to become an annual fixture.

On April the 16th the lady members, with some slight assistance from the sterner sex, gave an entertainment in the Ladies' Social Room which was much appreciated, and which might be repeated every twelve months, or oftener, with advantage.

The summer programme included a projected excursion to Leatherhead on June 14th, but on that day the rains came and the waters covered the face of the earth, so it was reluctantly decided to abandon the fixture. Several members, however, who had foregathered at the railway station in a hope of a clearance in the skies, organised on the spot an impromptu excursion to "America in London" at the Crystal Palace, where they had a first-rate time. We speak from personal experience. Those members who had purchased tickets but did not turn up received their money back, less a deduction for the actual out-of-pocket expenses of printing, etc.

With regard to finance, the revenue account shows a credit balance both in the prize and general funds, which in view of the increased expenditure necessitated by a larger membership and broader outlook, may, we think, be regarded as satisfactory. The advance in the amount received under the heading subscriptions is also very gratifying, in addition there was a welcome increase in the Governors' grant, which we hope will be continued.

Turning now to our membership-roll we have the pleasure to chronicle a further accession in strength. At this time last year the number of actual members was 39, this year it has reached the excellent total of 54, a net gain of 15, and 28 more than the year before.

If every member will bring the club prominently before their friends who are members of the Institute, or who can be persuaded to join, especially ladies, there is no reason at all why this total should not be vastly

improved, indeed considering the advantages offered by the club we look forward with hopeful expectation in this direction. As, however, there is always bound to be some slight falling off in membership at the close of each session, from various causes, a vigorous recruiting campaign is the only means of ensuring a permanent increase.

SOUTHAMPTON CAMERA CLUB.

The members of the above club met on the 15th inst. under the presidency of Mr. G. Vivian.

After ordinary preliminary business, the Chairman introduced Mr. W. A. Sims, representative of the Rotary Photographic Company, who gave an instructive demonstration, etc., on the use of the various printing and negative papers issued by the company. Exposures were made, and the prints developed and fixed in the presence of the members, and a large variety of specimen prints and paper negatives were passed round for inspection, including some very superior specimens of bromide prints toned with the hypo-alum bath.

News and Notes.

A RECEIVER and Manager Appointed.—In the Chancery Division of the High Court, before Mr. Justice Swinfen Eady, sitting as Vacation Judge, a motion was heard in which Messrs. Barclay and Co., Ltd., sought for the appointment of a receiver and manager of the Photographic Association, Limited.—Mr. Robertson, who appeared in support of the motion, said the plaintiffs were debenture holders, and they asked for the appointment of a receiver and manager. The motion had been adjourned for a fortnight, for the purpose of entering into negotiations for paying off the plaintiffs. The plaintiffs had not been paid off however, and the motion now came before the Court.—Mr. Vernon said he appeared on behalf of the company, and for second debenture holders. He was not in a position to oppose the motion, but he asked that the order should not be drawn up for ten days, as negotiations were still pending, and they still had hopes of settling with the petitioners.—On behalf of Mr. Parker, another debenture holder, it was stated that he did not oppose the petition. The debentures he held, although they purported to be second debentures, ranked as a matter of fact in priority to those of the plaintiffs. He suggested that a receiver and manager be appointed without prejudice to the claims to priority.—His Lordship asked whether the easiest way would not be to take judgment at once, and direct an inquiry as to priorities.—Mr. Vernon said that would be throwing additional expense upon his client. Eventually his lordship appointed the gentlemen mentioned in the notice of motion as receiver and manager.

CONSIDERABLE attention has been given by the Borough Polytechnic Photographic Society for the last three or four years to the promotion of practical instruction in photography as applied to amateurs, and we understand that some 70 ladies and gentlemen were added to the Society last winter almost solely by these evenings. The appended list of subjects for the coming season will be sufficient to show the scope of these elementary lectures, which are held every Friday. Add to this the privilege of also attending a similar series of more advanced lectures on Wednesday evenings, as well as the advantage of using at all times a well-fitted dark-room with an efficient lighting apparatus, and it will be seen that the subscription of 5s. per annum is a very modest one. The winter session reopens on Wednesday, October 1st, and the first instruction evening will be held on Friday, October 3rd. A full syllabus and other information can be obtained from the hon. secretary, Mr. P. C. Cornford, 103, Borough Road, S.E.:—1902.—October 3, apparatus—the choice of a camera, the functions of a lens, value of stops, use of swing back and rising front, accessories; October 10th, development—in theory and practice; October 17th, printing and toning P.O.P.; October 24th, lantern slide making; October 31st, bromide printing; November 7th, enlarging on bromide paper; November 14th, defects in negatives—prevention and remedy; November 21st, developers—their use and abuse; November 28th, enlarged negatives; December 5th, lantern slides—for production of tones; December 12th, trimming, mounting, and framing; December 19th, miscellaneous hints and formulæ. 1903.—January 2nd exposure and development by factors; January 9th, gaslight bromide papers; January 16th, intensification and reduction; January 23rd, control in printing; January 30th, platinum papers—development for tones; February 6th, enlarging; February 13th, clouds—their production and printing in; February 20th, home portraiture; February 27th, optical lantern—its management and uses; March 6th, composition—elementary rules; March 13th, developing architectural negatives; March 20th, bromide prints—toning and redeveloping; March 27th, carbon printing.

In "Photography as a Fine Art," a handsomely-illustrated volume just issued by Mr. Grant Richards, Mr. Charles H. Caffin makes, as his title suggests, a bold claim for the camera. It is not a new one, but it is here urged with unusual insistence and complacency. That, other things being equal, the difference between a good photograph and a bad one depends, in the main, upon the skill of the operator is obvious—it is a matter of technical dexterity aided by good apparatus. But it is the sun and the chemist, reinforced by the optical-instrument maker, which, in the last resort, create the photograph. The essential difference, from the artistic point of view, between an artist's picture and a photographer's negative is that the one has been generated by the brain and the other recorded by the lens. Nevertheless, the photographer is all the better for having a touch of the artist in him. The camera does not, as a matter of course, see Nature quite as it is. It used to be said that photography could not lie; but the extreme sophistication of such modern

work is the best answer to that ill-informed dictum. The lens distorts objects, confuses distances, destroys "values," and commits other sins against actuality. Its results, therefore, need correction, and, up to a reasonable point, the artistic taste and manipulative skill of the photographer are properly employed in smoothing out the crooked places. It is when this process is carried to extremes, as it not infrequently is, that what Mr. Caffin calls a "straight" photograph becomes a "fake." He draws a sharp line of division between the two; but it would appear from his own admissions that there are more ways than one of obtaining results which the camera could not achieve unaided. The operator who "touches" up a negative by taking out the high lights or deepening the shadows, is a clumsy practitioner beside his more expert rival, who procures undoubtedly artistic results in the course of developing and printing, by the aid of platinum paper, glycerine, and other ingenious expedients. We have no quarrel with these processes, since, after all, they are directed to replacing crudity by softness and gradation; but we must not call this kind of thing "fine art." It is very clever work, and there is no denying the beauty and charm of many of the pictures by American photographers with which Mr. Caffin's volume is adorned. To what extent the photographer is justified in modifying his picture, and whether it is ever allowable to alter it by pencil or brush, is a nice question, although, perhaps, one of no great importance in itself. It may, however, be said that the necessity for the "fake" is hardly established. It is often resorted to for the sake of producing some tour de force, which may be effective, but hardly carries conviction, and is certainly out of place in a craft which, not satisfied with being delicate and beautiful, aspires to be considered an art. Mr. Caffin gives a very good concrete instance of this. A model in scanty raiment was photographed in an attitude of slumber, lying upon a couch. By the use of brush and needle the sofa was converted into water; the young person appeared to be floating; and, with the title of "Nirvana," the trick was done. This is, of course, a more elaborate performance than the familiar device of removing on the negative a superfluity of waist, or a too great amplitude of arm. The book, we should mention, is of American origin, and deals almost exclusively with the work of such experts as Mr. Alfred Stieglitz and Mrs. Kasebier.—The "Standard."

MESSRS. NEWNES' LECTURES.

To the Editors.

GENTLEMEN,—You have been good enough in previous years to grant us space in your columns for the purpose of calling the attention of the public to our annual offer of lantern-slide lectures for the people. May we mention that we are loaning this year many new and interesting sets. Some of the old favourites, too, have been thoroughly revised and added to, and we feel sure will again prove acceptable to the general public. Anecdotes about famous folk, pretty pictures for all, gems of comic art, the beautiful homes of England, something about sailors, lecture lessons, etc., etc., may be enumerated as a few of the many subjects on loan.

To those of your readers who may be interested in this matter we shall be happy to forward full particulars by return, on receipt of their application.—Yours very faithfully,

GEORGE NEWNES, LIMITED,

Lantern Lectures Department.

Counting House and Editorial Offices,

8, 9, 10, and 11, Southampton Street, Strand.

THE LONDON COUNTY COUNCIL SCHOOL OF PHOTO-ENGRAVING AND LITHOGRAPHY.

To the Editors.

GENTLEMEN.—I have pleasure in enclosing, for your information, a prospectus of this school, the work of which is particularly identified with the printing craft. I shall be greatly obliged if you will assist our work by drawing attention in the columns of your journal to the fact that the eighth session will commence on Monday, September 29th, 1902.

The school is open to those who are genuinely engaged in business in any branch of the photo-mechanical, photographic, designing, illustrative, lithographic, engraving, and printing crafts, and no provision whatever is made for amateurs.

The courses of practical instruction are arranged to suit the following craftsmen:—

Photo Engravers.—Line and screen negative making, etching, proving, tri-colour work. Photogravure, and preparation of originals for reproduction.

Photo Lithographers.—Negative making, photo lithography, colotype (plate preparation, press and machine work), combinations of lithography and colotype.

September 19, 1902.]

Photographers.—Line and continuous tone negative making, print-
ing, enlarging, transparency making.
Lithographers.—Lithography, map and plain drawing, transfer
drawing, design, lettering, photo-lithography.
Designers.—Design, drawing, lithography.
Draughtsmen.—Drawing, design, lettering.

The School is well equipped with the necessary appliances for
study and practical work. It contains large studios for life and
elementary drawing, design rooms, lithographic studio, lithographic
press room, photographic studio, with electric light installation, dark
rooms, collotype preparation and printing room (with three presses),
drawing rooms, lecture room, etc.

Only those engaged in the trade are admitted. The fee which
limits a student to the classes is 3s. a term of three months, inclusive,
or those in receipt of not more than 30s. a week. For those in
receipt of more than this sum the fee is 7s. 6d. a term, or 15s. a
session of three terms. The Photo Process Department is open for
day instruction.—I am, dear sir, yours faithfully,

A. J. NEWTON,
Principal of the School.

6, Bolt Court, Fleet Street, E.C.,
September 1st, 1902.

PLATINOTYPE DEMONSTRATIONS.

To the Editors.

GENTLEMEN,—We beg to inform you that during the exhibition of
the Royal Photo. Society at the New Gallery Mr. W. H. Smith will
give demonstrations of the platinotype process, and of the working
of the oxy-magnesium portrait lamp on Tuesday, Thursday, and
Saturday evenings.—Yours faithfully,

THE PLATINOTYPE Co.

22, Bloomsbury Street, New Oxford Street,
London, W.C., September 16th, 1902.

ENLARGING BY ARTIFICIAL LIGHT.

To the Editors.

GENTLEMEN,—Enclosed we have pleasure in sending you copy of a
small pamphlet on "Enlarging by Artificial Light," which, we ven-
ture to think, contains useful advice to the worker with apparatus of
this kind. Many of the questions which are being constantly asked
of the photographic dealer are answered in this little work. We
think this pamphlet may be of sufficient interest to many of your
readers to warrant the favour of a notice of its publication.—Thanking
you in anticipation, we are, dear sirs, yours faithfully,

PERKEN, SON, AND Co., LTD.

99, Hatton Garden, London, E.C.,
September 15th, 1902.

COPYRIGHT.

To the Editors.

Gentlemen,—About the 24th June, 1901, a London firm wrote me
that I was recommended to them as being an expert at out-door
photography, and especially mountainous districts. The firm offered
to compensate me well if I would undertake to take certain views,
adding they had great difficulty in getting one they could rely on.
I wrote them in reply, saying I would undertake their orders,
promising attention, and guaranteed them good work, and stating
that what was not good could be rejected. I received a very cour-
teous reply and promise to send me on a list of subjects they required
at the "earliest possible date." No list of any kind was received
until the 24th August following. Immediately after that date the
weather (which had been very suitable for out-door work) broke up,
and consequently involved me in great difficulties, causing several
fruitless journeys to the same place to be made before I could obtain
the necessary class of negative.

In the firm's order, which was for nearly 40. 1-1 negatives, they
said if I found out subjects which I thought would sell I had a free
hand to take them—so in all I secured 68 negatives. To secure some
involved me in walking over 15 miles carrying my 1-1 outfit. I spared
neither time, effort, nor expense, but utterly failed to get the work
done until November, owing entirely to the weather and the difficult
subjects. In that month the representative of the firm called on me,
and found me finishing the work. There were some few not mounted,
so he took what I had ready for one district with him to obtain
his orders, and then came back for some of another district.

When he was with me the first time he saw some photographs
of one of the particular districts on the table, and one of which he
admired very much. I told him that was from one of my old nega-
tives. He asked me to let him have copies of that and six others
he selected from prints from other old negatives. I
lost no time, printed copies, and sent them on at
once to the firm in London at his request. When
with me the firm's representative said: "I see you have gone to great
trouble and expense, and the work is good, except a few, but I
found on my journey that some of the subjects were not selling sub-
jects" (although these subjects were stipulated in the firm's list), and

again: "I see you have had great difficulty on account of the weather,
but there is no remedy; we must do our best to meet each other." He
asked me to meet them in the best way I could, which I promised
to do, although admitting no neglect on my part. He said he would
get his firm to make me a liberal offer, and asked me in the mean-
time to reprint some few from the mountain negatives and shade
them in certain places, and then they would be all right. I endeavoured
to reprint them, but it being wet and dull weather every day, and
fearing (as I had no particular instructions which to print first) I
might keep them waiting too long, I got the 68 negatives together and
sent them to London by train, and wrote to them explaining my
reasons for so doing. I received no reply until about a month after,
although I had written them three times, and I then received a tele-
gram saying: "Negatives too late; writing." No fixed time was
mentioned for my work to be finished, save that they would be wanted
for publication in 1902. In course of a few days after the telegram
I received a letter and enclosed therein a cheque for £2 10s., asking
me to sign an enclosed receipt in full settlement of my claim, and
saying they had selected 5 negatives out of 68, and would send for
a few more if they required them, and that they were returning the
63 negatives, and that the £2 10s. was for the 5 negatives at 10s.
each. I acknowledged this letter by postcard, and said I would
write them later on, which I did, offering (without prejudice) to
accept £50 in settlement, and failing their acceptance of that offer,
I should charge them a guinea each negative and travelling expenses.
Receiving no reply, I sent an invoice for 62 negatives, not charging
them for the full number, as there were several negatives of the
same district which might not come in. I did not in any way refer
to the 7 prints before mentioned from my old negatives, which were
registered. In due course my claim for the negatives and travelling
expenses, £75, less the amount of their cheque, was tried, and I
obtained a verdict for £50 and costs.

After the trial I found they had taken large orders and were
producing postcards (coloured and plain) and coloured photos by
the thousand from one of the 7 photos from my old negatives. My
solicitor wrote them on the matter, and requesting them to stop pro-
ducing any more copies, and reminding them they had not paid for
them. To this their solicitor replied that they had paid for them,
and held my receipt and my written permit to use them, which I em-
phatically denied, and instructed my solicitors to apply for an in-
junction restraining the company from producing and selling any more
copies. This application came on in London, and was refused, and
the respondents are now threatening to apply for my committal unless
I deliver up the original negative of this particular photo, which were
copyrighted by me and were not in any way included in my claim
against the company in the assize action.

This seems to me a deliberate attempt on the part of a company
by virtue of their capital to over-ride and exterminate the value of
copyright in a private individual, and as that would be a most serious
matter to the profession, I shall be pleased to have the opinion of mem-
bers on the subject through the medium of your valuable paper.

Thanking you, Mr. Editor, for inserting the same in our Journal,
and apologising for the length of my letter, permit me to remain,
dear sir, yours very sincerely,
J. L.

** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOK-
SELLERS.—A Contents Bill is issued with each number of the JOURNAL,
and copies may be had on application to the Publishers.

** NOTICE TO ADVERTISERS.—A Revised Tariff for advertisements
in the JOURNAL is now in force. Blocks and copy are received subject to
the approval of the Publishers, and advertisements are inserted abso-
lutely without condition, expressed or implied as to what appears in
the text portion of the paper.

PIRACY.—C. Carlton writes: "A neighbour, who is a printer and publisher, persists in reproducing and publishing my photographs without consent and against my wishes. Can he be legally restrained from so doing? The pictures are not registered, but are my own personal work."—In reply: Unless you register the copyright, you have no remedy against anyone who copies your pictures.

POSTCARDS.—"TYNEMAN" asks: "Can you give me address of Continental firms who make a speciality of printing pictorial postcards for the trade?"—In reply: We do not know the addresses of foreign firms that do this class of work. Messrs. Wyndham, of Acton, will no doubt execute the work for you; so will any of the colotype printers.

POSTAGE STAMP CAMERAS.—GLADSTONE AND BARNARD say: "We shall esteem it a favour if you can give us the names of manufacturers or wholesale places where we can get postage stamp cameras. Messrs. James Lancaster and Son is the only firm we know."—In reply: Postage stamp cameras are supplied by Fallowfields, Houghton's, Marion's, or, indeed, by all the large dealers.

COPYING COPYRIGHT PICTURES.—"INTERESTED" wants to know whether he would be liable in copying a photograph that has no mention of copyright on either mount or picture, even if it is copyrighted, and whether the law allows a person making one copy of anything for himself?—In reply: Certainly he would. The penalty is for copying, whether for sale or not. It is not necessary that a copyright picture be marked as such.

TOUCHING UP PHOTOGRAPHS FOR COPYING.—"WORTH KNOWING" says: "Shall be pleased if you will inform me how to make up and how to apply a wash to paint out reflections, and make parts lighter in photographs previous to copying, as used by process workers?"—In reply: Ordinary water-colours are all that is necessary. The reflections may be subdued with a very light grey. The darker portions may be strengthened by going over them with a lighter colour.

CUTTING MACHINE.—CHANCELLOR AND SON write: "We shall be glad if you will kindly let us know if there are any agents in the three Kingdoms for guillotine machines made by Marshall, photo dealer, Boston? If so, we shall be much obliged if you will kindly give us the address of one."—In reply: So far as we are aware, there are not. Indeed, we have not heard of their machines. Possibly some of the large London dealers may know of them. Try such houses as Houghton and Son, Fallowfields, and the like.

LANTERN PLATES.—H. H. PORT writes: "On page 783 of your ALMANAC for 1896 you give a method of making dry collodion plates for stereoscopic transparencies. I wish to make some slides for lantern by this method. Kindly say what developer you recommend for this purpose?"—In reply: A good developer for the plates is an acid "pyro" one, say, pyrogallic acid three grains, acetic acid thirty minims, water one ounce. To this a few drops of a twenty-grain solution of nitrate of silver is added. After it has been flowed once or twice over the plate.

SPOILT FILMS.—"FIXED" says: "A few days ago I developed a roll of films from which I required prints urgently. Unthinkingly, I dried the same off with methylated spirit, with the result they are so coiled up it is impossible to print from them. I have tried soaking them in glycerine, but this has not given the desired effect. Can you advise me through your valuable paper what is the best to do in the above case?"—In reply: We expect the films are spoilt. The only thing we can suggest is that you again immerse them in spirit until the celluloid is lightly softened, then press them flat, and keep them so while drying.

STUDIO ASPECT.—J. J. RIDLEY says: "I am thinking of renting a fresh studio, but I cannot possibly have a north or east light. The only light available is the west. Of course, I am aware that I shall have a great amount of sun in the afternoon. What kind of glass would you recommend for studio? Can the sun be curtained out successfully, and yet give short exposures?"—In reply: A western aspect is not at all bad for a studio, though, of course, it is not quite so easy to work as one with a north light. The sun can be successfully curtained out without necessitating a long exposure. Thin "rolled plate" will be good for the roof, and ordinary glass for the sides. We do not undertake to answer correspondents by post.

SPIKE OIL OF LAVENDER.—"SPIKE OIL" writes: "Some years since we used to purchase at a neighbouring oil and colour shop and ironmongers, some spike or oil of lavender. It was a dark brown, thickish fluid, and very cheap—about 2s. a pint. In those days of experimental photogravure we used it to fix the dust on the plates by suspending the plate over a dishful. I sent to-day to a neighbouring chemist for some. He sent me an ounce of a turbid, white, watery liquid with a few oily globules in, and charged 4d. Can you tell me where I can obtain the genuine article?"—In reply: Spike oil of lavender may be had from any of the wholesale druggists—Messrs. Hopkin and Williams, Cross Street, Hattou Garden, for example.

LENS FOR SHORT STUDIO, ETC.—"SEASIDE" writes: "(1) I shall esteem it a favour if you will kindly advise me what lens to buy to take full-length pictures (cabinet size) in a small studio, only 13ft. from wall to wall. I have a set of three Ross's, and should like to have another of theirs, but do not know which to get. (2) I should like also to know where I can buy ready-cut circular P.O.P. paper?"—In reply: (1) We know of no cabinet portrait lens that will take a full-length picture in anything like so short a studio. A lens of the anastigmatic type might be obtained that would do it, but the perspective would then be so violent that the pictures would be most unsightly. (2) We do not think anyone stocks paper cut circular. Perhaps some of the makers would supply it so cut if you ordered it in sufficiently large quantities.

MARKED NEGATIVES AND GLAZING PRINTS.—"STAINS" says: "(1) I developed six plates, 1-1, the other day with pyro and ammonia. They, if anything, were about a third under-exposed on all of them. I found in some of the shadows streaky marks, just as though a snail had crawled over them. It shows a little in the printing. Can you tell me cause and cure? (2) What is the name of the material used to give mounted prints a gloss? I understand they are squeeged on and left to dry till they fall off. Is that correct?"—In reply: (1) "Snail marks" were not uncommon in the early days of dry-plate making, but we have seen nothing of them of late years. If they are due to the plates, they can be seen before they are developed. We rather suspect they are due to something in the development. (2) Simply squeeze the prints, while wet, on a ferrotype plate, and allow them to dry on that.

OPINION WANTED.—"OLD HAND" says "that a business is offered me, stated as follows:—Takings, £626; cost materials, £100 (A); rent and taxes, £100; sundries, £20 (B); total outlay, £220; nett profit, £406; outlay and profit equalling £626. The vendor states this is done on eight sitters a week, and that he employs no hands at all but one apprentice. (1) Does this sound true to you? (2) Is "A" a fair proportion? (3) Is "B" a fair proportion? (4) Would you not think several hands necessary? (5) Is not the average per sitter far too high to be correct?"—In reply: We see no reason why, as only eight sitters per week are taken, that two persons cannot do all the work. With regard to the profits we can say nothing, as we know nothing of the prices charged for the portraits. If they averaged a guinea and a half each, it would make up the sum said to be taken.

CAMERA CONSTRUCTION.—C. EVENDEN says: "I have been thinking over cameras and fancy there is room for improvement, and I am writing for your opinion, if you think one with the following features would be a financial success: For glass plates (or film plates), magazine to hold six or more plates, collapsible into compressed shape, so that one for 5 x 4 plates would go in ordinary coat pocket. Daylight loading can be loaded or unloaded, or night, sunshine. The plates to be shut up in light, tight compartments, so that leakage in camera or light from the shutter cannot reach them. Simple in construction, the neatest and most portable camera on the market, and one of the cheapest to make."—In reply: The idea is good, but are there not several cameras on the market already that fulfil the conditions stated by our correspondent? If he has anything that will fulfil them better, we should certainly say there is an opening for it.

PERMANENCE OF COLLODIO-CHLORIDE PRINTS.—"OTHELLO" writes: "I have been working platinum toned (with gold also) C.C. paper for about twelve months, and although I constantly read of the alleged permanence of C.C. over gelatine papers, I cannot understand why in my hands C.C. does not seem to stand the test of time. My platinum-toned prints are a splendid black, and really beautiful to see when finished, and my customers will have them; but it seems that in a month or so (often less) they begin to show yellow spots, and the black tone changes to a muddy brown. I at first suspected the mounts, but find that various samples act alike. I have no difficulty with P.O.P. prints, and recently a copy of my work was brought in, to order more, at least ten years old, that was simply perfect. If the process is not reasonably permanent, I don't want it, but if I could have it proved that it is, and the fault only in manipulation, I would try to accomplish the result. I may say I follow the manufacturers' instructions to the letter, and am not in the habit of being careless at anything."—In reply: Theoretically, collodio-chloride prints should be the most permanent of all silver pictures. We have some that were produced quite thirty years ago that show no signs of changing. But they were toned with gold only. We have never heard of prints by this process behaving in the way you say that yours do. We should certainly charge it to something in the manipulation, or to something in the baryta coating on the paper before the emulsion is applied.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published early in December next. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The edition for 1903 will be increased to 25,000 copies, a large number of which are already ordered.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1903. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will

be recorded, and wherever practicable new features of an informative nature will be added.

Secretaries of societies will oblige us by promptly forwarding lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, etc. Those firms who wish to take advantage of this feature should communicate with us not later than October 31.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRA.

Orthochromatic Screens. An article by Hans Schmidt in the "Photographische Mitteilungen," entitled "An Orthochromatic Lens without the Disadvantages of a Yellow Screen," illustrates the fact we so often meet with in photography, of the presentation of old ideas as new. As the writer is not a novice, but a skilled photographer, we are surprised that he should offer as a novel means of avoiding the inconveniences of a glass screen the old device of staining the balsam with which the components of a lens are cemented. Does the author believe he has made a discovery? If not, it would be preferable to write in such a manner that those who may read his communication should not infer that the idea is a new one. The staining of the balsam of a lens, so that the functions of a lens and a light filter may be combined in the same instrument, formed the subject of a patent by A. Buchett in the year 1893. Although the device avoids the slight loss of light by reflection, when the filter takes the form of a separate coloured or stained glass plate, there is a disadvantage, which is a very material one for the photographer of limited means. The rapidity of the lens is very considerably reduced, and it will be found necessary in practice to have two lenses, one for ordinary plates, for rapid work, and the other with the stained balsam for orthochromatic plates. There is, however, another way of converting the lens into a light filter, which was also recommended many years ago. This is by staining a structureless collodion with a suitable dye and coating the back surface of the lens with it. The collodion may be easily removed, but the optician must be called in if the balsam is to be stained. The article reads too much like a recommendation for a certain optician's wares.

The Sulphite Intensifier.

We recently published the translation of a note by Dr. Hauberisser, of Munich, upon the composition of the image obtained by intensification with mercury and sulphite of soda, and the conclusion he came to was that it consisted of chloride of silver, with an undetermined compound of silver and mercury and sulphur. Now Professor Valenta, of Vienna has looked into the subject, and he has proved that Hauberisser was wrong. He comes to the conclusion that a silver image bleached with mercuric chloride consists of silver-mercurous chloride $Hg Ag Cl_2$, and that when treated with sodium sulphite no compound of silver and mercury with sulphite is formed; but that according to the strength and duration of action of the sulphite solution the image consists of varying quantities of silver chloride, metallic silver, and metallic mercury. If the sulphite is allowed to act for a long time, and is strong, the whole of the silver chloride is dissolved, and metallic silver and mercury alone are left to form the image.

* * *

Orthochromatic Plates.

Last week we drew attention to a new plate manufactured by a German firm, in which the sensitiveness for blue is reduced almost to zero. We have not yet had an opportunity of trying these plates, but assuming the claims of the maker to be well founded, the manufacture of such a plate, for use without a colour screen, marks a distinct advance in orthochromatic photography. When we compare the orthochromatic plates of to-day with those of the early days of orthochromatic research, we are surprised that so little advance has been made. A very large number of sensitizers have been investigated, and much has been written upon the subject, yet to obtain orthochromatic effect, it is still necessary to use a light filter. The colour screen prolongs the exposure very much, and this loss of rapidity restricts very materially the scope of orthochromatic photography. In tele-photography this prolongation of the exposure is very marked. It would be a great boon to photographers if our manufacturers would turn their attention to the production of an orthochromatic plate giving correct values without the use of a screen. A rapid plate of this type would popularise orthochromatic photography, and we have no doubt it would soon command a very extensive sale. We do not think the risk of fog in development would be a serious obstacle.

* * *

The Progress of X-Ray Photography.

It is nearly seven years since Professor Röntgen published an account of the astonishing discovery with which his name will ever be associated. Meanwhile important improvements have been made in the application of the process to practical purposes, and a contrast of the results obtained in the early days of skiagraphy with those which are now possible invests an address by Dr. Rosenthal at the Augsburg Technical Association with great interest. Dr. Rosenthal exhibited apparatus of his own design, which is described as being of more simple construction and easier to manipulate. In the early days a skiagraph of the thorax required about 20 minutes' exposure; now it may be obtained in less than a second. Although the Röntgen rays are of value in the treatment of eczema, psoriasis, and other skin diseases, their chief application has been for diagnosis. In illustration of this a series of skiagraphs of diseased conditions of the heart and lungs, as well as of calculi in the kidneys and foreign substances in the lungs, were exhibited. Two other small instruments were also shown; one, a punctograph, for exactly determining the position of a foreign substance in

the human body, whilst the other, an orthodiagraph, is designed for the investigation of the exact form and position of the heart.

* * *

The Value of Red Light from a Therapeutical Standpoint.

From time to time the possible injurious nature of continued exposure to the red light of the dark room has been so much insisted upon that it may be well to note other and more optimistic valuations of the effect. Frequently, during the recent small-pox epidemic, attention was drawn to the fact that patients treated in a room to which light of red colour only is permitted to reach recover more speedily than when treated in daylight, and do not pit after the eruption subsides. Indeed, a few months ago, an article in that popular magazine, "Chambers's Journal," was devoted entirely to this subject. And now the latest addition to the list of the good effects of red light is its usefulness in preventing sea-sickness, it being stated that if sufferers would retire to their cabin and cover the lights with some fabric which allowed only the red rays to pass they would not become sea-sick. If this were not too good to be true there is no doubt that the advent of the new system would be hailed with delight by a large number of people with whom *mal de mer* is inseparable from thoughts of sailing. After such pronounced evidence of the value of red light it is scarcely probable that we shall hear much more of the evil effects of the usual dark-room light.

* * *

Sunlight and Electricity.

Professor Garbasso, of Turin, has been making a series of experiments in regard to the action of sunlight and the electric discharge, which would seem to suggest photographic possibilities. He finds, we read, that sunlight facilitates "the passage of the electric spark, the number of sparks which can be passed through the gap in darkness being doubled or trebled in the light, and the effect does instantly cease upon cutting off the light." By focussing the light on one or other electrode, especially the negative one, a continuous current is obtained. Screens of mica, or glass, or alum solution check the action of the light, but plates of quartz or Iceland spar permit it to pass. This action of light upon the electrode would seem to point to the possibility of transferring a picture to a sensitive surface by such means. A negative being placed upon the ends of a series of insulated wires would cause the sunlight to have greater or less intensity of action upon the passage of the current, so that a film impregnated with a chemical decomposable into a dark substance by the current, and placed across the opposite ends of the wires, should be impressed upon the film. Professor Mannelli is of opinion that the heat rather than the ultra-violet rays of the spectrum is the cause of the action. This fact ought not to militate against the possible effect we refer to, seeing that if the graduated action were possible it would be quite immaterial which part of the spectrum caused it. All that would be necessary would be to see that the negative was upon a basis that would not be opaque to the heat rays.

How to Cure Over-Exposure.

Whilst we have tables and exposure meters innumerable, it will always happen that occasionally the operator may meet with over-exposure, and if excessive the difficulty of overcoming its effects during development is by no means small. Many text-books strongly advise beginners to always err on the side of over-exposure, and trust to development to cure the ill. Many years ago the late W. K. Burton presented a paper to the Photographic Conven-

MISCELLANEOUS (continued).

WANTED, Roll Burnisher, 10 or 15 inch, Globe preferred; large developing dishes for enlargements, Enlarging Lantern, 8 or 10 inch Condenser; cheap for cash.—33 Heskey Street, Nottingham.

YATES Patent Printing Frame for Stamps and Victorias, cost 42s.; Ross Group Lens, 3,186, Carte Lens, 2 tripods (damaged), the lot 40s., or will exchange for Backgrounds (new or second-hand).—8 Peck Lane, Nottingham.

7-INCH Goerz Anastigmat Lenses, 1/6.8, with focusing attachment; price £6.—Address Z. 2, 24 Wellington Street, Strand, London.

15IN. x 12in. Camera, by Lancaster, double slide fronts and carriers, large tripod, wants polishing only, the lot for £3; a bargain.—Fitzgibbon Forde, Photographer, Sunderland.

Miscellaneous Trades.

ARTISTIO Finishing.—Monochrome, semi-tint, water colours. Exceptional value. If you want the finest results obtainable from your negative send to Henry Ward, Belgrave Avenue, Leicester.

ARE you satisfied with your Enlargements? If not, it will pay you to send for my list. Sound work, reasonable prices.—Address Henry Ward, Trade Photographer, Belgrave Avenue, Leicester.

ARTHUR L. RICHARD produces Enlargements of the finest quality and undertakes every description of photographic work; list free.—40 Sparsholt Road, Crouch Hill, N.

A FEW Surplus Specimens in Oils, Water, and Black and White, framed complete, to be cleared cheap.—Apply Elite Portrait Co., 267 High Holborn, London, W.C.

A1 RETOUCHING at photographers' own prices lessons given; cash and postage with order.—H. D. Atkinson, 153 Duke Street, Liverpool.

A 12 x 10 STUDIO Camera, by Dallmeyer, double swing back, 1 slide, £4, cost £40; 12 1/2 Meagher Studio Camera and strong Studio Stand, built specially for same, price £7, cost £45.—Smedley's.

A VERY fine 12 x 10 Portable Camera, complete, with slide, 3-fold stand, and case, worth £20, price £10 10s.; finest quality throughout.—Smedley's.

A 1-1 PLATE Studio Camera, with repeating back, 1 slide, complete, 1-1-pl. Portrait Lens and Shutter, price £6 10s.; 1-1-pl. Studio Camera, by Middlemiss, real beauty, double swing and repeating back, price £4, equal new.—Smedley's.

A MAGNIFICENT 12 x 10 Studio Camera, by Ross, double swing and repeating back, inner frames, carriers, and slide, cost £14, equal new, price £9; 10 x 8 ditto, by Watson and Sons, cost £11, price £7 10s.; both equal new.—Smedley's.

A CHANCE in a Lifetime.—About 20 first-class Showcases for Sale, size about 30 x 16, all fitted with interchangeable backboards, covered plush, most excellently made, cost 30s. each, price 12s. 6d. each, or £3 3s. half-dozen; all equal new.—Smedley's.

A VERY fine 12 x 10 Studio Camera, by Scovill, double swing and repeating back, and complete with slide and carriers, equal new, price £6; great bargain.—Smedley's.

A N opportunity which should not be missed.—1/2 Cantilever Enlarger, fitted with 8in. condenser, incandescent gas, price £5, stage carries 1-1 plate; Whole-plate ditto, with 10in. condenser, etc., etc., £7; will not be offered again at this price when season commences.—Smedley's.

A 24 x 18 STUDIO Camera, by Marion, has double swing back, also Studio Stand, cost £60, accept £15 lot; 15 x 12 Newmarket Studio Camera, merely shop soiled, sold at £25, price £18.—Smedley's.

A BELLOWS Studio Shutter, 4in., sold by other firms at 30s., price 20s.; 5 1/2in., 25s.; 4 1/2in. Thornton-Pickard, T. and I., cost £2, 18s.; 3 Thornton-Pickard Studio Shutters, 15s. each; 3in. Merial, T. and I., 18s.; 1 1/2in. T. and I., 10s.; 4in. Newman and Guardia Studio Shutter, 17s. 6d.; all to be cleared.—Smedley's, Blackburn.

A WHOLE-PLATE Outdoor Outfit, with 3 slides, R.R. lens, stand, and case, cost £16, price £6 10s.; 12 x 10 Outdoor Camera, 3 slides, magnificent specimen workmanship, well worth £20, accept £8; 15 x 12 ditto, £10 10s.—Smedley's.

A DALLMEYER'S 3 C. Cabinet Portrait Lens, absolutely as new; 2 C., 2 B., 3 D., 4 D., 5 D., Ross 3 A. C.D.V., No. 3 C.D.V., 3 A., No. 4, and No. 5 Portrait Lenses, all equal new, to clear, at ridiculously low prices; all perfect.—Smedley's.

A VISIT to see our Stock will not be lost, the experience will well repay you, and you will be doubly repaid if you make a purchase; we are now offering bargains never before heard of.—Smedley's.

A 12 x 10 UNIVERSAL Studio Camera, built to special order, swing and repeating back, complete, with slide carriers, inner frames, etc., cost £12 10s., price £7; simply shop soiled.—Smedley's.

A MAGNIFICENT 1-1-plate Studio Camera, over 3ft. extension, double swing and repeating back, 2 slides, 2 inner frames, etc., complete, with bellows, studio shutter, and a most elegant studio stand, the lot for £8; no firm could sell you this under double the price.—Smedley's, Blackburn.

A CHARMING 1-1 pl. complete Outfit, comprising camera, 3 slides, R.R. lens, stand, case, and shutter, £7 10s., cost £16; 12 x 10 Outfit, as above, £13; 15 x 12, £17 10s.; wonderful value; just half ordinary selling prices.—Smedley's.

A 12 x 10 COMPLETE Outdoor Outfit, very finest quality throughout, worth £30, price £13; 15 x 12 ditto, worth £40, price £17 10s.; hundreds of cheaper outfits if required.—Smedley's.

A VERY choice Inlaid Corner Chair, upholstered silk, 35s., cost £3 10s.; Inlaid Rosewood Settee, sold at £9, accept £4 10s.; Carved Oak Chair, 15s.; high-back Spinning Chair, 12s. 6d.; Head and Body Rest, 25s.; Imitation Stone Seat Accessory, only 35s., wonderful value; Sussex Seat Accessory, £4 10s.—Smedley's, Blackburn.

A CABINET Hot-rolling Press, both rollers nickelled, well finished rollers, 6 1/2in., gas or spirit, 25s.; 10 1/2in., £3.—Smedley's, Blackburn.

ABSOLUTELY the cheapest house in the world for all kinds of photo goods and material of every description; no inferior goods sent out; send for our bargain list.—Smedley's.

A N Optimus 1-1-plate Portrait Lens, £5; 3 B. ditto, £7; Dallmeyer 3 C., £9 10s., cost £27; Ross No. 4 Portrait Lens, cost £36, price £15; Ross No. 5, £20, cost £50; all equal new.—Smedley's.

A 1/2-PLATE Cantilever Enlarger, 8in. condenser, fitted for gas or oil, carriers down to 1/4 plate, stage carries 1-1-plate negatives, price £5; ditto, fitted with 10in. condenser, price £7.—Smedley's.

A 15 x 12 Portable Camera of superb quality, 3 slides, R.R. lens, case, and stand, complete, well worth £40, price £17 10s.; similar outfit in 12 x 10 size, £13; scores cheaper if required.—Smedley's.

A CHOICE 12 x 10 Newmarket Camera and Stand, slightly shop-soiled through being on exhibition, the finest camera in the world at any price, and indispensable in up-to-date studio, price £19; 15 x 15 ditto, £22 10s.—Smedley's.

A WATSON 10 x 10 Universal Studio Camera, double swing and repeating back, inner frames, double slide, equal new, built special order, price £6; 12 x 12 ditto, same maker, exactly as above, most magnificent instrument, never again equalled, cost £14, price £8 10s., new.—Smedley's.

A DALLMEYER'S Series 2, No. 4, Stigmatic Lens, equal new; £7; Ross-Zeiss Convertible Anastigmat Lens, giving 4 foci, 9 1/2in., 11 1/2in., 14 1/2in., 16 1/2in., casket complete, cost about £20, price £10, quite new; Ross 13 x 11 Rapid Symmetrical Iris, as new, £8 10s.; Dallmeyer's 12 x 10 R.R., £6 10s.—Smedley's.

A RTISTIC Retouching by West-End Retoucher, used to high-class work only; specimen negative retouched and returned post free.—Charles Lewis, 10 Chichele Road, Cricklewood, London.

A LL kinds of Enlargements finished by experienced Artist at moderate charges; also Retouching done (first class); lessons given in both branches.—Terms from Oscar Arndt, 35 Priory Road, Kilburn, N.W.

A RTIST (experienced); colours, photos in oil or water-colours; views, portraits, etc.; speciality copying views on canvas (oil).—F. Ramsay, Balmain, Goodrich Road, Dulwich, London.

BRUOE'S Non-shifting Retouching Medium; unaffected by varnishing; splendid tooth; advertised 9 years; used by best firms and schools; 1s. post free.—4 Villas-on-Heath, Vale, Hampstead, London.

BACKGROUNDS.—W. H. Fletcher's unrivalled artistic productions. Designs (returnable) 2 stamps.—Address Fletcher's Background Agency, Bridgwater, or to Studio of Painting, Rosebank, Winchester.

BROMIDE Enlargements.—Best results, prompt; postage extra: 8 x 6, 8d.; 10 x 8, 10d.; 12 x 10, 1s.; 15 x 12, 1s. 6d.; 18 x 15, 2s. 3d.; 20 x 16, 2s. 9d.; 24 x 20, 3s. 9d.—Crayon Art Co., 49B Brecknock Rd., N.

BROMIDE Enlargements.—Clean, sharp: 8 1/2 x 6 1/2 8d., 10 x 8 10d., 12 x 10 1s., 15 x 12 1s. 4d., 18 x 15 2s. 3d., 20 x 16 2s. 9d.—F. W. King, 23 Osmaston Road, Derby.

BROMIDE Enlargements.—One quality only: the best.—8 1/2 x 6 1/2 10d., 10 x 8 1s., 12 x 10 1s. 3d., 15 x 12 1s. 9d., 18 x 15 2s. 6d., 23 x 17, 3s. 6d.—Wilson Creighton, 402 St. Ann's Rd., Harringay, N.

BOARDMAN'S Electric Light Apparatus, used in most of the leading studios; invaluable during the winter months; pays for itself in one season.—Apply 10 Southwark Bridge Road, S E.

MISCELLANEOUS TRADES (continued).

BLACK-AND-WHITE Finishing, Retouching, Colouring Photos. Enlarging; good work only; terms moderate.—Address Miss A. Ramsay, "Balmain," Goodrich Road, East Dulwich, London.

BOOK-POST Wrappers, C.D.V., 17s. 6d. per 1,000; Cabt., 25s. (printed); tissue wallets, C.D.V., 2s. 1,000; cabt., 3s. 6d. 1,000; 1/2 pl. P.S. mounts, 10 x 8 board, 4s. 6d. 100; 1-1 pl. ditto, 12 x 10 board, 6s. 6d. 100.—Smedley's.

CABINET Mounts from 12s. per 1,000, 6 sheet; C.D.V.'s from 3s. 6d. per 1,000; about 50 varieties sent you on receipt of 6 stamps; all orders delivered immediately on receipt.—Smedley's.

CABINET Negative retouched, dozen prints toned and finished from same, on customers' own mounts, 3s.; cartes, 2s.; postage extra.—W. F. Smith, 562 Oldham Road, Middleton, near Manchester.

DO you handle Enlargements, small or large quantities? It will pay you to write for prices.—Modern Art Co., 1 Empire Quadrant, Nottingham.

DON'T waste money on blotting-paper for backing up your printing frames; there is nothing to equal our rubber sheeting; never wears out; price, 1/2 pl. 6d., 1/2 pl. 1s., 1-1 pl. 1s. 9d. per doz.—Smedley's.

DALLMEYER'S 18 x 16 R.R. Patent, equal new, £11 10s.; 18 x 16 ditto, by Watson, iris, £8 10s.; Dallmeyer 1 B. Portrait, £2; 2 B. ditto, £5; Ross No. 4 Universal, a magnificent lens for 15 x 12, work either in or out door, £11 10s.—Smedley's.

ENLARGEMENTS of superior quality only, in carbon, plat., and bromide; also retouching; prompt return; cash and postage with order.—Otto Looser, 153 Duke Street, Liverpool.

ENLARGEMENTS and all Trade Work.—Bromides, 12 x 10, 1s. 3d.; 15 x 12, 1s. 9d.; sepia bromides, 12 x 10, 2s.; opals, oils, carbons, finishing, prompt return.—Carey, 53 Sandmere Road, Clapham, London.

ENLARGER by W. C. Hughes, fitted 4 1/2 x 3 1/2 rectangular compound condenser, extending front, best varnished leather bellows, sliding light chamber, with bellows for light centring, quick acting portrait lens, with rack and glass cap, carrier for 1/4-plate negatives, Hughes' special 4-wick lamp, rising front, all in the very best condition, £6 2s. 6d.—City Sale and Exchange, 81 Aldersgate Street, E.C.

FOGGY days follow a wet summer.—Boardman's Electric Light Apparatus for portraiture work is used in nearly 100 studios.—Write or call, 10 Southwark Bridge Road, S.E.

HAVE your Negatives carefully retouched and returned in 24 hours; cabinet heads from 2d each; C.D.V. from 1d. each; all good work; cash and postage with order.—J. Hinchliffe, Mere Hall Studio, Bolton.

MOUNTS—Latest tints; name and address in gold; cabinets, 3s. 100, post free; orders executed same day; lists and samples free; Xmas mounts ready.—Crown Photo Manufactory, Rotherham.

MOUNTS of every description at your own prices; send along a list of mounts you require and prices you are willing to pay; I will guarantee entire satisfaction.—The old firm, Hands, 11 and 13 King Henry's Walk, Midway Park, N. Established 1876. This appears fortnightly.

MOUNTS! MOUNTS! MOUNTS!—Photographers be wise and do a kindness to yourselves by sending us a trial order; we will serve you promptly, and at a much less price than any other firm can offer the same goods for; all orders delivered printed day after receipt.—Smedley's

MOUNTS—500 different kinds always in stock; a single 100 at wholesale price; latest design cabinet mounts, 3s. 6d. 100, 3/6s. 1,000; 1/2 pl. P.S., cream or grey, 7 x 5 tint, 10 x 8 board, 4s. 6d. 100, 40s. 1,000; printed free on orders of 1,000.—Smedley's.

OUR marvellous Rex Burnishers have no equal; absolutely the best value for money on earth; both rollers plated; heats internally, gas or spirit; 6 1/2 in., 21s.; 8 1/2 in., 38s.; 10 1/2 in., £3; approval anywhere.—Smedley's.

ORDER your Mounts to-day and we deliver to-morrow any quantity; name and address printed free; we only charge about half the price other firms do, and quality is the best.—Smedley's.

PLATE-SUNK Mounts, 13 x 11, tint 20 x 16 board, cream on white or grey, 12 sheet, 20s. 100; 16 x 13, tint 24 x 19 board, 25s. 100; Oxford line, 1/2 pl., 3s. 6d. 100, 30s. 1,000; 1-1 pl. ditto, 4s., 35s. 1,000.—Smedley's, Blackburn.

PHOTO Buttons.—Football groups sell well and pay well; send us print of group, and we will make sample button free.—The Crayon Art Company, 49B Brecknock Road, N.

PHOTO Postal Wrappers, ordinary kind, C.D.V., 15s. per 1,000; cabinet, 20s., printed; other sizes equally cheap.—Canesi and Co., 16 Clerkenwell Green, London, E.C.

PHOTO Postal Wrappers, Canesi's Patent (a marvel), guaranteed the best and at popular prices; C.D.V., 15s. per 1,000; cabinet, 25s., printed; other sizes equally cheap.

PHOTO Postal Wrappers, Canesi's Patent, C.D.V., 15s. per 1,000; cabinet, 25s., printed; of all photographic dealers or of the Manufacturer; stocked in all sizes.

PHOTO Postal Wrappers, Canesi's Patent; indispensable to photographers; C.D.V., 15s. per 1,000; cabinet, 25s., printed; samples and prices free.—Canesi and Co., 16 Clerkenwell Green, London, E.C.

PHOTOGRAPHY is rather an expensive hobby, but you can save money and secure a discount by purchasing your apparatus and materials from R. Vale and Co., 36 Nelson Street, New Road, E.

PORTABLE Dark-rooms from 30s., Studios from £7 10s., built in sections to bolt together, easily erected; strongly built; well painted; free on rail approval; photos and prices.—Warne, Portable House Builder, Beaconsfield Road, New Malden.

PICTURE-FRAMER'S complete Trade Guide, 2s. 11., contains how to take orders, what to charge, etc.—Engert, 123 Wilberforce Road, N. Miscellaneous frames, cut-out mounts, sundries.

RETOUCHING.—T. S. Bruce (Est. 1886).—Finest finish; sharp return; prices moderate; postal and personal lessons; tinting; send for price lists.—4 Villas-on-Heath, Vale, Hampstead, London.

RETOUCHING, Colouring, etc.—Your season's retouching will be executed with skill and despatch at your own prices if submitted to Wilson Creighton, 402, St. Ann's Road, Harringay, N.

RETOUCHING.—Cabinet heads, 6d.; 1/2, 3d.; full length, 2d.; Carte heads, 31.; cash and postage with order; satisfaction and promptness guaranteed.—Miss Rawson, Church Street, Dereham, Norfolk.

RETOUCHING (highest class); Cabinet Vignettes, 6d.; 1/2, 3d.; full, 2d.; Carte Vignettes, 3d.; 1/2, 2d.; cash and postage with order.—Charles Sayer, 250, Albion Road, Stoke Newington, London.

RETOUCHING.—Negatives carefully retouched at photographers' own prices; prompt return; cash and postage with order.—Address Miss Bell, 88 Midway Road, N.

RETOUCHING (highest class).—Cab. head from 6d., 1/2 3d., or at photographers' own prices; specimen free.—Address S. Wright, Station Road, St. Ives, Hunts.

RETOUCHER requires work at home; over eight years' experience; photographers' own terms; best finish; prompt returns.—Miss Taylor, 160 Tollington Park, N.

RETIRED Photographer can supply Prints from R good up-to-date Portrait Negatives; state wants.—Pyro, 24 Victoria Street, Brighton.

RETOUCHER (20 years with first-class West-End R firms) requires Home Work; specimen free.—Walter, 25 Coptic Street, New Oxford Street, W.C.

RETOUCHING (first class); prompt return guaranteed; Cabinet vign. 6d., 1/2 31., full 21.; carte vign. 3d., 1/2 2d., full 1d.; cash and postage with order.—Jas. Denton, 27 Rigault Road, Fulham, London, S.W.

RETOUCHING (highest class).—Cabinet busts from 6d., 1/2 lengths 3d., or at photographers own prices; cash and postage with order; satisfaction guaranteed.—J. Logan, 11 Sylvan Place, Edinburgh.

RETOUCHER, artistic (trained by Mr. Harold Baker, 5 years' experience), undertakes photographers' surplus work at their own prices; prompt return.—Miss Elwell, 50 Goldshill Rd., Handsworth, Birmingham.

SEND for a sample Background, 8 x 7, usual price £2 2s.; highest class possible 21s.; say whether interior or exterior; cash returned not satisfactory; several sent to choose from if carriage defrayed.—Smedley's.

SEND for sample dozen 1/4-plate rubber pads for backing up printing frames, post free, 1s. 2d.; will save you pounds during this damp weather.—Smedley's.

STUDIOS (shop-soiled).—A few at about half usual prices; genuine opportunity; approval with pleasure.—Barton's, Lanford Street, New Cross.

SIX very choice two-guinea Backgrounds, all as new, photos sent on receipt of 3 stamps, price 21s. each, 3 for 50s., 6 for £4 10s.; also some choice Group Backgrounds; state requirements; anything on approval.—Smedley's, Blackburn.

SMEDLEY'S Great Bargain Sale now on; hundreds of cameras, lenses, backgrounds, and photographic implements of every possible description to be cleared; only say what you want.—Smedley's, Blackburn.

SEND us P.O. 3s. 6d. for 100 Cabt. Mantello Mounts, and we will surprise you; no other firm can offer them less than double the price; printed free if quantity taken.—Smedley's.

tion, at its Plymouth meeting, in which he described his attempts to overcome over-exposure by increasing the quantity of pyro and bromide. This and the increase of the amount of bromide, with, in some cases, the lessening of the quantity of accelerator, has been the usual text-book axiom. Now Dr. Precht, of the Technische Hochschule, Hanover, has been experimenting, and discovers in acetone sulphite a means of obtaining fairly decent negatives with exposures ranging from 4,000 to 20,000 times the correct one. His results obtained with an over-exposure of 4,000 and 7,000 are reproduced in the "Photographisches Centralblatt," and certainly, whilst still showing over-exposure, they are quite presentable pictures. The developer used was the commercial edinol developer, and to this was added from 0.8 to 1.0 per cent. of the acetone sulphite. The image appears in from two to three minutes, and the total duration of development is about normal, but Dr. Precht prefers to develop only for ten or twelve minutes, when he states that a negative is obtained absolutely free from fog, and which can be readily intensified, but development can be carried on till sufficient density is obtained. Besides edinol, pyrophan seems to have been the only other developing agent tried, and this was successful. Pyrophan, by the bye, is stated to be a condensation product of pyro with an amido substance, and is made by the Bayer Company.

* * *

The Combined Toning and Fixing Bath.

MM. Lumière and Seyewitz have been studying the various chemical reactions which occur in the use of the combined toning and fixing bath, and have come to some conclusions which are directly opposed to the generally accepted statements on this subject. Their experiments were carried out with a gelatino-chloride emulsion spread on glass, thus eliminating any errors which might be introduced by the paper support. The most striking result of their researches is the fact that when a combined bath is used without lead the result is by no means satisfactory as regards the colour, and toning takes much longer, whereas the introduction of a lead salt causes quicker toning, and the colour is more satisfactory. Further than this, they prove that there is absolutely no lead in the final image, and that the lead salt plays the important part of causing the gold to be deposited, as the lead of the double hyposulphite of soda and lead displaces some of the metallic silver of the image, and is in turn displaced by the gold. It appears to be immaterial whether the nitrate, acetate, or chloride of lead be used, but the quantity should not exceed 0.4 or 0.5 parts in 1,000 parts of the bath. They also found that after four minutes' toning nearly 20 per cent. of the silver was replaced by gold, and that after forty-five minutes 39 per cent. of the image consisted of gold. Toning baths with acid gave rise to the formation of pentathionic acid, and if lead be present as well to the corresponding lead salt, but they have also proved that the tones given by these salts are not stable. The reasonable assumption is that the best way to make a combined toning and fixing bath is to use a small proportion of lead salt, chloride of gold, and hypo, and make it alkaline by the addition of some alkaline, earthy salt such as chalk, or magnesium carbonate.

New Illuminants.

The photographer away from the convenience of gas ought soon to be as well catered for as his city brethren, for there have appeared of late descriptions of a number of new illuminants which appear to possess the elements of success. The Bulletin No. 185 of the French Physical Society contains statistics

by M. Denayrouze referring to the use of methylated spirit in the lamp which bears his name. The lamp consists essentially of a wick conducting the liquid by capillarity into a compartment where, by means of a copper bar heated by the flame itself, it is converted into vapour, which passes through a small channel into a sort of modified Bunsen burner which heats a mantle. M. Denayrouze estimates that his lamp would consume each hour 1.08 grams of pure alcohol or 0.64 grams of carburetted alcohol, and the cost would work out at about 0.0048 and 0.003 of a penny per candle power per hour. Petroleum for the same light, he calculates, would cost nearly five times as much—0.014. Then, again, ether is coming to the front for the same purpose. Photographers are familiar with the value of ether saturators for the optical lantern, and in what might be termed a popular modification of this air is saturated with ether vapour, and then carburetted with benzol vapour. In the new carburetter, made in France, the fibre of a palm-like tree, which is extremely porous and light, its specific gravity being between 0.11 and 0.12, is used as an absorbent, and will take up nine times its weight of ether. If ether air-gas is used alone it requires a mantle, as the flame is only pale blue, though ether vapour itself gives a white smoky flame. When the flame is required to be luminous benzol vapour is added, and the mixture keeps in the gaseous condition so long as it does not fall below 21deg. F. 40 or 50 grams of ether per cubic metre of ether-air gas gives a product resembling oil gas in stability. The latter only costs about half as much as the new gas, but this again has the advantage of simplicity in the plant required, and the rapidity with which a small installation can be put up. Ether-air gas, according to Langlois, gives a light of about $9\frac{1}{2}$ candles for every 6.7 grams of ether burnt.

A Photographic Atlas of the Moon.

In a communication to "La Société Française de Photographie," Monsieur Wallon gives an account of the method adopted by Messrs. Loewy and Puiseux, of the Paris Observatory, in making their atlas of the moon. This is a work upon which they have been engaged for some years, and it will be of great value to astronomers. The plates are being reproduced on an enlarged scale by photogravure from negatives taken with the large equatorial, which is the most powerful instrument of the Paris Observatory. The photographic objective of the great equatorial was made by Messrs. Henry, and is of 60 cm. aperture and 18 metres focus. Usually the lens is stopped down to 54 cm. aperture. The correction of the lens is for the chemical rays, and the adjustment of the focus is repeated each month photographically by trial and error. The image of the moon in the original negatives varies between 160 and 180 mm., according to the distance of the satellite from the earth. The exposures with Lumière, or Helios, extra rapid plates vary between $\frac{1}{2}$ and 4sec., according to the phase, and the clearness of the atmosphere. The lens remains stationary, but the plate is moved by a Foucault clock and cylindrical gearing. As the movement of the moon is variable, the problem is a complicated one, but 3,600 different rates of speed may be obtained by the mechanism, and it is therefore easy to make suitable adjustments. The shutter is a sheet of aluminium placed immediately in front of the plate. It slides in grooves, and is controlled by hand, by means of a rod and crank, so that the brightest parts of the moon's surface receive least exposure. A tubular sky-shade 1.50 m. in length is placed on the front of the lens when photographs are made during twilight. The plates are developed with amidol and anhydrous sulphite of soda to preserve the greatest trans-

parency in the deposit. The enlargements are made by electric arc light, and the lens used is a Lerebours and Secrétan single-achromatic meniscus of 310 mm. focus, with convex surface to the light, stopped down to 10 mm. This gives perfect definition of the grain of the negative over the entire surface of the enlargement 80 c. by 80 c. Various other lenses have been tried, but none have given such satisfactory results. Different methods of focussing have been tried, but the best criterion of definition has been found in the grain of the plate as seen in the image upon a white screen. A slight displacement of the lens removes the grain and gives a more agreeable visual image, but for exactness the grain is retained. To obtain equality of exposure and full detail in the shadows, the light is passed through a screen with a slit a few millimetres wide before it reaches the condenser. This screen is kept in motion, and can be used locally. The scale of enlargement varies between 10 and 16 times. The plates are backed with dextrine and red ochre. About 400 photographs have already been made, but a few difficult phases of the moon are still wanting to complete the atlas.

THE ALLEGED INSTABILITY OF COLLODIO-CHLORIDE PICTURES.

IN our issue of last week we replied to a correspondent on a question that is, just now, of more than passing interest to users of collodio-chloride papers. We here give an extract from our correspondent's letter. He says:—"I constantly read of the alleged permanence of CC. over gelatine papers. I cannot understand why, in my hands, CC. does not seem to stand the test of time. My platinum-toned prints are a splendid black, and really beautiful to see when finished, and my customers will have no other; but it seems that in a month or so (often less) they begin to show spots, and the black tone changes to a muddy brown," etc. The above is by no means the first complaint we have heard of collodio-chloride prints becoming spotty, or changed, in some way or other, within a comparatively brief period, though, we may mention, never in so short a time as this writer says. It is a noteworthy fact that in all the instances of rapid change that have come under notice the prints have been toned with platinum subsequently to being partially toned with gold.

The opinion has more than once been expressed by us that the collodio-chloride process should be the most permanent of all silver processes, and practice has proved that prints made in the very earliest days of it are still as good as at first. Some we remember commenting upon, that were shown in the Victorian Exhibition at the Crystal Palace, in 1897, that were printed nearly thirty years before, and they showed not the slightest change; and we have some by us quite as old which are still in their pristine state. The prints shown at the Crystal Palace were on paper that was made in Germany; those we have are on paper of other preparation. But all were toned in the sulpho-cyanide bath—the one that has been universally employed in this process until the, comparatively, recent introduction of the gold-platinum method of toning.

It has just been mentioned that, theoretically, this process should be the most stable of all silver processes, and for this reason: Collodion, the medium carrying the silver salts, forms no compound with the free silver present in this, as in all printing-out papers. It is quite an inert vehicle. The case is different with albumen, and with gelatine, as with them an organic compound is formed which, in the case of albumen, at least, is not entirely removed in the fixing and the after-washing of the prints, and it is this so-called "albumenate of silver" which

is usually said is the cause of so many albumen prints turning yellow with age. The same has been said with regard to gelatine, whether well founded or not, but with collodion no such compound is formed, and all the un-acted upon, by light, chloride is easily dissolved or rendered in a soluble condition in the washing waters, even when the fixing solution is comparatively weak.

It may be as well to point out here that there is an essential difference between the collodion papers of the present day and those that used to be made some thirty, or more, years ago, and that difference may have much to do with the present complaints of lack of permanence quite apart from the more modern system of the compound gold and platinum toning. When the process was first introduced (1864) the paper then employed was the same as that used for albumenising. It was simply prepared with a very thin coating of arrowroot before the emulsion was applied. The free nitrate of silver in the emulsion had little or no affinity for the preliminary coating, or for the paper below it; consequently nothing but the visible image, presumably, remained when the picture was finished. The case is different now. The commercial collodion papers have, instead of arrowroot, a pigmented coating said to be baryta. Now this coating, whatever it may be, has to be held to the paper by a cement of some kind or other, the nature of which we know nothing. It may be gelatine, starch, flour paste, or a mixture of them, together with something that will render it insoluble in water, for that it must be.

Now, it is quite conceivable that the free silver in the emulsion may, and probably does, form with this vehicle, or cement, an organic compound of silver which in the fixing of the prints is not dissolved or rendered sufficiently soluble to be removed in the subsequent washings. This is rendered the more probable by the fact that the fixing bath recommended by some of the makers of collodion papers—and the majority of them are made abroad—is very much weaker than those used either for albumen or gelatine. In the directions for a collodion paper now before us we are told to fix for about ten minutes in hypo one ounce, water twenty ounces. It will here be noted that this is less than half the strength that is generally employed with either albumen or gelatine papers, while the time of immersion is less. It is true that this strength of bath, and time of immersion, would be ample, provided we were dealing simply with the collodion film *per se*, say, if it were on a glass plate. But is that the case if, as may well be assumed, there is a silver compound in the pigmented coating beneath the collodion? If that is the case, it would seem that fixing in this strength of solution, and for this length of time, is quite inadequate, seeing that the collodion film is, to an extent, an impervious substance, and thus in a degree obstructs the free action of the fixing solution and the water from the compound beneath it.

We have on more than one occasion referred to the effect that this so-called "baryta coating" may have on the stability of gelatine prints that sometimes quickly show signs of deterioration; there, however, the conditions are somewhat different, inasmuch as, unlike collodion, gelatine is not an impervious material, for it is readily permeable both by the fixing solution and by the washing waters.

Having pointed out the difference between the conditions, both as regards the preparation of the paper and the method of toning, under which the collodio-chloride pictures that were made thirty, or more, years ago, which have so well withstood the test of time, and some of those produced now, which have proved so fugitive, we may fairly look for the cause rather in the direction of the preliminary coating of the paper than in that of the present method of toning first with gold and then with platinum.

NAPHTHALI P. SALONIKER, ESQ., INTERVIEWED BY A
PLAIN PHOTOGRAPHER.

HE *did* live in an ordinary house—at least, as regards its outside appearance, it was just like other houses. I rather wondered at this. I somehow expected to see him domiciled in an edifice without a roof, or with a wall chopped off, or something equally erie. Anyhow, the house was the only ordinary thing about him. Everything else was—like his “work”—extraordinary, but not extraordinary in a flattering sense. At least, I know I should consider myself insulted if I was told I was extraordinary—after the manner in which one would apply the term to Saloniker. To begin with, his appearance was distinctly sloppy—slovenly, people who were not art critics might call it. I will not go into details of his attire—to my mind they are painful, and besides it were superfluous to do so, when they have been responsible for so many people’s nightmares, after seeing his portrait (produced by kindred spirits) pervading the walls of the exhibitions. So I will content myself with remarking that his affectations of dress (or undress?) were quite in harmony with the impression his works created. Another extraordinary thing was the extraordinariness of the muddle and mess which appeared to be his inspiration. It was all one maze of muddles within messes, that room which he called his “studio.” I told him I came as a learner. I could never pretend, I explained, to attain such lofty heights of misty mysteriousness as he had climbed (I hardly thought it wise to add I did not want to). But I had to confess that I was one of the contemptible remnant who was content to make an ordinary use of the camera and photographic materials in general, so, of course, had no claim to be called an artist; but, for all that, I was not above learning. Would he show me some of his pictures?—might I learn something, at least, of the mysteriousness of his methods? He was very kind. He brought forth for my edification something very weird indeed, and informed me he intended it for the exhibitions. “That’s bound to score, you know,” said he, as he held the thing up to my bewildered gaze. As I looked on it, I marvelled at the idea of framing—on a sea of mount—a sooty, ragged piece of paper, and honestly thought it must be an entry for some new craze, such as a “Waste paper basket” competition. Evidently, as I gazed on, Saloniker thought words failed me—so they did—therefore he explained. “It’s the study of a nose,” said he. “Clever, isn’t it?” “Distinctly original in conception,” I murmured. “So glad you like it,” he replied. “Yes, I flatter myself it is a bit out of the common.” (“Thank goodness for that!” I inwardly ejaculated.) What I saw was something which might have been anything or nothing—mostly nothing—hiding itself (as, after all, well it might) in a thick murkiness of ink or some such medium, the whole thing indefinite and splodgy (and evidently worked up with a flue brush), marring the surface of what *once* had been good paper. I thought, too, that it was a pity that, even if they had given him a long hunt, Saloniker had not found either the scissors or the knife before he mounted the defaced paper; the tears round the edges looked horribly untidy. I could have cut four mounts out of the amount of paper he used for one. Then, apparently, he had not a straight eye, for the “study” was pasted all out of the centre. But, perhaps, that was to give room for the proper announcement of the title. The “study” certainly did require explanation, and doubtless the surrounding erratic wanderings of his pen did duty for embellishments. Or, perhaps, they were only to fill up. There did not seem to be any frame at all at first sight, but afterwards I discovered it, and could not help wondering how the glass kept in it. After all these internal musings, I felt I was bound to say something, so I remarked that I supposed he had

been influenced by reading of the Inquisition or French Revolution: “Don’t see what that’s got to do with photography,” said Saloniker. Neither did I; but I said that I thought perhaps he was striving by his pictures to make people realise the horrors of the atrocities perpetrated upon the victims of these periods of terror. He laughed in a pitying, superior sort of way. “We have to teach the multitude that the governing principle in art is to subordinate everything to the central object of your picture. To this everything else must be subsidiary. That’s why that nose is so strikingly clever. There’s no counter attraction—nothing to cause the eye to wander from the beauty of its curves—no competitive ears, mouth, or eyes.” I said it was quite right what he said about lack of attractions, and hazarded the remark that his views hardly found support amongst the works of any of the Old Masters, or, indeed, of any painters. They did not seem to care about illustrating amputations and other surgical operations. “Oh, no; you will find nothing like that little thing of mine amongst any of those old Johnnies,” said Saloniker. “But, then, you can hardly blame them. No doubt they painted with all the light they had, but then, of course, art had not reached that pitch of perfection it has now attained.” I inwardly mused as he talked about light, that he could not surely be taken too literally, as all his studies seemed to be made in the dark—if, indeed, not in the coalhole; but I only remarked, in reply to the foregoing, that I supposed in the brightest days of the Old Masters there were no Americans about. I might have learnt more of true art principles, but just at this point, Saloniker pulled out his watch, and said he had an appointment to keep with a girl of whose elbow he intended to create a picture, and he was sorry he could not prolong the interview. I said he need not apologise—I had had sufficient time to have my eyes opened. I did not tell him in what direction; but I do not mind telling you that I went away entirely convinced of the utter untenability of Saloniker’s theories of art. But then people tell me I am “so English.” I know I am, and why should I be ashamed of it? I have no objection to people admiring either the art of the Americans or the photographic productions of the Parisians, so what grounds have *they* for sneering at my liking for a clean English school of photography? As long as the latter is synonymous with sanity, so long may it flourish. It is at that rate bound to outlive mere eccentricity—a most inconstant quality. And some of us will not be sorry to say a long farewell to it. I know I will not.

“ENLARGING by Artificial Light” (referred to in our correspondence columns last week) is a little pamphlet published by Messrs. Perken, Son, and Co., Limited, 99, Hatton Garden, E.C., which deals succinctly with the production of enlarged images on glass (paper) and by projection. A list of enlarging apparatus and accessories is appended. The pamphlet, which is obtainable free, is instructive and useful.

LEEDS Technical School.—A class in the principles and practice of photography will be held during the session 1902-3. The class will meet on Mondays, from 7 to 8.30 p.m., in Room 11 (entrance from Rossington Street), commencing on September 29th, 1902. The teacher is Mr. S. E. Bottomley. The course is specially arranged to meet the requirements of both amateur and professional photographers, and is intended to give them a thorough knowledge of the principles underlying the theory and practice of pure photography. A syllabus has been compiled and includes:—The elements of photographic optics; the photographic camera—its adjuncts; the theory of light as applied to photography; the theory of the photographic image—development, fixing, printing, etc.; the practice and theory of gelatine dry plate process; composition and defects of dry plates—defects of gelatine negatives—causes and remedies; various methods of developing—a general knowledge of chemicals employed; printing processes—carbon, platinotype, gelatino-chloride, etc.; enlargements and lantern slides; applications of photography to scientific and technical purposes. Each lecture will be illustrated by practical demonstration; opportunity will also be given for the student to perform practical work. At the close of each lecture time has been arranged for the criticism of students’ work, and the clearing up of any difficulties that may arise. Every encouragement will be given to students wishing to take the examinations in theoretical and practical photography, under the City and Guilds of London Institute.

LONDON COUNTY COUNCIL SCHOOL OF PHOTO-ENGRAVING AND LITHOGRAPHY.

[Abstracted from the Prospectus.]

THE object of the school is to give instruction in the craft of producing surfaces for printing. Of the various classes held, some are concerned with the more artistic side of the work, others with the technical; there is, however, no real line of demarcation between the two, either in intention or practice, and the division is made solely for convenience of teaching. Instruction is given in the most important photo-mechanical processes, block proving, elementary photography, photographic copying, general lithography, map and plan drawing, transfer writing, design, lettering, and drawing.

The school is open to those who are genuinely engaged in business in any branch of the photo-mechanical, photographic, designing, lithographic, engraving, printing, and book illustrating crafts, and no provision whatever is made for amateurs. In some cases the classes are confined to those who are directly engaged in the particular branch taught. The Technical Education Board of the London County Council is open to consider applications from parents who intend placing their sons as apprentices to any of the above trades, and who may be desirous of giving them the advantage of a preparatory school training; but it is to be understood that such students must be duly apprenticed within some period to be arranged.

The practical instruction given is not intended to replace workshop training, but is preparatory or supplementary to it, and has also for its object the giving to those engaged in one particular department of a craft a knowledge of allied branches which, in the ordinary course of trade, they cannot obtain. The lecture courses are for the purpose of explaining more fully the technical principles and details of the various processes than is convenient during the conduct of the practical classes.

The school is excellently equipped with the necessary appliances for study and practical work. It contains a large photographic studio, with two cameras, and powerful electric light installation of the most modern pattern, two dark-rooms, sensitising room, glass cleaning and intensifying rooms, tri-colour dark-room, extensive etching and printing rooms—complete with electric light and all modern appliances—colloTYPE preparation and printing rooms, with three presses and all necessary equipment, a photogravure room, and a reading room and museum of specimens and examples. There are also two large rooms for lithographic drawing, and a press room, as well as separate studios for design, antique, and life and costume drawing.

Attention is called to the following new classes:—Photogravure. Proving. Preparation of originals for reproduction.

SYLLABUS.—EVENING CLASSES.—PHOTOGRAPHY.

The course of instruction deals with the production of negatives and positives required for the various photo-mechanical processes, and also for the reproduction of pictures, etc., by the usual photographic printing methods, as carbon, platinum, and silver. Beginners are required to join the elementary class, in which they receive instruction in the technology and practice of ordinary negative making and silver printing, and, later, in wet collodion photography as far as the making of line negatives from simple subjects. When they have mastered the technique of this class, which is elementary, they should take more difficult work in line negative making, as provided for in the advanced class, where, in addition, is taught the making of ordinary negatives (continuous tone) from originals in monotone, such as are required for the various light printing processes (carbon, platinum, silver), and for collotype, photo-

gravure, etc. In this class both wet and dry plates are used, and instruction is also given in the preparation of collodion. For students who have passed through these courses, and who are sufficiently advanced, arrangements will be made for demonstrating the method of copying originals in colour by orthochromatic methods, using gelatine plates and collodion emulsion. The class in screen negative making is confined to those who have a good knowledge of photographic methods (including wet plate work); and as the number of students that can be dealt with is comparatively small, preference is always given to those who are engaged in branches of process work where a knowledge of screen negative making will be directly and practically useful. The work of the various classes will be progressive, but, in order to help those who join after the opening of the terms when the classes commence their work, demonstrations will be given of the various processes on the first class night in each month, after which students will be able to work by themselves under the teachers' guidance.

Line and continuous tone negative making.—Beginners.—Teacher: The Principal (*pro tem.*).—Camera manipulation. Preparation of necessary solutions. Making ordinary negatives on dry plates of drawings and objects in relief. Manipulations in lighting, exposure, development, and finishing. Printing from the negative. Principles of wet collodion photography. Preparation of the silver nitrate sensitising bath. Glass cleaning. Coating. Sensitising. Exposing and developing. Intensifying. Stripping negatives.

Advanced line and continuous tone negative making.—Teacher: The Principal.—This course will deal with the more difficult branches of line negative work and the making of ordinary negatives, such as are required for the various contact light printing processes, as carbon, platinum, and silver, and for enlarging and collotype. The work is principally copying, but as far as is practicable, objects in relief will be dealt with. Instruction is given also in the making of transparencies for negative reproduction and for photogravure, and in printing by the albumen, silver, platinum, and bromide processes. The processes employed are wet collodion, collodion emulsion, and gelatine plates. The students are required to show that they have sufficient knowledge to enable them to profit by the instruction given. The class is confined to eight students.

Screen negative making.—Teacher: The Principal.—This course deals with the making of negatives by means of ruled cross lines and irregular grain screens. The work is a special department of negative making, and the class will be confined to those who are engaged in branches of process work where a knowledge of these methods will be directly and practically useful. In order to give greater facility for practice, the class hours have been extended. As it is important that operators should possess a knowledge of the printing processes for which their negatives will be used, it is strongly urged that all who have not this qualification should endeavour to obtain it, and for this purpose they are advised to join the special classes.

TRI-COLOUR PROCESS WORK AND COLOUR PHOTOGRAPHY.

A scheme of instruction in the above subject has been arranged in conjunction with the Northampton Institute, Clerkwell. The work will be divided into two portions: the first, which deals with the theoretical branches and the preparation of the colour filters, will be undertaken by the Northampton Institute; while the practical work of negative and block making will be carried on at Bolt Court. Although these courses are to a certain extent independent, it is hoped that students will endeavour to attend both. Very complete arrangements have been made at the Northampton Institute for demonstrating, in a strictly practical manner, the various

principles underlying tri-colour work, and excellent photographic equipment will be at the disposal of students.

Tri-colour block making.—The course will be confined to those who are practically engaged in business in process block work, either as screen negative makers, printers, or etchers. The practical work will consist of tri-colour screen negative making direct from the original, and also by the usual indirect method, transparency production, block making, finishing, and proving. Students who have no knowledge of etching are advised to join the enameline etching class, and those who cannot make screen negatives should join a negative making class. The class is limited to twelve students, and those who wish to join must make application in writing to the Principal.

The instruction will be given on Tuesday and Friday evenings, between 7 and 9.30. The following is the course of work, which extends over the whole session from September to June: Explanatory introduction to the process. The arrangement of apparatus. Preparation and testing of light filters. Making the negatives from a coloured original by the direct and indirect processes. Preparation of transparencies and screen negatives. Printing on metal. Etching and fine etching. Proving.

For the first part of the course, on Friday evenings, the tuition will be given at the Northampton Institute, where special arrangements for the work are made. Later, the Friday evenings will be devoted to work in the etching room at Bolt Court. On Tuesday evenings throughout the session the work will be carried on in the studio and dark-rooms at Bolt Court. Students joining the course after the commencement will be required to take up the work at the stage at which they find it. Each worker will, it is hoped, be able to complete at least one example, carrying out the various stages of the process himself.

Tri-colour process work.—A course of lecture demonstrations with practical work will be given on Friday evenings, at the Northampton Institute, commencing October 3rd. Tri-colour process work is now being rapidly taken up for colour illustrations, and its advantages in some respects are being realised. In order, however, to produce satisfactory results in an economical manner, great care is necessary in the preparation of the colour screens and the making of the negatives. Not only so, but due regard must be paid to the proper selection of the printing inks, and to the making of the blocks and printing therefrom. The object of the course is to give process workers a general account of the methods in use, and to point out the best conditions for obtaining correct colour representations with the minimum of hand work.

Colour measurement and photography and the theory of tri-colour.—Lecturers: Mr. A. J. Bull and Mr. Newton.—Syllabus.—Colour measurement.—Introduction. Nature of white and coloured light. Selective absorption. Primary pigment colours and primary colour sensations. Tri-colour theory of vision. Work of Young, Helmholtz, Maxwell, Koenig, and Abney. Colour patch apparatus. Methods of plotting colour luminosity curves and measuring colours.

Principles of colour photography.—Theories of the two classes of tri-colour methods. Explanation of Ives' and Joly's processes. Testing of colour filters. Explanation of Lumière's process and tri-colour printing; difficulties of correct rendering of colour by tri-colour half-tone, true printing colours, errors of registration, order of printing.

Practical work.—All students who wish to follow clearly the lecture course should attend the laboratory class held on the same evening. The laboratory work at the Northampton Institute will consist of the production and spectroscopic testing of the colour filters and pigments, and the arrangement of the

camera and lighting and production of the continuous tone negative. Students should familiarise themselves with the use of the spectroscope, colour top, and tintometer, and will have an opportunity of measuring and comparing and specifying colours. At the Bolt Court School screen negatives and blocks are prepared, and the necessary finishing, mounting, and proving of the blocks will be carried on. The instruction, however, at this school is reserved for those who are engaged in the photo process trade.

PRINTING AND ETCHING PROCESSES.

In this section instruction is given in the most important photo-mechanical processes. The various workrooms are well-fitted and furnished with all the necessary appliances for practical work, and the students have full opportunity given to them for obtaining a good knowledge of any process included in the section to which they desire to devote their attention. As far as is practicable, students may practise in the etching rooms when they are not in use for class instruction. Application should be made to the Principal for permission.

Line blocks on zinc, brass, and copper.—Teacher: Mr. F. Lamb.—This course deals with the making of relief blocks on zinc by the "roller" and "powder" processes. Laying tints. Rush work. Relief blocks for bookbinders.

Tone blocks on zinc, brass, and copper.—Teacher: The Principal (*pro tem.*)—This course is for the purpose of giving instruction principally in the enameline (or "fish glue") process, and its application to the production of half-tone blocks in zinc, copper, and brass, but albumen, dry enamel, and other methods will also be shown. Each student is taught printing and etching, but those who require special instruction in fine etching should join the class held for this purpose.

Fine etching.—Teacher: Mr. J. M. Johnstone.—In this class instruction is given in fine etching and finishing half-tone blocks. Students may take this course by itself, or in addition to the other etching classes. It is strongly recommended to those who wish to learn fine etching that (if they have not already had some artistic training) they should devote some time to drawing. Each student is required to provide himself with brushes. Demonstrations for new students on the first Wednesday in each month. A section will be devoted to advanced students, and special attention given to vignetting.

Collotype and photo-lithography.—Teacher: Mr. J. T. Butterfield.—This class deals with the making of the collotype plate with printing from the same, and with the production of photolithographs by the direct and transfer processes. The classrooms are fitted with all the necessary appliances for teaching the process, and the students have full opportunity for regularly practising the various operations. The class hours are from 7.30 to 9.30 on Tuesday evenings, but those who are able may also come for practice between 7 and 9.30 on Thursday evenings, by obtaining permission from the Principal. It is also required that all members of the class shall make themselves practically acquainted with the exposing of collotype plates, and for this purpose they may attend the school on Saturday afternoon or some other time during the day by arrangement. In addition to the work in the school, students will be given full opportunity of acquiring a knowledge by actual practical experience of the working of a collotype power machine. Upon such occasions the instruction will be given on Saturday afternoons, instead of Tuesday evenings.

Proving.—Teacher (to be appointed).—Demonstrations will be given, showing the conditions necessary for line and fine half-tone proving. The machinery required: Hand press,

machine presses; the ink, the paper. Underlaying, overlaying. Proving vignettes. Proving in colour.

Photogravure.—Teacher (to be appointed).—Principles of Intaglio etching. Making the negative. Sensitising the tissue. Making carbon transparency. Retouching. Graining the copper. Transferring to copper. Drying the film. Stopping out. Etching fluid. Etching the plate. Retouching copper after etching. Proving. Steelfacing.

The preparation of originals for reproduction.—Teacher (to be appointed).—Qualities required. The working-up of negatives, transparencies, silver prints. Bromide or black and white prints. "Half-tones" or engravings. Defective drawings. Catalogue illustrations. The use of the air brush.

Half-tone process work.—Lecturer: The Principal.—A course of six lecture demonstrations with practical work will be given on Friday evenings, from February 27th to April 3rd inclusive, from 8 to 9.30 p.m. This course will give the simplest possible exposition of the scientific principles underlying half-tone work, and also an account of the best practical methods and plant to be employed, the object being to give students engaged in merely one branch a knowledge of the process as a whole.

Lecture demonstrations.—Syllabus.—Object of breaking up continuous tone into line and dot for relief printing. Mechanical methods of converting bas-relief into line and dot. Use of V tool. Optical methods of breaking up. Use of cross-line screen. Conditions for securing true optical V. Influence of width of screen ruling. Shape of stop. Distance of screen and sensitiveness of plate on the result. Practical details concerning process cameras, lenses, and accessories. Lighting. Exposure and development. Preparation of blocks. Printing, etching, etc. Fine etching. Finishing blocks. Routing. Details of mounting and finishing machinery. Choice of paper and printing.

Time table of evening classes, L.C.C. School of Photo-engraving and Lithography.—Monday.—Screen negative making, 7 to 9.45; line blocks, 7 to 9.30; colour, 7 to 10. Tuesday.—Lithography, 7.15 to 9.15; tri-colour blocks, 7 to 9.30; collotype, 7.30 to 9.30; preparation of originals, 7 to 9.30. Wednesday.—Advanced line negative, 7 to 9; fine etching, 7 to 9.30; photogravure, 7 to 9.30. Thursday.—Lithography, 7.15 to 9.15; elementary line negative, 7 to 9.30; half-tone etching, 7 to 9.30; proving, 7 to 9.30. Friday.—Tri-colour lectures, 8 to 10; half-tone process lectures, 8 to 9.30. Saturday.—Colour, 2 to 4.30; the school is open from 2 to 4.30 for practice.

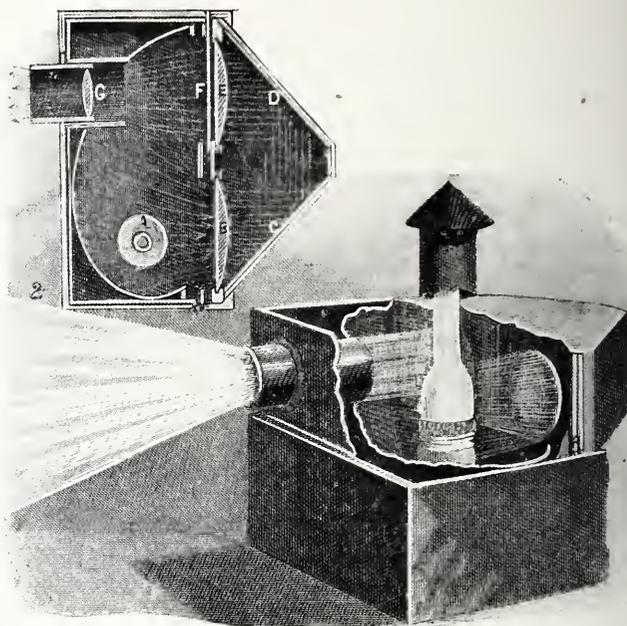

POISONING by Potassium Cyanide.—Messrs. Burroughs, Wellcome, and Co., write to the "Pharmaceutical Journal":—"Referring to the case of poisoning by potassium cyanide, reported in the 'Pharmaceutical Journal' of September 13, page 289, column 1, we notice you write that a man 'was found dead on Hampstead Heath with some broken tablets of potassium cyanide in his pocket.' It will, no doubt, be well known to the majority of your readers that we do not issue potassium cyanide tablets, but as others may be misled we should be glad if you would give similar prominence to a statement that your report was inaccurate. On the authority of the coroner we are able to state that the potassium cyanide found on the man was in rough lumps, and that its resemblance to tablets existed only in the imagination of the reporter."

In connection with the County Council of Northumberland's scheme of technical education, the local committee of the Hexham centre has arranged a course of twelve lectures upon Elementary Photography, which will be delivered by Mr. John Gibson, F.C.S., commencing Wednesday, October 1st, at 7.30 p.m., in the Guardians' Board Room, Town Hall Buildings, Hexham. The abridged syllabus is as follows:—Photography and its practical use in science, art, medicine, surgery, law, literature, agriculture, and commerce generally. Silver and other salts affected by light. The spectrum. Lenses and their construction, their use and misuse. The camera and its construction, and the principles and practices necessary in its use. Plates, films, and developers; negatives, good and bad. Causes of failure, and suggestions for improvement of imperfect negatives. Lantern slide making, and the use of the lantern in photography. Printing and toning of printing-out papers. Bromide, platinotype, carbon, and other printing and developing processes. Art in photography. Photography as applied to special subjects, with a brief outline of the same.

IMPROVED PICTURE PROJECTING APPARATUS.

[Reprinted from "The Scientific American."]

HERETOFORE magic lanterns have been devised either for projecting transparent pictures only, or for projecting opaque pictures only. Some transparency projectors, however, have been provided with an attachment whereby the same may be converted into a projector for opaque pictures. While this is suitable for certain classes of exhibition it nevertheless falls short of the requirements when it is desired to exhibit transparent and opaque pictures interchangeably; for considerable time is consumed, and trouble involved, in making proper adjustments necessary to effect the change from one class of picture to the other. Moreover, certain specially interesting pictures or objects—viz., those partly transparent and partly opaque—cannot be projected by such lanterns. With these conditions in mind Mr. George W. Smith, of Evanston, Ill., has recently produced and patented an apparatus which will project any class of picture or object without requiring any special adjustment. The invention is applicable to any kind of magic lantern, but more particularly to the form commonly known as the megascope.

As shown in our illustration, the invention comprises a lantern box, at the rear of which is hinged a reflection chamber having vertical walls arranged obliquely with respect to the front wall of the box. A light, A, for example a Welsbach light, is located at one side of the lantern box at one focus of an ellipsoidal reflector, the picture or object to be projected being inserted at the other focus. On the opposite side an opening is formed in the reflector for the admission of the objective tube. Rays from light, A, pass through a condensing lens, B, to one of the oblique walls of the reflector chamber. Reflectors, C and D, are provided on these walls and they act to reflect the rays back through a condensing lens, E. A transparent lantern slide, F, when placed before the lens, E, intercepts the rays and permits the proper gradations of light and shadow to be projected by lens, G, on to the screen. Such is the effect when a transparent slide is used. When an opaque slide is to be projected, the direct rays from lamp, A, and also the indirect rays concentrated by the ellipsoidal reflector, illuminate the front of the slide; and the proper image is thus reflected through lens, G, to the screen. If the slide be partly opaque and partly transparent or translucent, the lantern will operate simultaneously as a megascope and sciopicon combined, thus, with-

out any change, producing unique effects in a very simple, inexpensive and yet satisfactory manner.

The lantern should be very useful for scientific purposes for the reason that the same object may be projected by reflected light alone or by transmitted light alone, or by both simultaneously without removing the slide or changing the adjustment of the projector.

TELEPHOTOGRAPHY AND FLATNESS.

THE telephotographic lens has now so far gained a recognised position in every well-appointed photographic kit that no apology is needed for bringing to notice what has been considered one of its weaknesses, and endeavouring to trace its cause or causes, and indicating the direction in which a cure may be wholly or partially found. A general flatness or want of contrast has long troubled the telephotographer, until he has in many cases come to consider it due to some inherent defect in the optical system itself, and to reluctantly put his telephoto lens on the shelf, considering it more as a scientific curiosity than as a valuable working tool. A little consideration will show, however, that the telephoto lens, as such, has little to do with the trouble, which arises almost entirely from disregard of the conditions under which telephotographs have necessarily to be taken. Let us, for a moment, examine a good photograph of an open view, with a foreground of rocks, trees, or houses, with a distant glimpse of cliffs, or, perhaps, the turrets and spires of a neighbouring city. Here we find everything in harmony, the shadows in the foreground being fairly strong, while those in the middle and far distance become softer and less pronounced, as they were farther removed from the camera; in fact, we find a perfect example of "aerial perspective." Now let us cut a small opening, say the size of a postage stamp, in a sheet of paper, and place this so as to act as a frame to the small building or portion of cliff, of which we desire to obtain a record with the telephoto lens, and we shall at once recognise that we have a miniature picture which is suffering from an excessive lack of contrast, and which, if enlarged, would present the appearance of a rather poorly-defined telephotograph. Why is this? In the first place, it is probably due to over-exposure. The user of a telephotographic lens is apt to forget, in his earlier exposures, at all events, that he has no near foreground shadows to consider, and blissfully multiplies the exposure necessary for an ordinary view by the "square of the magnification," with the result that he gets a flat, washed-out looking picture, which convinces him either that the telephoto lens is a failure, or that the rule for calculating exposures is hopelessly wrong. In the latter case there is hope for him, for his investigations may lead him to the table of exposures formulated by Mr. Howard Farmer, which deserves a place inside the camera case of every photographer who cannot find a place for it inside his head. It runs as follows:—

With lens aperture $f.8$, instantaneous plates, sun's altitude not less than 25 deg., and either blue sky or white clouds.

Distance of nearest important object, if sun is not shining; or nearest important shadow, if the sun be shining on portion of the subject only:—10ft., 1 second; 10ft. to 30ft., $\frac{1}{2}$ second; 30ft. to 100ft., $\frac{1}{4}$ second; 100ft. to 100yds., $\frac{1}{8}$ second; 100yds. to $\frac{1}{4}$ mile, 1-16 second; beyond $\frac{1}{4}$ mile, 1-30 second. Subjects entirely in sunlight, or with insignificant shadows only, 1-10 second, for very near, to 1-40 second for open subjects.

It must be remembered that the above is a table of comparative and not absolutely correct exposures, and that time of year, the hour of the day, and the speed of the plate in use

will all take part in modifying the figures therein given; but it will, on the whole, be found to provide a good and safe starting point.

Atmospheric haze is a common cause of flatness, and although it is useless to expect any lens to penetrate a white mist, the effect of a blue haze may be in a great measure avoided by employing an isochromatic screen. If orthochromatic plates be used, any of the many forms of yellow screen or the liquid "ray filters" will be found to answer well, while with ordinary plates the green and amber screen invented by Mr. Burchett will be found very useful, without unduly prolonging the exposure. Heat haze or shimmer caused by currents of heated air rising from the earth will sometimes give trouble, but for this there is, of course, no remedy. As a general rule, telephotographs should be taken with a stronger or "harder" lighting than would be desirable for ordinary work, and many of the most successful pictures are to be obtained with early rays of sunrise or the oblique lighting of sunset.

Especial care should be taken to avoid reflections from the inside of the lens tube, which it is advisable to line with black velvet; the glasses of both positive and negative lens should be carefully cleaned immediately before use, for an amount of smokiness which would be negligible for ordinary work would seriously reduce the brilliancy of a telephotographic negative.

Telephotographic negatives require more patience and careful treatment in development than is usually accorded to them. Having avoided over-exposure, the next thing is to eschew under-development. A very interesting and profitable experiment is to make two identical exposures, and to withdraw one from the developing dish at the point at which you usually stop, allowing the other to develop for twenty minutes or even half-an-hour longer. This can easily be done by means of a vertical bath or mechanical rocker, while proceeding with other work. The difference in the printing quality of the negatives will be surprising, and in most cases the value of the additional development highly satisfactory.

Intensification may frequently be necessary, and an intensifier which does not tend to stain or block up the shadows is to be preferred. "Monckhoven's" cyanide of silver formula does well, and the single solution uranium intensifier is also suitable. The printing quality of a uranium intensified negative is, it should be remembered, much better than it appears. The ordinary mercury and ammonia intensifier has a tendency to "thicken" telephotographic negatives, or any others which in themselves lack contrasts, without giving the brilliancy to be obtained by the methods mentioned above.

It is hardly necessary to say that the plate used for telephotography should be one which will stand prolonged action of the developer without becoming veiled, and for this reason the most rapid brands should, as a rule, be avoided. Paradoxical as it may appear, it is nevertheless true that a slow plate may give a better result than a rapid one with the same exposure, for the former will stand "forcing" to obtain printing density, while the latter will begin to fog long before the high lights are sufficiently strong.

E. CLIFTON.

TRAILL-TAYLOR Memorial.—There will be a meeting of the committee at the White Swan Hotel, Tudor Street, E.C., on Thursday evening, the 25th September, at 7.30, with reference to this year's lectureship.

A SPECIAL list of mounts, albums, frames; special papers and materials for mounting photographic and other prints have been sent us by Mr. Jonathan Fallowfield, of the Central Photographic Stores, 146, Charing Cross Road, London, W. The list occupies 74 pages and an enormous variety of designs, tints, sizes, and shapes are listed and illustrated.

THE ATOMIC THEORY WITHOUT HYPOTHESIS.

[Abstract of Presidential address in Section B of the British Association.]

CHEMISTRY NOT THE SCIENCE OF THE MINUTE.

If chemistry is a science which rests upon the atomic hypothesis, and, therefore, would cease to exist in the form into which it has developed, should matter prove to be continuous and not discrete, nothing can be said against the view that it is a science of the minute. But I am sure there can be no one ready to maintain that, if the hypothesis of the atomic constitution of substances were an unfounded one, the atomic theory would have been a discovery of no great importance; and Dalton himself, instead of being the founder of the chemistry of to-day, would have been little more than the discoverer of the law of multiple proportions. For if, indeed, the chemist often works upon comparatively small amounts of substances, and consequently with very sensitive balances, that is, as we all know, only for reasons of economy, of time, materials, and apparatus; otherwise he works on the largest possible scale, with the object of attaining to the highest degree of accuracy and perfection. It is therefore only as interpreted by the atomic hypothesis that chemistry can be said to deal with the minute. When the atomic theory is expounded in the usual way, it is commonly and correctly stated that, on the assumption that substances consist of minute indivisible particles having weights or masses bearing ratios of the combining numbers assigned to them, the laws of chemical combination by weight necessarily follow, and are thereby explained. But then the converse is not true—that because chemical combination obeys the well-known laws substances consist of discrete particles. Nor does the assumption of the truth of the atomic hypothesis afford any real explanation of the facts expressed by the laws of chemical combination, or more comprehensively by the atomic theory, when that theory is given non-hypothetical terms. It is just as difficult to see why the atoms should possess the weights on chemical grounds assigned to them, as to see why substances interact in the proportions that they do; that they do so is, in either case, an ultimate fact, for which no explanation has presented itself. The atomic hypothesis masks this ignorance and deadens inquisitiveness. But if, after all, chemistry does not deal with the minute, or, rather, if it has no concern with the magnitude of single bodies or their molecules; if the atomic hypothesis is not the foundation of, or necessary to, the atomic theory, then it is certainly most desirable and important that the theory of chemistry, which, with all its modern developments, I take to be indisputably the atomic theory of Dalton, should be held and expounded without any reference to the physical constitution of matter, in so far as that remains unknown. The opinion that chemical theory should be developed without reference to the atomic hypothesis has indeed all along been held by many eminent chemists; but then the dilemma appears to have presented itself to them, that either the atomic hypothesis must be granted, or the atomic theory must be dispensed with, since it falls with the hypothesis. That dilemma I do not recognise, and the practice of chemists shows beyond doubt it is always ignored. Investigators use the theory, whether they admit it or not; teachers of the science find it indispensable to their task, however much they may deprecate, and rightly so, unreserved acceptance of the atomic hypothesis as true. Chemists have thought from the first to escape the adoption of the atomic theory by putting Dalton's discovery into something like these words:—Numbers, called proportional or combining numbers, can be assigned to the chemical elements—one to each—which will express all the ratios of the weights or masses in which substances interact and combine together. Perhaps the atomic theory is here successfully set aside by expressing what is an actuality as an unaccounted-for possibility. But then those who use any such mode of expressing the facts, without reference to the theory, never fail also to adopt the doctrine of equivalents, and thus, by this double act, implicitly give in their adherence to the theory. Divested of all reference to the physical constitution of matter, the atomic theory is that the quantities of substances which interact in single chemical changes are equal to one another—as truly equal in one way as equal masses are in another—and therefore, that chemical interaction is a measure of quantity of unlike substances, distinct from and independent of dynamical or mass measurement. Dalton, indeed, did not express himself in any such terms, but it is clear enough that his theory was that of the existence of another order of equality between substances than that of weight. Up to his time, the weight or mass of every ultimate particle of any substance whatever appears to have been assumed to be the same, the atoms being alike in every way. That assumption is still made by many thinkers, chemists among them; we meet it, for example, in the different forms of the hypothesis that the elements are all, in some way, physically compounded of a universal and only true element, as in Prout's hypothesis. Dalton saw things differently, and recognised that, on the assumption of substances being constituted of particles which never subdivide, weight or mass cannot be the same for every such particle, except in the case of those of any one simple substance. Therefore, having given some numbers showing what he believed to be the respective weights of the atoms of several simple substances, taking that of hydrogen as of unit weight, he

proceeded at once to invent symbols for these atoms to indicate, not only their distinctness in kind, but, above all things, their indivisibility and their equality, properties which the use of their atomic numbers would have inadvertently conveyed or even apparently denied, and could never have expressed or connoted. It was only in this immediate invention and use of chemical symbols that Dalton's conception found clear expression; and, again, it is by the universal adoption of such symbols that chemists have shown their real acceptance of the atomic theory, even while displaying, not infrequently, their scepticism as to its truth. Now, evidently, what the character used as symbol shall be is, theoretically considered, but a petty detail; the vital point is what the character symbolises, and that is the atom. It may be said, indeed, to represent the atomic number, since it stands in place of it; but it is made to do so only in order that we may for the time forget this number and have in mind the integral character of the atom. It is not the 4,006 parts of sodium hydroxide and 8,097 parts of hydrobromic acid that we are to think of when the formulæ NaOH and HBr are before us, as we too often strive to do; it is not these, from a chemical point of view, meaningless numbers of parts, but quantities which are equal in the sense of chemistry, that are expressed as such by these symbolic formulæ. The real purpose of chemical formulation is not to abbreviate or replace language, but to facilitate, if not ensure, abstraction from a non-contemplation of gravimetric numbers. I have just passed from atomic symbols to the formulæ of molecules; but this was not without warrant. In the form in which I have enunciated the atomic theory, it relates to the chemical interaction of substances, whether compound or simple, and the equality of the quantities concerned is the equality of molecules, since these are the quantities of substances entering into or coming out from single chemical interactions. Were it not, therefore, for fear of confounding it with the mechanical theory of that name, the atomic theory should be called the molecular theory of chemistry.

CHEMICAL EQUALITY.

Molecules are equal in the sense that they are quantities of their substances, which are interdependent and co-ordinate in any and every single chemical change in which they take part together. It is a form of equality for which no close parallel can be found. To give an example; the molecule of ammonia is equal to that of aldehyde in that it combines with it and with it disappears, or ceases to exist as such. For the same reason it is equal to the molecule of hydrocyanic acid, and molecules of aldehyde and hydrocyanic acid equal to each other, because they, too, combine and disappear as such in doing so. But the molecule of ammonia again equals that of aldehyde in effecting transformation of hydrocyanic acid and its own self into something else. And lastly, chemically equal or molecular are the products of these combinations; aldehyde ammonia, ammonium cyanide, and aldehyde-cyanhydrine, not only among themselves, but also with the quantities of ammonia, aldehyde, and hydrocyanic acid, from which they come and into which they return in other chemical changes. But with all this quantitative equality in transforming power, the substances produced are unlike and, each to each, peculiar to one of the three acts of chemical combination; and on this account exception may be taken to the treatment of molecules as equal chemical quantities. Yet the equality of molecules here asserted is but an extension of what is meant by the equivalence of certain atoms and radicals, since the atom and the radical are, nowadays, "conceptions entirely dependent upon and derived from that of the molecule (apart, of course, from the atomic hypothesis); and this universally allowed equivalence admittedly does not extend to the identity of the products of the replacing activity of the atoms and radicals. Quantitative equality and equivalency, it is true, have not the same meaning, equivalence being used to denote qualified equality, equality in certain specified ways, of quantities not equal in all other ways and possibly in no other. Quantities of different substances cannot, strictly speaking, ever be equal, and can only be styled so in the sense of being equivalent; for were they equal in every way the substances would obviously be the same. But this fact, if it ever strikes one, is ignored by universal custom, and quantities of substances, however unlike—feathers, air, water, salt, and what not—are taken to be all equal, even by chemists as by the world at large, if only they have the same weight, notwithstanding the incongruities of the substances. No quantities of different substances can, as such, be commensurable throughout; and when compared and measured through some common property, such as the possession of mass, the equivalence or pseudo-equality found by this means is not the same as that found when some other common property is taken as the means of measurement. The contention that chemical equality must be regarded as of as clearly defined a nature as gravimetric equality becomes the more weighty when it is reflected that our very definite views concerning gravimetric equality are due solely to the law of conservation of mass, the evidence for and against which, I may remind you, is just now to be discussed by Lord Rayleigh before the Physical Section. The mass of one pound of sodium remains unchanged when the metal is converted into salt, washing soda, or borax; if this were not the case, gravimetric equality would be just as definite as it is now, but physicists

would have to argue for its general recognition in much the same way as I am doing now for the recognition of chemical equality. In teaching chemistry the point is kept too much in the background, if not altogether out of sight, that the chemical equality of quantities of different substances is independent of all other relations of equality between them, and that, therefore, its validity is not affected by the fact of its terms agreeing with some and not with other terms of equalities determined in other ways. "Molecule" is a term of relation; it stands for an equal quantity, not for any particular quantity; but at such it is as easy to understand and as indefinable as an equal volume or an equal weight of a substance. The theory of chemical molecules or equalities and their relations to the equalities between the weights and gaseous volumes of different substances were brought to light, not by Richter's law of chemical combining proportions, and not by Avogadro's hypothesis as to there being equal numbers of particles in the same volume of different gases, but in the first place by Dalton's atomic theory and Gay-Lussac's law of simply related gaseous volumes in chemical change; and then, much more fully in the middle of the last century, through the brilliant work of Gerhardt, Williamson, Laurent, Odling, Wurtz, and others, in the purely chemical field. Dalton gave us the conception of the molecule, though confused with that of the atom, as the unit of measure of chemical activity in place of the gravimetric unit; the work of the chemists of the last mid-century gave us a fuller conception of the molecule, along with the notion of chemical change as being substitution in the molecule effected by what became known as double composition.

CHEMICAL COMPOSITION AND DOUBLE DECOMPOSITION.

Up to that time chemistry had been treated only as the science of compounding and decomposing or reducing. Far from being the science of the composition of substances, chemistry might be defined as being the science of the non-composition of substances, where that composition might have been looked for from the antecedents. If salt is verily a compound of sodium and chlorine, and can be broken up into these, why have the fragments not the marks on them of that whole of which they formed a part? It is true that 5,850 parts of salt become 3,545 parts of chlorine and 2,305 parts of sodium, nothing being gained or lost in weight; but to account for that there is no need of chemistry, a science which takes cognisance of the phenomena of change, and not of those of unchanged properties. The use of the word "composition" in industry cannot be discarded now, and all that is necessary to make it unobjectionable is to see that the term is always qualified by the prefix "chemical," when there is a possibility of mistake about its significance, and that that significance is carefully explained, if not defined and fully illustrated, before it is given over to the beginner. With exclusive reference to such facts as these, the chemical composition of a substance will, I think, be found to be satisfactorily defined as its having the power, capacity, or property of being wholly producible from and wholly convertible into, directly or indirectly, those substances of which it is said to be composed. A simple substance differs from one that is compound only in not possessing the power of being by itself convertible into two others, or of being produced alone from any two others. Simple substances are not less varied or less complex in their physical properties than compound substances, while their chemical constitution is often more problematic than that of many which are compound. The term "simple," therefore, is as misleading in the language of chemistry as "compound," unless defined and qualified in use by the word "chemically." In the great reformation wrought by the chemists to whom I have referred, but by Gerhardt in particular, the new light set up in chemistry was the notion of what came to be called "double decomposition" in chemical change. Its introduction into chemistry marked the ascendancy of the idea of the molecule as the factor in chemical change whose interactions with other molecules were to be considered, instead of those additions which, as chemical phenomena, never take place. It led also to new conceptions of the nature of the atom and the compound radical as being the quantitative and qualitative expressions of the powers possessed by substances to change into others, and to the conception of the valency of atoms and radicals as expressing the nature of the connexion of successive chemical changes. The fundamental value of double decomposition consists in its displaying threads running through chemical transformations which can be followed up. When two substances change into two others, and only then, there can be found, in most cases, relations of resemblance, both physical and chemical, between the before and after of a chemical change. Instead of the striking unlikenesses shown by the substances formed by quasi-addition to those from which they are formed, there are here met with the similarities of the outcoming to the interacting substances, and the similarities between the products of different interactions in which the acting substances are similar.

RADICALS AND ATOMS.

The notions of radical and atom are so intimately related as to be often used indifferently, the one for the other. The radical, ethylene, is always an atom of ethylene, the radical nitrogen always an atom of nitrogen. Radical and atom are, in fact, the qualitative and

quantitative aspects of the same thing. They are thus exactly parallel with substance and molecule. We can think of unquantified substance, and perhaps of an unquantified radical, but in chemistry we never really want such conceptions. In the interaction of double decomposition each substance by contact and union with the other develops and manifests a dual character by becoming distributed as the two new substances, with the consequence that each of these has certain properties the same as those of the one, and certain others the same as those of the second interacting substance. What is common in this way to one of the interacting and one of the resulting substances is a radical of these substances, of which there are evidently four in every double decomposition. These radicals of a single interaction are defined as whatever two parts of the powers of a substance to yield the simple substances of its chemical composition are, in certain interactions, continued separately from each other in the two new substances. But the pair of radicals developed in the various double decompositions of a substance being by no means always the same, one of the radicals of one pair must include in its composition part or all of one of those of another pair. To a limited extent and imperfectly, we can attach to a given radical certain of the properties common to its compounds; but it needs no greater insight than we have already to recognise that a substance cannot be what it is in one way without being in that way greatly affected by what it is in another. This is now a recognised but not sufficiently considered point, and I therefore welcome those publications of Professor Vorlaender, of Halle, in which he has been vigorously calling attention to the extent to which the properties of a substance, acid, basic, stable, and what not, depend as much as, if not more, upon the inter-relations of the radicals than upon the radicals themselves. One other thing I have to say about the radical; I plead for a return to the ending of the word radical with "al," now interdicted in the Journal of the Chemical Society.

IONS.

I have put off too long, perhaps, all reference to the properties of very dilute aqueous solutions of salts. The osmotic pressure and other dependent points which are particular in the behaviour of such solutions are in full accordance with the assumption that an electrolyte by dissolution in much water becomes a pair or a binary system of two interdiffused quasi-substances called "ions." These ions must differ from isolated substances in bearing equal and opposite quantities of electricity; in being each unknown apart from its fellow; and in having a composition not to be found in actual substances, though identical possibly with that which a radical would have were it a substance. The ions can indeed be separated from each other, but not to continue as themselves, since in the act of separating they form ordinary substances, either by uniting with other ions, or by two molecules of ion becoming one molecule of substance. In the former way of separation the ions of two salts interact on mixing their solutions; in the other way the ions become substances when their solution is placed in a galvanic circuit. The phenomena of ionisation, or, in other words, the particular properties of dilute solutions of salts, belong evidently to a change unlike all other chemical changes. It is a polarised chemical change, in which the equivalent and complementary products of the interaction appear apart and at remote surfaces of the mass of decomposing salt solution. Two points which call for notice in connection with my present subject are that an ion is one of a pair of quantities commensurate with the quantity of the salt itself, that is or would be in interaction; and that it is molecular in character, and therefore to be regarded as a relative and wholly variable quantity. Dalton's atoms were both the atoms and the molecules of present day chemistry, but much more the latter than the former. Although the chemical atom can now be no more than a dependency of the molecule, it is commonly set up as the starting point in chemical theory, and as having an independent existence as a quantity of the substance, while the molecule is represented as being a conjugation of atoms. But there cannot be two standards in reference to the same thing, and in molecular chemistry the atom must give way. The four radicals of a double decomposition are equal and chemically complementary. These chemically equal quantities of such radicals are atoms. The quantities of all other radicals are also atoms, but only those of proximate radicals, those of a single interaction, are equal. Similarly, the quantities of the four substances of a single interaction are all equal and are molecules, but the quantities of substances are not equal in other interactions. These others are treated as the simultaneous occurrence of two or more single interactions, which they can always be represented and sometimes demonstrated to be. Calcium hydroxide and hydrogen sulphide give calcium hydrosulphide and water by two single interactions together, which in this case can be easily distinguished, since the calcium hydroxide will also interact with only half as much hydrogen sulphide to form the insoluble crystalline calcium hydroxyhydrosulphide and half as much water as before; this calcium salt will then interact with as much more hydrogen sulphide as went to form it, and produce the very soluble crystalline calcium hydrosulphide. Therefore, and on other grounds, we say and know that one molecule of calcium hydroxide and two molecules of hydrogen sulphide give one molecule of calcium hydrosulphide and

two molecules of water. This is, of course, only the law of multiple proportions introduced into chemical interactions. The expression "two or more molecules of a substance" has a meaning only as indicating the number of simultaneous or successive single interactions which have led to the conversion of certain substances into others. Now, a similar but complementary state of things meets us in the case of radicals. Instead of the coefficients of molecules, necessitated by having to consider many chemical changes as being cases of two or more single interactions occurring together, there are the valency coefficients of the polyvalent radicals, called out also by such a compound interaction. Thus, in the above case, whilst the single interaction between hydrogen sulphide and calcium hydroxide shows calcium-hydroxyl as one of the radicals, the succeeding interaction between the calcium hydroxyhydrosulphide and more hydrogen sulphide shows the radical calcium-hydrosulphuryl, and the common part of these two radicals is the bivalent radical, calcium. It will be evident that to give the atom of the calcium radical as bivalent is a statement reciprocal or complementary to that of giving two molecules of hydrogen sulphide as interacting with one of calcium hydroxide. Chemical equality remains still the measure of the atom, but that, in complex changes, whereas the number of molecules in one substance marks the number of single interactions, the valency number of the atom marks the same thing for the radical. It is a matter of valency, and not otherwise a matter of the atom. The radical calcium is never actively bivalent in a single interaction; in other words, it is never equal to two atoms of hydrogen. As a simple radical it does not take part in such an interaction; but it does so as a radical of radicals, such as calcium-hydroxyl and calciumhydrosulphuryl, and then has the same measure as—is equal in exchange to—the atom of hydrogen, though carrying with it of necessity other radicals, a thing the hydrogen radical never does or can do. The quantity of the radical is the only proper and sufficient definition of the atom, whether the radical be that of a single interaction, or a radical of radicals, that is, a polyvalent radical. The atom is, therefore, the quantified power of a substance, as the compound of a radical, to produce other compounds of the radical, including its compound with itself, where that is possible. As with the molecule of a substance, so with the atom of the radical, it is of no fixed magnitude, and may weigh a kilogram just as well as only a milligram, or something much less. Being a relative quantity and nothing by itself, of its indivisibility there is nothing to be said outside its definition; whilst as to its being the smallest relative quantity interchanging in an interaction, it had only thus to be defined when there was uncertainty as to the molecule and the single interaction.

VALENCY AND FORMULÆ.

It has been impossible for me to discuss the nature of the radical and the atom without referring to valency, but it is itself a subject of such importance as to need special consideration. It does not seem right to me to say even the little I can say about valency without naming with the respect they deserve from us the distinguished chemists who laid the foundations of the doctrine and developed it; Williamson, Odling, Wurtz, Edward Frankland, and Kékulé. Valency presents itself as being the number of single interactions necessary in order to have a certain radical occur, first as that of one substance and then as that of another which has no other radical in common with the first substance. That ammonia possesses one atom of the radical nitrogen, and three atoms of the radical hydrogen, and that the nitrogen radical is trivalent and the hydrogen radical univalent are statements mutually based upon facts such as the following. Potassium nitrosulphate, which contains nitrogen but no hydrogen, is converted by water into a sharply defined single interaction, into potassium hydrogen sulphate, and into potassium imidosulphate, a substance which contains all the nitrogen along now with hydrogen. This salt passes, also sharply and by a single interaction with water, into as much more sulphate along now with potassium amidosulphate, which latter substance contains all the nitrogen and twice as much hydrogen as belonged to the imidosulphate. Lastly, the amidosulphate interacting with water gives a third quantity of potassium sulphate, equal to the last, and also ammonia, having all the nitrogen of the nitrosulphate started with, three times as much hydrogen as the imidosulphate, and nothing else. That is to say, the nitrosulphate and the ammonia have no other radical than the nitrogen the same, while three single interactions have been necessary to separate in this way the nitrogen radical from the three atoms of the potassiumsulphonyl radical. Therefore, the nitrogen radical is trivalent and its quantity is the atom. Chemical formulæ are symbolisations of deductions from experimentally ascertained facts, and are independent of the interpretation, commonly given to them as referring to the minute differentiated structure of substances. What is symbolised by position formulæ, and indeed by the formulæ altogether, are the chemical activities and abilities of the substance, and its derivatives, and their analogies with those of other substances. When not in interaction, a substance has no constitution and no formula. It is certainly not on any experimental grounds that it can be regarded as some spatial arrangement of unlike parts.

PROFESSOR EDWARD DIVERS, M.D., F.R.S.

THE BECQUEREL RAYS.

ONE of the discourses of the meeting of the British Association was delivered by Professor J. J. Thomson, on "Becquerel Rays and Radio-Activity." He described how Professor Becquerel, of Paris, took a quantity of salt of uranium and placed it near a photographic plate, protected from light by suitable screens, and kept the uranium in a state of phosphorescence by continued exposure to sunlight. On developing the plate after the experiment had lasted several hours he found a picture upon it, showing that something similar to Röntgen rays had been given out by the uranium. In all the earlier experiments the uranium was kept exposed to the sunlight, and was thus phosphorescing during the whole time of exposure. It happened, however, on one day that the sky clouded over during the experiment, and there was not light enough to make the uranium phosphoresce. Becquerel put his apparatus away and waited for better weather. The weather, however, did not improve, and Becquerel developed his plate, expecting to find a feeble picture. To his surprise, he found that the picture excelled all those he had previously taken, proving that the uranium emitted the rays even when it was not phosphorescing. This radiation was similar in penetrating power to that of the Röntgen rays, and Becquerel thought that at first that his rays, like ordinary light, were capable of being refracted, and that they could be polarised. This had been proved to be not the case. Becquerel rays were, in fact, a mixture of Röntgen and cathode rays. Evidence had been given to show that the cathode rays consisted of exceedingly small particles, called corpuscles, smaller than the atoms of any known substance, and moving at the rate of many thousand miles a second, the speed depending upon the extent to which the air had been removed from their path. Large as the velocity was, it was greatly exceeded by the velocity of the cathode rays given out by uranium, while another substance, radium, emitted rays moving at a still greater speed, velocities of over 120,000 miles a second having been recorded by Becquerel in this case. Among all the mysteries associated with matter, few, if any, were more startling than that afforded by these substances, in no way remarkable in appearance, which, without provocation and without intermission, emitted properties that travelled at a rate compared with which that of the fastest bullet was absolutely insignificant. If artificially prepared salts of uranium were examined, it was found that the activity was strictly proportional to the amount of uranium they contained. M. and Mme. Curie found, however, that several native minerals, and especially pitch-blende, although only a fraction of their bulk, consisted of uranium, were much more active than pure uranium; one of these minerals, chalcocite, was prepared artificially, and the activity of the product was found to be normal—that is, proportional to the amount of uranium contained. It seemed probable, therefore, that these minerals contained some unknown substance much more active than uranium itself. M. and Mme. Curie applied themselves to the task of separating this suspected substance. They found that a very radio-active substance, which has been called polonium, was connected with the bismuth taken from the pitch-blende, and also another substance named radium. A third substance had since been obtained, which seemed closely to resemble thorium, and was known as actinium. The amount of these substances was exceedingly small, smaller than the quantity of gold in sea water. The property of producing electrical conductivity in gases afforded a most delicate test of the presence of a radio-active substance. By this means it was possible to detect quantities of the material millions of times less than could be detected by chemical analysis, and thousands of times less than could be shown by the spectroscope; indeed, of the three substances mentioned, radium was the only one that had been detected by chemical or spectroscopic means. By successive purification of the barium obtained from pitch-blende, radium had been obtained, which was more than 100,000 times more active than uranium, and which, when enclosed in lead one-quarter of an inch thick, could produce greater effects than uncovered uranium. The radium made a sensitive screen phosphoresce; it showed the bones in the hand, and was so vigorous in action that it had produced sores on the skin of those who had incautiously handled it; and it emitted negatively electrified particles with a velocity approaching that of light. This continual emission implied that the radium was losing mass and energy, but the loss of mass would amount to only about one thousandth of a milligramme in a million years for each square centimetre of surface. But the amount of energy radiated was quite appreciable, being sufficient, if converted into heat, to melt in a million years a layer of ice of the same area as the radium, if more than a quarter of a mile thick. Loss of energy has been going on, it might be, for millions of years, ever since the radium existed. There must have been, therefore, a very considerable store of energy at the outset, and a very interesting question was the nature of this energy and how it was stored. Professors Rutherford and Soddy had given a satisfactory answer to this question by their experiments on the substance thorium, from which they had been able to separate its active constituents, obtaining two products, one minute in quantity, but intensely active (thorium X), the other, which contained practically the whole of the thorium, almost inert. This arrangement, however, did not last long. Thorium X began to lose its activity, and the

mass of thorium to gain it. After a few days thorium X became quite inert, while the thorium regained its old activity, and afforded fresh supplies of the thorium X. Ordinary thorium was thus steadily being transformed into the active thorium X, while this is continually passing into some inactive form; what this inactive form was we did not know, and its elucidation offered a most interesting problem, rich in possibilities. Rutherford found that thorium, besides giving out Röntgen and cathode rays, gave out a radio-active gas, which he called the thorium emanation. The activity lasted only a few minutes, and was given out only from the thorium X, and not from thorium in its normal state. This emanation resembled the new gases argon and helium in its refusal to combine with any other element. It was remarkable that the minerals in which helium occurred invariably contained radio-active substances, and the idea naturally suggested itself that helium might be very closely connected with the gaseous emanation from thorium X. Radium gave off an emanation more permanent than that of thorium. Radio-activity could be induced. If the substance was negatively electrified while in contact with the emanation, the radio-activity induced in it was very much increased. The intensity of this induced radio-activity did not depend to any great extent on the nature of the substance. A piece of paper could be made as radio-active as a piece of metal, but the property was not permanent, lasting for a few hours only. Elster and Geitel had made the remarkable discovery that substances could be made radio-active without the aid of thorium or radium, all that was necessary being to hang them up in the open air, and charge them strongly with negative electricity. The earth itself was negatively electrified, and the natural electrification on pointed conductors connected with the earth was sufficient to make them radio-active. The pointed leaves and spines of trees were always radio-active, and Mr. C. T. R. Wilson had lately shown that freshly-fallen rain possessed this peculiarity and retained it for about half an hour. It had been suggested that this induced activity pointed to the presence of another undiscovered constituent in the atmosphere, but experiments were described which showed there was no necessity for this hypothesis. The production of radio-activity in all bodies might be thus explained. The air always contained small bodies called ions, some charged with positive, others with negative, electricity. When a negatively electrified body was placed in the air the positively electrified ions were attracted towards it. Some gave up their electric charge, but those that did not would accumulate close to the surface of the body, forming a layer of positive electricity round the body. This layer would attract the negative electricity in the body, and when the attraction was very great the negative electricity would be pulled so vigorously that it would shoot out from the body with great velocity, approaching that of the cathode rays, and hence would give out cathode rays and be radio-active. It was in this way that the leaves of trees, and the countless objects on the surface of the earth acquired radio-activity, and, becoming, in fact, cathodes, discharged those rays, which had only comparatively recently been discovered by the help of the most elaborate apparatus, and yet were in all probability so widely distributed and so frequent, that there was hardly a patch of ground on the earth's surface which did not contain a source of these rays.

ASTRONOMICAL Photographs from the Lick Observatory.—The value to lecturers of the photographs taken with the great telescope and others of lesser size at this observatory does not need to be dilated upon by us, and the announcement of a recent departure by the authorities of the institution will be received with interest. The Bulletin No. 20 published by the Observatory contains the announcement by Professor Pickering that in consequence of the receipt by the authorities of so many legitimate requests for photographs of the moon, comets, nebulae, etc., taken at the Observatory they will be prepared to furnish copies from their negatives in print or lantern slide form. Application is to be made to the Director, who will, on request by teachers, lecturers, etc., give details of prices and other particulars.

THE British Association.—The meeting of the British Association at Belfast has been a fairly successful one. Many valuable papers were read, though there was no one, if we except Professor H. E. Armstrong's on technical education, of universal interest. There was a certain want, too, of what we may call "illuminating" papers, those which leave on the minds of the half-instructed a just impression that their knowledge and their opinions have been made at once wider and more definite. There has been a recoil of late years from such papers as too "popular," ending in a supply of lectures so technical that though they may inform those engrossed by their subjects, they are to the world—which the Association, it must be remembered, professes to address—simply unintelligible. The managers of the Association have, of course, many difficulties to contend with, every man who will contribute a paper worth hearing fighting for his independence; but a little more editing of a general kind would, we think, increase the utility of the Association without interfering too much with any idiosyncrasy. We have given up the old word "mystery," formerly considered necessary to describe any art or science, and the change marks at least a change in the general wish.—"The Spectator."

Exhibition.

THE PHOTOGRAPHIC SALON.

The tenth annual exhibition of the Photographic Salon, which was opened on the 19th inst. at the Dudley Gallery, Piccadilly, W., maintains the progress shown in the exhibitions of last year and the year before, and the collection of pictures is undoubtedly an interesting one; but, in contemplating it as an exhibition of photographs, one cannot avoid the impression that the majority of the exhibitors have treated photography less honestly than the compilers of the catalogue have treated the quotation which forms the "Forewords" to the catalogue, and which is avowedly "adapted from W. E. Henley, without permission." Without going into the question, either from the ethical or the art standpoint, of the legitimacy of combining two or more methods in the production of a picture, it is clearly desirable that, even if it is a legitimate practice, the productions should not be classed with results obtained by one method only. When a picture sent to an exhibition of paintings has been detected as a disguised photograph its author has justly been looked upon as having been guilty of a mean attempt at fraud, and, similarly, a picture, in the production of which photography has played a minor part, should not be allowed to masquerade as a photograph. It is unfair, both to artists who choose photography as their means of expression and to artists who rely upon the pencil or the brush.

The exhibition gallery appears in quite a new get up; a much less ambitious scheme of decoration than usual has been attempted, and the result is decidedly the most successful yet achieved. All direct light is obscured by a velarium or screen of thin white material, and with the light of a bright September day the effect is delightfully soft and particularly suitable for the display of photographs. What the effect will be when the London smoke has had its normal result on the white hangings and in the gloom of an autumn day remains to be seen; but, however, those responsible are to be congratulated upon the abandonment of the rag-bag style of decoration which was typical of the stage of art culture of the early days of the Salon.

In giving the opportunity of seeing what is being done outside our own country the Salon has always performed a useful function, and this year rather more than one-half of the exhibits are from abroad. It is, of course, difficult to generalise work proceeding from places geographically far distant from one another and subject to local influences which cannot be similar, but it is impossible not to recognise that there is a sentiment in natural British work which is characteristic, and which is entirely different from that of any other nation. It is a clean, healthy sentiment which finds no necessity for mythic suggestions, but it is not the fashion, and receives scant encouragement at the Salon. We do not for a moment wish it to be understood that we class all foreign work differently, but there is much of it in which there is very little to admire, still less to imitate, either in sentiment or in treatment. Photography is essentially the medium for realism, and to employ it when obscurity is necessary is to employ a medium for the work in hand which is far from the most suitable. In giving undue prominence to work which is of a character that does not appeal to our natural instincts there is a danger of discouraging efforts to perfect methods of work on our own natural lines. In some branches of painting we have no reason to be ashamed of native achievements, and in photography we have also a good record. To improve our system does not necessarily involve revolutionising it.

It is clear that the Salon has passed the period when it had to rely upon extravagance rather than merit for the notoriety necessary for its existence. If we except the comparatively small proportion of pictures which palpably owe their acceptance to considerations of policy or strategy, and those which there is reason to presume come into the same category, there is an almost entire absence of the commonplace stuff which used to form the padding of the exhibition. Most of those whose work we are accustomed to find here are represented, but we are prevented from attempting any comment on the numerous works which deserve notice by considerations of space. We understand the arrangement of the pictures on the walls was entrusted to Mr. F. H. Evans, and he has performed his task exceedingly well.

SALON "FOREWORDS."

(From the Catalogue.)

"Facts are not necessarily the end with them—they are only the means. They (these photographers) refrain from the vulgarity of full realisation, and essay no more than the pictorial expression of certain balanced and choice suggestions."

Adapted from W. E. HENLEY.

(Without permission.)

The Photographic Salon was first held in October, 1893. It was called into existence by a brotherhood or informal Society of Photographers called The Linked Ring, for the purpose of exhibiting only

those examples of contemporary photography which in their opinion give evidence of personal artistic feeling and motive, quite apart from purely scientific and technical considerations with which it was felt the pictorial possibilities of photography had too long been confused.

On these principles the Photographic Salon has since been annually organised and successfully maintained by The Linked Ring, the present Exhibition being, therefore, the Tenth of the series.

The Linked Ring, itself a democratic and cosmopolitan body, encourages everyone to send in examples of their photography, which are submitted to the adjudication of a Selection Committee on an equal footing with the works of the members themselves, so that as far as possible each exhibition shall represent the best pictorial photography of its year.

PHOTOGRAPHY IN A POETICAL LIGHT.

POETS and photographers have one thing in common, and that is, they gain their inspiration from, and spend some of their best efforts in, the admiration of nature. The sea, whose restless bosom, now placid and now roused to fury, is a never-ending source of delight to both. "The lowing herd that winds slowly o'er the lea"; "The wintry flood, in which the moon sees her unwrinkled face reflected bright"; "The stag at eve, that drinks his fill" "The tranquil convent's hushed repose and the splendours of a throne"; all these form subjects for pen and camera. A poet is as big a sun worshipper as a photographer, as many an "ode to the sun" can testify. There may be many poets who have owed to their cameras lasting memories of "pleasant haunts, clear springs, and shady groves," but I have not found a poem in praise of a sun-catcher. I have therefore had the temerity to supply that want. A man was once asked the meaning of a plagiarist, and his definition was—a playwright. Of course, plagiarism is a horrible crime if, according to the Spartan theory anent stealing, it is found out. It is, however, considered commendable to appropriate a man's ideas, though you must not appropriate his words. A nice distinction! This doctrine, not being on the Index Expurgatorius, I number myself among those who do such things. On a former occasion I drew inspiration from the great Bard, born and buried at Stratford, and (h)av(e)on this occasion done the same.

All the world's a field,
And all the men and women are photographers.
They have their cameras and their tripods.
And an amateur in his time has many fits,
Which are in seven stages. At first the ———,
Trembling and shaking in an infant's hands
Then the ———, with its daylight film,
Carried by schoolboy, dallying on his way
To take some snapshots as he goes to school.
And then the ———, wielded by a lover,
Trying portraiture, makes a woful picture
Of his mistress without an eye-brow. Then the ———,
Seeking to rival one of wider fame,
Excellent in workmanship, can be taken to the field of battle,
And successful pictures made, even in the cannon's mouth.
And then the ———, in nice brown case,
With good velvet lined; full of cut films
And great contrivances. The sixth stage shifts
Into the ———, handle on top and finder on the side;
The lens well mounted and angle wide enough
To take the world. And the joyful owner,
Turning again towards the view, snaps,
And rejoices in his work. Last camera of all,
That ends this wondrous catalogue,
Is the ———, with plates of ———,
Plus Bausch and Lomb, plus rigid front, plus Zeiss, plus
everything.

—A. C. B.

PHOTOGRAPHIC Optics in South London.—"Clicker," in the photographic columns of the "South London Observer," gives the following remarkable piece of information to a correspondent:—"Meniscus" is not the name of a lens. It is a term applied to a "plano-convex" lens, and without such, photography would be well-nigh impossible. Rays of light passing through an ordinary lens continue their oblique path. Consequently, as the corner of the plate is farther from the centre of the lens than the middle of the plate, it follows that one of the two would always be out of focus. A meniscus lens, by correcting the rays of light, passes them through parallel to each other.

New Apparatus, &c.

The Planiscope Lenses. Sold by J. J. Griffin and Sons, Ltd., 20-26, Sardinia Street, Lincoln's Inn Fields, W.C.

In drawing our attention to their new series of Planiscope lenses, Messrs. Griffin furnish the following details:—"These lenses are now made of superior glass, and consist of two optically-finished combinations. They are corrected for achromatism and are each of tested focus. We would particularly point out that the Planiscope lenses are not merely magnifiers, nor are they spectacle glasses. They may be used with confidence with any of the most expensive lenses on the market.

"We would also point out that we have improved the mounts by which considerably more latitude is given in the size of the hood to be used without any danger of the metal bruising by the strain. The lenses are made in four kinds: wide-angle, for increasing the range of the lens; tele-photo, for magnifying the image; copying, for taking pictures, flowers, objets d'art, etc.; portrait, for making large heads in portraiture and increasing softness." Fuller particulars are in a circular obtainable from Messrs. Griffin.

The Kodak Developing Machine. Manufactured and sold by Kodak Limited, 43, Clerkenwell Road, E.C.

"Daylight development" and the "abolition of the dark room" were once common subjects of discussion in these pages, and many are the devices we have examined whose object was to enable the photographer himself to attack the latent image from the pleasant envelopment of the whole of the spectrum rays instead of, as Robert Ball might say, in the miserable fraction of one-sixth or seventh. But the dark room still exists, an apparently permanent photographic institution. The ingenious and simple little machine before us should satisfy two aspirations common among the very large class of amateur film workers for whom the manufacturers are now catering; it is a daylight developing device *per se*, and may be so wholly regarded and used by those who do not object to the dark room; or, on the other hand, it enables the latter to be dispensed with. It is in the former aspect that the machine appeals to us, who, after twenty years' experience of dark rooms, do not at all object to them, and do not include amongst our photographic impedimenta a simple film-developing machine. Confining our references, however, to the daylight uses of the instrument, few words of ours are needed to describe its functions, which are entirely obvious. Once you pressed the button and allowed somebody else to do the rest for you; with this machine you can do the rest—or part of it—yourself. You wind your exposed film through your developing solution, fix, and wash all in the one closed receptacle.

The following illustrations and condensed description show how the instrument is manipulated up to the point when the developer is poured into the machine and the cover is replaced upon it.

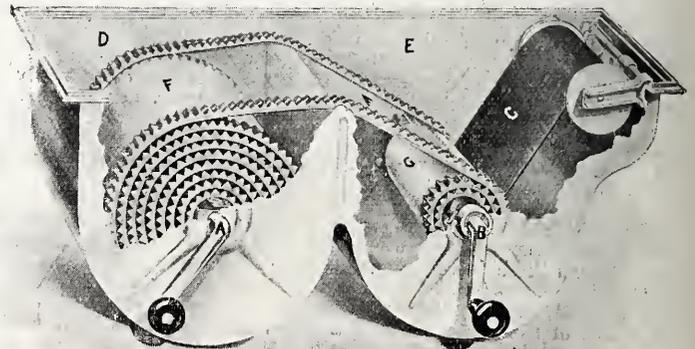

Fig. 1.

The celluloid Apron F F, Fig. 1, should be rolled back and forth several times between Arbors A and B (that you may understand its workings) bearing in mind when you are turning the cranks that A is always to be turned to the left, and that B is always to be turned to the right. Before development the Apron (F F) is all rolled on to Arbor A and will be entirely in compartment D. The spool of exposed

film is then placed in the carrier at opposite end of machine, and the end of black paper is fastened under the wire guard on Arbor B, and the crank turned to the right until the word "Stop" appears. We now hook the apron to Arbor B and pour developer into compartment E, put on cover of machine, and continue turning slowly to the right until development is complete. A moment's study of the machine and cut will show that as the apron is rolled on to Arbor B the black paper winds with it, and that the film lies next to the black paper, face up (see G), while the corrugated rubber bands at each edge of apron allow free access of the developer to the face of film and leave a sufficient space between the film and the next layer of the apron to allow the developer to flow freely and openly.

To use: Attach one end of celluloid apron to Arbor A by means of the two hooks, slipping them over the lugs on arbor. (Fig. 2.)

Fig. 2.

II. Turn to the left on crank attached to Arbor A and wind entire apron into compartment D, maintaining a slight tension on apron in so doing, by resting one hand upon it. (Fig. 3.)

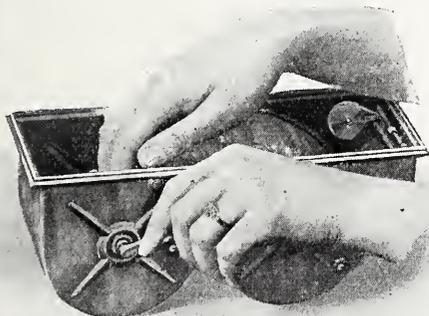

Fig. 3.

III. Throw back spool carrier by lifting it up from underneath. IV. Adjust the bearing to take the cartridge which you intend to develop. There are four notches in the arm which supports the spool carrier. The first (giving shortest length) is for Pocket Kodak and No. O Folding Pocket Kodak, the second for No. 1 Folding Pocket

Fig. 4.

Kodak and No. 1 Panoram Kodak, the third for No. 1 or No. 2 Brownie, and the fourth for No. 1A Folding Pocket Kodak. Slide the carrier along until the lug engages the proper notch. (Fig. 4.)

V. Place spool in carrier so that the black paper will lead from top as shown in Fig. 5, and then push carrier back into place in machine so that it occupies position shown in Fig. 1.

VI. Prepare developer and fixing solutions.

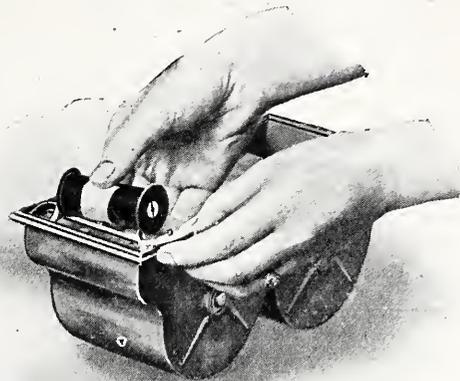

Fig. 5.

VII. Break the gummed slip that holds down the end of black paper, thread the paper underneath wire guard on Arbor B (Fig. 6), and turn slowly to right until word "Stop" appears on black paper.

Fig. 6.

As a guidance in practical work the Kodak Company publish the following development table:—

Snap-shots.—Temperature 60 to 65deg. Fahr., 5min.; 70deg. Fahr., 4min.; 45deg. Fahr., 8min.

Time Exposures.—Temperature 60 to 65deg. Fahr., 4min.; 70deg. Fahr., 3min.; 45deg. Fahr., 5min.

(Use developer at 60 to 65deg., if possible.)

(Never use developer above 70deg.)

When there are both snapshots and time exposures on the same roll, develop for the snapshots, but in such cases be careful in making your time exposures not to over-expose them.

Used with care and thought, this clever device has the capability of rendering itself distinctly serviceable to the user of roll films.

The Crossed Swords Platino Matt P.O.P. Agents: Charles Zimmermann and Co., 9 and 10, St. Mary at Hill, London, E.C.

The distinctive features of this new claimant for photographic favour are that it is coated on an extra stout support; tones to a variety of colours, and gives a "platinum black" deposit by the use of a combined platinum toning and fixing bath, supplied by Messrs. Zimmermann for that purpose. Three specimen prints of excellent quality, of differently coloured deposits, are before us; and we have ourselves made practical trial of the paper, and succeeded in obtaining rich black images by the aid of the special bath referred to. Physically the behaviour of the surface is all that could be desired; the paper appears exceedingly simple to work, and the command over the colour (or tone) of the image seems to be wide and certain. We append the official directions for use, and are of

opinion that the Crossed Swords Platino Matt P.O.P. is a useful and pleasing variation in collodio-chloride printing:—

Carefully read the instructions for various tones before printing. Observe scrupulous cleanliness both in dishes and hands. Do not finger the surface of the paper. Always blot off surface water to assist drying.

To obtain platinum black tones with combined toning and fixing bath.—This can only be done with the bath sold specially for the purpose, of which 3½ ozs. added to 3½ ozs. of water will tone a 1s. packet of the paper.

Printing.—This need not be carried too far, only until the prints are fairly dark, not bronzed.

Toning.—The prints must be placed, one by one, quickly, in our special toning and fixing bath, without previous washing. (The bath, as sold, being diluted with an equal quantity of water.) The bath must be kept, during the toning process, at a temperature of 65 degrees to 70 degrees Fahrenheit, and on no account must it be allowed to go colder or warmer. When the bath is cold brown tones will be obtained. When the bath is hotter it will spoil and give greenish whites. To keep the bath at an even temperature in cool weather it is a good plan to stand the dish, containing the solution, in a larger dish containing warm water. Toning and fixing will take 15 minutes. After the first eight minutes the prints may be removed if they have reached a desired colour. Toning being finished, swab the print over with cotton wool, and then wash for 30 minutes.

Dry by pressing between blotting paper and then expose to the air. Drying should not take more than 30 minutes, or the print may lose the deep black tone.

The following tones may also be obtained by carefully following the directions:—Carbon red tones.—Toning bath: Water, 13 ozs.; borax, 40 grains; chloride of gold, 1 grain. Print about as for black tones, not too deeply; wash in three changes of water, immerse in water 20 ozs. salt 2 drams, until the print has turned yellow. Rinse and then tone. When a very slightly lighter colour than desired is obtained replace in the salt solution for five minutes, rinse and fix in hypo 2 ozs., water 40 ozs., freshly made. Carbon purple and violet tones.—Toning bath: water, 9 ozs.; acid hydrochloric, 3 ozs.; gold chloride, 3 grains. Print very deeply, wash thoroughly and tone until desired colour is reached. Wash again and fix in hypo 2 ozs., water 40 ozs. Less acid gives bluish violet. More acid gives red violet—purple. Toning may be stopped at any stage. Carbon sepia tones.—Toning bath: Water, 18 ozs.; pot. chlor. platinate, 7½ grains; acid phosphoric, sp. g. 1.120, 1 dram. Print as for black tones, wash in three changes plain water and three washings of ammonia 880 1 oz., water 100 ozs., or until the prints become lemon yellow, wash again thoroughly and then tone. Wash and fix. Hypo, 2 ozs.; water, 40 ozs.

The paper can also be toned in any bath, combined or separate; the following single toning platinum bath giving excellent results in black tones: Water, 20 ozs.; pot. chloro. plate, 15 grains; acid phosphoric 1.120, 2½ drams. Print not too deeply, and wash well in three or four changes. Tone until the picture is blue black, wash very thoroughly and fix in hypo 2 ozs., water 40 ozs.

Commercial & Legal Intelligence

MESSRS. ELLIOTT AND SONS, LTD., of Barnet, have sent us a sample set of their new season's show cards and specimens. Prints on the firm's various papers are mounted on tastefully designed supports, in monochrome and colour. Each card is very artistic, attractive, and striking. Dealers may have a supply of the cards gratis on application.

Mr. W. E. DUNMORE, of the New Auction Mart, 33, Gerrard Street, Shaftesbury Avenue, W., informs us that he has received instructions to offer by auction the stock of a wholesale photographic dealer. The stock includes N. and G., Shew, Adams de Luxe, Reflex, Nydia, Kodak, Tella, and Klito cameras; a large number of all makes of stand cameras; Ross, Cooke, Dallmeyer, and other lenses; backgrounds, enlargers, lanterns, cinematographs, phonographs, and optical goods. The sale takes place at 5 p.m. on October 1st.

THE "P.P.A." and Fire Insurance.—Many members of the Professional Photographers' Association, while desirous of taking advantage of the facilities offered by the Association for securing a reduction in their fire insurance policies, having expressed a preference for treating direct with the Fine Art Insurance Company, the following notice has been issued:—"Professional Photographers' Association. Re fire insurance. Dear Sir,—I beg to inform you that the committee have arranged that members can send their policies direct to the Fine Art Insurance Company, if they apply to Mr. Alfred Ellis, Hon. Sec., 51, Baker Street, W., for a signed proposal form.—Yours faithfully, Alfred Ellis, Hon. Sec." The committee had not foreseen the possibility of objection to effecting insurances through the executive of the Association, and have taken the earliest opportunity of meeting the wishes of members in the matter.

THE Warwick Competitions.—The following is the list of awards of the Warwick Competition for the current month:—£1 prize: E. Collingwood Pitt-Johnson, 4, Lambridge, Bath, "A Village Home"; £1 prize: Wm. Henderson, 43, Church Street, Chenstow, Mon., "Chepstow Castle"; £1 prize: Russell Hiron, 33, New Buildings, Grosvenor Road, London, S.W., "Canadian Arch, Illuminated"; £1 prize: A. J. Jepling, 2, Hyverlog Street, Cardiff, "In the Mer de Glace"; £1 prize: T. T. Mathias, 2, Priory Street, Cardigan, "Paddling"; £1 prize: Charles Medhurst, 29, Park Place, Cardiff, "Bunch of Grapes"; £1 prize: Alfred Shaw, 296, Stamford Street, Ashton-under-Lyne, "The Woodman"; £1 prize: Reginald A. Silk, Royal Naval Sick Quarters, Portland, "X-ray Photograph of needle in finger"; £1 prize: Miss A. M. Walters, Forthampton Vicarage, Tewkesbury, "Harvest"; £1 prize: J. A. Wilson, Knowhead, Ballymena, "A Dog Jumping."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

S pt.	Name of Society	Subject.
23.....	Croydon Natural History	<i>Rotograph Papers.</i> Mr. Sims.
20	Southampton Camera Club.....	Ramble Print Competition and presentation of Medals and Certificates to the President.
Oct		
2.....	London and Provincial	Discussion upon the Fading of Albuminized Paper.
2	Liverpool Amateur.....	<i>Enlarged Negative Making.</i> Mr. Anyon.

ROYAL PHOTOGRAPHIC SOCIETY.

[From the "R.P.S. Journal."]

NOTICES.

SATURDAY, September 27th.—There will be a private view of the Forty Seventh Annual Exhibition at the New Gallery, 121, Regent Street from 11 a.m. to 4 p.m., and in the evening commencing at eight o'clock a conversation at which members, exhibitors, and their friends will be received by the President and Council.

Monday, September 29th.—The exhibition will be opened to the public. Members will require their cards of membership to secure admission. The doors will be open daily from 10 a.m. to 6 p.m. until Tuesday November 4th, and on Monday, Thursday, and Saturday evenings from 7 to 10 o'clock.

The Society's dinner takes place at the Cafe Royal, Regent Street, at 7 o'clock. Applications for tickets (half a guinea) should be promptly addressed to the secretary.

Tuesday, October 7th.—First informal meeting at 66, Russell Square at 8 p.m.

Tuesday, October 14th.—Ordinary meeting, at 66, Russell Square.—At this the first ordinary meeting of the session, the President, Mr. Thomas R. Dallmeyer, F.R.A.S., will deliver his annual address and present the medals awarded by the judges at the forthcoming exhibition.

Tuesday, October 28th.—Technical meeting, at 66, Russell Square.

LOCKERS.

For the convenience of those members who make frequent use of the dark rooms and enlarging room, and consequently desire to have their chemicals upon the premises, the Council have installed a number of lockers capable of enclosing bottles, materials, and apparatus of large size. These lockers will be let to members who make application to the secretary at the nominal annual rental of 2s. 6d., payable in advance. In this connection it should be stated that the Society will not be responsible for material left upon the shelves or about the rooms, a practice which the House Committee intend to discourage as much as possible. Those who find it convenient to leave their chemicals, etc., behind will therefore do well to engage the lockers that have been provided.

CAMERA CLUB.

The following extracts are taken from "The Journal of the Camera Club" for September:—

"It is with great regret that we have to announce the loss through death of two of our members. Mr. James William Groves was Professor of Botany at King's College, and will be recollected by many members by the interesting and graphic lecture he gave us upon 'Japan.' Although not well known to the generality of members, owing to his infrequent visits, being a country member, those who had the pleasure of his acquaintance highly appreciated him as being a well-informed, well-travelled, and most pleasant companion. Our other member, Mr. Arthur Kennedy, was drowned while bathing at Bacton. He was a Fellow of the Royal Astronomical Society, and a frequent attendant at the club, especially when the subject of the lecture was the one in which he was deeply interested, and we have frequently been indebted to him for the assistance he gave in the discussions by his able and lucid remarks.—It will interest our members, and especially his numerous friends in the club, to hear that, on July 14th, at St. James's Palace, H.R.H. the Prince of Wales (Grand Prior of the Order of St. John of Jerusalem) presented Colonel Richard Holbeche (who is a Knight, and the Librarian of the Order) with a special South African medal for conspicuous services to the ambulance department in connection with the mobilisation of the detachments of the St. John Ambulance Brigade who proceeded on active service to South Africa, and with the despatch of ambulance material and medical comforts for the sick and wounded troops at the seat of war. Colonel Holbeche has been for many years a member of the committee of the club, but has felt obliged to resign, as he finds that his duties as Librarian of the Order, and his recent election upon the committee of the Army and Navy Club, of which he has been a member for more than twenty years, will not allow him to devote the time that he would wish to the affairs of our club. He assures us, however, that he will continue to do all that he can to assist in promoting the *bon camaraderie* and prosperity of our club in the future as he has so cordially done in the past.—We have pleasure in announcing that during the forthcoming season a new attraction will be added to the Camera Club for those of its members who care for a serious game of whist. A year ago some old whist players who, owing to the invasion of 'Bridge,' found difficulty in getting a table at their clubs resolved to make an effort to preserve the old game by founding a club, limited in numbers, from which 'Bridge' should be excluded. The success which met their efforts shows that their action filled a want, and 'The Ferry Club' is now an established institution. It has arranged to play on

Wednesdays in our club house from 5 p.m., and it is hoped that many of our members who are qualified players will take the opportunity of joining. Mr. Henry E. Davis, the treasurer of the Ferry Club, will gladly furnish inquiring members of the Camera Club with further particulars.—The influence of the club is far reaching, and there is hardly any branch of abstract or applied science, physics, or mechanics in which some one of our members does not play a prominent part. In our last number we had the pleasure of recording that our most popular member, Mr. Gamble, the second officer of the London Fire Brigade, had received the Order of the Red Cross from the German Emperor. Mr. Gamble, however, is not our only fireman. The chairman of our committee, Mr. H. Thomson-Lyon, who was over last week at the French National Fire Brigade Competition at Caen, has received from the Maire of Moret-sur-Loing a warm letter of thanks for the assistance he had rendered to the Company of Sapeurs Pompiers of that town. Although Moret possesses but 2,000 inhabitants, its fire brigade is one of the best organised in France, and at the Caen trials it carried off the three principal prizes. Moret lies about 1½ hours south of Paris, is within a couple of miles of Fontainebleau, and those of our members who seek a picturesque situation, combined with good and economic living, might do worse than spend a week there.—One of our oldest members is Mr. S. L. Hinde, who is now Assistant Commissioner in the East African Protectorate. Popular as he is, and deservedly so, among all who know him in his various capacities, as a surgeon, a soldier (for he was in the service of the Congo Free State and retired as captain after several years of hardship and hard fighting), as the author of 'The Fall of the Congo Arabs' and 'The Last of the Masai,' as a sportsman who has contributed some of the finest specimens of large game to the Natural History Museum, and lastly, but not least, in our estimation, as a most enthusiastic supporter of our club, it gave his friends a sort of melancholy satisfaction to be able to entertain him as their guest on the eve of his departure for a further period of duty abroad. The other guest of the evening was Mr. Routledge, who has been for some time a most energetic and useful member of the committee, and who has resisted the charms of India, and even the Vale of Cashmere, in order to place himself under the auspices of Mr. Hinde, in hope that he will be able to prove himself as great a *shikari* and return with the *spolia opima* of a true sportsman, and also of a skilled photographer."

BRECHIN.

THE members of the Brechin Photographic Association held their annual meeting on Wednesday evening, Mr. J. Kirk, President, presiding over a large attendance. The treasurer's report showed a considerable balance at the credit of the Society. The secretary in his report stated that the outstanding feature in the year's work was the large increase of the membership, which clearly proved that during the year a practical resuscitation had taken place. Last year there were 25 members, compared with 55 ordinary and 11 honorary members at present, showing a gain of 41 for the year. It was also stated that a stimulating and instructive feature had been introduced in the form of a circulating portfolio. All the present office-bearers were re-elected, and Messrs. D. Watt, J. Steele, G. Douglas, and W. Dunn were added to the Council. Mr. Ross moved that it was desirable for the purposes of mutual help to form a union of the local societies, and that the secretary be instructed to communicate with the Dundee and East of Scotland Association as the senior body, asking them to take the first steps. This was unanimously agreed to.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

SEPTEMBER 17TH.—

Mr. F. A. Haylett gave a practical demonstration on "Enlarging." He passed round samples of negatives which he considered of the right density for the process. Those which were too thin for printing in any other process were eminently suitable for enlarging, provided they were full of detail. Hard negatives would not give good enlargements.

He used an optimum lantern, and the illuminant was acetylene gas, the generator being home-made. The exposure for the bromide paper was gauged by exposing a strip in sections for 10, 20, 30 seconds; 25 seconds was considered correct for the negative used, enlarging from ¼-plate to 15 x 12. Rodinal was the developer used, ½oz. to 12oz. of water. The resulting enlargement was successful.

He also exhibited a sketch showing how an optical lantern was not necessary, provided one had a condenser and camera. It showed a large box to contain the illuminant; in one side the condenser was fitted, and the camera with negative in place of the ground-glass screen was placed on a support outside, against the condenser. The same lens used for taking the negative could be used, if it was of a rapid type.

New Books.

"Photographic Faults and Failures: Their Cause and Cure." Price 2d. With 24 illustrations. Compiled and arranged by Rev. F. C. Lambert, M.A., Ashstead, Surrey. Published by Cadett and Neall, Ltd.

A veritable *multum-in-parvo*, and worth a good many twopences. The author seems to have set himself the task of discovering every possible way in which the photographer can blunder in his work up to the stage of the finished negative, and provides a remedy for every ill to which the plate or film is heir. The illustrations are exceedingly instructive, and the booklet is undoubtedly a useful compilation.

"Photography as a Fine Art." By Charles H. Caffin. 192 p.p., illustrated. Price 10s. 6d. London: Published by Grant Richards, 43, Leicester Square.

The title of this book is not well chosen. Properly it should be: "An

Appreciation of the value of some American photographers and one Scotchman." The latter is Mr. J. Craig Annan; the former, Mr. Steiglitz, Mr. Keiley, Mrs. Kasebier, Mr. Clarence White, Mr. Steichen, and one or two others. An author who undertakes to examine the claims of photography to be considered as a fine art should give evidence of being qualified for his task. First of all he should know the history of his subject. Mr. Caffin does not; or, if he does, he is guilty of some unpardonable omissions. Has he never heard of the work of Hill and Adamson, Reylander, Robinson, Adam Salomon, Julia Margaret Cameron, P. H. Emerson? These were eminent students and professors of pictorial photography before the advent of a handful of ebullient Americans. Again, the historian should be accurate. Mr. Caffin gives an entirely erroneous account of how the Photographic Salon came to be formed; and repeats the tiresome fable that the R.P.S. showed itself inimical to progressive pictorial work. The evidence is conclusively against Mr. Caffin and others of his kind. We fear that our author has only very perfunctorily gone over the ground he so daringly set himself to traverse. He writes pleasingly of the photographers whose work he illustrates, and perhaps ascribes too great an influence to the work of Mr. Craig Annan, whose fine photographic qualities, which are partly referable to the nature of his environment, we nevertheless freely recognise the book as a whole gives us the impression of having been undertaken in a moment of unreflective enthusiasm, for the treatment of the subjects is quite casual, and unscientific. Boiled down it would make a *passable* magazine article; but in professing to examine a question that has exercised men's minds for at least half a century, it falls enormously short of its possibilities. Finally, for Mr. Caffin's special edification, we may say that there no longer exists the smallest necessity for such a book—at any rate in Europe, where, according to us, every intelligent photographer has long since satisfied himself that it is absurd to claim for any kind of photography whatsoever the distinction of being a "fine art." The book is well produced; the illustrations are good, if unrepresentative; but we cannot resist the conclusion that it is a misfit in photographic literature.

"The Leeds Camera Club Syllabus and Exposure Note Book."

The preface to this useful little book is as follows:—"In bringing out this Exposure Note Book and Syllabus for the second time in its present form, it is hoped it will be of the same use and interest as the former one. Colour photography may appear to receive more than its due proportion in the syllabus, but at the present it is in such a form, both with regard to ease and cost of working, that more of our members might take up the study and practice with interest to themselves and fellow-members. The Infallible Meter Company and the Watkins Meter Company have again given us permission to use their latest tables, for which we heartily thank them; at the same time the officers and committee desire to thank all those who have in any way given their assistance in the compilation of this booklet." The quotation modestly outlines the scope of a production which does its compilers and the Leeds Camera Club a very great deal of credit. It is a decidedly useful pocket-book, full of sound information likely to help the photographer in his camera work. We congratulate the L.C.C. on doing something more for its members than opportunities for sitting and talking.

News and Notes.

It is with very great regret that we have to announce the death of Mr. John Birtles, who was formerly associated with the business management of this JOURNAL and its "Almanac." The deceased gentleman, who died at Stapleford Abbots, Essex, on the 18th instant, in his 66th year, retired from business about four years ago. His connection with the JOURNAL dated back to the year 1861, when the paper was published at Liverpool by the late Mr. Henry Greenwood. The funeral of Mr. Birtles, who leaves a son and two daughters (to whom we tender our sincere sympathies in their bereavement) took place at Havering, Essex, on Tuesday last.

REPORT of the Paris Observatory for 1901.—As usual, the annual report of M. Loewy contains much to interest the astronomer, both professional and amateur. It begins with reference to the determination of the solar parallax by means of observations of the planet Eros, in which our neighbours on the other side of the Channel have taken a prominent part among the fifty observatories in various parts of the world which have been engaged in this most important research. So far, it would seem that the details of the observations made in various parts of the globe have been published in a tabular form, and the meridian observations of stars of reference have been reduced, and the results issued in the shape of circulars from the French National Observatory. Paris seems to have been fortunate in obtaining a large number of photographs of the planet and its surroundings. No hint is given as to the final results deduced or deducible from the discussion of the great mass of observations so far as it has proceeded. The second item of interest in the report deals with the redetermination of the difference of longitude between Greenwich and Paris, the operations in connection with which would seem to have been zealously carried on; but here again we must await the publication of the final results. Incidentally there is a description of a very ingenious modification of the ordinary mercurial reflecting bath, by the aid of which a meridian instrument may be levelled, the nadir point determined, etc., which, originally invented by M. Hamy,

would seem to have been brought to perfection by M. Gautier. Then we learn that the last volume of the "Catalogue de l'Observatoire de Paris" is finished, embodying the results of 387,474 observations, and that 31 maps have been added to the Stellar Atlas of the observatory. After this the report goes on to speak of the photographic atlas of the moon of MM. Luewy and Puiseux, of which several parts have appeared. It is only a week before writing these lines that I had my first opportunity of seeing this monumental work. For beauty and accuracy it has never been surpassed, nor, as far as I know, equalled. To the selenographer it must be simply invaluable. As I remarked last year, one misses the exquisite lunar heliogravure which used to form such a charming frontispiece to the Report. Of the mere routine meridian work, the photographic chart of the heavens, with its concomitant measures of the plates, of the Meteorological Department, the distribution of time, etc., I will not say more than that they show a perennial activity which must tend to preserve the position of the Paris Observatory among the chief and most efficient of those institutions. The Report well repays perusal.—A Fellow of the Royal Astronomical Society in "The English Mechanic."

Correspondence.

THE AMSTERDAM EXHIBITION.

To the Editors

Gentlemen,—We are pleased to inform you that we received information to-day that we have obtained the highest award (Diplome d'Honneur) at the Photographic Exhibition, which is held in Amsterdam, and we shall be greatly obliged if you can find space in your valuable JOURNAL to announce this.—Thanking you in anticipation, We are, yours faithfully,

THOMAS ILLINGWORTH AND Co., LTD.

Willesden Junction, London, N.W.,
September 22nd, 1902.

THE LEEDS CAMERA CLUB.

To the Editors.

Gentlemen,—Herewith I enclose you an advance copy of the "Syllabus and Exposure Note Book" of the Leeds Camera Club for the session 1902-3.

I may also mention that anyone desirous of joining the L.C.C. can do so now at a reduced subscription of 3s. 6d, available for the rest of 1902, thus enabling them to attend all the lectures from the opening of the session.

I shall be glad to supply nomination forms and any other information to applicants.—Thanking you in anticipation, I am, dear sirs, yours faithfully,

F. G. ISSOTT,
Honorary Secretary.

62, Compton Road, Harehills, Leeds,
September 18th, 1902.

CIRCULAR P.O.P.

To the Editors.

GENTLEMEN,—We notice in this week's issue of your valuable journal an inquiry for circular P.O.P. We beg to say we can supply either P.O.P. or bromide paper cut to any size, for professionals or amateurs, in circles.—Thanking you in anticipation, we remain, yours obediently,

EDMEADS AND Co.

30, Burchell Road, Peckham, S.E.,
September 22nd, 1902.

[Messrs. H. and W. Green, of The Crown Photographic Manufactory, Rotherham, and other correspondents, write to the same effect.—Eds. B.J.P.]

PHOTOGRAPHY AS A FINE ART.

To the Editors.

GENTLEMEN,—Herewith I forward you a cutting from the "Daily Mail." I think it is a pity that people that know nothing whatever of our profession should run it down as they do. I have read Mr. Ciffin's book, "Photography as a Fine Art," and to my mind he has proved beyond a doubt that photography is an art. I was arguing with somebody to-day, and they said, "Where does the art come in? It is all mechanical work," but I say, "No. It is not all mechanical.

Is posing, is lighting, is retouching mechanical? No, certainly not." When he retorts, "You have a prepared surface on which to place your image, and chemicals to bring it out." "Yes," said I, "quite true, but the painter has his canvass, his palate, his paints, the image, whatever it be, is put there by his brain; so is the image we photograph." Now, my motive in addressing you is to ask if you cannot do something through the medium of your valued B.J.P. to uphold the name photography holds, and, to my mind, is entitled to. Gentlemen, I hope you will not consider I am presuming in writing thus to you, but I love my profession, and, if I can help it, will not see it run down.—I am, gentlemen, respectfully yours,

F. V. C.

September 15th, 1902.

"The American invasion of our London photographic exhibitions has been promptly followed up by a bulky and pretentious attempt at justification of their methods in the shape of a volume by Charles H. Ciffin, entitled 'Photography as a Fine Art' (Grant Richards).

"We have heard much of 'art photographers,' but the 'Fine Art Photographer' is entirely an American invention. It is useless to try to convince these manipulators of the camera that a 'faked' photograph is, at the best, only a very inferior imitation of a work of art, and that a photograph can only be artistic when it is frankly mechanical—an apparent paradox the truth of which has, however, been admitted by many of our best photographers. The American attempts at photographing the 'soul' of the sitter, and of scratching upon photographic prints to make them look like etchings, or crayon drawings, or anything rather than what they are, are nothing short of ridiculous.

"The examples chosen as illustrations for the book include many attempts of this kind, though the most extreme cases have been carefully omitted. M. Robert de la Sizeranne has tried in vain to prove that photography is an art, and Mr. Ciffin had an even more hopeless task in trying to convince us that it is a 'fine art.'

THE PLATINOTYPE DEMONSTRATIONS.

To the Editors.

Gentlemen,—Referring to the notice which you kindly inserted in last week's JOURNAL *re* demonstrations of our process, and of the working of our oxy-magnesium lamp during the exhibition of the Royal Photographic Society at the New Gallery by Mr. W. H. Smith, we shall be glad if you will kindly correct same, substituting "Monday" for Tuesday, the evenings on which these demonstrations will be given being Monday, Thursday, and Saturday.—Thanking you in anticipation, we are, dear sirs, yours faithfully,

THE PLATINOTYPE COMPANY.

22, Bloomsbury Street, New Oxford Street, London, W.C.
September 23rd, 1902.

A LOST CAMERA.

To the Editors.

Gentlemen,—A tourist, a week since, had the misfortune to be robbed of all his luggage at Perth, and among other things of a 5 x 4 Goerz-Anschutz folding camera fitted with the Goerz double anastigmat, series III., No. 1, No. 108,779. May I ask you to kindly publish this note in your next issue, in order that any dealer or photographer having this camera offered to him may communicate either with the Perth police or myself.—Yours faithfully,

C. P. GOERZ.

4 and 5, Holborn Circus, London, E.C.,
September 23rd, 1902.

THE R.P.S. DINNER.

To the Editors.

GENTLEMEN,—I shall be glad if you will allow me, through your columns, to remind our members and friends that the Society's dinner is fixed for Monday, September 29th, at the Café Royal, Regent Street, at 7 o'clock, and to ask those who intend to take part, but have not yet signified their intention, to let me know at the earliest possible moment.—I am, dear Sirs, yours faithfully,

A. W. W. BARTLETT,
Secretary.

66, Russell Square, London W.C.,
September 20th, 1902.

DARK-ROOM BENCHES.

To the Editors.

GENTLEMEN,—We can testify to the efficacy of the treatment of dark-room benches with the special solutions referred to in your notes on this subject in a recent number of BRITISH JOURNAL. Our chemical laboratory benches have been coated with these same

containing SILVER, GOLD, & PLATINUM, melted and purchased at their full Market Value by

J., J. J., & T. G. BLUNDELL,
199 (formerly 162), WARDOUR STREET, OXFORD STREET, W.

Four doors from Oxford Street.

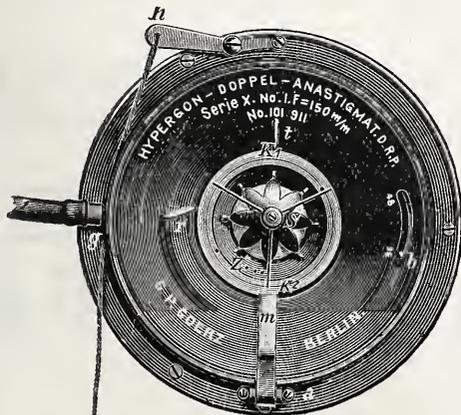

NITRATE OF SILVER of Best Quality at the Full Reduction. CHLORIDE OF GOLD at Lowest Prices for Cash. Consignments attended to with dispatch.

GOERZ

HYPERCON DOUBLE ANASTIGMAT.

Series X, F 22, Angle 135°

SPECIAL LENS

for wide-angle interiors, architecture, landscapes, panoramic views, etc. The angle of this new lens (135°) entirely surpasses that of every other special wide-angle lens. The circle of illumination is extremely large, a plate is covered by the HYPERCON DOUBLE ANASTIGMAT of a focus equal to one-fifth of the plate's diagonal, or one-fourth of its base. With all other special wide-angle lenses, under the most favourable circumstances, the base of the plate is only equal to twice the focus.

Astigmatism and curvature are, over the whole of the angle, entirely removed; the sharpness even to the corners of the plate is consequently excellent.

OBTAINABLE OF PHOTOGRAPHIC DEALERS.

THE "TEB" COMPETITION.

To the Editors.

GENTLEMEN,—By same post we are sending you a box of our "Teb" competition photo Christmas cards, together with particulars of the competition, and hope that you will be able to notice them in the next issue of your valuable journal.

Thanking you in anticipation, and for past favours.—Yours faithfully,

CHARLES TYLER AND ENGLAND BROS., LTD.

79, Copenhagen Street, Caledonian Road, King's Cross,
London, N., September 18th, 1902.

We append particulars and rules of the competition.—ED., B.J.P.]

LIST OF PRIZES.

Half-plate.—First, £5 5s.; second, £3 3s.; third, £2 2s.; and twenty of 21s., £21.

Cabinet.—First, £5 5s.; second, £3 3s.; third, £2 2s.; and twenty of 21s., £21.

Five by Four.—First, £3 3s.; second, £2 2s.; and fifteen of 1s., £15 15s.

Bullet or $3\frac{1}{2}$ by $3\frac{1}{2}$.—First, £3 3s.; second, £2 2s.; third, £1 10s.; and fifteen of 21s., £15 15s.

Quarter-plate.—First, £5 5s.; second, £3 3s.; third, £2 2s.; and thirty of 21s., £31 10s.

C.-de-V., Nipper 2, or $3\frac{1}{2}$ by $2\frac{1}{2}$.—First, £3 3s.; second, £2 2s.; and fifteen of 21s., £15 15s.

Scout 2, F.P.K., Memo Frena, $3\frac{1}{4}$ by $2\frac{1}{4}$, or Brownie 2.—First, £3 3s.; second, £2 2s.; and fifteen of 21s., £15 15s.

Scout 1, Brownie, or $2\frac{1}{4}$ by $2\frac{1}{4}$.—First, £2 2s.; second, £1 1s.; and twenty of 10s. 6d., £10 10s.

Nipper 1, Bantam, or Pocket Kodak.—First, £2 2s.; second, £1 1s.; and twenty of 10s. 6d., £10 10s.

Midget.—First, £2 2s.; second, £1 1s.; and twenty of 10s. 6d., £10 10s.

Making a total of £231 9s.

RULES.

1.—The "Teb" photo Christmas card competition is free to all photographers, amateur or professional. Prints by any process may be submitted, and the subjects can be of any description, as each class of subject will be judged on its merits.

2.—All prints must be mounted on or in one of our "Teb" photo Christmas cards taken from box purchased.

3.—Prints which have been entered for competitions before and have won prizes will not be eligible for this competition.

4.—A coupon will be included in each box of cards, which must be filled in and forwarded with the print. It must be quite understood that only one print can be submitted with each coupon. If the coupon is of a paste-on-type, the coupon must be pasted on the back of the mount. If a slip-in mount is used, the coupon must be pasted on the back of the print and inserted together in the mount.

5.—For prints which are required to be returned, there will be found a space on the coupon in which to mention same, and a stamped addressed envelope with the number of the coupon and size of print distinctly marked on the outside, must be enclosed with the print to ensure the return of the correct print without delay.

6.—In all cases the decision of the judges shall be regarded as final and without appeal.

7.—Any number of prints can be submitted by each competitor, but each print must bear a coupon. Competitors cannot obtain more than one prize for any one size print, but may compete for prizes in each size.

8.—All winning prints become the property of Messrs. Charles Tyler and England Brothers, Limited, together with the right to reproduce them, but none will be returned unless stamped addressed envelopes are sent.—(See Rule 5.)

9.—Prints must be received by Messrs. Charles Tyler and England Brothers, Limited, 79, Copenhagen Street, King's Cross, London, N., not later than December 24th, 1902, and the small label attached to coupon must be pasted on the outside of wrapper.

10.—The result of the competition will be published during the first fourteen days in January, 1903, in the "Amateur Photographer," "BRITISH JOURNAL OF PHOTOGRAPHY," "Photography," and "The Photographic Dealer."

JUDGES.

R. Child Bayley, Esq., Editor of "Photography"; Thomas Bedding, Esq., Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY; Arthur C. Brookes, Esq., Editor of "The Photographic Dealer"; A. Horsley Hinton, Esq., Editor of "The Amateur Photographer."

C.C. PAPER.

To the Editors.

GENTLEMEN,—The troubles with C.C. paper which your correspondent, "Othello," puts before you in the JOURNAL, September 19th, are very real and perplexing. I have used a well-known brand of paper for some time, and succeed in obtaining some beautiful results, both red and black; but at times things go wrong, and spots appear upon mounted and finished prints only.

Only lately I sent home a batch of pictures, quite free from surface blemish when they left my studio, but, the family being away for holiday, the parcel remained unopened for about three weeks. A few days after the return to town of my customers the pictures were returned to me, covered in spots (as per sample of the packet enclosed), with the request that I would furnish some explanation.

One remedy for this complaint is, thoroughly wash between each operation, and let the pictures be perfectly dry before packing.

There may be other remedies, and I, with "Othello," should be glad to know them; but I have found this a cure in some cases.—

Very truly yours,

LANG SIMS.

437, Brixton Road, London, S.W.,
September 22, 1902.

PHOTOGRAPHIC FETISHES.

To the Editors.

GENTLEMEN,—In an article entitled, "On Some Photographic Fetishes" in your issue of September 19th, it is stated: "If there be an absolutely inextinguishable statement in photographic technics, it is that depth is not a function of any particular form or material of construction of a lens, but is solely governed by the relation of effective aperture to focus." As a matter of fact, this "inextinguishable statement" is itself an obsolete fetish, for, in addition to effective aperture and focal length, the position of the stop relative to the nodes of the lens is now known to be a factor governing depth. As a consequence, lenses of the same focal length and aperture may give different depth; thus, a telephoto lens has greater depth than a rectilinear of equivalent aperture and power, while a rectilinear has greater depth than a similarly equivalent lens of "single landscape" construction. In the latter case the differences are extremely small, excepting with very near objects; but, nevertheless, they exist.

Another factor affecting depth is the quality of the definition, which also depends on constructional features. Depth formulæ are all based on the hypothesis that a lens produces a perfect point image from a point object; but no lens does this. At the best, the image of a point is a disc, the size of which depends on the degree of correction attained, and the larger the disc the less is the available depth, assuming that depth is limited by a certain amount of permissible confusion of focus. For example, if we take 1-100th of an inch as the diameter of the largest allowable circle of confusion and the lens is so poor as to be incapable of producing a smaller disc, it is obvious that there can be no available depth at all.

The characteristic feature of a modern high-class lens is good marginal definition, and, as depth is a matter of importance principally in the case of objects near the margin, it stands to reason that a good lens will give a more serviceable amount of depth than a poor lens. Depth in the centre of the plate is not a matter of any great consequence, but with an indifferent lens the centre is the only spot in which any appreciable amount of depth is likely to exist with a fair-sized aperture.

With reference to the use of single lenses for architectural work, I quite fail to see that a belief in the utility of rectilinear lenses is of the nature of a fetish at all, and only wish that absolutely rectilinear lenses were more generally available. The curvature of a straight line is evidence of distorted proportions, but the effect of curvature is not always apparent until the distortion is considerable. The simple fact that little or no curvature is evident in a result produced by a single lens does not by any means prove that the photograph is satisfactory as an architectural record. Architects generally have small faith in the accurate drawing of trade photographs, and their little faith is not likely to be increased if they are encouraged to believe that photographers do not as a rule take all reasonable precautions to guard against distortion.—

Yours, etc.,

C. WELBORNE PIPER.

September 20th, 1902.

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—A Revised Tariff for advertisements in the JOURNAL is now in force. Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

Answers to Correspondents.

- * * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.*
- * * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.*

PHOTOGRAPHS REGISTERED:—

- H. W. Hood, The Willows, Linthorpe, Middlesbrough. *Photograph of a baby at a typewriter.*

SITUATION WANTED.—J. W. B. writes: "I wish to obtain a situation in Germany as retoucher. Will you kindly give me the name of the best German paper to advertise in for same?"—In reply: A list of the principal German papers is given in our ALMANAC.

SPOTS ON PRINTS AND NEGATIVES.—"PERPLEXED."—We can add nothing to what we told you in the previous reply. It is clear that, as some negatives out of the same batch of plates turn out spotty while others are free from defects, the spots are due to the manipulation, and not to the plates. Did you try filtering the water through flannel, as we suggested?

BROWN POSTCARDS.—A. C. Z. says: "Will you kindly give the formula for sensitising 'vandyke brown' postcards, such as are sold in packets (Mallandain's)?"—In reply: We do not know the formula by which Mr. Mallandain prepares his postcards, as he has not published it, and it is not very likely that he will do so. Possibly, for a good fee, he would supply you with it.

DARK VIGNETTES.—"VIGNETTE" asks: "Will you kindly inform me if a special vignette frame is required to procure photos as enclosed? If so, will you please state how they are done?"—In reply: There are different ways of producing dark vignettes. They may be vignettted in the camera, or done by double printing. If you refer to page 163 of our volume for 1901, you will find an article on the subject.

INSURING NEGATIVES.—H. SYMONDS says: "I want to have some valuable negatives enlarged. There is great danger in their being broken in transit, or in the enlarger's hands. Is there any way of insuring them?"—In reply: The railway company will insure the negatives during transit. Possibly some of the insurance companies will grant a "floating policy" on them that will cover the risk while in the enlarger's hands, but we are a little doubtful.

"AMICUS."—The only thing we can suggest is that your friend's daughter apprentice herself to a good photographer to learn the business, or such part of it as she desires to follow. If no premium is paid services must be rendered in lieu of it. We should say that probably a couple of years would be expected at, perhaps, a very small salary. Better consult the advertisement columns of the JOURNAL. We may as well tell you, as you will see from them, the labour market is already overstocked with lady assistants.

VARNISHING PRINTS.—H. MANDSELL says: "A customer of mine recently asked me if I would varnish an album of photos, which were taken in India, and were beginning to fade. He had been told in the letter accompanying the photos that if he took them to a photographer and had them varnished it would preserve them. I have never heard of such a process. Can you advise?"—In reply: The prints may be varnished with a varnish such as is employed for maps and the like. It may be obtained from most artists' colourmen. But we may tell you that it will have but little effect in arresting the fading of the pictures.

SPOTTY PRINTS.—"SPOTS" writes: "I enclose a couple of pieces of P.O.P. paper, and you will notice some spots, of which I have had a good many lately, and can't discover the cause. I use the sulpho-cyanide toning bath, usual formula. If you could give me any idea of the likely cause of them, should be awfully obliged. They seem to start in the toning bath."—In reply: The spots are caused by particles of matter that have come in contact with the prints while they are wet, and so reduced the silver. It rather looks as if there were particles of iron rust in the water in which the prints were washed prior to toning.

EBURNEUM.—"MINIATURE" asks: "Will you be kind enough to inform me by what process is the little miniature (now enclosed) made? And do you know of any firm doing this class of work, and what would be about cost? I have an order for a dozen from two prints, and my clients want something better than the bromide enamelled process."—In reply: The picture is by the eburneum process, introduced many years ago by the late Mr. Burgess, of Norwich. It is a collodion positive (taken from a negative), backed with a mixture of gelatine and zinc white, and when dry stripped from the glass. The picture has been returned, as desired.

PURCHASE OF BUSINESS.—"ARTHUR" says: "I am anxious of opening a studio, and think it best to purchase a going concern. Would you be good enough to let me know what amount of capital it would be advisable to sink to purchase a business showing net profits about £150 to £200 a year? I should do my own operating and

retouching, and want to do a good-class business; cabinets 21s. or 15s. a dozen."—In reply: If you consult our advertisement columns you will be able to gather the market price of such a business as you require. On page 585 ante you will find an article "Some Points in Connection with Goodwill," that will give you useful information.

SPIRIT PHOTOGRAPHY.—J. W. P. says: "(1) I enclose a cutting from the 'Two Worlds' about the photographing of a spirit. I am rather interested in it, if it is possible. I understand that Sir Wm. Crookes has successfully experimented. It is hard to believe such things are possible. I don't mean an imitation of a spirit, but a reality. A reply to this will be greatly acknowledged as a favour. (2) What is the meaning of lenses named as 1B, 2B, 1A, 3D, etc.?"—In reply: (1) It is the first time we have heard that Sir Wm. Crookes has been successful in taking spirit photographs, and we very much doubt its correctness. We have seen many so-called "spirit photographs," but all we have seen we have put down as frauds, and most of them very clumsy ones too. (2) The terms are those used by Mr. Dallmeyer to designate the different kinds of his lenses. They are merely trade terms.

PHOTOGRAPHY AT NIGHT.—S. A. C. says: "I should be glad if you could give me some idea as to the best illuminant for taking an instantaneous photograph of a large concert room with audience and performers? I have the opportunity of taking such a group, but am a little in the dark as to whether it can be done successfully without expensive apparatus, not having touched this side of photography. It would be a good advertisement if successful; but as I have but recently started in business, would rather keep out of it if it was likely to be a failure."—In reply: If electric arc lights are not available, you must employ flash lights—rightly distributed. If you have had no experience in this direction, you must not be too sanguine of success in the first attempt. Better make some preliminary trials the night before the picture has to be taken. We do not undertake to answer correspondents by post.

AN UNSATISFACTORY TRANSACTION.—M. O'GORMAN writes: "Could you inform me what redress I have against — and Co., of —, to whom I sent a number of stereoscopic films for development? Half the negatives were returned to me ruined by being cut through (one of the stereoscopic pictures being in each case cut in half). Some of the negatives which were not cut were spattered with mud. The delay in execution has lasted now for many months. The negatives were important, and I had to put the matter in the hands of a solicitor. When the negatives were sent they were spoilt, as described."—In reply: As you have already placed the matter in the hands of a solicitor, he, knowing all the circumstances of the case, can advise you better than we can. On the price lists of those who work for the trade there is usually a notification that they will not hold themselves responsible for any accidents that may happen to negatives while the work is being executed.

STUDIO BUILDING.—"STUDIO LENGTH" says: "I am about to open another studio in connection with my own here, and have selected excellent premises, but am met with the usual difficulty of studio building. The only place possible to convert into a studio is a room on the first floor, and I feel very uncertain about it, as I cannot get the top light. It is my intention of glazing the greater portion of the length by removing two windows and carrying the whole two feet forward, as I will try to define by sketch. I would like to know if in your opinion it will be at all satisfactory? I have been accustomed to surmount difficulties in lighting in the studio, having worked in some difficult ones. But my own here is very convenient, having had it built to my own liking, and I have a length of 42 feet. In the new one I would only be able to get 20. Do you think this enough for general work? I am afraid I will take rather badly to it now; but, then, one has to make the best of circumstances."—In reply: So far as we can judge from the sketch (though the height, and aspect, of the proposed studio is not given), we should say that good portraits could be taken in it; particularly as you say you have already had to surmount difficulties in lighting. Twenty feet is certainly short for a studio for professional work. If you could possibly increase the length it would be a great advantage.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published early in December next. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The edition for 1903 will be increased to 25,000 copies, a large number of which are already ordered.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1903. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

Secretaries of societies will oblige us by promptly forwarding lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, etc. Those firms who wish to take advantage of this feature should communicate with us not later than October 31.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRA.

Protective Colouring.

It is curious to note how constantly man, with all his boastful powers, is obliged to hark back to the ways of Dame Nature, and humbly plagiarise her works. The adoption of kharki as the right colour for military uniforms on the veldt of South Africa is simply a copy of what Nature has been doing ever since the world began. She has given the animals, both beasts and birds, whose lives were passed on the desert sands of Egypt, a sand-coloured clothing of fur and feather, while in the Arctic regions their uniforms are white as snow. This protective colouring in mimicry of their surroundings is a well recognised trait of animal life. The naval lords have now determined to give all the battleships a coat of grey paint, in protective mimicry of sky and sea, and this certainly is a move in the right direction. But, as all photographers know, much will depend upon the natural lighting of those warships whether the coat of paint prove really effective for the end in view. With a bright sky at their back they will look, under certain conditions, quite black; while, should the sky be murky and the light full upon them, they will stand out almost white in tone. Nature has arranged matters very cleverly in the case of various sea birds, who are grey above and white underneath when their bodies only receive the lesser reflective light from the water, so that they will often appear of a colour so like their surroundings that they are all but invisible. On grey days our grey warships will be pretty safe, but their new coat of paint will not suit other climatic conditions much better than did their old colouring.

* * *

Fakements. Much misdirected ingenuity has been expended upon the business of making the product of a photographic negative as unlike a photograph as possible.

Recently we culled another fake from the pages of that excellent journal, "The Scientific American." The article to which we refer is entitled, "Some Modifications of the Normal Photograph," and directions are given by which a sharply focussed image may be blurred, and tiresome detail eliminated. In the first place, the double back of the camera should be of the American pattern in which the shutter slides right out of its grooves. This operation having taken place, and while the cap is yet on the lens, a translucent shutter made of dulled celluloid is slid in front of the sensitive plate. A piece of round glass will answer the same purpose, which is to produce a negative such as one would obtain by shifting the lens out of focus. It is also recommended that this translucent screen may be placed at different distances from the plate, according to the effect desired, finer details being eliminated, and breadth secured. Another effect is obtained by placing over the sensitive plate a thickness of fine, thin muslin, stretched over a frame of common tin, or thin brass plate, the frame being placed in the holder along with the plate. We are further told that a lantern slide produced from such a negative, and well coloured, appears on the screen more like a painting than a photograph. We feel that we must protest against this recommendation to sophisticate the photographic negative. If a sharp image is objected to, the celluloid, ground glass, or muslin can be interposed between negative and paper in the printing frame, leaving the beauties of the original image unimpaired. If detail in pictures is really so detrimental to artistic effect, the beauty of detail with which Dame Nature has adorned every tree and shrub must be equally so, and we ought all of us to wear spectacles, the glasses of which are covered with fine muslin or rendered semi-translucent by some other means, in order to correct her faulty handiwork.

* * *

Processes in the R.P.S. Exhibition and their Nomenclature.

It is interesting to note, year by year, the different processes by which the pictures passed by the Committee of Selection and shown at the Royal Photographic Society's Exhibitions are produced, more particularly in the pictorial section. For some years past the carbon and the platinotype processes have prevailed. This year carbon takes the palm, as there are, out of the 290 pictures shown in this section, 93 by this process, as against 85 by the platinotype process, with but 54 by the bromide. The "Gum" process shows an increase this year, as there are 25 by that, one of which is described as being "Pouncy's process." This leads one to ask if these are not all "gum," and "gum-bichromate" prints by Pouncy's process, though he gets but little credit for it by its present workers? This, in great measure, is due to the majority of them not knowing who was the real inventor of the gum process. Photographers in the Colonies who read these statistics must not assume that the processes represented at this Exhibition bear any relation to those by which the majority of the commercial work in the old country is produced, for it does not—therefore to them it might be misleading. According to the catalogue there are but four pictures described as being in silver, yet there is no question that there are very many times the number of silver prints produced in everyday work than there are by all the other processes put together. How many times this number may be it is of course impossible to say, but amongst professionals and amateurs it must be hundreds of times as many. The term "silver" applied to the four pictures that are shown under that name is somewhat vague. Are not "bromides," "chlorides," "albumen," "platinum-toned," etc., all silver

pictures? Again, are not all "gum," "gum-bichromate," etc., pictures in carbon? The first carbon process was a gum process—the same as that now worked. Future historians, taking up the catalogue of the Exhibition of this year, for example, might assume from it that silver printing was, at this period, almost obsolete, while, indeed, it is possibly in its zenith, at least for commercial work.

* * *

Anomalies of Artistic Copyright.

One day last week there was an article in the "Standard" under the above heading, on a treatise, recently published (Murray) by Mr. E. J. Macgillivray. The article gives extracts from the book, and is of such interest to photographers that we give it on another page, as it shows the anomalies that exist under the present laws with regard to copyright, more especially in our colonies, under the International Copyright Act. In a letter in our contemporary a few days later Mr. John F. E. Grundy, hon. sec. of the Society for the Protection of the British Fine Art Copyright in the Colonies, the president of which is the president of the Royal Academy, further points out these anomalies. In his letter Mr. Grundy calls attention to the fact, from a case that was taken through various Canadian courts, that while Canada is a party to the Berne Convention, and Canadian owners of copyright have full protection in Great Britain and elsewhere, the British owner, by reason of the Canadian local *status*, has no such protection in Canada. Thus, while this colony has every advantage under the Berne Convention, she gives nothing in return. In his letter Mr. Grundy points out that this decision will probably be taken advantage of by other colonies, and may very materially affect the value of copyrights, and the British export of reproduced art, which is increasing in proportion as the colonies expand in population and wealth. As the law now stands, a Canadian photographer, under the Berne Convention, has perfect protection of his copyrights here and elsewhere, but the British photographer, as we pointed out a short time ago, has no protection against the piracy of his work in Canada, though it is one of our own colonies, yet he has in France, Germany, most Continental countries, and even in Japan. The object of the above Society is to remedy this state of things if possible.

* * *

Seizure of Pirated Copyright Works.

It must be patent to everyone that publishers of copyright music, particularly that of the most popular type, must of late have suffered severely by the piracy of their work. This is evidenced by the sale of copies by street hawkers for less pence per copy than the publishers price is shillings; and still more galling to them is the fact that these pirated editions are sold as copyright music. The printers of it, and those who vend it to the hawkers, are difficult to discover, and if they are discovered they are men of straw, from whom no substantial damages can be recovered. A short time ago an association was formed by the publishers to protect their rights, and this they did to an extent by taking the law into their own hands—by employing men to seize by force the pirated copies found in the possession of the hawkers. Several cases have come before the police courts as a result. In the majority of cases the magistrates were in sympathy with the publishers, but still the business flourishes. Last week a caution to the following effect to hawkers and pedlars of pirated copyright music, under the Musical (Summary Proceedings) Copyright Act of 1902, was issued by the Metropolitan Police. This empowers any constable to seize without warrant, on the

request in writing of the apparent owner of the copyright, or his agent, any pirated copy. On seizure the piracies shall be conveyed before a Court of Summary Jurisdiction, and, on proof that they are infringements of copyright, shall be destroyed, or otherwise dealt with as the Court may think fit. There is no such law with regard to pirated photographs. Some years ago hawkers used to carry large stocks of pirated copies of portraits of celebrities, but of late this business seems to have died out. At the time to which we refer photographic piracies of engravings of large size (about 15 by 12), were very common, they being hawked outside railway stations and public-houses, but the same difficulty was then experienced by the owners of the copyright as that now experienced by the music publishers, namely, getting at those who actually produced the piracies. If, perchance, they were got at, they were but "men of straw," and nothing could be got beyond the confiscation of the negatives, and such prints that might be found. The greatest piracy that photographers now suffer from is from the illustrated press, and the publishers of local views in cheap albums. But here they always have a substantial redress, that is, if they have taken the precaution to register the copyrights in their work. This they too often neglect to do, and then complain loudly if it is pirated.

* * *

Thunderbolts and Meteorites. It is astonishing that the tradition of the thunderbolt, meaning a solid mass of matter which is ejected from the clouds during a thunderstorm, should have survived so long as it has. Every season brings its quota of stories of these remarkable occurrences, and during the past few weeks we have heard of one or two more. Only the other day a correspondent of the "Times" described how he and others distinctly saw something strike the ground, raising steam at a particular spot. Unfortunately, he adds, "we had not time to go and verify the spot, where the bolt, if it were such, was seen to fall." A few years ago, at an exhibition held by the Meteorological Society, if we remember rightly, a few alleged thunderbolts, with most circumstantial notes by persons who have seen them fall, were on view. One was a lump of coal, and another was a delapidated brick, but they were picked up near the place where a flash of lightning was seen to strike, and, of course, they passed as thunderbolts. We can easily imagine how the idea of a thunderbolt first arose, in the difficulty of the ignorant mind understanding how a deadly blow could be struck otherwise than by something of a solid description. And the mythical bolt has become associated with the meteorite, and as several of these can be seen in our national museum, one weighing many hundreds of pounds, careless visitors are apt to mix up two things which have little relation to one another. A photograph of a thunderbolt ought to have come to hand before now, considering the many alleged instances of their occurrence, but we have never yet heard of such a picture. Meteorites are far from common, for most of those which we see as "shooting stars" are dissipated into dust in the act of becoming visible. It is almost a pity that they are so rarely found, for they are very valuable. The chief of the Natural History Museum, at Berlin, was reported as having recently paid as much as a sovereign per gramme for one, a statement which at once aroused the cupidity of certain evil-disposed but ingenious persons, who thereupon set up a meteorite manufactory! These counterfeiters must have done their work in a very clumsy manner, for the fraud was quickly detected and they were arrested. The method by which they produced their fictitious meteorites was then made known. After possessing themselves of a piece of

rock, they burnt the stone so as to induce the formation on its surface of a black crust, which they made shiny with a coating of lampblack and molten sulphur. As a real meteorite is mostly composed of metallic iron, its specific gravity would be very different to that of any kind of stone, but the forgers were doubtless ignorant of this method of testing the true from the false.

* * *

Platinum. Those chemists who were fortunate enough to possess themselves of basins and other receptacles of platinum, say, thirty years ago, before the price went up, are now congratulating themselves on the circumstance that these vessels are in value equal to those of pure gold. At that time platinum had little employment except in the chemists' laboratory, and that only because of its acid resisting qualities. Soon afterwards the demand suddenly increased. The metal was wanted for photography, but still more urgently for the electric glow lamp. Each of those little glass bulbs has a couple of fine platinum wires fused into its foot, so that the necessary connections may be made to carry the current to the carbon filament within. Other metals have been tried for the same purpose, but platinum is better than any. The amount of metal in each lamp is very little, for the price of the complete article is now less than one shilling, but so many millions of these lamps are now in use that the aggregate amount of platinum which they consume must be very great. The supply of the metal is not equal to the demand, and hence the rise in price. Hitherto the chief source of supply has been the Ural mountains, and the total yearly amount mined there hardly exceeds six tons. No wonder is it, then, that, as an American would put it, "there is not enough to go round." But possibly it is reserved to America to find the remedy for this state of things. According to the "New York Sun" a supply of the valuable metal has been discovered in two places in Washington, near Princeton, and at the Olympia mine on Kennedy Mountain. The ore from one of these districts has been assayed, and the verdict is that it contains platinum in commercial quantities. It seems that it is impossible as yet, owing to the presence of deep snow, to ascertain the extent of the platinum bearing rock, but the ground has been staked, and the matter will be thoroughly investigated in the spring. We also learn from the same source that the Canadian Government sent an expert to Klondike in December last to report on the alleged discoveries of the heavy white metal in that region. It seems that a Government metallurgist had stated that certain consignments of gold which had reached him from the gold workings there contained considerable quantities of platinum, and that he believed that the miners were, in their ignorance, throwing platinum nuggets away to the tune of thousands of dollars' worth daily. We are not told whether the expert returned and made his report upon this important matter, but possibly we shall hear more later. It would seem, then, that there is a likelihood of the world's platinum supply being enriched by contributions from both America and Canada, and should these anticipations be realised the price of the metal will, of course, go down. Photographers will, with many others, reap the benefit of this, and the beautiful printing process which depends upon platinum as its mainstay will find fresh adherents.

* * *

Dressmaking by Photography. Although this summer has, by reason of its unseasonable character, been the worst for the practice of photography for many years, more attention has been given by the

daily Press to the camera and its works than we have yet known. It is good for all engaged in the business of photography, whether they be studio workers, or dealers, or manufacturers, that this should be the case, for it means advertisement of the best kind at a very cheap rate. The other day appeared an illustrated article in the "Daily Mail," for example, which gave an interesting account of the manner in which Parisian costumiers are utilising photography in the carrying out of their business, and possibly by the perusal of such an article photographers in this country may see a new opening for their talents, although for some reason or other the enterprise seems to be rather difficult of realisation in the absence of French models. We all know what the ordinary fashion plate is like, a picture in which an impossible human form—impossible because a figure so constructed could not exist—is clothed with the latest devices of the fashionable milliner. Now it seems that the big dressmakers have not been wholly satisfied with these artistic creations, although those of London and New York were careful to get the best work by sending over each season capable draughtsmen to the gay capital. So that something better is being attempted, and the notion originated in Paris itself, where a Madame de Boutrelles conceived the idea of gathering round her a collection of beautiful damsels, whose business it should be to dress as models for being photographed. These girls, selected from the smaller Paris theatres and music halls for their figures and faces, the figure being, perhaps, the more important of the two, are dressed in the latest creations of the best dressmakers, who send in dresses six months before the opening of the season. And the word "dresses" comprises hats, boots, and even umbrellas. Then these young women are photographed in different positions by two of the best photographers, and the pictures are sent out broadcast, and are sold at good prices to expectant dressmakers all the world over. A single photograph, we are told, accompanied by a working description of the garments shown, will cost from £8 to £10. The pay of the models ranges from four to five shillings for the morning's work, about three hours, and the girls are only too glad to add in this way to their scanty salaries. Moreover, they like it. What woman is there who would not enjoy a constant change of attire, even if the plumes be but borrowed? Then occasionally the damsels come in for a perquisite in the shape of a soiled gown, and they also have a few copies of the photographs presented to them. But not all young women are built in the particular way which is required for this work. The conventional idea, as embodied in the fashion plate of old, clings to the new system. They must have small heads and small hips. The ordinary English woman is too clumsy in make. "Dainty, slender little feet, too, combined with a tall, slim figure, are almost a monopoly of Parisian girls." Of course, we do not believe this, and fancy that it would be far more easy to find girls with the necessary "points" in our own country than in any other. We think that the system could well be started over here, and would flourish well in competent hands.

* * *

Chemists Combine.

The recent reprint in the JOURNAL (page 726) of Mr. Jones's able résumé of "The Law Relating to the Sale of Poisons" is interesting to photographers generally, and, as many of our readers are pharmacists, was no doubt appreciated by them also. The present unsatisfactory position of the chemist or pharmacist is, judging by the correspondence columns of the drug Press, greatly agitating the rank and file of the qualified pharmaceutical body. The main point of discussion is

apparently in relation to the "title." Briefly put, the case stands thus: The Pharmaceutical Society (a chartered body) elaborates a scheme of education, appoints examiners, and conducts examinations which, judging by the proportion of rejected, are stiff enough to satisfy an exacting critic. As a reward for the time and mental labour expended, the successful candidate is entitled to call himself a chemist and druggist, or pharmaceutical chemist, as the case may be—a title conserved to him, as most people imagined, by the Pharmacy Act of 1868. Meanwhile, there have sprung up various drug companies, who, as limited liability combinations, arrogate to themselves the title of chemist, while being, as a fact, aggregates of men with no qualification whatever. The person, therefore, who in all good faith serves his apprenticeship, studies the usual subjects, takes the courses at one or other of the schools, and finally, by good luck, passes his examinations, finds himself at the finish, when prepared to practise the profession for which he has qualified himself, confronted by a company composed of unqualified persons, who, by some mystic virtue of incorporation, are allowed to use the same designation without let or hindrance. What one person may *not* do under divers severe pains and penalties, seven unqualified men may do with impunity! The subject is interesting to every one of us, for at the least we may be parents or guardians, with sons or wards to introduce to a profession, and it is well to go into such matters with eyes wide open to the possibilities and results. From the purely photographic point of view the branch of the subject most closely concerning ourselves is that of the poisons, such of them, that is, that may be required for purposes of photography. It is not so long ago that we had frequent complaints of the restrictions placed on the sale of certain scheduled poisons required for business purposes by members of our craft, and the difficulties placed in the way of their purchase. There were many, no doubt, who viewed the multiplication of certain drug stores with comparative equanimity, under the impression that the restraint to trade (more apparent than real, perhaps), owing to the difficulty referred to above, might be thereby greatly modified, but on the contrary we have not, we are bound to say, found mercuric chloride, for example, any easier to get at the drug store than the more orthodox pharmacy, and the reason is probably that the manager of the store, himself, may be, a qualified man, has no personal interest in the concern. His only interest so far as relates to poisons is—knowing the usual risks, regulations, restrictions, and liabilities—in the main to save himself by letting them severely alone, and, when one thinks of it, there is no reason why he, having, as we have said, no personal interest in the matter, should take the risk. As a matter of fact, the store manager has to reckon with two forces instead of the one which overpowers the legitimate and single-handed pharmacist. Whereas in case of error or other mishap the latter has to fear the vagaries of a coroner, the former has, in addition, his company to square with, for, although the seller is the mulcted party, it is the company or proprietor who is expected to pay the piper. The "Pharmaceutical Journal" implies that a future amended Pharmacy Bill would most probably deal with the matter of titles in a manner different to that anticipated, *e.g.*, the profession of analytical chemists undoubtedly requires consideration. The minor examination certificate of the Pharmaceutical Society is clearly insufficient evidence of skill in the important branch of pure chemistry—it is not intended to be—but it confers the abbreviated title of chemist to which the owner thereof may tack on at will the analytical adjective. Clearly the Institute of Chemistry is entitled to consideration. As a

matter of common justice all round, the whole position deserves settlement on the fairest lines alike to the pharmacist and the chemist, while the unqualified contingent, with designs on conserved titles and professions, should be individually and collectively made to understand that the only honest and straightforward course thereto is through the examination room.

LANDSCAPE ACCORDING TO SEASON.

THERE is an expression which we have occasionally heard applied to a certain class of workers, which, although not to be found in any dictionary, is like a few other words of base coinage rich in forceful meaning. The word is "groovy," and it is rightly applied to those men who allow the same wheel to traverse the same rut, month after month and year after year. There are not a few of these men to be found among photographers; workers who are content to do things exactly as their fathers did before them, and who take little heed to make themselves acquainted with the advances which are being continually made, and with the trend of photographic affairs generally.

A photographer must be judged by his work, just as a tree is known by its fruit, and we can readily pick out the "groovy" man by examining his show case, or the album of specimens which lies on his reception room table. His portraiture is all of the old shoppy kind, with the ancient form of background, with its wretched pillar and curtain, or the familiar balustrade, and the pictures are filled up by old-fashioned accessories which resemble nothing found in an ordinary habitable room. But it is to his landscapes that we would wish just now to call attention, and more particularly to those pictures of the surrounding scenery which form such an important part of the work of those who are fortunate enough to have pitched their tents in districts haunted by tourists.

There are always some noted spots of which the tourist is likely to require a picture, and as a rule the tourist is content with what is offered him provided that the view is sharply focussed, that it is black and white in tone, and that it is well mounted. He knows, as a rule, nothing about values, nor does he concern himself about atmosphere or any of the finer pictorial features which would appeal to a competent judge at a photographic exhibition. He requires only a faithful transcript of the view to which he has taken a fancy, and he gets it. The local photographer has, of course, learnt the best time of day to get that view properly lighted, and in taking the negative he generally concerns himself about nothing else. He will rightly count upon so many dozens of prints from that negative selling in a favourable season, and that is sufficient for him. The same wheel runs in the same rut year after year, and he sticks to his groove.

Has it ever occurred to him that he might increase the number of his clients by paying a little more attention to the aspect of Nature according to the different seasons? Let him, for example, take one of the stock views, such as the High Tor at Matlock, Friars Crag at Derwentwater, or Stybarrow Crag at Ullswater, in its spring, summer, autumn, and even wintry aspects, making a careful study of each exposure, and turning out faultless and suitably toned prints from his negatives. Some of the groovy men would doubtless laugh at such a proposal, and would say that such work would not possibly pay. Or "we must leave that kind of thing to the amateurs," forgetful that the line of demarcation between the amateur—using the word in its true sense—and the professional is so narrow that it is difficult to define. We remember the time when

the gelatine plate was said to be "all very well for amateurs," and when the bulk of the profession held that view. They were too "groovy," and it cost some of them a painful effort to get out of the old (wet) rut.

Another objection to landscape according to season would be urged by those who have not kept themselves abreast of modern advances in photography. We should be told that there would be little difference in the aspect of a landscape taken in either spring, summer, and autumn because photographs are dead to colour effects, and the result must in all three cases be variations of black and grey. This is true in one sense, but let the experiment be fairly tried, and the man who is not too rigidly bound to the old groove will quickly see that he has a new power in his hands. Let him first carefully examine his stock pictures, and ask himself if the funereal aspect of the grass and trees is really true to Nature? A fair way of putting it is this: Would an accomplished engraver, who, like the photographer, has to translate colour into what is technically known as tint—would he represent the same trees and grass with these inky tones?

That such false rendering can be altogether avoided is well known to all up-to-date photographers. But what is not so generally known is that in the case of mixed foliage, where greens of many different hues appear in one picture, there is an enormous advantage in working in the early spring, that is, so soon as the branches are well clothed. With an ordinary plate, preferably one of the slow kind, and without the help of any colour screen, foliage may at this time of the year be most beautifully rendered. The light is at its best, the foliage is new, and it will be found that the various tones of green are differentiated on the plate in a manner which is quite impossible later on in the year, when the sun has ripened the leaves to a more or less non-actinic condition. We are convinced that the sable tint of the foliage in many photographs is due to the fact that the taking of the negative has been delayed until too late in the year.

Then, with regard to autumn photography. If what we have written be true, the foliage must by this time be so seasoned with the heat of summer that its power of reflecting light into the camera must have almost disappeared. And this is certainly the case with most years, the present one being quite abnormal in its paucity of sunshine. But let us not be in a hurry. In a very short time the leaves will give up their green livery and will array themselves in red, russet, orange, and gold. Black as ink these tints will photograph if we used the plates we recommended for spring work, but with an orthochromatic plate and a screen, used with that mixture of brains which has been recommended as one of the necessary constituents of a good developer, we can change all that gloom, as if with a rub of Aladdin's lamp, into a scene of life and beauty.

Again we seem to hear the voice of the groovy one pleading that, if the old type of picture sells, his end is gained, and that, although there may be some advantage in using colour sensitive plates, it is more or less of a fad, and would cause difficulties in the dark room which he does not care to face. If the public is satisfied what more can be wanted?

To this we would reply: "Is there no satisfaction in endeavouring to educate the common taste, which is confessedly at a low ebb, in favour of better things?" And if this should not appeal to our groovy friend, we might hint at the possibility of someone seeing the force of what we have been advancing, and become a serious competitor in the same field.

We need not point out the advantage of using colour-

sensitive plates in the winter time, for most photographers know how they clear up mist and give a wonderful delicacy to the tender shadows on snow. We have only to look at some of the wondrous alpine scenes produced by good workers to see what can be done under wintry conditions. We have no mountains, it is true, but we have waterfalls, which are splendid objects when gripped by the frost, and we have plenty of landscape which assumes a new beauty under the influence of hoar frost or snow. Nature is almost as fond of changing her dress as is a fashionable beauty, and she does so without running up a milliner's bill.

TRIBULATIONS OF A PRESS PHOTOGRAPHER.

"Why not take up press photography?" Jones suggested, when I said that I wanted a little easy work to add to my income. The idea sounded, on the face of it, an excellent one. I bought a book about the subject and read therein a glowing account of the profits of the profession. It seemed a grand idea to go and take an old tombstone, or a railway accident, or a football match, or something of that sort, and get ten-and-sixpence for your trouble. The work was congenial, and at least five pounds a week ought to be forthcoming. With high hopes I sallied forth and purchased a camera and the necessary materials.

The camera rejoiced in the title of the Guinea Snappy, and (so the shopman assured me) was the best and cheapest on the market. His enthusiasm, I fancy, ran away with him. If the Snappy is the cheapest piece of photo apparatus, then all I can say is, the average button-presser must be a millionaire. But I am anticipating.

I didn't know much about photography, so decided to try my hand on something easy first. I therefore put in a roll of film, and (the day being a sunny one) went to Downing Street. The *Morning Post* had said there was to be a Cabinet meeting, and I thought it would be a good plan to obtain snap-shots of Mr. Chamberlain and Mr. Balfour.

When I arrived at Downing Street, a large crowd had already gathered, and, to my annoyance, I couldn't get anywhere near the front. The opposite pavement was empty, except for a group of privileged individuals in rather shabby suits and soft hats. They were Press-men, I heard somebody say. Encouraged by this, I asked a policeman to allow me to pass across. "Journalist?" he asked. "Yes," I answered, boldly. "Wot piper?" he inquired, and methought I detected a suspicious glint in his eye. "Tuppenny Pictorial," I hazarded. "Um," he commented, rudely; "I've just passed the 'Tuppenny Pictorial' man. 'E's over there. Do you want to speak to 'im?" I hastily disclaimed any such desire, and withdrew.

At that moment there was a stir in the crowd, and a hansom drove swiftly up. It passed nearer to me than I had expected, and I had a glimpse of an orchid and an eyeglass. Wildly I pointed the Guinea Snappy, but it was too late. Joe had escaped scatheless.

Some of the onlookers departed, and I was able to force my way into the front row. I waited patiently, trying to look unconcerned beneath a fire of vulgar chaff from some unpleasant people behind, who insisted on inviting me to take their "likenesses," and when I refused, facetiously inquired whether I'd got the camera on the "ire purchis systim."

Finally, another hansom approached. Inside was Mr. Balfour. Carefully aiming, I caught him (as I supposed) full in the

middle of my film. Click! went the shutter. This time, at any rate, I was successful.

The Press-men still stayed on, so I stopped, too. Other notabilities came now and then, but I knew none of them, and didn't want to waste more films than seemed necessary. The Pressmen, however, recognised each, and made notes as they passed. In the end a very important-looking personage drove up and ponderously alighted. The pompous way he walked convinced me that he was a minister at the very least, and I obtained a perfect snap of him. As I was contentedly winding off the film, I saw some of the Pressmen smiling. The vigilance of the constable having now relaxed, I crossed and asked who the fat man was who had just passed. "Did you get a good picture of him?" one of the soft-hatted folk inquired. "Yes, a grand one," I replied. "That's good," he remarked, "because he's the Foreign Office butler."

No; I can't say that I was very happy that morning. Snap-shooting Cabinet ministers was harder work than I had supposed. However, I went home to develop my films, hoping for the best. Even now, I believe some of them might have been good, but for unforeseen accidents. I had no dark room, so utilised the bath-room. Just as I started developing someone thumped on the door. It was my brother, who said he wanted to have a bath. Of course, I refused this very unreasonable demand. But he wouldn't go away, and kept rattling the handle. This somewhat flurried me, and in my nervousness I upset one of the dishes and got the roll of film coiled round my right leg. My trousers show the mark of the chemicals to this day, in a curious spiral strip. My brother departed at last, seeing that the lock of the door would not give way, and I finished off the films. Frankly, the results were disappointing. Even the butler seemed blurred. Somebody must have jogged my elbow when I pressed the button. As for Mr. Balfour—well, my aim was slightly incorrect. I obtained a splendid picture of the ear and part of the head of his cab horse. In the distance are some chimney pots. They are beautifully clear. But I am afraid no editor wants a photo of half a horse's head and a group of chimney-pots. That's the worst of editors. They're so conservative.

What annoyed me most was to find in the following week's papers two faultless snap-shots of Mr. Chamberlain and Mr. Balfour. In the background, amongst the crowd, my own figure is distinctly visible, flourishing the Guinea Snappy. One of the soft-felt hattites had evidently taken the picture.

I spent quite a month trying Press photography. I photographed Royal processions, prize givings, athletic sports, yacht races, and dozens of other events. Once I nearly got a grand view of the King, but a six-foot square Union Jack fell down and wholly enveloped me and my Guinea Snappy at the exciting moment. On another occasion I took two splendid photos of Madame Bernhardt entering her carriage at the door of the Garrick; but both were on one strip of film, and the divine Sarah's smile stretches for nearly a yard across the picture. Nevertheless, I sold it as a curiosity to a magazine, and duly received a cheque for half a guinea.

That ten-and-sixpence is all I ever made by Press photography. My expenses came to £8 11s. 7½d. Which proves that, even with a Guinea Snappy, the game is an expensive one.

My brother now owns the Guinea Snappy. He bought it from me for a shilling, and at present keeps a tame white mouse in it. I have banked the shilling as a nucleus of a fund for purchasing a new pair of trousers and re-painting the bath-room floor.

ANOMALIES OF ARTISTIC COPYRIGHT.

[Reprinted from the "Standard."]

his Treatise upon the Law of Copyright, recently published (Murray), Mr. E. J. Macgillivray remarks that the present law is bad, both in substance and form. Those who have anything to do with literary or artistic property are encouraged by the observation that they should comprehend it, in so far as it is comprehensible, and reminded that there are probably more pitfalls for the unwary in dealing with copyright than with any other branch of the law. The reasons for this are many. In itself, the subject is naturally complex, but more than anything, the defects are due to the bad drafting of a great number of very old Statutes. The Literary Copyright Act was passed thirty years ago. Engravings are protected by an Act made in 1734, and last amended in 1836. The Sculptors Act dates from 1813. Dramatic and musical work comes under an Act of 1833 and the Literary Copyright Act together. The most recent of them all, the so-called Fine Arts Act, was passed in 1862 for the protection of paintings, drawings, and photographs. One of the anomalies of the subject must certainly be considered the fact that engravings had been protected one hundred and twenty-eight years before the pictures from which engravings had been made were protected. A painter had no remedy after his picture was published against an engraver, but the engraver had a remedy for the reproduction of his engraving. The general principle of all the Acts is to give protection to any original work after it is published. Before publication, the protection an author or artist has for his work is not under the Copyright Acts, but under the Common Law. He might get damages, or an injunction, or both, before he publishes, but not under the Acts. What amounts to originality or to publication is, "mutatis mutandis," generally applicable to all varieties of work. Publication is the act by which the public are given the opportunity of viewing the object, but payment to view is not necessary. After the work is published, then the right to make copies for certain definite periods belongs to the author, or some one representing him by licence or assignment, exclusively of the rest of the world. This right is copyright; but no action can be brought for infringement unless certain formalities prescribed by the Acts have been observed. One of these formalities is registration at Stationers' Hall. It is required for books and for paintings, sketches and photographs, but not for engravings and sculpture. There must have placed on them before they are published the proprietor's name and the date of publication. Why should there be this difference? Mr. Macgillivray describes registration as a mere useless and troublesome technicality. If there has been an infringement of literary copyright, as there may be even before registration, the proprietor cannot sue until he has registered, but he may register on the day he issues his writ. In the other case, where registration is required, he cannot sue for infringements that have taken place before registry. In America things are more simple. Registry is applicable to all cases of copyright. "There is no common law right after publication, and therefore if a work is published without the proper formalities having been observed, it becomes *publici juris*, and anyone may make what use of it he pleases."

There must be originality for any work to be protected by the Copyright Acts, but there need not be artistic merit. Literary and artistic copyright, in the meaning of literature or art, are irrelevant epithets. There must be individual workmanship, either in methods or design, but the Courts will not inquire into the artistic merits of the result. In photography

the English Courts will protect almost anything as original that is not a professed copy of some existing picture, or sculpture, or photograph. If it consists in the representation of some object, however coarse and commonplace, or however mechanical the reproduction may be, a photograph may be original. Americans have resented giving protection to photographs which in execution and design are often infinitesimal in their "originality," and they require some evidence that by the choice of subject, of arrangement or otherwise, an artistic effect has been produced. How little originality implies artistic individuality appears from the fact that under the term engraving are included prints taken by lithography or any other mechanical process by which prints or impressions of drawings or designs are capable of being multiplied indefinitely. Maps, charts, and plans used to be included under artistic copyright, but they are now subject to the law relating to literary copyright. But it is still uncertain whether they must be registered or have the name and date only put on, as in the case of engravings. There is a curious diversity in the terms for which the protection against copying is given, and they are evidently quite arbitrary. Literary copyright is for the author's life and seven years afterwards, or for forty-two years; engravings are protected for twenty-eight, sculpture for fourteen years, and another term of fourteen if the author is then alive and retains the copyright; paintings, drawings, and photographs for the author's life and seven years. Contrast this with the simplicity of the American provisions applicable to all kinds of work. Copyrights are granted for twenty-eight years, and the author, inventor, or designer, if he be still living, or his widow and children if he be dead, may have the exclusive right continued for a further term of fourteen years on taking certain steps. One great advantage of a similar simplification would be the easier working of the International Copyright Acts, which give the protection of our Statutes to works published in certain foreign countries—for example, the countries under the Berne Convention, which enjoy our copyright by the International Copyright Act of 1886.

Another equally senseless set of provisions are those which relate to the place where the subject-matter of the copyright is made or published. It is not certain whether engravings must be made within the British Dominions; but they must be first published there. Sculpture need not be made, but it must be published there. It was intended by the Act of 1862 that engravings, pictures, and photographs should be independent of either the place of making or publication; but, as often happens in English law, another Act which was not suspected of having any effect on the Act of 1862, made first publication in the British Dominions necessary. There is no restriction as to the nationality of the artist in regard to engravings; it is extremely doubtful whether a sculptor must not be a British subject or resident within the British Dominions. A painter, or sketcher, or photographer must have these qualifications or his work will not be protected; but whether he must possess them at the time the work is produced, or when he seeks the aid of the law against infringement, is uncertain. But there is a more striking anomaly still. An artistic work of any kind produced in the British Dominions is only protected in the United Kingdom. If it were a book it would be protected throughout the Empire. Mr. Macgillivray explains the matter thus:—"It was evidently intended that artistic works should be placed on the same footing, but unfortunately the distinction between the literary and artistic Acts was overlooked. None of the artistic Copyright Acts extend their protection beyond the United Kingdom. The result is that artistic works are only protected in the Colonies and Dependencies under local legislation." Such

Acts are, of course, not inconsistent with the Imperial legislation; and, moreover, every British possession can make its own law extending or curtailing the Imperial Acts for its own territory, so far as regards works which have their origin in that particular Possession. The monopoly of news in foreign telegrams given by some Colonies is an example of this kind of protection which is not to be found in any Act passed by the British Parliament.

The question who is the owner of the copyright is often not at all easy to answer. The author or artist is not always the person who is the proprietor at the date of publication. An engraver who does a work on his own behalf is the first owner. Also if he does it for another if it be entirely his own production. But if he is so employed, and his engraving is taken from another work of art, or if he does it with a design or invention, or material and instructions belonging or supplied to him by the employer, then the copyright belongs to the employer, and not to the engraver. If the relation of master and servant exists, probably as in the case of literary copyright, the copyright belongs to the master. Assuming the common sense of this rule, why in the case of sculpture should there be this difference—that the employer of a sculptor is the owner without any assignment of the copyright which becomes his, though he may take no part in the invention or design of the work? Suppose that at the request of a friend a sculptor makes, gratuitously, a bust or statue for a charitable bazaar, the copyright would probably belong to the friend and not to the sculptor. But we get another distinction when the work is a painting, a sketch, or a photograph. Such a work done gratuitously for another person by the author would give the right of multiplying copies to the author alone. In the case of a customer who gives good or valuable consideration—pays money or gives a benefit in some form or another—the copyright vests in the customer and persons to whom he may assign the right. The right may be reserved to the author, however, by agreement in writing. Thus the copyright of an ordinary photograph belongs to the customer. If it is taken for the photographer's benefit, that he may print and sell copies of a popular character whom he has induced to sit, then it is taken for and on behalf of himself and not his sitter, and the copyright will belong to him. But the sitter may demand that negatives may be taken for his own use, or that he may have copies at a reduced price. What is the result? Quite inconsistent decisions have been given. In one case the copyright was held to be the sitter's, and the photographer could not prevent reproduction by another person to whom the sitter had granted permission. In another, it was held to be the photographer's, and probably that is the true view, though it is safer to put the terms into writing. The right to restrain a photographer from distributing prints of a photograph of a person who has been taken by surprise or without permission does not depend on copyright law. The subject has on other grounds the right of preventing such a liberty being taken with his personality.

Infringement by copying gives rise to very curious questions. The copyright in engravings and sculpture is not so extensive as it is in paintings, drawings, and photographs. It is doubtful whether the copyright in an engraving or a piece of sculpture can be infringed, except by some process which reproduces the characteristic qualities of the execution. A photograph may be a breach of copyright of an engraving as a reproduction of the engraver's work; but unless a print of any kind should so reproduce this, it will not be a breach of copyright. Even if the design and invention are the engraver's own, and not taken from a drawing or painting, it may be that it cannot be protected as part of the engraving, but must be registered

under the Literary Copyright Act, or as a painting or sketch under the Fine Arts Act. As to sculpture, it is doubtful whether it must not be reproduced by a process imitative of the sculptor's art, and whether merely copying it in picture, sketch, engraving, or photograph as a design would be a breach of copyright. Copyright in paintings, drawings, and photographs is larger. Any method whereby copies are made of them may constitute an infringement, whether the design or the process of execution is reproduced. Thus the copyright in a photograph of an Old Master might be infringed by another photograph repeating the method of execution. But forming *tableaux vivants* would not be a reproduction of a picture, nor a sketch in a newspaper of the *tableaux vivants* themselves. Rough sketches of individual portraits taken from a copyright photographic group was held not to be an infringement.

Evidently we are here amongst the niceties of copyright law; and it is not much assistance to say that the general idea of subject matter and treatment may be taken from a work of art without infringement of copyright. What is and what is not infringement in such cases depends, as Lord Herschell said, on the effect produced on the mind by a study of the picture, and of that which is alleged to be a copy of it. The little less or the little more is not only an artistic question, but one of fact for the jury, as lawyers say, though judges have to decide it. These are obscurities which cannot fairly be said to belong to the law, but are due to the intrinsic nature of the subject. Many others are unnecessary difficulties arising from the chaotic state of a congeries of old-fashioned Statutes. We have only dealt with a few of the points raised by a limited department of copyright law, and, in regard to infringement, have only spoken of the infringement by actual making of copies. There are other infringements, such as importing copies or exposing copies for sale, in which various innocent persons may find themselves involved; and in such matters as these the law is confused, because it is badly stated. Why do we always seem to have been on the eve, as Mr. Macgillivray says, of a general codification and amendment of the Law of Copyright since the Royal Commission on Copyright was appointed twenty-eight years ago, and yet without anything having been done? Mr. Macgillivray's answer is that it is owing to dissensions among those interested in copyright, failure to come to a satisfactory arrangement with the Colonies, and want of time in Parliament. Which of these is the most potent cause he does not explain.

BACTERIOLOGICAL PHOTOGRAPHY.

THE ubiquitous bacterium, like the poor and the weather, is always with us, commanding our attention in one way or another, sometimes asserting its power a little too vehemently, and altogether knocking us out of time. It is very wonderful when one considers the insignificant size of bacteria, what an important part they play in our daily life; how absolutely essential are some forms to our well-being, while others swiftly and certainly destroy us! Thirty years ago comparatively little was known of their wide reaching, all embracing influence in the world; but to-day the study of bacteria has become an important science, and the literature on the subject is fast assuming unwieldy proportions.

Bacteriological photography may be divided into two sections, the first dealing with the photography of the entire growing colonies of bacteria in culture tubes and dishes, and the second dealing with the photography of the individual bacterium, forming the most difficult and exacting work in photo-micrography.

Cultivations of bacteria are grown in various media, enclosed in test tubes and petri dishes. To photograph these cultivations an ordinary camera and R.R. lens can be employed, but special care must be given to the lighting and position of the tube or plate, as the case may be, so as to obtain an undistorted and truthful rendering of the colonies of bacteria within. As some species of bacteria only grow in liquids, and others again liquefy the media on which they are growing, it becomes necessary to keep these cultivations level, and to invert the camera over them while taking the photograph. For this purpose, an intelligent blacksmith or mechanic will, for two or three shillings, make a very useful piece of apparatus. This consists of a species of giant retort stand, the iron upright rod measuring about 3ft. in length, and certainly not less than $\frac{1}{2}$ in. in diameter. The base to which this upright is attached may be either a large heavy horseshoe, or heavy three-cornered piece of iron, to form a stand. A clamping eyelet that will travel smoothly up and down the iron rod, and has a screw drawn out from one side to screw into the bush on the bottom of the camera, must also be supplied. This simple piece of apparatus, if properly made with a stout iron rod, and solid base, so as to be perfectly rigid and free from top-heaviness or vibration when the camera is attached, will form a most useful adjunct, and can be used also as an upright photographic camera, which will be found very convenient for many purposes.

In photographing culture tubes and plates, a dead black background should be used, as it throws up into strong relief the growing colonies of bacteria. The photographs may be taken by either daylight or artificial light; and a couple of incandescent gas burners screwed in such a way as to direct the rays of light upon the culture tubes or plates will be found very useful for night work. Very handy screens can be made at home from old round tobacco tins and the funnel-shaped tops of a couple of half-gallon paraffin cans; a round hole, 2in. in diameter, being cut in the side of a bottomless tobacco tin, the funnel-shaped top is cut off the paraffin tin (the neck having been cut away so that there is an opening 2in. in diameter), and soldered into the opening in the tobacco tin. The two screened lights should be placed to right and left of the camera, and in such a position that the whole culture tube is evenly illuminated without any bright reflections on the glass surface. The best results will be obtained with a maximum exposure, and fairly rapid development, good bold contrasts being aimed at as much as possible. A thin sheet of tissue paper, or very fine ground glass, placed in front of the source of illumination, will be found very useful in getting rid of troublesome bright points of reflected light on the surface of the culture tube. On the whole, petri dish cultivations will be found easier to photograph than tubes, particularly if a vertical stand such as I have briefly described is employed.

In the second section of bacteriological photography, success can only be obtained by the exercise of the greatest perseverance and care, coupled with the employment of the best microscopic objectives. The microscope stand itself must be as firm and rigid as possible; it must possess for focussing the usual rack and pinion coarse adjustment; and a very accurate fine adjustment; it must also have a centring and focussing substage. If a great deal of high power work is to be done, a good graduated mechanical stage will be found a boon and a blessing. Most of our representative manufacturing opticians now turn out microscopes specially adapted for high power and critical photo-micrographic work, at varying prices. A really high-class instrument at a very moderate price is turned out now by Messrs. R. and J. Beck., Ltd., of 68, Cornhill; it is

called the "London." I have had one of the large models in daily use for a year, and it has given me the greatest satisfaction, and produced first-class results. Messrs. W. Watson and Sons' magnificent "Van Heurck" microscope, and Messrs. C. Bakers' "Nelson Model" are most splendid instruments, well worth the high price charged; but the price is unfortunately beyond the purse of most English scientific men, and consequently many an earnest worker must be content with the somewhat inferior German microscopes which have found their way into too many of our colleges and laboratories. I sincerely hope that Messrs. Beck's example will be followed by the other British microscope makers, and that in time we shall see nothing but good English instruments in use.

The objectives required are $\frac{1}{6}$ th, $\frac{1}{8}$ th, and $\frac{1}{12}$ th oil immersion, with three good eye-pieces. And here again, whether we work with apochromatic objectives and compensating eye-pieces, or with achromatic objectives and Huyghenian eye-pieces, must depend upon the length of our purse. If we can only afford achromatics, then buy the best English make. A good substage condenser is absolutely essential, and either an apochromatic or achromatic should be employed; the Abbé chromatic illuminator cannot be recommended for critical high power work. For illumination either oil, gas, mixed jet, or electric arc can be employed. Personally, I prefer either the mixed jet or a good oil microscope lamp, such as Beck or Watson will sell for photographic work, with a condenser attached.

The great difference in price between apochromatic and achromatic objectives is a very serious matter for most people who are taking up this branch of microscopy, and for this reason I have during the past year worked solely with a set of achromatic objectives supplied to me by Messrs. Beck., Ltd., in my scientific research work, and in making the photographic records thereof. The result has been most satisfactory—I may say far in excess of my most sanguine expectations. In all my work, I make it a rule to use a screen made of a saturated solution of acetate of copper, between the source of illumination and the substage condenser, held in a glass cell $\frac{3}{4}$ in. thick, 4in. deep, and 3in. broad. This screen, in conjunction with a three-quarters cone method of illumination, gives the very best results obtainable.

Slides of bacteria from which photo-micrographs are to be made should be much more deeply stained than is usual for ordinary microscopic examination. Some attention must also be paid to the stains used, the best results generally being obtained from specimens stained with carbol-fuchsin or gentian-violet.

Before the final focussing and exposure are made, the whole apparatus must be allowed to become thoroughly warmed, so that there may be no fear of expansion and alteration of focus during exposure.

Isochromatic plates must, of course, be used, and, personally, I pin my faith on Messrs. B. J. Edwards' series. Great contrast must be aimed at in development, which must be carried much farther than in medium power work.

Lastly, be patient and determined to reach the highest standard you can set; let every failure be an object lesson in what to avoid, and your efforts will be crowned with the success they deserve.

F. MARTIN DUNCAN.

THE Emperor of Germany has, through the German Ambassador, accepted from Mr. Richard N. Speaight, for his private library, a copy of "Children's Portraits," which he lately compiled with the object of raising £1,000 towards the funds of the Children's Hospital, Great Ormond Street. The copy was specially bound in vellum and Russia leather similar to the one presented to the Queen. Messrs. F. and R. Speaight still have a few copies left, which may be obtained for half-a-guinea each on application at their studio, 178, Regent Street.

THE CONVERSAZIONE OF THE R.P.S.

[By a Visitor.]

THE purposes for which the many members of the Royal Photographic Society attend the annual conversazione are doubtless somewhat varied, but to us the benefits of the private view of the exhibition have always been secondary to the more congenial social opportunities it affords. Indeed, it would be difficult to choose a more unsuitable occasion to study the exhibition than the night of the conversazione, and so we wended our way to the New Gallery, anticipating the pleasure of meeting old comrades and shaking the hands of friends who only on such occasions come across our horizon.

Once inside the entrance, and while depositing our coats and hats, a glance round shows many familiar faces, and not half the width of Fountain Court had been crossed before our friend Mr. Sanger-Shepherd greeted us, and took us along to his charming exhibition. The photographic world owes a deep debt to Mr. Shepherd for his energetic work in connection with trichromatic photography, and we were informed that great progress had been made recently with this process, as by means of a specially designed camera the three exposures were made simultaneously, and by this means, and with a lens working at *f.4*, breaking waves had been successfully photographed.

Mr. Shepherd showed us this camera, which is a marvel of elegant design and workmanship, and also introduced us to his new light measuring instrument and new hand-fed arc lamp, both of which are beautifully made and worthy of high praise.

We were just leaving Mr. Shepherd when Miss Acland joined us, and showed us her most interesting specimen of three-colour superposed work on paper. The work is all the more creditable as in one case it is enlarged work. There are, we fear, few ladies who would care to so thoroughly go into this delightful process as Miss Acland.

Going back again to Fountain Court, we were announced to the President, and heartily greeted by our old friend; private conversation was, alas, not possible, so we hastened to glance at the Pictorial Section ere more friends claimed our attention.

Somehow or other we felt that the work was ordinary—there did not seem to be anything standing out about the others; but there is much good work exhibited nevertheless. Had we to make a selection, we should favour Nos. 30, 51, 62, 131, 149, 157, 277, and 283. No. 277, "Across the Presbytery," by H. R. Campion, is especially charming, and is a fine piece of delicate handling, and we were not surprised to hear that a visitor had purchased it. Why this failed for the medal as against No. 281 is a conundrum more than one of our friends have asked us. However, this section will be fully treated elsewhere, so we must away.

Probably the two things we heard most discussed were the Kodak patent developing machine and Mattos paper. This latter is a printing-out paper which seems capable of giving wonderfully fine, rich effects, and resembles platinum in many respects. The company who are selling make an interesting exhibit in the South Room, but we cannot congratulate them very much on the excellence of the subjects chosen for illustration.

Alongside we find pictures by Mr. Furley Lewis, among which we noticed Mr. A. Haddon's, Dr. Fincham's, and Mr. P. Everitt's portraits. These are all excellent, but, alas, the portrait of Dr. Fincham served to call up sorrowful thoughts on our poor friend's sad illness. Few have worked so strenuously for the reform of the Society as this gentleman, and many were the kind and sympathetic words we heard spoken of him during the evening.

The professional sections are well represented, and much excellent portrait work is exhibited. Mr. Ives' parallax slide and Mr. Senior's fine Lippmann colour photograph of the spectrum of an arc lamp were particularly interesting exhibits, and we noticed some very creditable three-colour work on paper, and spectrum and microscopic work. Many old friends were there, and many were chatted with, and many others we knew we caught a glimpse of now and then.

The band played pleasant tunes in Fountain Court, everyone seemed happy, and altogether a most enjoyable evening was spent. We trust that we may be spared to attend the forty-eighth exhibition, and heartily tender our congratulations to all parties responsible for the arrangements at the New Gallery.

THE CITY OF MANCHESTER MUNICIPAL SCHOOL OF TECHNOLOGY.

PROSPECTUS OF THE DEPARTMENT OF PHOTOGRAPHY AND THE PRINTING CRAFTS.

THIS department deals so far as is practicable with the most important requirements of the photographic and printing industries.

The work of the department is divided into the following sections:—Photography, lithography, printing, drawing and design, and bookbinding.

Photography.—Under the head of photography it is proposed to deal with the subject as a whole, because it is only by a knowledge of the fundamental principles underlying the craft that its special applications can be properly understood.

The photo-mechanical processes which represent an important industrial application of photography will be very fully dealt with; and will form the most important section of this branch of the work of the department.

In general photography particular attention will be paid to the art and technology of negative making, and more especially to the optical and physical principles which underlie the various methods of procedure, an understanding of which is necessary on the part of those who desire to become good craftsmen, while due consideration will be given to light printing processes, and chiefly to those which may be regarded as types, and which are of importance in the industry.

In lithography the work will be divided into two portions; the one dealing with the production of the printing surface and the other with the printing from the same surface. It is hoped that those who have chosen this branch of work as a calling will not neglect to pay attention to the photo-mechanical processes, having regard to the probable effect, as in the case of wood-engraving, which the advance in these processes is likely to have in modifying methods of picture production.

The letterpress branch comprises composing, press, and machine work, electrotyping and stereotyping. The various branches of compositor's work will be dealt with as fully as is practicable, especial attention being paid to the cultivation of a simple and good style in display work, and to tabular and technical matter, and the arrangement of catalogue text. As well as general press and machine work the printer will have every facility given to him to study the printing of process blocks. For the electrotyper the careful reproduction of process blocks offers a field of study for which full convenience exists, and it is proper to remark that this branch of work, judging by the results daily seen in practice, has not received that amount of intelligent attention which it deserves.

The binding of editions of books and magazines in one and the same style required for the publication of large editions, is

work which can only be undertaken satisfactorily in the workshop, for it is principally a question of the proper use of special machinery. But there is a large and important branch of the binder's business which deals with the book as an individual item—the work of the ordinary hand binder. For such work there must always be a good demand, and it is the purpose of this section of the department to deal with those who are engaged in such craft. Regarding a book primarily as an object of utility, that which makes such object lasting and convenient to use should receive the first attention of a good workman. The final ornamentation which a book may receive enhances its value if made with good taste and judgment, but properly considered, it is only an excellence when accompanied by sound construction. The department will concern itself with teaching the best and soundest methods of forwarding as the first object of importance.

In drawing and design the classes will be arranged to suit the particular needs of those who are engaged in the crafts with which the department deals. In many branches of the industry knowledge and skill in drawing is essential to success. Such knowledge and skill can only come by continual observation and sustained practical study, and it is hoped that students will recognise such methods as the only road to success in this as in any other branch of work. Every effort will be made to make the work interesting, particularly in the training of the observation so as to understand the nature and characteristics of the object to be depicted, which is the essential condition to good and thoughtful draughtsmanship. The work which comes under the head of Design, will be such as is required for the methods of reproduction employed in the printing crafts. It should, however, be recognised that to become a good designer requires the possession of natural qualities, which cannot be given by class teaching though they may be developed by such. But what is possible is that a student may become properly acquainted with the methods employed in the craft for which he essays to design. Dealing only with reproduction work there are in every process limitations, some inherent, others only imposed because of economic reasons, without a knowledge of which a man cannot succeed in his work. Such knowledge constitutes a part of the designer's stock-in-trade. The faculty of being able to put this knowledge and the skill acquired to successful use, to be able to produce beautiful and appropriate designs, is, however, an endowment of Nature.

Equipment.—The department contains the following:—Photographic studio, with three dark rooms, photographic enlarging room, etching and collotype preparation room, block mounting workshop with router, power saw, guillotine, bevel planes, etc., lithographic printing room, with machine and four presses, composing room, machine and press room, with two cylinder machines and two platen machines, electrotyping and stereotyping rooms, lithographic drawing and design studio, and bindery. The plant and apparatus constituting the equipment are thus very complete, and have been selected for the purpose of giving sound practical instruction in the principles, technique, and practice of the various crafts concerned. Particular attention has been paid to the general arrangements for work in the various sections. The scheme of instruction includes lecture, class demonstrations, laboratory, and workshop practice. The classes will be held both during the day and evening. The day classes will extend from September 22nd to July 31st, and the evening classes will run from September 29th to the month of May. Short courses of lectures will be given on certain evenings in the week during the summer.

Certain courses of day instruction will be arranged over

periods varying from two to three years which will have for their object the preliminary training of those who desire to enter the various crafts concerned, and such a training may be regarded as preparatory to apprenticeship in a business house.

The department is under the direction of Mr. Charles W. Gamble.

New Books.

“*Photographische Bibliothek.*” Vol. I. “*Das Photographische Pigment Verfahren.*” Vogel-Hanneke. Verlag von Gustav Schmidt, Berlin.

The work, originally written by the late Dr. H. W. Vogel, has entered upon its fourth edition, and the revision of the text, with supplementary chapters upon Gum Bichromate, Artigue, and Ozotype processes has been undertaken by Herr Hanneke, the present editor of the “*Photographische Mitteilungen.*” The volume gives a short history of the carbon process, and full directions for working it in the various applications to which it has been put. The chapters upon Gum Bichromate, the Artigue and Manly process, will be welcome to those who wish to study more recent developments in bichromate printing.

“*The Royal Borough of Kingston-on-Thames.*” 145 pp. illustrated. Price 1s. Published by the Homeland Association, Limited, St. Bride's House, 24, Bride Lane, Fleet Street, London, E.C.

The latest addition to the Homeland series has been written by Dr. W. E. St. L. Finny, Mayor of Kingston-upon-Thames. The book is published locally, by Messrs. Phillipson, of Kingston, and Messrs. Bull and Son, Surbiton. We are informed that the King has been pleased to accept a copy of the volume. Chapters are devoted to the Parish Church, the Coronation Stone, Richmond Park, Kingston as a Boating and Angling Resort, Hampton Court and its Surroundings, Ham, the Dittons and Esher. The book is illustrated by photographs by Mr. W. F. J. Hodgson, and drawings by Mr. E. E. Bristow. It also includes an Ordnance Survey map on the one-inch scale. Dr. Finny has compiled a volume full of fascination and interest which we are glad to possess. We are sorry, however, that so sympathetic an author is not better treated by the photographer and the process engraver.

THE Edinburgh Photographic Society's annual exhibition of photographs will be held in the Society's Hall, at 38, Castle Street, Edinburgh, from Saturday, November 22nd to Saturday, December 6th, 1902. The judges will be Messrs. G. Ogilvy Reid, R.S.A., Edinburgh; Harold Baker, Photographer, Birmingham; Charles Sweet, photographer, Rothesay. Entries close on Saturday, November 8th, 1902. For any further information, or entry forms, application should be made to the hon. secretary of the Society, Mr. J. S. McCulloch, W.S., 3a, North St. David Street, Edinburgh.

EDUCATIONAL SCIENCE.—At the meeting of the British Association Prof. Henry E. Armstrong deplored the British indifference to Science, and the result—the outstripping of British trade and commerce by Americans and Germans. “If,” said he, “we reflect on the bareness of the life lived by the majority—on the debasing conditions under which very many are placed—on the terrible evils consequent on indulgence in drink—surely we must agree with Tyndall that the essential point is to raise life to a higher level, to elevate the general tone of thought, and that it is our duty to consider more seriously than we have done hitherto what use can be made of the forces at our disposal for the purpose. If we will but picture to ourselves how most of our difficulties, and especially our slow advance, are consequences of lack of imaginative power, or, perhaps, rather of failure to exert the power which, though latent in most of us, is not sufficiently called into being by practice; if we will but consider how much of our success has been due to the exercise of imaginative power, we may be led to propound a fruitful theory of education—a theoretical basis on which a sound educational structure may be reared. It has been well said by Carlyle ‘that all that man does and brings to pass is the vesture of a thought.’ In fact, the illustrations which may be given of the value of theoretical conceptions, of imaginative power, are innumerable. Taking recent events, if we consider the success achieved by the late Mr. Rhodes, the narrow-sighted will say he was a practical man; a man who did things, and led others to do. Those with broader views recognise that at heart Mr. Rhodes was a theorist, an idealist, a man of imagination, and hence his success. And men such as Lord Roberts and Lord Kitchener, whose immense services to the nation have been so universally admitted of late, are not merely practical soldiers of experience, but men gifted with powers of insight and imagination; men able to apply theory to practice. Some of those who were unsuccessful in the late campaign are concurrently reported to have gone out to South Africa openly deriding science, and it will be well if the lesson taught by their failure be not disregarded by their colleagues. The importance of the part played by theory in science cannot be exaggerated. We have only to think of the influence exercised by the Newtonian theory of gravitation, by the Daltonian theory of atoms, by Faraday's conception of lines of force, by the wave theory in its varied applications, by the Darwinian theory of evolution; we have only to

think of the way in which the reflections of one weak man indited at his study-table in a secluded Kentish village have changed the tone of thought of the civilised world. Such theories are the very foundations of science; whilst facts are the building stones, theories furnish the designs, and it is the interpretation of facts in the light of theory, and the considered application of theory to practice, that constitute true science. The marvellous development of scientific activity during the past century has been consequent on the establishment of fruitful theories. If teachers generally would pay more attention to theory, their teaching would doubtless be more fruitful of results; facts they know in plenty, but they lack training in the considered use of facts."

Exhibition.

THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

[FIRST NOTICE.]

It was hardly to be expected that the forty-seventh annual exhibition of the Royal Photographic Society, which was opened to the public on Monday last, at the New Gallery, Regent Street, W., would disclose any startling innovations, in spite of the fact that the notice "under entirely new management" might have been displayed at the entrance. As a matter of fact, the galleries present the old familiar appearance; and it is only in unimportant matters of detail that any change has been made. The general arrangements are as before; the west room is devoted to selected pictorial exhibits, the north and south rooms to displays by professional and trade photographers, the balconies to scientific, technical, and photo-mechanical exhibits, and the Fountain Court to the stalls of opticians, apparatus manufacturers, photographic dealers, etc.

The most noticeable change is in the room devoted to pictorial photography. We commented last year upon the somewhat gloomy appearance the dark colouring of the walls produced, and we understood that the then acting hanging committee had decided upon lining the walls if their services were again called into requisition. This decision this year's committee has wisely adopted, and the result is that a very great improvement has been effected. The work, perhaps, has not been carried out with quite ideal taste, as far as the decorative effect is concerned, but the undyed canvas employed is admirably suited for displaying the pictures.

We regret to find that in pictorial photography the steady progression that has for many years marked each successive year's exhibition has not been maintained. We understand that nearly 1,700 pictures were submitted to the selecting committee. The number hung is 290. In spite of the fact that about 60 less than last year were deemed worthy of a place on the walls, the average quality is distinctly behind that of last year's exhibition. Unfortunately, no compensating improvement is to be found in the section devoted to technical and scientific photography. In the rooms devoted to professional and trade photography, where each exhibitor decorates and arranges the space allotted to him, according to his own taste, there is certainly an improvement in the get-up of the exhibits, and the general effect naturally gains by the absence of the crude colours which in former years have been chosen by some of the exhibitors in their attempts at decoration.

PROFESSIONAL AND TRADE PHOTOGRAPHY.

Perhaps the most striking professional photographer's exhibit is that of Wm. Croke, of Edinburgh. The space, the entire wall facing the door in the south room, is that occupied by Mr. Croke the year before last, and he has adopted the same tasteful scheme of decoration. The number of pictures exhibited is only 17, and it should be a valuable lesson to those who have to get up exhibits of a similar kind to observe the impressive effect produced by restricting the works in number and using the utmost discrimination in the selection. With one exception, all are portraits, the exception, "The Edinburgh Town Council in Session," commands attention for the success achieved in the treatment of a subject extremely difficult to render by photography in an acceptable manner. The portraits, naturally, have Mr. Croke's easily recognisable individuality.

T. C. Turner, of Hull, and 17, Upper Street, Islington, N., has arranged his space with considerable eye to effect. His pictures deserve to be closely studied by photographers who desire to turn out work of the highest perfection, following the ordinary lines of studio portraiture. The cabinet portraits, though possibly not possessing the qualities that would secure acceptance by the selecting committee of the pictorial section, are almost really perfect specimens of work of their kind. Two enlargements of an exceedingly refined type, having all the delicacy of a pencil drawing, will undoubtedly meet with general approbation.

Miss Lena Connell, of 50, Grove End Road, St. John's Wood, N.W., shows a very marked improvement over last year's exhibit, both in the

quality of her work and in the get up of her exhibit. She has covered her wall space with canvas of a very suitable tint, and all her pictures are uniformly framed and printed in carbon of the same colour. Paradoxically, the exhibit is conspicuous from its quietness. The effect is exceedingly good.

Purley Lewis, of Stratford Studios, Kensington, again gives a very favourable impression of his work. Several of his portraits are of well known figures in London photographic circles, and an opportunity is therefore afforded of recognising his skill in preserving the characteristic personality of his sitters. He has chosen a wall covering of a pleasing warm tint, and his exhibit, as a whole, is tasteful and effective.

Miss Catherine Edmonds, of the Abingdon Studio, 118, Westbourne Grove, W., has among her studies many which are exceedingly good. Some of the portraits of children are delightful in their daintiness of treatment, but her display distinctly loses by being somewhat overcrowded, and by being carried too high. Considering the size of the frames, a few of the pictures could have been omitted with advantage, not only to the exhibit as a display, but on account of their not reaching the general standard of excellence. The background is quiet and pleasant in tint, and on the whole the exhibit is of good effect.

W. Hoffer, of 26A, Soho Square, W., shows a series of Alpine studies, taken in Austria and Bavaria.

In the north room, Samuel J. Beckett, of 20, Baker Street, Portman Square, W., again falls into the error of showing too much, but the general effect of his exhibit is certainly better than that of last year. A carbon enlargement of large size forms the principal piece, and is a passable piece of work; but, in this case, it was rather a mistake to show a print from the original negative. Though every picture will bear inspection, taken individually, the collection, for the reason we have given, does not give the favourable impression that it ought to.

Johnson and Hoffmann, of 31, Devonshire Street, Portland Place, W., and Calcutta, make a large display, principally of portraiture. As the firm is essentially an Indian one, most of the subjects show a connection with our Eastern empire, many of them being native Indian princes. There are some good photographs of Indian temples, etc. The exhibit is an imposing one, but the decorative scheme is not beyond criticism.

Reinhold Thiele and Co., of 66, Chancery Lane, W.C., have a number of enlarged portraits of well known people, many of them in the theatrical profession. They are good specimens of professional photography of the ordinary kind.

Martin Jacolette, 38, 40, and 42, Harrington Road, South Kensington, S.W., exhibits three portrait studies, which are highly finished and effective.

Window and Grove, of 63A, Baker Street, W., have some interesting portraits. Miss L. Caswell Smith, of 305, Oxford Street, W., shows that she aptly follows in her late brother's footsteps. W. Bates and Son, of Chertsey, have three portraits in carbon. Alfred W. Goodman, of Belvedere, Kent, has three pictorial subjects; and James B. Hawke, of Plymouth, has a large composition group, containing, perhaps, some hundreds of heads. It is an exceedingly clever piece of work of its kind.

Among the exhibits of trade photographers, the Autotype Company, of 74, New Oxford Street, W., make an imposing show; they occupy the whole of the end wall in the north room, and have judiciously avoided overcrowding their space. Their exhibit includes enlargements in carbon from negatives, by Alfred Ellis and Walery, Henry Spink, C. Reid, Madame Lallie Charles, Langfier, W. J. Byrne, and other well-known photographers; also autotype reproductions of paintings and specimens illustrating the effects in carbon of various colours.

Thomas Illingworth and Co., Ltd., the Photo Works, Willesden Junction, N.W., make an effective display of work in carbon tissue of their manufacture, which evidently produces most satisfactory results, and, as regards range of colours, surely there is something to suit everyone. The winning prints in the recent Illingworth competition are also exhibited.

J. N. Gotz, of 215, Shaftesbury Avenue, occupies his space with specimens of printing in "Chromatype," which will appeal to admirers of gum-bichromate printing. Some of the specimens of printing in two different coloured pigments are interesting.

The Rotary Photographic Company, of 14, New Union Street, Moorfields, E.C., exhibit specimen prints on Rotograph bromide and Rotokon gaslight papers, samples of photo-mechanical printing, for advertising and other purposes on Rotograph paper, and produced by their patented automatic machinery; also specimens of the publications of the company.

The Berlin Photographic Company, of 133, New Bond Street, W., have a large display of reproductions of paintings. They are principally in photogravure. The work is admirable, and the collection forms quite a picture gallery in itself.

Society, referred to the year 1902 as memorable in two respects. It was the centenary of the discovery of photography by Wedgwood, and it saw the completion of fifty years of life of what is now the R.P.S. The first President, Sir Charles Eastlake, was also President of the Royal Academy. In those days photography was an infant—a new arrival in which artists took a deep interest. That interest he thought had never been lost, and, although the fact was not so much acknowledged as it was fifty years ago, there was no doubt whatever that photography had been and was still of much real value to the artist. Succeeding the first President came Sir Frederick Pollock, the Lord Chief Baron, an able man in every way, who saw the Society increase its usefulness and strength to a large degree. He was followed by Mr. James Glaisher, a distinguished man of science, who, the President was glad to say, was still in good health and a respected Honorary Fellow of the Society. The next President was Mr. John Spiller, who had always shown, and still maintained, a warm interest in the Society's affairs, and following him that pillar of strength in photographic work, Sir William Abney, who had done so much for the science and theory of the process. To Sir Trueman Wood, the next President, the Society owed a deep debt of gratitude for his influence in securing for it Royal recognition. The President's immediate predecessor, the Earl of Crawford, followed Sir Henry in the chair, and was instrumental in acquiring the present exhibition accommodation at the New Gallery, and the spacious premises at 66, Russell Square, a step which it required some courage to take. The President believed that through the efforts and influence of his predecessors the Society was now firmly established and engaged in good work. It gave what he considered to be the best guinea's worth that any unendowed Society offered, but it was most essential that the membership should be largely increased. It was finance alone which prevented the proper display of the museum, the improvement of the accommodation, and so forth, but he hoped that at no distant date any trouble on that score would be dispelled by a large acquisition of new members. So far as his policy of efficiency had been carried out, he begged to thank those around him for their help, and for the good-will which had been so generally extended towards him. He coupled with the toast the name of Sir Trueman Wood, and the toast being honoured in the usual way, Sir Trueman Wood made reply in a speech relieved by several humorous touches. He had always taken an interest in the Society, perhaps because it sprang from one with which he was still more intimately connected. It was at a meeting of the Society of Arts that the suggestion was made that a Photographic Society should be formed, and it was very gratifying to find that the Society was now in so flourishing a condition. He saw no reason why the Royal Photographic Society should not rank with any other scientific society in the Kingdom (although, perhaps, it had not in the past), especially when one considered the exceptional position in which photography stood. Photography, in his own recollection, had been sneered at at places where now no meeting was complete without some photographic contribution.

The toast of the officers, council, and committees gave Dr. Evershed an opportunity of eulogising these gentlemen's work during the present year, and of making allusion to the pathetic circumstances which prevented the attendance of Dr. Fincham, to whom the idea of the dinner had occurred.

Professor Unwin acknowledged the kindly way in which the last toast had been proposed and received. He felt that he had been chosen to respond because he was one of the most irregular attendants at the meetings. He could, however, with the more modesty accept the praises offered in the toast. For his apparent neglect of the society he must offer the excuse that a society having much older claims upon him met on the same day and at the same time as the R.P.S. In the words, however, of the Dutch proverb, "The man on the bank sees best," he could say that he had seen that much time had been spent in carrying on the society's work. He hoped that the changes through which the society had passed would result in still greater progress being made. He thought that no scientific pursuit had a greater power than photography of leading one into pleasant employment, society, and friendship, and he looked in the near future to an effort on the part of the members to persuade still more of their friends to join the society.

Mr. Francis Ince, speaking to the toast of "The Visitors," assured them that it gave the society much pleasure to receive visitors on these festive occasions and at gatherings at Russell Square. The society was formed, however, for research, as well as pleasure, and with a desire to raise photography in the scale of the sciences and arts. He was sure every member would do all he could to advance the society and the science and art of photography. Photography was walking hand in hand with the X rays, and rendering great services in conjunction with other studies and pursuits. He only hoped that many of the visitors would see the force of his remarks and become valued associates and members.

Mr. Wm. Crooke, of Edinburgh, responded, and thanked the society for the welcome extended to him and his co-visitors. Taking the pro-

poser at his word, he expressed his willingness to come within the ranks of the society, and called upon those for whom he was replying to raise their hands and undertake in the near future to offer themselves as recruits. Mr. Crooke's action was followed by cheers, and the raising of seven or eight signals of assent.

Mr. J. T. Ashby, in an excellent speech, gave the toast of "The Press," extolling their virtues, and generally making them pleased with their achievements.

Mr. Thomas Bedding, who responded, reminded the members that through the dark ages the Journal of which he had the honour to be the editor had been a strong and consistent supporter of the R.P.S., and assured the company that it was his aspiration that the BRITISH JOURNAL OF PHOTOGRAPHY should continue to support the society. In the ordinary course of events, the president, Mr. Dallmeyer, would vacate his office in February next. He, the speaker, believed it might be taken for granted that Mr. Dallmeyer's successor in the presidential chair would be the society's old and staunch friend, Sir William Abney.

Mr. T. C. Turner, of Hull, proposed the toast of "The President." At no period of the society's history, he said, was it more necessary that the president should be a gentleman of culture and capable of showing sympathy with the varying aspirations of photography. The president, he knew, sympathised with all, and would help to dispose of the view that the society was merely a scientific society. As a professional photographer, he had been most pleased to see that the society intended to give to him and his colleagues some of the attention that was their due. The professional photographer, by his work, formed the idea of photography as an art, which the public at present entertained. The amateur work of photography was seen by comparatively few. Now, around these tables were men of very opposite views, but evidently perfectly happy together. Surely this betokened that the time had come when all bitterness could be sunk and a happy amalgamation of everything in photography brought about. He had much pleasure in proposing the toast of "The President of the Society," whose first duty should be to bring about this most desirable united front.

The President briefly replied, and passed on to the Earl of Crawford the credit for the initial move that had resulted in greater attention being given to the professional and wider interests of photography in recent years. He thought that whatever was best in photography would survive, whether in scientific, artistic, or professional circles. He hoped to see the time when all differences should cease and when the society had become the channel through which everything that was effected or attempted in photography should pass. Finally, he asked the members to give their hearty thanks to Mr. Ellis, the Dinner Committee, and the stewards for all that they had done to make a success of this dinner.

Commercial & Legal Intelligence

GAGGED and Robbed.—Mrs. Beales, owner of an extensive photography business at George Street, Croydon, was alarmed by seeing in her bedroom a man, who quickly stuffed a piece of rag in her mouth to prevent her arousing the household. When she recovered at daylight yesterday morning, an examination resulted in the discovery that the place had been forcibly entered, ransacked, and money and property to the extent of about £200 stolen.—"Evening News."

RE Frederick Thomas James Morris, photographer, late 137, White Ladies Road, Bristol.—The above-named debtor appeared for his public examination at the Bristol Bankruptcy Court, on Friday last, before Mr. Registrar Harley. Replying to questions put by the Official Receiver, debtor stated that his statement of affairs showed liabilities amounting to £232, due to unsecured creditors, and his deficiency he estimated at £2 7s. 11d. The examination was ordered to be adjourned for a month.

LIVERPOOL Amateur Photographic Association.—The winter session of the above Association was opened on Thursday week, when a large attendance of members assembled at the rooms in Eberle Street to hear a lecture by Mr. E. R. Dibdin, entitled "The Pre-Raphaelite Movement and Its Relation to Photography." The lecturer traced the history of the movement from its inception by Rossetti, Holman Hunt, and Millais, and dwelt upon its influence on British art as evidenced by the work of J. S. Burton, Maddox Brown, Burne Jones, Byam Shaw, and others. The lecture was illustrated by a large number of slides, including examples by Turner, Mulready, Millais, Hunt, Rossetti, Constable, Burne Jones, and Byam Shaw. Dealing with the relation of the movement to photography, Mr. Dibdin showed, by means of slides, the great amount of detail in the pictures of the brotherhood, the result being in many instances almost photographic in effect.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Oct.	Name of Society.	Subject.
3.....	Leicester Literary	{ <i>My Cruise amongst the Fjords of Norway.</i> Col. Barrington Baker.
6.....	Oxford Camera Club	Short address by the President.
8.....	Leeds Camera Club.....	{ <i>Lumière Process of Colour Photography.</i> Mr. T. K. Grant.
8.....	Croydon Camera Club	{ <i>The Practice and Profit of Photographic Surveying.</i> Mr. George Scameil, F.R.P.S.
8.....	North Middlesex Photographi.....	{ <i>Through the English Lake District with a Camera.</i> Mr. J. A. Hodges, F.R.P.S.
9.....	London and Provincial	{ <i>The Carbon Process.</i> Mr. Thomas Illingworth.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

SEPTEMBER 24TH.—Mr. J. R. Gotz gave a demonstration on "Chromotype." It is a carbon process, but, unlike the usual process, it gives direct prints without reversal. It is, in fact, "gum bichromate," but the results are finer and detail better rendered than in the average gum bichromate print. In this it more resembles the Artigue carbon paper. Paper coated with pigment and a binding material is sensitised in a bath of 5 per cent. solution of potass bichromate and 1 per cent. ammonia, or a 4½ per cent. solution of the bichromate, with a certain proportion of potass chlorate added. The first bath requires less exposure, while the second gives more brilliant prints.

Exposures are gauged by actinometer.

The development is carried out by soaking the print in warm water for half-an-hour, and then it is supported upon a board set on end in a large metal bath of water kept at 100deg. to 110deg. by means of a gas-jet underneath. The water is dashed all over it as in ordinary carbon work. Fine sawdust (pine or box wood) in the water hastens development. The paper should have a margin of about an inch all round the print to prevent damage during development. No safe-edge is necessary. High lights can be strengthened by means of a soft brush, taking care to work with the print under water.

It is most suitable for large work, but some small prints shown had very fine quality.

MARPLE AND DISTRICT PHOTOGRAPHIC SOCIETY.

ON Thursday week a lantern lecture was given by Mr. C. J. Atkinson, in the Society's Rooms at the Marple Recreation Club. The slides were chiefly views in and about Hexham Abbey Church and Carlisle Cathedral. The lecturer made his descriptions very interesting, and concurrently communicated many useful devices by means of which he had overcome most of the familiar but inherent difficulties of interior photography. An instance of this kind, worthy of notice, was the altar-tomb of Queen Etheldreda in Hexham Abbey. Upon the flat stone which lies over the top there is incised a design of a cross with vine-leaves and fruit. This extends along its full length, and ordinarily would be looked upon as impossible for a direct photograph. Mr. Atkinson, however, secured a rubbing and copied this in the camera. The resulting slide showed the design in white upon a black ground, and probably no other means would have better translated its exceptional beauty. Another slide showed the crypt taken by flashlight. This is the oldest portion of the building, said to go back 1,300 years. The view thrown upon the screen showed the interesting tool-marks in the masonry apparently as distinct as on the day they were made. There was also shown a very good reproduction of the East window in Carlisle Cathedral.

The average merit of the slides was excellent. The subjects were selected mainly for their historical associations or for some other educational signification; but in every instance the point of view and the tone and masking of the slide preserved their best pictorial effects. The quality of relief or modelling in some cases was surprisingly realistic.

Mr. Atkinson epitomised some of the most important conditions of success in the photography of architecture, for example:—Always use backed plates. Don't have the light coming from a point directly in front or behind the camera. Shield the lens from side light as much as possible. Expose for the shadows. Select a dull day for interiors, and a bright day for exteriors.

BLAIRGOWRIE.

THE monthly meeting was held in the club rooms on the 23rd ult. The secretary was instructed to arrange for one of the R.P.S. lectures for next month. A debate took place on, "Should classes be abolished in exhibitions?" The theme was heartily discussed pro and con, but the large majority of those present were in favour of classes being retained.

BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.

HON SECRETARY'S SEVENTH ANNUAL REPORT—1901-1902.

I HAVE again the pleasure of presenting a report of the society's work for another year.

The following summary will at once show the growth of our membership during the past three years:—

	Ordinary Members.	Patrons.	Total.
1899-1900	37	9	46
1900-1901	83	9	92
1901-1902	108	10	118

The average registered attendances at the various meetings of the society for the same periods are as under:—

	WINTER SESSION.		Total Weekly Attendance.
	Ordinary Meetings.	Instruction Evenings.	
1899-1900	17	20	37
1900-1901	28	30	58
1901-1902	45	38	83

SUMMER SESSION.

	Ordinary Meetings.	Summer Outings.
1899-1900	14	10
1900-1901	23	15
1901-1902	38	17

The monthly lantern slide competitions have now been in vogue for three seasons, and the following table will indicate the support they have received in that time:—

	No. of Slides.		No. of Competitors.	
	Junr. Div.	Senr. Div.	Junr. Div.	Senr. Div.
1899-1900	116	10
1900-1901	129	13
1901-1902	153	81	20	9

From these figures it may be taken that the division into junior and senior classes has proved highly satisfactory.

The seventh annual exhibition compares very favourably with its predecessors, as will be gleaned from the following statistics of members' work:—

	Framed Prints.	Lantern Slides.	No. of Exhibitors.
1899-1900	110	76	19
1900-1901	190	104	25
1901-1902	171	120	33

It was hoped that a second collection of members' slides would have been formed during the year, but only about half the required number was received. The committee again appeal to the members to assist them in completing this second collection at an early date.

The enlarging apparatus was inaugurated on November 1st, 1901, and since that time the register shows that it has been used on 157 occasions by 35 members.

The half-yearly print competitions, which have been held under Rule 12, have not met with that support which would warrant their continuance during the coming year, only the minimum entry of three in both the junior and senior divisions having been received in each case.

The monthly print competitions in connection with the summer outings, although not largely supported, have proved their usefulness in affording some interesting criticisms by the judges.

It is pleasing to record that in spite of a small deficit on the late exhibition, the finances of the society are still in a very satisfactory state, and the committee have been enabled during the past year to purchase a thoroughly up-to-date optical lantern and jet, in addition to replacing some old dark-room gear by more useful apparatus.

Your committee desire to record their grateful thanks to the following gentlemen for their generous donations towards our funds in the year just closed:—Edric Bayley, Esq., L.C.C.; Sir E. Durning Lawrence, Bart, M.P.; E. Lloyd, Esq., J.P.; Albert T. Harris, Esq.

It will be observed that I have merely recorded the progress of the society in a few facts and figures, and have made no attempt to enlarge on the many more or less important events which have occurred from time to time throughout the year.

I think the society may well be congratulated on the work it has accomplished during the past twelve months, as well as on the very prosperous condition in which it finds itself at the close of its seventh year.

News and Notes.

PHOTOGRAPHIC Classes.—Those desirous of obtaining tuition in pictorial and general photography cannot do better than attend one or both of the classes at the Cripplegate Institute, in Golden Lane, Cripplegate, E.C., which are under the direction of Mr. John H. Gear, F.R.P.S. There will be held, we gather from the syllabus, every Tuesday evening, at 6.30, commencing on Tuesday, October 21st next, a practical class for bromide and carbon enlarging, enlarged negatives and lantern slides, also transparencies, in a process of colour photography, and at 8 o'clock every Tuesday evening there will be a lecture and demonstrating course upon general photography. These classes are sure to be very popular, and as the numbers admitted must necessarily be rather limited, early application should be made. They are open to amateurs and professionals of both sexes. A well-appointed class and dark room has been recently provided, which will contain the most modern apparatus for the use of the students.

NOTTINGHAM Mechanics' Institute Camera Club.—At the annual meeting, held September 23rd, the Secretary reported that fifteen meetings and a very successful exhibition had been held and six excursions organised. The membership had increased sixteen on the year, now standing at 107. The finances showed a balance in hand of £3 17s. 7d. The following were elected officers of the Club for the ensuing year:—President: The Duke of Newcastle. Vice-Presidents: Lord Henry Bentinck, M.P., Edward Bond, Esq., M.P., J. H. Yoxall, Esq., M.P., Colonel Sir Chas. Seeley, and Messrs. W. J. Abel, S. Bourne, A. Brown, F. N. Ellis, A. Pyatt, G. H. Wallis, C. B. Wright, and H. Tolley. Hon. Secretary and Treasurer: W. Ward, 14, Stratford Terrace, Nottingham. Committee: Messrs. A. W. Flowerdew, T. Wright, T. K. Gordon, A. Elack, J. Anderson, W. R. Anderson, P. W. Crane, and E. H. Atkin. Album and Slide Secretary: Mr. A. R. Hartley. Curator of Survey Prints: Mr. J. T. Radford.

VOLCANIC Eruptions and Sky Effects.—“The discovery of an order of luminous night clouds at a height above the earth so greatly exceeding anything which had ever been observed, even of the lightest cirrus,” says Mr. E. W. Maunder, in “Knowledge,” “was remarkable enough. More remarkable still were their variations; for they were not by any means a permanent phenomenon, and diminished in frequency of appearance from the time of their first discovery. From 1885 to 1889 they were seen before midnight; later they could only be detected in the morning hours. Their movements were more interesting still, and were such as might be caused, if, though travelling with the earth, they were but lightly subject to its attraction, and experienced some retardation as they travelled with it. From any point of view, the existence of these clouds must be regarded as most remarkable. That clouds could exist at all at a height greater than the highest stratum to which we owe twilight, and that so existing they should be an occasional and variable phenomenon are entirely unexpected discoveries, and still remain unexplained. Can it be that they are one of the by-products of the great volcanic eruption of Krakatoa in 1883? If so, they may be looked for after any great series of volcanic outbursts, such as that which commenced with the destruction of St. Pierre in Martinique in May, 1902, even though these eruptions cannot compare in violence with that of Krakatoa. Three striking sky effects followed that great eruption of 1883. The first was comparatively restricted both as to area and time, and took the form of a remarkable colouration of both sun and moon. At Batavia, in Ceylon, at various places in India, the sun was seen to be blue or green; blue when at the zenith, changing through green and yellow to total obscuration near the horizon. A much more lasting effect was that which received the name of ‘Bishop’s Ring,’ having been first reported from Honolulu by the Rev. S. E. Bishop. This ring was a remarkable species of halo to be seen on every fine day surrounding the sun from its rise to its setting, and even occasionally round the moon. During the day the sun is invariably surrounded by an intense silvery brightness slightly tinged with green, and at a distance of about 20deg. from the sun this tint sometimes changes gradually into a pink or pale violet, and fades away at about 45deg. . . . an orange-tinted haze extending about 45deg. from the moon was also seen on several nights. The third result of the eruption of Krakatoa was the occurrence of ‘Afterglows’ at sunset and ‘Foreglows’ at sunrise. The regularity of their colouring was particularly striking. Four colours in particular have been noticeable in these afterglows, and in a fixed order of time and place—orange, lowest and nearest the sundown; above this, and broader, green; above this, broader still, a variable red, ending in being crimson; above this, a faint lilac. The lilac disappears; the green deepens, spreads, and encroaches on the orange; and the red deepens, spreads, and encroaches on the green, till at last one red, varying downwards from crimson to scarlet, or orange, fills the west and south. These magnificent afterglows reappeared, but on a diminished scale, after the Martinique eruption of May, 1902.” Prof. Herschel described the afterglow of June 26th. “The sun set about 8h. 25m., and a quarter of an hour later a long, low belt of sky in the N.W. had grown orange-yellow, whilst the ruddiness of the sky in the east had by the same time risen nearly to the zenith. Between the two there lay a white tract about 30deg. in width, which was gradually invaded and at last quite occupied by the advancing ruddy colour from the east. About 8h. 55m. from the zenith down to 30deg. above the place of sunset, and for 40deg. or 50deg. on either side of the vertical line through it, was a broad

expanse of rich, rose-coloured, lake-red light. This red glow sank rather rapidly in height, and by 9 p.m. it had subsided into a brighter glow near the horizon.”—“Knowledge.”

MALLEABLE Glass.—It has long been the effort of the glass-makers to produce a glass that would have all the clearness and beauty of ordinary glass, and at the same time possess a toughness which would render it as little liable to fracture as many of the other manufactured articles of use and beauty. It is well known that the ancients discovered and made use of a process of manufacturing malleable glass; and in the glass-making world, it has naturally been expected that it would be in the old world that the process would sooner or later be reinvented. It is to an American, however, says “The Scientific American,” that the credit of having discovered the method of making malleable glass is due. Mr. Louis Kauffeld, of Matthews, Ind., has succeeded after many years of endeavour in producing a glass which will withstand extremely rough usage without breaking. Although the process is not known to anyone except the inventor, he has stated that the lime and lead which are used in the manufacture of ordinary glass do not enter into the composition of his malleable ware. The secret lies principally in the chemicals which are used and the proportion of ingredients which form the compound, although the furnaces and crucibles play an important part in the process. The two chief things to be avoided in connection with the crucible are intense and prolonged heat from without and the corrosion of the raw materials within—two dangers of which nearly every glass-maker knows the ruinous effect. The effect of corrosion is readily proved by heating for a long time in a small crucible such substances as borax, red lead, or potassic or sodic carbonate. After a crucible has been in constant use for several months, and especially if it has contained flint or lead glass, the back and body will be found to be covered with innumerable small dents, which have undoubtedly been formed by corrosion. The complaint so commonly heard of specky glass arises from the presence in the glass of white particles of an infusible aluminate formed by the combination of the alkaline or metallic ingredients of the glass with the alumina of the crucible. If the corrosion becomes concentrated at one point and prolonged for a considerable period a breach is formed, through which the molten glass escapes into the furnace. Knowing the dangers that have to be encountered in this way, Mr. Kauffeld is extremely careful in the selection and preparation of the clay as well as in the construction of the crucibles. The finely sifted raw clay, on its arrival at his manufactory, is mixed with a proportion of burnt clay considerably coarser in grain, varying in amount from one-ninth to one-fifth of its weight. The coarser particles tend to bind the clay and render the finished crucible less liable to crack from variation of temperature. Only those who have lost in this manner a valuable compound can appreciate what an important part the crucible plays in the glass-maker’s success. The tests which the inventor will make for anyone who cares to visit him in his shop in Matthews are certainly conclusive. For instance, a chimney was placed in a pail of ice water, and after having remained a sufficient length of time to become as cold as the water, was taken out and immediately placed on a lamp with the blaze turned as high as possible. The blaze on the wick was turned so as to flow directly on the chimney, and the smoke which collected on the chimney ran down with the water without injuring the chimney. Next a chimney was placed over a small gas stove containing clay bricks used in heating such stoves. The fire was turned on full, the chimney remaining on the bricks. The fire finally brought the temperature to such a stage that one side of the chimney was drawn in and dropped down, and no crack was shown in the glass; but for a slight roughness on the outside, the glass was as clear as when placed in the fire. Another test which was made was to place cold water in the chimney and hold the same over a fire until the water boiled. A large bulb was blown from the glass and filled with about one pint of water. It was then placed over the fire and allowed to remain there until it had boiled dry without apparent effect on the glass. Four chimneys were taken from the packing room and dropped one by one into a pail of boiling water. The chimneys were then hastily shifted into a pail of cold water that had just been drawn from a well, and the glass was not broken. A further test was made by nailing up a box containing glassware, every nail being driven in by hitting it with a chimney. The most remarkable feat of all was the making of a perfect lamp chimney by using a chimney as a mold and blowing hot glass into the same. Both the new chimney and the mould came through the test perfectly whole, uncracked and unscarred. In appearance this malleable glass is much like the common product; it is, if anything, a little clearer than the glass now in use and in its molten state is much more elastic. It can be made of the thickness of a sheet of paper or as heavy as any in use, but in every instance it is tough—a dainty table glass could be handled as roughly as a skylight and no harm result. The advantages conferred by this toughness, in the wide variety of glass utensils for domestic use, are very numerous.

As You Were.—The volume is no longer found in the best circles, but there was a time when no home was complete without it. Its production was the first mark of confidence paid to a new visitor (sometimes it was the last), and it proved especially useful in filling up the dreary waste that came when the wells of conversation gave out. It was generally stuffed with contents to the point of repletion, so that the clasps never would embrace each other, and the head of the family used to say, despairingly, that something would certainly have to be done to it, speaking darkly of the necessity of tearing up poor Uncle Herbert (in view of the way he left those houses away from the family), and hinting that those with whom engagements had been broken off should be burnt. “We ought really,” the head would say, “to keep it to the family. There’s no room for outsiders, unless it’s the dear

ld Queen." "But," someone would argue pathetically, "you wouldn't surely tear up Mr. Barkinson? It wasn't his fault that he went and became engaged to someone else. Besides, he looks gentlemanly in his photograph, at any rate." The degree of friendliness on which one stood with a home circle could always be ascertained by one's position in the book. If you came immediately after the sedate members of the family (father and mother in one picture, with father resting his hand lightly on mother's shoulder, and mother wearing her chain of office, which was generally illuminated in gold; Helen, the eldest daughter, with thoughtful expression as one confronted with difficulty in finding a rhyme; and Jennie, taken on a winter day apparently, for the artist had caught her in a snowstorm; the boys in a group and houldering themselves into a good position), if, I say, you came immediately after these, then you were in the first flight, and it was safe to drop into tea almost any afternoon. If, later on, you found yourself transferred to a part of the album where portraits of Captain Matthew Webb and Lady Dudley were sprinkled, it meant that your popularity was waning and that you ran a great risk of being left out of the party given on New Year's Eve; if eventually you were buried, two deep, under coloured photographs of ferns at the very end of the book, then it was fair to assume that friendship had gone with the snows of yester-year, and that when you did pay the infrequent visit your portrait had to be dug out with a paper-knife and cleaned up with bread. The family album was an inconvenient book when the family had advanced notably in the world. Relations had become strained and had to be kept away, so that sometimes a fraudulent system was arranged of keeping a double set of books, one called the Best Album and the other the Second Best; and the Second Best was a skeleton in the cupboard, brought out furtively on evenings when superior children had gone to bed, and the parents wanted to think of old times when they were hard-up and happy. Men in the Second Best had unfashionable whiskers which went round underneath the chin; they wore a black cloth coat with an unaccustomed air; a flat-brimmed silk hat generally stood on the floor by their side, much as though it were a valued family relic—which, indeed, it was. Ladies were costumed in silk gowns, the train standing out stiffly; a cameo brooch at their throats; their hair in a net, and an aggressive smile which they appeared to have pinned on their faces at the express command of the photographer. Also in the Second Best were young couples with arms around each other's necks in a terribly plebeian fashion, and the parents who had achieved success would sit and look at one of these—"You were a good-looking girl, my dear, then." "Your head of hair was quite black James, at that time"—and would wonder whether, after all, money was able to buy everything. The ages of man found themselves set out frankly in the family album; juvenile portraits of the girls were generally extracted by them and put away somewhere, lest the pigtailed with scarlet bows, the leghorn hat and the elastic side boots should betray their age or raise the injudicious smile. But a thoughtful man could see his life set out there from the age of one, when a mother's hand held him to prevent disaster to the picture, and his baby waist (not otherwise to be distinguished from the rest of the small body) was indicated by a broad pale blue sash; an astonished look on the face suggested that something of a startling nature of being done with a toy by the specious artist. Later, he was a knickerbockered lad with a toy gun and carefully-smoothed hair, a look of haughty patriotism on his face. The next came at eighteen years, when his hair was still smooth, excepting for a single erect spike that never would keep down, daring pomatum and brushes to do their best and worst; he wore a flower in his coat; a suspicion of a moustache, which was only a suspicion, had been deepened into assurance by the aid of a black pencil. All these things showed that he was one who hoped the other sex could be allured by the tricks of personal adornment. There was a long gap after this, and in the next he was in a family group, if you please, with little ones around—little ones who had not in every case become big ones, for some had gone to sleep quite early in their lives and had never awakened to tell of their happy dreams. And reviewing these milestones in life, many a one must have thought how pure and clean he was when the journey began, and what a dusty, smirched and tired-out traveller he had somehow managed to become.—W. PETT RIDGE, in "The Christian World."

A PHOTOGRAPHIC Society for Cambridge.—In consequence of the brilliant success attained by the Photographic Exhibition recently held in the Corn Exchange in connection with the annual show of the Cambridge and District United Horticultural Society, there has been a general outcry in the town for a local camera club. In response to the wishes of many persons interested in photography, Mr. C. S. Addison convened an informal meeting at the Llandaff Chambers, Regent Street, on Wednesday evening last week, in order that the advisability of forming such a club in Cambridge might be thoroughly considered and discussed. It was attended by about fifty enthusiastic photographers—both ladies and gentlemen—the gathering including Dr. W. H. Bansall (Downing Grove), Mr. and Mrs. C. S. Addison, Mr. and Mrs. Charlton, Messrs. F. H. Sanderson, H. A. Chapman, D. J. Scott, F. S. Stoakley, T. J. Sowdon, A. Barrett, Alphonso Smith, J. H. Leech, G. H. Tyndall (Ely), A. J. Mouel, E. S. Peck, G. E. Hardwick, W. Atkinson, H. J. West-Knights, A. G. Swannell, W. R. Billing (Elsworth), R. P. Benham, J. Winship, jun., W. H. Hall, and W. C. Squires. Dr. Bansall, who was unanimously voted to the chair, said, in opening, that they had had a photographic convention there, and the photographic convention had given them a lead and stirred them up, and they all thought they ought to have a camera club in Cambridge. It seemed to him an absolute disgrace for a place like Cambridge, an old historic University town—only Oxford can hold a candle to them in the whole world—not to have such a club.

There they were, with boundless subjects in all directions, and yet they had no camera club. He thought they ought to do their level best to see if they could not form one—not only a mere "flicker," but one that was going to last. Bury St. Edmund's, with a population of only 17,000, had a flourishing camera club, and he hoped the want of one would not be long felt in Cambridge. There was a camera club there, he believed, some long time ago, and he would ask one of the members of that defunct club to speak. Mr. Sanderson said there was not the slightest doubt that in a town like Cambridge there ought to be a well-established photographic club. They had at one period a club in the town, but unfortunately it went the way of many clubs that had been started in Cambridge, and it died from what he considered the very worst of all diseases—lack of interest and want of enthusiasm among the members. Prior to that—in the early eighties—there was a similar club in existence in connection with the University, but that shared the same fate. They had subsequently had a club formed by a fair number of members in connection with the Y.M.C.A. They recognised the club—he had been closely connected with it several years in judging work at their little exhibitions—but what they wanted was a club that was unsectarian—and he thought it ought to be social to a large extent, but not political. In forming a club they must have a good membership; they must be very enthusiastic, and every member should feel that the success of the club depended upon his own exertions, or it would be a failure. If they fell in with that, he fancied there would be a possibility of running a club successfully, but it meant that there must be a sticking to it. Mr. Addison thought Cambridge had exceptional advantages and facilities for those interested in photography. He was very sorry to see that in the last exhibition some of the exhibitors had not made that progress since the previous year that one would have expected. Some of the gentlemen who attended considered it was due to the want of a society. Those who were working in the town were not able to see what others were doing, and he considered, if not a camera club, a portfolio club should be started. Since then several gentlemen had expressed to him a wish that there should be a camera club, and asked him to convene a meeting. If they decided to form a society, there were several things to bear in mind, namely, whether they would have a room of their own, how many members they were likely to get, what sort of club they would make it, and the question of officers. He would suggest that the club be made as social as possible, and he would like to see a large membership, because then they could do so much more. He was sorry to say that some were waiting to see what sort of a club it would be before they became members. Really, it would be what they made it. If they could not get many members, they would have to be content with a room once a week or once a fortnight for occasional meetings and lectures, but if they got a larger number, say 200 or 250—they ought to get quite 200—they would have a lot of help from out-lying districts. He had promises from a gentleman at Ely, and from several in villages round Cambridge, so that everything bade fair for the formation of a good society, and one with plenty of members. A question that wanted a deal of debating was whether they would admit undergraduates; there were many pros and cons. He had had promises from several resident members of the University who would be pleased to support the club if it was formed, but, as to undergraduates, it seemed to be the feeling of several people that he had spoken to that they should leave them to form a club of their own. Another question for consideration was whether it would be desirable to have a dark-room, studio, or lecture lantern for the club. Upon the members depended what the size of the club would be, what the subscription would be, and whether any entrance fee would be charged. It had been put forward that if a club was formed, a subscription of 5s. or 7s. 6d. would meet the requirements. Mr. G. H. Tyndall said he would like to see a club formed, because in Ely one had to work alone, and did not get criticised, and one got conceited until one was taken down. He thought he could find nine or ten members. Mr. Chapman thought that unless they could get sufficient members to insure practically the success of the club, they must adjourn the meeting. Mr. Addison ought to feel certain about what number of members was likely to join the club, as on the number depended the subscription, and the two combined would settle whether they had a meeting once a week or once a fortnight or permanent rooms. Mr. Addison said he had not taken any names of members because there was nothing tangible to work upon. Mr. Sowdon said, as far as he knew, the members of the Y.M.C.A. Camera Club did not look upon that proposal as any opposition, and from what he could make out there would be a certain amount of support received from them if there was a club formed. Mr. Stoakley, in order to set the thing going, moved that a club be formed, with a subscription of 5s. or 7s. 6d. This was carried nem. con., and at the suggestion of Mr. Sanderson, the chairman asked all who would pledge themselves to become members to show their hands. Almost everyone did so, and after papers had been handed round for intending members to give in their names and addresses, Dr. Bansall announced that they had got fifty members, and expressed the opinion that if they meant anything the ship ought to float. Some discussion took place as to the title of the new club. Three suggestions were made, namely, "Cambridge and District Camera Club," "Cambridge Camera Club," and "Cambridge and District Photographic Society," and eventually the last-mentioned title was chosen by a large majority. Dr. Bansall was unanimously chosen president, and Mr. F. H. Sanderson vice-president. No one could be found to take the secretarial duties on, and Mr. C. S. Addison undertook to fill the office pro tem. Mr. J. H. Leech was elected hon. treasurer; Mrs. Charlton, Mrs. Addison, and Messrs. Chapman, Scott, and Stoakley were appointed to form the committee, with power to add to their number, and it was left to them to draw up a scheme for the working of the club and to formulate rules.

THE SUBSTRATUM IN GELATINE AND COLLODION PRINTS.

To the Editors.

Gentlemen,—With reference to your remarks on the probable effects of the substratum in gelatino and collodio-chloride prints, may I point out that if the gelatine or collodion film is stripped from a finished print an image is found on the substratum, and this fact appears to indicate very positively that there is combination between the silver and the emulsion and the vehicle of the substratum.

I enclose a specimen of a stripped gelatino-chloride print, showing a distinct, though faint, image on the substratum. The upper portion of the divided print has been exposed to sunlight for five hours, to see if any change took place, but with no result.

Evidently the lower image requires to be as perfectly fixed and washed as the upper one, if the result is to be permanent. I cannot supply a similar specimen from a collodion paper, as the stripping operation is not easily carried out without rubbing out the lower image. If, however, you take a very deeply printed image, and, with a pad of wool dipped in spirit, gently rub off the film, in some spot where there is a violent contrast of light and shade, the substratum image can be seen pretty clearly.—Yours, etc.,

C. WELBORNE PIPER.

September 26th, 1902.

PHOTOGRAPHY AS A FINE ART.

To the Editors.

Gentlemen,—The question introduced into the current number of your Journal by "F. V. C." is one of interest to me. My sympathies extend in the same direction as "F. V. C.'s"; still, I am not convinced. I write unbiassed, and I am open to conviction, but it appears to me that all known methods of producing photographic prints are mechanical processes.

It is true that artists working in photography so far subjugate their processes to their artistic ideas as to produce very poetic results. But does that make the means they employ an art? Let us imagine, firstly, a painter sitting before an empty canvas. He calls into his brain the vision of a subject he desires to paint. With dexterous and careful touches of his brush, inspired by his genius and by his knowledge, he creates upon the canvas the image he has in his mind. The colour is laid thinly here and loaded "impasto" there, according to the prompting of his inventive mind and as to the necessities of his subject. The painter is an artist; he has created a work of art. The means whereby he created it is an art, because the very existence of the feeling and sentiment contained in the picture depends upon the inspired technique. This technique (or handling of the colours and brushes), cannot be imitated, perhaps not even reproduced perfectly, by the artist himself. It is tolerably common knowledge that a painter does not achieve the same success in a replica as in the original work.

It is possible that "F. V. C." may not realise the full truth of my meaning, unless he has studied the painter's art. I refer to the individuality of handling which enables one to distinguish between the work of one artist and that of another. It is sufficient for my purpose to name Sir J. E. Millais, J. S. Sargent, and G. F. Watts. No one could mistake the technique of either of these painters, if he understood technique at all. I could, of course, name all the great artists with equal truth. An expert can proclaim a picture to be an original work or a copy by this individuality in the technique.

In painting from landscape nature the process by which an artist evolves a picture is the same. He conceives his subject, makes it his own, and treats it accordingly. The technique of Turner, Constable, and Crome differs as much as the sentiment conveyed in the subjects they treated. The technique is a part of the inspiration, and that which will suit one picture will not do for another. If we could assume it possible to exchange the handling of one picture for that of another the sentiment of the work would be destroyed.

Secondly, let us suppose the artist-photographer, who is anxious to

produce a work of art by photography. He conceives a subject. At the outset he finds there are so many things in the way of securing his desire that he has to give up one idea after another as impossible. At last he hits upon one he thinks will succeed as to lighting, background, exposure, and so on. We will suppose he has a fairly practicable poetic idea—say, a figure subject. He arranges his background, poses his model, or models, and takes infinite pains to get everything, as far as he can, just right. He knows, however, that his sensitive plate is so unsympathetic that it will make the details he wishes to keep subordinate appear of even greater importance than they are in nature. That is the consequence of an inartistic process. The artist has to content himself with the knowledge that by sundry mechanical contrivances, dodges of development, and retouching tricks of printing, ozotype, etc., he may be able to achieve the result he is aiming at. The exposure made, he develops his plate, restraining some parts of the subject and accelerating others. Having done all that can be done in development, he retouches. Now, the very fact of having to retouch a negative proves that the previous processes are in themselves inartistic, or the artist would not have to correct the mechanical errors committed by his sensitive plate. But even here the work put upon a negative is very mechanical, spotting out holes, scraping down blotches, subduing the hardness of outlines and the like, floating on matt-varnish, and scraping parts of it off again. When the negative is prepared, the printing process (if in pigment) perhaps more nearly approaches an art than any other part of photography. I fail to see any art in printing in P.O.P., bromide, or platinum. Pigment processes lend themselves to some amount of artistic treatment, but is it not the subjection of mechanical means to the artistic sensibilities?

Anyone with poetic instinct will produce in photography, or by any other means, a work of more artistic merit than one without that instinct. Also, the person not endowed with the true æsthetic feeling cannot create a work of art in oils or water colours. I have a great admiration for some of the photographs in the Salon, but the artist-photographers, whose work they are, were artists first and photographers afterwards.—I am, gentlemen, your obedient servant,

C. W. C.

September 26th, 1902.

ON VARIOUS SUBJECTS.

To the Editors.

Gentlemen,—Some time ago a correspondent asked about something to take out the plates from developing dish, so as to save the fingers from contact with it and prevent their staining. I am using for development, dishes which are so exact in size that I could not take the plates out if I had not arranged a small and useful contrivance as follows:—I take a piece of brass ribbon, thin, but strong enough, which I bend round the edge of dish and along the side, and bend again to go under the plate about half way the length of it. With this I lift the plate out of developer to look at it, and save my fingers very much, and this exact size of dish allows me a great saving of developer, the plate laying almost flat at the bottom; the whole of it is used on top of the plate.

You gave also a way to make a dish, which is not eaten up by waste water and chemicals, but I found this a rather complicated affair however, said to be very simple. I use simply a suitable box, with a hole at one corner, for the wastes to run off. This box is lined with lead, and, so as not to use it up too rapidly or scratch it, I stand my dishes on two strips of wood. I have used the same box or large dish, as it looks like, for nine years, and it is as good as new.—I remain, yours very truly,

ALBERT LEVY.

Asnières (Seine).

THE GRÜN LENS.

To the Editors.

Gentlemen,—I was very much amused at the humorous paragraph in your Journal this week, but that feat would have been an easy one, compared to what I did last night. When I tell you that I succeeded in taking a three-colour negative of Alhambra ballet you may open your eyes; but it is true for all that, and I could make a coloured lantern slide from my last night's negative, but I trust, with the experience I have gained, to be able to have some better lantern slides made from three-colour negatives, taken at the Alhambra, to show at the Croydon Camera Club meeting on the 15th of October. It is curious to relate, but I have found it so, in photographing the illuminations, etc., that the red lights are apparently more actinic than the blue by night. Of course, I suppose that there is proportionately much more red than blue in artificial light, but apparently there is more difficulty in getting good exposure for blues and yellows by night than for the reds. Your article on depth of focus for lenses interested me, and

ou always miss one fact—that is, that, although your statement is true in theory, it is not so in practice. You will admit that the infinite point of a very short focus lens is much nearer at hand than that of a long focus lens, therefore objects much nearer to hand are within the infinity point. This alone gives a greater practical depth of focus, so you must qualify your statement, and say that if the lenses have the same focus they will have equal depth at equal apertures; but, again, if a lens has a very flat field, like the planar, it will not have so much depth of focus, as if it has a slightly curved field, because practically, or in practice, you can choose your picture, so that the curvature of the field enables you to bring your objects at the side of the field into focus if they are standing further back, at the same time as your central figure standing nearer to you, because the more distant objects, necessarily having a shorter focus, and the curvature of field making the focus at the edges shorter, the two foci coincide, and so you get a sort of artificial depth, which in practice is decidedly useful.—Believe me, dear Sirs, sincerely yours,
The Hall, Southwick, Brighton.
September 26th, 1902.

EDW. F. GRUN.

P.S. —I enclose one or two of my last photos of Alhambra ballet.

THE LOST GOERZ CAMERA.

To the Editors.

Gentlemen,—In reference to my letter of the 23rd, I am pleased to inform you that the gentleman whose luggage was stolen from him has since recovered the same.—I am, dear Sirs, yours faithfully,

C. P. GOERZ.

4 and 5, Holborn Circus, London, E.C
September 27th, 1902.

A STEREOSCOPIC AGENCY.

To the Editors.

Gentlemen,—I have pleasure in advising you that I have been appointed sole British agent to the house of Levy et ses Fils, of Paris, for the sale of their well-known series of lantern slides and stereoscopic views on glass. All communications, therefore, concerning these goods should be addressed direct to me here in order to avoid delay. All accounts will likewise be rendered and received by me. It is safe to say that Messieurs Levy's enormous collection of lantern slides is the largest in the world, whilst the quality and technical excellence of a "Levy" slide are so well known among lantern experts as to render further comment unnecessary. A number of operators are continually travelling the globe, increasing and renewing this vast collection, so that the views shall be quite up to date. I shall at all times be willing to wait upon you with specimens or collections for selection, and am confident that business will result, as we are now enabled to place before the trade slides of a higher quality and at a cheaper rate than has hitherto been known.—Yours faithfully,

SAMUEL J. BECKETT.

20, Baker Street, London, W.

C.C. PAPER.

To the Editors.

Gentlemen,—Apropos of your interesting article on the alleged instability of collodio-chloride papers, I have had some experience which I may perhaps mention. I used C.C. paper of English make for several years, and do not remember having seen a faded print. I found one a few days ago, which had been made half-a-dozen years, and was perfectly fresh and not yellowed in the whites. I abandoned the paper, however, because the print surface was so very easily damaged. In inserting a print in a frame or an album, a customer frequently scratched it very badly. About six years ago a professional friend made me a batch of matt C.C. prints, toning them with gold and then platinum. Half-a-dozen of this batch are before me as I write, and are as fresh as when made. Some other prints of the same batch, however, which were exposed in a show-case, rapidly yellowed, and the image lost its black, and turned a pale, dirty brown, not more than a tenth as strong as the original print.

I have also some prints on Blanchard's paper, toned with platinum. These have been slowly fading for ten years, and now the spotting shows as distinctly darker markings. The paper has not yellowed, however. The firm with whom I was, at once abandoned the use of this process, when they feared its instability, and it is to be regretted that so many professionals of to-day are to be found issuing from their studios, as platinotypes, or "platinos," prints which have not the reputation for permanence of the true platinotype processes. This, persisted in, must eventually bring the public to doubt the permanence of any printing process.

Platinotype will give as excellent results as any platinum toning process, if the right kind of negative is obtained. It is, however, to be feared that the use of P.O.P. and other similar papers has gradually produced indifference as to the quality of portrait negatives, and some experience of photographers' negatives leads me to the conclusion that a very general idea obtains that almost any sort of negative may be printed from, by keeping in use, half-a-dozen papers of varying characteristics. This "mixing" has the obvious disadvantage that it prevents the printer acquiring a perfect knowledge of each process, unless he be an exceptionally able man. More care in negative making and a steady adherence to one or two mastered processes would cause many printing troubles to vanish.—I am, yours, affectionately,

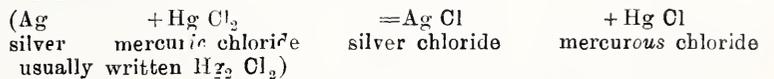

C. H. HEWITT.

The Rembrandt Studio, Gateshead-on-Tyne.
September 30th, 1902.

INTENSIFICATION.

To the Editors.

Gentlemen,—Happening to notice a report of the meeting of the London and Provincial Photo Association, in your issue of the 19th inst., in which Mr. Welford introduced a problem of anent effects produced relating to mercurial intensification, which no one present seemed able to explain, it came as a surprise to me to note how little some leading photographers study the chemistry of photography. Mr. Welford asked why it was that when a negative had been bleached with mercuric chloride and allowed to dry, and then exposed to daylight for a considerable time, nearly double the intensification was produced on its being blackened than would be the case if the negative were blackened immediately after bleaching. It is only necessary to have an elementary knowledge of analytical chemistry for one to give the reason. The explanation is, that before the reactions mentioned the negative consists of metallic silver in a fine state of division, embedded in gelatine. On submitting this to the action of mercuric chloride the silver robs the mercuric chloride of some of its chlorine and reduces it to mercurous chloride (a white insoluble substance), and the silver becomes silver chloride. If the bleached negative is immediately treated with ammonium hydrate, the silver chloride is dissolved out, and the mercurous chloride is blackened; but if the bleached negative is allowed to dry and submitted to the action of daylight for some days, the silver chloride also blackens through chemical change, by the liberation of chlorine, and becomes insoluble in ammonium hydrate, which accounts for the increased density. Some of your readers may feel interested to know what chemical reactions take place when intensifying negatives by the bleaching and blackening process.

—Yours, etc.,

W. GUTTENBERG.

OPINION WANTED.—"PYRO" says: "I enclose a few prints to show average quality of my operating and retouching. Would you kindly give me your opinion on same; also what salary I could ask, as I wish to apply for a situation?"—In reply: We are sorry we cannot speak very highly either of the photography or the retouching. We should advise you to improve yourself both in photography and in retouching before you apply for a situation; you will then be less likely to meet with disappointment.

BOOK ON THE STUDIO.—W. H. B. asks: "Can you inform me if there are any books published relating to the studio, as to the manner of commencing a photographic business; also giving hints regarding same?"—In reply: "The Studio, and What to Do in It," by H. P. Robinson, and "The Lighting in Photographic Studios," by P. C. Duchochois, are good works, but they do not give any information about commencing a business, and there is no book published on that subject. The books named may be had through any of the dealers.

URANIUM INTENSIFYING.—BURNISHING.—A. STANLEY asks: "(1) Would you kindly tell me how to make up a good uranium intensifier—one that you can redevelop after? (2) Also what is the best method to adopt with a twin-roller burnisher to obtain high polish on print?"—In reply: (1) Uranium nitrate, 12 grains; potassium ferricyanide, 15 grains; water, 4 ounces. (2) Heat the rollers and pass the prints through with good pressure on them; but first lubricate the prints with a solution of Castille soap—1 grain of soap in 1 ounce of alcohol.

STEREOSCOPIC PORTRAITURE.—"AMATEUR" says: "Kindly tell me (1) which is the most perfect class of lens to use in stereoscopic camera for taking portraits (stereoscopically). (2) Would a pair of single lenses be preferable to R.R.? (3) What focus would be best for this purpose, 6 inches? (4) Also what would be the best focus and type of lens to use with stereoscopic camera for interiors, such as ordinary rooms?"—In reply: (1) A pair of R.R.'s, or a pair of the anastigmatic type, or a pair of portrait lenses. (2) No. (3) Yes, six inches for portraiture. (4) Four inches, as they will include a fairly wide angle. They should be either R.R.'s or anastigmats.

SPOTS ON COLLODIO-CHLORIDE PRINTS.—"MATT PAPER" says: "I was very interested in 'Othello's' letter in your last issue respecting the permanency of Collodion Matte Paper. I have taken the liberty of sending you a few prints which have the appearance of the same trouble, namely, fading marks. These spots are only noticed in the matte paper. The manipulation of paper is exactly as laid down in the formulæ. I have never found this trouble with the Glossy C.C. Can you give me any idea what the cause may be?"—In reply: In last week's issue there is a leading article on the subject. We presume the prints sent were toned first with gold and afterwards with platinum. It is important with this method that the prints be tolerably well washed between the two tonings: was this done?

VEILED LANTERN SLIDES.—"OXALATE" writes: "I have been using the Ferrous-Oxalate Developer for Lantern Slides, but find that, notwithstanding the use of an acetic acid clearing-bath immediately after development, there is a slight bluish milky deposit on the finished slide. This is very slight, and would be of no consequence in a negative. I believe that there is a special clearing-bath (for use after fixing) to remove this, but have mislaid formula. I should be much obliged if you could let me have this at your early convenience."—In reply: The deposit is, no doubt, oxalate of lime, owing to the water used containing lime. It may be removed by immersing the slides, after the final washing, in water slightly acidified with hydrochloric acid, say five or six drops to each ounce of water.

TRICHROMATICS.—C. S. A. writes: "I should feel much obliged if you could give me any information on the following points:—(a) Where can Hoffman's trichromatic carbon tissues be obtained? (b) Where can I find any details of Dr. Mieth's investigations and results in

trichromatic photography? (c) Can you give me the name of any sound work dealing with the theory of three-colour work, that is to say, going into details from the spectroscopical point of view?"—In reply: The firm that sold the tissues has gone into liquidation, but you might try Herr Hoffman, Cardinal Film Gesellschaft, Coln a Nippes, Germany; or Romain Talbot, Berlin. (b) No details have been published beyond those given in our paragraphs. (c) "Photography in Natural Colours," published by Marion, is the only English work; but, in German, Hübl's "Der Dreifarben-photographie," published by Knapp, of Halle, is the best.

PRICE OF NEGATIVES.—"LOCHIEL" says: "In a certain country district in which I have been residing for some time past I spent much of my spare time taking half-plate views of villages and local features of interest. These having turned out rather well, a local dealer, with the intention of publishing an album of local views, has offered to buy my negatives. As there is no other of the same place on the market, I think there is a good field for such a production. As I have several dozen negatives at my disposal, I fancy the views he would publish would be altogether reproductions from them. Would you be kind enough to say what you would consider a fair price for me to ask per negative?"—In reply: So much must depend upon the quality of the negatives, and the interest attached to them, that we can scarcely appraise their value; but we should say that from half-a-guinea to fifteen shillings each would be a fair price. All such things are a matter of mutual arrangement. This, we imagine, would be about the price the publisher could get the views retaken for.

SEPIATYPE PAPER.—H. SHIMWELL says: "In last year's Almanac there is an article on making sepia-type paper, the instructions of which I have followed out exactly as far as I know. It states that a small quantity of gum arabic solution is to be added to the ammonia ferric oxalate to keep the image on surface of paper, and also to prevent precipitation of the silver when the silver citrate solution is added. All seemed to go well till this citrate solution was added to the ferric oxalate, when apparently the whole of the silver was precipitated, leaving a muddy-looking liquid, with most of the silver, I should say, at the bottom. Could you say what has gone wrong, and whether I can rectify matters, or, at any rate, get back the silver from the solution?"—In reply: We are sorry to say we cannot tell what has gone wrong, unless sufficient gum was not added. If the silver is precipitated, the supernatant liquor may be decanted and the precipitate added to the stock of residues, which, we presume, you save, as most professionals do.

COPYRIGHT.—A. W. JOHNSTONE says: "On Royal Oak Day in 1900 or the previous year a man took a photograph of two ladies. In August, 1900, one of the two died, and this being the only known photograph of the lady, the man was approached on the matter, and he, being a working-man 'amateur'—one of the sort who sell cabinets at about sixpence each—offered to do some from the one he had. He copied—or had copied for him, I should suppose more likely—a cabinet bust from the small photo whereon the two ladies were together. The work is disgraceful, and I have been asked by the family if I can do B. and W. enlargements for them, but he has printed 'Copyright' on the photos he has done. He has put no number of copyright on the prints, and refuses any information, neither will he give permission for anyone to make a negative. Can you tell me how I stand in the matter, and whether, say, by making alterations in the dress in an enlargement, I should be justified in undertaking the work? And, again, can a photograph which is a copy of part only of another one (a group in this case) be copyrighted?"—In reply: If the picture has been made copyright, it would certainly be illegal for you to reproduce it or any portion of it. The mere altering of the dress would not protect you at all. Perhaps, after all, the picture is not copyright, but that you can only ascertain by searching the register at Stationers' Hall.

STUDIO BUILDING.—R. W. writes: "In your Answers to Correspondents last week I see a letter from 'Studio Length,' which, I think, I could reply to better than most photographers, and possibly give you a hint for the future. My studio is on the 'single slant' principle; it is on the first floor, has no top lights of any kind, and is 24ft. odd inches long. By taking out part of the floor above I got a window 14ft. high, and the width I made about 11ft. In addition to that I have on either side a window which was part of the original building. In practice, I find, firstly, I seldom or never work with the large window open lower than about 7ft. from the ground, and I don't think I ever uncover the side windows at all. I have blinds on the large window, running both up and down. In less than half a minute I can put the entire studio in total darkness or flood it with light. I've now had three-and-a-half years' experience of this kind of studio, and find no difficulty either in lighting or exposure, nor would I go back to skylights on any consideration. Apart from the lighting, a side light has many other obvious advantages. You can have a studio on any floor you like, which widens the range of suitable premises. If your studio is not on the roof, it is cool in summer, and can be easily warmed in winter. You are also safe from leaks, and have less dust or soot. 'Studio Length' can rest assured a very few weeks will convince him a high side light is the best; but I can't say I would care for a studio only 20ft. long—if I could, I would have mine about 30ft."

* * * Owing to pressure, several articles, letters, answers to correspondents, and other items are unavoidably held over.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published early in December next. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The edition for 1903 will be increased to 25,000 copies, a large number of which are already ordered.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1903. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

Secretaries of societies will oblige us by promptly for-

warding lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, etc. Those firms who wish to take advantage of this feature should communicate with us not later than October 31.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRA.

The Focal Plane Shutter. We see that a patent has been granted in Germany to the firm of R. Huttig and Fohn for a new variety of focal plane shutter. Usually the width of the slit is regulated by reducing the length of the chain, or cord, connecting the margins of the aperture in the blind. The new method, forming the subject of the present patent, provides a number of slits of different widths in the blind. The slits are separated from each other by a sufficient amount of material to completely cover the plate. This permits of the apertures, which are not in use, being wound upon the rollers. The advantage, of course, lies in the facility with which the aperture in the blind may be changed by simply revolving one of the rollers. On the other hand, the length of the roller blind is considerably increased.

* * *

Extra Rapid Lenses. A letter from M. E. Krauss, of Paris, to the "Bulletin" of the Association Belge de Photographie, places in a very clear and concise manner before the reader, the disadvantages which are inseparable from the large aperture of a lens. M. Krauss is the licensee of the Carl Zeiss Optical Works, and in writing of such rapid lenses as the Planar and Unar truly says that their large aperture should be regarded as one which may, rather than must, be used. The distance beyond which all objects appear to be sharp depends upon the focus of the lens, the relative aperture, and the permissible circle of confusion. It may be deduced from the

formula:— $P = F^2 \frac{x}{n} d$, in which P represents the distance of apparently sharp objects; F, the principal focus of the lens; d, the relative aperture; n, the co-efficient of definition; n is variable, being often taken as one-tenth millimetre and sometimes as one-hundredth of an inch. From this equation it will be seen that to increase the depth of focus, either the principal focus, or the aperture, must be diminished. We have frequently expressed surprise that

amateurs should insist upon having lenses of the most rapid type for hand camera work, when plates of the highest sensitiveness are to be had at popular prices. The lenses are usually stopped down, for there are very few opportunities when the requisite depth of focus can be obtained with a large aperture.

* * *

Stereoscopic Photography. The stereoscope appears to be receiving far more attention in France than in this country at the present moment. Dainty cameras for the purpose are being manufactured by various firms, and they are remarkable for their lightness and compactness. In this country the most popular size for stereoscopic work is $6\frac{1}{2} \times 4\frac{1}{4}$ in., but the French are using smaller sizes. M. Pilleux, for instance, recently placed upon the market a stereoscopic camera called the "Six-treize," $2\frac{3}{8} \times 5\frac{1}{8}$ in. It is made of metal, and the plates are carried in dark slides. Another camera, called the Altostéréo Quart, made by C. A. Steinheil fils, of Paris, has some novel features. The plate is 9×12 c. ($3\frac{1}{2} \times 4\frac{3}{4}$ in.). Three lenses are provided; two of $8\frac{1}{2}$ cm. focus for stereoscopic purposes, and one of 13 cm., placed centrally, for taking single pictures on the whole-plate. One shutter serves for the three lenses, and the stereoscopic pair may be used by capping the ordinary lens, or vice versa. By interchanging the components of the lenses, or using the separate halves, a great variety of foci may be obtained. A special stereoscope is also supplied, with eye-pieces of short focus corresponding to the photographic lens. The stereoscopic views are thus seen in precisely the same manner as the photographer saw them from the spot where the camera stood. With a transparency the effect is quite realistic. A square 5×4 camera could easily be altered for similar use.

* * *

The Gum-Platinum Process.

Some members of the school of mucid photography have at last seized upon the beautiful platinum process to help themselves out of their difficulties in obtaining a satisfactory range of gradation. This new departure forms the subject of an article in the "Photo-Gazette" by M. Ch. Sollet, who states that M. Herbert Silberer was the first to exhibit prints by this combined process at the Camera Club, Vienna. Mr. Holland Day also exhibited a print by the process at the Paris Salon. We are familiar with the laboured efforts of some of the school to strengthen their prints by repeated applications of pigmented gum, supplementary exposure, and development. We are, therefore, not surprised that they should turn to platinum to obtain delicate half-tone or deep shadows. The combined process is recommended for either purpose, and as it is said the platinum print gives facilities in both directions, we fail to understand why bichromated gum should be combined with it, unless the photographer is compelled to help out an unsatisfactory negative. Development may, of course, be controlled with the brush! As the pigmented gum process is not purely photographic but largely dependent upon the brush, why should these people give themselves so much trouble with double printing, development, and other fake? Why not apply the colour direct with the brush, instead of juggling with photography? Is it necessary that there should be a scapegoat to bear the burden of their sins?

* * *

The Advancement of Chemical Industry in Germany.

We read, from a source we have no reason to doubt, that the number of trained chemists employed in German factories was, in 1885, something like 1,700, and now is no less than 4,500. We are also told that nine big dye stuff works have from

nine to over one hundred chemists each employed. This is not altogether pleasant reading, seeing that the coal-tar colour industry had its origin in England, and within few miles of the metropolis. Now this business is almost if not quite, extinct in this country. What makes the matter still more unpleasant reading is the fact that the supply of much of the material used in the manufacture of the colours is drawn from Great Britain. When we last passed the extensive works at Greenford, now a few years ago, where the coal-tar colours were first made, we noticed they were in ruins, and the ground was "to let." One may very naturally ask why this very profitable industry has slipped out of our hands? Is it due to superior chemical knowledge or to a certain lack of British enterprise? We are rather inclined to the opinion that the latter is the main reason. Where is the British factory that employs over a hundred skilled chemists, or anything like half that number, devoted to making improvements in any manufactures? It is noteworthy that all the new developing agents used in photography have their origin abroad. At one time all of our old friend "pyro" was made in England, and now we question if any at all is made in this country.

* * *

Nature of Metallic Radiations.

The series of articles by Professor Rutherford and Mr. Soddy, on the radio-activity of thorium compounds, which has lately been appearing in the "Chemical News," and which we have before referred to, is now concluded, and the last portion contains a most interesting résumé of the various aspects of the work done, and their indications as to the theory of the radiations. It is pointed out that all the most prominent workers in the subject agree in considering radio-activity to be an atomic phenomenon, that is that the radiation is not so much what the popular conception of the word implies as the effect of almost infinitely small particles. "In each case the radio-activity appeared as the manifestation of a special kind of matter, in minute amount. The emanation behaved in all respects like a gas, and the excited radio-activity it produces as an invisible deposit of a highly active material. . . . The position is thus arrived at that radio-activity is at once an atomic phenomenon, and the accompaniment of a chemical change in which new kinds of matter are produced. . . . The idea of the chemical atom in certain cases spontaneously breaking up is not of itself contrary to anything that is known of the nature of atoms." The fact that these material particles are so minute that, although they are constantly being evolved and detached from the mass that emits them, the latter appears to become no lighter in the balance is referred to as follows:—"The changes brought to knowledge by radio-activity, although undeniably material and chemical in nature, are of a different order of magnitude from any that have before been dealt with in chemistry. The course of the production of new matter, which can be recognised by the electrometer by means of the property of radio-activity after the course of a few hours, or even minutes, might possibly require geological epoch to attain the quantities recognised by the balance."

* * *

Vulgarisation of X-Ray Work.

As the very opposite of the scale of grandeur of conception comes the latest news regarding the progress of X-ray work, and this is neither more nor less than a penny-in-the-slot machine invented by an American. The appearance of the machine is similar to that of the now familiar kinematograph machines to be seen at the railway stations.

penny is put in the slot, you move a lever, put your hand, whatever you wish to examine, into a box without sides, and look down at it through a fluorescent lens, which forms the top of the box. The coin on being inserted closes the primary circuit of an induction coil worked by a few dry cells, and the vacuum tube is in position immediately below the object to be observed. A popular scientific contemporary says:—"All that is now required is the penny-in-the-slot dentist." It appears to me rather, that all that is now needed is a penny-in-the-slot photographic machine attached so that the observer can take his skiagraph away with him.

* * *

Street Dancers. The snapshotting fraternity who are always on the look-out for humorous incidents in our busy streets, would do well to keep an eye on what may possibly happen on the route of the new electric tramways at such time that the current is turned on for the first time. More especially should they direct their expectant attention on that line which is now approaching completion, and which finds its terminus at Farringham, for the system there adopted is the underground conduit system, which has vagaries of its own. They have seen a tram system in Paris, and the inhabitants of one of the streets through which the rails pass had recently quite a new experience of its ways. The pedestrians on the pavement were astonished to see the people in the roadway suddenly beginning to caper and dance as though possessed. The dancers did not seem to be enjoying the pastime in any way, for their faces showed anxiety rather than exhilaration, and when they saw that their fellows on the pavement were not participating in their antics, they stepped on to the higher ground, and immediately their capers ceased. What could be the reason for this saltatory exercise? The performers hurriedly explained that they had been dancing against their will. That as they walked along a sudden tingling sensation had attacked them in the legs, and that they had had no alternative but to lift their feet high from the roadway. One victim said that the sensation was the same as that which he had experienced in an electric bath. This statement gave the key to the mystery. Something had gone wrong with the underground electric cable, and the current had been short circuited through the damp wood pavement. The thoroughfare was at once cleared, and the current was cut off. We may hope that someone turned a camera towards the strange scene when this unique al fresco dancing academy was in full swing. As we have already indicated, there may possibly be opportunities in London for witnessing and photographing a similar performance.

* * *

Autumn and Autumn Pictures. "Chill October"—with an extra chill at the time of writing—is now with us, and the summer, or such summer as we have had, is over. Still there is plenty of work for the camera, for at no time of the year, not excepting "glorious spring," are there such a variety of tints on the foliage to be seen, when the sun is shining, as in the early autumn. Unfortunately, photography, in monochrome, cannot do full justice to them, and photography in "natural colours" is not sufficiently advanced to be of much practical value in this direction. Still much may be done. It may not be generally known to many of our younger readers that the greater number of the late Mr. Vernon Heath's best works were taken in the autumn, and that was his favourite time for working by reason of the long shadows cast on the

breadth of effect he could then obtain. Burnham Beeches was his happy bunting ground at this time of year, and we all know the artistic pictures he produced in this neighbourhood. Indeed, it is said that his pictures of the beeches was largely instrumental in inducing the City Corporation to secure them for the use of the public. All the early pictures of Mr. Heath were taken by the wet collodion process, and the later ones by the gelatine process, but all these were taken before orthochromatic photography was in vogue. Had he had that power at command there is no question but that his results, excellent as they were, would have been still better; yet they are still unsurpassed either for technical or artistic qualities. Many enlarged pictures about 30 x 24 are to be seen at the entrance to the Guildhall library, and they well illustrate what was accomplished in the wet collodion days, alike artistically and technically. At the present time photographers have a greater power at command in the shape of isochromatic plates. With those specially sensitised for the purpose, even if used without a colour screen, much may be done in the truly rendering the various and gorgeous colour tints than was possible till recently. We would therefore advise our readers who desire to secure autumn pictures with all their glory to embrace the opportunity while it lasts.

* * *

Pictures in Newspapers. We are all more or less students of the daily Press, and it must have occurred to the more thoughtful of newspaper readers that the custom of inserting occasional pictures is on the increase. The question naturally arises: Are all journals destined in time to become illustrated journals? There is no doubt at all that the first illustrated newspaper, "The Illustrated London News," was founded because many journals were in the habit of giving their readers occasionally pictures of some particularly interesting occurrence, and the readers seemed to appreciate the attention. Even the stately "Times" did not disdain to do this. But of late years it has become a common thing to see illustrations in newspapers which have hitherto refrained from anything of the kind. In Coronation week the "Times" published a full-page drawing of the interior of Westminster Abbey as arranged for the great ceremonial. Since then it has devoted a half-page to a plan of the naval review at Portsmouth, and on a more recent date it has given its readers a plan of the proposed dais and amphitheatre at Delhi for the Coronation durbar. The "Daily Chronicle" a year or two back gave its readers some line drawings of very fine quality, and the other dailies have more than once flirted with art. As to the halfpenny dailies, they give illustrations of some kind or other in every issue, some of which, considering the difficulties of quick printing, are highly creditable to their producers. The evening papers are also to the front with pictures, some of them publishing political cartoons which are generally of a milk-and-watery nature. The weekly journals, which have more time for preparation, are also indulging in illustrations of a very sketchy kind. As to the cheap comic sheets, they are all pictures, and if their humour is somewhat strange, and a little bit vulgar, there is no harm done, and they find many admirers. Of course, this surfeit of illustrations is due to the introduction of the photographic process method of block production. They are necessarily of a rough description, for the speed at which a daily newspaper is printed is incompatible with fine work and careful execution. We should hardly think that ephemeral work of this kind can be much valued by newspaper readers generally, a large proportion of whom glance at the journal and leave it

behind them in the railway carriage which brings them to town. But the production of these pictures must bring employment to many thousands of workers, and in this way the art of photography, without which they would have been impossible, has brought a fresh boon to mankind.

* * *

Malleable Glass.

This dream of the inventor would seem according to published accounts to be actually realised, for, as we noted last week, the "Scientific American" gives chapter and verse to prove it. Mr. Louis Kauffeld, of Matthews, Ind., U.S.A., is the inventor, and on the authority of that journal we here recapitulate the tests he will make, or has made. "A chimney was placed in a pail of ice-water, and after having remained a sufficient length of time to become as cold as the water was taken out and immediately placed on a lamp with the blaze turned as high as possible. The blaze on the wick was turned so as to flow directly on the chimney, and the smoke which collected on the chimney ran down with the water without injuring the chimney. Next a chimney was placed over a small gas stove containing clay bricks used in heating such stoves. The fire was turned on full, the chimney remaining on the bricks. The fire finally brought the temperature to such a stage that the side of the chimney was drawn in and dropped down, and no crack was shown in the glass; but for a slight roughness on the outside the glass was as clear as when placed in the fire. Another test which was made was to place cold water in the chimney and hold the same over a fire until the water boiled. A large bulb was blown from the glass and filled with about a pint of water. It was then placed over the fire and allowed to remain there until it had boiled dry without apparent effect on the glass. Four chimneys were taken from the packing room and dropped one by one into a pail of boiling water. The chimneys were then hastily shifted into a pail of cold water that had just been drawn from a well, and the glass was not broken. A further test was made by nailing up a box containing glassware, every nail being driven in by hitting it in with a chimney. The most remarkable feat of all was the making of a perfect lamp chimney by using a chimney as a mould and blowing hot glass into the same. Both the new chimney and the mould came through the test perfectly whole, uncracked, and unscarred." All this reads like a fairy tale, and we feel that judgment should be reserved till a sample of this wonderful glass is to be seen in this country; it is so easy to invest a simple phenomenon with an air of the marvellous. As an example, let us suppose that if the "Scientific American" had stated, water was boiled in an ordinary glass tumbler over a naked glass flame, it would have appeared extraordinary, yet this was done in the early days of Fletcher's gas stoves, only in his case it was to show the excellence of the gas and not the glass. Then, again, we are inclined to say about that packing case that it must have been a very tiny one, or the glass chimney a sort of weapon we are not familiar with here under the designation. What such glass might mean to photographers if unbreakable lenses could be made with it, need not be here dilated upon. We await developments.

* * *

Oil Lamp and Lanterns.

With the advent of long evenings lanterns that have lain dormant from last season are now being unearthed, not perhaps so much for immediate use for displays as for preliminary trials of slides made from negatives taken during the summer season. In very many instances the lamps, when first used, prove nothing less than a positive nuisance to the

household as well as to the owner of the apparatus. We were forcibly reminded of this when calling on an amateur friend the other evening. We found him trying some slides he had made the night before in a lantern that was being used for the first time for many months, and he was complaining loudly of the smoke and "stink" the lamp was giving off. We need not have had our attention called to that, as we were perfectly cognisant of it directly we entered the house. His case was similar to many others—the lamp had been left at rest with the wicks in it, and with some oil left in the reservoir. The wicks had merely been trimmed and fresh oil added, with the result just mentioned. The lamp, we were told, had not been emptied and the wicks removed for the reason that the lantern might be wanted again before the season quite closed so it was left and forgotten. Now it is more than probable that this is by no means an isolated case, even by hundreds, therefore a few hints may be of use to some who are situated as our friend was. In the first place, the stale oil should be emptied out, the wicks removed and thrown away. The reservoir should be rinsed out with fresh paraffin, or, better, with benzoline, and the outside also cleaned with benzoline. The burners should next be taken in hand, and all incrustation carefully scraped off, and the racks carefully brushed out with benzoline. The whole should then be put out in the sun to sweeten. We have now, practically, our old lamp converted into a new one—that is supposing the burners and racks are in good condition. If they are not they must be repaired. New wicks must be obtained, and care should be taken that they exactly fit the burners. Before the wicks are put in it is a good plan to bake them in the kitchen oven or lay them in front of the fire for half an hour or so, so as to drive out all traces of moisture. When this is done the lamp will be found to yield a better light, and the wicks will last much longer. One set of wicks should last an entire season if care is taken at the starting. It may as well be pointed out to those who may purchase lanterns and use them without previous experience, that when they are found to give off unpleasant fumes the cause must be sought for not in the construction of the lamp, but rather in its cleanliness, *i.e.*, the fumes arise from the vapourisation of the stale oil on the outside of the reservoir, or from that on the outside of the burners. The outside of the lamp and the burners should always be carefully wiped with a dry duster before the lamp is lighted. If this were always attended to there would be few complaints of well-constructed lamps smelling.

* * *

The Old and the New.

If anyone were to take the pains to search through our columns for the few past years, he would find much evidence of that constant battle which is going on between advocates of the old and picturesque and upholders of the new and utilitarian. Our readers have been again and again advised to photograph such and such an old building because it is doomed to destruction, and something ugly and more useful will presently take its place. This reconstruction, which is too often but another name for vandalism, is not peculiar to London, but is rife all over the country, and in other countries as well, and lovers of the picturesque must be constantly on their guard against it, and do what little they can to stem the advance of the destroyer. The latest example of this aggressive attempt to destroy that which is old and venerable is seen in the decision of the Oxfordshire County Council to take down the wooden bridges at Sonning, on the Thames, and replace them by structures of iron piles and steel girders. The wooden bridges are per-

are not especially beautiful in themselves, but they harmonise with their lovely surroundings in a manner which steel girders will certainly not do. A bridge is an erection which may be made extremely elegant, and a great ornament to the landscape, or very ugly, according to the ability of its designer. We have plenty of examples of both kinds on the Thames already, and for comparison's sake we may cite Waterloo Bridge as a specimen of beautiful structure, and that strange construction of ironwork known as Lambeth Bridge, as a fearful example of unmitigated ugliness. The tendency to replace stone, brick, and wood by iron and steel is, unfortunately, rampant just now, one of the chief reasons being that many of the old bridges will not bear the weight and stress of the modern traction engine with its train of springless trucks. These monstrosities belong to those who very often have the power to influence the local authorities in whose hands the fate of a bridge may rest. In this way the beautiful is sacrificed to the useful, and the bridge which has been a delight to many generations is pulled down and made into road material, while the awfully straight steel girder takes its place. What is going on in Sonning to-day will, we may feel sure, be repeated in many another place to-morrow, unless some body like the Antiquarian, or the Society for the Protection of Old Buildings, bestir themselves. And a bridge is peculiarly public property, for it gives a distinctive character to a place which without its presence would be colourless to the extreme. We are not so unreasonable as to suppose that a bridge can stand for ever without need of reconstruction, but what we do maintain is that a beautiful object, be it a bridge or any other building and an object which has long been a delight to those who dwell near it, and to visitors to its neighbourhood, should not be ruthlessly destroyed, or so altered in appearance that its best friends cannot recognise it. Photographers can, perhaps, do more than most persons in bringing influence to bear on this question of vandalism, for they have it in their power to show the picturesque side of things. It would be serviceable just now to exhibit some good pictures of old Sonning bridges, in juxtaposition with photographs of some of the steel girder erections which, unfortunately, can be found without any difficulty.

SOME PHOTOGRAPHIC FETISHES.

It is unfortunate that Mr. Welborne Piper should have sent the communication which we recently printed, as it will have a tendency to perpetuate some of the erroneous ideas which it was our purpose to endeavour to remove. Mr. Piper must, for example, in the course of his experience, have met numerous instances of the man with the eyes of such "splendid depth of focus," and, again, others without number who, wanting a very quick lens, reject all offered to them because "they have no depth." It would be idle to explain to them the relation of the lens pupils to depth, or the faint differences entirely negligible in practical work that would be brought about by varying the distances of their diaphragms from one or other Gauss point. The depth they can appreciate is simply that brought about by varying the effective aperture, and we insist in the strongest manner that their, and the usual, appreciation of, depth is a fetish which ought to be destroyed. For logical accuracy we might have excepted the telephoto lenses, though they are virtually a combination of two instruments that would not be sought in such a survey as we made. Mr. Piper's remarks about marginal epith are entirely gratuitous. When making the comparison between a first-class rectilinear lens and a cheap

simple lens we expressly limited it to the area of sharp definition of the latter, and in view of further misapprehension we might say that we should not deem such a lens as a railway lamp bull's-eye to come within the scope of our remarks. The lens manufacturers' advertisement to which we objected did not refer to what is generally known as the anastigmatic type, and a comparison of marginal definition between the latter and the old rectilinear type cannot be made, as there is no definition with the latter at an angle of aperture which with the former would result in sharp definition.

Mr. Piper says that "depth in the centre of the plate is not a matter of any great consequence." This is quite erroneous, for, apart from the fact that with a very quick portrait lens the central region is the only part where there is good definition, and that when a photographer does compare lenses for depth he looks at where the image is sharpest to make the comparison, if we take, for example, the portrait photographer's work, the centre of his field is of the highest importance, and he would be willing to give a very high price for a quick lens that would give him depth in that part when taking such subjects as two heads or two figures on a plate, or even a figure group. The belief that such a lens is obtainable by the use of some unknown construction and some special glass is a fetish to be destroyed. With regard to single lenses for architectural subjects we never questioned, as readers of Mr. Piper's letter would think, the utility of "rectilinear lenses," nor did we advise their general disuse; we pointed out that a landscape type of lens was capable under certain restrictions of taking negatives of buildings or architectural structures in which no deviation from rectilinearity would be noted, or that would require a rule or compass to detect any. We repeat that the belief in the necessity for a rectilinear type of lens for all architectural work is a fetish to be abolished, and one whose existence has a tendency to prevent many a photographer from undertaking architectural work well within the limits of his instrument.

As to architects having small faith in the accurate drawing of trade photographs, we have to say that our experience of trade photographs of architectural objects is that the majority of them are wonderfully good, especially so when the surrounding conditions are taken into consideration. Those who undertake that class of work are usually provided with high-class lenses to meet every contingency, but that does not interfere with the fact that, within the restricted limits as described by us, a landscape type of lens would be available, and if of anastigmatic construction its range would be less restricted.

WHY is the sky blue? Tyndall answered a generation ago, "Because there is a predominance of the smaller waves of light, which are blue, reflected from the minute corpuscles in the atmosphere." The air is not blue; otherwise pure white light would not come as it does through a blue medium. In his graphic style Tyndall observed, "A broad cliff reflects the Atlantic roller as easily as the ripple produced by the sea-bird's wing." So a cloud reflects all rays, and looks white; its corpuscles of vapour are large enough to throw back light-waves of all sizes. But in the upper regions of the air there predominate infinite numbers of particles so small that they do not throw back the larger red, yellow, and green waves, but only the smaller that are blue, and thus blue is the predominant though not the exclusive colour of the sky. At the annual congress of the Swiss Society of Natural Sciences, M. Spring has called this accepted theory in question. He reports that "he has experimented with luminous rays under almost all conceivable conditions, injecting them into agitated solutions"; but although he could obtain red, yellow, violet, and the rest, "under no conditions could he obtain blue until, by the aid of electricity, he secured a pure atmosphere, in which blue was clearly discernible." Here M. Spring comes to the conclusion, whatever it may mean, that "the blue of the sky is purely chemical in origin, and is an essential quality of the air."—"The English Mechanic."

FILMS AND OTHER FOIBLES.

BY AN AMATEUR OPTICIAN.

I HAVE had my holiday, in a blaze of sunshine interspersed with a couple of days' drenching rain. I took with me a hand camera and six dozen celluloid films, and a stand camera of larger growth. Theoretically, films are a heaven-sent boon to the weary tourist; practically, give me plates, and I will put up with the weight; theoretically, films are extremely easy to work, and sensitive—six dozen will go into a quarter-plate box; practically, I would rather take a dozen good plates and be certain of my results. I have sung the praises of films to my customers times innumerable, but it must be noted that films require careful usage and humouring; films are like babies who can't walk and want everything done for them; plates are stronger, and will stand alone, and in a sense are more reliable. I like to back my films up (in the carriers) with something thick and fairly heavy, and in the development of them it is almost imperative to make use of all the little sundries which have been devised by practical workers for the purpose of facilitating their after treatment; film holders for use during development are almost a *sine qua non*. The washing operation may, however, be carried out in the ordinary trough, if the film be on a fairly tough support, as is usually the case. In the drying of the film the amateur frequently finds himself handicapped; after many years of intermittent film work I prefer my own method of drying, the particulars of which are as follows:—Procure a stout pulp board from a mount dealer, cut out of it three or four pieces 15 x 12 or 18 x 16, or other convenient size; by means of broad tape and thin glue (or brass hinges may be used) form these boards into a three or four fold screen, cover one side of this screen with blotting paper, then, having the films properly and sufficiently washed, take one at a time, carefully press between folds of soft clean linen and pin to the screen by two corners; when the screen is full it is reared up on end and the films allowed to dry.

Films on celluloid—here I refer to the "altogether"—have one grave fault indigenous to the film tribe, rollable and rigid; this is that the film—here I mean the gelatine and chemical film—is extremely thin, unnecessarily thin, I consider. It is incredible that this can be the same film that is spread upon glass. I am addicted to an occasional enlargement by the process of film transference and stretching, also I require one now and then to reverse for process work, and it requires a perfection of skill aided by a large amount of luck to do this with certainty with the film on celluloid; needless to say, I have failures. Why should not the celluloid have a tougher and thicker layer is a question which I feel sure many film workers must feel inclined to ask of the makers; certain it is that the film removed from any good plate is considerably thicker and tougher.

Last year I mentioned a cheap "casket" set with which I had achieved some very good results; I would not like to withdraw a single word of last year's report, which was mainly, if not altogether, commendatory. It is an error to term these lenses rapid, remembering that the term has been for so many years applied to a class of lens which really deserves the appellation. This is no drawback in nine times out of ten in outside work with the casket set referred to; it is when we are doing some architectural work indoors that one begins to wish the combination were more rapid. You have to sit in a drowsy old church while the light, such as it is, is working its own sweet will on the sensitive plate, and time passes very slowly; it is not proper to smoke, hardly safe to sleep, and the literature to be found in the pews is scarcely of the lively and breezy sort which I, for one, like best at holiday times; while to

import such seasonable literature as "Photo Bits" or "Sloper" seems incongruous to a sensitive and naturally reverent mind. No, the lenses are not quick, but they serve, and the best results this year are on plates, and with, for the most part, the lenses mentioned. Whiling away the time in one country church, I was mildly interested in the official Book of Common Prayer; it dated from the reign of King George, and the alterations, neatly written, from George I. to IV., then to William IV. and Victoria, and more recent to Edwardus Septimus, filled up all the margins and a little over; they want a new prayer book there badly, and I was strongly tempted, while there, to present a new set, but, alas! for the ephemeral nature of good intentions: An excellent object lesson demonstrating the value of a portable set of lenses was made use of. From the dining room of the rectory (the host is a pillar of the church) there is a very excellent view of the picturesque old church and garden; it was just the subject for experiment with a set of lenses, and I got the very thing desired by the use of the fourteen inch lens on whole-plate without leaving the room. Now, presuming one on the outside of the fence and a fractious bull is in the pasture, how much more comfortably we can get the picture wanted by the insertion of a long focus single combination, remaining in a safe place meanwhile. Try photography with the bull intervening, and you are glad you bought the casket set.

One of my best views was taken under the circumstances following:—It had been raining all day—once or twice we had covered ourselves with wraps and sped off into the garden, a veritable bit of virgin forest, with its luxuriant undergrowth and wealth of tree and shrub. Rain was descending relentlessly, but about seven o'clock in the evening I got out the camera, and under the shade of a sheltering umbrella focussed a previously selected spot; the main idea, I'm afraid, was something to pass the time, but I wanted to see how the subject would turn out. It was a case of dripping wet: water was dropping from every leaf; there was a soft gentle light, and the ground—where visible—was covered with little pools of water; a long exposure was given, and the negative is quite a success—as a printer; but the presentment is entirely a failure so far as a representation of a weeping woodland scene is implied; it looks, in fact, like a very good view of the subject taken in sunlight, and is very good, because—in sunlight—the picture would have been difficult to take; certainly the exposure would have been puzzling.

In the operation of development it is not well to be slavishly bound to one formula; an occasional digression is advisable and may be useful. It is an easy matter to get wrong in the direction of exposures with one's drop-shutter work; changes of light may pass unnoticed, and persons have been known to insert a smaller stop for a particular subject, and then forget to change it again, the succeeding exposures getting rather less influx of light than they require. However that may be, it is possible to find one's exposures turning out rather badly with the developer to which we have accustomed ourselves. I do not know of any better developer than the pyro-metol combination of the Imperial D.P. Co. Here it is:—

"IMPERIAL STANDARD" DEVELOPER.

No. 1.	
Pyrogallic acid	55 grains.
Metol	45 grains.
Metabisulphite of potash	120 grains.
Bromide of Potassium to	20 grains.
Water (boiled or distilled) to	20oz.
No. 2.	
Soda carbonate (washing soda)	4oz.
Water (boiled or distilled) to	20oz.

For use take equal quantities of No. 1 and No. 2.

Metol, however, has always played such pranks with my cycle (other reducers when combined with caustic alkalis will sometimes cause the same disturbance), that I use it only as a *dernier ressort*. Metol is so valuable that one is almost obliged to make use of it on occasions. Anyone afflicted with tender and sensitive finger ends should totally abstain from contact with the solutions. Personally, I indulge in half-a-dozen other tight-fitting rubber finger stalls, which are worn on the thumb and two first fingers of each hand. With the aid of the above-mentioned developer and the finger coverings referred to, a good proportion of my films turned out trumps, and last, but by no means least, I have had no symptoms to date of the objectionable irritation and soreness at the finger ends.

I have felt constrained to call the attention of my customers to what I consider a great fault in the construction of some (heretofore very well made) printing frames. The old-fashioned frame, apart from the "well" shaped article, with its plate-glass bed, is made with the two ends brought down flush with the negative. Now this serves a very useful purpose, because when using a soft brush to clear away any dust that may have got on the surface of the negative, there is a clear space through which, at either end, to brush away any small particles that may have got thereon. Compare a frame of this sort with a so-called improved pattern, neatly made in white wood, but with the grave fault that the negative is in the position of being at the bottom of a box; then try to brush the dust out, and you will see a vast pull in favour of the old pattern. It is much the same with cameras; the improvements, to an up-to-date camera, are somewhat difficult to find. I use an up-to-date camera, but my thoughts often turn to that which I was wont to carry in the seventies and eighties. There is another advantage in having a printing frame with the ends down—by the way, the bulk of the stiffening might be on the front of the frame—and this is, it allows the negative to be shifted, one end marked out, or one portion vignettted. Of course, as a rule, a good piece of thin plate glass should then be used as a support for the negative.

A CORRESPONDENT sends us another of "Clicker's" profundities, from his "Camera Causerie" in the "South London Observer," Sept 27th. Speaking of the use of the "stop," he says: "Its function is to concentrate the light."

DISAPPEARING WESTMINSTER.—Mr. Archer Clarke writes: "A considerable number of houses and streets will be non est before next summer in the older parts of this city. Great College Street, behind the Abbey gardens, the residences of many noted men: Great Tothill Street, now a slum, where equally noted persons lived here. One or two window frames are remaining, and so are many door faciae in this street; all the old wharves from Lambeth Bridge to Palace Gardens are also doomed."

At the South-Western Polytechnic, Manresa Road, Chelsea, S.W., a course of about twenty-five lectures on Photography, suitable for the City and Guilds Examination, will be given by Mr. E. Senior on Monday evenings at 7.30, commencing October 6th, with practical instruction in negative making, enlarging, platinum, carbon and silver printing and general studio work. The photographic department contains a large studio fitted with a powerful arc lamp and every appliance for work at night, with a spacious dark room and electric light enlarging plant. All chemicals and necessary apparatus will be provided; but students must find their own sensitive plates, papers, etc. Syllabus: Light and its application to photography. Various kinds of illumination used in photography. Lenses for photographic purposes. Testing lenses. Preparation and use of colour screens for isochromatic photography. Various forms of cameras, stands, etc. Testing cameras. Apparatus for rapid exposures. Preparation of gelatine emulsions. Negative making. Length of exposure. Under and over exposure. Theory and practical use of colour sensitive plates. Theory and practice of developing, fixing, clearing, intensifying and reducing gelatine plates by all the principal methods in use. Landscapes, etc. Lighting and general arrangement of surroundings. Rules for selection of point of view. Use of view cameras. Best conditions for obtaining portraits in studios, ordinary rooms, and out-of-doors. Theory and practice of printing on the various silver printing papers, including vignetting, printing in clouds, tinted borders, etc. Printing with salts of iron and chromium. Theory and practice of printing and fixing. Mounting and finishing, enlarging and reducing. Determination of conjugate foci. During the session demonstrations in the method of obtaining photographs in natural colours will be given.

PHOTOGRAPHY AS APPLIED TO ILLUSTRATION AND PRINTING.

[Cantor Lecture delivered at the Society of Arts]

I.

THE object of this and the following lectures will be to explain generally, and, as far as possible demonstrate, the means and methods at present employed in the production of illustrations by photographic processes for the printing press.

It is not expected, and I do not propose to give you, close technical details or exact formulæ of the working. Those dry bones of my subject may be ascertained by those who wish it from the numerous text-books, dealing with every branch of photo-mechanical illustration, or special information may be obtained in a practical form by attending the admirable lectures given by the technological classes organised by the polytechnic institutions and London County Council. I shall, therefore, to the best of my ability, endeavour to describe in simple language the general principles of the various processes, and by means of the lantern and of examples, demonstrate how the results are obtained.

If there happen to be any gentlemen present who are specialists, hoping and expecting to be instructed and enlightened in the particular working of one or other of the processes, I can only say that as far as these gentlemen are concerned, I humbly apologise for appearing before them, for I am about to talk to my uninitiated friends, and try to tell them what is going on in the world of process illustration.

The present methods generally employed in the production of printing press illustrations by photography may be epitomised as follows:—

Photo lithography.

Type block.—Reproductions from line drawings.

Type block.—Reproductions from wash drawings and photographs.

Photogravure. Rembrandt photogravure.

Collo type.

Woodbury type.

Type block.—Reproductions by the three-colour process.

There are many other photo-mechanical processes in existence, but to describe them all would occupy much more time than the limits of these lectures permit; it will, therefore, be necessary to deal only with the typical processes I have named. They are in one way or other allied to all known photo-mechanical methods of producing illustrations by means of the printing press; and whilst they cover the scope of my subject, such details as I can give you about them will no doubt also more than absorb the time at our disposal.

Photo-lithography is named first, because it is, I believe, one of the earliest, if not the earliest, practical application of photography to modern illustration by the printing press (I am excepting Fox Talbot's photo-intaglio process for the moment).

I hope I am right in assuming that you all know generally about photographic negatives and positives, and that you are aware there are several kinds of negatives and positives employed in the making of blocks and printing surfaces in photo-mechanical processes; those that are necessary will be described in their place. I may say now that the old (1857) collodion process of negative making still holds its own for process work against the more modern dry plates, though there are several successful process workers now using only gelatino-bromide dry plates for their productions. The first thing necessary for a photo-lithograph is a good clean sharp negative of the subject which is to be reproduced. This negative may be made of collodion or gelatine, but it is necessary that the negative

should be what is termed *dense* in the parts representing the whites, and that the lines should be clear glass. Generally speaking, photo-lithography is only employed for reproductions of line subjects, such as maps, plans, and architectural drawings, though there are modifications of the process for tone work, which I will mention later.

Now I must describe to you a principle which is the foundation of nearly every photo-mechanical process, viz., the action of salts of chromium in combination with organic substances. If a solution of gelatine in water charged with a small percentage of bichromate of potash is spread on paper and dried in the dark, and then exposed to light, it will be found that the gelatine surface has lost its solubility, and has acquired a new property, that is to say, it will no longer absorb water and dissolve, but will remain permanently hard, horny, and insoluble. This curious light action was discovered as long ago as 1839, by Mungo Ponton, and it is to-day the basis of a whole range of beautiful processes of illustration comprising carbon printing, photo-lithography, photogravure, photo-etching, and engraving, Woodburytype, collotype, and others.

Organic substances of the nature of gelatine, gum, starch, fish glue, isinglass, dextrine, etc., are all affected in the same way when treated with any of the bichromates, and the varied use of these substances often constitute the difference between one process and another.

To return to the subject of photo-lithography, here is a sheet of gelatinised paper not treated with bichromate, and it can be exposed to light indefinitely without altering its nature. This sheet has been soaked for a few minutes in a three per cent. solution of bichromate of potassium in water, and dried. The light seems to act in two definite ways on bichromated gelatine: first, by rendering it insoluble; second, by causing it to lose its property of absorbing water, or swelling. This sheet of gelatine has been exposed to light under this negative for a few minutes, and if examined closely you will observe a faint brownish tinted image of the lines of the negative. Now another curious property of this oxidised gelatine is taken advantage of. I have said that it refuses to take up water, conversely, if it refuses water, it will admit of being greased or inked, and if a roller, charged with printing ink, is passed over the surface of the gelatinised paper whilst it is in a dry state, the ink will "take" all over the paper, but immediately the sheet is dipped in water the ink is loosed or repelled from the soluble portions, and adheres only to the parts where the light has acted and rendered the gelatine insoluble. The sheet now shown indicates the effect of the treatment described, the lines represented by the clear portions of the negative, through which the light has penetrated, retain the ink, whilst the dark or shaded portions of the negative are soluble, and refuse to retain any of the ink, at once giving a positive reproduction in *ink* of the lines of the drawing.

The inked-up photographic print of the lines of the drawing now shewn to you is technically known by the name of a photo-lithographic transfer, because it is used for the purpose of transferring the ink on its surface to a lithographic stone or a sheet of zinc, from which base it is printed from in the ordinary lithographic printing press, and any number of copies reproduced. I think I need not describe lithographic printing further than to state that the principal substance used for this purpose of a printing surface is a porous limestone known as Solenhofen slate: the surface of this stone is polished smooth and level, and it possess the property of greedily absorbing both greasy ink and water; if a drawing is made upon it with an ink composed of grease and lampblack dissolved in soap, the grease sinks into the stone, and each line of a design so

drawn forms a permanent printing surface which, if the stone is damp, will take ink from a roller charged with printing ink and give it up again to a sheet of paper pressed in contact with the face of the stone. To prevent the ink "taking" over the stone when using the roller, the stone is dampened with water between each impression. The stone absorbs water everywhere except where the inked lines occur, which, being greased, naturally repel water, the simple principle being that a lithographic stone accepts ink and ink only where there is already ink, and water only where there is no ink. Zinc and aluminium plates are used instead of lithographic stone for printing from, and they are treated and used in precisely the same way as the stones; these metal sheets have the advantage of being lighter, cheaper, and easier to store and handle.

You will observe that we have only spoken up to the present of the reproduction of designs drawn in line, but within the last ten or twelve years considerable numbers of excellent illustrations have been produced by this process of drawings, which are in monochrome, and of photographs. The difficulty which occurs in dealing with reproductions of subjects which are represented by continuous graduated shades from black to white (that there is no known printing surface or ink (excepting, perhaps, Woodburytype) which will distinguish any intermediate tone between black and white, in fact, the printing press is only capable of rendering two shades, viz., black and white. This difficulty has, however, been practically overcome, and is now quite possible to produce the graduated shades of a photograph, for instance, though the graduations are not homogeneous, but are subdivided into granulations or grain arranged close together for the deeper shades, and separated or becoming finer for the lighter tones, giving to the eye the effect of unbroken shades, though they are really not so. I shall have to speak of this in dealing with half-tone negative for block printing a little later; at present photo-lithography is before us, and the problem of reproducing half-tone by this process. Many methods have been devised for breaking up the gradations into lines, stipple, or dots, and much ingenuity was exercised by the earlier experimentalists to produce the effect of half-tone in photo-lithography. The names of Dallas, Pretsch, Bolas, Waterhouse, Ives, and Husband are landmarks in its history. The idea throughout was the production of a grain or texture which would be to some extent discriminating, that is to say, form automatically groups of large, close grains in the deepest shadow, graduating into finer and finer grain until the lightest tints were reached. It was found that the addition of a hygroscopic salt, like calcium chloride, to the ordinary gelatine and bichromate coating for the lithographic transfer, had the effect of breaking up the texture of the gelatine image, and permitted of a transfer being made of monochromes or photographs. The process has been further developed by Messrs. Sprague and Co., who employ a method analogous to collotype for obtaining their transfers. The results of the process in their hands are very successful, and are largely used for commercial and artistic illustration. Photo-lithography generally is an important process, and it is employed for the rapid production of plans, maps, machine drawings, facsimile reproductions of manuscripts, and notably in the Ordnance Survey Department at Southampton.

BLOCK REPRODUCTIONS OF LINE DRAWINGS.

The next important process in order of seniority and usefulness is the line block process on zinc, and it is curious in regard to it that the present methods of working are almost identical with those adopted by the original inventors. Another singular point is that the medium for sensitising the metal plate which to-day gives the finest results, namely, bitumen is the sub-

stage which M. Nicephore Niepce discovered in 1827 as being sensitive to light, and he submitted photographed images on a plate coated with a film of bitumen, to the Royal Society of his country in the year named. The process has now been in use for the past thirty years or more, and the principle of photo-lithography just described to you largely enter into the working of the line block process.

The first requisite for the production of a good result is a suitable original: the drawing should be made with perfectly black lines throughout, it is of no consequence how thin the lines are, but they must be black; it is important, too, that the scale of reduction should not be too great; the best proportion is for the drawings to be made about one-third larger than the required block. The paper used for the drawing should be white and smooth in texture.

The negative for a line block is made preferably by the wet plate or collodion process, because of the facility with which the plates can be intensified, and the clearness of the lines; the negatives for this process must be reversed, so that the resulting picture may be non-reversed, which result can be obtained in two ways, first, by photographing through a prism or mirror attached to the lens, or second, by stripping the film, carrying the image off the glass, and turning it over.

The reversed negative is next printed on the metal which is to form the block in the following manner:—A piece of polished and perfectly flat zinc is cut to the proper size, and freshly polished in water until it is free from all trace of grease; it is then sensitised by either flowing over it a solution of asphalt in benzol, or, as is more generally used because of its rapidity, a solution composed of egg albumen, water, and bichromate of ammonia; an even film of this solution is floated over the metal, and is dried by gentle heat; as soon as it is dry, it is sensitive to light, and is at once placed in a printing frame over the negative; a few minutes' exposure to daylight, magnesium, or electric light, is sufficient to oxidise the albumen where the light has obtained access to it through the lines of the negative; the plate is then covered all over with a thin coating of ink from a printer's roller charged with ink, to which a little turpentine is added, and is then dropped into a flat dish containing cold water; the inky surface of the plate is then gently rubbed with a pledget of cotton wool, and the ink coating, together with the unused albumen, leave the plate together, except in the places where the light has acted through the negative and rendered it insoluble, the result being an image of the subject photographed on the metal, covered with a greasy, acid-resisting ink; in this state the plate is ready for the first stage of the etching process, that is to etch or bite away with acid all the metal surrounding the lines, and render the pictures in high relief, so that it may be printed in a printing press in the same way as type. The etching of such a plate is the simplest thing possible in the abstract, but a considerable amount of skill and experience is required to carry the etching to a successful issue.

The theory is that a metal like zinc is quickly dissolved or etched by nitric or hydrochloric acid, so long as there is no grease or varnish on the metal to interfere with the dissolving action of the acid; that is so, but in the case of the plate we have to deal with a very thin protective coating, and with lines which are so narrow that they might be represented as knife-edges. There is also an element to be reckoned with in the fact that the acid not only etching downwards, but sideways. It is, therefore, necessary to proceed with some caution, and the first etching is performed for a few seconds only in a very weak acid, just strong enough to taste acid; after this the lines are slightly re-inked with a roller, and whilst the ink is

wet, it is dusted with powdered asphalt or resin, and afterwards heated to melt the powder into the ink. The etching proper is then proceeded with, and occupies two to five hours, but it is by no means a straightforward operation. For a time, every few minutes the plate is taken out of the acid bath, and further strengthened with ink and resin, and as the etching proceeds, the piled-up ink on the lines is heated and melted, so that it runs down the sides of the lines, to protect them from being undermined by the acid—when a sufficient depth is attained to make the lines high enough to ink sharp and clean in the printing press, the whole of the etching ink is removed, and the tops only of the lines carefully re-inked. A finishing etching is then given to remove the shoulder and steps on the sides of the lines caused by the various inkings and meltings. When finished, a properly etched plate should have each line firmly and cleanly cut, and be supported by a pyramidal-shaped base. The plate is now ready to be trimmed and mounted on wood type high for the printing press.

REPRODUCTIONS OF WASH DRAWINGS AND PHOTOGRAPHS.

Save as regards line blocks, until early in the '80's, it can be said that there was no process in existence by which paintings, wash drawings, or photographs could be "processed," to use a bad term, into the form of a surface-printing block for the press, and the introduction then of the half-tone block marked an epoch in the history of photographic illustration which has done more to revolutionise the making of pictures than almost all the other processes put together. The origin of the process cannot be definitely claimed by any particular investigator. Its development was the result of a kind of evolution of Bullock's process of 1866. Meisenbach, of Munich, patented a half-tone process in 1882. Mr. Ives, of Philadelphia, Mr. W. B. Woodbury, and others were experimenting and publishing results in rapid succession, until within a period of a very few years the process as it now exists was practically established. I recollect very clearly the "dark ages" of the half-tone process, when all kinds of expedients were adopted to break up the gradations of a photograph into lines or dots by the interposition of a texture of silk or fine linen; also the days of wire gauze, ruled lines on paper, and other similar processes. The Americans were first in the field with an improved device for breaking up the image into dots, which was so much superior to anything invented in Europe that almost every other method was dropped in its favour. I refer to the diamond ruled screens made by Mr. Max Levy, of Philadelphia. These screens or gratings are so essential to a description of the half-tone process that I will occupy a few minutes of your time in telling you how they are made. A sheet of the finest plate glass is selected and is coated with a varnish composed of asphalt and wax. The coated glass is placed on the bed of an automatic ruling machine of extremely accurate construction, and capable of ruling lines of any degree of fineness up to 500 to the inch, the cutter of the machine is diamond pointed and gauged to cut lines of any desired width. The lines are ruled diagonally at 45 deg. across the glass, and the number to the inch varies according to the kind of work for which the screen is required, for newspaper printing the lines may be fifty or sixty to the inch, for commercial and catalogue printing 100 to 130, and for finer magazine or book illustration 150 to 200 to the inch. When the ruling of the glass is completed, the ruled surface is subjected to the action of the hydrofluoric acid, which eats into or etches the lines laid bare by the diamond, and forms a channel which is filled up with an opaque pigment. This enamel is baked in the lines in an oven, and then the surface is carefully polished until the lines are perfectly level, and the spaces represented by clear glass are bright and

transparent. Two of these ruled glasses are required for each screen, laid together with the lines crossing at right angles, and cemented with Canada balsam. As may be imagined, the screen gratings are somewhat expensive, a piece measuring 12in. by 10in., of 175 lines, costs about £25; whilst large screens of 24in. by 18in. are charged at £100 or more. I am glad to state that we have now an English firm (Messrs. J. E. Johnson and Co.) who rule these screens excellently, indeed, there is little to choose between this work and the best American, which is a comforting thing to say in these days, when it is habit of the ever present pessimist to decry everything that is English and all that the Britisher does.

To produce a half-tone block from a picture, wash drawing, or photograph, this ruled grating is placed in front of the sensitive plate, but not in contact with it. The screen distance from the sensitive plate is a point of importance in making the negative, and the skilful operator has to determine this distance according to his experience, and to the character of the subject which is to be photographed. If it is placed too close, the resulting negative will present what is known as a gridiron appearance, if it is too far away, the dotting will be too close in the lights, and too small in the shadows. You will understand how necessary it is to keep a nice balance in this matter in the case of a picture which is built up entirely of an infinity of dots, shadows being represented by grouping of dots, close together, with smallest of spaces between middle and light tones, by dots of different graduations in size, and the highest lights of pin point dots only. Everything is represented by dots, yet they are so accurately graded in relation to the light and shade of the original, that the eye does not detect them, unless examined closely, and the half-tone picture appears as a practical facsimile of the original from which it was photographed.

The method of printing half-tone negatives on metal is similar in most respects to that described for line blocks on zinc, with this difference, that most half-tone blocks are now etched on copper, and the sensitising solution generally employed for this metal is a compound of fish glue, albumen, chromic acid, water, and bichromate of ammonia. The copper is carefully cleaned with Tripoli powder, and washed, the sensitising solution is then flowed over it twice or three times, and placed on a revolving table, where it is rapidly whirled, in order to spread the coating thinly and evenly over the whole surface; the coating is then dried by gentle heat in a yellow-lighted room, and the plate is now ready for exposure under the half-tone negative; three to ten minutes' exposure to an electric arc light completes the printing, when the plate is removed to a bath containing cold water, and soaked and washed under a spray of water until the unacted-upon compound is dissolved out, an operation occupying five or six minutes. The image on the metal at this stage is almost invisible. In order to enable an examination of the film to be made, the plate is dipped into a solution of methyl violet, which dye immediately stains the film, and brings the picture into view. If all has gone well, the surface is dried either by flowing it with methylated alcohol or gentle heat. The next operation has an important effect, namely, a hardening of the delicate glue picture into a substance resembling enamel, and this gives the method its name—the enameline process. The plate is simply heated to a high temperature over the flame of a large Bunsen burner; during the progress of this "burning in," or enamelling, the image changes curiously; the blue picture gets pale, then grey, and eventually vanishes entirely; after a few seconds, as the plate gets hotter, the image appears as a faint brown, and gradually increases in

strength until it fully attains a rich chestnut brown tint, when the heat must be withdrawn, and the plate is cooled off. The plate has now a picture fixed upon it, which is formed of strong, hard, impermeable coating of enamel, and which will bear any reasonable amount of etching without further protection. The etching bath is made up of neutral perchloric acid of iron dissolved in water, and of a strength which registers 35 deg. with a Beaumé's hydrometer. The plate is first subjected to a general etching all over the plate, sufficient to give the block a printing depth; that is, to etch away the space round the dots forming the picture, so that the plate may be inked over with a printer's roller charged with ink, and a first proof of the photo-etched picture pulled in the press. In most plates made by this process a further and local etching must be performed. The dulling of the general effect caused by the interposition of the necessary screen grating has to be removed as far as possible, and this is done by artists who are specially trained for the work. The parts of the picture which are in shadow and are usually correctly rendered by a properly-exposed negative, are covered over with varnish, and the next tones are etched again, then these tones are covered up, and the high lights are treated until the resulting picture, when proofed, correctly represents the original. The plates are then trimmed by engravers, bevelled to admit of being rivetted to the wood mounts, and are mounted type-high for use in the printing press.

Many efforts have been made during all the years these mechanically grained blocks have been in use to find a means of producing a printing surface which would give a pleasing result with an irregular grain like that given by collotype or photogravure, but the results so far have been disappointing; perhaps some of this disappointment may be due to the fact that the eye has been trained by years of use to look for and expect the smooth, clean results given by the mechanical ruled screen, and that any other result, though it may in a measure be more artistic, is not acceptable. I would like to mention, however, in closing this lecture, that Mr. Wheeler, of Bushey, has introduced a new screen for half-tone work. This promises much in the direction of the making of pictures which are free from mechanical effect, and are yet sufficiently delicate in texture to retain the finer details. His screens have no pigment in the graining; they are formed by a delicate etching of the surface, which leaves the plate very transparent, and the breaking up of the image to form the printing surface appears to be formed by causing the surface of the screen to act as if it were made up of an infinity of lenses. Some examples of this process will be shown to you, and will be found extremely interesting.

J. D. GEDDES.

THE Report for the year 1901 on the museums, colleges, and institutions under the administration of the Board of Education has been issued. Among other interesting items, it may be mentioned that the year was marked by a large falling off in the number of visitors to the western galleries of the Victoria and Albert Museum who received special assistance or facilities for the examination of the collections for scientific instruction and research. There was also a diminution in the total number of visitors to the Museum, the total in 1901 being 836,848 as compared with 1,017,314 in 1897, since which year there has been a steady decrease. The most important events in the history of the Royal College of Science during the year reported upon were the retirement of Sir Norman Lockyer after forty-four years' total service, and of Sir Arthur Rucker after fifteen years' service. Similarly the report of the Geological Survey is exceptional, since it records the retirement of Sir Archibald Geikie after a service of more than forty-five years. The Solar Physics Observatory was very busy during the fifteen months with which its report deals, viz., from October, 1900, to December, 1901. Bad weather entirely prevented observations of sun spots on 127 days throughout this period, and 171 nights during the same time were wholly bad for observing purposes, leaving 201 nights available, on which occasions the observers attended.—"Nature."

Exhibition.

THE ROYAL PHOTOGRAPHIC SOCIETY'S EXHIBITION.

[SECOND ARTICLE.]

THE PICTORIAL EXHIBITS.

The presence of a few striking pictures in an exhibition does more towards creating a favourable impression than a profusion of good but unsensational work, and, as there are few pictures in the present exhibition which stand out from their companions on account of size, boldness of treatment, or exceptional interest of subject, it is probable that the general opinion of the exhibition of 1902 will not be that it is one of extraordinary merit. We must confess that, in our opinion, which is uninfluenced by the considerations we have referred to, this section of the exhibition falls considerably below the standard of that of last year or even the year before. A glance at the list of exhibitors shows that many of the best known pictorial workers whose pictures have been among those which gave a tone to the whole collection are not exhibiting, while among the work of aspirants who have yet to win their spurs there is very little that shows decided signs of promise. Probably the decadence arises, not from one cause, but many. There is no reason to suppose that any irreparable injury has been wrought or to doubt that those who have stood aloof will again accord their support when the organisation of the exhibition has been placed on a sounder basis.

The judges have been liberal in their awards, no less than six medals having been given. With Percy Lewis the receipt of a medal seems to have become an annual event. The particular picture which has pleased the judges most is entitled "A Venetian Market," but the merit of his three exhibits seems so evenly balanced that the choice is but a matter of personal feeling. Although his individuality of treatment is evident in all, he has somewhat altered his methods, and has adopted a less sketchy style. This was almost inevitable in choosing carbon for his prints. W. T. Greatbatch is represented by two woodland scenes, similar in character and treatment as their titles suggest, "Woodland Mists" and "Autumn Haze." The former has received a medal. They seem to be unsophisticated samples of photography, and, if not very ambitious according to modern ideas of pictorial work, they are interesting, apart from being very pleasing pictures, from the evidence they show that legitimate methods of control are sufficient for pictorial effect. The frames are unhappily chosen. Equally straightforward examples of photography are the contributions of J. M. Whitehead, one of which "Where Once the Garden Smiled," has received an award. Though small in size, there is no want of breadth. "The Rose is Sweetness—the Gardener's Pride," by Wm. A. Stewart, is a pleasing picture at the first glance, but it hardly bears examination. We cannot help wondering why a gardener should be garbed in some strange robe of silk—it is the only texture in the picture that is recognisable, and why he should wear a sash. The print is mottled all over, which possibly may be a help to effect in this particular picture, but which, one cannot help suspecting, is due to carelessness, especially after viewing Mr. Stewart's other exhibit, which is already fading badly. "Seven Pines," by Frank R. Fraprie, another of the medalled pictures, is an inoffensive little work, but most people will wonder why it received an award. The remaining medalled picture is by John H. Gash, and is entitled "Marketing." The scene is apparently in Normandy. The quaint costumes of the peasant women and curious architecture make it interesting, and the grouping is happy, but it is far from beyond criticism as regards its tone values; in fact, there are no tones in the lower part of the scale, and the fault is not disguised by the unnecessary diffusion of focus adopted.

One of the most imposing pictures and occupying one of the most prominent places in the gallery is "The Deserted Mill," by M. Arbuthnot. It is a gum print, and, as in many gum prints, a gain in breadth has been secured at the expense of truth of tone. The theme is a somewhat hackneyed one, and one would probably guess, from subject and treatment, it was of Continental origin; this, however, is not the case. It is, on the whole, a creditable piece of work, and its author deserves an encouraging word. Equal prominence has been given to a large photograph, by J. C. Warburg, entitled "Summer Heat." The print, which is described as being by Pouncy's process, is of a pleasant cool green tint, and any other year than this we should have said that summer heat was the last atmospheric condition it suggests. As a specimen of photographic skill it is noteworthy on account of its size, but it possesses little pictorial interest. Of Mr. Warburg's other four examples, "A Surrey Roadside" is, perhaps, the most passable. "The Park Palings," which really represents the iron posts and rails, is evidently an enlarged snap-shot, and it possesses just the combination of good and bad qualities that the average snap-shot displays as produced by the average snap-shotter. Mr. Warburg's colleagues on the hanging committee surely have treated him unkindly in not suppressing such immature attempts as those which bear his name.

Dr. Grindrod has no less than six pictures. His work is always interesting, on account of its boldness and freedom, and its breadth of effect, but there is no one that we know who stands on an equal footing with him whose work suffers so much from carelessness and inattention to details. "Carting Trowse," for instance, is full of anomalies in its tones, which would strike the least educated eye. J. C. S. Mummery has shown far better work than that to be seen here. In "Low Ebb," he has a good effect of atmosphere and a sufficiently pleasing composition, but the technique of the picture has an unpleasant characteristic, which we can only describe as "scratchy." The "Village Street" is not so happy as a composition; its cramped foreground quite spoils it, but in treatment, in tones, and in other respects it is admirable. John H. Gear's "Scharzwald Peasants" is a careful piece of work, and, in spite of many good qualities, is not quite satisfying; probably the interest in the figures and the landscape is too evenly balanced. His "Tivoli" is much more successful, although the subject is a less ambitious one. J. Page Croft is another member of the selecting committee whose colleagues have tempered justice with mercy. He is certainly not fulfilling the promise of his youth, as far as photography goes. Always prone to extravagance, experience should have taught him restraint, but it has not, and he attempts things far beyond the warrant of either his art knowledge or his technical skill. Surely his own sense of beauty should have led him to suppress "A Photo Sketch," which apparently represents the nude figure of a woman suffering from some loathsome disease, which has distorted her, body and limb. The picture is as vulgar as its title. "A Portrait," a girl with a veil, is his simplest and best work.

The brothers A. and F. Read show two landscapes of decided promise. When they learn to strain less after effect and to satisfy themselves with simpler subjects, they will do well. The half-dozen pictures by R. Eickmeyer are all full of that daintiness and feeling we are accustomed to in his work. "A Portrait" (157) is a charming head unconventionally treated. An attempt in gum, entitled "Over the Hills to the Poorhouse, I'm Wending my Weary Way," shows the usual defects of that process in unaccustomed hands.

Among the portraiture, a noticeable work is "A Glasgow Journalist," by W. Ralston, in which reflected light is used to produce a striking effect. "A Portrait," by Dudley Hoyt, is good, but the treatment, though possibly legitimate in photography, is not of a kind that would be adopted with any other medium. Jas. Auld sends a far more attractive head than that which received a medal last year. W. M. Warnecke has a very pleasing portrait of a lady. F. Hollyer's portrait of Professor W. C. Unwin is entirely successful. "A Haddon, Esq.," by Furley Lewis, is also a commendable work. "Lady Anglesey," by H. Walter Barnett, can hardly be called a fair specimen of his work. R. N. Speaight has two admirable portrait studies, and R. Fellows Willson's one contribution is quite up to his usual standard. Two capital little portraits or figure studies, by C. F. Inston, are happy in subject and delightful in treatment.

W. A. J. Hensler has in "Epping Forest," a very well worn subject, but it is well treated.

Pierre Dubreuil's five works in gum are equally examples of the control and the absence of control in that process. A portrait of a painter shows the latter and the portrait of Mr. D. the former. H. Stuart, whose work in carbon was always noticeably good, this year sends a very modest-sized gum, which is not a great success. W. Rawlings has in "A Field of Thistles" a good subject, but it is hardly successful. "The Seaweed Cart" is better, but neither is equal to Mr. Rawlings' usual work. J. Fielder Hadens's "Harvest" seems to us a very commonplace photograph, although it is chosen for illustration in the catalogue. "In the Gloaming" is far better both in subject and in treatment. Douglas English has made an interesting picture of mice, and several of his pictures of the smaller animals in the technical section would be distinct acquisitions to the pictorial section. W. J. Croall also shows upstairs a lion's head, which has very considerable pictorial value; indeed, it is a far better picture than his pictorial exhibit. "Nemo me impune Lacessit," by Robert Mackay, has an equal right to be exhibited in either section. It is a group of thistles; as a decorative work it quite deserves its place among the pictures.

The exhibition contains some notable studies of breaking waves by Joseph Appleby, and which are refreshing examples of straightforward photography. Architecture seems to be quite unfashionable now, but among the few examples there are some distinctly commendable. "Promenoir Staircase, Mont St. Michel, Normandy," by Alfred Bedding, is characterised by its harmonious tones. "Across the Nave, Beverley," by J. W. Hodges, is another well-managed interior; and "In the South-West Tower, Chichester" gives Wm. A. Clark an excellent opportunity, which he has availed himself of; and "An Ancient Chamber," by John Schofield, is a carefully executed piece of work, and there is some good work by H. R. Campion.

Miss Acland contributes the one photograph in colours which the pictorial section can boast of. We cannot justly describe it as in the colours of nature, but it is very tiny, quite inoffensive, and interesting in its way.

"On a Moorland Road," a study of sheep, by J. B. Johnstone, strikes us as being one of the best things in the exhibition. It is certainly not faultless, for it has precisely the faults which are so difficult to avoid in a photograph when a low scale of tone is adopted—there are dozens of examples of the same defect in the room—but the grouping, the arrangement, and the general effect are extremely good. It is most unfortunately hung at the lowest level. Of the three pictures by W. C. Wickison, "A Hampshire Farm" is the most interesting, but the subject seems somewhat reminiscent of the "warranted hand painted" oil paintings of the cheap furniture shops. It is, however, a distinctly clever work, in spite of its artificial appearance. "Winter," by Thomas Wright, is a very effective piece of snow scenery. From a pictorial point it is rather too crowded with incident, but is just the picture to appeal to the general public. Another picture which will be popular is "Friend or Foe," by John Smith, which represents a child making advances to a cat.

Of course, there are many other pictures that deserve notice with those we have commented upon, but however fully we were to record our own impressions a greater amount of instruction could be gathered from a single visit.

TRADE EXHIBITORS.

The first experiment, the year before last, in providing space for the display of their wares by manufacturers and photographic dealers, though otherwise successful, resulted in an assemblage of stalls decorated so that the noble fountain court presented something the appearance of a fancy fair. The same fault cannot be found now; and, although the intention is quite as well achieved, the appearance is very much more in consonance with the dignity of the Royal Photographic Society.

Messrs. Wellington and Ward have arranged their space in the usual tasteful manner, and display enlargements on their various grades of bromide paper, also enlargements in carbon and specimen negatives on their celluloid film.

Messrs. J. H. Dallmeyer, Ltd.—The chief attraction is the long-expected "Adon" telephotographic lens. This differs from ordinary forms in being attached to the front instead of to the back of the ordinary lens. It can be adjusted to work at the same infinity focus as the ordinary lens, and thus the focus can be adjusted before the attachment is applied. The "Adon" is in itself an image-forming lens, and it can be used by itself as an ordinary lens. An important advantage in this over the usual form of telephoto attachment is that the light intensity of the ordinary lens is but slightly diminished, and its use in a hand camera is therefore quite possible. Another novelty is a new camera back for studio cameras, which allows the sensitive plate to be brought into position for exposure in a fraction of a second after focussing has been performed. It is extremely ingenious and undoubtedly useful.

Messrs. Sanger Shepherd and Co. have many new and important pieces of apparatus which will be of great interest to those who are engaged in the production of photographs in natural colours. There is also a new light measuring instrument, and a new hand-fed arc lamp for projection purposes.

Messrs. Ross, Ltd., have an attractive display of their lenses, of various types, also cameras of their own and other makes to which their lenses are fitted. They also show lanterns for enlarging and projection with their special forms of arc lamps and high power lime-light jets, their new pattern prism binoculars, and other specialties of the firm.

Mr. C. P. Goerz shows examples of his anastigmatic lenses, including the last new series and the ingenious "Hypergon" lens for including an extremely wide angle; the Goerz-Anschutz camera, Sector shutters, various photographic accessories, and the Trieder binocular. Some good specimen photographs are also shown.

Messrs. W. Watson and Sons have an admirable selection of cameras of various kinds, including their latest patterns, their focal plane shutter, adaptable for time and instantaneous exposures, and convertible Holostigmat lenses, with specimens of their performance. A new patent shutter release is also shown, which seems to be without the disadvantages of the ordinary pneumatic ball and tube.

Messrs. Burroughs, Wellcome and Co. make a good show of specimens of their "Tabloid" photographic chemicals. There is also to be seen here Wellcome's Photographic Exposure Record and Diary.

The Kodak Company make a good display of their wares. The new developing machine for developing roll films in daylight is on view. The method of using it and other simple demonstrations are freely given.

The Platinotype Company show numerous specimens of platinotype printing. They have also a full equipment for the platinotype patent lamp for portraiture, and demonstrations are given at intervals in the evenings.

THE TECHNICAL SECTION.

Scientific, technical, and photo-mechanical exhibits reach a total of some one hundred and fifty examples, somewhat less, if memory serves aright, than was the case last year. The exhibits illustrate the

applications of photography to astronomy, spectroscopy, radiography, natural colour rendering, copying, investigations into the structure of metals, the microscope, ballooning, and natural history work.

ASTRONOMY.

The Astronomer Royal contributes the lion's share of the astronomical examples. They consist of transparencies showing the solar corona, as photographed at Sahdol (1898), Ovar (1900), Sumatra (1901), and Mauritius (1901). The credit for the work is shared by Mr. Christie (Astronomer Royal), Mr. F. W. Dyson, and Mr. Maunder, and the instrument employed has been the Thompson Coronagraph, O.G. 9 inch diameter, with plates varying from lantern, process, and ordinary to specially rapid backed plates. The visitor will also find photographs of the Pleiades, taken with the Thompson Reflector, with an aperture of 30 inches and a focal length of 11 feet 4 inches. The same instrument was used for the photograph of the Great Nebulæ in Orion (1899), and in Andromeda (1898). There is also a photograph of the moon (age 231 hours) taken with an arrangement forming a telescope of 50 feet focal length, which is of excellent quality. Sir Norman Lockyer shows the corona of May 28, 1900, and two frames of star spectra, which speak for themselves to those who appreciate or follow this method of studying the heavenly bodies. Of equal interest is the exhibit of Captain E. H. Hills, who deals with the eclipse of January 22, 1898, as seen from Pulgaon, in India. The two frames he sends in contain spectrum photographs of the sun's limb at the points of second and third contact, taken a few seconds before and after contact, and at actual contact. The work of another well known astronomer, Mrs. Maunder, also calls for reference. She exhibits carefully prepared drawings from her photographs of the solar corona in the eclipse of May, 1901, both of which have been very highly spoken of by experts in this field of work.

THE X RAYS.

Dr. R. Norris Wolfenden, Mr. C. Thurston Holland, and Mr. Frederick H. Glew are responsible for the interesting exhibits coming under the above heading. The first-named gentleman devotes much of his time to deep sea dredging in the Orkney and Shetland waters, and the creatures he brings up are subsequently thoroughly examined by means of the Röntgen rays. We do not propose to describe in detail the Doctor's exhibits, which show marvellous skill, but will pass on to the others. Mr. Holland's pictures are of a more surgical interest. They show the location of foreign substances in the human body and limbs, and the site of fractures or other disorders of the bones. Mr. Glew's single exhibit is a radiograph of an injected baby, showing the system of blood vessels with startling clearness. Altogether, this class is of a very instructive character.

PHOTOGRAPHS IN COLOURS.

Small though the number of these exhibits, they cover nearly all of the processes in use. Mr. W. E. Brewerton some years ago, when the exhibition was held at Pall Mall East, took a medal for a method which he still practises, with some success. He shows two prints—"A Poppy Field" and "A Group of Fruit." In each case the blue sensation is rendered by means of a ferro-prussiate print, while the reds and yellows of the originals are in the form of carbon prints, superimposed upon the ferro-prussiate base. There are faults in both examples, but not more so than in the other processes of colour reproduction. Close by are the exhibits of the Lumière N.A. Company, Limited, produced by the superposition of three stained films representing the three primary colours. The prints on paper, which are here shown by the enterprising firm, are from still-life subjects. They produce the colours of the original, with more truth perhaps than the casual observer is prepared to admit. We are so accustomed to view objects in their natural colours that the strength of the colouring does not force itself upon us, but one has only to consider the images seen upon our focussing screens to admit that by some mental process we largely ignore the true intensity of the colours of objects seen in the ordinary way. Processes of colour photography appear to the writer to render what actually is, rather than the human perception of colour in things, and one is naturally led to question whether this is the correct way to approach the subject of colour rendering, or whether the results should conform more closely to the milder sensation of colour in which nature presents itself to our imagination. Adopting the first standpoint there can be no question that the exhibits in question are strikingly good, seen without the originals before us. The paper prints are more to our liking than the same firm's vivid glass transparencies, in which the bounds of colouring are somewhat overstepped. Miss Acland, of Oxford, is well known for her untiring pursuit of the problem of colour rendering. She chooses the Sanger Shepherd superimposed films method in the case of transparencies, of which she has made a good many, but the paper prints she now exhibits are by a modification of the same process worked out by herself. This notice deals essentially with the technical exhibits, but for the purposes of describing Miss Acland's exhibits we must include a print displayed in the pictorial section, also made after her method of working. There came before us, therefore, five prints—two reproductions from coloured miniatures, a red lily, a portrait of the Hon. Lady Acland, and a view of the X fleet in Torbay. The foundation blue print consists of an ordinary bromide

print, bleached in ferricyanide of potassium, washed, treated with perchloride of iron, rinsed, followed by a hyposulphite of soda bath, again washed, cleared in a dilute sulphuric acid bath, and finally washed. The pink and yellow prints are made upon bichromated gelatine tissue, containing a small quantity of silver bromide for the purpose of assisting the dissolution of the gelatine in the subsequent operations. These bichromated gelatine prints are squeezed to pieces of glass, edged with rubber solution, and coated with collodion and again with rubber solution, in order to keep the gelatine films firmly on the glass supports. The prints so mounted are soaked in cold water, developed with warm water, fixed, and washed. When dry, the prints are faintly stained pink and yellow respectively, coated with rubber solution, to hinder the dye from running, and finally covered with collodion. The blue bromide print is then mounted on card and coated with thin varnish. A particular gelatine solution is then flowed over the print, and the pink print placed in register above it. When dry, the two prints are stripped away from the glass and made ready for the yellow print as before. Variations on this procedure were made for some of the prints, to the extent of omitting the silver bromide, and consequently the fixing, as well as in other directions.

Another example of colour work is the transparency of Mr. E. A. Jahn. This again is by the Sanger Shepherd process, and the subject, "Daffodils and Anemones," is pretty well rendered. Mr. Edgar Senior is represented by a Lippmann photograph of the arc spectrum, which is very good indeed, and a frame of two photomicrographs of sections through the "blue" and "red" of one of these photographs, multiplied respectively 4,520 and 2,700 diameters. The laminae, to which the whole of the colour is due, are very well rendered, but it suggests itself to our mind that it would have been better to have enlarged the two sections to the same magnification, so that the thicknesses and distances of the laminae, to which the different colours are due, might be kept in their relative proportions. As it is, the laminae in the two photographs are shown at about the same size, and one has to remember that the magnification in each case is different.

PHOTOGRAPHY WITH THE MICROSCOPE.

The series of micro-photographs by Mr. Ernest A. Lewis, F.C.S., chemist to Muntz's Metal Company, call for special mention. They show at different degrees of magnification the structure of metallic alloys, such as copper and manganese of various percentages, copper and aluminium, zinc and iron, zinc and silver, zinc and copper, zinc and antimony, zinc and cadmium, etc. Similarly instructive, when time is given to sufficiently consider the work, is the exhibit of Dr. Clowes, consisting of photomicrographs taken in connection with the long series of experiments in the bacterial treatment and destruction of crude sewage. The actual photographic work with the microscope is that of Dr. Albert Norman, whose reputation for this class of research is one of long standing. We wish that some of his more recent work at the problem of photomicrography in natural colours could have been on view. The cultures photographed were, it should be added, by Dr. Houston.

Dr. Edmund J. Spitta has also a reputation amongst photomicrographers which is second to none. His three exhibits at the New Gallery amply maintain this reputation. He shows the amphipleura pellucida x 4,200 diameters. It was photographed with the exhibitor's new arrangement for obtaining pure monochromatic light with the mixed jet. This arrangement enables the "beads," which are about 1-100,000 inch in diameter, to be seen and to be photographed. Dr. Spitta has been over four years in accomplishing this feat with the limelight. White light fails to render these dots. Yellow, green, or, better, blue-violet, light is wanted. Many experts have tried with the aid of prisms to get this blue-violet light, but there is not enough of it and that is not direct. Dr. Spitta believes that he is the first to photograph these dots by limelight. Van Heurck did so with solar light, in an imperfect manner and with apparatus costing a good deal, whereas Dr. Spitta has succeeded with an ordinary microscope, the usual condenser, and a Zeiss 1.40 apochromat. Those who are able to judge speak of this achievement of Dr. Spitta's with unlimited praise. The second and third photographs are the amphipleura pellucida x 10,000, a single diatom photographed by limelight at 2,000 diameters and re-enlarged; and an excellent photograph of the entire proboscis of a blow-fly made with the Conrady one-inch semi-apochromatic series, and a double green screen. Mr. Frederic E. Ives contributes twelve photomicrographs made with a small fixed focus box camera and adjustable fixture.

PHOTOGRAPHY FOR THE NATURALIST.

There is quite a fair collection of animal pictures, the palm being carried off, we think, by Mr. Douglas English with his several frames showing the old English black rat (almost, if not, extinct) in three characteristic attitudes. The four little prints of a dormouse engaged in his antics and the three pictures of the squirrel are very clever. There are also four pictures of a repulsive-looking creature—the polecat, intent on the body of a rabbit. One of the pictures is enlarged, and shows the animal about three-quarters natural size. Mr. H. Nouaille Rudge is the exhibitor of four enlarged photographs

of a spider monkey, an ostrich with mouth open, and two vultures, all of which are good, but perhaps a little hard, due no doubt in part to the nature of the gallery lighting. Miss E. L. Turner has some dainty little photographs of the coal and blue tits, the lesser white-throat, and the young red-backed shrike—the latter being a series showing the rapid feather development during the ten days following the hatching of the bird. Other exhibitors in this class are Mr. W. L. F. Wastell and Mr. W. J. Croall, both with pictures of a lion, which, though very differently treated, do both gentlemen credit. Dr. Lindsay Johnson, with Mr. J. J. Webb, show several frames illustrating "Scenes in the Life of the Chimpanzee Consul II." The pictures are doubtless faithful enough records, but they call for no especial notice. Mr. R. A. Malby's "Night jar," showing the close resemblance which the plumage of the bird has to the rough bark upon which it rests, may also be mentioned; but there is nothing particular about it, or about Mr. B. H. Bentley's "Grey Parrot."

BALLOON PHOTOGRAPHY.

The only balloon photographs on view are those of the Rev. John M. Bacon, well known for his explorations amongst clouds and air currents in recent years. His pictures tell us nothing new, but are none the less interesting on that account. He shows a photograph entitled "Sunrise over the Medway," and bearing an additional note to the effect that night still obtains on earth. We have no information as to the altitude from which the photograph was taken, but are inclined to put the question, Whether at the elevation in question the balloonist can claim to be appreciably ahead of the earth in regard to sunrise or behind in the matter of sunset? Perhaps Mr. Bacon's best and most popular picture is that of "Trafalgar Square from three-quarters of a mile above Soho." This is remarkably clear, and as a plan of this part of our city not easy to be beaten. The principal buildings, bridges, and thoroughfares stand out with an amount of distinctness that engages the attention at once. Mr. Bacon and his daughter have done much to popularise these unusual aspects of town and country, and the lecture on balloon photography which he is announced to give at the Gallery on Saturday, October 11th, should bring together a large audience. We should like to ask a question about No. 311, "Cloudscape above London," the frame of which bears a note to the effect that churches may be seen below. Where are the churches? Diligent search fails to reveal them to our eyes.

REPRODUCTION PROCESSES.

There is a very marked falling off in the number of exhibits coming under this head compared with previous years. Messrs. Bemrose and Sons, Limited, have on view two frames, containing respectively eight reproductions of carbon and silver prints and six reproductions of coloured mezzotints. The work has been executed with all the care and skill usually associated with this firm's productions, but it seems a pity that there is nobody to compete with them on this occasion. Close by is a platinum print from a negative of Solomon J. Solomon's "Blind Beggar," made by Mr. H. W. R. Child, who devotes himself to this work very considerably; and next to it is a copy of an oil painting of the "Virgin and Child," by Dr. Lindsay Johnson, which does not appear to call for comment. With a brief glance at Mr. Gus Rochefort's copy of an old print, we come to the exhibits of Mr. J. Hort Player, who shows a series of copies from engravings made by a method which he has utilised for some years. The negatives from which these positive pictures have been printed were obtained by passing sunlight through a solution of picric acid on to the back of sensitised paper placed face downward in close contact with engravings. The sensitised paper is thus interposed between the source of light and the engraving to be copied. It was for similar results that Mr. Player secured the R.P.S. medal a year or two ago.

MISCELLANEOUS EXHIBITS.

There is a number of exhibits which do not fall easily into classification. Amongst them are five frames of blue carbon prints, showing the peculiar forms taken by frost crystals on window panes. Mr. James Leadbeater, who shows these prints, finds a special pleasure in recording these phenomena, apparently, for on previous occasions we have seen similar examples of his work. Mr. Paul Stellbring shows an interesting photograph of lightning; and a picture of a multiple lightning flash taken at Balham by Mr. J. Howden Wilkie is good of its kind. The Royal Observatory also lend an example of lightning photography. In Nos. 349 and 351, Mr. H. T. Malby has two excellent examples of the use of the telephoto lens on near objects, compared with pictures made with the ordinary lens, that is with the negative element removed. In both cases the telephoto picture is decidedly in advance, in point of merit, of the smaller photograph. Mr. Bagot Molesworth has one exhibit—"Sunshine and storm clouds in the high Alps"—a telephotograph from a point ten miles distant, taken at the moment when a gleam of sunshine breaking through the clouds illuminates the mountain summit. Close by is a good flashlight picture by Mr. Thomas Robertson, showing an incident down in the mines—a man pushing along a trolley under a low roof. Mr. John C. Warburg has here also a little frame, containing a print

entitled "Sand ripples," which is almost effective enough to find a place amongst his other work in Section I.

There is a wonderful series of photographs by Dr. Vaughan Cornish, whose studies in sand ripples, cloud waves, and the like at last year's show attracted so much attention. He contributes this year, in addition to some ordinary snow scenes in the Selkirk Mountains of British Columbia, a number of photographs of snow "mushrooms." These peculiar formations of snow reach as much as 12ft. in diameter, and are shown, as a rule, upon broken tree stumps of 2ft. to 4ft. diameter. The snow itself is rendered in a splendid manner, but apart from excellencies of this character, the objects themselves deserve attention. One of the most weird is that of a snow cap of very large size supported on the top of a telegraph pole. The straining of the wires is very clearly rendered. Views of ice hummocks on the frozen St. Lawrence also possess interest of their own.

Sir Norman Lockyer exhibits frames of arc spectra of plant ashes (such as spinach ash and straw ash), volatilised on silver poles, showing the varying intensities of the lines due to the principal constituents. Of a similarly analytical nature are the spectrum photographs of meteorites, volatilised on poles of silver, and the volcanic dust from Martinique. Both show the lines of the metallic elements present.

From the Cape come several frames of exhibits by Mr. A. J. Fuller and Dr. Marloth. They are all noticeable for their excellent technique. Mr. Fuller has photographed specimens of a very destructive moth which, coming from Mauritius and Bourbon at the end of 1899, wrought great havoc amongst the fruit crops. The same exhibitor shows a picture of the Karroo plant, which stores water within its leaves for its nourishment during the long drought. Dr. Marloth shows photographs of a number of succulent plants, ferns, orchids, and various flowers, at different altitudes of Table Mountain. These technically excellent prints are well deserving of examination.

THE APPARATUS.

There is more apparatus, and its interest is also greater than in recent years. Mr. James Wheeler contributes a direct ray printing box, designed to the securing of a right-angled incidence and avoidance of side reflections. Messrs. Penrose and Co. show the latest form of Tallent's diffraction spectroscopic camera. A new slit, more sensitive in adjustment, is provided, and one or two commendable changes are made. Messrs. R. R. Beard exhibits an enlarging apparatus fitted with his electric arc lamp, 9in. condenser, rotating negative carrier, and a means of swinging or tilting the negative to correct inclined lines. Messrs. Taylor, Taylor, and Hobson show their new Cooke focussing lens, which contains within itself a means of focussing objects at various distances from the camera. It is particularly suited to hand cameras, which, fitted with the lens, require no bellows or ordinary focussing mechanism. The mere rotation of the mount alters the focus of the lens by the separation of its elements.

Mr. Edgar Senior has on view a sensitometer designed to facilitate the selection of the screens for use in three-colour photography. The apparatus is based on Sir William Abney's method, and is dealt with in Penrose's Annual, 1901. In connection with this exhibit must also be mentioned the specimens of trichromatic inks and an example of the test showing the method of using the sensitometer. Last, but not least, for it has gained the Society's medal, comes Mr. F. E. Ives's parallax stereogram. We have already published a note upon this very clever device, which is made to produce the illusion of a solid object standing in space between the glass positive and the observer's eyes.

THE SLIDES.

The lantern slides are most disappointing in number, and those selected for exhibition may be quickly disposed of. Those that will arrest one's attention more than the others are by Mr. Ellis Kelsey, who exhibits five night effects, the most striking being the man in bed reading by candle light, "Firelight," and the cyclist. A score of stereoscopic prints include a number by Mr. F. E. Ives, having definite objects in view. These are photo-micrographs of diatoms made with an oil immersion objective, and Mr. Ives took them in order to study the relation of the diffraction image to the dioptric image, and to see whether his procedure might not be helpful in the study of minute structures, and perhaps settle some vexed questions.

The method of procedure is believed to be new, in that the difference between the two images is brought about solely by decentering the diaphragm at the back of the substage condenser, so that there can be no suppression of diffraction pencils at the back of the objective. So far as the exhibitor is aware, it has always hitherto been the practice to cover half of the back of the objective. The amplifications vary from $\times 300$ to above $\times 2,000$. In the examination and study of some of the results it is necessary to take into consideration the roundness of the field of the objective, which makes the plane of sharp definition vary where there is no alteration of object distance. (An achromatic hand stereoscope is provided for the examination of this exhibit.)

THE "L. N. A." THREE-COLOUR PROCESS.

RECENTLY the directors of the Lumière North American Company gave the Press, both lay and photographic, the opportunity of ascertaining the steps that were being taken to popularise trichromatics on glass amongst the general public. A well-attended demonstration, at the Holborn Restaurant, was followed by a luncheon and an optical lantern display. Briefly, what the company has done is to place within the reach of the photographer, for a comparatively small sum, the materials for producing three-colour transparencies by the stained film process. Three screens, three dye solutions, the bichromate sensitiser for the positives, the printing surface, and clearly written instructions not above the mental comprehension of the youngest photographer comprise the "L. N. A." three-colour outfit. Great interest was manifested in the demonstration at the Press view, and subsequently at the luncheon (presided over by the chairman of the company, Mr. E. Llewellyn White), Mr. T. K. Grant lucidly explained the principles of the process. The projected transparencies were of excellent quality, and the company may, at any rate, be congratulated on having imparted to the majority of its journalistic guests a clearer idea of practical trichromatics than, in many cases, had hitherto been possessed.

It may be added that the materials for the "L. N. A." process are obtainable at the company's address, 4, Bloomsbury Street, New Oxford Street, London. We subjoin a description of the working details, taken from the "Book of Colour Photography":—

The production of a lantern slide or transparency in natural colours resolves itself into three divisions:—

- (1) Production of the three negatives necessary.
- (2) Printing the three positives.
- (3) Dyeing and mounting positives.

THREE NEGATIVES NECESSARY.

The three negatives necessary must be taken on three special plates with the use of light filters supplied. The ordinary dark slides are employed and the three exposures made as rapidly in succession as possible, care being taken that the camera be not moved between the exposures. The filters must be so placed that they come between the object photographed and the sensitive plate, and also in such a position that they may be easily changed when needed. The position filling these requirements most readily is immediately in front of the lens. They may be so attached by the use of a small adapter or carrier which clips to the lens hood, and allows of the easy insertion or withdrawal of a screen.

THE PLATES TO BE USED.

For use with the blue violet filter we employ the Lumière Extra Rapid Blue Label plate; with the green filter, the Lumière Orthochromatic Series A; and with a red filter the Lumière Orthochromatic Series B. These plates being specially prepared, showing high sensitiveness to the colour rays passed by these filters, should be always employed. The use of any other plate will materially affect the quality of the results, and is to be avoided.

THE RIGHT EXPOSURES.

The exposure through light filters is naturally more extended than would, under ordinary circumstances, be the case, and with the filters supplied it will be found necessary to give an exposure—using the blue screen—of four times that necessary without its use. As, for instance, if the normal exposure on a subject, without screen, were $\frac{1}{4}$ of a second, we should have to give an exposure of one second through the screen.

With the green screen, an exposure of six times this duration must be given; and with the red sixteen times; so that the three exposures will read as follows:—

Blue screen	1
Green	6
Red	16

THE DEVELOPER.

Having made the exposures, we next proceed to develop our negatives, and as the negative most suited to the process is one containing the maximum of detail and softness, all harsh contrasts must be avoided. To obtain such a negative, we advise the use of dianol, which should be prepared as follows:—

Water	250 c.c. or 9 ozs.
Anhydrous soda sulphite	8 gr. or 120 grains.
Dianol	1 gr. or 15 grains.

CAUTION.

Before taking the plates from the slide, the developing dish and solution should be placed in readiness, and the dark room light turned to its lowest point. The dish should be sufficiently large to take the three plates, and it is best to use a large quantity of developer, as by this means the complete covering of the plate is assured. On taking the plates from the slides they should be numbered, or marked, to render them easily distinguishable, the use of a lead pencil on the film

side being perhaps the simplest method. The extra rapid plate should be marked 1; the Ortho A plate, 2; and the Ortho B plate, 3.

Place the three plates in the dish in such a manner that the position of the E. R. blue label plate is known, as this is the plate we examine during development. After pouring on the developer, cover the dish and rock freely.

At the expiration of a minute, the E. R. plate may be withdrawn from the developer, and momentarily examined by turning up the light. Care should be taken to keep the dish well covered during the examination, as the plates therein are sensitive to red rays, and fogging would result. The high lights of the subject will be found well marked if exposure has been correct, and the plate must be returned to the developing dish and rocked for a further three minutes. At the expiration of this period the plates should be rinsed, and placed in an ordinary fixing bath for ten minutes. Care should be used that the light be not turned up before the plates are thoroughly fixed unless the dish cover is in position. When fixed, wash as usual, and place to dry.

PRINTING THE THREE POSITIVES.—SENSITISING.

Take three pieces of the special film supplied, and immerse for two minutes (by artificial light, or very subdued daylight) in the sensitizing solution, the temperature of which must not exceed 65 degrees.

DRYING.

These should then be suspended in a dark airy place to dry, which operation should not be too prolonged. Film sensitised at night should be ready for use next morning.

PRINTING.

When dry, prints may be made on this sensitive film, after carefully cleaning the back of the support the negative being placed in an ordinary printing frame, and the emulsion or gelatine side of the film turned away from the negative, so as to print through the support. A "safe edge" is preferably provided, and can be made by the use of an ordinary lantern mask, or by gumming slips of black paper round the sides of the negative—so as to frame the picture as it were. When the image is visible in faint detail, printing will have proceeded sufficiently far for development, which is accomplished as follows:—

MARKING.

The three pieces of film are removed from the frames and marked carefully for identification. This is most readily performed by clipping the corners of the tissues with a pair of scissors. From negative one, one corner should be clipped off the print; from negative two, two corners; from negative three, three corners removed. This marking is necessary, as it is our guide when dyeing, and must be carefully carried out in all cases if error is to be avoided.

DEVELOPING.

Now immerse one piece of the printed film in a dish containing warm water, a temperature of 90 degrees to 100 degrees being the most suitable for use. Rock the dish, and portions of the gelatine will be seen to dissolve away, gradually leaving a positive image printed on the support, and of a creamy white colour. When all the soluble parts have been dissolved, this should, viewed by transmitted light, present a well graded appearance, and reproduce all the detail of the negative.

CLEARING.

This positive must now be cleared or rendered transparent, which is accomplished by immersion in a bath composed as follows:—

Hypo	2 ozs.
Schering's Photo Formalin	2 drams.
Potassium ferricyanide	24 grains.
Water	20 ozs.

The same process is used with the remaining two prints, and a short wash and drying in a position free from dust will complete the second step of the process.

DYEING AND MOUNTING POSITIVES.

It now remains to dye and mount the three transparent prints that we have produced. Three bottles of dye are contained in the cabinet, the contents of which are ready for use, and may be employed over and over again until exhausted. It is at this point where we find the necessity for the careful marking of negative and print that has been previously advised. The print with one corner clipped (taken from the extra rapid plate) is immersed in the yellow dye (No. 2). The print with two corners clipped (taken from the Ortho A plate) is placed in the red dye (No. 3), and the print with three corners clipped (taken from the Ortho B plate), is dyed blue in the blue dye (No. 1).

Dyeing takes from one to two hours, according to the temperature of the solutions, but as it is possible to a large extent to adjust the final results, no particular care is necessary. When dyeing is judged sufficient, that is to say, when the picture presents a full range of tone and detail, the prints should be removed from the baths, rinsed, and placed to dry in a position free from dust.

ADJUSTING FINAL RESULTS.

When dry, we can readily judge if they are correct by placing in temporary superposition. For this a supply of clips (procurable at any stationer's) will be found useful. Place the yellow and blue prints in register, and clip together at the side, afterwards adding the red monochrome, and again clipping the three together.

REGULATING THE COLOURS.

Should there be shown an excess of any colour, this may be regulated by the use of a solution of ordinary glue—about 1½ drachms of glue to a pint of water. To mix, allow the glue to swell in cold water, then dissolve. In this solution any of the monochromes may be reduced by immersion. Should, however, any need strengthening, this may be effected by a further immersion in the proper dye bath.

MOUNTING.

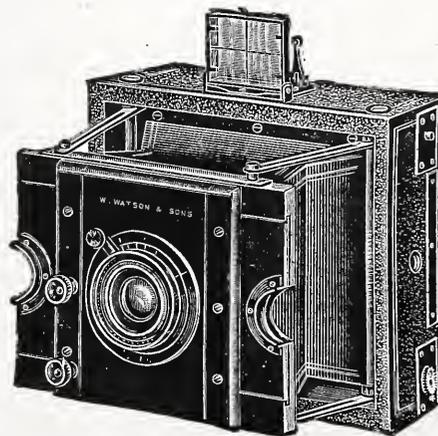

When the monochromes needing alteration have been adjusted, and all three are judged correct, the blue positive should be placed in position on a cover glass, and fastened securely by gummed paper slips. On this, in correct register, should be mounted the yellow and red monochromes, which are retained in position in the same manner. A suitable mask and cover glass will complete the transparency. Many advantages will be shown in lantern slides prepared by this method, by which the maximum of transparency is attained, as they will stand heat well, and will not be found to expand or lose register in the lantern, as is so frequently the case.

If preferred, the monochromes may be cemented together with Canada Balsam.

New Apparatus, &c.

A Focal Plane Camera. Sold by W. Watson and Sons, 313, High Holborn, London, W.C.

It is some years since hand cameras of the type which forms the subject of the present notice found their way on to this market; but, such is the curious conservatism of the English photographer, it is only recently that we have perceived signs of appreciation of a class of instrument the practicability and efficiency of which, in competent hands, is easily demonstrable. Some photographers of our acquaintance—men of long experience—go so far as to pronounce the focal plane camera as the ideal machine for rapid work. Observe how beautifully simple and at the same time scientific is the manner of its use. Holding the camera to the eyes, you sight your object through the cross-wired finder over your lens plane, and the most delicate touch of a little pin by the index finger of the right hand releases the slitted blind, and your exposure is made. You take, in fact, a veritable shot at your prey. In the very early days of the hand camera we published in these pages an article predicting the advent of such an instrument as that before us; and we are glad to see our ideas taking concrete shape. There is evidently a growing

demand for focal plane hand cameras, and Messrs. Watson, we think, are wise in entering the market with the beautiful little instrument before us. Here are its main features concisely summarised: The camera is of fixed extension; focussing is effected by a lever movement controlling the lens, which moves posteriorly or anteriorly in a tube; the focal plane shutter allows of both time and instantaneous exposure being given. A half plate when folded up measures 8in. by 7in. by 3in.; the camera front moves horizontally and vertically; black leather is used to cover the instrument, the body of which is made of ebonyed mahogany.

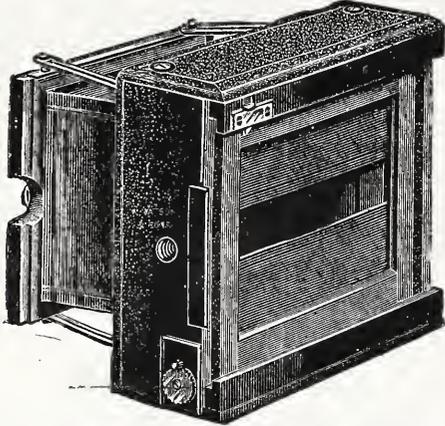

Messrs. Watson supply the following instructions for working camera: To open the camera, draw the front out by means of the two projecting grips provided, as far as it will go, the slotted metal arms will then spring into position and hold it securely.

To focus the picture, set the lever so that the bevelled edge of it coincides with the figure indicating the distance of the objects. The figures marked indicate distances in yards.

To close the camera, press out the supporting arms on one side, letting the front of the camera on that side go back slightly, then press out the arms on the opposite side, when the front, being released, can be closed into the body.

To set the shutter, wind the blind by means of disc having two projecting knobs on one side of the shutter as far as it will go; discharge by pressing the knob on the front edge of body.

To alter the width of slit (in half-plate shutters), pull straight out, but do not turn, the small bright milled head on the numbered disc, and wind the knob on the opposite side of shutter until the width required—as shown by the figures on disc (which represent the width of slit in m/m)—comes opposite the little vernier projecting over disc. Then release the milled head on disc, which will lock the blind in position; now wind up the blind. This applies to half-plate shutters only. For $\frac{1}{4}$ -plate

and 5 by 4 the top one of the two milled heads is turned to the left to open the slit and to the right to close it. When the figure 5 shows at the aperture, the slit is fully closed. The width of the slit should not be altered after the shutter is wound up.

Time exposures.—Pull the small lever up to the letter T, and pull out small milled head on disc. Wind the blind right up and press and release the discharger; the shutter will remain open till this is pressed again to close it.

Shutter speeds.—The speed of the shutter can be altered by turning the bottom milled knob, and the exact exposure will be shown from the figures 1, 2, 3, 4, 5, and 6. The most useful speeds result from the following combinations:—

Indicator.	Width of Slit.	Exposure.
1	Full opening	1-5th sec.
2	Full opening	1-12th sec.
1	60	1-20th sec.
3	60	1-35th sec.
6	60	1-80th sec.
6	40	1-125th sec.
6	25	1-200th sec.
6	15	1-300th sec.
6	10	1-500th sec.
3	5	1-600th sec.
5	5	1-800th sec.
6	5	1-1,000th sec.

A careful examination of this camera disposes us to regard it with high favour. Either a Goerz or a Holostigmat lens may be fitted to it; and it is adapted to take a special form of changing box. We were particularly struck with the dark slide sent for our inspection. This had flexible roller shutters, and thus, to uncover the plate, all that is necessary is to wind the shutter of the slide out of the focal plane—a very neat and convenient device.

The "Wellington" S. C. Papers: Art White and Art Tinted. Manufactured and sold by Wellington and Ward, Elstree, Herts.

We have received for trial sample packets of these varieties of printing papers, which have just been added to Messrs. Wellington and Ward's series of Slow Contact Papers. Since these Papers were placed upon the market about twelve months ago, the Wellington and Ward brand has become a favourite printing medium with many photographers. At the time of the introduction of Velox, the first of the slow gas-light papers, we pointed out that the supercession of the dark-room and the certainty with which exposures could be timed, and identical prints obtained, offered facilities to photographers which they would readily appreciate. In adding two new kinds to their series of slow contact papers, Messrs. Wellington and Ward place a further power in the hands of the printer. These varieties are of the moderately rough type, and impart to the print a pleasing grain, which adds much to the charm of many photographs, especially in the larger sizes. The tinted paper is of a rich cream colour, and rather coarser in texture than the white. We obtained very fine prints from a negative of average density and long scale of gradation. The developer we used was Rodinal, diluted with 30 parts of water, to which a slight addition of bromide of potassium was made. The characteristics of the emulsion are excellent, the prints showing pure black in the deepest shadows, a wide range of delicate half-tone, and faultless high lights. We think these new papers will be much appreciated both by professional and amateur photographers. Messrs. Wellington and Ward also issue a booklet entitled "Notes on the Use of the Wellington Papers," which occupies 62 pages, and is full of information relating to manipulative details. From this booklet, which is now in its third edition and is obtainable on application to the firm, we take the following lists of the Elstree firm's specialities, in addition to those above noticed: "Wellington"

Bromide Papers.—Ordinary, in rough and smooth. Enammo, a glazed surface paper. Useful where ordinary printing on chloride paper is inconvenient. This paper is also made in a thick grade for post cards, menus, and other such like work. Special Thick, smooth surface, like thin card. When printed with a margin it requires no further mounting, and is suitable for Christmas cards, menus, etc., and post cards. P.O.P. (ordinary), a gelatine chloride (print-out) paper. For the phosphate and formate toning baths, or the combined bath. P.O.P. (special), a gelatine chloride (print-cut) paper. Specially manufactured for the sulpho-cyanide bath. It is also suitable for the formate and combined toning baths. P.O.P. (thick), a gelatine chloride (print-out) paper. Specially suited to the printing-off from small negatives. Films (celluloid), daylight cartridges, etc., for all daylight loading cameras. Films (gelatine), suitable for snapshot work, negatives for carbon and collotype work, and for use in the ordinary slides. Carbon Tissues, specially suited to exhibition work. In various colours. Post Cards (sensitive). These are manufactured in S.C.P., special thick bromide, special thick enammo, and thick P.O.P.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Oct.	Name of Society.	Subject.
10.....	Croydon Natural History	{ Focal Plane Shutter and its Uses. Mr. W. Kilbey.
10.....	Borough Polytechnic.....	{ Bromide Printing. Mr. F. W. Banister.
11.....	Royal Photographic Society of Great Britain	{ Photography from Aloft. Rev. J. M. Bacon.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 2ND.—Mr. A. Haddon in the chair.

A very important and interesting discussion on the "Fading of Albuminised Paper" was opened by Mr. A. L. Henderson, who remarked that, although the experiments of twenty or thirty years ago may have been conclusive, such experiments would differ now. A very faded specimen was passed round, which Mr. Henderson had come across at the seaside, and being the work of an excellent photographer, the manipulation could not be the cause. In the first place, it was pointed out that an imperfect base may be the fault, as we do not know what the paper of to-day is either bleached or sized with. Another reason, the albumen may be in a stale state, as it used to be kept a long time to obtain a higher surface. Also, albumenate of silver may remain in the print, and cannot be removed by any known solvent without dissolving the image also. The atmosphere, again, plays an important part, especially sea air; as Mr. Henderson remarked, he has come across many more faded prints at the seaside than anywhere else, there being something in the sea air which will not only attack the image, but also the paper base, and is an action which we do not yet understand. The fault may also be in the fixing; the fixing bath should be slightly alkaline; also if the fixing bath is used too strong, which has the effect of dissolving the metallic silver, whereas a weaker bath will not.

The cards the prints are mounted on are still another cause; some cards contain impurities which are bound to come through the print.

In regard to the toning with lead and gold, Mr. Henderson said that Messrs. Lumiere had experimented to try and find traces of lead after toning in such a bath, and had come to the conclusion that the lead does not remain in a properly toned picture. Mr. Henderson also remarked that he could produce prints toned with lead and hypo only, and no gold. Such prints were made years ago, and are good to this day. In regard to the keeping qualities of albumen paper, Mr. Henderson gave a formula which was the result of 40 years' experience. The silver bath contains 40 grains to the ounce, a chief cause of blistering being in the use of a stronger bath; the preparation of the paper being three grains of citric acid and one grain of gelatine per ounce, which should be filtered through cotton wool or a sponge, and the paper floated for about four to five minutes, afterwards fuming with ammonia. The gelatine prevents the free silver being acted on so much by the air.

Mr. A. Haddon gave it as his opinion, that the fading of an albuminised print is not due to the paper itself, but rather to the albumen; especially is this the reason now that the albumen is fermented; also prints made on albumen paper now do not stand so well as those made years ago.

Mr. J. E. Hodd remarked that water no doubt plays an important

part in the fading of a print, as some waters contain injurious salts, which remain in the paper after the print is removed from washing water and hung up to dry, therefore it is a good plan to soak off as much moisture as possible before drying.

CORNISH CAMERA CLUB.

THE annual meeting was held last week. Mr. R. Pearce Couch, the vice-president, occupied the chair in the absence of Mr. Baily, the president. Mr. A. Pool, the treasurer, read the statement of accounts, which showed that the club started the year with a credit balance of £5 8s.; subscriptions received amounted to £23 17s.; making a total of £29 5s. The expenditure amounted to £26 19s. 1d., leaving a balance in hand of £2 5s. 11d. The expenditure was heavy owing to the extensive alterations and improvements effected, for which Mr. T. James was paid £10 6s. 3d. The accounts were unanimously adopted. Mr. R. Pearce Couch was elected president in the place of Mr. W. E. Baily; Mr. Henry Stewart was elected vice-president in the place of Mr. R. Pearce Couch, Mr. A. Pool was re-elected treasurer, and Mr. H. Tonkin was re-elected secretary. Messrs. W. Colenso, H. Wood, and H. Bradbury were re-elected on the committee, and Mr. Edward Uren elected in the place of Mr. Henry Stewart. Mr. W. E. Bailey was elected a patron of the club, and Mr. W. Bailey was re-elected auditor. A hearty vote of thanks was accorded the secretary, treasurer, and officers for their duties, and all present expressed pleasure at the position now attained by the Cornish Camera Club.

SOUTHAMPTON CAMERA CLUB.

THE members of the above club held the last meeting of their summer programme on the 29th ult., when the President, Mr. W. Burrough-Hill, occupied the chair. After the election of several new members, the deferred lantern slide competition between Messrs. Trigg, Compton, Jurd, and De Silva (who had tied during the winter programme competitions), took place, and after a very keen contest, resulted in Mr. A. De Silva winning the silver medal (given by the Rev. E. C. Bennett) with a splendid pair of slides, the winner being closely followed by Mr. W. H. Trigg. The 1902 Ramble Print competition was then conducted, the conditions being the production of three prints, by any process, from negatives obtained during two or more of the outings of the season. After a very severe contest, Mr. Geo. R. Johnson deservedly won the silver medal given by the hon. sec., Mr. S. G. Kimber. The contribution of the winner was a very fine series of toned platinotypes, representing scenes from "North Stoneham Park," "The New Forest," and "Salisbury Cathedral." The second place was taken by Mr. E. J. Evans, who pressed the winner very closely with an admirable set of prints in black platinotype, one being of "St. Cross," and two of "Salisbury Cathedral." The president then presented the silver medals referred to above, and also one given by Mr. W. Jarvis, to the holder of the greatest number of club certificates of merit, for the print competitions of the season. This medal was won by Mr. R. E. Jurd, who won certificates for "Portraiture," "Animal Studies," and "Snapshots." The following club certificates of merit were also presented for lantern slide competitions: Mr. R. E. Jurd, "Still Life"; Mr. W. H. Trigg, "Architecture"; Mr. J. T. Compton, "Landscapes," and Mr. A. De Silva, "Animal Studies." For print competitions, Mr. A. De Silva, "Landscapes," and Mr. C. C. Cook, "Architecture." It was announced that the "Winter Programme" will commence on the 13th instant.

DECIMAL ASSOCIATION.

THE report of the executive committee, which was issued on June 4th last, referred to the efforts they were making to bring before the Conference of the Colonial Premiers the question of adopting the metric weights and measures throughout the British Empire. It is most satisfactory to record that one of the final acts of this Conference was the passing of a resolution in favour of the proposed reform. This is regarded as a most important step in advance, and should greatly facilitate legislation in the House of Commons. The Committee are also pleased to report that as further evidence of the rapid growth of popular opinion since June 4th, twenty-six more Members of Parliament have signified their approval of the Association's programme. There are now 292 Members pledged to support a Bill in the House of Commons.

Information has recently been received from the United States which shows that there is every prospect of a Bill being passed at the next Session of Congress, by which the Metric Weights and Measures will be rendered compulsory in all the State Departments at Washington (other than those which deal with the survey of land), to be followed later by the general adoption of the system throughout the country. The Executive Committee have, as a matter of national pride, been most anxious that this country should lead rather than have to follow the United States, and all who are in favour of the aims of this Association are urged to do their utmost to stimulate the movement. On the initiative of the Lord Mayor of Sheffield, the Town Council of that city recently passed a resolution in favour of the adoption of the Metric Weights and Measures throughout the British Empire. Copies of this resolution were forwarded from Sheffield to over 400 Town and County Councils. Many of them have acted on the suggestion, and after passing the resolution have notified the Board of Trade and the Members of Parliament representing their division. The following is a copy of the resolution referred to:—
"In the opinion of this meeting it is most desirable in the interests of education and commerce that the Metric System of Weights and Measures should be made compulsory throughout the British Empire, after the lapse of such time as may be necessary for preparing for the change from the present system. That a copy of this resolution be forwarded to the President of the Board of Trade and to local Members of Parliament."

It will be seen that a considerable amount of pressure is now being brought to bear upon the Government, and the present is a most favourable time for strong action.

CROYDON CAMERA CLUB.

THE opening of the winter session took place on Wednesday, the 1st inst., and drew a crowded attendance of members, who were addressed by the President (Mr. Hector Maclean, F.R.P.S.) on photography in general and the club affairs. In the course of his observations, he drew attention to many instances which had come to his notice of members of photographic societies ultimately acquiring positions of distinction and emolument, their initial photographic knowledge having been acquired by attending the meetings. Besides many other interesting topics ably dealt with, special attention was drawn to a collection of 57 prints arranged on the walls, all of which had been taken in the course of five days during the holding of the Convention at Cambridge by Coun. J. Noaks. These he regarded as unusually good examples of sustained topographical work. Later on the President explained the working of the Kodak developing machine, and successfully developed a spool by its aid.

During the evening the hon. sec. (Mr. E. A. Salt) showed two novelties of the Autotype Co., one being a matt double transfer paper having a medium rough surface, which he thought a welcome departure, the other being a pyramidal grain single transfer paper, especially suitable for small work. Mr. S. H. Wratten exhibited an ingenious little invention of his own in connection with a glue pot, the formation of thickened scum on the surface of the liquid glue being prevented. Mr. L. G. Kough showed a new kind of silver paper which might shortly find its way on the market. Capital tones were obtainable with a solution of borax without gold.

By the kindness of Sir David Salomons (a vice-president of the club), the members paid a visit to Broomhill on Saturday last, the Eastbourne, Hove, and Tunbridge Wells societies being also included in the invitation. Over 80 guests were present, and a really enjoyable time spent.

Sir David gave some interesting displays of "trick" cinematographs, and a short concert on his electrical orchestration. A fine display of motor cars was also on view, including one which cost £1,800. Apart from these special features, Broomhill itself may aptly be described as a "Mansion of Marvels." A hearty vote of thanks to Sir David Salomons, proposed by Mr. Joseph Chamberlain (hon. sec. of the Tunbridge Wells society), seconded by Mr. Maclean, and supported by the representatives of the other societies, was carried with enthusiasm.

Commercial & Legal Intelligence

VELOX Postcards.—Messrs. J. J. Griffin and Sons, Limited, of 20-26, Sardinia-street, Lincoln's Inn-fields, W.C., draw our attention to their Velox postcards. These are put up in packets of twelve, and sold at 1s. In each packet Messrs. Griffin include one border negative and mask. Different negatives are put in the packets. Velox postcards are manipulated in precisely the same way as Special Velox, and they take ink readily without any tendency to smudging. For the convenience of their customers Messrs. Griffin put up the border negatives and masks separately in boxes of twelve assorted at 1s.

COMPENSATION for a Photograph.—In the London Sheriff's Court on Monday last, before Mr. Under-Sheriff Burchell and a special jury, the claim was heard of Mr. H. J. Dalby, photographer, of Woolwich, against the Woolwich Borough Council, for compensation for disturbance. It appears that the Woolwich Borough Council has secured powers to take the premises 82 and 83, Wellington Street, Woolwich, along with others, as the site of new municipal buildings which they proposed to erect. Mr. H. F. Dickens, K.C., and Mr. Corrie Grant were for Mr. Dalby, and Mr. E. Boyle, K.C., with Mr. J. Courthope Munro, appeared for the Woolwich Borough Council. In the course of the hearing, the sum of £300 was settled as far as compensation for loss upon fixtures, stationery, etc., was concerned, Mr. Dalby to be entitled to remove everything, and the nett profits of the business were agreed at £675 per annum; and for Mr. Dalby it was contended that the rental value of the premises he was to give up was £250, although as recently as 1900 the nett assessment was only £93. Further, for Mr. Dalby, it was argued that he would have almost insuperable difficulty in securing premises from which he could carry on his business as advantageously as before. For the Council, evidence was given to the effect that £165 or £170 was the outside value of the rental of the premises, and that 500 guineas would be ample compensation for disturbance. The jury awarded Mr. Dalby £2,000, including £300 for loss on fixtures, etc.

THE Science of the Workshop.—In a paper on this subject read by Mr. William Taylor, of Leicester, before the British Association at Belfast, it is complained that technical schools do but teach more or less backward shop practice, so that the workman out of the shop cannot really improve his knowledge or practice by attending a school. Yet there is a science of the workshop. Its material is scattered in books and papers, and much is known to men of experience, but the author knows of no attempt to gather such knowledge into more attainable form. The teaching of the shop has been all wrong. The schools cannot teach methods, but have tried to do so and have failed. What they should teach is principles, as embodied in the physical properties of materials and their effect on cutting and shaping, stresses generally, photomicrography, alloys, the flow of solids; these are all examples of the science which underlies shop work. How little, for example, is known of tool steel

by most shopmen! How blind we have all been to the action of superheated steam on cast iron. Look at the failures to make a satisfactory boiler stay-tap, the money lost in striving to secure an even contraction of the hardened tap. Take the question of flow of metals. It is said that a milling cutter of 3in. to 4in. diameter with deep teeth on face and edges has actually been formed cold from a blank by hydraulic pressure. Time to allow of flow appears to be an element in all processes of rolling, extension pressing, etc., of metals, but there is no written matter to teach others. So many of the best shop men do not or cannot write; we use the word in its narrower sense. It is a pity it is so, for much valuable knowledge is lost for lack of the setting of it down, and too often when handed down by tradition the essentials become blurred and debased. Practice soon forgets scientific reasons, and loses its best part. The decadence of the workshop tends to keep out the better men, and shop work becomes set apart as a thing to be avoided. The science of tools and materials can alone add something to the sordid life of the shop. There are so many half-known facts to be explained. Why will a saw that cuts steel break to pieces if set to cut copper? What limits or fixes the speed of various cutting or abrading agencies? Cannot our technical schools teach the principles that enable men to think out these matters? This is what they should attempt.

THE Metric Weights and Measures in U.S.—The Secretary of the National Bureau of Standards at Washington has recently sent the British Consul General in New York the following resume of what has been done in the United States:—"In 1893, in accordance with the order of the Secretary of the Treasury, April 5th, 1893, the metric prototype standards, the metre and kilogram, were adopted as the fundamental standards of the United States, from which the standard yard and pound were to be derived. As you know, the international postal rates are based exclusively on the metric system, and all the larger offices in the United States are provided with metric scales. Metric weights are used in the coinage of all the subsidiary silver currency. Our five-cent piece also is exactly two centimetres, and weighs five grams. All the states and territories of the United States have been provided, by order of Congress, with carefully-prepared copies of the metric standards. Congress authorised the signing of the Convention of 1875, establishing the International Bureau of Weights and Measures, for the construction, care, and comparison of the metric standards. As you are aware, the metric system has been for many years, and is to-day, the legal standard in Porto Rico and the Philippines. In 1894 Congress adopted the international units of electrical measurement, which are based entirely upon the metric system." From the above it will be seen that the United States have taken a long step towards the adoption of the metric system, and as far as their fundamental standards are concerned, they are to-day upon a metric basis. The Secretaries of the Treasury from 1847 down have repeatedly urged upon Congress the importance of adopting the metric system. The delegates representing the United States in the Pan-American Congress of 1889 were instructed by the Secretary of State to favour the adoption of the metric system as the basis of the unification of the weights and measures of all the countries represented. Among the Associations favouring the system are the National Board of Trade of the United States, the American Steel Association, the American Export Association, the American Institute of Electrical Engineers, the New England Cotton Manufacturers' Association, the National Association of Builders, the American Chemical Society, the American Medical Association, the National Academy of Sciences, and the American Metrological Society. The Committee of Coinage, Weights and Measures, to which a recent Bill on the subject was referred for consideration, adopted a favourable report by a vote of 15 to 2. The matter will probably come up early in the next Session of Congress.

THE Right of Privacy in the United States.—A trade-mark case of unusual interest was recently decided in the Court of Appeals of New York State. The case in question, *Roberson v. Rochester Folding Box Company and the Franklin Mills Company*, appellant, involved the right of the defendant to use the plaintiff's portrait as a poster in advertising the Franklin Mills flour. In this State no precedent for such an action is to be found in the decisions of the Court of Appeals. For that reason the decision now handed down is one of considerable legal importance. Chief Justice Parker, who wrote the prevailing opinion, held that the right of privacy—founded upon the claim that a man has the right to pass through this world without having his picture published, his business enterprises discussed, his successful experiments written up for the benefit of others, or his eccentricities commented upon—would, when recognised to the fullest degree, result not only in a vast amount of litigation, but litigation bordering upon absurdity. For, the right of privacy once legally asserted, it would necessarily be held to include the same thing if spoken instead of printed; for one, as well as the other, invades the right of privacy. On grounds, therefore, of public policy, and on examination of the authorities which have indirectly dealt with similar cases, the Court was led to the conclusion that the so-called right of privacy has not as yet found an abiding place in our jurisprudence, and that the doctrine cannot now be incorporated among our legal principles without doing violence to settled principles of law. It therefore seems that there is no possible means of preventing one's picture from being used as an advertisement. But the plaintiff always has his action in tort, if he can show that he has suffered actual injury. Furthermore, the New York Penal Code provides ample punishment for the malicious publication of pictures. In his dissenting opinion, Mr. Justice Gray holds more liberally that an individual has a right to privacy, which he can enforce, and the invasion of which equity will prevent. The right of privacy, in Judge Gray's opinion, or the right of the individual to be left alone, is a personal right, which is not without judicial recognition and is the complement of the right to immunity of one's person. The common law regarded individual personal property as inviolate. When,

as here, there is an alleged invasion of some personal right or privilege, the fact that early commentators on the common law have not discussed the subject is of no material importance in awarding equitable relief. Judge Gray takes the broad view that, because the preventive power of a court of equity has not hitherto been exercised in analogous cases, no valid objection can be made to the assumption of jurisdiction in the particular circumstances of the present case. The performance of an act by a defendant which is wrongful because constituting an invasion in some novel form of a right to something which is conceded to be the plaintiff's, and as to which the law provides no adequate remedy, should be enjoined. The case came up before the Court on demurrer from the Appellate Division, the opinion of which was reversed, the Court standing, four for reversal and three for affirmance.—"The Scientific American."

THE R.P.S. EXHIBITION.

To the Editors.

Gentlemen,—Those who have the welfare of the Royal Photographic Society at heart must have noticed, with feelings of approaching consternation, a curious fact in connection with the pictorial section of the present exhibition. Three members of the Selecting Committee, and also some members of a certain postal club, have an overwhelming number of pictures accepted.

The figures for three members of the Selecting Committee are:—

Mr. J. Page Croft	6
Dr. Llewelyn Morgan	5
Mr. J. C. Warburg	5

The total number of frames in the pictorial section is 290, contributed by 177 exhibitors. If the contributions of these three are subtracted the numbers are 274 frames and 174 exhibitors, or an average of 1.5 per exhibitor, while these three members of the Selecting Committee contribute 16 between them, or nearly four times the average, and the general average would be lower if the works of the members of the postal club alluded to were excluded from the calculation.

A Selecting Committee should be above suspicion, but when members accept their own work four times as liberally as that of others, can they claim to appear so? This fact is the strongest possible evidence of the utter unfitness of these men for the task that they have undertaken, and of the principles that have apparently influenced their decisions. The quality of their work does not affect the question. If it were the best in the room instead of being as crude as it is, the argument would still remain the same. The acceptance of their own works in much greater numbers than those of others is the fact that condemns them hopelessly. There can be no confidence in their judgment.

There were some men on the Selecting Committee whose ability and impartiality are beyond question. It would be interesting to hear what explanation they can give. Did they protest? Were they out-voted? It would also be interesting to hear what Messrs. J. C. Warburg and J. Page Croft can say in defence of their position. It appears, in the absence of explanation, to be absolutely indefensible.—I am, Sirs, yours truly,

HENRY W. BENNETT.

Granville House, Arundel Street, London, W.C.

To the Editors.

Gentlemen,—Each year I consider the exhibits in the pictorial section more disappointing. Being photographer to practically the largest firm in London, and having close on twenty years' experience, I know for a certainty that if I turned out work similar to 75 per cent. of the pictures (?) hung, my place would not be worth twenty-four hours' notice.

Where is the pictorial effect, say, in Nos. 8, 107, and 148? The last number, I notice, is "Not for Competition," and no doubt the exhibitor knew it would otherwise have failed to be accepted.

Again, No. 152, "Really," this is beyond comprehension, how it ever was allowed to be hung. I wonder if any of the judges knew what the "Smear" is supposed to be. Of course, this is also "Not for Competition." No. 245 (medal).—I would ask any artist to try and find the "Roses." Unless it was labelled, no one would ever have dreamed roses were supposed to be there, and the gardener, undoubtedly, looks like a "doctor of science."

How on earth No. 279 could have been chosen for a medal, words fail me. There are four or five dead black trees, stuck up in the sky, without absolutely any foreground. My poor pictorial mind would, without doubt, have chosen No. 277 in place of the "black sticks."

I understand that 1,700 pictures were submitted, and only 290 hung. Would it be possible another year to engage an extra room for the

Rejected," and charge admission? I feel sure a good round sum would result. It would give the profession an idea of the great anxiety and trouble the judges had in selecting. I would be glad if some competent artist would answer following:—

1. Why are "Fuzzy Wuzzy" (or out of focus) photographs considered artistic?
2. Are there any professional photographers exhibiting in the pictorial section or only amateurs?
3. Would any photograph absolutely in focus be accepted and hung? The professional exhibits are well worth studying for hours, but in the pictorial section, taken it all through, should never have seen daylight.

I asked a well-known artist his opinion of the pictorial section whilst viewing same. He was candid, and expressed rather stronger views than my own, and finished with the remark, "The judges should be given an opportunity to state their reasons why absolutely 'unpictorial, unartistic' pictures were ever allowed to be hung as representing the art. Perhaps they had no option."

In conclusion, Mr. Editor, allow me to say I am not one of the exhibitors and never exhibited, nor do I know personally any exhibitor.—Yours faithfully,
M. R. P. S.
P.S.—I enclose card.

C.C. PAPER.

To the Editors.

Gentlemen,—For the past week or two there has been quite a host of correspondence on the C.C. Printing-out Paper. For the past ten or twelve years I have used nothing else. In looking over my old prints I cannot find one faded or showing spots. There are many advantages to be gained in printing on C.C. The first is the rapidity of printing (about half that of albumenised paper; (2) no spotting of negative while printing in damp, winter weather; (3) greater ease in toning in comparison with albumenised paper; and (4), the time one may keep the paper or the prints after printing without showing any bad effects. (A print was left by accident in the printing frame for over six months, when toned and fixed, and no difference could be observed from one freshly printed and toned.) I do not write as a novice in this style of printing. I have printed as much as a ream in a week, and in sizes 25in. by 16in. I have seen a batch of fifteen of half size hung up to dry and not a defective print in the lot. There is very little chance of this occurring if the prints are treated with due care. I always put my prints through a 5 per cent. solution of common salt, and thoroughly wash them before toning, to make certain that all the salts of silver are converted into chloride of silver. You may call it a fad, if you will, but this mode of treating them I have practised for more than thirty years, and during my whole experience I have never been troubled with white spots. The printing is not conducted by highly paid male operators, as I have found girls do the work equally as well.

One correspondent says he has given up C.C. paper, as it is easily scratched; for the same reason he might as well give up carbon printing, as it is quite as easily damaged by scratching.

I have not the same experience of the C.C. Mat. Paper, and it is quite possible that the short time that it is allowed to be in the gold bath may tend to a want of permanency.—Yours, etc.,
JOHN STUART.

Studio, Helensburgh,
October 6th, 1902.

To the Editors.

Gentlemen,—Since writing you on the subject of C.C. matt, I have looked up three photographs of American origin by this process (toned gold-platinum), and find they are in absolutely perfect condition. Two of them are four years and the other six years old, but they have been framed all the time. This is reassuring.

I had last year a very similar experience to Mr. Lang Sims. Having placed some pictures face to face when not quite dry to make room, I found them next morning quite spoilt with spots.

My impression is that matt C.C. plat toned is all right if kept perfectly dry, but dampness seems more fatal to it than to any other process; but I would cheerfully welcome any facts on the subject. I deprecate Mr. Hewitt's idea that C.C. is used by photographers to defraud their clients. Of course, some may so do, but to my mind platinum-toned C.C. is far superior in appearance to genuine platinum, and many of my sitters think the same. The egg-shell gloss improves upon the crudity of platinum paper.

Then again, it is not the inability to produce suitable negatives for platinum printing that causes photographers to use C.C.

Mr. Hewitt doubtless knows that to produce a really good platinum toned C.C. print as good a negative is required as for a genuine platinumotype. A thin, waxy negative is useless.

Personally, I sell C.C. prints for what they are, and do platinumotype, if demanded, from the same negatives.—Yours,

OTHELLO.

October 4th, 1902.

LECTURES ON THE FOCAL PLANE SHUTTER.

To the Editors.

Gentlemen,—Our Mr. Eustace F. Wallis is arranging for a number of lectures during the coming winter to various photographic societies upon "The Focal Plane Shutter," and, as there may be some societies whom we have not written to, we shall be glad if you can find space in your valuable paper to make the announcement that we shall be pleased to receive communications from the secretaries as to date, etc.

The lecture will be illustrated with lantern slides and apparatus, and will be a useful explanation of the action of shutters, lenses, etc., given by a lecturer well acquainted with his subject, and accustomed to giving popular addresses.—Yours faithfully,

WALLIS BROS.

Kettering, October 2nd, 1902.]

ORTHOCHROMATIC PLATES.

To the Editors.

Gentlemen,—We notice your remarks in this week's JOURNAL re orthochromatic plates, and in reply to them, beg to bring to your notice the fact that such a plate as you mention has been upon the market now for about three months. We refer to the orthochromatic plates made by Westendorp and Wehner, and for which we are sole agents. These plates are specially sensitised for the yellow and green rays, and consequently do away with the use of a yellow screen. They are extremely rapid, yet can be developed in a proper ruby light with safety.—We remain, yours obediently,

EDMEADS AND Co.

30, Burchell Road, Peckham, September 29th, 1902.

EXHIBITION AT ST. PETERSBURG.

To the Editors.

Gentlemen,—The St. Petersburg Photographic Society, under the most august patronage of His Imperial Highness the Grand Duke Michael, Heir Apparent, and by permission of the Imperial Ministry of Finance, proposes to hold an international exhibition at St. Petersburg in the spring of 1903.

In transmitting herewith the programme and rules of the exhibition, together with blanks for information and inventory, the committee of the Society invite all persons connected with the Government, or with societies, and all private persons in England who may have photographic collections or who use the photographic process in any form whatsoever in their business, to take part in the exhibition. All English amateurs or professional photographers, and all manufacturers of photographic appurtenances are also cordially invited to exhibit.—Yours, etc.,

W. GRACHEFF, President; BORIS AGLAIMOFF, Secretary.

St. Petersburg, Fontanka, 64, September, 1902.

PHOTOGRAPHY AS A FINE ART.

To the Editors.

Gentlemen,—I have read the articles on above subject with very great interest, especially "F. V. C.'s" indignant letter, and "C. W. C.'s" straightforward question. The article referred to by "F. V. C." in the *Daily Mail* was written by a person who was ignorant of his subject, or else thoroughly in error. That photography is mechanical, in the hands of most photographers, is beyond dispute. The following is an instance. The photographer will take out his camera, take several views in the course of a few hours, and call the results (probably finished on highly glazed P.O.P. or bromide) pictures. The painter, on the other hand, will previously think out his subject, find out what time and sort of day most effective, and go time after time till he obtains the desired result.

The comparison is obvious. The photographer secures some ordinary photographs, devoid of any sentiment or pictorial interest, and the painter is repaid for his thought and perseverance with a picture expressing his feelings. If the photographic artist would adopt the painter's plan, he would then know if a broad or minute, delicate, or bold effect most in keeping with his ideas, and work earnestly and perseveringly, most probably have to come several times before he obtains a result in harmony with his thoughts. By finishing his picture in carbon, he will have nearly every known colour to choose from, and the picture so greatly under his control, that if he chose he could so alter as to be beyond recognition. It is at this stage where he has to emphasise or modify, as his feelings prompt.

By intention, I have omitted the intermediate stage between the taking and finishing of picture. If the picture has been thoroughly thought out, what alterations the photographic artist has to make, can be done on the carbon picture with much more truth and reality. If he has expressed himself with truth and conviction, the result will be a work of fine art, in the truest sense of the word.

I said the very great majority of photographers are mechanical. Why? Because they cannot see or express themselves in the same way as the artist. This difficulty may perhaps in some small way be overcome by studying art, but personally I think an artist is gifted from his birth, and that it cannot be mastered by any other. To be in any way

a fine art, photography must have an artist at the head, who has mastered the mechanicals (it can be mastered, and has to be), it will then be a fine art, in which he can show the poetical sentiments he desires.

In conclusion, I would ask our leading artist photographers, if they do not think it time to state their opinions in the daily papers? I certainly think the criticism now written on photography as a fine art will make our artists widen their thoughts and subjects, but we must also remember that the public are being convinced one way or other. Let our leaders, therefore, write at once to all the leading papers (laying aside all false modesty and non-de-plumes), distinctly and convincingly, to prove that photography is a fine art in the hands of an artist.—Yours, sincerely,
HERBERT BALL

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

A. Salmon, 169, Hampstead Road, N.W. Photograph of Canadian Arch, White hall.

J. Graham, 17, Ordnance Terrace, Chatham. Photograph of old Viaduct New Road, Chatham, demolished.

H. W. Harrison, 18, The Crescent, Bude. Photograph of "Rough Sea at Bude."

J. Rushton, Dockray Street, Colne. Three photographs of Colne Cricket Club.

ADDRESS WANTED.—L. AND W. E. BAKER write: "Can you oblige us with the address of the English representatives of the papers of the American Aristotype Company?"—In reply: So far as we know, the company have no representatives in this country.

BOOK WANTED.—PROCESS writes: "Would you kindly let me know which you consider the best text book containing instructions for making half-tone blocks; that is, with the screen?"—In reply: The book that will probably suit you best is "Half-tone Process on Zinc and Copper," by Julius Verfassner.

STALE PLATES.—HUGH ROSS writes: "Please say what is wrong with this plate. The whole box of them are marked more or less the same way. You will notice marks of paper that keeps the plates separate in box."—In reply: It is a case of stale plates. The plate sent has deteriorated by long keeping.

ADDRESS WANTED.—J. BENGHIAT writes: "Please let me know the address of any dealer in collodion materials, ferrotype plates, etc."—In reply: Messrs. Mawson and Swan and the Autotype Company supply collodion. Messrs. Fallowfield, Charing Cross Road, supply all the necessary materials for working the ferrotype process, and make a speciality of them.

BOOK WANTED.—W. F. writes: "Could you give me the name of a good book upon bromide printing and enlarging? I want something beyond the ordinary text book; something suitable for an advanced operator."—In reply: The best book we know of is "Bromide Paper: Instructions for Contact Printing and Enlarging," by Dr. E. A. Just. Any of the dealers will procure it for you; the price is 1s. 6d.

TRANSFERRING P.O.P.—INQUIRER writes: "Would you kindly inform me of a simple method of transferring a small P.O.P. print on to a silver locket?"—In reply: Mount the print, after being alumed, face downward on the locket with starch. When dry, abraid the back of the paper, and, after moistening it, carefully rub it away with the finger. It will require some little patience to do the work successfully.

PLATE FOR COPYING.—TENWICKE writes: "May I trouble you to tell me what would be the best plate, etc., to use in copying some old oil paintings? Would a yellow screen be necessary, as I have not one? Never having copied paintings, shall greatly value any hints you may kindly give."—In reply: Use one or other of the isochromatic plates as now supplied by most of the makers. The results will be much better if you employ a colour screen than if the pictures are copied without one.

PRINTING PROCESS.—VERY LATEST writes: "I should esteem it a favour could you inform me where I can get a paper so fashionable in U.S.A. It has a soft, velvety appearance, quite like a down on the surface. It is in black and white, but rather a brown tone in shadows."—In reply: There are several papers made in America that are not on the English market. We do not know of any that answers your description. Had you sent us one or two specimens to see, we might possibly have been able to help you.

DEVELOPER STAINS.—A. H. S. writes: "I got the recipe, as below, from your valuable JOURNAL, and have found it to be an excellent one. There is but one drawback, namely, it stains the fingers very badly. Could you give any remedy for this defect? Metol, 80grs.; hydroquinone, 8grs.; soda sulphite, 200grs.; soda carb. sicc., 360grs.; potass bromide, 10grs.; water up to 20ozs."—In reply: If

care is taken in handling the plates, the fingers will not be stained. Hold the plates only by the edges, and rinse the fingers under the tap after contact.

PORTABLE STUDIO.—C. J. FARMER writes: "I am about to have a portable studio made on wheels to go to villages with. Could you give me a few hints on the size and the light for same? I thought of having it 18ft. long."—In reply: Eighteen feet would be short for the studio; four or five feet longer would be preferable, and the width might be, say, nine or ten feet. We should suggest that all one side be opaque, and, say, four feet six inches at either end of the other side also opaque; the rest glass, to about eighteen inches to two feet from the floor.

BOOK WANTED.—E. G. B. writes: "(1) Can you tell me if there is such a work as 'The Chemistry of Photography'? If so, what is the price, and who publishes it? (2) In toning Alumenised Paper, is a grain to a sheet (the usual size) about the right proportion for the gold?"—In reply: (1) Yes: Meldola's book. The price, we think, is 2s. Or "Chemistry for Photographers," by Townsend, price, 1s. These books may be had through any of the dealers. (2) From one to two grains will be required for each sheet, according to the depth of toning. For light red-brown tones, a grain will suffice; but for purples more will be necessary.

EXPOSURE.—G. DUNKERLEY writes: "Could you kindly inform me the exposure required, under favourable conditions, to photograph the forthcoming comet; say, with Imperial special rapid plates and stop f/10? Also whether any precautions will have to be taken to counteract the effect of its motion."—In reply: We are unable to give any idea whatever, as the light from the comet is so feeble. You can only arrive at the exposure required by a few tentative experiments. We do not expect you will be very successful with an ordinary camera, unless it is mounted in the same way as an astronomical telescope is, to follow the motion of the comet.

PYRO-STAIN WANTED.—STAIN writes: "Can you suggest any liquid that would be suitable for imparting to negatives a similar yellow-brown stain to that on negatives developed with pyro-soda? I find old pyro-soda developer is unsuitable for several reasons, and the colour left by ammonium picrate is a lemon-yellow, which seems to lack the printing-quality of the pyro-stain."—In reply: Any of the soluble-in-water coal tar colours will stain the film, but we do not expect that any of them will yield the same results as the stain of a pyro-developed plate. Old pyro solution will probably give the best result.

URANIUM INTENSIFIER, ETC.—E. STANLEY writes: "Please say if, with uranium intensifier, you simply bleach white and then redevelop in daylight. If there is a better method, kindly let me know. I do not care to use mercury, on account of its poisonous nature. What is the best preservative to keep paste mountant for six months?"—In reply: Simply use the formula as given. There are many different ways of intensifying negatives (see pp. 1,077-8-9 of the Almanac). Although the bichloride of mercury is poisonous, with ordinary care you would not be likely to suffer any ill-effects from its use. The best preservative would be a small quantity of carbolic acid, but we should much prefer to always use paste freshly made.

P.O.P.—DUSSELDORF writes: "Can you tell me of any book of instructions for working P.O.P. with the combined bath? I have been used to the separate bath till I came to my present place at Derby, where I had to get into using this combined bath. I manage it fairly well, but do not get the tones the same one day as the next. I make the bath very carefully, and try all I can, but I'm afraid if I don't improve I shall lose my berth, and that I should be very sorry to do. Could I get a book from the makers of the paper that would explain defects and troubles of combined baths?"—In reply: You should have no difficulty in working the combined bath, if you follow the instructions issued with the paper you employ. We do not think any of the makers of papers issue a book specially on working with the combined bath. Usually the combined bath is considered easier to work than the separate toning and fixing method.

* * * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOK-SELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published early in December next. This year's ALMANAC reached a total of 560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The edition for 1903 will be increased to 25,000 copies, a large number of which are already ordered.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1903. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

Secretaries of societies will oblige us by promptly for-

warding lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, etc. Those firms who wish to take advantage of this feature should communicate with us not later than October 31.

The publishers ask us to remind advertisers that many of the advertisement pages of the ALMANAC are already booked, and that, to ensure insertion and good positions, orders and copy should reach them without delay.

EX CATHEDRA.

American Optics.

"The Greatest Show on Earth!" The invention of this phrase will keep green the name of Barnum for many generations. It appealed most effectively to the patriotic bias of the American people, and thus became a splendid advertisement. Mr. Worcester R. Warner, of the American Association of Opticians, may claim a high position in the esteem of his fellow-countrymen as an exponent of the art of Spread Eagleism, if the following extract from the *Optical Journal* correctly represents him:—"The modern system of making objectives by the scientific method, instead of the old cut-and-dry plan, has given us the best telescopes ever made. This system first calls for small prisms made from the same glass as the objective. These prisms are carefully tested and their indices of refraction determined, from which data the curves of the objective are computed. Carefully made appliances enable the optician to work closely to these computed curves, thus producing the most nearly perfect objectives ever attained. We may be justly proud of the fact that this system is wholly American, and its success is so marked as to ensure its early adoption by all makers of telescope objectives, who can master the optical and mathematical principles involved." Mr. Warner must be a bold man to expect that we should shut our eyes and swallow optical pabulum of this kind. It may appeal to an American audience, but we respectfully decline to believe him, unless he can offer us some evidence for his assertions. We are old-fashioned enough to believe that we are indebted to Fraunhofer for the method of determining the refractive index of glass by means of a prism. His determination of the lines in the solar spectrum opened the way to the exact computation of the curves of an object glass. Dr. von Seydel supplemented the work by giving us the formulæ for computing the path of the extra-axial rays. Is this the cut-and-dry plan which has been superseded by American opticians? Per-

haps the *Optical Journal* can supply us with further particulars.

* * *

The Artigue Process.

From the *Revue Suisse de Photographie* we gather some interesting particulars concerning the origin of this photographic process, by which very beautiful results may be obtained. Monsieur Eugène Rouge writes that Monsieur F. Artigue made the discovery in 1878. It had been his habit to copy architectural drawings by coating paper with a colloidal substance containing pigment, and after exposure developing it with cold water and a sponge. On one of these drawings a water-colour sketch had been made, and after development it was found that the sketch had been very perfectly reproduced in half-tone. Unfortunately, Monsieur Frédéric Artigue died before he could complete his experiments, but his son, Monsieur Victor Artigue, recognised the value of the process, studied it and perfected it. The first prints were exhibited at the International Exposition of 1889. The paper may now be had as a commercial article. It requires some dexterity in manipulation and does not keep well after it has been sensitised, but some very fine results may be obtained by its means.

* * *

Modulation in Portraiture.

In an article on "Questions of the Day," published in the *Atelier des Photographen*, the merits of the old portrait lens for studio use are discussed in comparison with modern anastigmats. The complaint of the professional photographer is put in a rough and ready form by the statement that X.Y.'s anastigmats are advertised for a 10in. x 8in. plate, but will not give a good carte de visite half-length portrait. The image is flat, without pluck, the high lights are wanting, and there is no modulation. "The old Dallmeyer portrait lens of thirty years ago suits me much better, and it gives a portrait of far better quality." The writer of the article admits that the photographer is right, if he compares the image obtained with a portrait lens of large aperture with an anastigmat of only moderate intensity, but maintains that the difference is entirely due to the larger relative aperture of the portrait lens. In illustration of this, he recommends the photographer to take a lens of large aperture and insert a stop with two small apertures as wide apart as possible. If a bust or some similar solid object be focussed, only one plane will be in sharp focus and the image will be double in the other planes. From this it will be seen that the various parts of the surface of the lens are different points of view, each forming a more or less different image. The result is a diffusion of the image in all parts of the picture, excepting the plane which is accurately focussed. This diffusion, contrasted with the sharp portions of the image, gives atmosphere and relief. Whilst this is true, we do not think this accounts for the whole of the difference between portrait lenses and anastigmats of the same rapidity. The portrait lens has a round field and a small area of fine definition. The anastigmat has a flat field and a large area of fine definition. Consequently the photographs must differ far more in sharpness than the writer accounts for by his experiment. In dealing with the bust, the professional photographer can urge very good reasons for his preference for the old Petzval lens.

* * *

Deceptive Trade Statistics.

The well-known saying, that you may prove anything from statistics, is well illustrated by a paragraph in the *Photographische Chronik*. We should not draw attention to it

but for the fact that it deals with figures which must be of great interest to those who deal in photographic goods. The writer prefaces his remarks by the statement that whilst foreign photographic apparatus is preferred in Germany, although the home-made articles are better, foreigners are so convinced of the superiority of German goods, that the efforts of other countries, especially France, have had but small success in securing foreign trade. Definite statistics are given by Belgium, whose imports of scientific apparatus were the following:—

	From Germany.	From France.		From Germany.	From France.
	fs.	fs.		fs.	fs.
1891 ...	520,000	305,000	1896 ...	537,000	426,000
1892 ...	430,000	296,000	1897 ...	578,000	590,000
1893 ...	371,000	275,000	1898 ...	590,000	489,000
1894 ...	419,000	277,000	1899 ...	597,000	452,000
1895 ...	414,000	302,000	1900 ...	712,000	502,000

At first sight these figures appear to be strikingly in favour of Germany, but a closer analysis will show that France has made very substantial progress, and that Germans may be deceiving themselves by a very plausible statement of the facts. If we take the entire trade for the period of ten years the percentage of German goods is 57.5. The following are the percentages for each year, and it will be seen that Germany only rose slightly above the average in 1900:—

1891.	1892.	1893.	1894.	1895.	1896.	1897.	1898.	1899.	1900.
p.c.									
63	59	57	60	58	56	54	55	57	59

If we compare the progress of the trade of both countries, taking the year 1891 as a basis, the figures are considerably in favour of France, viz.:—

	1892.	1893.	1894.	1895.	1896.
	p.c.	p.c.	p.c.	p.c.	p.c.
Germany	- 17.3	- 28.6	- 19.4	- 20.4	+ 3.3
France	- 3.0	- 9.9	- 9.2	- 1.0	+ 39.7

	1897.	1898.	1899.	1900.
	p.c.	p.c.	p.c.	p.c.
Germany	+ 11.1	+ 13.5	+ 14.8	+ 36.9
France	+ 63.9	+ 60.3	+ 47.5	+ 64.6

Even the volume of the increase is in favour of France when we compare the year 1891 with 1900. It will be seen that Germany's trade increased by 192,000fr., whilst France's advanced 197,000fr. In other words, although France exported to Belgium in 1891 about two-fifths less than Germany, she has secured more than half of the increase of trade when we compare 1900 with 1891.

Invisible Guns. There seems to be quite a craze just now for making things invisible. Only the other day we pointed to the efforts which were being made in this direction in the case of our warships, which, for the future, are to receive a coat of grey paint. The position of artillery has already been screened from view by the use of smokeless powder, and now, on the initiative of an officer at Aldershot, the still further precaution is being tried of painting the guns, their carriages, and their limbers, of such a colour that they will be inconspicuous against all kinds of backgrounds, so far as that is possible. But the manner in which the guns tested, a battery of six, have been painted is certainly curious. Instead of giving them a neutral tone they are painted rainbow fashion, with streaks of red, blue, and yellow, and we are told that at a short distance these colours blend into a confused mass that renders each gun difficult to locate, whatever its surroundings may be. "At 800 yards," says the report from which we quote, "the outline of the gun is lost, whilst at a thousand it harmonises with trees, open grass land, sandy plains, or broken country." This is no doubt perfectly true, but exactly the same effect would have been produced by painting the guns with a good neutral tint, say, that pigment

known to artists as "Payne's Grey." We all know that, according to an old theory, a mixture of blue, red, and yellow should produce white. But in practice a dirty neutral colour results from their admixture. Even with the far purer tints employed by Mr. Ives to represent the three-colour sensations in his lantern kromskop, their mingling is very far from representing a pure white. To reach this ideal we must reconstitute the actual coloured rays forming the solar spectrum, as Sir Isaac Newton did long ago. But to return to the guns. It seems ridiculous that they should be disfigured in the way described, and we cannot imagine anything more incongruous than these harlequin-painted guns appearing on the parade ground in company with well drilled and well groomed soldiers. It is a fad based on ignorance, and the sooner that the gaily coloured weapons are painted over in a sober tint and made to look respectable the better.

* * *

A Notable Meteorite. It is a curious coincidence that, just at the time we were writing the other day about the rarity of meteorites one should have been seen to fall and captured in these islands. Another curious coincidence is that the fall took place close to Belfast, at the time that the meeting of the British Association was in progress there, for the event is one of such extreme rarity that it would naturally arouse the keenest interest among savants. A photograph of the meteorite has been published in the pages of our contemporary *Nature*, but we trust that a better reproduction will be available soon, for one cannot expect an ordinary newspaper print to show the delicate markings on the surface of such a stone. The story of this strange visitor is an interesting one. At a certain farm at Crumlin (Co. Antrim), about ten miles west of Belfast, on September 20th, at half past ten in the morning, a labourer was gathering apples. He suddenly heard a terrific and awe inspiring sound, and something dropped with a thud within twenty yards of the spot where he stood. Then he saw a cloud of dust rising from among the wheat close by, and on closer inspection found a hole in the ground. He ran to the farmhouse for a spade and dug that something up, from a depth of thirteen inches. It proved to be stone, very hot to the touch, which measured $7\frac{1}{2}$ by $6\frac{1}{2}$ by $3\frac{1}{2}$ inches, and its weight subsequently proved to be 9lb. $5\frac{1}{2}$ oz. This is the largest stone which has been seen to fall from the sky to the British Isles for 89 years, and is larger than any which has fallen in England itself since the year 1795. Of course, this visitant from space made a great impression on the populace, as well as upon the soil, and hundreds flocked to the farm to see the "thunderbolt." The news came to Mr. Fletcher, the principal of the mineralogical department of the British Museum, and he immediately telegraphed to Crumlin for further particulars. He had had to deal so often with reports of bogus finds of this character that he was cautious in his inquiries; but as this seemed to be a genuine case, he journeyed down to Crumlin and investigated the matter on the spot. His experienced eye at once saw that the meteorite was a true visitor from space, and he was able to gather from the eyewitness of its fall, all particulars concerning it. The farmer proved willing to part with his prize, and the Crumlin meteorite now reposes with other historic stones of the same kind at the Natural History Museum at South Kensington. The question naturally arises, "How many meteorites fall in the course of a year in unfrequented spots and get buried in the soil?" It is just a chance that this one had a witness to its flight, and we should think, seeing the thousands of

square miles of land that remain unoccupied even in these well-peopled islands, that many such falls must occur without anyone being aware of them. And as the sea covers nearly three-fourths of the globe, it is evident that the chances of a meteorite being drowned rather than buried are about three to one. There is an interest attaching to these metallic bodies which is quite peculiar to them, for they are the only substances which reach this earth from the immensity of space: reminders that there are other worlds than that upon which our lives are passed.

* * *

Irish**Photographs.**

In spite of the circumstance that great efforts have been made of late years to call attention to the beauties of the Emerald Isle, and to attract tourists there, it is obvious to those who visit our photographic exhibitions, that camera pictures of Ireland are not nearly so numerous as those which find their origin in other parts of the United Kingdom. The meeting of the Photographic Convention a few years back, at Dublin, had the natural effect of setting cameras to work at the Irish Capital and in its vicinity, and we may hope that in a minor degree the recent British Association meeting, at Belfast, may have operated in like manner. But the fact remains that Ireland is not the happy hunting ground of the photographic tourist that it might be. Some account for their abstention by political considerations, and some blame the hotel accommodation, but no one can truly say that the country does not offer much in the way of beautiful scenery. The lakes of Killarney are far famed for their wondrous beauty and their poetical associations, and it would be difficult to find a neighbourhood of greater grandeur than that presented by certain parts of Co. Antrim. There is one spot here which has only quite recently been made accessible by the engineer of the Northern Counties Railway Company, and photographers would do well to turn their attention to it. It is known as the Gobbins Cliffs, which may be described as a series of basaltic precipices, edging the sea for some miles. Along the face of these pillared cliffs the railway company have cut a path, and where there is need of such an aid to progress, they have thrown light girder foot-bridges from point to point. This is the case at one well-known spot, known as the Man-o'-War Sea Stack, a rugged pinnacle of basalt, which stands out from the cliffs, and has now been connected with the mainland by means of these steel connecting links. A good photograph of this grand place appears in the current number of the *Irish Naturalist*, which also calls attention to the number of sea birds, of seals and porpoises, which may be seen playing about the spot. There are also some curious caves to be explored here, among them one which has been closed by a fall of rock for the past forty years. The debris, estimated to represent a weight of 500 tons, has now been removed, and the cave is once more open to inspection. Most spots in this country of ours are overrun with camera bearers, but this one has hitherto been an exception, for the reason already given. It has been one of those few seaside places where access to the sea is forbidden by natural barriers. Such another place is Boscastle, on the northern coast of Cornwall, where one can walk for miles along the top of the rugged cliffs, and get occasional peeps of the waves far below, without a chance, unless at the risk of broken bones, of getting down to the sea-shore. Possibly some day an enterprising municipality will do for Boscastle what a go-ahead railway company has just done for Gobbins Cliffs in Co. Antrim.

THE IDEAL DARK-ROOM.

IF there is one thing above others connected with photographic practice which shows little improvement as compared with earlier conditions, it is undoubtedly the dark-room. Even the best equipped and most up-to-date of these indispensable chambers for development would hardly tend to make any worker of bygone days feel much ashamed of himself, or disposed to admit that nowadays we manage things better. It is certainly rather surprising, considering the striking progress that has been made in other directions, in cameras, lenses, plates and papers, and, indeed, photographic appurtenances in general, that so necessary and vital a matter as the convenience and comfort of the place in which the most important of our operations are carried out, should have attracted so little attention. Possibly the photographer has got so used to a philosophic belief that a certain amount of unpleasantness is inseparable from that stage of his work that he has not troubled his head about the matter, preferring rather to advance, when he does advance, on a line of lesser resistance.

We are not all alike, however, and instances, very rare unfortunately, may be found here and there of dark-rooms which are a joy and delight to work in, and a source of health and pleasure to their wise and fortunate possessors. The best example we ever saw of how things might be done, when thought and contrivance were cleverly directed on the subject was the dark-room of a most energetic and enthusiastic young photographer, who has just sailed for South Africa, with the intention of establishing a high-class studio in the Transvaal. It was a perfect model of the ingenious adaptation of every means and detail to the one end of producing good work with comfort and facility. Our friend had selected a fairly large room for the purpose, having as he averred a strong dislike to the "condemned cell" system of development. A large window of ruby glass provided the necessary illumination, which was artificial and proceeded from outside. Incandescent gas burners were used, and sufficed to give a bright and cheerful, but perfectly safe light all over the room. The plan of having them outside had, of course, the advantage of not taking away any of the interior air, and thus materially adding to the freshness and coolness of the room. The amount of light, it should be said, was regulated from inside. Our friend preferred as much as possible, which he quite correctly maintained was free from any risk if the plate were not held too near nor left uncovered too long.

The developing bench, which ran along one side of the room, was novel in construction. The upper part or shelf consisted of a number of round parallel wooden bars placed at about a quarter of an inch apart, so that all drippings and splashings would run down the spaces between, and yet sufficiently close to form practically a solid bench. These bars or rods were treated with a waterproof varnish or preservative of some kind, as indeed was all the woodwork in the room at all liable to contact with water or chemicals. Another new departure was in the sink, which instead of being, as usual, on a level with the bench, was placed on the ground, being formed in reality of a flooring of white enamelled tiles, the width of the bench, and sloping slightly inward towards the drainage openings. The outer edge of this novel sink consisted of a margin of glazed bricks, about six inches high, running the length of the room. The whole, in fact, reminded one in principle of the modern art tile and stone substitutes for fenders, that help to beautify many of our up-to-date drawing-rooms. The water supply was liberal and the taps numerous, each one provided with a rose to minimise

splashing. The pipes supplying the taps were encased in felt to secure a more equable temperature in winter another aid to which was to be noted in the fact that the hot air pipes which warmed the dark-room at that season were carried at a short distance below the water pipes. Truly a model arrangement! We were informed that very little trouble was found in developing satisfactorily even on the coldest days. A point about the developing bench which we must not omit to notice was its unusually low height. Inquiry elicited the fact that this original worker preferred doing most of his work sitting down, a position of comfort which his ingenuity and resource certainly seemed to entitle him to. At one end of the room was noticeable a rocking shelf, capable of holding perhaps a dozen whole-plate dishes, and kept in motion by a simple clock-work contrivance.

It goes without saying that so well regulated a dark-room was amply provided in the matter of shelves and cupboards. The chemicals, measures and solutions required for immediate use were kept on a handy and accessible shelf just above the bench, stock solutions and larger bottles and jars being relegated to a higher level. Instead of labels, each bottle had a square portion of its surface ground, and the contents written thereon in water-proof ink. Everything was most systematically grouped, also according to its chemical composition or the purpose for which it was intended.

On the opposite side of the room were situated the drying cupboards for plates, films, and prints; an arrangement in which our friend pardonably took some pride. The shelves of these cupboards were arranged at different distances, and grooved top and bottom to take different-sized plates. A thoroughly efficient current of air for rapid drying was secured by ventilators communicating outside, and prevented from carrying dust by muslin screens in front. The doors, it should be said, were practically air tight, and the whole treated with several coats of enamel paint. The cleanliness and practicability of this system scarcely needs pointing out. Drying boards were also reserved for films and prints. The ventilators were not only dust tight, but likewise prevented from admitting light, and the cupboard was occasionally useful, therefore, for dry-plate manufacturing purposes—a thing, however, which its owner rarely cared to meddle with.

The operations connected with the making of enlargements were well provided for, a good enlarging camera being one of the features of the place. Our friend distinctly preferred to use artificial light for this purpose, and we noted that again the lantern and source of illumination were placed outside the dark-room, the camera and easel being placed within. Heat and stuffiness were, evidently, to be rigorously banished. Near the ceiling, and stretching tightly from wall to wall, were numerous waxed cords, for the suspension of enlargements during the period of drying, which, owing to the admirable system of ventilation, took place rapidly. A few remarks on the more purely architectural details of this ideal dark-room may help to complete the general impression. The flooring was of some hard wood, naturally polished; the walls and ceiling were whitewashed. There was nothing special about the actual framework of the room, for it was not one that had been originally designed for photographic purposes. Its owner, indeed, expressed some satisfaction that, in his coming tropical field of action, he would be able to start entirely *de novo* in a building of his own design and construction, when he would be able to put into practice sundry ideas as to the best way of erecting walls, with a view to securing equable temperature all the year round.

We have here a sufficiently literal and prosaic presentment of what may be, and actually has been accomplished in the direction of the perfect dark-room, and the contrast between such a one as that just described and the average apartment that satisfies most of us may well form fruit for meditation. True as it undoubtedly is, that satisfactory and excellent work may be readily produced with a minimum of those labour-saving and comfort-giving conditions that we have shown are at all events within our reach, it requires but little reflection to see that the possibilities and potentialities of photographic achievement must be added to materially where what was once a task is made almost a luxury. There is still far too much that is old-fashioned and behind the times in our working methods and surroundings, and anything that can shake us for a moment out of a rooted habit of easy-going complacency, and lead us to the conviction that there may be other and better ways than our own, admirable though they may be, is to be welcomed as aiding the universal movement of progress that in the end benefits everyone.

THE ELECTRIC CURRENT IN THE STUDIO.

WHETHER regarded as a luxury for general use, or as a necessity for studio work, in some localities, through exigencies of atmospheric conditions, or a late hour of working, the use of electricity as a light producer, and for other purposes, is a boon whose value it would be difficult to over estimate; yet the question arises, Whether the general body of photographers are sufficiently alive to its importance; or, having adopted it, they sufficiently realise its possibilities or are acquainted with its commercial limitations? Particularly with regard to one aspect of the latter were we surprised recently at the ignorance of the owner of a studio who, some time ago, had a complete electric installation to replace his gas fittings. We should have deemed it entirely superfluous to have mentioned such a matter had we no viva voce proof of the need to do so, in this one instance, at least. We refer to the fact that when electric wiring and lighting have been installed it is needful, before bringing it into use, to acquaint the fire insurance office with whom the property is insured with the fact of the application of the electric current, whereupon they will either send an inspector or otherwise assure themselves of the work having been properly carried out, so as to insure freedom from undue fire risks. Having done this, they will endorse the policy with a certificate to that effect, indemnifying the insurer against loss through fire caused by the current. If such indemnity be not obtained, the policy, by its terms, would become void, and the insurer would have no remedy against fire losses through the electric current or any other cause.

Already electricity is used to a considerable extent as a power agent, for driving apparatus, small or large; for ventilation purposes; for actuating a motor; for drying negatives; and a variety of minor uses, the need for which seem to spring up as soon as the current is laid on.

Up to the present time the electric current is prohibitively costly for heating a room of large dimensions, but for apartments of smaller proportions its application is increasingly convenient. Many elegant and useful pieces of apparatus in the form of electric stoves are to be purchased. We are informed that the cost of the current for this purpose is less than might be imagined, from the readiness with which the current can be switched on or off as required. Indeed, this is one of the great advantages of the electric current as against gas or solid fuel. The various switches are almost always so placed as to involve a minimum of trouble in turning off the current, so that upon entering or leaving a room the switching on or off

becomes a mechanical routine act; while, as everyone knows, a gas fire or gas burner is usually left "on" if the room be left for a moment, a moment that sometimes is expanded into hours. For this reason, though the initial cost of electricity for a given lighting or heating effect may considerably exceed that of gas, the quarter's electric energy account not infrequently falls below the average gas bill for a previous corresponding period. In estimating the relative cost of gas and electricity this is a most important factor, but one too often lost sight of. In this direction the gain experienced through saving decoration expenses, owing to the great cleanliness of electric lightings, is now an old story, requiring nothing beyond a passing mention. Although, for heating large apartments—studios, for example—electricity may be costly, the local application of the current is so very convenient that its use may be recommended. For example, small studios with a special electric heating attachment complete, are now purchasable, and would be found extremely useful for many photographic purposes. We may now expect to have upon us the season of cold weather and low temperature in the water supply. The extent to which low temperature reduces the power of the pyro developer, for example, needs actually measuring before the full effects of its power in this direction is known. Indeed, we should not be wrong were we to state that at temperatures slightly above that of freezing point nearly twice the amount of pyro is used to produce a given density in a given time when compared with the same solution at, say 60deg. F.

The enthusiasm which surrounded the exponents of Röntgen-ray work has now entirely subsided, and, as far as we can learn, there are very few photographers who undertake the work. We think this falling off of interest is largely owing to difficulties in connection with the electric current. A large induction coil is a very costly instrument, and an excess of current would quickly lead to its destruction. We find that on the whole the preference is given to an "accumulator" for the current production. It has, of course, many objections; the accumulator once charged requires, for example, to be periodically recharged, as, otherwise, it would, if left intact for some considerable time, become quite useless. There is thus a primary inducement to use the current from the main, and if an efficient resistance be supplied, we think that for all the usual Röntgen work a photographer need fear no opposition.

It has been our purpose to include the use of electric light in the studios, but already we have exceeded the bounds of our space in dealing with one aspect of the subject, and we shall therefore leave over for another occasion the important question of the use of the electric light for studio purposes.

THE Perth Convention.—On Monday, September 22nd, a meeting was held at the rooms of the Society of Natural Science, in connection with the arrangements for the eighteenth annual convention, which, by the invitation of the photographic section of the above society, will be held next July in Perth. The Convention has been to Scotland on three previous occasions, viz., to Glasgow twice and Edinburgh once. The meeting has never been held so far north before, and doubtless many members will embrace the opportunity of making the acquaintance of the many attractions and beautiful scenery in the immediate vicinity of our city. Mr. Henry Coates is taking great interest in the forthcoming gathering, and Sir Robert Pullar will be president. An influential reception committee is being formed, and the meeting should unquestionably prove a great success. Usually between 300 and 400 members attend the annual convention. The programme will be opened with a conversazione, lectures and papers will be read at the evening meetings, excursions will be organised, and there will be an exhibition of pictures and photographic apparatus open free every day, so that the inhabitants of Perth and district will have ample opportunity of making themselves acquainted with the many up-to-date contrivances in connection with the art science of photography. The local hon. secretaries are Mr. A. Rodger and Mr. Mackenzie.—"The Perthshire Constitutional."

THE STABILITY AND THE FADING OF ALBUMEN PICTURES.

ALBUMEN paper, though far less used by amateurs and by some professionals than formerly, is by no means yet extinct among the better class of photographers who still employ silver printing. The same may be said with regard to those on the Continent and, possibly, in America. Gelatine papers, we think it would be safe to say, are proportionately more largely used in England than in any other country, but for what reason we shall not here inquire; it is only albumen paper we are now considering.

We have many albumen prints in our possession that have been in existence for forty years and more, that are still unchanged. In the course of a discussion on the subject the other evening, one of the speakers, it may be mentioned, showed a number of prints that he had himself made twenty years ago, and only one of them had faded. With these facts before us, it is clear that albumen pictures are not necessarily fugitive, and they show conclusively that if those which have faded had been treated precisely the same as those which have proved stable, they also would not have faded.

It will be interesting to consider some of the causes assigned for the fugitiveness of so many modern prints, and see how far they are really tenable. One suggestion is that the base may be at fault, as we do not know what the paper of to-day is bleached or sized with. Did we know that at any time? We think we are correct in saying, and we say it without hesitation, that the paper used for albumenising now is precisely the same as it was thirty and more years ago. This paper is, and always was, made in one of two factories—the Steinbach, Malmedy, and the Kleiber “B.F.K.” Rives, firms. Most of that now employed is that by the latter firm, and these two firms are the only ones that were ever able to supply a paper that could be successfully used for albumenising. These papers, we may safely say, are essentially the same now as they were in the early days, except in price, for since the “combine” of the two concerns, their price has been considerably increased. Hence we may dismiss this cause and fairly assume that the paper itself is as of old.

One of the most tangible causes of fading alluded to was the presence in the finished picture of a silver compound, “albumenate of silver.” This was pointed out some thirty years or so back by Mr. John Spiller, who went very fully into the subject at the time. He then showed that, although this compound was soluble in hyposulphite of soda, it took a very long time for its solution—much longer than it took for the fixation of the print. He also showed that the “albumenate of silver” was soluble, and could be quite removed in a solution of carbonate of ammonia without injury to the albumen. But this was never much used in practice. Now, of course, the prints of old all contained this albumenate, but probably less in quantity, because the coating of albumen was thinner than now. Of late years the demand has been for highly glazed paper, and the albumenisers have met it by using stale and decomposed albumen, which gives a higher gloss than fresh white of egg does; also by thickening it by evaporation, or by the addition of dried albumen. But the use of decomposed albumen is by no means new; it was employed fully thirty years ago. It might well be surmised that, theoretically, the use of decomposed albumen might affect the stability of the prints made upon it; but is that idea borne out in actual practice? We happen

to have some by us made on paper of the most foetid description, which, when being sensitised, could be smelt throughout the house, yet they are still unchanged.

One very prolific cause of fading of albumen prints, and it applies also to gelatine and, indeed, to all silver prints by whatever process they are made, is an impure atmosphere in conjunction with moisture. If prints are kept absolutely dry, even in the presence of an impure atmosphere, or if they are mounted on impure mounts—also a prolific cause of deterioration—they will undergo but little change for many years.

There is one very important point in connection with the stability of the old prints, as compared with modern ones, that does not seem to have been touched upon in the discussion—namely, difference in the conditions under which they were made, as compared with present conditions, and that difference is of much importance. The paper of old bore a thinner coating of albumen than at present, and it was sensitised on what would now be considered a very strong bath—from sixty to ninety grains of nitrate of silver to the ounce of water, and it was used neutral, or nearly so. Furthermore, the negatives then used were of quite a different character from those now in vogue. They were collodion, very strong in the lights, and quite transparent—quite clear glass—in the shadows. Consequently the image, when printed, was well into the body of the paper, and was not confined almost, if not quite, to the albumen coating, as now. Often with a strong negative the print could be very distinctly seen on the back of the paper. As a consequence, the image was composed of a far larger amount of reduced silver than is the case now, and, of course, this, by its quantity, would resist pernicious influences much better than would the more attenuated image of the present day.

There is a very cogent reason why so many of the old pictures have so well withstood the test of time, which has been suggested to us by some of the old workers. It is this: Photographers some thirty or forty years ago took more interest in the stability of their pictures than is the case now. They gave more personal supervision to the work, or employed men who thoroughly understood it, and applied their knowledge in everyday practice. To-day we know that the work is too often entrusted to girls who know nothing whatever about it beyond what they have been instructed to do mechanically to secure nice-looking prints. Now there is nothing to be said against females doing the work; indeed, as a rule, they are more careful than lads when they have been properly taught their business, but this the majority have not been—they know nothing whatever of the theory of the subject and the necessary conditions that ought to be fulfilled which would conduce to the stability of their work. This remark applies equally as well to gelatine as to albumen prints.

The rapid fading of either albumen or gelatine prints may in all cases be attributed rather to their producers than to the processes themselves. This fact is one that is too often overlooked when comparing the relative stability of different processes, whichever they may be.

SEVERAL Continental and two or three English photographic periodicals, says “Process Work,” seem to be making a great deal of fuss about a three-colour portrait from life made by Dr. Miethe. Whilst the result is good, there is nothing very wonderful about it. Three-colour portraiture has been frequently done during the last few years, and as good an example as Dr. Miethe’s is to be found in the “Process Year Book” for 1901, between pages 56 and 57, the work of Messrs. John Swain and Son, Ltd. We may also point out that Messrs. Lumiere and Mr. Sanger Shepherd have shown numerous portraits by their colour transparency process. We mention the above facts with no desire to depreciate Dr. Miethe’s work, but only to remind our contemporaries to give more credit to the productions of their own country, which they so frequently ignore.

PHOTOGRAPHY AS APPLIED TO ILLUSTRATION AND PRINTING.

[Cantor Lecture, delivered at the Society of Arts.]

II.

PHOTOGRAVURE.

HISTORICALLY, photogravure, or heliogravure, is quite the earliest process of photomechanical printing rendered practical for the uses of illustration by the printing press, and its history is full of interest for the student and experimentalist. We are, however, not concerned specially in matters historical this evening, and I am expected to explain to you only its principles, some methods, and just how the process stands to-day in its relation to modern illustration.

Photo-intaglio engraving, as its name implies, is just the opposite in effect to the photo-relief blocks, which were described in the first lecture. The principles of working are, however, practically the same as for type blocks, the results being obtained by the employment of a photographic image in combination with bichromated gelatine. The lines or gradation of the picture are sunk below the general surface of the metal, and the inking of the picture, instead of being done by means of a roller, is effected by forcing the ink into the sunk lines with a dabber, the surface of the metal representing the subject is then wiped clean, and the impression is made by pressing a soft, sized paper in contact with the plate by heavy pressure; the pressure forces the paper into the inked lines or depressions forming the picture, and brings away the ink—the tones of the picture being represented by dark masses of ink in the deepest depressions, and by lighter gradations in the shallower portions, until the surface of the metal is reached, giving pure white.

Whilst photogravure justly stands at the head of all processes for artistic illustration, it is one which calls for more individual skill on the part of the engraver than almost any other. There is much uncertainty in the general results, and often more than one plate must be etched before a satisfactory effect is obtained, even then sometimes a good deal of help must be given to the plate by means of the burnisher, scraper, and graver, operations which remove the process from the mechanical, and call for higher artistic qualities than are generally essential for other processes.

The importance of the process renders it desirable that some demonstration of its working should be given, so that the uninitiated may better understand its principles, and I am glad to state I shall be enabled to show you some of the practical details this evening, through the kindness of Mr. Howard Farmer, who has sent Mr. Symmons equipped in order to render us this service. The various operations will be slower than my description, but if you will permit it, I propose to make a break in my paper at one or two intervals, to tell you the essential points as the experiment progresses.

There are several methods of preparing photogravure plates, notably Fox Talbot's process, invented just about fifty years ago, and which is to-day, in practice, the principle of the most modern process; Klic's process, a modification of Fox Talbot's; Woodbury's process, which is, I believe, adopted by the French house of Boussod, Valadon, and Co.; Waterhouse's process, in which an electrotype plate is prepared from a sand-grained gelatine relief; Dr. Albert's process, and many others, only differing in slight details from the first-named.

The operations of preparing a photogravure plate by the process founded by Fox Talbot, are as follows:—The first requisite is a transparency or positive picture on glass of the subject which it is desired to engrave; the transparency may be made by the carbon process, or by any of the dry plate processes, but if the latter is used the transparency must be reversed.

This positive on glass should be as perfect as possible, free from spots or defects, and full of detail. A piece of finely-polished copper is next selected, and carefully cleaned with Tripoli powder and water until the surface is free from the slightest trace of grease; after drying, the plate is ready to receive a graining of powdered asphalt or resin, so that the photographic image, when etched into the plate, will have the necessary roughness or grain to hold the ink required for printing. The powdered asphalt is placed in a box with an arrangement for creating a cloud of asphalt dust within the box, depending on the kind of grain required, whether coarse, or medium, or fine. An interval of some minutes is allowed to elapse before opening a door in the side of the graining-box and placing the plate face upwards for the dust to fall upon it. Three minutes is generally sufficient to ensure that the copper surface is evenly coated with the grains of asphalt. The plate is then taken out and placed on a plate of sheet-iron under which is a Bunsen burner, or is held over a flame of gas, to melt the powder so that it adheres firmly to the copper. As soon as it is cold the copper is ready for the next operation, namely, to have the gelatine resist carrying the picture transferred to it. The gelatine resist is prepared by printing an image from the transparency already referred to on a piece of sensitised carbon tissue, which is a surface of gelatine (backed with paper) mixed with some pigment like oxide of iron or carbon, and sensitised with bichromate of ammonia. The printing is carried out in the same way as for an ordinary carbon print, save that the resulting image is negative instead of positive. The printed carbon paper is immersed in water for a few minutes, and is then squeegeed to the grained copper surface, and developed with warm water until all the unacted-upon gelatine is dissolved, leaving only the negative picture on the metal. This print forms the "resist" for the subsequent etching-in of the picture, and carries the whole of the gradations of tone of the picture. As soon as the print is dry (it can be dried either spontaneously, or, if the grain is asphalt, by the application of methylated spirit) the etching of the plate may be proceeded with, but it is an operation requiring some care and skill in order to secure perfect results. The etching solution is perchloride of iron, which should be pure and neutral; the strength of the solution is important. Generally speaking, three strengths of solution are required, the first, tested by Beaumé's hydrometer, should register 38 to 40 degrees, and only attack the deepest shadows of the plate. Four or five minutes' etching with this solution is usually sufficient; then a solution of 35 degrees replaces the first, and the etching will be extended to the middle or half-tones for another period of four or five minutes; the third strength of solution is next taken, and the etching will attack the lighter tones up to the high lights. As soon as this is apparent, the etching is complete, and the plate is plunged in water and carefully washed, the resist and protection varnish removed, and the plate is ready for proofing in the press.

The graining of asphalt mentioned is commonly used for giving the etched surface a sufficient "bite" to hold the printing ink, but there are several other grains employed, notably, the mechanically ruled screen grain seen in half-tone blocks. This grain cannot be applied to the copper in the same way as resin or asphalt powder, but it can easily be added to the transparency used for printing the resist, or it can be printed on the carbon resist carrying the picture by giving it a short secondary exposure after the picture image has been printed. The advantage of the mechanical screen is that it gives a stronger grain to the plate, and admits of larger and more rapid printing. Photogravure plates of this kind deeply etched may be printed from at the rate of 500 or more per hour in a copper-plate printing machine. The Rembrandt intaglio process, which, by the way,

is a secret one, employs a grain of this nature, and from my observation it gives softer and smoother results than ordinary photogravure, though it lacks the brilliancy and strength of the latter. I cannot tell you how the process of Rembrandt intaglio printing is carried out, but from experiments I have made in this direction I am inclined to the opinion that the plates are bent on to a cylinder of a machine similar to that used for printing wall papers, and that an ink composed of dextrine or starch with a pigment replaces the usual greasy ink, also that a scraper or knife is used for "wiping" the plate, in the same way as in the old process of Docteur printing. I have some examples printed in this way which closely approach the Rembrandt.

COLLOTYPE.

I have on the syllabus of subjects to be considered this evening, the processes of colotype and Woodburytype printing; either of them would supply abundance of interesting material for an entire paper, but the limited time at our disposal will admit of my giving you little more than an outline of their principles and working. The colotype process is worked universally, and is known by a variety of names; the Germans call it "Lichtdruck," the French "Phototypie," the Americans call it "Phototype," and we English have given it the titles of "Photo-print," "Helio-type," "Autotype," "Phetophane," "Photomezzo-type," "Graphotone," etc.

The process is based on the well-known action of light on bichromatised gelatine, and is allied to photo-lithography, with this difference that in colotype the exposed image in gelatine is employed for the actual printing surface, and not only can line subjects be printed from it, but copies of photographs, paintings, and drawings. It renders half-tones so accurately that when prints by colotype process are made on highly-glazed paper, with a suitable ink, there is scarcely any perceptible difference between them and ordinary silver prints; platinotype and bromide prints can also be closely imitated. The process is largely used for the production of view books, facsimile copies of engravings, copies of paintings, "art study" portrait work, and for commercial illustrations. I have explained in a previous paper that when a film of bichromate mixed with gelatine is exposed to light under a negative, then washed and dried, it will, when treated like a lithographic stone, absorb water where the gelatine film was protected from light by the dense portions of the negative, and will take ink and form a printing surface in the places where light has obtained access to the film through the negative. A colotype plate will not only take ink where absolutely clear glass occurs in the negative, but it will take ink in the half-tone in exact gradations corresponding to the amount of light passing through the negative. This property is most valuable, and, as a matter of fact, constitutes the process.

The preparation of colotype plates is not difficult, and the operations can be described in a few minutes. The printing plate is formed of a piece of plate-glass of about $\frac{1}{2}$ in. in thickness, ground on the printing side to give a better hold to the gelatine. In order that the film may withstand the heavy pressure of the printing press, it is found necessary to coat the plates first with a substance containing albumen, water-glass, and water. This solution is spread over the cleaned glass in a thin coating and dried. The sensitising solution for colotype printing is composed of Coignet's gelatine 3oz., albumen 1oz., water 25oz., and bichromate potash $\frac{1}{2}$ oz. The exact proportions are not arbitrary, and different operators modify their solution as experience guides. The sensitising solution is carefully filtered through flannel, and, whilst warm, is poured over the surface of the "substratumed" glass plate in a fairly thick film; the coated plate is then placed on accurately levelled supports

in a drying-chamber or box, and heat is applied to the bottom of the box, which is made of sheet iron. Considerable heat is required to dry the plates, and the grain or texture of the plate is affected by the speed of the drying; about four hours is the usual time occupied. When the plate is dry and cool, it is ready for exposure under the negative; the qualities necessary in a colotype negative are that it must be reversed, and be of full printing strength. A negative that would render a full rich print by any silver printing process is the proper standard for colotype. The margins of the negative are masked with thin opaque paper or tinfoil, so as to permit of the picture being printed with a clean edge on paper with proper margins. The time required for the exposure under ordinary conditions, as regards light, is from twenty minutes to half-an-hour, but this is a matter which can only be fixed by experience. The image on the plate cannot be examined during exposure, and an actinometer scale is used for gauging the amount of light. After exposure, the plate is taken into a room lighted a dull or yellow light, and washed in running water for about half-an-hour in order that all the soluble unacted-upon bichromate may be removed from the film, after which the plate is allowed to dry spontaneously, when it is ready for printing.

The printing may be performed in an ordinary Albion press used for letterpress printing, or in a lithographic press. For rapid printing, or for long runs, special steam driven presses are constructed, with cylinder pressure, on which it is possible to print two to three hundred copies per hour.

When the plate is fixed in position in the press, it is first wetted all over with a sponge and water, or with a solution of common salt, glycerine, and water, which, after being allowed to act on the gelatine for ten or fifteen minutes, is sponged off and the plate is rolled up with ink. If the printing is being done on a hand press, a coating of ink is applied first with a leather roller, which inks up the shadows and stronger parts of the picture. This inking is then followed by another with a gelatine roller, which inks up the half-tones and details of the subject. A sheet of ordinary printing paper is now placed over the inked surface, and pressure is applied. The result is a permanent ink print on paper of the negative used. If the printing is done on a steam press, the operations are, of course, more mechanical, but the finished result is practically the same. Large plates can be successfully dealt with at machine, and pictures on paper up to 40in. by 30in. can be printed.

The colotype process has had a long and successful career, and the beauty and delicacy of its results, when properly printed, are fully equal to that of any other photo-mechanical process, but of late years the advances made in half-tone blocks, and more especially in the machinery constructed for printing them, has to some extent covered the ground hitherto occupied by colotype illustrations alone, and though the half-tone block can never oust or replace colotype for many kinds of illustration, yet it is sufficiently a rival to restrict its expansion and scope from a commercial point of view.

WOODBURYTYPE PRINTING.

Amongst all the processes for obtaining printing press pictures by means of photography, I think that of the late Mr. W. B. Woodbury is the most audacious from a purely photographic aspect. He aimed at the highest ideal, and attained it. His process is the only photo-mechanical one which, in the printing press, realises the gradations of tone without grain or texture of any kind; and Mr. Woodbury's working out of the process was so complete, that the operation of working it stands to-day precisely as he left it. The only variations since introduced do not alter the main principle of his invention, and refer more to mounting and transferring of the printed results than to the

process itself. The idea of the process emanated from the carbon print, in which the picture is formed in all its gradations by various thicknesses of pigmented gelatine, the shadows, representing the greatest thickness, being in relatively high relief, and the high lights the lowest. Reasoning backwards, Mr. Woodbury conceived the idea of making an electrotype mould of a carbon picture, and using the mould so obtained as a printing surface by covering it over with warm pigmented gelatine, and by flat pressure attaching a sheet of paper to the pigment, so that when the gelatine jelly was set he could detach it from its mould, and thus by repeating the operation obtain unlimited copies. This was practically the Woodburytype; but of course there were difficulties and imperfections, which the inventor quickly set to work to overcome. He found that a thick film of gelatine and bichromate, when exposed under a negative and washed, gave a very high, sharp relief; and he also found that when this relief was perfectly dry it possessed the property of being absolutely incompressible; in other words, it was as hard as steel, and could be used as a die. The relief film of gelatine was placed on a block of smooth, hardened steel, with raised edges; upon this was laid a sheet of type metal or lead about $\frac{1}{2}$ in. thick, and the arrangement was then placed under a hydraulic press capable of exerting a pressure of about 40 cwt. to the square inch. The pressure forced the lead into the gelatine image with such accuracy that every shade and detail of the relief was impressed. The raised edges round the steel block prevented the metal from squeezing out, and on being detached, a mould in lead was obtained which could be used as a printing surface for thousands of copies. The seemingly delicate relief in gelatine was quite uninjured by this treatment, and would serve for any number of further pressed moulds.

The printing press for these pictures is special, but quite simple. It is formed of a cast iron base, on which is fitted a movable table to hold the mould, which is bedded down on to it with gutta percha; over the table is a hinged lid, faced with plate-glass, with a lever attachment for giving the pressure. The printing ink is a solution of gelatine in a hot state to which a pigment is added to give any desired tint or tone to the resulting print.

In printing the lead mould is first oiled to prevent the gelatine sticking, and a pool of the warm ink is poured on to the middle of the mould; over this pool is laid a sheet of paper waterproofed with shellac, and the lid of the press is brought down over the whole, and pressure applied. The pressure squeezes out over the edges of the mould all superfluous ink, and all that is left is that retained in the graduated hollows and depressions of the lead mould; the warm ink sets in a few minutes, and on opening the press the paper support is removed, with its gelatine copy of the moulded picture firmly attached to it. This is the Woodburytype print, and it only requires drying and dipping in a bath of alum to render it absolutely permanent. The beauty and finish of these prints is beyond question, and the only drawback to them for some purposes is that they must in all cases be mounted before they can serve as book or other illustrations. There is no means of printing them directly on paper with a margin, though this difficulty has been surmounted in a round-about way by transferring the thin gelatine pictures to prepared plate paper.

The Stannotype process is a modification of the Woodburytype, and was also invented by Mr. Woodbury. It has almost gone out of use now, and it will be sufficient if I explain that the printing is done direct from the gelatine relief by covering it over with a thin foil of tin. The foil prevents the wet gelatine ink from actual contact and destroying it. The printing is carried out in the same way as for the Woodburytype.

J. D. GEDDES.

THOUGHTS ON THE R.P.S. EXHIBITION.

[From a Correspondent.]

A VISIT to such a many-sided exhibition as that of the Royal Photographic Society is of, what many would call, a paradoxical character. It is instructive and amusing. The quantity of the latter compared with the former is small, no doubt, but the superior wisdom of the visitor will be sure to find something to laugh at in the varied work that is displayed for his benefit, and the more this emotion is aroused in him the more will he need stimulation by that instructive force which is always present in generous quantity, in order to combat successfully with that spirit of ignorant ridicule which is the birthright of the narrow-minded, self-contented, individual.

It is the man of large sympathies who will enjoy his visit the most, for though there will doubtless be work exhibited which does not meet with his approval, nevertheless the variety of the fare will act as a stimulant to his mental faculties, arousing within him a series of emotions which will inevitably be subjected to a critical analysis. We can excuse anyone for being down on technical faults where these are obviously capable of eradication, but the more closer manifestation of the brain, the evidence of the spirit which prompts the work, can only be accepted as it is presented; for a man's ideals are not so sensitive to violent changes as they are to the more gradual alterations which time produces in us all.

"*Tempera mutantur, et nos in illis mutamur*"--it is always so, some of us hurry along, others are content to go more leisurely, we all think ours is the best way; and so the symmetrical balance between the plus and the minus quantities remains more or less constant, unless some sudden rush takes more over to a new sensation than it leaves behind, when, for a time, the novelty claims an impropotional prominence, which, however, is short-lived, for the majority will return to their inherited ideas, and things will again run on in their good old way.

And this very real undercurrent is manifested in the photographic pictorial work of the present day.

Men are returning gradually from the pursuit of the ridiculous, and the wild flights of a feverish imagination, goaded on by the spirit of novelty; are becoming less noticeable; and the evidence of more sober thought is manifested in their work.

And it is probably on account of this that we did not find any single piece of pictorial work which seemed to stand out above the others, but there was, to us, a more healthy tone about the exhibition viewed as a whole, which gave us more pleasure than the obviously neurotic manifestations which were prominent a few years ago. And yet, perhaps, we are wrong in using the word "ridiculous;" though we may not agree with the efforts which in a hasty moment we characterised with this expression, are we so sure that we are just in using it? The author of the most advanced piece of impressionistic work, doubtless took endless trouble to produce the specimen which we, in our hastiness, might laugh at.

But in the more sobered atmosphere of mental examination we would perhaps be truer to our own feelings were we to call it mistaken, pathetic, and miserable, but not ridiculous. And so, gentle reader, whoever you are, do not go to the Exhibition with the intention of condemning everything that does not agree with you, but rather take these very pictures for your more careful consideration, and do not leave them until you are quite certain what it is you do not like in them, and how, were you to have had the original handling of the subject, you would have treated it; then you will have reaped much benefit by your examination, as well as have the satisfaction of being fairer to your opponent and truer to yourself. We well remember being much impressed by the condensed philosophy contained in the sage remark of P. H. Emerson, in the second edition of his well-known work, "Naturalistic Photography."

He is speaking of art in general, and thus defines it:—"Art is the application of knowledge for certain ends." It will be observed that the broadness of this statement is its chief characteristic. We are told that art (not any one particular manifestation, but the sum total of it), is of a subjective character. Mr. Emerson proceeds:—"But art is raised to Fine Art when man so applies this knowledge that he affects the emotions through the senses, and so produces aesthetic pleasure in us, and the man so raising an Art is an Artist. Thus photography may be, and is, in the hands of an artist, a method of expression producing works of fine art, because no such works can be produced by one who is not an artist, and moreover the real test as to whether the result of any method of expression is a fine art or not, depends upon how much of the intellectual element is required in its production." So we see that, while art is subjective, the result of art—that is, a work of art, is the objective. We cannot help feeling that many of the exhibitors in this year's R.P.S. show have fully realised the truth of this statement—they are, in fact, Artists, and their work is quite capable of arousing within us feelings of aesthetic pleasure. Nor do we find this evidence of individuality confined to any particular class of work. In the landscape pictures there is ample evidence of artistic feeling made manifest by sound technical manipulation, the portraits as a whole give us the expression of the character of the individual, with a praiseworthy subordination of distracting accessories, and the architectural work is invariably well chosen and handled with a poetic reverence.

We have throughout the Exhibition ample manifestations of the intellect employing a wonderful process for the illustration of its emotions, and the quiet realisation of its possibilities, in the hands of competent artists, augurs well for the future prosperity of photography as a Fine Art. It is not our present intention to go piece for piece through the work exhibited, for this has already been done, but rather to draw attention to certain of the exhibits, which appeared to us to be specially interesting and instructive. Professional photographers cannot afford to neglect the work of our leading amateurs, and in many cases it is the amateur who gives the initiative in some particular method of treatment. We will take some of the portraits in the Pictorial Section, and examine them. No. 32, "Portrait of a Gentleman," by Charles Sweet, is worthy of careful attention as an example of quiet, dignified treatment.

The subject is well lighted, and the expression quite natural, while the pose is easy and picturesque. No. 36, "Monteith Randell, Esq.," by E. Montague Treble, is another good piece of work. The subtle way in which the light is managed emphasises the dignity of the white hair, while losing none of its detail. The pose again is most natural, and entirely suitable. In No. 98, "A Scottish Professor," by John Moffat, we have as good an interpretation of the individuality of a striking man as anyone could desire. The pose is perfectly natural, and the treatment of the cloak is eminently graceful. The expression is in no way forced, while the anatomy of the face is fully rendered. No. 131, "Portrait," by Dudley Hoyt, is a striking piece of work, though we do not like the vignettted effect at the bottom. The subject herself has apparently a striking individuality, and the artist has succeeded in conveying an impression of firmness of character by his treatment. The way in which the face is lit is well suited to the subject, and the drapery and irregular line of the hat, with the light flowers therein, give an unaffected grace to the picture. The drapery is particularly well handled, being neither too great nor too little in quantity, and the result of placing it below the shoulder is to set off the strong and large face by a well-balanced proportion of the body. No. 156, "Rev. Alex. Whyte, D.D.," by R. S. Webster, is de-

serving of the same criticism as we bestowed on No. 32, and the quiet and simple treatment of a dignified subject is worthy of special praise.

We have singled out the above portraits because they seem to us to be examples well worthy of being followed by those who make portraiture their speciality.

In no case is the treatment in any way theatrical, but the individuality of the sitters has been grasped and illustrated in a most commendable and pleasing fashion. The centre of interest was always the face, and the subordination of the dress, etc., was never overdone. The backgrounds were quite plain and dark, and so did not distract the eye from the sitter.

It is such work as these examples which raise photography to a high level; not those crude efforts in which the subject is rendered in an unreal and inhuman manner, with an exaggerated expression, harsh lighting, and with all the anatomy obliterated. Another very fine piece of work is the picture by Mr. Fellows-Willson, No. 283, entitled "A Pretty Maiden." It was this print which won for Mr. Willson the special "Gravura" prize in Messrs. Illingworth's recent carbon competition, nor can we in any way find fault with the wisdom of the judges in awarding him the prize. Apart from the picturesqueness of the subject and the perfect technique displayed, we draw special attention to the lighting of the face. The way in which the fine, though large, chin is done justice to by the effective handling of the light and shade is a particularly interesting and instructive illustration. Before leaving the pictorial section we would wish to draw attention to No. 157, "Portrait," by Rudolf Eickemeyer, junr. Here we have a particularly fine subject treated in a way which, in our opinion, does her no justice whatsoever. The hair is thrown into a wild state of disorder, and is then cut off at the top of the head by the trimming of the picture. The mastoid muscle on the right side is carefully extinguished, and no evidence is given of the scapula. Those would undoubtedly have been visible to a certain extent in the original on account of the poise of the head, and their removal does not contribute to the dignity or naturalness of the production. Such efforts as these do not, we fear, appeal to us as being even picturesque. Novel they have even ceased to be; and we are glad to see a steady return to sounder and more unaffected work on the part of many regular exhibitors. Photographic portraiture is a subject which has to be attacked from many sides if the result is to approach a state of perfection. Broadly speaking, we may divide it into scientific and artistic sections. The artistic side must predominate, and the science of the process must be utilised for the illustration of the artistic conception. Neither portion can in any way be neglected—all must be under the direct control of the worker, and all steps must be taken with the goal—that is, the final result—a pre-determined conception.

Unless this is done, the worker will be like a man on a treadmill, never able to see further than the step in front of him, but, if the broader method is adopted, and full advantage taken of previously acquired knowledge of all matters having any relation to the task in hand, the result will cease to be analytical and will become synthetical in its character. And this is a very great fundamental distinction, which must be carefully learnt and laid to heart by all those who desire to produce work of a lasting value on account of its sound character, rather than to achieve to a short-lived notoriety as the producer of some odd freak, which is a pitiful testimony to the violation of truth. In all art the final result must be the objective, and the methods of realising that end subjective thereto. The infinite ideal may not be capable of realisation, but we must do all in our power to make the finite conception as perfect as possible. And so it is probably on account of this that we do not bestow praise

October 17, 1902.]

such works as Nos. 174, 185, 273, and 278, to mention some and. We do not doubt that their authors have meant them to be such as they are, and therefore they would, from what we have said, be specimens of synthetical work; but the reality of the conception is too indefinite to please us, and no sensations or aesthetic emotions are aroused within us by our contemplation of these efforts. It is just the other way, though, with the work of W. Crooke and Furley Lewis, to mention the two professional exhibits which most attracted us. The picture of Mr. Lowney by the former is really a very fine example of photographic work. Here we have a most life-like portrait of this well-known gentleman, the result of very careful and experienced operating.

This example is a striking illustration of synthetical treatment. We can imagine Mr. Crooke conceiving the ideal of Mr. Lowney in his mind, and setting himself the task of illustrating his impression. It is the artistic qualities which first attract and the subjective handling of the photographic processes is the further evidence of the power of the artist.

There are many ways in which this subject might have been handled, but the method chosen by Mr. Crooke would be difficult to improve on.

The treatment is eminently simple, the background dark and calculated to set off the figure. The lighting reveals the full character of the face, and no anatomy is lost; the pose is perfectly natural, and the photographic technique of a high order.

We must bestow a similar criticism on some of the works of Mr. Furley Lewis. Notably No. 4, "Girl at Piano," calls for admiration. The subordination of objects not directly connected with the artist's ideal is admirably managed, while the pose and the expression are so perfectly natural that the whole work seems redundant with life. The technique is especially good, and the complete work a charming picture. His portraits of Mr. Haddon, Mr. Everitt, and Dr. Fincham are also excellent examples of sympathetic treatment and artistic skill. Perhaps the lighting on Mr. Haddon's nose is a trifle too strong, but this can easily be toned down in the print if desired. The mounting and general finish of his work proclaim Mr. Lewis a skilled and tasteful worker, and we shall look forward with pleasure to an inspection of future specimens of his work. His treatment of Mr. Snowden Ward we do not think is so happy, the excessive width of the picture, caused by both arms being stretched out and holding a big book, is rather distracting, but the lighting of the face is very good, and the expression thereof most pleasing.

The specimen exhibited by Mr. Walter Barnett, No. 269, Pictorial Section, we must own does not please us so much as some other examples we have seen. The pose is somewhat stiff, though the arrangement of the skirt is graceful, but the hands are too obviously posed to look natural; the lighting of the face, too, is not beyond criticism.

The technical section of the Exhibition does not call for any particular notice in this article. There is evidence of much skill and patience in the fine specimens of microscopic work shown by Mr. Spitta, and the examples of three-colour superposed prints by Mr. Brewerton and Miss Acland are exceedingly interesting, though a little crude in their colour. The process, however, seems one of great promise, and will undoubtedly be heard more of in the near future. Mr. Senior's beautiful specimens of Lippmann's interferential colour photography only serves to remind us how very few there are who have succeeded with this method. And yet to hold a specimen in one's hand is to hold the power of almost calling colours into being—surely here is a grand field for the experimentalist.

Mr. Ives' parallax stereogram well deserved the medal which was awarded to it, but the method of its production has already been dealt with in these columns, so we will be content with this passing notice.

We have no space now in which to take up the question of the merits or demerits of the landscape work, but our readers must forgive us and reap what benefit they can from our observations on portrait work. And so we came away from the New Gallery feeling that inside it there are many examples of artistic and scientific interest and that a visit thereto by a thoughtful person could not fail to be interesting as well as instructive. Some specimens there were which bore evidence of synthetic treatment, others did not do so; but, viewed as a whole, the work is undoubtedly good, though the absence of any one striking piece of work is to be regretted.

New Books.

"How to Buy a Camera." By H. C. Shelley. 144 p.p. 41 illustrations. Price 1s. 6d. nett. London: Published by George Newnes, Limited, Southampton Street, Strand, W.C.

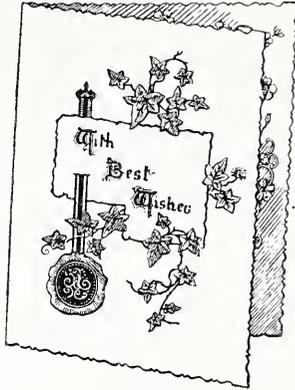

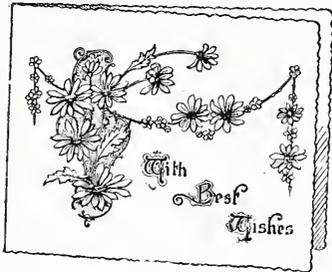

"Why buy a camera?" asks Mr. Shelley, in the very first sentence of the opening page of his last contribution to the popular literature of photography. The following fourteen pages take up the answer to the question, and we have seldom read an abler or more convincing plea for one of the most fascinating hobbies of the time. If our business in life were the selling of photographic apparatus, we would persuade Messrs. Newnes to let us reprint this chapter, so that we might distribute it amongst those unfortunate people who have yet to make the acquaintance of camera work. It would bring in converts by the thousand. Mr. Shelley is fairly comprehensive in his description of the principal types of cameras now before the public, and by no means sticks so closely to his text as to turn his book into an expanded catalogue. Thus he discourses of lenses and shutters; the rest of the outfit; the dark-room and its fittings; and films, plates, and printing papers. In nearly every instance the price of the article written about is given. Mr. Shelley wisely refrains from frightening the novice by the exclusion of all references to theoretical matters; and the book can be cordially recommended as a useful and reliable purchasing guide. New cameras are nowadays placed on the market with great frequency. If a second edition of the book is called for, Mr. Shelley will have ample opportunity of adding to the list of instruments which he describes.

"A NEW PHOTOGRAPHER."—I have happened upon a new photographer, and shall gladly give his address to anyone who is desirous of undergoing the ordeal by torture of the camera. To be photographed is no amusement. Almost unconsciously you become self-conscious. But, after all, it is not so bad as the dreadful moments which people must go through when, in full (or, to be more exact, scanty) evening dress, you have to keep an appointment at the studio of a portrait painter at eleven o'clock in the morning—a piercing north light from the studio window beating upon you remorselessly withal.—Guinevere, in "The Referee."

PICTORIAL Postcards and Charity.—Why should not the pictorial postcard craze be turned to artistic and practical account? asks a correspondent of the "Morning Post." The near approach of Christmas suggests that these cards might be made entirely to take the place of the antiquated and meretricious Christmas greeting cards, which, when once looked at, become useless. To begin with, the postcard would save a world of time in packing, and even in stamping if sold ready-stamped; secondly, it might contain artistic suggestions of the season more suited to the improved tastes of the public than the prevalent robin and the portentous plum-pudding. Why should we not follow the example lately set at Cadiz, and hold a Pictorial Postcard Exhibition in aid of a charity, an exhibition which might be contributed to by artists and amateurs from the highest in the land to the lowest. The King of Portugal to the Cadiz "show" contributed artistic scenes from his own brush, while other pictorial trophies were merely "finished" off by the epigrams, aphorisms, or autographs of great men, from the German Emperor to Coquelin, from Sagasta to Saint-Saens. Such an exhibition in London at the present time besides providing artistic souvenirs for Yuletide, might help to cope with the distress threatened by the return from the war of over two hundred thousand men. Though some eighty-five thousand may get back again to their old positions, some seventy-five thousand yet remain to be provided for, not to speak of those who during the war took the place of the reservists at home, and who naturally are now without work. Any exhibition and sale in aid of the societies which provide employment for reservists, discharged soldiers, and others, would or should meet with hearty support, for none can find it in his heart to let these men—who have earned medals, and bars innumerable—spend their first Christmas at home in destitution. So that all could unite in helping the exhibition it might be divided into sections, the artist section composed of signed sketches on post-cards, the authors', the political, the dramatic and musical sections consisting of pictorial cards chosen by celebrities and signed by them, the philatelists' sections consisting of rare stamped cards from all parts of the world. Surely some philanthropic person will lend house or hall for the purpose, and some fair ladies preside at the stalls.

New Apparatus, &c.

Christmas and New Year's Mounts. Sold by George Houghton and Sons, 88 and 89, High Holborn, W.C. As usual, at this season of the year, Messrs. Houghton make a point of drawing the attention of amateur photographers to a very large and varied stock of mounts for prints which it is the pleasing custom of friends to exchange at the great winter festivals. The stock is described and illustrated in a 24-page list which is before us, accompanied

by a selection of the cards. These latter beggar description, so great is their variety, so numerous their styles, designs, tints, and shapes. We must rely upon the annexed illustrations to give the reader some idea of a few of the samples; consultation of the special list will assure him that Messrs. Houghton are catering for all tastes, and that in the production of such a simple thing as a small photographic mount a vast deal of artistic skill and ingenuity may be concentrated.

The Paget Prize Self Toning Paper. Manufactured and sold by the Paget Prize Plate Company, Watford.

Self toning papers, to make use of a familiar locution, are 'in the air' of the photographic world, and we are not surprised to hear on all sides that the Paget Company are meeting with great success in popularising this simple and effective method of printing. The process is essentially one for the busy worker, notably that important supporter of modern journalism, the Press photographer, whose finished results are as a rule wanted with the utmost rapidity for reproduction purposes. It is this facility for rapid proofing which gives the "self toning" process a peculiar value. But the colour and quality of the image in these days of eclecticism of photographic taste are such that they are pleasing to most if not all eyes. The deposit reminds us of that obtained by a favourite printing method of our photographic youth: "plain paper," so called because it was non-albumenised. But in those days matt surface effects had not many adherents. During the last few days samples of the latest make of Paget matt self toning paper have been submitted to us, and we have pleasure in directing the attention of our readers to the merits of the process. At first sight the prints made for us reminded us of carbon images, so accustomed have we been to associate pigment printing only with the familiar "warm brown" colour. Adherence to the appended simple instructions produced excellent specimens of printing; and, judging by the finished examples placed before us, the Paget Company have mastered the art of preparing a paper having the valuable characteristic of yielding uniform results. We have seen great numbers of such prints produced by amateur as well as professional photographers, and there is no doubt the paper has earned very great popularity on that account.

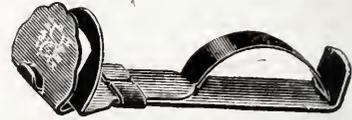

Instructions.—Print a little deeper than finished print is required (about the same as for P.O.P.). To obtain a warm, brown tone, wash print in running water, or several changes, for five minutes, then place in fixing bath (Hypo. 2ozs., Water 1 pint) for fifteen minutes; wash thoroughly and dry. If a colder tone (bluish purple) be desired, instead

of first washing, place print in a solution of Common Salt in water, about 2ozs. to the pint, for ten minutes, then rinse in water, and fix as above.

Note.—The colour of the print cannot be judged while wet; its final tone is not arrived at until quite dry. Prints may be quickly dried in front of the fire as they do not soften like gelatine. They may be burnished or enamelled in the same way as ordinary Collodion or Albumen prints, but cannot be enamelled by simply laying down on glass like P.O.P.

Tylar's Spring Grip Card Stands.

We have received from Mr. Tylar, of Birmingham, a small box containing twelve spring grip card stands. These stands are very strongly made, and the photographs or cards are held by means of a spring.

The "stands" afford a very simple and easy means of showing mounted photographs or cards in a window or on a mantelpiece without damaging the photograph in any way. They are sold in boxes of twelve for 1s.

Mr. J. T. FRENCH instructed the South London Photographic Society in the art of bromide enlarging at their last meeting. In the course of the evening three enlargements were made with a lantern of Mr. French's own manufacture, using the incandescent gas-light, and successfully developed with rodinal. After the demonstration the lecturer was plied with questions. A vote of thanks to the lecturer ended the proceedings.

PURE magnesium only should be employed in all flash-lamps. Compounds containing chlorate of potash, saltpetre, etc., should not be used; they are not safe. Compounds ignite when a light is applied to them, but not so with pure magnesium. It will not ignite except when finely divided and blown through a flame. The Todd-Forret is thus a safe piece of apparatus to use. We have tried some interesting experiments with pure magnesium powder, and also with the magnesium mixtures. We made a small heap of pure magnesium powder, and tried to ignite it, but it would not burn, do what we would; in fact, it put the light out when we laid it on the heap. We then dropped on acids and other oxidising agents, but without effect. Another lot of the same sample of pure powder was taken and fired off in a Todd-Forret lamp. The result produced was such as we expected, namely, a large, most brilliant, and intensely actinic flash. We next mixed some magnesium powder with chlorate of potash, saltpetre, finely-sifted sugar, and other aids to combustion. With a match we most readily ignited one and all of the mixtures, which we had placed in heaps. One of them immediately fired when a drop of acid was allowed to fall on it. We did not try any of the mixtures in a lamp; we took the experience of others for granted. Our readers can draw their own conclusions, but, in a word, we should say that pure magnesium will not ignite in the open, and in a lamp it is perfectly safe. Magnesium compounds or flashlight mixtures are dangerous when used in lamps, and when in the open may ignite by the mere contact with an acid.—Andrew H. Baird's "Photographic Chat" for October.

The earliest human likeness.—The Hon. Auberon Herbert recently wrote to the "Times" a communication under this heading with photographs of the stones of which it speaks. He considers these stones to be examples of very early carving. They undoubtedly bear a certain resemblance to human faces. Mr. Herbert says that he also finds in the Ringwood gravel pits "a very large number of stones which are quite clearly meant to represent different types of animal life. They are generally very little worked. The workers have taken advantage of the many naturally curious forms which are constantly to be found among the flints, and with a few little cuts—sometimes very dexterously and artistically applied—had given life and movement to the stone. I am leaving England for some time, but hope on my return to take photographs of these animal forms, and as long as the supply lasts shall be glad to send copies to those interested. But perhaps in this matter nothing is so convincing as the human profiles. Some of my rather sceptically-minded friends still give help and comfort to their disbelief by the theory of fractures by frost and flaws in the flint; but I think you will agree with me that the frost-flaking or flint-flawing can hardly be held to account for the little work of art of which I send you the photograph. I expect you will be as much startled as I was by the type of face—a type that does not represent one's mental picture of the early stone-workers; but I am strongly impressed with the feeling that we have never yet done anything like justice to the civilisation of this early race. At the same time I ought to confess that their attempts at full-face drawing in flint betray a much lower kind of art. There are a good many of them, and they are much like the scrawls of a child—two eyes, and a mouth somewhere or other down below; and they suggest our friend the monkey nearly as much as the man. They distinctly inspire less confidence in the dignified appearance of our worthy ancestor. I should be very glad if some suitable arrangement could be made by which this particular stone could be examined and criticised. Meanwhile there is a fine bit of work waiting for anyone who will carefully study the beds of this district, leaving all old prepossessions behind him."

Commercial & Legal Intelligence

At the International Exhibition for Photography and allied industries, Amsterdam, August and September, 1902, the well-known photographic "Agfa" articles of the Actien-Gesellschaft für Anilin-Fabrikation, Berlin, S.O. 36, viz., Agfa dry plates, Agfa flat films, Agfa rollable films, Agfa developers, Agfa specialties, etc., have received the diploma of honour, being the highest distinction.

At the Guildhall Police Court on Thursday last Welford Mitchell, errand boy, of Kenning Road, Greenwich, was charged with stealing a large quantity of photographic dry plates, cards, etc., value about £30, the property of his employer, Frank Butcher. Goods had been missed for some time, and suspicion fell on the prisoner, who was stopped as he was going home the previous day. Part of the goods were found upon him, and when Detective Greenough went to his residence he found about £27 worth of stolen property. A remand was granted.

Photo Frauds.—At the Westminster Police Court on Friday last, Ernest F. Hopper, 24, of High Street, Plumstead, and Charles Davies, 46, of Darwin street, Walworth, were brought up on remand on a warrant charged with conspiring to obtain money by false pretences. Mr. Muskett prosecuted on behalf of the Police Commissioner. A number of young women, domestic servants, barmaids, etc., were called, and deposed to paying deposits to the prisoners for photographs. When they went for a sitting they found that they had been swindled. The prisoner Hopper, when arrested by Detective-Sergeant Baxter made a long statement, blaming his fellow prisoner, Davies, for his fall from honest paths. He now repeated that he was acting solely under the instructions of Davies. The prisoners both asked to be dealt with summarily. Detective-Sergeant Baxter said that he had had Davies under observation for two years, during the whole of which time he had defrauded the public. Hopper absconded, or both men would have been arrested before. Mr. Sheil sentenced Hopper to three months' hard labour, and Davies, whom his worship described as a regular scoundrel, to six months' hard labour.

Wholesale Thefts at Messrs. Butcher's.—At the Guildhall Police Court on Friday last, Annie Price, a stock-keeper to Frank Butcher, photographic apparatus manufacturer, of Shoe Lane, was charged with stealing a hand camera, dry plates, printing frames, etc., the property of her employer. Detective-Sergeant Hallam said he saw the prisoner at her employer's premises on Thursday. He told her the boy named Mitchell, under remand, had stated that she had been stealing goods, and asked her if it were true. She replied that she had borrowed a hand camera, and in answer to further questions, said she had taken other goods. She was subsequently charged, and upon her residence being visited goods to the value of £2 16s. belonging to the prosecutor were found. The prosecutor said the girl had been in his service for about three years, and he did not wish to further press the charge against her. She was most respectably connected. She was remanded on bail of £25.—The Prosecutor: Will you take my bail, sir?

The Alderman: Yes; it is very kind of you.—Jessee Barrow, 13, the same service, was also charged with stealing a camera, two dozen plates, and a quantity of mounts, value 16s. Detective-Sergeant Hallam deposed to the arrest and the subsequent search at prisoner's address, where he found a camera, two lenses, three dark slides, and other articles, value about £30. He was remanded.—Percy Rowler, 17, also pleaded guilty to stealing photographic goods, and was remanded on bail, the prosecutor becoming surety.

RE Ed. John Murray, residing at 5, Thurlow Park, and trading at 8, Union Street, Torquay, photographer. The first meeting of the creditors interested under this failure took place at the offices of the Official Receiver, Exeter, last week. The summary of accounts showed gross liabilities amounting to £606 12s. 2d., all expected to rank for dividend. The assets amounted to £415 14s. 3d., made up of cash deposit with solicitor for costs and petition, £10 stock-in-trade; fixtures, fittings, etc., £400; book debts, £5 14s. 3d. These, after deducting £21 5s. for dis-trainable rent, preferential rates, taxes, wages, etc., leave a deficiency of £190 17s. 11d. The cause of failure alleged by debtor was losses in the photographic business, and through an action for alleged misrepresentation in connection with the purchase of the business. The Official Receiver's observations were to the effect that debtor commenced his present business in March, 1901, with a capital of about £600, having previously been in business at Bath and York. In the present year he became involved in an action with the person from whom he purchased the Torquay business, claiming that the turnover was less than represented. This action he lost at the Devon summer assizes. Early in June, 1902, he got control of about £500, his wife's money, and on August 12th he paid her £266 11s. 5d. on account thereof, being the whole of his bank balance at that time; the bulk of the difference went to his solicitors. There were no trade creditors. The unsecured creditors included one for £148 8s. 7d., and one for £95 18s. 7d. for law costs, and one for £100 balance of purchase money of the business. There was £234 still due to the wife. Mr. A. L. Honey, of Exeter, was appointed trustee. Messrs. Helson, Torquay, appeared on behalf of debtor.

SCIENTIFIC Literature in England and Germany.—Germany leads the world in scientific research, and it is therefore perhaps natural that handbooks on various branches of theoretical and technical science should multiply more rapidly in that country than in our own. When one compares the scientific publications of recent years in the two countries, one is struck, however, by the wide gap that separates the English and German text-books, says the "Electrical Review." The majority of the former deal with elementary science, and are designed for the preparation of students for some particular examination. A large proportion of them are written by ambitious teachers, whose qualifications to be considered

an authority on the particular science, are based on a London Science Degree or upon a South Kensington "Honours" Pass. In this type of text-book our supremacy is undoubted and unassailable. The German publications, on the other hand, in most cases pre-suppose an acquaintance with the elementary facts of the science with which they deal, and are intended for experts, or for those who wish to become experts, in the various branches of study. The latest example of this difference in the scientific publications of the two countries, is the announcement of a series of monographs—on applied electro-chemistry—by the well-known German firm of Wilhelm Knapp, of Halle. The first and second of these volumes, dealing with the electrolytic production of oxygen and hydrogen and the extraction of aluminium, have already appeared. In this country we have barely arrived at the point of recognising electro-chemistry as a special branch of scientific study, and only one University has yet appointed a special lecturer on the subject. The elementary text-book on Electro-chemistry, designed for cramming students for a South Kensington "pass," has yet to appear; but possibly some diligent science school teacher is even now preparing it for publication. In Germany most of the Universities have been equipped for some years with laboratories for electro-chemical work, and special Professors or Lecturers for this branch of physical science have been appointed. A large number of students have taken up electro-chemistry as a special study, and useful research work has been carried out by these men when working for their Ph.D. degree. An educated public has therefore to some extent been created in Germany, to whom the present series of handbooks will appeal, and as some of these monographs will no doubt be translated and re-produced in Paris, London, and New York, the venture may prove a financial success for the firm which has been bold enough to undertake it. Whether successful or the reverse, the publication of a series of German handbooks on applied electro-chemistry, is a proof not only that our Teutonic cousins have more faith in the future of this branch of applied science than we ourselves, but also that their system of education is better fitted than our own for following up and developing new branches of scientific study.

THE Weak Places in "Trusts."—We see some hope that the rather absurd panic which American capitalists have recently produced in the British public, and indeed in the public of all Europe, is at last passing away. It really seemed for a few weeks as if Englishmen believed that Americans had discovered some new secret for trading with success, and would in a year or two strip them, and with them all other Europeans, entirely of their commerce. Partly owing to the success of great co-partnerships like the Standard Oil Company and the Steel Trust, a success dependent upon artificial conditions due to the American craze about Protection, and partly to the wails of sensational journals, a kind of horror seized the European mind. Americans were credited with limitless resources and boundless recklessness in throwing them away, and the gravest men began to believe that the Austrian Chancellor was right, and that the "American peril" would prove a terrible reality. Europe might go hungry while American billionaires put up onyx staircases. An event of no great importance in itself has this week in part dissipated the delusion. A great American "Combine" endeavoured to obtain a monopoly of the wholesale trade in tobacco, and after a brief struggle with the British importers, who combined against it, was compelled by its losses to accept terms of peace which leave the British still masters in their own field. It was perceived at once that Americans, however wealthy and however bold, did not always win in a trading campaign, and confidence was restored almost as quickly as it had disappeared. Then it was announced that the great Shipping "Combine," which was to purchase all British shipping and destroy at a blow all British maritime prosperity, attracted the attention of the British Government, had been foiled, and had been foiled. The all-powerful Mr. Pierpont Morgan, who could "buy anything," from a State or a Royal palace to a rare volume, shrank from a contest with a capitalist far greater than himself—namely, the British Treasury—and accepted terms which leave the British liners in British hands, and, if we read the agreement aright, make it his interest to work with rather than against the British people. Indeed, we doubt if he ever desired to work against them. The cloud of despondency was lifted, and we may, we think, trust that, whatever the future may have in store, British capitalists and industrials will meet emergencies with some confidence in their own resources and their own enterprise and brain-power. They will have both to think and to exert themselves; but they are not opposed by industrial Genii with magical means, but by men like themselves, with nothing special in their favour, except that, being accustomed to deal with the transactions of a very large continent, they get the habit of planning enterprises upon a very large scale. Even that scale may be exaggerated in the popular mind, for, though American millionaires, having no permanent interests or ambitions except money-making, grow richer than our own, we also have the habit and power of combination. If we called the Midland or the Great Western a "Trust," we should perceive that we also can create and manage successfully "gigantic" businesses. The truth is that there are two or three weak places in the vast American speculations of to-day. One but little noticed, which was pointed out to us some years ago by one of the earlier millionaires, is that they rather overtax the brain-power available for their management. It is very hard, even for a State, to obtain a succession of great statesmen, and these vast businesses demand as much mental capacity and more sedulous and harassing attention. Their owners have therefore to pay enormous sums for competent management, sums often ten times those paid to statesmen, and are liable even then to pick the wrong men, while they themselves become constantly victims to nervous and cardiac disorders. They do not last like the statesmen, and, owing to difficulties of health, they do not gain, as the statesmen do, the full benefit of their experience. "Money worries" are very harassing, but no fortune will keep a man in full mental strength if a doctor has to see

him twice a day. As the generation of founders dies out this difficulty will be felt more and more, for remember, though you can hire business ability as well as other forms of intellect or knowledge, you cannot hire the courage which will risk ruin to employers in order to make a coup. Another weak place is that a "Trust" must be held in shares; that the only way to establish a monopoly by sheer force of capital is to incur, or at all events risk, loss at first, as it is said—we do not vouch for the legend—that the American Tobacco Combine has done, and that shareholders, however big, soon grow weary of losses the end of which they do not clearly see. Even rich individuals weary of baffled hopes and demands the limit of which is not fixed, and shareholders are not either specially far-sighted or sustained by the pride of dictatorship. Continental observers say—for instance, M. de Witte, no mean authority, has said—that under the American system dividends are secured by the Tariff, and the managers of American "Trusts" have a free hand outside the States; but the argument surely displays some ignorance of human nature. What kind of shareholder is that who, when 20 per cent. might be divided, is content to see 15 of it thrown away in speculation? He would rather take the odd 15 and speculate for himself. He limits waste, and to establish a monopoly by sheer bribing-power or by resolve to undersell, requires that waste at first shall be without limits. And the third weak place is the bitter hostility that monopolies have created ever since the days when the prophet Isaiah denounced those who "lay field to field till there be no place" for the poor. The profit of monopoly can only come either from raising prices or stopping the fall which competition would produce, and the former result, at least, is resented with a bitterness compounded of suffering, broken hopes of free careers in the trade monopolised, and of the widely-spread hatred to the very rich. The Americans have no instinctive Socialism; they admire millionaires, and they are penetrated with the Protectionist fallacies; yet it is doubtful whether disgust with Trusts will not undermine the Tariff. No Government in Europe can long resist severe pressure from below, and the means of restricting the action of, and therefore of impeding the profits sought from, great combinations of capital will ultimately be discovered.—"The Spectator."

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM—There will be a meeting of the Council, at Anderton's Hotel, Fleet Street, London, E.C. on Tuesday, October 21st, 1902, at 6 o'clock. Agenda:—To receive balance-sheets of the Cambridge meeting. To revise the standing orders. To discuss the preliminary arrangements for the Perth meeting. To elect an honorary secretary. General business.

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY—Section G (Photography).—A meeting of the above society was held in the Council Room, Town Museum, Princes Street, on 3rd October, when a lecture by Colonel Barrington Baker, entitled "My Cruise amongst the Fjords of Norway," was given, and illustrated by lantern slides. There was a very large attendance of members, and the lecture was thoroughly enjoyed.

The Editor of "Black and White Budget" writes:—May I draw your attention to the fact that we announce a competition for coloured photographs (transparencies or prints) in "Black and White Budget" this week? As this is the first time that a popular paper has ever offered a prize for current photographs, it may be worth your while to draw the attention of your readers to the fact. Our object in setting this competition is to help in popularising the department of photography which has hitherto been confined to the few. All prints and transparencies, except the prize winners, will be returned to the competitors, provided stamps are enclosed.

At the Cripplegate Institute, Golden Lane, Cripplegate, a photographic class, open to both ladies and gentlemen, is, as usual, conducted by Mr. C. W. Coe. During the winter term, 1902, a course of eleven practical lessons in development, printing, and toning, etc., specially arranged for amateurs, will be given. The following is the syllabus:—No. 1.—Introductory. No. 2.—Apparatus. No. 3.—Plates and Exposures. No. 4.—Development (Lessons in). No. 5.—Development. No. 6.—Printing Processes. No. 7.—Printing, Toning, and Finishing, P.O.P. No. 8.—Carbons, Bromides, and Platinotypes. No. 9.—Enlarging. No. 10.—Mounting and Finishing. No. 11.—Defects and their Remedies. The classes commence on Friday, October 24th, 1902, at 7.15 p.m.

The application of the stereoscope to lantern projections has proved a fruitful field for the ingenuity of inventors. M. J. Mace de Lepinay now describes a very simple method of producing the desired effects. He projects two pictures side by side on the screen, and provides each observer with a pair of prisms the angle of which depends on the distance of that observer from the screen. Taking the two images at a distance of one metre apart, the angles of the prisms used are 12 deg., 10 deg., 8 deg., and 6 deg., for distances of 4.5, 5.4, 6.8, and 9 metres, the accommodatory power of the eye enabling intermediate distances to be used without further multiplication of prisms. One of the advantages of the system is the convenient and portable character of the prisms when mounted in the form of spectacles for observing the projections.—"Nature."

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION—The usual meeting of this society was held on Thursday week in the rooms, Eberle Street, the president (Mr. E. R. Dibdin) in the chair. Mr. Fred. Anyon gave a practical demonstration of enlarged negative making. Dealing with his subject in his usual lucid and interesting manner, Mr. Anyon pointed out the advantage to be gained by making an enlarged negative over the usual method of enlarging direct on to bromide paper. The crux of the whole process lies in the production of a suitable positive from the original small negative, and Mr. Anyon gave details of his process, which, judging from results passed round the audience, left nothing to be desired. Mr. Anyon developed a couple of enlarged negatives, the result proving that with care in producing the positive there was absolutely no loss of fine detail and a total absence of granularity in the enlarged negative.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Oct.	Name of Society.	Subject.
17.....	Borough Polytechnic.....	Printing and Toning P.O.P. Mr. F. W. Bannister.
17.....	Croydon Natural History.....	Demonstration on the Sanderson Camera and other New Apparatus. Miss Houghton.
22.....	Leeds Camera Club.....	Platinotype: How to Obtain a Variety of Tones. Rev. J. Beauland, M.A.
22.....	Borough Polytechnic.....	Combination Toning and Fixing. Mr. Ernest Human.
22.....	North Middlesex Photographic.....	Some Curiousities of Vision. Rev. F. C. Lambert, M.A.
22.....	Birmingham Photographic.....	A Demonstration of The Making of Lantern Slides by Contact. By Mr. Harold Baker.
22.....	Ashton-Under-Lyne.....	Demonstration on Glycia P.O.P. By Mr. Samuel Woolley.
23.....	London and Provincial.....	Open night.
23.....	Liverpool Amateur.....	Exposure. Mr. Alfred Watkins.
23.....	N.-W. London Photographic.....	Peeps in Paris Mr. Walter Booth.

ROYAL PHOTOGRAPHIC SOCIETY.

OCTOBER 14TH (Ordinary Meeting), Mr. Thomas R. Dallmeyer, president, in the chair.—The meeting gave its hearty support to the Council who, the president announced, had resolved to congratulate His Majesty the King, as the Society's patron, on his coronation and on his happy return to health. Nominations of forty candidates for membership were read, and seven candidates were duly elected members. Presents of old apparatus and examples from Mr. A. L. Henderson, and the parallax stereogram and stereo-photomicrographs by Mr. Frederic E. Ives, were acknowledged. The affiliation of the Cape Town, Johannesburg, Christchurch (N.Z.), East Ham Teachers, Welcome Institute, and Catford Photographic Societies was announced. It was resolved to confirm the Council in their action in supporting the objects of the Decimal Association.

Medals.—The president read a list of the awards at the current exhibition, and presented them to the representatives of the successful exhibitors. Mr. W. T. Greatbatch was represented by Mr. P. Bale Rider, and it was announced that his medal picture had been purchased by the Society. Mr. John H. Gash received his medal through the secretary Mr. Bartlett, who has also desired to transmit their awards to Mr. Frederic E. Ives, Mr. F. R. Frapie, Mr. W. A. Stewart (exhibit purchased by R.P.S.), Mr. J. M. Whitehead (exhibit purchased by R.P.S.), and to Mr. Percy Lewis.

The chair was then taken by Mr. A. Haddon, and the president read his annual address. Mr. Dallmeyer's address reviewed the educational facilities offered to students in photography from the time of Sir William Abney's course at Chatham in 1863 to the present time, touching upon the several papers read before the Society in which photographic technical education was the theme. The government support extended to continental centres of teaching was contrasted with the lack of this support in Great Britain; and then followed an account of the good work which, despite this fact, was being accomplished here. The president then outlined the efforts made by this society as far back as 1890 to secure the support necessary for the starting and maintenance of a Photographic Technological Institute. The then Lord Mayor received a deputation on the subject, and the question of funds was discussed. This effort, although commending itself to Sir Henry Isaacs, failed to attain success, however, and the Society had up to the present only itself to thank for its flourishing condition. The advocacy of such an institute originated, it is believed, with Dr. Emerson in his Naturalistic Photography (1839), when he wrote: "We fondly hope that a college of photography may one day be instituted, where good art and science training may be obtained, where regular classes will be held by professors and regular terms kept, and where some sort of distinguishing diploma, such as Member of the Royal Photographic College, will be given to all who pass certain examinations." The necessity for such an institute has also been dwelt upon by many other eminent men since it was first mooted, and the president went on to enquire whether the iron was not now sufficiently hot for them to strike again, and so endeavour to obtain adequate recognition of our science and efficient means to pursue it. Finally, he hoped that next year, the Society's jubilee year, would be thought not an unsuitable time for the incoming president to lend his influence to promote such an end.

A vote of thanks was passed to the president.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 9TH.—Mr. A. Maekie in the chair. Mr. A. L. Henderson passed round some excellent prints made about 1845, from negatives by Sir Charles Fellowes, to show the sort of work done in those days. The prints were on albumen paper and in good condition. Mr. Smith showed a splendid telephotograph of the dome of St. Paul's, taken from a distance of 2,000 feet with a magnification of 25 diameters. Mr. Thomas Illingworth gave an extremely interesting and practical demonstration on the carbon process, and after explaining the elementary stages, as to what the process is and what the tissues are, proceeded to show how simple the developing and transferring, both in single and double really is.

To those who only use the tissue in small quantities Mr. Illingworth recommended that the tissue should be purchased insensitive and sensitised as required, by immersing for two or three minutes in a solution of potass bichromate 7oz., water 1gal. Drying the tissue is most important, as on this the after quality of the picture largely depends. It must not dry too quickly, or take too long, four hours being about the average time, and the tissue must not be dried in a room where there are any acid fumes or gaseous odours. Mr. A. Haddon remarked on the formula given for sensitising, containing no ammonia, as the tissue is likely to become more insoluble with plain bichromate than if the solution is slightly alkaline. Mr. Illingworth agreed with this, and said they always add three drams liquid ammonia to each gallon of solution. Mr. J. E. Hodd remarked that in making some carbon transparencies he had noticed small black particles in the tissue, which interfere very much when making enlarged negatives. Mr. W. J. Ramsey suggested that no doubt these particles were due in the manufacture of the pigment, to the colour being insufficiently ground; as, especially in transparency tissue, the grinding must be very thorough. In regard to some difference on the opinion of the best actinometer, Mr. W. D. Welford said he considered the best form to be one which prints up to a certain number or letter, and can be left out without any attendance whatever until that number or letter is reached. Re the continuing action of light on a piece of exposed tissue, Mr. Henderson wished to know if this action could be imparted to a piece of unexposed tissue, by being placed in contact, under pressure, and put away in the dark for a time, and if so, how long it would take?

Mr. A. Haddon said it was quite possible for such action to take place, as the same way that this continuing action goes downwards in a carbon pigment, so it would go upwards if another tissue were placed in perfect contact.

Mr. Illingworth remarked that he did not think a picture could be produced in this way; but, at the same time, such action does go on, in a piece of partially exposed tissue, and becomes more quickly insoluble if allowed to get at all damp.

Mr. R. J. Beckett asked if drying the tissue after sensitising on ferrotype sheets, or like substance, was advisable, to which Mr. Illingworth replied that this method of drying the tissue he had found most satisfactory, and has numerous advantages, one being the fine surface that is obtained; and another, the less chance of fog from impurities in the atmosphere or unsafe light. Mr. W. J. Ramsey remarked that in his practice he had always dried the tissue on a collodion plate which, for making enlarged negatives, gave a very fine texture, and enabled a close contact to be obtained, thus ensuring absolute sharpness of detail.

A most hearty vote of thanks was proposed to Mr. Illingworth by Mr. S. H. Fry, seconded by Mr. J. E. Hodd, and carried unanimously.

CAMERA CLUB.

The following are extracts from the Club Journal for October:—Members, on their return to town after the vacation, will find that considerable alterations and repairs have been effected in the Club. In the case of the dining room, by the removal of the large bookcases, a considerable amount of much-needed space has become available for diners. The whole room has been re-painted and decorated, and other improvements which have been made there and in the service room will, it is believed, add considerably to the comfort of the members. The committee room has also been thoroughly done up, and when rearranged will probably be available for the use of members when not required for meetings. The studio has also been cleaned, and the cameras, etc., put in thorough working order, while the photographic department in the basement has received the attention it so much required. The library of the Camera Club contains a large number of very valuable books dealing with scientific, artistic, and photographic subjects. These it is proposed to remove to the late enlarging room, which, fitted as a library, will afford greater facilities for arranging and keeping the books in order than has hitherto been possible. This will also provide a snug and comfortable study for those who wish to consult the works upon the bookshelves. As regards the ordinary books of reference, space will be provided in the club room for those which are in constant use. It is hoped that these alterations and improvements will meet with the approbation of the members, and render the Club more attractive to them and their friends in the future.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

At the meeting of the General Committee held on 10th October, it was reported that, in view of the opinion that had been expressed at the previous meeting, that some members might not like to disclose the particulars of their insurance to the officials of the Association, an arrangement had been made with the Fine Art and General Insurance Company to receive applications direct from members, and to allow the agreed discount, provided the application be made on a form issued and signed by the hon. secretary of the Association.

Applications for membership were read and accepted from Messrs. Frank Bishop (Marion and Co.), London; J. Byron, New York, U.S.A.; and I. Saunders, Birmingham.

Correspondence was read referring to the proposed meeting in Birmingham for the purpose of forming a local branch of the Association. It was announced that Mr. Alfred Ellis (hon. secretary), and Mr. T. C. Turner (hon. secretary of Local Branches Committee) would attend the meeting to explain the objects of the Association, etc.

Several letters were read asking advice on questions of copyright, and the hon. secretary was instructed as to the reply. A letter from a member stating that the Plate and Paper Makers' Association had

declined to acknowledge him as a dealer was ordered to stand over for fuller information. Letters were read referring to:—The right of photographers to the supply of electric current for photographic printing purpose in the daytime on the terms it is supplied for motive power: A suggested method of reserving copyright by notice on cards of terms, bill heads, and receipt forms:—The suppression of itinerants who obtain money for photographs which are never delivered. The subjects were ordered to be placed on the agenda for consideration at the next ordinary meeting in December, and also to be referred to local branch meetings. Notice of the committee was directed to an advertisement in a Birkenhead newspaper offering free cabinet portraits. The matter was referred to the Liverpool Branch.

SOUTHSEA PHOTOGRAPHIC SOCIETY.

THE members of this Society foregathered in large numbers at the headquarters, Pembroke Road, on Wednesday last week, when the winter session was inaugurated with all the pleasure attendant on a musical evening. Mr. W. G. Lewis (the president) occupied the chair, and, in the course of a few introductory remarks, said that an excellent programme was complete in the printers' hands for the season, and would shortly be issued to the members. The work during the summer had been more or less of an individual character, and one gentleman had secured as many as 400 negatives. He had heard on all sides of the immense amount of work done by members during the holidays, and the exhibition which they were looking forward to in December would no doubt be a most successful one. The one last year was the most popular ever held in that part of the world, and he ventured to say that the forthcoming one would be quite equal to it, if not superior. Mr. F. J. Mortimer, the Society's courteous hon. secretary, had arranged a delightful programme. Mr. G. Washington Allen's humorous recitations and the comic ditties of Mr. Sam Bolt constituted the lighter element of the proceedings, while the banjo selections by Messrs. J. Holloway, P. R. Denham, and F. J. Mortimer were vociferously applauded. Mr. C. E. Pilcher's fine renderings of "Take a pair of sparkling eyes" and "A Soldier's song" gained undeniable encores, and in response to a similar compliment, Mr. F. J. Lawton substituted "Father O'Flynn" for "Long Ago in Aleala." Mr. C. Wyatt sang "Down the Vale" in tasteful style, and was heartily recalled, while other vocal items of much merit were contributed by Messrs. H. M. Schofield ("The Toreador" and "On the road to Mandalay") A. Debenham, Gilbert Wood, and J. Holloway. Mr. W. C. Coasby played "The Broken Melody" as a cello solo, and a pianoforte selection was given by Mr. M. Holloway, who admirably discharged the duties of accompanist.

SOUTHAMPTON CAMERA CLUB.

THE members of the above club held the first meeting of their winter programme on the 13th inst., under the presidency of Mr. G. Vivian, when Mr. J. D. Haysom delivered an illustrated lecture on "A Visit to Germany." The lecturer cleverly conducted his audience on their imaginary trip on the Rhine, describing many of the charming old castle ruins with which it abounds, and giving several quaint and romantic legends connected with them. He also gave graphic descriptions of various beautiful monuments on the route, including that of the Emperor William at Coblenz, and the memorial to the Emperor Maximilian at Nuremberg. The tour included visits to Cologne, Mainz, Worms, Weisbaden, Munich, Lake of Constance, and Strasburg, and the lecture was suitably enlivened throughout by numerous lantern slides. On the proposition of the chairman, Mr. Haysom was accorded a hearty vote of thanks for his interesting and instructive discourse.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE following are extracts from the Report for the year 1901-2:—Your Council have pleasure in presenting the Eighteenth Annual Report, which covers a year of unprecedented change and advancement. The attractions of the new meeting room and dark room have proved more than sufficient to counterbalance the increased subscription, and have amply justified the new policy recommended by your Council. The number of members elected during the year is 45. Further improvements in furnishing and heating the meeting room will shortly be carried out, but the dark room is practically completely furnished, and is fitted with such a variety of apparatus that every member of our Society is placed on a level in the matter of the necessary tools wherewith to complete and carry out those processes which with insufficient apparatus form so great a bar to the average photographer. It is recommended by your Council that the policy of adding to the apparatus provided for members' use should be carried out as far as the financial position of the Club will allow. It is further their opinion that the Society should provide all apparatus necessary for use in the scientific side of photography, and not as has hitherto been the case, make provision for pictorial workers only. As a suitable path for further advancement your Council would emphasise the fact that at present no provision whatever is made for photomicrography, and that its study is practically neglected by the members.

The financial position of the Club still remains eminently satisfactory. On reference to the balance-sheet it will be seen that a sum of £122 1s. 8d. has been spent in furnishing, and that of this sum £72 5s. 1d. has been taken from the current account. To spend so large a sum from the current account in furnishing, without an adverse balance, augurs well for the future financial condition of the Society. Considerable legal expenses have been necessitated, but as by its employment the Society is relieved from a burden of about £15 per annum, the money has been well spent. The programme has been of the usual interesting description,

and commenced with the opening of the new rooms by Alderman Edwards, the Lord Mayor of Birmingham. Mr. W. T. Greatbatch, F.R.P.S., is to be congratulated on having for the third time won the medal of the Royal Photographic Society. This medal has been won by some member of our Society every year for the past six years, and we believe this establishes a club record. Under the able directorship of Mr. P. B. Rider, the club's portfolio has been re-organised, and with the most successful result; a large number of members contributing, and awaiting its monthly appearance with interest. Your Council are desirous of expressing the indebtedness of the Club to Mr. Whitworth Wallis, who has now fulfilled his year of office as president.

Your Council have pleasure in reporting the success of the annual exhibition, the number of pictures submitted and the number accepted being greatly in excess of the previous year. Our thanks are again due to the Royal Society of Artists for their kind permission to hold our annual exhibition in their galleries. The financial result was also excellent, and largely contributed to by the energy displayed by members in disposing of tickets, the number sold being greatly in excess of any previous year. The attendance of the public was also about 1,000 more than in the previous year.

The inability, through illness, of our president, Mr. Whitworth Wallis, to open the exhibition was most unfortunate, and Mr. Wallis had the sympathy of the Society in being prevented from making any public appearance from so unpleasant a cause. Your Council at practically the last hour called on its chairman, Mr. A. J. Leeson, to perform the opening ceremony, and with the courtesy and kindness which Mr. Leeson has always displayed, he at once accepted the onerous duty. The best thanks of the Society are due to Sir J. B. Stone for the pictures to the number of 424 produced by him and loaned to the Society by the Board of Education, South Kensington, where they have been on exhibition. In the open section 460 pictures were received from 146 competitors, of these 237 pictures from 100 senders were hung, and included 59 pictures from 14 members, the rest being contributed by non-members. The lantern slides included 63 sets of 4, of which 60 sets were accepted. In the members' section A, 95, and in section B, 30 pictures were hung—70 pictures in all being rejected. In the Warwickshire Survey section, 291 prints were contributed by 18 members and friends.

The optical lantern is still maintained in thorough repair. For the future the enlarging lantern will remain permanently fixed in the dark room, and will always be available for use by any member who may desire to either enlarge or make lantern slides. This lantern is of excellent construction, and will enlarge or reduce either whole plate or the smallest film. The extreme simplicity of fixture should make its use very general among members, the only operation necessary being to turn up the light, insert the negative to be enlarged or reduced, and focus. The Society are indebted to Mr. A. H. Saunders for a set of slides of various subjects, contributed early in the year. Your Council desire to impress on members the necessity of increasing our present collection of lantern slides. These slides are loaned to members and are much appreciated, but new sets are sadly needed. The lantern curator will be pleased to receive gifts of slides at any time.

Warwickshire Survey (Curator's Report).—The survey work of the past season compares most favourably with that of previous years, both as to the number of workers and the quantity and variety of the photographic records obtained. The president of the Society, Sir J. B. Stone, M.P., and 15 members and friends, contributed to the grand total of 291 prints, all of which were shewn at the Birmingham Photographic Society's exhibition in February—March last. The subjects treated were varied, and besides those from the out-of-the-world corners of the County, scenes in Birmingham and the immediate neighbourhood were well represented. The old Theatre Royal, the City markets and fairs, and the interesting workings of the weights and measures department were exhaustively treated.

CROYDON CAMERA CLUB.

MR. GEORGE SCAMELL, the well-known hon. secretary of the National Photographic Association, on Wednesday the 8th inst., before a large attendance of members, gave an anecdotal lantern lecture, illustrating the utility of photographic surveying and recording, and the pleasure to be derived from its intelligent pursuit. The slides shown were from negatives, and prints from which had been accepted by the British Museum.

Technically excellent, a most interesting series they made. It is only possible to briefly epitomise the many historical, literary, archaeological, and antiquarian points illustrated and referred to. The size of the prints Mr. Scamell considered of little importance, though whole plate was preferable. The prints themselves should, of course, be executed in a permanent process, either platinum or carbon. A saddened expression was observed to pass over the features of a prominent member at no mention being made of his favourite "bi gum," a permanent process in itself. Can it be that the lecturer thought that if this method of reproduction were employed tremendous changes in a locality might be indicated, when, as a fact, none had taken place.

Mr. Scamell strongly advocated the use of a scale in the picture, or failing that, the introduction of a figure. The points of the compass should also be indicated, and a correct description sent in with each view. He also recommended deeply sunk mounts to avoid damage to the prints by surface friction. In Warwickshire they had adopted a standard mount of this description, and upwards of 30,000 prints had been mounted thereon.

His own plan was to select a map of a county, or section of a county, and indicate the points of interest by dots, he subsequently, so to speak,

"did the dots." In this way he had nearly exhausted Hertfordshire. It was a good plan to allot specified areas to various individuals to avoid clashing as far as possible. In seeking fresh fields to conquer he found the "Way About" series most useful, and the assistance of an archaeologist should be obtained when possible. In conclusion, Mr. Scamell urged the members to look through their negatives, when probably some of value would be found.

Among the visitors present was Dr. Hobson, one of the photographic secretaries of the Photographic Record and Survey, who, in the course of the discussion which followed the lecture, dwelt upon the aims and objects of the Society he represented, and invited the aid of those present.

On the motion of the President (Mr. Hector Maclean, F.R.P.S.), a warmly-expressed vote of thanks was adopted.

Several of those present submitted their names for election to the National Photographic Record Society.

LEEDS CAMERA CLUB.

A SPECIAL general meeting of the members of the above club was held on Friday last, the 10th inst., for the purpose of considering the advisability of removing the headquarters of the club.

It had been generally observed for some time that the rooms at the White Swan Hotel were insufficiently large to accommodate the large number of members attending the lectures, and a sub-committee was appointed recently to make enquiries with a view to more commodious quarters being secured.

The sub-committee having reported favourably on the accommodation to be found at the Athenæum, on the motion of Mr. Howe, seconded by Mr. Yewdall, a resolution recommending that the club headquarters be transferred to the Athenæum Buildings, of Park Lane, Leeds, was unanimously adopted, the removal to take place forthwith, the time of meeting to be as usual, viz., 8 p.m.

This step is only preliminary, it is understood, to securing exclusive club premises in the future.

A vote of thanks to the proprietor of the White Swan Hotel for his unflinching courtesy concluded the business.

LONGTON AND DISTRICT PHOTOGRAPHIC SOCIETY.

THE first meeting of the session was held at the Sutherland Institute on Thursday, October 2nd, when a practical demonstration of enlarging, suitable for beginners, was given by the honorary secretary, before a goodly attendance of members. Mr. Mottershead, whose lecture was very helpful to those who engaged in photography, spoke of the convenience of making enlargements instead of taking large direct prints, and of the advantages of a small apparatus over big outfits. He demonstrated the methods of obtaining enlargements by daylight and by artificial light, and described the process of making enlarged negatives for carbon and platinotype work. He next pointed out the necessity of negatives being free from stain and free from excessive contrast; and dealing with developers and irritant poison of metal compounds, he quoted recipes from Dr. Grun. Using an apparatus employed for the first time, and demonstrating with negatives borrowed from members, Mr. Mottershead then gave a practical illustration of producing pictures, giving hints on "dodging" and "faking," vignetting, light, pencilling and shading.

News and Notes.

MESSRS. J. and J. Brown, the Studio, Annan, writ: "Re your correspondent's enquiry for the Aristotype Co. in last week's JOURNAL; Messrs. McGhie and Co., 75, St. Vincent Street, Glasgow, are the agents for this country."

CRIPPLEGATE Photographic Exhibition.—The fourth annual exhibition of the Cripplegate Photographic Society will be held from 24th to 27th February, 1903, at the Cripplegate Institute, Golden Lane, E.C. Entry forms will be ready shortly, and those exhibitors desiring a copy should send in their names to the hon. secretary, Mr. Alfred T. Ward, Cripplegate Institute, Golden Lane, E.C.

THE Hove Camera Club's exhibition will be held on November 27th, 28th, and 29th. Entry forms are now ready. There are seven open classes, four for prints and three for lantern slides. The judges are Messrs. C. Job, J. C. S. Mummery, and F. Davey. Free conveyance of photographs will be given between Southampton, Hove, and Southsea exhibitions. The three societies also offer a special award (an artistically designed silver plaque).

THAT the number of people who write, or, in some cases, attempt to write, is very considerable is clearly evidenced by the success of the Writer's Year Book. This publication, which is a commercial directory for professional writers, photographers, and artists, only came out in July, but the demand for it has proved so great that a second edition has been found necessary and is now ready, and to be obtained from the publishers, at Granville House, Arundel Street, Strand.

NOTTINGHAM Camera Club (Mechanics' Institute).—The hon. secretary of the Nottingham Camera Club writes: "I have much pleasure in forwarding you a copy of the winter programme of the Nottingham Camera

Club. You will see that our exhibition is fixed for February 12th, 13th, and 14th next, when gold, silver, and bronze medals will be offered for competition in the open classes. The prospectus, which will be ready next month, and full particulars may be obtained from the exhibition secretary, Mr. Arthur Black, 9, Bower's Avenue, Nottingham."

THE Royal Photographic Society of Great Britain.—The following is the programme of lantern lectures to be given at the New Gallery, 121, Regent Street, on Monday, Thursday, and Saturday evenings at 8 o'clock:—Saturday, October 18th, "Colour Photography," by E. Sanger Shepherd, Esq., F.R.P.S. Monday, October 20th, "Swiss Glaciers, etc.," by Eustace Young, Esq. Thursday, October 23rd, "In Spanish and Portuguese Waters," by R. Child Bayley, Esq., F.R.P.S. Saturday, October 25th, "Mountaineering from a Woman's Point of View," by Mrs Aubrey Le Blond.

DEVONPORT Camera Club auspiciously opened its session in the large hall of the Technical School on Wednesday evening last week, when Mr. F. O. Bynoe (R. and J. Beck, London) delivered a popular illustrated lecture, entitled 'Photographic Facts,' to an audience numbering nearly four hundred. The lecturer outlined the principles of pinhole photography and simple lenses, and explained in detail the difference between a cheap lens of the ordinary type and the highly-corrected instruments of modern production. A large number of lantern slides were exhibited, the subjects ranging from lightning flashes to Mr. and Mrs. Cronje at St. Helena and Mafeking Day scenes in London. Mr. Bynoe emphasised the importance of photographers joining a society, where they might meet others of kindred tastes and obtain criticism and advice.—"Western Morning News."

ONE of the advertisers in our "Almanac" writes: "Does not the enclosed strike you as being very funny? Our 'Almanack' advertisement has brought us many enquiries from abroad, but we do not remember anything approaching this. If you think it good enough for the BRITISH JOURNAL you are welcome to use it":—"I take the liberty of addressing you with the view to enquiring if you would care to have photographs of the Coronation Durbar, to be held on the 1st of January next at Delhi. I may mention that I am an amateur photographer, and will be on special duty with the Foreign Secretary at Delhi during the Durbar, and will have special facilities for taking photographs of the Durbar functions. The chief among these will be the Viceroy's State entry into Delhi, accompanied by the Duke and Duchess of Connaught and the Indian nobles, all mounted on elephants; the Proclamation in the Durbar Amphitheatre of the Coronation of His Majesty as Emperor of India; the grand review of 40,000 troops; the fireworks; investiture of the Orders of the Star of India and Indian Empire; Indian Art Exhibition: International hockey, polo, football, and cricket matches, etc., etc. In the event of your caring to have photographs of all these functions, I shall be prepared to supply you with as many copies of each, on the following terms, viz.:—That you supply me, free of cost, landed in India, with a high-class half-plate Film Kodak, fitted with a good lens and shutter, and with spools sufficient for 100 exposures, I supplying all the other necessary materials, such as developers, paper, etc. After the Durbar all the negatives will become your property. References permitted to—. If you are agreeable, please send camera out as soon as possible, by Parcel Post, insured, and specify how many copies of each photograph you would like to have, and if of any particular subjects. If you are agreeable to the proposition, please be careful to see that the camera and fittings are of a superior class, as the better the camera the better the pictures."

THE Scientific and Technical Exhibits at the Royal Photographic Society's Exhibition.—This section of the Royal Photographic Society's exhibition appears to be rather smaller than on the two previous occasions, that is, since the larger accommodation of the New Gallery made it possible to represent adequately this side of photographic work. We hope that this is not an indication that the section is receiving less attention and is likely to suffer extinction, the fate that we regret to observe has overtaken the apparatus section, except, indeed, so far as concerns the trade stalls and a few exhibits that appear to be out of place in any of the existing departments. The most striking novelty in the Gallery is a "parallax stereogram" shown by Mr. F. E. Ives. No details are furnished, but we believe that the photograph is taken by means of a lens of large diameter obscured except for two apertures, one on each side, so that it acts in a similar way to the two lenses of the ordinary stereoscope camera, but that the two images are superimposed. In front of the sensitive plate there is placed a screen with vertical lines on it, alternately opaque and transparent, at such a distance that each image will impinge upon the plate in narrow, vertical strips, and in the shadows of the opaque lines cast by the light transmitted by the other opening in the lens. The two images are thus received on the plate in narrow, alternating strips. For viewing, the eyes take the place of the openings in the lens, the lined screen remaining in position to keep the two images separate. The correct position for the eyes is indicated by two holes in a board, no other apparatus being necessary. The effect is perfect. The only example of colour photography by the Lippmann process is a photograph of the spectrum of the arc light by Mr. Edgar Senior. This is an improvement on Mr. Senior's previous noteworthy results, being taken with a narrower slit, but still the colours shown are not quite the same as those which one sees in the direct spectrum. It seems not unlikely that the differences are inherent in the process. Of other prints in colour, Mr. Brewerton contributes some in which the blue print is in Prussian blue, and the red and yellow superposed carbon prints, and Miss Acland some copies of miniatures by a modification of the Sanger Shepherd three-film process. These results are admirable, but they are not convincing. It would be better if an object were used less valuable than a precious miniature and more convenient than a landscape, so that the object and the copy could be exhibited side by side.

It is well known that very good results can be obtained; we want now to see how near they are to perfection. Mr. Hort Player exhibits some splendid examples of his method of copying engravings by superposition. The ordinary relative positions of the engraving and the sensitive paper are reversed, the light passing through the sensitive paper before it illuminates the engraving. A yellow screen is used, and potassium iodide is added to the developer. The whiteness of the ground, the blackness of the lines, and the sharpness of the detail are excellent. Photomicrography is well represented. The most notable examples are a series of photomicrographs taken in connection with the bacterial treatment of sewage, exhibited by Dr. Clowes. The enlargements vary from about natural size up to three thousand diameters. These fifty or more photographs may well be accepted as a model of what this kind of technical work should be. Mr. Ives has twelve photomicrographs made with a small and simple apparatus that is not described. The results would do credit to any apparatus, and show what may be done by care and skill without elaborate conveniences. Among the other work of this class that deserves commendation is a series of microphotographs of etched alloys by Mr. Ernest A. Lewis. Astronomical and spectroscopic photography is well represented by very fine work from Sir Norman Lockyer, Captain Hills, the Greenwich Observatory, and others. Some of the spectra have no wave-length scale attached, or any other indication of the part of the spectrum represented, and others bear no indication of the facts sought in their preparation or of the facts that the spectra demonstrate. If a little information of this kind were invited by the Society's officers and incorporated in the catalogue, the exhibits would gain vastly in interest. This want of information is also manifest in the "multiple lightning flash," fourfold, by Mr. J. Howden Wilkie, presumably taken with a swinging camera, and in other cases. There are many other exhibits that deserve more than a passing mention. Snow formations, huge "caps" and "mushrooms" are illustrated by Mr. Vaughan Cornish. Balloon photographs, Röntgen-ray work, the photography of animals and meteorological photography are represented by collections of good and in some cases unique examples.—"Nature."

A SPYING Machine.—I see that one of the big cinematograph firms is putting on the market a new kind of photographic clock. The idea is so simple that I wonder it has never been thought of before. You put the clock on the mantelpiece in the usual way, and every time it strikes the hour and half-hour it also takes a living picture, so to speak. A shutter opens, a film is exposed, a sharp click is heard, and then if you have been careful to go out of the room just before, you can see for yourself whether after all it is the cat that nips the whisky down an inch at a time, or whether it's the new cook. The clock not only takes the photograph, but it develops and "fixes" it all at one go. So that after cook has solemnly protested by the ashes of her father and the temples of her gods that she is a strict teetotalarian, you have simply to produce the ace from your sleeve, as it were, and scoop the pool. One does not like to think much about a mechanism of this sort, which after all is hardly fair cricket. Still, in modern times what with the scramble for the chips and the rush for unmerited social distinctions, I should hesitate to say that there will be no demand for it. Merchants who keep a staff of people to do work while they themselves are taking up a systematic course of drinking will doubtless rush for a mechanism that will secretly record what was taking place in the office at the stroke of every half-hour. If at 10.30 the photograph shows that Smith was not in his place, and at each succeeding half-hour the same phenomenon is to be observed up to one o'clock, the pain of a stormy personal interview will be spared to both sides. Mr. Smith will simply receive a little note suggesting Saturday as a convenient day for parting, and his employer will have no need to reproach himself with injustice. Of course, the long and vexed question as to whether your haughty neighbour, Mrs. de Tomkings, really does take breakfast in her curl-papers or not can now be settled. In the fierce rush of social rivalries there is no room for mercy. All that there will be room for is one of these new patent clocks. You make Mrs. de Tomkings a present of it, and say you'll come in again at the end of the week and show her how to wind it up. At the end of the week you call again and scoop out the pile of finished photographs from the internal clockwork. And if you have had the rare luck to get a picture not only of Mrs. de Tomkings in negligé breakfast attire, but also of Mr. de Tomkings in his shirt-sleeves disdainfully throwing the ham and eggs across the table, your hour of triumph will have come, and the supremacy of these upstarts will be gone for ever. Young ladies who have waited for years for a likely beau, and have got one at last, will be able to make sure of him under the new system. It will be all very well for the young man to write a cold, harsh letter a month or two later, and deny that he ever entertained any such ridiculous thoughts, and to protest that he cannot allow these ungenerous insinuations to be made against him. As I say, that will be all very well, but it won't fill the bill so completely as it did in the old times. If the young lady has played the game skilfully, she will have been careful to see that the young man was in an imploring attitude on his knees just on the chime of 10.30, when the new patent clock had got its little eye cocked on the scene. And if the young man on being confronted with the photograph should say in an off-hand way that it merely represents him in the attitude of politely attempting to borrow half-a-crown till Saturday, the matter may be left to the jury with confidence. The damages could hardly be less than a clear thousand, anyway. The vexed question as to whether or no the housemaid entertains a strange policeman in the kitchen and regales him on the balance of yesterday's mutton and a considerable instalment of to-morrow's beer, can be easily settled with one of the new patent clocks. If, when Mary is taxed with the surprisingly consumptive appearance of the mutton bone, she alleges that the shrinkage is due to the weather or the cat, her confusion will be assured by the production of the usual automatic photograph. If there is a faithful picture of

the kitchen with a policeman seated expectantly at the table, while Mary is seen to be scooping an able-bodied helping out of the family joint with her own fair hands, I don't see that she will have any case. And if the next photograph should show Mary seated on her admirer's knee, it will be a clear call for a month's notice in lieu of wages, without the option of a fine. This new invention will work a lot of mischief unless it is taken in hand in time. I can quite see that. Ladies will arrange to have one of them fitted up at their husband's clubs; and if on that evening when he was kept so late at the office and came home so tired and talking so thickly, the photograph record shows him at the club card-table raking in the pool with a joyous smile, he will probably come to hear of it. There is, of course, the prospect of a still greater tragedy in the contingency of a man arranging to go down and spend the evening at his club, while his wife sits up for him at home. So far, all will be well. But if it should subsequently turn out that all the periodical photographs taken of the club-rooms that evening did not include the absent one on any occasion, the interesting if troublesome question of whereabouts will arise once again with a dismal emphasis. I think we shall have to form a syndicate and buy this invention up before the inventor gets a better offer from the ladies.—Arnold Goldsworthy, in "Black and White Budget."

THE R.P.S. EXHIBITION.

To the Editors.

Gentlemen,—There is never any lack of criticisms of exhibitions, but they are usually so obviously tinctured with a sense of personal grievance, with an undercurrent of "Why was my splendid work rejected?" that their value as criticisms is seriously impaired. The criticism of "M. R. P. S." is of quite a different character. It seems suffused with a redolence of collodion and iron developer, and is pleasantly reminiscent of dark tints and head rests, of pinholes, comets, and lines in the direction of the dip; in fact, of the good old days when a negative, without spot or blemish, was something to be proud of. And yet there is internal evidence in "M. R. P. S.'s" letter that he can have known but little of these delights of the past, for twenty years ago the old order of things had already given place to the new.

A criticism, to be of any value, must be the opinion of one possessed, at least, of two qualifications, knowledge and impartiality of judgment. As "M. R. P. S." writes under a pseudonym (which he is perfectly entitled to do, and I intend to follow his example), before his opinion can be taken seriously, it is necessary to form an estimate from whatever evidence there is available of his competence to judge. As to his impartiality, his statement that "he is not an exhibitor, and has never exhibited," is not conclusive, though there is not the slightest reason to doubt its truthfulness. As to his knowledge, he tells us he has had twenty years' experience, that he is photographer to practically the largest firm in London, and adds that if he turned out work similar to 75 per cent. of the pictures (?) hung his place would not be worth twenty-four hours' notice. I do not know which is practically the largest firm in London, or which firm turns out the largest amount of work, but I am acquainted with the work of several firms who are among the largest, and if his firm should happen to be one of these I can quite endorse his statement; but it is also the fact, and probably it has never dawned upon him that if he could turn out work similar to 75 per cent. of that hung he would be in a position to command an income far beyond the salary that even the largest firm in London can afford to pay.

But the clearest indications of "M. R. P. S.'s" capacity and his powers of observation are afforded by the three pointed questions he asks, and I shall probably best perform the analysis by answering the questions, although I may not answer to the description, "some competent artist." He asks (1) why are fuzzy wuzzy (or out of focus) photographs considered artistic? They are not; neither are well defined photographs considered inartistic. The finest definition and extreme diffusion of focus are equally compatible with artistic merit. (2) Are there any professional photographers exhibiting in the pictorial section? There are. How about H. Walter Barnett, Jas. Auld, Miss Catherine Edmonds, Wm. Gill, Fred Hollyer, Dudley Hoyt, John Moffat, Furley Lewis, John H. Gear, Chas. Sweet, R. N. Speaight, R. Fellows Willson, and W. M. Warneuke? Surely the names, if not the work, of some of these must be familiar to the photographer to practically the largest firm in London. (3) Would any photograph absolutely in focus be accepted and hung? Certainly it would. There are dozens of pictures absolutely in focus on the walls.

Seriously, such a criticism as that of "M. R. P. S." is absolutely unworthy of notice, but it is instructive, as showing the incapacity of the average photographic operator to appreciate anything outside the groove in which his own work runs. The pictorial section of the exhibition of 1902 is, unfortunately, not a representative one. It

is admitted on all hands that it is the worst the society has held for years, and there are ugly rumours afloat as to the impartiality of its management, but at its worst there is ample material for useful study for those who are intent upon learning. The ordinary portrait photographer has to work to please his clients, and, as a rule, his clients are commonplace people, and prefer commonplace and conventional work. Perhaps it is not his business to educate their taste, but that is no reason why he should not educate his own. That among the cultured class there are many who appreciate, and are willing to pay adequately for, work of a higher standard than the so-much-a-dozen frequently respected names in the ranks of professionals are those of men whose output is small, whose charges are high, whose incomes are good, but whose work is possessed of that artistic merit and individuality which are incompatible with wholesale production and ordinary commercial methods. It sounds very well to despise the amateur and to scorn his methods, but it is not common-sense, and therefore not business. We cannot abolish him, neither can we extinguish his influence. It is he who lines the walls of our exhibitions, it is his work the visitors come to see, and it is the impression of his work they carry home with them. If "M. R. P. S." wants proof of the far-reaching influence of amateur work he can find it where probably he would least expect to—in the professional section of the present exhibition; it is there, but it may require more observant eyes than his to recognise it.—I am, yours, etc.,

A MEMBER OF THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.
October 15th, 1902.

To the Editors.

Gentlemen,—I am dealing fully with Mr Bennett's letter in this week's PHOTOGRAPHY, which kindly gave me the opportunity of replying in the same number which contains Mr. Bennett's attack.

The following particulars should be sufficient to disprove Mr. Bennett's statements, but should any of your readers require more, I must refer them to PHOTOGRAPHY. The selection committee on the first day numbered eleven members, all but three unknown to me.

They had all the photographs before them for selection, the names of the authors being withheld. It says little for Mr. Bennett's common-sense that he should suggest the possibility of collusion on the part of eleven men mostly strangers to one another. Some of my work was accepted almost unanimously, some of it was thrown out with equal decision, the same in the other cases mentioned. As nobody voted on their own work, and as the committee did not know whose it was, the bona-fides of the committee should be obvious to even a rejected contributor.

Mr. Bennett complains of Dr. Morgan and my having the "overwhelming number" of five frames, and Mr. Croft having six. In 1900, when Mr. Bennett himself had six, Mr. Croft had ten, with a totally different hanging committee. Mr. Bennett would throw out good work if it were contributed by the committee; he will find few to agree with him. He accuses by insinuation some members of the Postal Camera Club, who were on the committee, of partiality towards their club. The P.C.C. contributes annually one-sixth and one-seventh of the whole R.P.S. Exhibition. This year it has forty-seven frames, two years ago, allowing for change of membership, about sixty. Next time Mr. Bennett finds a mare's nest, perhaps he will think twice before sending it to three photographic papers.—Yours, etc.,

21, Pembroke Gardens, W.

J. C. WARBURG.

To the Editors

Gentlemen,—Doubtless the statements made by Mr. Bennett in your last issue are quite correct, but "twas ever thus." A similar state of things has existed for very many years, and will, in all probability, continue to exist until the judges and members of the selecting and hanging committee are debarred from exhibiting, in Section I., either for competition or otherwise, and not more than two pictures (in this section) are accepted from any exhibitor.

This new departure might deprive the Council of the assistance of some of its present members, who happen also to be members of the selecting and hanging committee; but it would tend to restore the confidence of the exhibiting members generally, and give some of their excellent work a reasonable chance of being accepted.—Yours truly,

DROP SHUTTER.

To the Editors.

Gentlemen,—I read with some interest the remarks re. hanging of exhibition pictures. The best way to get at the respective merits of the "hung" and "unhung" pictures would be to organise an overflow exhibition of the pictures that were refused by the hanging men. I venture to say that such an exhibition would be most interesting, and would probably be more "photographic" than the "photographic" exhibition at the New Gallery, and that probably most subjects could be recognised without having to look for their meaning in the catalogue. I would myself gladly share in such an exhibition.—I am, Sirs, yours faithfully,

October 15th, 1902.

F. R. P. S.

THE SOUTHERN EXHIBITION.

To the Editors.

Gentlemen.—Our forthcoming exhibition, I am in hopes, will be the finest and biggest ever held in the South. Last year's record will be hard to beat. I know, but, as no doubt you are aware, Southampton and Hove are both co-operating this year, and the "triple award" should prove a great draw. Intending exhibitors should make haste and write to Southampton Camera Club (hon. sec., S. G. Kimber, Oakdene, Highfields, Southampton), Hove Camera Club (hon. sec., A. R. Sargent, 55, The Drive, Hove), and Southsea Photographic Society (hon. sec., F. J. Mortimer, 10, Ordnance Row, Portsea), for entry forms and particulars. There is a generous array of awards, and a special silver plaque I am designing will be awarded by the three societies to the exhibitor of the best work through the three shows. The three societies are also paying all carriages between the exhibitions, which will be a great saving to the exhibitors. The dates are: Southampton, November 13-19; Hove, 27-29; and Southsea, December 15-20, inclusive. We have now opened our winter season in earnest, and started last week with a highly successful smoker. Altogether, I hope we shall have a very progressive time in the South this season.—I remain, yours truly,

F. J. MORTIMER.

Southsea Photographic Society, Pembroke Road, Portsmouth.

KEEPING PLATINUM PAPER.

To the Editors.

Gentlemen.—In your issue of January 31st last you inserted a note from me on the above subject, but it elicited no comment, so I write again, enclosing two prints, illustrating my point, which was, that platinum paper would keep almost indefinitely if good quicklime were used instead of the ordinary calcic chloride. All that is necessary is to place in the reservoir at the bottom of the calcium tube three or four lumps of good hard stone lime, and leave it there till it falls to powder, then replace with fresh lumps; this will only be necessary after some three or four months. Do not fill the receptacle too full, as the lime expands as it absorbs moisture. One great point is, that with lime there is never any liquid produced, as may be the case with calcic chloride, which deliquesces, and may get on to the paper and ruin it.

One of the prints sent (from a rather thin snap-shot negative) was produced from paper stored with lime before my last note, and therefore at least eight or nine months old, and you will see that the whites under the mark are really white, while the other, stored with calcic chloride since July 1st, i.e., only three and a-half months, yields only degraded whites. Both prints were made to-day, and developed together. To those who only use platinum paper occasionally this ought to be a serviceable hint, as I know of several who have given up the use of this paper because of the difficulty of keeping it long enough.

If properly kept and properly used, I consider that nothing beats platinum paper for a certain class of negative, and that with ordinary care fewer failures should result from its use than with any other form of printing-out paper, to say nothing of its beauty and permanency.—I am, yours faithfully,

J. H. BALDOCK

Croydon.

October 13th, 1902.

MESSRS. BECK'S LANTERN LECTURES.

To the Editors.

Gentlemen.—We propose to send round to the photographic societies in the United Kingdom the enclosed letter, and as there may be a number of societies the addresses of which we may not be able to obtain, we think a notice of this letter in the columns of your valuable Journal would be of great interest to many of your readers.—Yours faithfully,

R. AND J. BECK, LTD.

68, Cornhill, London, E.C.

October 9th, 1902.

[COPY.]

BECK-STEINHEIL AND TELEPHOTOGRAPHIC LENSES.

Dear Sir,—In view of your winter gatherings, we think you might like to have a set of our lantern slides for exhibition to your members. They are in many ways unique; they are not the common run of landscape photos or speed examples—beautiful, perhaps, but which depend more on the light and the plate used than on actual optical excellence.

They are examples of definition, both in ordinary and telephotographic work, which are outside the pale of the snap-shot photographer.

Incidentally, they show that English manufactured lenses are not one whit behind the imported foreign article, but are, to the critical observer, ahead.

If these slides would interest your members, we shall be pleased to receive a note as to what date would suit you best.—Yours faithfully,

R. AND J. BECK, LTD.

THE WASHINGTON ANCESTRAL HOME IN NORTHAMPTONSHIRE.

To the Editors.

Gentlemen,—Absence from town has delayed attention to the reports, which, I find, have been so industriously circulated during the past few weeks, to the effect that the management of the Universal Exposition, St. Louis, 1904, have made overtures, to owners or agents, for the purchase and removal of the house known as Sulgrave Manor, the ancestral home, in Northamptonshire, of one branch of the Washington family. I therefore bespeak space in your columns to say that no such thing has been so much as thought of or suggested, much less seriously considered. Perhaps I may be permitted to assure the public that the Exposition authorities do not contemplate the transfer, from England or any other country, of buildings or monuments which have become interesting, either by lapse of time or by association with men and events.

Even if the management were inclined thus to proceed with the Sulgrave Manor House, they would, I fear, scarcely have time, before the close of the Exposition, to enter upon the prolonged discussions and contentions, or to decide the disputes and doubts, apparently inevitable when the Washington genealogy is involved. If they should muster courage to enter upon such a course, they might face the necessity, from time to time, for adding another building to their list. As Pope's interrogatory line suggests that there is a tendency among doctors to disagree, so the student, with an interest, however slight in heraldry, is forced to conclude that the same conditions are not wholly wanting in the genealogists, who, drawn from all quarters of the globe, deal with the origin and history of the English Washingtons. I am, Sirs, yours very truly,

GEORGE F. PARKER,

Commissioner in the United Kingdom of the Universal Exposition.

Sanctuary House, Tothill Street, S.W.

October 11th, 1902.

THE KODAK DEVELOPING MACHINE AND TIME DEVELOPMENT.

To the Editors.

Gentlemen,—We beg to advise you that we are now prepared to arrange dates with photographic societies for our representative to attend and give an address and demonstration in connection with the above subject.

The developing machine has created a very strong impression amongst all classes of photographers. It makes the Kodak daylight system complete, and, from the point of view of popularising photography, is so efficient that we think it marks a step comparable only in importance to the introduction of the daylight loading Kodaks.

The uniform quality of the results obtained with the machine, even when very considerable variations in exposure exist, cause general surprise, and we are desirous of making arrangements, so that all should have an opportunity of seeing the appliance at work. The machines can be seen in operation at our branches, and we shall be pleased to provide an interesting demonstration at any meeting where a fair number of people are gathered together. With this end in view, therefore, we shall be obliged if you will kindly give the matter publicity in the columns of your esteemed Journal.—Thanking you in anticipation, yours faithfully,

KODAK, LIMITED.

43, Clerkenwell Road, London, E.C.

October 13th, 1902.

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

Answers to Correspondents.

- * * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.*
- * * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.*

PHOTOGRAPHS REGISTERED:—

- J. R. Jones, 161, High Street, New Brompton. *Two photographs of the New Brompton Football Club, 1902-3.*
- G. H. Stanford, 190, Christchurch Road, Boscombe. *Two photographs: arrival and departure of H.R.H. Princess Henry of Battenberg at and from St. John's Church, Boscombe.*
- J. Hourston, 11, "The Studio," Govan, N.B. *Photograph of United Free Church, Barr, Ayrshire. Photograph of Kirkcaldie, near Barr. Photograph of Village of Barr.*
- H. J. Unwin, 42, Commercial Road, Hereford. *Photograph of group of Freemasons.*
- A. J. Ashbolt, 29, High Street, Southampton. *Photograph of Mark Bell.*

UNDECIDED.—As you seem to have no practical knowledge of professional photography we should advise you to stick to teaching—particularly as your prospects seem so promising in that direction.

LIPPMANN PROCESS.—"ROM" asks: "Could you inform me if any other metal than mercury could be employed in the process of colour photography by Lippmann, or is it that mercury alone will produce the half-wave length?"—In reply: No other metal will answer the purpose.

FLASH LIGHT PHOTOGRAPHY.—"PYRO" asks: "Where can I obtain full particulars and instruction in flash light photography?"—In reply: So far as we are aware there is no book published on the subject. Some who are working with flash lights will, probably, give you instruction in their use, for a fee.

VIEWS OF THE CORONATION.—H. K. (British Columbia) asks: "Can you oblige me with the address of some photographer from whom I can get some 8 by 10 views of the Coronation, and at about what price for unmounted prints?"—In reply: Messrs. Spooner and Co., Print Publishers, Strand, W.C., will supply views of the Coronation procession, but we cannot say the actual prices, but they are very moderate. Better communicate with them.

HYDROCHLORATE OF TEREBINTH.—"A WESTBURY READER" says: "I saw in 'The British Journal of Photography' some weeks ago that hydrochlorate of Terebinth or artificial camphor is commercial in France. Can you give me any information as to where I can obtain the same, as I have tried many chemists in England without being able to get the right thing?"—In reply: It is possible that it may be had from Hopkin and Williams, Cross Street, Hatton Garden, E.C. If they do not supply it we do not know where it is to be had.

COPYRIGHT.—H. MASON says: "May I ask your opinion on the following case? A certain paper reproduced one of my photographs in their illustrated paper, for which they paid the usual fee of 10s. 6d. for one reproduction, but after using it themselves they sold it again to some tobacco people, who reproduced it in their cigarette cases. Am I not entitled to an action for so doing?"—In reply: If the picture is copyright and you sold the right, stipulating that the picture should be used for only one reproduction we should say that you have cause of action.

FLASH LIGHT.—F. E. G. says: "Can you oblige me with the constituents of a practically instantaneous flash powder, and proportion of each, also where obtainable? I think I saw an advertisement in JOURNAL two or more years ago. Of what is Maloni's powder made?"—In reply: Numerous formulæ have been published for flash light compositions, but they are all more or less dangerous to compound, and use. We should advise you to use either magnesium or aluminium powder alone with one or other flash lamp or else the Flash-axe candles sold by Messrs. Fuerst Bros., Philpot Lane, E.C. Mr. Maloni, we believe, keeps his formula as a trade secret.

STAINED FILM—PERPLEXED says: "The enclosed negative films, together with several others, were developed with pyro-soda, and prior to fixing were good negatives. However, when placed in a hypo bath of full strength which had previously been used for fixing bromide prints developed with amidol, they were all more or less stained red. Can you explain why, and suggest a remedy?"—In reply: The stained portion seems to have been exposed to light before it was fixed, and that has set up a reversed action. Part of the film is a negative and the other part a positive. The remedy is, not to expose the negatives to light until they are fixed.

STUDIO.—"PERPLEXED" says: "I am about to have a wooden studio built, and have been in negotiation with the builders of the removable studios advertised in your columns. I find, however, that in submitting plans to the local authorities, they would not pass them unless covered with galvanised iron; could you, therefore, give me the address of any firm who make a speciality of studio building?"—In reply: If the local authorities will not permit a wooden studio to be erected, we should advise you to have one covered with galvanised iron. This any local builder will construct for you if you furnish him with the design that will suit your requirements.

VIOLET BLACK TONES.—TONE says: "Would you kindly give me a toning bath formula for violet black tone on Paget P.O.P., as enclosed portion? I toned this myself about two years ago on Paget paper,

but forget the formula. I think it is a borax and gold bath, but do not know the proportions. I can get the same tone with ordinary sulphocyanide bath, but it uses too much gold."—In reply: Here is a formula for a borax toning bath: Water, eight ounces, borax, eight grains, chloride of gold, one grain. But whether that will yield the tones you desire on that paper we cannot say. Whatever bath you use will require a good quantity of gold to produce black tones.

VIEWS IN SOUTH AFRICA.—THE PHOTOCOL COMPANY write as follows: "Having had an enquiry for a series of views of places of interest in South Africa, we should be glad to know whether you could put us in communication with a firm or person who holds good negatives capable of enlargement of, say, 24 by 18, of places of geographical, historical, or natural interest in Cape Colony, Orange Free State, Transvaal, and Natal, and if so, whether you can let us have in the first place a list of such subjects, together with some idea of approximately the cost of loan of same for re-production purposes, which may be obtainable."—In reply: We regret that we cannot give the desired information. We suggest that you communicate with some photographer in South Africa, say Messrs. Duffus and Co., Cape Town.

COPYRIGHT.—A. WEBSTER writes: "(1) Could you kindly give me the following information re registering photograph. Explaining my position you will see it means a saving to the town man, and a great loss to me. Nearly all my work is out in the country, so, of course I always take the views when the light, trees, etc., are best. I find a mean fellow in town has copied several of my best pictures, and I intend stopping him. Can I register a photograph of a hall without permission even if several copies are sold? (2) Also, is it best to register photographs before any copies go out of the shop? In future I intend to register all my best negatives. (3) Do I send two unmounted prints and 1s. 7d. for each view? If you will answer this I shall esteem it a great favour."—In reply: (1) you can register at any time, but that will not protect prints sold prior to the registration. (2) Yes, certainly. (3) If you send us two unmounted copies, and 1s. 7d., we will effect registration for you.

RESIDUES-COPYRIGHT.—"COPYRIGHT" asks: "(1) What is the best chemical to precipitate the gold in old sulphocyanide toning bath? (2) My best plan to recover in the following instance. Recently I photographed a local celebrity. I was not paid for doing so, and I copyrighted the negatives, to be the more sure of the right to the negatives. The sitter has since died, and a newspaper firm in the town where he lived have brought out a little 1d. book or booklet, with his portrait from my negative on cover. The sale of these has not been great, perhaps four or five thousand at most, but I consider I have lost over the sale of his cabinet portraits, as many would be content with the reproduction and would not order from me."—In reply: (1) The gold may be precipitated with liver of sulphur—or by a solution of sulphate of iron, after the addition of a little sulphuric acid to the toning bath. (2) The best plan will be to sue the newspaper for damages or for penalties—or both—and if the case be as you state you will certainly recover. Better place the matter in the hands of a solicitor well versed in copyright law.

DAMAGED PLATES.—"DEDIUMUS" writes: "I should be obliged if you will kindly answer the enclosed query. I ordered a dozen dry plates of a local dealer. When they came in I noticed that the box seemed injured at the corners, and pointed this out to the dealer. On opening the box in the dark room I found the box so defective that I only placed one trial plate in the slide, and transferred the others to a light-tight box to return to the dealer, if, as I found to be the case, the trial plate was fogged (half-way across the plate). The dealer sent the box and plates back to the maker, who admitted the plates being fogged, but said it was through the box being cut with a knife at the wrong place. This was not the case, the box being opened in the usual way; and, even had it been so, being done in the dark room, would not have affected the trial plate. I may mention that the plates were merely laid in the box without any wrapping of paper of any kind, so that when the box received any injury in transit, or otherwise light reached the plates and partly fogged them. Does not this imperfect packing render the maker liable, though, I suppose my remedy would be against the dealer of whom I bought them?"—In reply: Your remedy is, of course, against the dealer who supplied the plates, and not against the makers. We, ourselves, should certainly have refused to purchase plates in a damaged box.

ALBUMEN PAPER QUERIES.—P. J. HUDSON asks: "Will you kindly answer me the following questions? A few years ago I used to do a little photography, and it was nearly all albumenised paper used for printing. I was compelled through circumstances to leave photography alone, and now, on resuming it, I find it is all P.O.P., which I find certainly very troublesome in toning, etc. First of all, I get so many scratches on the film, then uneven toning. I enclose two prints with small spots on them; I may say the spots were partly visible before entering the toning bath. I used (according to Mr. Watkins' suggestion) a weak salt and alum in the first washing. Can you tell me the cause of failure? 2.—Is there any advantage in P.O.P. over albumenised, excepting the glossy surface? I mean, can albumenised paper be toned to give as good regular results and colour as P.O.P.? 3.—Are there any professionals still sticking to albumen and turning out good work? 4.—Is there any advantage in the use of isochromatic plates in portraiture?"—In reply: 1.—The cause of the yellow stains is that the prints were allowed to stick together while in the fixing solution, and the cause of the spots is particles of foreign matter in the water in which the prints were washed prior to toning. 2.—None. Albumen paper will yield as good, or better, tones than P.O.P. 3.—Yes, certainly. 4.—In some cases yes, as when the sitter is dressed in bright colours, and a coloured screen is used.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published early in December next. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The edition for 1903 will be increased to 25,000 copies, a large number of which are already ordered.

The striking favour with which past ALMANACS have been received is the surest proof that the lines upon which the publication is produced meet the requirements of its readers and supporters. Upon such lines we propose compiling the volume for 1903. At the same time, we shall be pleased to receive and consider suggestions for increasing the value of the ALMANAC in directions which may occur to our readers as susceptible of improvement.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

Secretaries of societies will oblige us by promptly for-

warding lists of officers and other details for inclusion in the directory of photographic societies. We shall also be glad to receive any additions that may be made to the list of telegraphic addresses of the trade, etc. As usual, a section of the ALMANAC will be devoted to notices of the latest introductions in photographic apparatus, etc. Those firms who wish to take advantage of this feature should communicate with us not later than October 31.

The publishers ask us to remind advertisers that the advertisement pages of the ALMANAC are nearly all filled up; a few remaining positions will be available until the 27th instant. To secure insertion orders and copy should be sent without delay.

EX CATHEDRA.

Movement of Stars shown by Photography.

Sir David Gill, some little time since, suggested that the brighter stars, as a whole, had a movement in regard to the fainter stars, as a whole, and Mr. Carpenter has recently been examining, the last seven or eight years, Oxford stellar photographs, to ascertain if they lend any confirmation of this movement. Mr. Carpenter's results were looked upon as so important that the whole of the Oxford staff were deputed to examine a certain belt of stars, and they found that there was a movement to the extent of 0.002s. per year per magnitude, but in an opposite direction to that found by Sir David Gill. This result offers such important cosmic considerations that we may be sure it will lead to further photographic research.

* * *

A new Light-Sensitive Material.

A writer in a recent number of *Nature* (P. G. Nutting) gives an account of his experiments upon the action of light cyanin, which show it to possess a very pronounced sensitiveness. A freshly fused sample of this chemical was exposed to light, and it was changed from a deep metallic bronze to a plum colour, and, thirdly, to a steely blue-black. Less than a minute of direct sunlight sufficed. It was found, too, that the effect was purely brought about by light and not by heat; the lantern, indeed, had the opposite effect: it reversed the colouration brought about by light. An interesting part of Mr. Nutting's letter is his statement that by an exposure of thirty hours he had obtained easily recognisable photos of small, well-illuminated objects. A remarkable point about the light action was the fact that its maximum lay in the yellow region. A spectrum taken from a Nernst lamp was thrown on to a piece of ground glass washed over with fused cyanin. The effect was "very strong in the yellow, just perceptible in

the adjacent red and green, and imperceptible in the blue and violet.

* * *

The Bremer Arc Lamp.

An important consideration in choosing an electric lamp is the comparative cost of the light per unit of time, and this form of lamp compares most favourably with any other. The French periodical *Electric Lighting* for the 4th inst., gives an account of some photometric experiments recently made by M. Laporte in Paris and Professor Wedding in Charlottenburg, thoroughly discusses the results obtained, which, it may be said, do not very closely coincide. With regard, however, to the particular point we are treating, the relative cost, both observers agree as to the superiority of the Bremer pattern over any other form of arc lamp. The peculiarities of the construction and working are first, in the carbons, which are saturated with certain chemicals, which volatilise and become incandescent in the arc; and, next, in their position: instead of being placed end on, as it were, they lie almost parallel, and are provided with a reflecting board. The makers claimed an efficiency three times greater than that of any other form, and the experimenters named agree as to the great amount of superiority—0.6 Watt per spherical candle, and 0.4 per hemispherical candle (with a 400 Watt lamp), as against 1.1 and 0.65 respectively for ordinary lamps. The distribution of the light is also very favourable—for an angle of 50deg. on each side of the vertical it was nearly uniform.

* * *

Cost of Various Lights.

A valuable contribution to the cost of other forms of lights will be found in the following table by Professor Lommer, extracted from the *German Export Review*:—

Source of Light.	Price of Material in Marks.	Per Hefner-candle and Hour.		
		Consumption.	Pfennig.	Penny.
Incandescent gaslight...	1,000 l = 0.13	2 l	0.026	0.0031
Incandescent petroleum light	1,000 g = 0.23	1.3 g	0.03	0.0036
Bremer light ..	1,000 w. h. = 0.50	0.4 w. h. 0.6 w. h.	0.02, 0.03	0.0024, 0.0036
Arc lamp without glass bell..	1,000 w. h. = 0.50	1 w. h.	0.05	0.0060
Incandescent acetylene light	1,000 l = 1.50	0.4 l	0.06	0.0072
Petroleum ..	1,000 l = 0.23	3 g	0.07	0.0084

Solubility of Glass.

In considering the occasional unexpected and somewhat erratic behaviour of sensitive films, a factor which cannot be ignored, is the possible solubility of the glass supporting medium, and a paper read before the British Association meeting by Professor Frank Clowes, D.Sc., throws some light upon the subject. He was treating the question of the action of distilled water on lead, and had found that if ordinary aerated distilled water was freed from its dissolved gases by being boiled in glass vessels, and then allowed to re-aerate itself by exposure to air, it did not regain its original power of acting on lead. Professor Clowes found this to be due to the inhibitive power of silicates dissolved from the glass, and the inhibitory power varied with the degree of solubility of the glass, when vessels composed of different kinds of glass were employed. It is, however, to be observed that the contact of cold distilled water with

cold glass did not produce a similar effect. Still, the fact of the solubility of glass is a fact always to be borne in mind, especially in view of the popular idea of the complete immunity of glass against the action of chemicals.

* * *

Enlarged Negatives.

The majority of amateurs now-a-days rarely take anything but small cameras into the field, relying on making enlargements from the negatives at some future time, which is sometimes done, but more often not. In most instances, if an enlargement is made by the amateur himself, it is on bromide paper, as rarely can he obtain, even from the same negative, half-a-dozen or less results of equal merit. At a recent meeting of the Longton and District Photographic Society, the method of making enlarged negatives for carbon or platinum printing was described. It has always been a matter of surprise to us that amateurs, and some professionals for that matter, so much neglect this method of working. When once an enlarged negative is made, it may be used for printing by any process, and one can get prints in any colour and on any surface paper. Furthermore, the negative, when obtained, can be re-touched or "faked" to any extent, which the amateur can do for himself. The neglect of this method of making enlargements is the more surprising seeing that no more trouble is involved in making the enlarged negative than there is in making an enlargement on bromide paper, beyond making a transparency. If the enlarged negative is made on paper, and there are now some negative papers on the market that are practically free from grain, the cost is little more than that of bromide paper. When these papers are employed the negative may be used for carbon printing by the single transfer method, the simplest of all processes for amateurs to employ, and one that particularly lends itself to any amount of modification or "faking," in the development. Such negatives can, of course, be used equally as well for the platinotype process, or for printing on P.O.P., or any other paper. Therefore, it does seem strange that this method of producing enlargements is so much neglected.

The Royal Arms.

Notwithstanding all that has appeared in these columns with regard to the use of the Royal Arms, and those only who are entitled to use them on their circulars, bill heads, price lists, etc., there is, evidently, much misconception on the subject, as evidenced by the queries we are often called upon to reply to in the "Answers to Correspondents" column. Here is one just to hand. In effect the writer says: "A few years ago I took to the order of a nobleman here a group, a shooting party, including the King, then Prince of Wales. To make sure that the Prince had a copy I sent him one, and have an acknowledgment of its receipt with thanks. Am I entitled to put the Royal Arms on my shop front and price lists, seeing that the King was only Prince of Wales at the time?" Now our correspondent's letter is very similar to others we received during the late Queen's reign. One would have surmised, after all that has appeared in our pages on the subject, that under these circumstances no one can be so entitled to use the Royal Arms, or to style himself photographer to the King. Even supposing that photographers are called upon by His Majesty, or any of the Royal Family, to execute work for them, that does not entitle them to use the Royal Arms. If they do so they render themselves liable to a penalty of £20, also for using any arms so resembling the Royal Arms such as are calculated to lead other persons to believe they are carrying on business or trade under such authority. To use the

Royal Arms in any form the Royal Warrant to do so must first be obtained. One often sees on shop fronts and on letter headings and the like "By official appointment to the Queen," with the Royal Arms attached, and it is a question as to whether tradesmen are now entitled to use these words. The announcement implies by appointment to the present Queen, an honour they may not possess. Of course, they are entitled to use the arms and to say by appointment to the late Queen, etc. Even were "late" not added, we surmise that in a case of prosecution, if one were instituted, the penalty would only be quite a nominal one. Still, it would seem, from a legal point of view, that although one may have held a warrant from the late Queen, that does not entitle one to still say by appointment to the Queen, unless a new warrant has been formally granted enabling one to do so.

The Spy Scare Abroad.

It may be well to once more call the attention of those who may be contemplating wintering on the Continent, that in many places a camera in any form is looked upon by the authorities with suspicion. We read from a Cherbourg telegram, one day last week, that the Special Police Commissioner attached to that port visited the room of a German officer, who was about to embark for America, and seized a number of photographic plates, which were alleged to concern the French national defence. It appears that the officer was not further interfered with, and was allowed to embark, but all his plates were confiscated. The spy scare is not confined entirely to France, but exists in other Continental countries as well. For example, His Majesty's Consul-General at Genoa has just forwarded to the Foreign Office a translated copy of a decree of the Prefect of the Province of Genoa, regulating the police service in the neighbourhood of fortresses, fortified places, or places of defence in that province. It will be seen from this decree, a copy of which will be found in another paragraph, that it is more stringent than in most places on the Continent. For instance, it is forbidden to stop for any reason whatever in the vicinity of fortifications; or to proceed along the branches of roads which give access to fortifications, or make photographs or sketches from any place whatever within a very wide area. Travellers with photographic cameras, it seems, who wish to go to places within the prescribed area will have to leave their cameras with some representative of the military authority, such as policemen, gendarmes, excise guards, etc., who will tell them where they will be returned to them. It is to be hoped that those Italian officials with whom the apparatus is deposited are of a less inquisitive turn of mind than is the case with some in whose hands photographic apparatus have been temporarily placed, as some have found to their after annoyance. We would advise all those who propose visiting the prescribed districts to leave their cameras safe under lock and key at their hotels rather than have to entrust them to the keeping of policemen, gendarmes, and the like.

* * *

Travellers Italy.

His Majesty's Consul General at Genoa has forwarded to the Foreign Office a copy of a decree of the Prefect of the Province of Genoa, of which the following is a translation, regulating the police service in the neighbourhood of fortresses, fortified places, or places of defence in that province:—

"Decree:

"Article I. It is forbidden (a) to stop for any reason whatever in the vicinity of fortifications; (b) to proceed along the branches of military roads which give access to

fortifications; (c) to take bearings or photographs of, or to make sketches or views of, or in any way to study, the naval station of Spezia either from merchant ships anchored in the port, or on the island of Palmaria, or from any place whatever included within the perimeter of the following line:—Levanto, Monte Gualterola, Monte dei Vagi, Borghetto di Vara, Brugnato, Rocchetta di Vara, Calice di Cornoviglia, Monte Alpicella, Monte Castellaro, Il Poggio (above Bolano), Monte Grosso (above Caprigliola), Monte Carbolo, Monte Pizzacuto, La Pizza, Monte Sagro group, the heights of Carrara, Avenza.

"Travellers with photographic cameras who wish to go to any places within the said line must deposit their cameras with some representative of the military authority, such as military posts, Royal Carabineers (gendarmes), policemen, excise guards, and forest guards. The officials entrusted with this surveillance and who receive the cameras will, on each occasion, inform the owners of the cameras where they will be returned to them. The photographic cameras to be deposited by travellers do not include those packed in trunks or those that are not in working order.

"Article 2. Persons infringing this regulation will be reported to the judicial authorities in accordance with Articles 140 of the Law on Public Safety and 434 of the Penal Code. Police officers, gendarmes, excise guards, and forest guards are entrusted with the execution of the present Decree.

"Given at Genoa on the 19th day of September, 1902.
(Signed) GARRONI, Prefect."

SOMBRE PICTURES.

Most of the best photographic pictures have a touch of sombreness about them. This is partly due to the fact that the conditions which lend themselves best to pictorial photography are ones struck in a minor key. Plain expanses relieved by a simple, salient object, the whole in a low light, are the usual and conventional elements. They are Gray's "Elegy" kind of pictures, with a pronounced "tolling curfew," "weary ploughman," and "parting day" air about them. The result is pleasing, but rather monotonously so after a while. It is like too regular porridge for breakfast, nourishing and digestible food enough, but in time one gets to long for the smell of broiling ham, or the tasty flavour of sardine.

The absence of colour is another condition making for dullness. We, or our children, will probably gain this, possibly after all with a tincturing of sorrow at having gained too much, for unregulateable excess of colour will be worse than the present excess of detail. It is pretty certain that when the full and true colours of nature are expressed in a photographic picture, without their having been first mixed in an artist's brain, we will not be over-pleased with the result. But colour must, for the present, be left wholly out of the question.

Is the sombre tone of the photographic picture inevitable? We think not, but that it is due in a great measure to convention, governed by the consideration of higher worth instinctively felt as associated with the subdued and the grave. We are in an age which takes serious views of things. Whether it be due to advanced mental culture, to touchy nerves, enlarged livers, over-sensitive stomachs, knowledge of microbes, current literature, the income tax, or a mixture of them, one cannot very well say, but it is certainly the case that a sober picture of a serious subject is thought to require more in the making than a breezy and joyous one. This is not confined by any means to photographic pictures, but will apply all

round. We say nothing against the value of the serious and the grave, but would like to point out also the worth of the cheerful and the gay. Life should not be regarded as painted throughout of a chocolate brown unrelieved by a lighter colour. Life in itself is quite good enough to enjoy, and even if a man is disposed to postpone his larger enjoyment till he gets to a future world, how is he to sufficiently value the brightness and colour he always pictures as its chief features without having gained something of a power to do so in the apprenticeship of the present life and world? Pictures in particular can help in this and have a cheery effect, and cheery pictures are photographically possible. They are harder to make than dull ones. It is easier to photograph storm than sunshine, the sedges and the still marsh pool than the hurrying, twinkling ripple of the mountain brook.

It is, of course, essential that the would-be producer of a bright picture should be himself of a bright disposition, be of a psychological piece, as it were, with his subject. There are more dull and heavy men than bright, still there are plenty of the latter who produce sombre-toned pictures because they have hesitated to climb over the palings that bound in the region of orthodoxy. Let them venture to do so, and strike out confidently into the wide and sunny stretches outside. Many a man has had a flash of inspiration as to a picture, that with care and thought in execution might have turned out a great success. But it has been so much at variance with the run of good pictures that he has seen, appeared to lend itself so grudgingly to the usual photographic procedure, that the idea has been allowed to die. Now these sudden flashes are not likely to occur when one is not in good spirits, and are generally of a cheerful complexion. They are not suggestions of funerals, tombstones, fadings, and ebb tides. These indicate liver trouble, which in its mental effects in other directions than the photographic, do not "make for righteousness."

Let a sunny glimpse of a quaint corner of the sea hamlet be tried, the childish defender on the ramparts of the sand castle on the beach, the harvester taking his welcome draught of cider, the carrier yarning from his cart with the cottager in the lane, a breezy breadth of heathery moor, with a jolly-looking keeper with his gun and dogs in the foreground, and so on, anything as long as it is cheerful.

To come down a little in practical working it is largely a question of hand camera, a large stop, quick exposure, cautious development, and intensification.

But even in portraiture, and with a stand camera, surely the men in the photographer's window and show case are not all of the same depressing, grave order, the women all so stately and dignified, the maidens so sedate. Their faces must relax often into kindly smiles, or at least into expressions a little less suggestive of the seriousness of life. They merely need a little encouragement to be natural, and to display their happiness.

Why not try it on these lines? He who could double the blades of grass in the world has ever been regarded as an acknowledged, though impossible, benefactor. There is an equal reward awaiting him who can double the smiles in the world, and he is a possible, possibly photographic, benefactor.

STIRLING and District Photographic Club.—The first annual exhibition will be held in Carson's Hall, Port Street, Stirling, on Wednesday and Thursday, 28th and 29th January, 1903. The judges will be Miss Harvey and Messrs. Robert Kidstone and William Rodgers. The following are the open classes: F.—Landscape and river scenery; marine studies. G.—Portraiture and figure studies. Exhibits should be sent to Mr. J. Cargill, 7, George Street, Stirling, not later than January 21st, 1903.

THE EDUCATION OF PHOTOGRAPHERS.

[Presidential Address to the Royal Photographic Society.]

THE past fifty years of the society's work is obviously the theme of your next President's address, for the year 1903 will commemorate the Society's Jubilee, and we can but hope inaugurate a successful future of greater national importance in its work and undertakings.

The past year has not been remarkable for any striking advance in either the science or practice of photography. The most notable achievement is due to the skill and patience of Mr. Edgar Senior, whose success in preparing and taking Photo-micrographs of sections of Lippmann colour photographs of the spectrum, has demonstrated experimentally the truth of the theory that the various colours are due to "stationary waves" of different periods of vibration, and is in itself a further confirmation of what is known as the wave theory of light.

Our membership is steadily growing, and thanks to the organisers of the Affiliation Scheme, we are in touch with nearly every Photographic Society in Great Britain and many in the Colonies, and last, but not least, the society itself offers greater facilities for the performance of work in this building than it has hitherto afforded. It seems to be an axiom, in this country at any rate, that for an institution to obtain the support of public bodies in furthering any branch of technology, that institution must first be an independent success; we ourselves can at present only increase our sphere of usefulness and become recognized as a "success" by a greatly increased membership, for it is only the lack of funds which has prevented this society in the past from taking its proper place in carrying out efficiently the work of one of the most important branches of technology.

The educational facilities which are offered to students in photography in this country have considerably increased of late, but are in the main chiefly elementary and seldom afford opportunities for research.

So far as I have been able to trace the first systematic instruction in this country was given by Sir W. de W. Abney in a course at the Chatham School of Military Engineering in 1868. The syllabus used was embodied in Abney's first edition of "Instruction in Photography" (published in 1871) and consisted of notes printed at the school for the use of the class and officers of the corps. The theory was taught in the laboratory and the practical work in the Photographic School; the lectures were accompanied by experiments to illustrate them, and the class worked at the practical part experimentally as they went along.

The publication of Abney's volume was a great stride in raising the young science from the qualitative to the quantitative stage. The keynote of research was, as in all sciences, accurate record of experiment followed by scientific and practical deductions. The rapid progress of our knowledge of photography has done much to upset the popular fallacy that laboratory work and practical achievement seldom march together. So much are they bound up together that every institution for the teaching of photography should provide means for original research.

In following up the facilities for public instruction in photography we find that in November, 1891, the late M. Leon Warnerke contributed a paper to this society on "Photographic Technical Instruction on the Continent of Europe," and described very fully the advantages which were offered in photo-technical education at Berlin under Professor Vogel at the Royal Technical High School founded in 1881, at the Royal Educational and Testing Establishment for Photographic and Printing Processes under Dr. Eder at Vienna, and also the technical instruction in photography given at Brussels, Ghent,

and St. Petersburg. In each case the funds for teaching were contributed by the respective governments. One felt very keenly how greatly such an institution, offering splendid opportunities for scientific and technological research, would benefit this country, if a similar step had been taken by our Government.

In June, 1892, Mr Howard Farmer contributed a very interesting paper to the society, in which he pointed out M. Warnerke's omission of the mention of the Regent Street Polytechnic and of the great and valuable work it had carried out despite the fact that the school was founded by the private enterprise of Mr. Quintin Hogg, and supported by fees paid by the students. This institution was founded in 1883, and has continued to have an uniformly successful career in teaching students in both theoretical and practical work, and in preparing them for the examinations held at the City and Guilds Institute. Special courses of training are now given to those taking up (a) Portraiture as a profession; (b) Photo-engraving and tri-colour work as a profession; (c) Retouching, finishing in black and white, and colouring as a profession.

In addition to this Polytechnic School of Photography at Regent Street, there are in London a number of other schools which include photographic education in their prospectuses.

The London County Council School of Photo-engraving and Lithography at Bolt Court is devoted to the training of those who are engaged in business in any branch of photo-mechanical, photographic, designing, lithographic engraving, printing and book illustrating crafts, but no provision whatever is made for amateurs. The school is under the direction of Mr. A. J. Newton (successor to Mr. Gamble), who is glad to welcome students who wish to carry out research work in photography or in any branch of artistic reproduction, and to give personal supervision. The principal himself has facilities for original work which might be expedited by the aid of assistants.

The Battersea Polytechnic, the Birkbeck Institution, the Borough Polytechnic, the Chelsea Polytechnic, and the Woolwich Polytechnic, all include courses of lectures on the practical and theoretical aspects of photography under the direction of Mr. Edgar Senior, and are arranged to suit the requirements of both amateur and professional students, the course covering the ground included in the examination of the City and Guilds Institute.

The Goldsmiths' Institute is under the direction of Mr. W. T. Wilkinson, and includes a course of practical instruction open to amateurs and professionals.

The Adys Road Continuation School, East Dulwich, is under the direction of Mr. G. G. Lewis, and includes two courses, "a combined course of chemistry and light bearing on photography," and "a practical course in chemistry and light as applied to photography."

At the Cripplegate Institution an elementary class is held by Mr. C. W. Coe, and a more comprehensive general photographic class is conducted by Mr. John H. Gear, who is also a lecturer in pure photography to the Thornton Heath Branch Polytechnic under the Corporation of Croydon.

The Acton and Chiswick Polytechnic conducts a photographic department presided over by Mr. G. C. Laws, and is conducted on similar lines to the Regent Street Polytechnic.

The London Chamber of Commerce has recently undertaken examinations in both the theoretical and practical aspects of photography in connection with the Commercial Education Department, but at present offers no special inducement for research work.

The Northampton Institute, Clerkenwell, under the direction of Dr. Walmsley, offers the greatest facilities for the study of optical appliances used in photography. This institution,

which is largely supported by the Technical Education Board, has hitherto worked in close co-operation with the school at Bolt Court, and the instruction and practice of experimental physics required by the students of tri-colour work have been provided in the laboratories and by the staff of the Northampton Institute. It is now proposed by the governing body to establish a new department for advanced opto-technics, and a report on the subject has been submitted to the Technical Education Board of the London County Council (under the direction of Dr. Garnett), with a request that the Board will assist in the provision of the funds necessary for the equipment and maintenance of the department. If this department meets with the Board's approval, facilities for research work in connection with all matters relating to design in optical instruments, including photographic lenses, will be provided in this institution.

I have endeavoured to give a complete list of the institutions in London where photographic classes are held. In the provinces, I am only aware of the Leeds Technical School, the Northumberland County Council Technical Education Committee at Hexham, the School Board of Aberdeen and the Municipal School of Technology at Manchester. I may mention incidentally, that I understand the Prime Minister will open a new branch of this latter institute to-morrow which, will include opportunities for the study of photographic technology such as have not yet been approached for completeness in this country. It will be directed by Mr. Gamble, formerly of the London County Council School at Bolt Court.

So far as I am aware, the examinations held at the City and Guilds Institute take the highest standard as a test for photographic efficiency, and I believe that nearly all the students who receive general instruction in photography at the institutions I have enumerated can be specially prepared to take these examinations.

I need not remind you that success in these examinations is the chief recommendation to the Fellowship of this Society. The necessity of establishing a single and satisfactory portal for admission to the Fellowship has long been in the minds of your present and past Councils, and it is hoped that at no very distant date a scheme may be submitted which will be satisfactory to both the Fellows and Members of the Society.

In setting forth the opportunities which are available for instruction in photography I have throughout had in mind the position which this society ought to take. It should be pre-eminently the leading institution in photographic technology. A very earnest attempt to form such an institution was made by this society in October, 1890, when Mr. Kenrick B. Murray, Secretary to the London Chamber of Commerce, accompanied by Mr. Glaisher, Captain Sir W. Abney, Dr. Lindsay Johnson, Colonel Gale, Sir Henry Trueman Wood, and Messrs. England, Robinson, and Bird accepted an invitation from the Lord Mayor to discuss the question of a proposed Photographic Institute. It was then stated that this society was desirous of initiating and supporting such a scheme if there was any likelihood of the necessary funds being available.

The project commended itself to the then Lord Mayor, Sir Henry Isaacs, and it was thought that a well-considered scheme would not only have had his support, but that a sum of ten thousand pounds might be forthcoming. The following were the main divisions of the work proposed:—

1. Science.
2. Education.
3. Art.
4. Industry.

As you are aware, gentlemen, this effort unfortunately proved unsuccessful, and the society has up to the present time only

itself to thank for its more flourishing condition, which is due to the guarantee and financial aid of its own membership.

The idea of forming such an institution was first promulgated, I believe, by Dr. Emerson in the first edition of his "Naturalistic Photography" (1889), where he writes:—

"We fondly hope that a college of photography may one day be instituted, where good art and science training may be obtained, where regular classes will be held by professors and regular terms kept, and where some sort of distinguishing diploma, such as Member of the Royal Photographic College, will be given to all who pass certain examinations. . . ."

In February, 1892, Professor Meldola contributed a paper to the society "On Photography as a Branch of Technology." There is no doubt that the prophecy which he quoted from the "Edinburgh Journal" of 1843, "that photography would take the highest rank among the inventions of the present age," has been realised. There is not a science, art, perhaps scarcely an industry in which photography has not played a most important part, often indeed being the pioneer process of investigation. Perhaps the least important of its applications are the most popular ones, namely, the taking of portraits and landscapes, although the pleasure derived from the practice of the art and its commercial value must not be overlooked. Being a branch of technology of the first order of importance, and appealing as it does to both the arts and sciences for recognition it should also appeal to the nation at large. I have not attempted to present to you a picture more vivid than that portrayed by Professor Meldola in 1892, indicating the necessity for such an institution, but merely ask you members of the society, the thousands of members who are affiliated to our Society, the London Camera Club, the Photographic Convention of the United Kingdom, the National Photographic Record Association, the Professional Photographers' Association, and the nation at large, which owes so much to photographic technology, whether the iron is not now sufficiently hot for us to strike again, so as to obtain adequate recognition of our science and efficient means to pursue it.

The occasion of the Jubilee of the Society will be a most fitting one, and I venture to hope that my successor, whom we have every reason to believe will be one who has rendered pre-eminent services to photography and to this society, will lend his great influence to promote a fresh effort in this direction.

THOMAS R. DALLMEYER, F.R.A.S.

YORKSHIRE Union of Artists.—A lecture will be delivered on Saturday, November 1st, 1902, at the City Art Gallery, Leeds, by Mr. E. Rimbault Dibdin, entitled, "The Magic Carpet," with photographic lantern pictures taken chiefly by the lecturer. The following is the synopsis: The lecturer's text is taken from the pleasant tale of "Prince Ahmed and the Fairy Pari Banou"—The True Magic Carpet and the weaving of it—Water and life inseparable—A river the visible embodiment of the wonderful system by which life is made possible—Our love of rivers, and their unfailling charm—The course of a river to be preferred by the seeker for beauty, to the most approved tourist route—The source—The river's infancy and childhood—The first dwelling—A digression upon dogs—The haunt of the water nymphs—The lost poet—The boundary of Pan's dominion—The first chapel—The first bridge—The property-owner and his devices—The first town—Up-river towns and their characteristics—Canals, with a digression upon canal boats—Country churches and graveyards—The market cross—A river's tributaries—The Lost Poet's curious allegory—The varying characters of rivers; their stupendous powers—Intimacy of streams with rural life, and all that is most beautiful in it—Rural homes, past and present—Onward and downwards towards the estuary, through ever-changing scenes of beauty—Ponds, lakes, and tarns—Winter metamorphoses of water, and their part in Nature's business—Winter in colder regions—Our protection from extremes by one of the great rivers of the ocean—The glacier, the solid river of snowlands—Niagara and its wonders—Subterranean rivers—Intimate relation of rivers and clouds—The glorious return of Spring—Wreckage on the shores of Time—The Lost Poet once more—"A vision of the Gods"—Conclusion. The chair will be taken at 7.30 p.m., by Mr. W. Edwin Tindall, R.B.A.

PHOTOGRAPHY AS APPLIED TO ILLUSTRATION AND PRINTING.

[Cantor Lecture, delivered at the Society of Arts.]

III.

TRICHROMATIC photography and three-colour printing is the latest and by far the most important development of photography in the whole range of processes of illustration invented or evolved during the past half century, and it is a subject that I approach with some diffidence. It has been dealt with in this historic hall on several occasions by giants in the world of modern research, men who have devoted years of investigation to every theory and every detail. I hope that it will not be considered presumption in me to attempt to raise my voice on such a matter and in such a place. I am invited to place before you my version of these processes, and I will to the best of my ability endeavour to explain the principles and working of the three-colour process from the practical point of view of a worker, but I will not try to put before you or to make you understand the formidable theories surrounding and enveloping the whole question of colour analysis, of Fraunhofer lines, molecular swings, the undulating theory of light, or the like; not that I, for a moment, wish you to understand in this art or science of the photographing of colours that theory goes for little, or that practice is everything; without theory the process as it now stands would be a vain thing, and we workers have no other feeling than gratitude towards those patient investigators who have found out and established rules and measurements for every operation, the exact spectrum colours to be used, the proper methods of sensitising plates, the relationship between spectrum colours and pigments, the tabulating of exposures for each colour and light condition. In almost every problem which may be presented to the experimentalist or workman, all these things are recorded, and are to him who reads, power.

Having stated this much, I must explain that the general principles upon which trichromatic or three-colour photography is based are as follows:—It is an accepted theory in the case of every object in nature or art exhibiting colour in any form or combination, that colour or colours result from the three primary colours which form white light, alone or in combination. These primaries I may name roughly, red, blue, and yellow. [Mr. Symonds will now, by means of the photo-spectroscope, make a photograph before you of the spectrum of a beam of light given by the electric arc; the little experiment will be instructive in two ways: it will enable you to see the spectrum on the focussing screen of the camera, and the result of the photograph will show the effect of the different colours and their colour values on the photographic plate.] I may as well say at once that the three colours named now as the primaries are not scientifically red, blue, and yellow; they are, to be more exact, red, green, and purple violet; but these latter spectrum colours cannot be employed successfully in the form of pigments in the printing press, and as that is the principal object in view in this paper, it will simplify matters if I speak of these primaries all through as red, blue, and yellow. It is known to all of us that the white light of daylight or the sun is composed of, and is the result of a combination of, coloured light; analysis by the spectroscope shows it to be composed of all the colours of the rainbow, yet all these colours may be reduced to three, the ones I have roughly named, red, blue, and yellow. If three glasses are coated with films of the three primary colours, and by means of a triple lantern are projected on a white screen, the three discs, on being superimposed, will produce white light—that is to say, the three separate colours projected one over the other will give us pure white. It is interesting to note, and necessary to remember, that the same

colours in the form of a pigment or ink, superimposed or printed over each other on paper, form not white, but black.

The principles of these interesting phenomena of light were laid down in 1861 by Clerk-Maxwell, and they have been elaborated since by many investigators. A French scientist named Ducos du Hauron early applied the principle to photography, and since his day we have had Ives, of Philadelphia, Vogel, of Berlin, Lippmann, of Paris, Wood, in America, and in this country, Abney, Joly, Sanger Shepherd, and many others.

Having established the principle that all combinations of pigmental colour in, say, for instance, a painting, are formed out of the three primary colours, the next step for the photographer is to obtain negatives from the painting, which, so to speak, automatically dissect out from the original each separate colour mentioned, and so make three distinct photographic records of the reds, blues, and yellows entering into the composition of the subject. This result has been attained by the employment of plates which are so sensitised as to be affected specially by two only out of the three primary colours. The action is controlled in photography by the use of what are known as light filters, which are transparent screens of coloured pigment, placed before or behind the lens, which admit at will any two of the three primary colours to the sensitive plate, and absorb the other one. The rationale of the process may be described thus:—The negative used for printing the red colour sensation is made to see yellow and blue combinations, and is colour blind or insensitive to red and its combinations. The blue plate sees reds and yellows only and their combinations, and is colour blind to the violets, and the yellow negative sees red and blue only, and is colour blind to yellow. Having obtained these negative records of the colour analysis of the subject, and, supposing the exposures are correct, and the colour value in each properly balanced, it only remains to convert the three photographs so obtained into printing surfaces by any process rendering half-tones, say collotype or half-tone blocks, and from this printing surface to reproduce the separate colours impressed in printing ink in their own colours on paper. The block representing the yellow is printed first in yellow ink; over this picture is accurately registered the block representing the red, and printed in red ink; and finally the block representing the blue is printed over the yellow and red impression with blue ink; the result will be found closely to approximate to the original in all its colours and combinations of colour, from the palest tints to solid black.

This, shortly stated, is the whole process of trichromatic reproduction. I will now try to explain in a little more detail how these results are arrived at. The process is yet young, and though the theory is perfect, the practice is not altogether so. Many difficulties have to be contended with, amongst which, I may mention that we have yet to discover plates and sensitisers which will respond accurately to the spectrum curves laid down for each colour sensation. We have also still to find light filters which will effectually stop the action of light rays which are not wanted. Then the interposition of the grained screen required for the production of a surface-printing block degrades and flattens the gradations for the picture, rendering skilled artistic aid necessary in the etching of the plate. The selection of standard printing ink colours is a further element of trouble, because inks of great purity and brilliance are necessary, and it would seem as if pigments of the requisite quality are difficult to obtain, unless more or less fugitive colours are employed. There is hope in this direction, however, and our best ink makers are making laudable efforts not only to supply a reliable standard, but are gradually nearing the ideal as regards purity and permanence of colour.

I have stated that the plates used for trichromatic photography must be specially treated, so that they may be more or less sensitive to light from different sections of the spectrum. Ordinary plates sensitised with bromide of silver are affected principally by the blue violet rays, and a great deal of patient research has been devoted to the finding of substances which will control and vary this action so that other rays may exert an equal reducing influence on the salts of silver. It has been found that certain dyes added to the collodion or emulsion have a controlling influence in the required direction, and this idea has been followed up until there are now a number of colour sensitisers and colour sensitive plates on the market, prepared on scientific principles, and answering most requirements. As just mentioned, ordinary untreated photographic plates are most sensitive to the blues and violets of the spectrum. A solution of erythrosine dye renders the plate sensitive to green and yellow, and a solution of cyanine dye alters the range of sensitiveness through the orange up to the red. The spectrum plates made by Messrs. Cadett and Neall and the orthochromatic plates prepared by M. Lumière, also the collodion emulsions supplied by Messrs. Penrose and Dr. Albert, are all excellent for the purpose of trichromatic photography, and it is not now so necessary for the experimentalist to sensitise his own plates, as was the case some few years ago.

The light filters for making the separate colour negative may be in two forms, liquid or dry. The liquid or wet filters are made of dyes in solution held in tanks or cells of optically flat glass. Dry filters are made of similar dye in a solution of gelatine or collodion, with which optically worked glasses are coated, dried, and sealed with a cover glass to prevent injury. The latter are found most convenient for working, though it is held by some experts that superior results are given by the wet filters. The dyes and pigments used for making light filters are numerous, and no particular standard has yet been settled; each plate manufacturer and operator recommends or adopts some modification which suits his particular working, and in their hands the end seems to justify the means. In my experience, I have found that dyed collodion filters, if carefully made, answer every purpose.

A collodion is made containing five or six grains of pyroxyline to the ounce of mixed alcohol and ether, and the dyes are dissolved in alcohol, and are added to the collodion until the solution is deemed of sufficient strength for coating the plates. Dyes that will not dissolve in alcohol are dissolved in water, and the glass plates, coated with plain collodion and washed, are dipped in a bath of the aqueous dye until the film of collodion is saturated with the requisite strength of colour. It is generally necessary to coat two separate glasses for each colour filter, and to cement the two together face to face with Canada balsam. Sometimes coloured glass is used in combination with dyes, but there is no particular advantage in doing so, because the dyed films are less liable to interfere with the action of the lens than glasses which are coloured right through. In practice, for three-colour block printing, the filters are varied in the colours and strengths, so as to adapt them to the particular standard of printing ink used for printing the blocks.

The following dyes or their equivalents form a basis for most filters for three-colour work:—

For the red printing negative	2	} Brilliant yellow.
	1	
For the blue printing negative ...	1	} Cochineal red.
	2	
For the yellow printing negative...	2	} Naphthol green.
	1	

Glasses are coated with each of these colours, and cemented together in pairs in the order given. One colour usually pre-

dominates over the other; for example, the green used in the red record is the dominant colour, and the red used in the blue record dominates the yellow.

The sensitive plates used with these light filters may be either collodion emulsion or gelatine dry plates, modified, as I have already stated, in their scale of colour sensitiveness so as to be specially active to only two of the primary colours in each case.

The plate for use with the "green-yellow" screen must be sensitive particularly to the green and yellow rays, and not at all to the reds, which are not required in this record. The plate for the "red-yellow" screen must only be active to those rays and not to the blues, whilst the plate for the "violet" screen must see blue and red, and be colour blind to the yellows.

I have mentioned that there are several excellent grades of commercial plates available, which fulfil with fair accuracy the theoretical conditions just named, as regards colour and sensitiveness. They are all carefully made, and provided they are not stale, the operator is safe with almost any of the makes—Cadett's, Lumière's, Ilford Chromatic, or Edwards', or collodion emulsion may be substituted if the dark-room conditions are complied with.

I do not propose to go through the operations of photographing, more than to say that in addition to the precautions ordinarily taken with rapid dry plate work, there are others to be observed in consequence of dealing with plates which will instantly fog if exposed to the rays of the customary ruby dark-room lamp. Only the faintest red light must be used for the red and yellow printing plates, whilst, for the development of the blue plate, a green light must be used, and very little of that. The best means of all is to develop in the dark, first carefully working out the exposures and developing time by Hürter and Driffeld's tables of factors. I would also commend Sir W. Abney's colour sensitometer to those who are testing or working plates and screens of unknown quantity. It is a *sine qua non* that the development of three-colour plates should be exactly right; intensifying and reduction afterwards may be resorted to to correct under or over development, but this course is never quite satisfactory, the proper balance of colour value is disturbed, and troublesome corrections may be necessary before the printing plates are deemed satisfactory.

It is, of course, one thing to prepare plates and colour filters which will work accurately with spectrum colours, but it is another matter to deal with the reproduction of objects or pictures containing compound colours (sometimes two or three painted over one another). In the case of water-colour drawings it is frequently puzzlingly difficult to account for the apparently false effects given in the colour negatives, though photographed under conditions which seem perfect; but a little consideration shows how possible it is for errors in colour values to be recorded. White light is always present in photographing any object, and it is reflected in a greater or less degree from every colour, there is also the paper or canvas on which the drawing is made, giving out white light in proportion to the strength or weakness of the wash or colour upon it; this agency will always cause a disturbance of colour values, and has to be reckoned with in the most perfect process of colour reproduction. So that, save in exceptional cases, you will understand why it is necessary to aid the colour plates by careful retouching and etching. This artistic assistance applies more particularly to the preparation of blocks for the printing press.

The camera for three-colour photography should be constructed with a view to the greatest rigidity and fixed to a solid stand, which, when in position, can be securely fastened down to the floor of the studio. The lens must be of the most rapid

type, and for direct working on plates through a half-tone screen will require a prism attachment to reverse the image. The colour filter may be behind or in front of the lens combination; in front is most convenient, and a simple slide arrangement attached to the hood of the lens or prism is all that is needful.

Having succeeded in making a set of trichromatic negatives, the next important step is to obtain prints from them on paper or glass in the proper colours, and to superimpose one over the other, in order that the reproduction of the subject photographed may be complete. Happily it is not necessary for the amateur or experimentalist to have a photo-engraving installation to attain this desirable result, and we have to thank Mr. E. Sanger Shepherd and M. Lumière for having devised methods of printing from three-colour negatives on their films of sensitised gelatine, which are afterwards dyed with the primary colours. When these films are dried and cemented together (the whole process, I may say, is at once simple and ingenious), the finished results are in every way interesting and charming. The processes are within the reach of anyone possessed of true photographic patience, and I cordially recommend them to your consideration.

The process of translating three-colour negatives into blocks for the printing press, and the subsequent production of copies of the subject in colours on paper, is already a scientific industry both in this country and abroad, and it marks a new epoch in artistic illustration. There are two methods in vogue for the making of colour blocks from the negative records. The first is called the "indirect" process, and differs from the "direct" process, in that the colour negatives are made without the interposition of the mechanical screen grating, consequently transparencies on glass must first be made of the three separate negatives. From these transparencies negatives with the indispensable grain are made, and are printed on copper or zinc for etching in the ordinary way.

In the "direct" process, the original colour negative has the half-tone screen placed in position before it during the exposure, and the result is a grained negative which can be printed direct on metal, without going through the operation of preparing transparencies and grained negatives from them. The advantage of the "direct" method is a saving of two operations, and the disadvantage is the increased exposure caused by the interposition of the screen grating.

It is necessary to explain that the mechanical ruled screen cannot be used at the same angle for all the plates. The usual angle is 45 degrees for an ordinary block by the half-tone process, but if all three negatives were printed with the grating at the same angle, two disagreeable things would occur. First, the colours of the three separate printings would be, so to speak, entangled, one dot of colour would be printed over the top of the other, and would be lost (to get the colour-value in the tones of a picture in dots it is essential that the spots of colour should be side by side, and not superimposed); second, there would be a curious *moiré antique* pattern introduced by interference which would utterly spoil the picture. These troubles are avoided by arranging the angles of the screen grating each about 30 degrees to the other, one at 15 degrees, another at 45 degrees, and the third at 75 degrees.

The negatives are printed on copper in enameline, and etched in relief by the half-tone block process already explained. The etching of the plates is carried out by artists who not only know how to deal with the mechanical portions of the work, but have a knowledge of colour and colour values, and on their skill and knowledge much depends as to the ultimate success of the reproduction.

The printing of the blocks is carried out in the ordinary printing press, and the plates are treated in all respects as

the usual type block, but it is requisite that the printing press used for this purpose should be of the very best construction, and capable of being made to register one printing over the other with the utmost accuracy. The block for the yellow printing is first arranged in the press, and impressions are taken in yellow ink on paper having a fine texture and surface. The red printing block is next fixed in the same position in the press as was occupied by the yellow, and is inked with red ink. The impression is made over the previously printed yellow, and is registered, so that it fits exactly over every part of the yellow picture, the result being an impression containing all the yellows and reds of the original. The blue printing plate is next placed in position in the press, and the same precautions observed as to the registering. After inking the plate with blue ink, the impression is pulled over the two printings in yellow and red already made, and the result is the complete picture containing every shade of colour of the original, no matter whether the original is from nature, a painting, water-colour, object of art or commerce.

J. D. GEDDES.

SOME ASPECTS OF PROFESSIONAL PHOTOGRAPHY.

[A Lecture delivered at the Opening of the Polytechnic School.]

LONG experience as a teacher and conversation with many young professionals has convinced me that they frequently fail to grasp some of the elementary conditions which lead to success. The keynote of this lecture is the hope that a hint or two may be useful. And first, what is a professional photographer? When we speak of a professional photographer, we usually refer to someone whose calling or employment is photography; but the term has two other distinct meanings, and it is these to which I intend referring. The word professional means pertaining to a profession; and a profession is defined as a calling, or employment, not mechanical, and requiring some degree of learning; it is also defined as the collective body of persons engaged. For example, when we refer to a doctor as a professional man, we mean not only that he earns his living by his prescriptions, but also that he is learned in the same; and further, we speak of the profession of medicine, because there is a collective body of persons contained in it. Leaving the first meaning of the word (that it implies learning) for the present, let us turn to the second one. If we look up the directories and see what proportion of professional photographers are engaged on different classes of work, omitting from consideration photo-engravers, who form a distinct calling of their own, we find that they are almost exclusively portrait photographers, or that the work they do is for portrait firms. In the London and suburban directories there are about 600 photographers, and we find the vast majority are portrait artists, only about a dozen being general workers. In country districts the proportion of portrait artists would be found still greater. Again, in the case of the Professional Photographers' Association, of which our Chairman to-night, Mr. William Grove, is the President, I do not know whether there is any special reservation made, but probably it would be found on inquiry that at least ninety-five per cent. of the members are portrait photographers. Yet again, we find in the advertisements for assistants in the trade papers dozens of retouchers, operators, printers, and others, who work for the portrait photographer, to one who is wanted for general work. Again, at the professional section of the Exhibition of the Royal Photographic Society, the exhibit is almost entirely portraiture. This truth is on the surface very remarkable, as an enormous number of photographs of other objects than human faces must

be taken daily, and yet we find they are represented by very few firms engaged exclusively in general work. Obviously, portrait photographers themselves do a large amount of this general work, but only as a fraction of their business. Let me illustrate this in another way: It is extremely difficult to open and run a business as a general worker unless in conjunction with trade printing or enlarging, or with some special mode of photomechanical printing, or something of the sort; there are, it is true, exceptions, such as photographing paintings, architecture, and others where men with unusual abilities and aptitudes have by the mere force of their superiority become very successful specialists. But what I wish to be understood is this—that in these sections of work there is no collective body of persons engaged; that, while they are included in the craft, photography as a profession is in the main limited to portraiture. It will be useful to indicate what I believe are some of the reasons of this. One is that in a great many cases the public do not criticise general work, and are satisfied with or accept photographs which require comparatively little skill in their production. In the case of a seaside resort, a sharp view of the beach from the pier, looking east, and showing the Grand Hotel; another looking west, and showing the bathers; and a third of the pier from the promenade, with a steamboat approaching, are usually all that is expected. Another reason is that this work can be done without special premises or appliances; a carriage has to be photographed; it is simply taken outside the coachbuilder's shop, and any objectionable parts of the background are blocked out in the negative. A third reason is undoubtedly the universal practice of amateur photography. A fourth that no idealising, by which I mean retouching or finishing, is necessary. It is, indeed, surprising how many subjects in general work are idealised out of all recognition, simply by plain, unaided photography.

Now the opposite of these conditions holds in the case of portraiture. In the first place, the sitter, so to speak, is nervously conscious and critical, and it is of the first importance that he should both respect and have complete confidence in the taste and skill of the photographer; even then both he and his friends are hypercritical and difficult to satisfy. In the second place, a specially designed studio, with appliances, is essential. In the third place, you all know the flattering (?) remarks the ladies make concerning the photographs of themselves taken by their amateur friends (there are, of course, exceptions). Fourthly, in portraiture you have to idealise somewhat with very skilful retouching and finishing; it is, indeed, a perfectly fair statement to say that retouchers have made the names of many portrait photographers, especially in their first beginnings. Here, then, we have the two sides—the portrait photographer, with his exacting clients, his special premises, and his skill in idealising; and, on the other hand, the general worker, who suffers from untrained competition, and very frequently also from want of appreciation of really skilful work on the part of the public.

Now I would ask you young professionals who want to get on and to become independent, to recognise these differences, and the conclusion they lead to. I want you to understand that while as young men you may be perfectly happy as craftsmen in any section of work you undertake, that when you get older you will probably have further responsibilities, and require more comfort and freedom from anxiety. That, speaking broadly, when you reach forty or more, a position as a general worker or assistant in photography is not usually an over-remunerated or enviable one, that the real profession of photography by which you can in any part of the world, where openings occur, start in business and become independent, is portraiture.

Further, I would ask you, having recognised this fact, to act upon it while you have the privilege of living in a great city like London and the energies of youth to help you—advantages, I am afraid, you will never fully realise until you lose them—and acquire in your own person all the knowledge and skill required for the practice of portraiture, not forgetting the little needful put by to provide necessary appliances. Also to those assistants who have no present idea of going into business on their own account, I would say, without in any way injuring yourselves in your special work, you will probably find that a knowledge of all the sections into which portraiture is divided sufficient to undertake them if required, will be of great and permanent service to you some time or other. Please do not think I am endeavouring to advertise this school. We can, in any case, only give you a small part of your requirements, and this small part I would just as soon that you gained it from your chum in the next department where you work, or that you went to some other school—sooner, if they teach you, or treat you better. But if you are without any obvious opening in a special line, do not rest until you have acquired the essentials which will enable you to take full advantage, when the opportunity comes—which it nearly always does—to gain independence and the satisfaction arising from being the controller of your own life.

OPENING OR BUYING A BUSINESS.

I am sorry I cannot give you any statistics as to how many portrait studios are opened in this country yearly—but the number must be very considerable, I should say not less than one hundred, probably a great many more, and you as workers in London have far greater opportunities of taking advantage of these openings (except possibly in the matter of capital) than any others. You have the prestige of working in the great city, you have the best chance of getting employment and therefore training in many of the leading firms, you have endless possibilities at exhibitions, society meetings, galleries, art schools, shop fronts, etc., of examining and criticising and comparing other work with your own and of raising your own work to the highest standard. You have the facilities for study and association with other workers afforded by this and a dozen other photographic schools. You are trained in the most up-to-date and energetic business methods which exist in England. You have unrivalled conveniences in the way of cheap travel and excursions for finding out where openings exist, besides advantages in many other ways. Could you but fully apprehend the enviable position you occupy, both in fact and in the eyes of many isolated workers and thousands of others in poorer countries, you would go home from here to-night new men in thought, feeling and purpose.

If you asked me to give you something more definite, if you want, in fact, a formula as you would for developing plates, I would state, make up your mind while yet young—say 25—how you intend earning your living when you are 40 years of age or thereabouts, and whether you think of striking out for yourself. Don't think it is so far off that you can neglect it, for not only do the years pass with ever increasing rapidity, but the power of acquiring skill and knowledge also diminishes with equal rapidity. Begin, therefore, at once by saving a little, never mind how little, but put it by regularly. You will be sorely tempted at times, but whatever you do, do not spend it—the value of this saving is not so much to accumulate money as to teach you discipline and that you are master of yourself. At the same time work things along, by which I mean get the necessary knowledge and experience as opportunities occur. At first and for some while, perhaps a few years, everything may seem against you, then if you have kept to your purpose

and to your duties to your employers, things will begin to come easier, and by the time six years have elapsed you will find yourself master of the situation, and will certainly want no advice from me. There are many circumstances which give rise to new openings for starting in business. A better position in town or street to attract custom. Better work. A special line or new style. A new suburb or place where there is no opposition or it is inappreciable. Greater personal attractiveness. Better business methods. In several places in Australia many people have their portraits taken at least once every year, giving a percentage of business in proportion to the population vastly greater than holds in England. The use of capital in fitting up more pretentious premises and developing a proportionate business. There is also a very considerable amount of buying and selling studios going on, more especially in the suburbs and Provinces. The chief points to mention in connection with buying a business beyond those which are obvious to everyone is that of being extra careful in respect to a very new business or a very old one, a most notable tendency existing for new businesses to go remarkably well the first season or so, and then, if they have not been founded on real excellence of work, or a real want, to die away. In the case of a very old business it is possibly in a state of decay beyond restoration. It is perhaps hardly necessary to mention these various points, any worker who has, through several years at least, been steadily preparing himself, not being likely to strike out either rashly or without proper inquiry and foresight. It is the man who suddenly thinks he will start in business and who has made no proper study or preparation who usually comes to grief.

STUDIOS: THEIR DESIGN AND POSITION.

We next have to consider studios, and in order to do so in a sensible manner, must not only bear in mind the purpose for which they are to be used, but also the fact that they are part of a scheme for attracting business. If you wished to work amongst the well-to-do in any town, you would not build your studio in a dirty street, although the rent, the light and the structural condition of the place might be better than the best you can get in a more suitable locality. The first consideration therefore which you have to bear in mind is that the position of your studio is not only a good one, but the best possible; if it is not the best possible or approximately so, you at once invite competition. Therefore, in looking for premises or a position to build, do not be discouraged by the apparent impossibility of getting where you wish into starting at an inferior place. Sooner or later if you stick to it you will get where you want and what you want; or, if after long trial you really cannot get where you wish, start somewhere handy and let your fitments in your own private intentions be temporary for the purpose of moving when the opportunity occurs.

Next to locality you have to decide on the position and character of your studio, in relation to its affording facilities for conducting your business, and increasing your reputation. In country places, where land is cheap and the surroundings open, studios are generally built on the ground or first floor, and no fault can be found with these positions; but in large cities it has become customary to build studios on the roof, or close to the roof. We will, with your permission, trace the cause of this custom, as I consider it has been largely a case of follow my leader, and what may have been very correct, because necessary, twenty years ago, has become quite unnecessary and even fatal to success at the present time. When portraiture was first started, some sixty years ago, the Daguerreotype process and the lenses then in vogue necessitated the person whose portrait was required having his or her head

jammed into an instrument of torture, and keeping it there quite still for half-an-hour or so, and this, too, in bright light out-of-doors, the long exposure determining this procedure. After a while the Daguerreotype plate became, with the aid of bromine, more sensitive; also the Calotype, and later the collodion process, came along, the latter bringing with it a great increase in sensitiveness; but still the exposure in dull weather was very considerable, and this in my view determined the conservatory as the form of studio, and its position on the roof in towns as being a desire to obtain the maximum quantity of light; but as a place to conduct a lady in evening dress, or for the general convenience of business, one can hardly imagine anything less suitable. Consider only the difficulties with smoking chimneys all round in keeping the place clean and presentable, in keeping it at an equable temperature, and watertight. Consider the difficulties of a low roof, in order that the studio may withstand wind pressure, and the abomination put up with in the form of a multiplicity of blinds, in order to control a mass of glazing, handy, perhaps, for growing tomatoes under, but hardly the ideal place for practising modern portraiture, or raising the public estimation of the photographer as an educated man. Probably most men will agree with these sentiments, but is it really essential that photographers should spend their lives with the smoke, up among the chimney stacks, instead of on the ground, among their fellows in business? Take a plate and under expose it on a sitter in the studio. In nine cases out of ten it will give what is called a hard or chalky negative. This means that the high lights are still sufficiently exposed, but the shadows under exposed. Repeat the experiment with one-half or one-fourth the usual exposure, and the same result will probably happen. Try another experiment: take a piece of clean white blotting paper, pin it on the studio reflector or the wall opposite the window, and photograph it, with part of the reflector or wall included. You will find that the reflector or wall, although white or very light in tone, will photograph as black against the white blotting paper. What do these experiments mean? They mean, in the first place, that the reflector and studio wall, although white or light in colour, are slightly yellowed by the light and the smoke and dust to which they have been exposed, and that, therefore, they reflect a very small fraction of the actinic rays—that is, photographically speaking, they are as black as ink. They also mean that in such a studio nearly the whole effect of lighting is obtained by direct light coming through the windows or blinds; or, to put it backwards, it is owing to the lack of reflected light that the large extent of window area is essential. Try another experiment. On the shade side of a sitter place a big reflector covered with clean blotting paper, and take a photograph. You will now get a horribly flat picture, although the correct exposure is reduced maybe to one-fourth of what it is without the new reflector. Now close in your direct window light, take another photograph, and brilliancy is again recovered, combined also with very quick exposures. We may discover in this way that there are two distinct methods of lighting, one in which all except the darkest tones are obtained from the skylight, and the other in which all except the lightest tones are obtained from reflected light. In the first you have an interior which is nearly all glass; in the second comparatively little glass. I am afraid you are already beginning to perceive that I am forgetting myself, and rapidly falling back into an ordinary Tuesday's class lecture, for these things are A B C to the many talented photographers who are helping us with their presence to-night, and to them I offer my sincere apologies. But I am anxious to give the ill-shaped roof studio and the conservatory studio a bad name to-night, and to give the young members of the profession

who later will be building studios of their own good reasons for departing from precedent, and making their studios decent brick structures, conveniently placed for business, a pride and a pleasure to work in, and comfortable and attractive to their clients. It was the late Mr. H. P. Robinson, our most talented artist photographer, who said the side-light studio will become the studio of the future. Should not Mr. Robinson's future now be the present, and is it not evident that with modern advances in plate manufacture, in lens construction, the necessity for so much skylight, and therefore the roof studio, is now a thing of the past? I have pointed out that a small glazed area (10ft. or 12ft. long by 8ft. wide) is ample, providing that proper and frequent attention is given to the surface of the reflectors and the walls of the studio; there is also no need for them to be a glaring white: they may be almost any tint of pink, purple, or blue, and yet retain their full power of reflecting the actinic rays. If, then, it is admitted that a side-light studio with a moderate window area is efficient, the whole argument which justifies the existence of the roof studio falls to the ground, for, with the aid, if necessary, of Chappui's reflectors for the low light, a studio light of the dimensions I have suggested can be obtained on the ground or first floor almost anywhere. Further, for the same reason, the glass or conservatory form construction can be dispensed with. Do not think I am speaking of these side-light studios from the theoretical point of view—there are now plenty of such in use, including quite a number of my own design, all of which, I believe, are giving complete satisfaction to their owners. We now come to our last heading—"Making a Reputation." Do we not all realise to-day that the practice of photography is becoming less and less a matter of lenses, cameras, and chemicals, and more and more a case of refinement in taste and treatment? I am not referring here to art. You may or may not be artists, but if you are honoured by a sitting from a king, your photographic reproduction should show someone who is every inch a king; your reproduction of a lady should be every inch a lady; and your reproduction of a soldier every inch a soldier. On the degree of power you possess in getting this quality in your work, combined with good taste and technical excellence, so will your reputation in the main depend. Everything, therefore, which will aid you in this respect should be thought out, worked out, and utilised—the significance of pose, the poetry of curve, and the magic of the light play should be a never-ending study. The invaluable help which can be given by a lady with good taste in the studio—a help never yet properly recognised—should be taken full advantage of. The art of the hairdresser and the dressmaker also should be requisitioned, for they are frequently the making of a difficult model. I do not mean that you should keep these specialists on the premises, but give the needful hint to clients. Besides this fundamental quality in your work, there are indirect ways of helping to make a name. During the past ten years or so, and contemporaneous with the growth of amateur photography, there has sprung up annual exhibitions of photographs in every part of the country; all these have classes open to professionals, which offer excellent opportunities for self encouragement and heightening a reputation. Again, publishing in a small way is very helpful. If there are one or two special views in your district, get good negatives, and have them reproduced and published in photogravure, which gives a quality quite unattainable by any purely photographic process. I referred in my opening remarks to a profession being a calling requiring some degree of learning. In almost every home nowadays one of its members practises photography, and wants help and advice. You ought to be the person whom he looks upon as the real authority, and to whom he comes for advice to take

him out of his difficulties. Not only should everything be done to encourage the public estimation of you as an authority in the subject of your profession, but everything should also be done which prevents or discourages such estimation. This is the great defect of the roof and conservatory studio—it is almost physically impossible to keep such a place really nice, the approach, the setting, and the surroundings being all formidable enemies: at its best a box of optical tools and a workshop, and I cannot close my remarks better than by expressing the belief that no one thing would do more to raise the reputation of the profession, both individually and collectively, than the general adoption of the side-light studio, a construction which enables the photographer to take as great a pride in the æsthetic decoration of his studio as he does in his work, and with equal benefit to himself—a decoration which, I need hardly say, should not be an ideal of stuffiness and mustiness, but one of actinic lightness, of neatness and of purity, of silver-grey distemper, white marble, and roses.

E. HOWARD FARMER.

Exhibitions.

PICTORIAL PHOTOGRAPHY IN YORKSHIRE.— EXHIBITION AT LEEDS.

Thoroughness is the chief attribute that Yorkshiremen lay claim to. Whether in the arts of peace or war, in matters social, political, or otherwise the native of the county of the broad acres possesses somewhat of the conceit of the Yankee, who has been known to boast that he can beat creation. As in the case of the Yankee, it is desirable, if one wishes to live at peace with those embraced in his immediate environment, to concede a large percentage of the 'Tyke's' claims. Should one dare to go beyond that, he must confine himself to addressing the outside world in whispered humility. These ideas were borne in upon the writer when he paid a visit to the Leeds Fine Art Gallery at the opening of the Fifteenth Annual Exhibition in connection with the Yorkshire Union of Artists. On making one's way to the North Room, which has this year been devoted to exhibits of pictorial photography—so they are described, and it would be injudicious on the part of any self-respecting person to take exception to the description—the visitor is struck by the excellence of the work of the kindred spirits, the oil and water-colour brushmen, on the walls. This, however, by the way. To come to the "Exhibition of Pictorial Photography," it may at the outset be stated that it claims to be international in its character, inasmuch as it embraces the work of British, French, German, and American artists. This is not the time or place to discuss the *raison d'être* of pictorial photography, which, as many people know, has its supporters as well as its opponents. Leaving out the arguments pro. and con. as to the general principle, it is safe to say that the Leeds Exhibition this year, so far as the art of photography is concerned, is decidedly interesting. In extent it has, we believe, perhaps been beaten by a neighbouring town; but it is only fair to Leeds to point out that the Bradford collection was not confined to the pictorial, while that in the West Riding metropolis is. Another excuse for Leeds—if excuse were needed—could be found in the fact that the present is the first exhibition of the kind ever attempted in the city, while some other towns in the north have previously, with more or less success, ventured upon similar lines. To summarise the results in a sentence, it would not be very incorrect to say that the British exhibits are characteristic; that the French are, both in subject and treatment, Frenchy—*très chic*; that the Americans have no very distinctive characteristic about them; and that, as to the German, there was an almost unanimous feeling that it were better had they been left to waste their alleged sweetness in the Fatherland. To deal with these last first, the Teutonic idea of pictorial photography, as represented by the specimens shown, is hardly likely to appeal to the taste of the ordinary sane Briton. Raphael, Dante Gabriel Rossetti, and Burne-Jones have their admirers, and rightly so too, because their work was largely idealistic; but sickly sentimentalism in semi-colour photography, especially when one fails to see what the artist is aiming at, is reducing the art dangerously near to the level of the grotesque. Our German neighbours are represented by a series of so-called landscapes, which, to a Britisher, accustomed to ordinary photography, look, to say the least of it, decidedly queer. One instance will suffice to indicate the exhibits of Kaiser Wilhelm's subjects. There is a suspicion of a semi-coloured portrait of four trees, upon which the sun has had the remarkable

effect of casting four elongated footpaths, with the weirdest of possible surroundings. Luckily for German art, these works have been grouped together, and one is inclined to suspect the Hanging Committee of having perpetrated a practical joke, inasmuch as they have been relegated to a corner which has to be carefully sought out lest they might be passed by. Some visitors may possibly have much to be thankful for.

Noblesse oblige—we next come to the works of our Gallic neighbours, who are represented to a large extent by figure studies, delicately and tastefully treated. Some of the most noteworthy examples of French production are those of Pierre Dubreuil, R. Demachy, C. Puyo, M. Bergon, and G. Grimpel.

There is no marked characteristic in the exhibition which would enable anyone to distinguish between the English and the American productions, and in order to economise space they may be embraced under the same category. Mr. J. Craig Annan has a clever character photo. in "The Etching Printer" (500); Mr. Clarence H. White produces two excellent ideas of "Spring" (502 and 513); Mr. Percy G. R. Wright has secured a thoroughly Dutch scene in "A Zaanadam Windmill" (515); and Mr. F. Rust's "Murmuring Brook" (517) arrests one's attention.

Mr. Alex. Keighley's "Grace before Meat" (514) shows the master-hand in the selection of his subject; and Mr. Archibald Cochrane has several striking examples of his camera's work, including "The Sculptor" (525) and "The Quarry Team" (551). Exceedingly noteworthy are the examples of the work of Mr. J. H. Gash, a fine carbon worker; Mr. S. L. Coulthurst, Mr. J. Croisdale Coultas, Mr. Harold Baker, Mr. A. Horsley Hinton, Mr. Rawlings, Mr. R. Bourke, Mr. W. T. Greatbach, Mr. C. Moss, Mr. F. Hollyer, Mr. W. R. Bland, and Mr. J. M. Whitehead. Mr. W. Thomas, a Yorkshireman, who spends most of his business time in London, has turned to excellent advantage the moments he can snatch between those devoted to his legal duties, a fact which is fully evidenced by several examples of his clever enlargements hanging on the walls.

Leeds photographic artists have sad reason to regret the death of Mr. W. J. Warren, who was devoted to the art, and was a leading spirit amongst the amateurs. His memory is revived by several striking specimens of his work, the last print executed before his death being "On the Quay" (662). Mention certainly ought to be made of a clever bromide enlargement of the entrance to the "Temple of the Tooth" at Ceylon, by Dr. Arthur J. Clayton, and of some character photos. by Mr. Percy Sheard, Mrs. Gertrude Käsebier, and Mr. J. Page Croft. Although numbering less than 400 photographic specimens, this section of the exhibition is well deserving of a close inspection, as it contains several features of interest alike to professionals and amateurs.

The frames are tastefully hung on a background of blue canvas, and the arrangement speaks well for the skill and selection of the Hanging Committee, Messrs. R. Bourke, J. C. Coultas, F. Rust, and Charles B. Howdill.

The Exhibition was formally opened on the evening of Tuesday, the 14th inst., at a social gathering by the Lord Mayor and Lady Mayoress (Alderman and Mrs. A. Edmund Butler) in the South Room of the building. The function was attended by a considerable number of artists and other professional gentlemen, many of whom were accompanied by ladies. The scene was of a brilliant character. In the Central Court an orchestral band, under the leadership of Mr. Irwin Sawdon, went through a very pleasing programme of music, which included excerpts from Wagner, Brahms, Edward German, Batiste, Chassaigne, Dvorak, Gounod, Rubinstein, and other composers. Light Refreshments were supplied in the North Room, which was hung with many of the chief oil-paintings on exhibition. Here the Lord Mayor was introduced by Mr. Edwin Tindall (Honorary Secretary of the Yorkshire Union). In declaring the Exhibition open, the Lord Mayor said: I have been asked on this occasion to address a few words of welcome to this Union of Artists, and I have great pleasure indeed, in my capacity as Lord Mayor of Leeds, in so doing. I am informed that this is the Fifteenth Annual Exhibition held in different parts of Yorkshire, and the third of them held in Leeds. You have only to go round these rooms and look at the works exhibited on the walls to understand that Yorkshire artists have no fear of being left behind in the race for honours. I bid you artists welcome here, and trust you may find the result of your artistic labours may meet with remunerative rewards as they deserve. I have again great pleasure in congratulating the artists in the Exhibition, and trust the results will be satisfactory to the Society; and I now declare this exhibition of pictures open. On the motion of Mr. E. Tindall, seconded by Mr. W. H. Thorp, a hearty vote of thanks was accorded to the Lord Mayor and Lady Mayoress for their presence that evening, which brought the proceedings to a close.

ROTHERHAM PHOTOGRAPHIC SOCIETY.

On Wednesday, Thursday, Friday, and Saturday (October 15, 16, 17, and 18) the Rotherham Photographic Society held its thirteenth

annual exhibition in the Rotherham Drill Hall, the largest public room in the town, and received a gratifying amount of patronage. There were eight competitive classes—viz., three open, four members, and one for local juniors; and the judging was undertaken by Messrs. C. Barrow Keene, F.R.P.S., and T. A. Scotton, of Derby. Their awards were as under:—

OPEN CLASSES.

A.—Photograph, any subject (previously medalled). Silver Medal: "Thoughts of Youth," Edward W. Strong, Windhill Vicarage, Shipley, Yorkshire. Silver Medal: "Leafless," A. W. Cooper, Preston.

B.—Photograph, any subject (not previously medalled). Silver Medal: "Norman Crypt," Thomas E. Carey, Gloucester. Silver Medal: "Ebb Tide," G. T. Harris, F.R.P.S., London. Silver Medal: "Cotton Grass," A. W. Cooper, Preston.

C.—Lantern slides (sets of four). Silver Medal: A. Bailey, Leicester. Bronze Medal: T. R. Bell, Acomb, Yorks (colour slides). Bronze Medal: S. Hughes, Sheffield.

MEMBERS' CLASSES.

D.—Photograph, any subject (Dr. Baldwin's prizes). Bronze Medal: "Genre," W. Firth. Bronze Medal: "Architecture," C. E. Davies.

E.—Lantern Slides (set of four). Silver Medal: J. C. Cox.

F.—Holiday Work (Miss Mary L. Egerton's prize). Silver Medal: "Architecture," H. C. Hemingway.

G.—Photographs from negatives less than ½-plate (six prints). Silver Medal: J. C. Cox. Certificate: J. R. Woodcock.

LOCAL CLASS.

Non-Members, age under 18 years.

H.—Four Prints ¼-plate or under. 1, G. H. Hatfield; 2, F. W. Shaw.

The opening ceremony was performed by Mrs. G. W. Chambers, of Clough House, and there was a representative company. Mr. E. Dale Hubbard, M.S.A. (the new president) occupied the chair. Each evening there were musical programmes and cinematograph and lantern-slide shows. The screens containing the photographs were lit by electric incandescent lamps, a special installation having been put into the hall for the purpose. So far as the entries went, there were seventeen in the "previously medalled class," ninety-nine in the "not previously medalled," and twenty-three sets of lantern slides. The members' section might have been stronger, and it was noticed that there was more versatility in regard to printing process and mounting.

EDINBURGH.

FOR the sixth year in succession the Edinburgh Industrial Exhibition has been held in the Waverley Market, Edinburgh. The exhibition comprises all classes of home work, and includes a photographic section, consisting of no less than 36 classes; it is questionable if any other photographic exhibition, far less photographic section of an exhibition, has as many classes—which is a matter for sincere congratulation, at least from a reporter's point of view. The exhibition is run on popular lines, with the Royal Engineers' Band playing daily—the hall is spacious, and makes a delightful promenade—with the result that thousands visit it. The photographic section, that part of the exhibition with which we are particularly interested, is evidently not managed by experts, and it would be interesting to know the names of the members of the Hanging Committee, as their work is a powerful object lesson in "how not to do it." The list of entries contains very few names of well-known exhibitors—none of the local exhibition celebrities having entered. Amongst those from a distance might be mentioned W. J. Byrne, Richmond, who has some fine portraiture on show, including a series of Coronation portraits; Graystone Bird, Bath, who exhibits some of his dainty work; W. D. Brown, Lanark, who shows some good technique; C. E. Ross and J. Drummond Sheil, Edinburgh, also show good work; Thos. Kent, Kirkwall, shows some "small" work of a high order of merit; James Walker, Birkenhead, takes several "firsts" with work of rather unequal value; Miss Eames, Isa Llangollen; Miss McLauchlan, Edinburgh; Dan Dunlop, Motherwell, also show, but hardly improve their reputations. R. Readie, Edinburgh, gives promise of better work to follow some of the good work he has on exhibition; his "first" in Class 46 being a "true" rendering of a landscape. Although about 400 photographs are shown, the result can hardly be called inspiring. The prize awards were not all shown on the second evening of the exhibition, and what tickets were up were so large that they entirely obliterated many of the winning pictures.

THE Photographic Club.—On Wednesday evening, October 29th, 1902, at eight o'clock, Mr. H. Snowden Ward, F.R.P.S., editor of the "Photogram," will give a lecture on the "Marvels of Photography."

Commercial & Legal Intelligence

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for the current month has been awarded to Mr. Stanley Kemp Welch, jun., 57, St. George's Square, London, S.W., for his negative, "A Happy Little Mother."

In the recent compensation case of "Dalby v. The Woolwich Borough Council," Mr. Arthur Mortlock was retained as expert for Mr. Dalby, to give evidence as to disturbance, etc. He also settled the amount of fixtures, damage to stock, etc., with Mr. Bowen, of Messrs. Norman and Bowen, Covent Garden, and Mr. Scrivener, Surveyor (Messrs. Fuller and Fuller, 70, Queen Street, Cheapside, E.C.).

At the Stockton County Police Court, on Wednesday last, a man named Wilmot H. Turner was charged with embezzling several sums of money, the property of T. P. Cummings, photographer, North Road, Stockton. Several witnesses said they had paid the prisoner money for photographs, which they had never received. The man was seen at Eaglescliffe Junction by P.C. Dodds, who challenged him. The prisoner bolted and Dodds gave chase. A road sweeper upset the man with a brush, and the officer arrested him. He was committed to the Sessions. Prisoner was also committed to the Sessions for the larceny of 2s. 6d. from Mrs. Harrison, Eaglescliffe. He represented that he was the manager for Messrs. A. and G. Taylor, who were doing a cheap line. Messrs. Taylor said they knew nothing about him.

The following is the list of awards of the Warwick Competition for current month:—£1 prize, H. Avery, 319, Queen's Park Road, Brighton, "Country Life"; £1 prize, Miss A. Baird, Bellerive, Lausanne, Switzerland, "Chateau de Chillon"; £1 prize, R. A. R. Bennett, Walton Manor Lodge, Oxford, "Bargaining"; £1 prize, G. W. Clark, 1, Montholme Road, London, S.W., "Peasant going to Market"; £1 prize, H. B. Cookson, Kingswinyard, Dudley, "Play!"; £1 prize, H. H. Lee, 69, Wandle Road, Croydon, "A Study"; £1 prize, F. Pinder, 245, Manchester Road, Burnley, "A Bit of Old York"; £1 prize, H. A. Roberts, Mostyn, Glossop Road, Sanderstead, "Fishing Boats, Lowestoft"; £1 prize, A. F. Scott, The Nurseries, Knighton, Leicester, "Reapers"; £1 prize, T. Upton, 16, Aberdeen Road, Lewes Road, Brighton, "Studies at the Fish Market."

THE Fine Art and General Insurance Company.—Statement of Accounts for the Year 1901.—The net premium income amounts to £69,966 17s. 2d., as compared with £66,374 8s. 1d. in 1900. The satisfactory increase in the year's profits shows the business has been well and carefully conducted. The revenue account of the year shows a net balance at credit of £11,634 5s. 6d., to which has to be added the sum of £745 5s. 1d. brought forward from 1900, making a total of £12,388 10s. 7d. now to be dealt with. Out of this sum the board recommend that a transfer be made to the reserve fund of £8,000, increasing that account to £35,000; that a dividend of six per cent., free of income tax, be paid on the share capital; and that the balance of £2,182 6s. 7d. be carried forward in account. The investments, which have been increased during the year by £10,000, are detailed in the balance-sheet, and have been taken, as usual, at cost price. The board have taken advantage of current rates to increase considerably the company's holding of British Government securities. The management of the Fine Art and General are to be congratulated on the profitable outcome of last year's working, the more so that, running their business on a lower rate level than the Tariff offices, they have managed to come out so well on the right side. They have, of course, had ample opportunity of criticising the results of the various Tariff offices, and are certainly entitled to a justifiable pride in the accounts they are able to present, and if we were to put words to unspoken thoughts born of friendly rivalry, we fancy that "they didn't know everythin' down in Judee," might be found simmering on the competitive side of the brains that so ably guide the fortunes of this free lance of the insurance world. It is evident, in considering the collective wisdom of insurance experts, that the business acumen of the Fine Arts executive is a factor to be reckoned with, and the more general recognition on the part of the Tariff offices has done not a little to soften the asperities sometimes engendered by the keen competition of the younger office, and if the Fine Arts will, in its turn, contribute to the amenities, each side will discover that there is room for both, and that the action of one on the other is a tonic, bracing on the one hand and restraining on the other. The report for 1901, the first year in the second decade, shows an addition in net premium income of £3,600, and by a coincidence the losses show a similar decrease, the total of the former reaching £69,966 and the latter £40,186, or 57.4 per cent. The expenses and commission, at £20,498, absorb 29.2 per cent., leaving as credit balance on the year's trading £11,643, which, with £745 from 1900, places at the disposal of the directors £12,388—£8,000 of this is bodily carried to reserve fund, thereby increased to £35,000, whilst the dividend of six per cent., an increase of one per cent., absorbs £2,200, and £2,182 is carried to the new year. No insurance man but knows that this is good business to come out of a year that has been notoriously bad, and although the accounts do not show how much is contributed by the burglary, contingency, and accident departments, we shall probably be correct in ascribing the growth in revenue and in profit principally to the fire department. The office has now arrived at a position when the separate workings of its various sources of income might be stated with advantage, and if the mention in the report that since the beginning of the current year the business has continued to show satisfactory progress is still upheld, the control will detract nothing from its high credit by severally stating the results of the business in which the company is

engaged. The Fine Arts are fortunate in having no serious competition in the non-tariff world, and as they are wise they will adhere to the policy of profit making, at which they are adepts, rather than fight for the residue of business they have hitherto let pass them. The following are the figures for the past five years:—

	Premiums.	Loss Ratio.
December 31, 1897	47,730	58.6
December 31, 1898	56,105	64.8
December 31, 1899	64,132	63.9
December 31, 1890	66,374	66.0
December 31, 1901	69,767	57.4

—“The Citizen.”

ROYAL Photographic Society lantern lectures will be given at the New Gallery, 121, Regent Street, W., as follows:—The lectures commence at 8 p.m. Monday, Oct. 27th, “Round about Chamonix,” by Mr. John Gunston; Thursday, Oct. 30th, “A Tour through Switzerland,” by Mr. Samuel J. Beckett, F.R.P.S.; Saturday, Nov. 1st, “A Trip through Spain,” by Mr. James A. Sinclair, F.R.P.S.; Monday, Nov. 3rd, “Camera Notes by an Amateur Field Naturalist,” by Mr. Douglas English, B.A., F.R.P.S.

PHOTOGRAPHY as a Fine Art.—In its literary supplement on Friday last “The Times” published the following review of “Photography as a fine art” by Mr. Charles H. Caffin:—Can photography be reckoned among the fine arts? This is the question propounded by Mr. Caffin on the first page of his book. Almost everybody is an amateur photographer nowadays, and the idea is flattering to the general. Yet most of us will be inclined to return an instinctive negative to the demand. This handsome volume, however, is designed to prove by argument and example that photography is so to be reckoned, and if we are not convinced it is the fault neither of Mr. Caffin's letterpress, which is enthusiastic and eloquent, in the style of Corinthe (U.S.A.), nor of his illustrations, which are for the most part excellently chosen and reproduced. Paul Delaroche, on seeing a daguerreotype for the first time, is said to have exclaimed “Painting is dead.” This was too anticipatory. The camera has not yet quite superseded the palette, though it is impossible to deny the immense influence which photography has had for good and also for ill on the practice of artists, especially of draughtsmen. It has made for ever impossible a certain sort of loose drawing (Rowlandson; Phiz's illustrations to Dickens; Thackeray's to his own novels). It has raised in a sense the standard of precision. On the other hand, it has been responsible for a particularly stupid kind of drawing—null, void, unstructural, unselective, inexpressive, inhuman. Specimens are to be found everywhere. They have only a mechanical semblance of truth, without any of the interest or play of life; they are based on photography, and imitate where they do not actually copy it. Reputations (of a sort) have been founded on this misuse of the camera. No doubt the photograph can be, and has been, of much service to real artists, in whom it generally inspires a sentiment curiously compounded of admiration and aversion. Its capacities and its unintelligence alike fill them with despair. Nor are they likely, we think, to be converted by the persuasions of Mr. Caffin or the efforts of the “artistic” photographers which he reproduces. Many of these are charming in their way, and some are exceedingly clever. But no mechanical process, however much variety of manipulation it may admit, can be really a substitute for the work of the artist's hand and brain. A photograph, whether in or out of focus, however “large in conception and beautiful in feeling,” however skilfully arranged as regards subject, scale, and lighting, however cunningly schemed to simulate the effects and mannerisms of particular painters, remains a photograph still. Cut and contrive it as you will, and give it whatever sounding label you like, it cannot take the place of a picture. It will always betray itself in over or under definition, in falsification of values, in the stolid emphasis it puts on the wrong things, in its blank omission of the very points on which the accents should be put. In his anxiety to avoid the natural fault of the photograph, which is to give far too much, the modern “artistic” photographer runs to the opposite extreme and swamps everything in a general monotone of fog. Even the best of Mr. Caffin's examples err in one way or the other, sometimes in both. Take a piece like Mr. Steichen's “Pool, Evening,” one of the best of the landscape studies here; try to forget that it is a photograph and conceive it as a picture. Taken so, it is at once too empty and too detailed; parts of it are smudged away into nothingness, yet there are irreducible superfluities. Or take some of the portraits, Mrs. Kasebier's, for instance, extraordinarily dexterous and ingeniously put together to look like old or modern paintings, yet for all their pains deplorably irresponsible and unselective, overdoing this and missing that. Now “all painting,” as Goya said, “is sacrifice and *parti pris*.” To sacrifice for the photographer means to smudge and to efface. The children's heads in Mrs. Kasebier's “Sisters,” on page 78, emerge hard and unchildishly grim from an abyss of blackness, “irrecoverably dark, total eclipse.” In the most charming of her photographs, the portrait of “Miss D.” the head is too black, the cheek and ear and hair disappear into a monotone, while the sleeve and scarf are far too much defined. Of the “manipulated” photographs, such as Mr. Eugene's “Nirvana” (described by Mr. Caffin as “an interesting experiment; by the use of the brush and needle the sofa on which the model reclined has been converted into water”), and the “Portrait of a Child,” in which “the dress has been etched, apparently to make an effective contrast with the face,” we can only say that we dislike them heartily. Artistically speaking, the combination appears about as acceptable as a mediocre violin accompaniment to an excellent piano-organ. On the whole, it seems safest that the painter and the photographer should remain detached, each learning what he can from the other, but refraining from direct appropriation of his methods.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Oct.	Name of Society.	Subject.
24.....	Borough Polytechnic.....	{ Lantern Slide Making by Contact. Mr. F. W. Giegg.
24.....	Croydon Natural History.....	{ Exhibition of Home-made and New Apparatus.
27.....	Southampton Camera Club.....	{ The Possibilities of a Modern Camera. Mr. Frank C. Wardell.
28.....	Birmingham Photographic.....	{ A Demonstration of Bromide Enlarging. By Mr. F. L. Ball.
28.....	Leeds Photographic Society ..	{ Light and Lenses. Mr. Edgar A. Heywood.
29.....	Leeds Camera Club.....	{ The Motor Car as an Aid to Photography on Various Tours in Yorkshire. Mr. Geo. Thistlethwaite.
29.....	Croydon Camera Club.....	{ The Capabilities of a Universal Camera. Mr. Frank C. Wardall.

30.....	N.-W. London Photo. Society.....	{ Bi-Annual Competition. Mr. Styles. Medal is offered for the best Composition of a Landscape.
30.....	Camera Club.....	{ Sculptured Tympana of the English Norman Doorway. Mr. Charles E. Keyser.
30.....	London and Provincial.....	{ Suggestions. Mr. W. Thomas.
31.....	Borough Polytechnic.....	{ Development—in Theory and Practice. Mr. Ernest Human.
31.....	Croydon Natural History.....	{ Demonstration by Messrs. Lumière on their New Colour Photography.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 16TH.—Mr. T. E. Freshwater in the chair.

In regard to a theory brought forward at the previous meeting as to the continuing action of light on a piece of exposed carbon tissue, and such action affecting a piece of unexposed tissue if left in contact long enough, the result of an experiment on these lines was passed round by Mr. Featherstone, which proved that such action could affect a piece of unexposed tissue, although the image was very faint and too flat to be of any practical use.

Mr. A. L. Henderson, referring to toning baths, remarked that he was of the opinion that a better chance of permanence in a silver print would be obtained by the employment of silicate instead of sulphocyanide or other agents, in conjunction with the gold or platinum, as silicate of potassium would throw down the metal as a silicate of that metal, which in theory and practice would be a more perfect deposit than any other.

The subject of the “Henderson Award” was brought before the meeting by the chairman, and the hon. secretary made a proposition from the committee as to the best means of making the award. Numerous propositions and amendments were advanced and discussed, the meeting terminating with no decision being arrived at.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

EDINBURGH BRANCH.

A MEETING of the Edinburgh branch was held at 38, Castle Street, on Friday evening, 17th October, at 8 o'clock, Mr. Alex. Inglis in the chair. Present: Messrs. Inglis, Burns, Auld, Swan, Watson, Patrick Bibbs, Balmain, and Moffat.

The treasurer made his first annual report, showing a small credit balance. The chairman read a letter from the hon. secretary of the Association, in which the following subjects were suggested for discussion:—(1) Should the electric light committee of the town be approached with the view of their supplying electric power at motive rate to photographers for printing purposes. (2) The prevention of fraudulent practices by dishonest photographers. (3) Should photographers adopt the Kodak Company's principle of preventing their copyright photographs from being undersold by those to whom they supply them at wholesale prices.

The following questions were also discussed:—(1) Is it more profitable in a photographer's business to employ male or female workers? (2) Does the awarding of medals at exhibitions do good or otherwise to the professional photographer? The above subjects were fully discussed, and a vote of thanks to the chairman terminated the proceedings.

The date of the next meeting was fixed for Friday, December 12th. Subjects to be discussed: Plates; returned proofs.

LIVERPOOL BRANCH.

A MEETING was held on Friday, October 10th, 1902, at the Alexandra Hotel, Dale Street, Liverpool, Mr. G. Watmough Webster in the chair. The discussion was resumed on fire insurance, and it was decided that each member using the information gained should act on his own initiative to get his premiums at least one-third reduced, or bring the matter up

gain. The question of Post Office methods, etc., was discussed, and many useful ideas were ventilated. The chairman explained a capital system of stamp checking which had been used in his establishment a long time. It was proposed by the chairman, seconded by Mr. Dondew, and carried, that the hon. secretary be empowered, on his own initiative, to write to any photographer he might think likely to become a member, and invite him to join the Liverpool Branch of the Professional Photographers' Association. Mr. Vanderbilt proposed and Mr. Morris seconded, that a dinner be held at headquarters on Friday, November 28th, tickets to be 5s. each, morning dress. Mr. Warrington, Mr. R. Brown, and the hon. secretary were appointed the dinner and entertainment committee. It was decided to hold the next meeting Friday, November 14th, at 8 o'clock, when all business left over will be completed.

LEEDS CAMERA CLUB.

THE opening of the new rooms of the above club at "The Athenæum," Park Lane, on Wednesday last week, was inaugurated by an address on the above subject from Mr. W. Thomas, whose lectures are always well received, and whose presence brought a crowded audience together. Mr. Bourke, in introducing Mr. Thomas, referred in sympathetic language to the sad loss the art of photography had sustained in the death of Mr. J. W. Addyman, an ardent worker, and the secretary was instructed to forward the following resolution to the family: "That the members of the Leeds Camera Club now assembled respectfully tender their sincere sympathy to the family in their sad bereavement," which resolution was passed in silence.

Mr. Thomas, in opening his remarks, referred to the Leeds Exhibition, stating that he thought the collection of pictorial work shown there was one photographers need not blush for, and a visit to the Gallery would do them all good. They would be able to see what others in different parts of the country were doing, and enable them to understand the object with which they set about their work. He would suggest that the members of the Society and all others interested in photography would receive distinct advantage if they could be taken round the Exhibition in parties by arrangement, under the guidance of some leader who had made a life study of picture making, and he was pleased to be able to announce the names of four clever and highly-respected artists who were exceedingly well qualified for such a task, and who had kindly consented to give their time and services to such an object, viz., Messrs. J. W. Brooke, W. G. Foster, Lester Sutcliffe, and W. E. Tindall, and he ventured to think they would have a pleasant and profitable time of it. To hark back to the subject of his lecture, his first suggestion would be that they should arrange for a local painter to execute a black and white sketch of an accepted subject as a standard for members to work to, this sketch to be loaned out during the year to members, and at the close of the year an examination of the results produced by photography be made by the painter. It was immaterial for the purpose in view whether the sketch were true or false; what they had to do was to try by means of their photographic implements to get as near as possible an approach to the result the painter had given them.

His next suggestion would be that a quarter-plate negative of exceeding good quality should be obtained, and from that a good high-class bromide enlargement secured and exhibited in the Society's rooms, or loaned to such members as desired it, and he thought they would learn more about photography in a short time by adopting this course than in a year's result of work.

Again, he would pay great attention to the younger members of the Society, who were far more important to the continued life and prosperity of the Society than the "old fossils." It was by the new blood, by those that he might term "coming on," that photography would have to be carried on in the future, and it was an important element in a Society's life and work to keep them together and create the greatest interest in the work of the Society. He would further point out the advantages to the Society of taking some standard work written by those who had carried out investigations by pure photography, and devoting an evening to the reading of a chapter and afterwards discussing same; many pleasant and instructive times might thus be passed. Proceeding, in regard to developers he thought that if a series of plates of the same subject be taken, given the same exposure under standard conditions, developed to the same point by different developers under like conditions, and then passed into the hands of a small committee, they would find the results extremely interesting and of great value in their daily work as photographers. The lecturer afterwards read several extracts from Ruskin on the duty and necessity of observing nature's truths in art, and following a series of lantern slides was shown, illustrating the effects produced by out-of-focus conditions, and a most instructive and enjoyable evening was brought to a close by a hearty vote of thanks to Mr. Thomas for his presence there that evening being accorded with acclamation.

CROYDON CAMERA CLUB.

AN unusually crowded attendance of members assembled on Wednesday, the 15th inst., to hear a lantern lecture by Dr. E. F. Grun upon the recent advances he had made in his now well known liquid lens.

In the course of his remarks on introducing the lecturer, the president (Mr. Hector Maclean, F.R.P.S.) described the lens as the most remarkable optical invention of the century, and stated it frequently happened regarding notable inventions, that they were first sneered at by specialists, next laughed at by the world, and finally pecksniffed by astute capitalists.

Dr. Grun, who spoke with lucidity and an invigorating freshness of style, as a preliminary asked his hearers to bear in mind that the lens system he had adopted was contrary to all the rules of mathematical optics. Academic men had told him that his system was an impossible one, and that on the lines he had laid down it would be impossible to get

an aplanatic, anastigmatic, or even achromatic lens. For photographic work, the Doctor thought an absolutely aplanatic lens was not required, an opinion, we think, which will hardly be shared by the majority of photographers, who (except for special purposes) have a partiality for a lens capable of the finest definition at full aperture. The lecturer then passed on to a clear exposition of the action of crown and flint glass lenses, the effect of their curvatures, their limitations, and defects. The relationship between refraction and dispersion was next considered, and it was pointed out that the more diffraction and less dispersion one could obtain from any specimen of glass, the more valuable from an optical point of view that particular glass would be. The introduction by Messrs. Abbe and Schott of the Jena glasses, possessing high refractive indexes combined with low dispersive power, had enabled opticians to obtain lenses of great rapidity, with a flat field, and freedom from astigmatism. In his lens he had availed himself of oily and non-volatile fluids, free from turbidity, and had obtained a high initial intensity, with good correction, as the members might judge for themselves later. Objection had been raised as to the employment of liquids on the ground that an alteration of temperature would cause a great alteration in the system. This was not so in practice, no discoverable alteration took place between 40deg. and 150deg. Fah. Dr. Grun here had two grievances to ventilate, one against the modern lens makers for surrounding their lenses with a certain amount of mystery, the other in calculating the $\frac{U-I}{ND}$, not from the total dispersion, but from the

medium dispersion between the C and F lines. This might be all very well for telescopes, but for photographic lenses, between F and G was the most important part of the spectrum. The members looked quite sympathetic when the Doctor went on to say that this had "thrown him off the scent" for some time, as an amateur lens maker. He did not propose going into the question of spherical aberration that evening, but his audience had no doubt been somewhat interested in a question that had been recently raised concerning depth of field. In THE BRITISH JOURNAL OF PHOTOGRAPHY for the current week, there was a paragraph querying the necessity for rapid lenses, and giving the old and fallacious statement that with a large aperture it was not possible to get depth. He strongly disagreed with such view, and subsequently, in answer to a question, said that depth of field, apart from aperture and focal length, was greatly influenced by the quality or nature of the glasses and construction of the lens. The more rapid the lens the better, but it must possess depth of field.

The address, which was interspersed with humorous touches, extended over an hour, and was listened to with marked attention. This probably did not signify a complete assent to all that the lecturer had advanced. A large number of lantern slides, taken chiefly from the pits of various theatres, were then shown on the screen, and judging from the more recent slides, Dr. Grun is to be congratulated on the improvements he has made in his lens. The definition may fairly be described as good, and considering the conditions under which the photographs were taken, the results astonishing. The illumination being the usual stage lighting, a truer effect was obtained than if flash-light had been employed. The lens, a quarter-plate one, had an equivalent focal length of 6 inches, and an effective aperture of f/2.5. Exposures varied according to the light and circumstances; quarter second was frequently given, a momentary pause in the play being watched for. Some of the photographs had only received 1-50th second, but here, as might be expected, under exposure was apparent. Moonlight scenes were next shown, receiving about 15 seconds. In some cases this had proved more than sufficient, a daylight effect being produced. A striking slide illustrated the capabilities of the lens in combination with a telephoto attachment. An instantaneous exposure was given with a magnification of 6 diameters, at a distance of over a mile. Some experimental three-colour photographs of stage effects with ordinary lighting were next passed through the lantern. As attempts, if not very successful ones—they deserve notice. In answer to a question by Mr. G. W. Watson as to whether the fluid contained in the lens system, could be tinted so as to dispense with the necessity of a separate light-filter, Dr. Grun replied that it could be so tinted, and he had applied for a patent for the application of the idea. The Grun lens hand camera was then inspected, and created a favourable impression. The hon. secretary (Mr. E. A. Salt) in opening the short discussion which followed, deprecated the idea that any mystery attached itself to the modern anastigmat. These were patented and their formula open to all who understand them. As regards depth of field, for a given circle of confusion, and assuming all aberrations corrected, and the field flat, depth, he thought, purely depended upon the effective aperture, focal length, and position of the stop in reference to the nodal points. The last factor (apart from telephoto work) he understood, only became appreciable when working at close quarters, and might, in the ordinary way, be disregarded. He considered the slides shown capital, and was glad to hear that a non-volatile fluid was employed by Dr. Grun. It would be quite a new experience for an operator to have the back combination of his lens driven into his skull, together with fragments of the focussing screen, owing to a sudden rise of temperature.

Mr. C. E. Kenneth Mees said he was exceedingly pleased to have been present and to have heard so remarkable a paper. He dissented from a differentiation which the President had made earlier in the evening between "Scientists" and "Inventors." He knew of no important invention in which the discoverer was not a scientist, or had not shortly after become one. As to Dr. Grun's remarks about dispersion, he suggested that the dispersion from F to H might be proportional in all glasses, to the dispersion from C to F, and that the effect of a curve on the focal length might also be proportional to the difference in refractive index of the media it separated. He considered rapid lenses most desirable, and as the result of some recent experiments on the limits of exposure, wanted the fastest lens he could obtain. The peculiar field of the telephoto lens was a good

example of the effect of the construction of the lens on the depth of field.

Dr. Grun having briefly replied, the President, in felicitous terms, moved a vote of thanks, which was heartily seconded by the Rev. Henry J. White, and carried with loud applause.

Mr. A. E. Isaac ably handled the lantern as usual.

CROYDON MICROSCOPICAL SOCIETY.

On Friday evening last, Mr. Wardall, representing Messrs. Houghton, gave an interesting exposition of the Sanderson camera in its various forms, fully describing its uses, peculiarities as distinguished from all other cameras, and its capabilities, clearing up in the most satisfactory manner points upon which certain of the members were doubtful. He also demonstrated the Beck-Steinheil Tele-photo lens as applied to low, medium, and high power, lucidly explaining how to obtain the best results. The Beck-Harris colour screen was also shown and explained, and a most intellectual evening was brought to a successful close by the exhibition of a number of very beautiful lantern slides, illustrating what can be done with the above cameras, lenses, and screen. On the motion of Mr. Baldock, the chairman, a hearty vote of thanks was given to Mr. Wardall for his very successful demonstration.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

OCTOBER 15TH.—Mr. E. R. Dibdin (president) in the chair.

The lecturer for the evening was Dr. Llewellyn Morgan, who gave a practical demonstration of the platinum process, dealing with the various means by which the print may be developed. The lecturer gave a number of very useful hints as to the keeping of the paper, temperature of the baths, etc. He also demonstrated the method of obtaining warm brown tones on platinum paper, which was recently published by Mr. C. F. Inston, another member of the Society, and developed several prints, which on being passed round the audience were much admired.

HILLSBORO' AND DISTRICT PHOTOGRAPHIC SOCIETY, SHEFFIELD.

THE monthly meeting of the above Society was held on Wednesday, October 8th, in Makin's Schoolroom, Hillsboro' when a lecture by Mr. G. P. Goerz on "What can be done with a Hand Camera," illustrated with lantern slides, was read. The lecture was listened to with very great pleasure, and was both interesting and instructive.

After the lecture, several slides belonging to the members of the Society were shown through the lantern.

There was a good attendance of members, several new ones being proposed, bringing up the total membership to about 50.

WOLVERHAMPTON Photographic Society.—On Monday, the 13th inst., Mr. James Gale gave a lecture entitled, "An Introduction to Architectural Photography," his remarks being illustrated by some fifty excellent slides made by himself.

THE Rontgen Society's ordinary general meeting will be held on Thursday, November 6th, 1902, at 20, Hanover Square. The chair will be taken at 8.30 p.m. Agenda: Minutes of last meeting; nominations; the President will open the session with an address.

WE regret to learn of the death of Mr. H. J. Dalby, photographer, of Wellington Street, Woolwich. The deceased gentleman, who succumbed to an attack of pneumonia, was a member of the committee of the Professional Photographers' Association.

THE Royal Photographic Society of Great Britain.—On Tuesday, October 28th, at 8 p.m., at 66, Russell Square, Mr. William Gamble will give a demonstration of the Sinop Collotype Process. The Society will be pleased to welcome anybody interested in this process.

THE Lumiere North American Co., Ltd., of 4, Bloomsbury Street, W.C., inform us that they are willing to demonstrate the L.N.A. process of colour photography to approved photographic societies. Applications for dates should be made at earliest, and average attendance quoted in all cases.

THE Thornton-Pickard 1902 Prize Competition.—We are asked to announce that, owing to the large increase in the number of entries, it has not been possible to publish the list of prize winners as early as in former years. The judges have, however, nearly completed their work, and hope to announce the names of the winners next week.

"How to Look at Pictures" is the title of a book which Messrs. Bell will publish immediately. The author, Mr. R. C. Witt, intends it for those who are interested in pictures and painting, but have no special knowledge of the subject; and from want of some such guide, fail to obtain the full enjoyment from their visits to picture galleries and exhibitions. It will be fully illustrated.

At the annual meeting of the Grangemouth Amateur Photographic Association, Provost Mackay and Rev. Mr. Hamilton were re-elected hon. president and president respectively. Dr. McGowan was elected vice-president; Mr. Marshall, hon. treasurer; Mr. Walter Bain, hon. secretary; and Mr. Maryon, asst. secretary. It was decided to hold a three-days exhibition in April, 1903, on dates to be announced shortly. In the open section there will be classes for (a) Landscapes and Seascapes, (b) Portraiture and Genre work. Silver and bronze medals will be awarded in each class, and there will be a gold medal for the best picture in the exhibition. The names of the judges, with whom arrangements have not yet been quite completed, will be a guarantee of the awards being according to merit. Full particulars will be obtainable shortly from the secretary for the exhibition, Mr. F. W. Maryon, Marshall Street, Grangemouth, N.B.

Correspondence.

* * * Correspondents should never write on both sides of the paper, notice is taken of communications unless the names and addresses of the writers are given.

KODAK, LIMITED, v. THE PHOTOGRAPHIC TRADE.— A CLEAR STATEMENT OF THE CASE.

To the Editors.

Gentlemen,—The restrictive policy of Kodak, Limited, towards the photographic trade has now been before the public for nearly two years, and among the many statements and counter-statements which have been made it is to be feared that the real points at issue are in danger of being obscured. We, therefore, think that the time has now come for a plain statement of the case.

Nearly two years ago Kodak, Limited, issued a circular to the trade threatening to refuse to supply any photographic dealer with Kodaks and films who sold any roll-film camera or films not made by themselves. It is absurd for anyone to contend that this was not an attempt to secure monopoly. Thanks, however, to the opposition of the public and the trade combined, this attempt to restrict trade failed, and, after about twelve months, the objectionable conditions were withdrawn.

This withdrawal was, however, only in order to create a monopoly by different means. Photographic dealers were then informed that they would not be refused supplies, but that their profit would be reduced to about one-half if they sold rival productions. To insure their usual profit they were required each month to sign a declaration that no roll-films or roll-film cameras had been sold or kept in stock except those made by Kodak, Limited.

Retail dealers, although resenting almost to a man this attempt to restrain them from free and open trading, have, many of them, especially the smaller ones, been obliged to accept the conditions. Even those who, upon principle, have resisted the objectionable conditions imposed, and have decided, rather than submit to them, to lose half their normal profit upon all Kodak roll-films and apparatus, are not left alone. Pressure is brought upon them in every conceivable way to induce them to refuse to supply all other roll-film apparatus than that sold by Kodak, Limited. This continual pressure upon the retailer is very difficult for him to resist, and it is in order to put a stop to such a state of affairs that the Photographic Trade Association have decided to appeal to the public to assist in defeating the evident aim of Kodak, Limited, to secure a monopoly for an American company for American-made goods to the exclusion of everything British. If the public insisted on having the particular make of roll films and roll-film apparatus they desired, the attempt at monopoly would be frustrated.

The next point to be considered is: What is the tendency of the policy of monopoly and restriction? The accumulated experience of all countries goes to show that although a patent to secure a monopoly for a few years is an advantage in order to encourage invention, monopoly of any permanent nature is most injurious to all concerned. All stimulus to invention goes; quality is not improved, and prices are not reduced without wholesome competition, and not only the trade but the public suffers from the effects of monopoly. Kodak, Limited, have done much in the past for the photographic public; but they have fully reaped the reward by making every possible use of the patent laws. Any further monopoly would bring about a state of stagnation that would ruin the industry.

In addition to this it may be confidently asserted that the attempt to restrict trading will not be confined to roll-film cameras and roll-films. A monopoly, being an artificial system of trade, it needs constantly bolstering up and adding to if it is to succeed. This has been seen in every monopoly and trust that has been put in operation, and will be the case with all attempts to monopolise any branch of the photographic trade. It may be pointed out in support of this statement that in America the Kodak Trust control the bulk of the photographic trade, with the exception of plates and chemicals, and that quite recently they have acquired an interest in the manufacture of plates, the object of which it is not difficult to guess. The logical outcome of the position is, that if the public allow themselves to be dictated to by Kodak, Limited, in the matter of roll-film cameras and roll-films, before long the only free articles left may be chemicals.

The Photographic Trade Association, which includes several hundreds of photographic dealers, wholesalers, and manufacturers in Great Britain is concerned in: The prevention of any monopoly; the giving a fair field and no favour; free trade for all.

To show that the Association is a thoroughly representative and influential body, a list of the Council is given below:—W. M. Ashman (Bath); A. H. Baird (Edinburgh); M. Ballantine (J. Lizars); George Barclay (George Barclay and Sons, Limited); C. Beck (R. and J. Beck, Limited); F. Bishop (Marion and Co., Limited); G. M. Bishop (Marion

and Co., Limited); Arthur C. Brookes (Editor of "The Photographic Dealer"); W. F. Butcher (Butcher and Sons); J. Christie (Sheffield); M. W. Dunscombe (Bristol); J. J. Elliott (Elliott and Sons, Limited); G. Frost (Alton); R. Green (City Sale and Exchange); J. Henderson (Aberdeen); George Houghton (George Houghton and Son); E. W. Houghton (Houghton and Son); F. K. Hurman (Newcastle-on-Tyne); L. M. Isaacs (J. Levi and Co.); I. Joseph (Charles Tyler and England Brothers, Limited); F. V. A. Lloyd (Liverpool); D. A. Lowthome (London); J. Lillie Mitchell (London Stereoscopic Co., Limited); H. F. Purser (Busch Camera Co.); A. S. Spratt (Spratt Brothers); C. Tyler (Tyler and England Brothers, Limited); C. H. Watson (Watson and Sons); J. B. B. Wellington (Wellington and Ward); Jesse Williams (Cardiff); J. Brooke Wilkinson, Secretary.

The history of photography shows that its steady advance has been due to the survival of the fittest of all the inventions and processes that have from time to time been introduced. Without a free and open market new methods cannot be put on their trial. It was not always those that promised best that have proved most successful. Actual trial is the only means of testing a new process; and it may safely be asserted that had any large monopoly existed in times past many of the valuable inventions and processes now in use could never have been tried.

The ultimate decision rests with the photographic public. British manufacturers have no desire to exclude goods of any make, whether British or foreign, from competition. They ask for nothing but a free and open market, and they have a right to expect the support of their countrymen in their British opposition to an American monopoly.—We are, yours faithfully.

THE PHOTOGRAPHIC TRADE ASSOCIATION.

89, Farringdon Street, London, E.C., October, 1902.

THE KODAK COMPANY'S REPLY.

To the Editors.

Gentlemen,—An opportunity has been afforded us of replying at once to a circular now being issued by the Photographic Trade Association. The circular charges us with attempting to secure a monopoly in rollable film goods, and contains further a statement of the objects of the Photographic Trade Association, and gives a list of the gentlemen forming its council.

Monopoly.—However absurd it may seem to the Photographic Trade Association, we simply repeat that we do not seek monopoly. In the first place, it should be clearly understood that, apart from our rollable film business, the whole of our goods are sold on precisely the same principles as those of any other manufacturer. With regard to our rollable film business, our conditions are framed to protect our customers from the many flagrant imitators of our products that are put upon the market by manufacturers who are endeavouring to make a trade by the aid of our prestige and our trade names. This cry of "Monopoly" is a device resorted to by such manufacturers and wholesalers, under the shield of which they hope to get facilities for diverting to themselves some of the vast trade we have created in rollable film goods. We intend to hold our own by good quality and good service, and the only monopoly we seek or care for is that which the public choose to give us. We have made the rollable film trade, and have in the past had from eight to nine tenths of it in our hands. Practically the same state of affairs exists now. Most dealers find it best worth their while to sell only rollable film goods of our manufacture on account of the world-wide reputation and uniform quality possessed by our products and the universal demand there is for them, and further to avoid complication of stock. What we want to point out is that they use their own discretion solely as to whether they shall sell only our goods or whether they shall sell imitations as well as our goods.

If any dealer states that he is not allowed to sell other rollable film goods than those of our manufacture he is saying what is not true. As far as this company or its conditions are concerned, it is open to him to sell just whatever he elects to sell. He can sell even those articles that everyone admits to be piracies, and at the same time he can stock and supply our products also, and net a discount from us varying from 14½ to 23½ per cent.—discount superior to what are secured on many staple articles in other trades. Extra discount on some items, amounting in all to more than 35 per cent., can be secured if he elect to sell our rollable film goods only. In such event there is no undertaking called for on his part. Any extra discounts he is entitled to he claims as a legal right. He is not bound by any engagement; he can change his mind and his practice at any time he pleases.

Anyone who takes the trouble to understand our conditions of sale will see that they are framed in the interests of the trade, and to protect to some extent the thousands of Kodak users—beginners and uninitiated—against the danger of their being deceived by other articles made up like ours being handled together with our goods.

As regards these imitations, all your readers are probably not

aware that in every single instance the get-up of our appliances is closely imitated, and our gauges, special and peculiar to ourselves, are exactly and minutely copied. Not only is this so, but such imitations are actually offered to the public under the description of our registered trade names. Purchasers desiring our goods have over and over again, to our knowledge, been supplied with other products sold under our trade-mark descriptions. No doubt the great success of the apparatus we have introduced, and the enormous trade we have created, tempts the imitator. We wish it distinctly understood that we make no complaint of such a state of things. We look upon it as a penalty of our success. A few parasites may, after all, be good or us. We can leave this part of the subject to the public. As far as we can see, people are coming more and more to recognise the fact that imitations sold and pushed forward as being "just as good," are not to be relied on for quality or uniformity, and it is very questionable whether many people, upon reflection and full information, would desire to encourage such an imitative trade, or the practice of substitution, which is bound up with it. It is not, however, as we have said above, our desire to take exception to imitations provided they infringe no patents or trade-marks. It is only as far as they lead to substitution practice that we take cognisance of them; and, as competitors with the imitators, and to protect our Kodak users, we have simply framed our conditions to hold our own against them. The policy we have followed, and still intend to follow, is to do our best by the persuasion of good terms, good quality, and fair prices to get the trade and the public to favour our products.

A good deal has been made of the Kodak Company having ceased to use the channel of the wholesalers for distributing their goods. The reason of this will very easily be understood by business men. The wholesalers are middlemen, and the modern tendency is to do without the middleman and the factor. Both the retail dealer and the public benefit thereby in getting goods that are fresher, and securing the benefit in the cost of goods to them of such extra discounts as are in the habit of being taken by the middlemen.

The active element of the Photographic Trade Association is composed principally of these wholesale dealers, and their object in making the present stir is to secure sympathy for their substitution goods, which they have incited the imitative manufacturers in Germany and in this country to produce.

The association was brought into being with the express object of working up animus against the Kodak Company, and for no other purpose. The largest and most famous of the plate and paper making firms in the country are not in any way concerned in it.

The trade in the States.—As regards the conditions of Kodak trade in America the facts are these: The prouts to the dealers on Kodak goods in America are larger to-day than at any previous time. The conditions in force there were voted for by 95 per cent. of the trade before they were instituted. Similarly, retail prices to the public have been considerably diminished and better value given with every step in the progress and improvement of production.

The association seeks also to mislead the public by playing upon a pseudo-patriotism. It is alleged that the Kodak conditions are made to secure monopoly on an American company. The impression sought to be given is that all our Kodak goods are made in America. This is by no means true. Some of our products are, it is correct, made in the States, but Kodak, Limited, is an English company, and is the largest British manufacturer of photographic goods, employing at its British branches and factories over 700 employees and hands, all British subjects. But even the American Kodak Company is not altogether the foreign concern our competitors would have the readers of this circular believe, for nearly three-quarters of the shareholders in that corporation are British.

In view of these facts, we think the prejudice of the Photographic Trade Association in this matter will be readily understood.—Yours faithfully,

KODAK, LIMITED.

43, Clerkenwell Road, London, E.C.
October 21st, 1902.

[The appearance of both the foregoing letters in the same number of the JOURNAL is due to a suggestion of our own that readers should have both sides of the controversy simultaneously presented to them. Our correspondence pages are open to the reception of letters on the subject; but our own comments on the situation are reserved until such time as we may think it desirable to terminate the discussion. It is, however, right to say that, during the last few weeks, efforts have been made by the editors of the photographic Press, acting in perfect agreement throughout, to reconcile the differences existing between the Photographic Trade Association and Messrs. Kodak, Ltd., but without success. The ventilation of the matter in these and other columns may, it is hoped, enable the photographic public to acquire a correct understanding of the present position as to the sale of roll films and cameras, and we are therefore open to receive expressions of the views of those interested.—Eds. B.J.P.]

THE BIRMINGHAM PHOTOGRAPHIC SOCIETY.

To the Editors.

GENTLEMEN,—We desire to call attention to the following points of importance, which may be of interest to other Photographic Societies, who, dissatisfied with present conditions, may desire to raise their subscription in order to provide increased facilities for members, but who hesitate to adopt such a course.

Twelve months ago the Birmingham Photographic Society were in occupation of rooms in a quarter of the city, which, to speak moderately, was not the most salubrious or the most fitting for a society of its standing and reputation. The sole conveniences were the use of a meeting-room, a second small room being used for the storing of exhibition plant. The apparatus available was an enlarging lantern, which required carting home before use, and an optical lantern, utilised once monthly, for members to test lantern slides.

The natural result of so slight advantages accruing to membership resulted in decreased numbers and slight excess of expenditure over income. At this critical period in its history, the society fortunately possessed a strong council, under the chairmanship of one of its oldest and most enthusiastic members, Mr. A. J. Leeson, under whose able guidance a bold and determined measure was agreed upon by the council, being no less than a recommendation to the society to increase its subscription from 10s. 6d. to 21s., the object being the provision of first-class accommodation in both meeting-room and dark-room, and the bettering of the programme of fixtures; entire dependence on such increased facilities being relied on to, if possible, retain the present membership, and also for the attraction of new members.

The society accepted this recommendation, and our annual report for this year shows most conclusively the wisdom of the course adopted, as during the year no less than 45 new members were enrolled, while the total resignations have been 25, of which 13 were due to members leaving the district, and 4 to illness.

The new rooms are facing the main central square of the city opposite the Town Hall, and are on the second floor, being reached by a lift, and consist of one meeting-room, 33 feet long, 24 feet wide, 15 feet high, and dark-room, 23 feet long, 10 feet wide, 15 feet high, also a general storing room.

The meeting-room is most conveniently and comfortably furnished and fitted with the electric light, while the dark-room, in which four members can work at the same time, is illuminated by eight electric ruby glow lamps, fitted with variable intensities of light, to suit different speeds and classes of plates and paper. There is also an enlarging table, 14 feet in length, and fitted with every desirable movement necessary for accurate and rapid work, and designed to enlarge from $\frac{1}{4}$ -plate or whole plate to 24 by 20 in either plates or paper. This table is unique, being the first made of this size, to suit special club requirements, and is of teak throughout. By its aid the manipulation of large size plates is so easy that lady members are quite enthusiastic in its praise.

In addition, lockers, washing sinks, drying racks, hot water supply, and fixing table, together with two lead-coated troughs, 4 inches deep and each 7 feet long, are provided.

The society view with satisfaction the fact of every member having equal facilities for all classes of work, and the advantages above-mentioned were plainly evident in our last exhibition, when 51 members exhibited, in comparison with 34 the previous year.

The total cost of these alterations has been £122, and of this sum £72 has been provided from the current account without creating an adverse balance, while the remaining £50 was provided from the club reserve account, still leaving in hand a rent reserve of £50.—I am, yours very truly,

H. VOOHT-CORNISH,
Hon. Sec.

October 16th, 1902.

THE BAUSCH AND LOMB COMPETITIONS.

To the Editors.

Gentlemen,—We enclose you a booklet relating to the 3,000 dollars offered by Messrs. Bausch and Lomb as prizes for photographs obtained with any cameras in which their lenses have been used.

We should esteem it a favour if you would kindly call the attention of the photographic public to this fact, stating that we should be pleased to supply any quantity of these booklets for distribution, if our customers would kindly favour us with their names and the number of booklets they would like.—We are, gentlemen, yours faithfully,

A. E. STALEY AND Co.

35, Aldermanbury, London, October 16th, 1902.

PHOTOGRAPHY AS A FINE ART.

To the Editors.

Gentlemen,—In your issue of October 10th, Mr. Herbert Ball refers to my notice in the "Daily Mail" as having been written by "a person who was ignorant of his subject, or else thoroughly in error." Although the opinion he holds of my knowledge is a matter of

supreme indifference to me, I am glad to seize this opportunity for explaining at greater length a few points which the naturally limited space of the "Daily Mail" forced me to suppress. The range of the so-called Fine Art Photographer's ambition is such that it is next to impossible to speak of his absurd attempts in general. Let me, therefore, just choose a few striking instances.

Not even an indignant enthusiast, like Mr. Ball, will maintain, that the camera can idealise. But the most rabid realist, if he has any claim to the name of a painter, will idealise, whenever he attempts to paint the nude. His picture has the additional attractiveness of dexterous technique. With a few bold brushmarks he can suggest the lovely tones of the epidermis, of the blood coursing through the veins. In this idealising, and in this technique, lies the essential difference between the nude and the naked. A well-painted nude will never look—let us say it straight out—indecent. Now, the camera is incapable of producing a "nude." The photographer can do nothing but give a crude rendering of the naked form with all its accidental defects. The painter can render a more or less impersonal type; the photographer merely gives the portrait of a person so lacking in modesty, that she exposes her body to everybody's gaze.

Some modern "art photographers" have had the bad taste of giving photographic versions of sacred subjects. Here, again, the painter may use the model, but he only uses her as a basis upon which he builds his ideal of, say, the "Virgin and Child." The photographer who exhibits a "Virgin and Child," seen through the camera, is guilty of an offence which borders closely on blasphemy.

If a painter occupies himself with still-life, he will make his canvas attractive by his technical skill. If a photographer takes a snapshot of a heap of carrots and onions, and enlarges it to more than life-size, until all outlines and forms get so blurred that one can hardly distinguish them, he shows neither taste nor dexterity, but is merely absurd. Who would care to own such a print, except a person who has been so mystified by the operator's pretentious "bluff" that he is shaken in his own sound conviction as to what is, and what is not, beautiful.

If a painter uses a rough canvas he can adjust his technique accordingly. He can use thick paint where he wants a smooth, flat surface. The photographer who prints his negative on canvas can do nothing of the sort. Light and shade, foreground and distance, objects of smooth or rough surface, appear cut through by the annoying little squares which look as mechanical as the dots and lines of a coarse half-tone block.

A photograph can only be artistic when the photographer is conscious of the limitations imposed by his process. And the same rule applies to all arts. A photographic print which has been "faked" until it looks like a very inferior charcoal drawing or etching is no more artistic than a marble statue of Venus painted in flesh-colour.

There certainly is such a thing as artistic photography; but nothing could be further removed from it than the presumptuous Transatlantic fakes which have been foisted upon us lately.—I am, yours, etc.,

THE ART CRITIC OF THE "DAILY MAIL."

THE IMPERIAL COMPETITIONS.

To the Editors.

Gentlemen,—We shall esteem it a favour if you will put a short paragraph in your next issue to the effect that the last day for receiving entries in our Competition, for which we offer £500 in cash prizes, is the 31st inst.—Yours truly,

THE IMPERIAL DRY PLATE Co., LIMITED.

October 16th, 1902.

A CORRECTION.

To the Editors.

Gentlemen,—A curious error has crept into your report of the proceedings of the L.P.P.A. of October 9th. You say: "I passed round prints from negatives taken in 1845 by Sir Charles Fellows." It should have been by Sir Dominic Colnaghi. The former gentleman's name is quite familiar to me, but I do not know him personally.—Please correct the mistake, and oblige, yours truly,

A. L. HENDERSON.

Westmoor Hall, Brimsdown, Ponders End, Middlesex, Oct. 17.

THE R.P.S. EXHIBITION.

To the Editors.

Gentlemen,—The sentence with which Mr. Warburg ends his letter in the BRITISH JOURNAL OF PHOTOGRAPHY of October 17th indicates that he considers that he has effectually answered my criticisms. A careful consideration of this letter and his longer communication to your contemporary *Photography* will show that he has evaded rather than answered the crucial points at issue, and that he has, in fact, strengthened the position taken by my first letter. I propose to answer his two replies together, and quote from both indiscriminately.

Mr. Warburg says: "The selection committee on the first day numbered eleven members, all but three unknown to me." The italics

are mine. What are the facts? About six months ago Mr. Warburg was corresponding with many of these men whom he now states were unknown to him, asking them to co-operate with him in an effort to control the selection of the pictorial section at the coming exhibition of the Royal Photographic Society. This was followed by the issue of a circular letter, signed "J. C. Warburg," to a large number of the members of that society, asking them to vote for him and a few of his friends, so as to give them the controlling influence in determining the character of the next exhibition. It was hardly dignified for Mr. Warburg to write begging the members to elect him but it succeeded in giving to him and the clique working with him a sufficient number of seats to have a controlling vote in most divisions of opinion. Can Mr. Warburg explain how these men were sufficiently well known to him six months ago to join with him in issuing this circular and at the commencement of the work of the selecting committee they met as strangers?

Mr. Warburg says further: "It says little for Mr. Bennett's commonsense that he should suggest the possibility of collusion on the part of eleven men mostly strangers to one another." I have not suggested "collusion on the part of eleven men," but I have just shown that some of these men were working together for a definite object for months before the exhibition, and that "strangers to one another" is a mere quibble. This "pictorial wing," as they called themselves, was able to control most of the decisions, and Mr. Warburg is well aware that the committee was far from unanimous, some of the acceptances and rejections were determined by a majority of one vote only. The members of the "pictorial wing" could almost always carry their point.

Mr. Warburg stated that I "accuse by insinuation members of the Postal Camera Club of partiality towards their club." I may inform your readers that Messrs. Bland, J. Page Croft, and Warburg, members of the selecting committee, are all members of the P.C.C., and I would merely add that these men have been working for months to secure a preponderance of the work for which their club is noted.

In each reply Mr. Warburg, almost as his first point, says that, in selecting, the names of the authors were withheld. I wish to call your attention to the fact that it was Mr. Warburg, and not I, who raised this question, and I do not propose to discuss it beyond pointing out that it cannot be necessary for the names to be written on their works in order that members of circulating clubs should be able to recognise each other's pictures. Mr. Warburg alludes to me as a rejected contributor. Will he kindly explain how he is aware whether I sent any work or not, if the author's names were withheld?

Mr. Warburg professes to quote from my letter that, "even if the work of individual members of the committee were the best in the room it ought not to be hung," and then proceeds to refute what he calls a pernicious doctrine. Of course, it is easy to confute a statement that has been distorted specially for contesting, but Mr. Warburg is well aware that I said something quite different. My argument was that, even if it were the best, if members of the committee accepted their own works *four times as liberally as those of others* they were not above suspicion, they could not claim to be impartial; a totally different statement from Mr. Warburg's misquotation and an incontestable axiom. Mr. Warburg might, at least, have the common fairness to quote my arguments correctly.

Next there is a most refreshing exhibition of modesty on the part of Mr. Warburg. He defends the fact that the work of some members of the committee was accepted so liberally by saying that they "hung the best work." This is simply delightful! They hung their own work four times as liberally as that of others, because they knew that it was the best! Is further argument necessary to show the absolute unfitness of the "pictorial wing" for the delicate and important task of judging the competing works?

Mr. Warburg argues that because I and others have had a large number of frames hung in other years I cannot consistently criticise him and his friends for the number that they show this year. The two cases are not parallel. What I have criticised is men hanging their own work and that of their friends so much more liberally than that of others, a totally different matter. There are none so blind as those who will not see.

The facts that stand out in bold relief, the importance of which Mr. Warburg's reply has done nothing to lessen, are:—

1. The correspondence between certain men early in the year with the object of co-operating to influence the present exhibition.
2. The issue of a circular letter by Mr. Warburg asking to be elected with others, so as to form a controlling body on the selecting committee.
3. The acceptance of their own work by three members of the committee nearly four times as liberally as that of others.
4. The acceptance of works from the members of the Postal Camera Club, of which three members were on the selecting committee, twice as liberally as from other accepted exhibitors, while many well-known men had their work rejected, this making the proportion still more unfair.

5. The acceptance of work from the Postal Pictorial Photographic Club, which was also represented on the selecting committee, nearly twice as liberally as from other accepted exhibitors.

Pictorial excellence is not the distinctive quality of the members of these two clubs alone. There are now many men who are producing pictures by photography, but there can be no question that the work of one particular "school" only has received recognition from the pictorial wing. A selecting committee should be catholic in its tastes, and absolutely impartial and above suspicion in its judgments. Has the committee dominated by the pictorial wing conformed to this standard?

It would be interesting to hear how far other members of the committee, Messrs. Gunston, Ashby, Croke and Gear, for example, support Mr. Warburg's views of its work.—I am, gentlemen, yours truly,

HENRY W. BENNETT.

October 20th, 1902.

[We append the "Pictorial Wing" Manifesto which Mr. Warburg sent to his fellow members of the Royal Photographic Society earlier in the year.—Eds., B.J.P.]

We, the undersigned fellows and members of the Royal Photographic Society, realising the importance to the Society's pictorial exhibition of capable, broad-minded judges and selection committee, who shall have the confidence of all schools of pictorial photography, have pledged ourselves to support the following gentlemen at the forthcoming election. In view of the fact that a large number of esteemed judges have refused to serve at the forthcoming exhibition, we have decided to collectively support only a small list. We ask your votes for the following candidates as being worthy of your suffrages:—

As Pictorial Judges:—W. R. Bland, Esq., F.R.P.S.; J. C. S. Mummery, Esq.

For the Pictorial Selection and Hanging Committee:—W. R. Bland, Esq., F.R.P.S.; J. Page Croft, Esq.; Llewellyn Morgan, Esq.; M.D.; J. C. S. Mummery, Esq.; J. C. Warburg, Esq.

We would urge on every member of the Royal Photographic Society, whether supporting our list or not, the importance to the society of voting for candidates who are capable and broad-minded.

J. T. Ashby, Loughton; J. S. Bergheim, London; W. R. Bland, F.R.P.S., late Vice-Pres. Derby Photo. Society; Evelyn Boden, F.R.P.S., Derby; Francis A. Bolton, F.R.P.S., Staffs; Robert Bourke, Past President Leeds Camera Club; S. R. Brewerton, F.R.P.S., Tunbridge Wells; S. L. Coulthurst, Vice-Pres. Manchester Amateur Photo. Society; J. Page Croft, Birmingham Photo. Society; Alice M. Dumas, Bromley; J. H. Gash, Leeds Camera Club; John Gunston, Wimbledon; Maude A. Craigie Halkett, Edinburgh Photo. Society; Elena Hellmann, F.R.P.S., London; Harold Holcroft, Wolverhampton; W. G. Jamieson, Aberdeenshire; Percy Lund, Editor "Pract. and Jun. Photo."; Hector Maclean, F.G.S., F.R.P.S., Pres. Croydon Camera Club; J. W. Marchant, F.R.P.S., Vice-Pres. North Middlesex Photo. Society; Llewellyn Morgan, M.D., Past Pres. Liverpool Amateur Photo. Association; Harry Quilter, F. C. Shardlow, Editors "Photo. Art Journal"; Leslie Selby, Past Pres. W. London Photo. Society; Percy Sheard, Pres. Batley and District Photo. Society (Judge of the Yorks. Photo. Union); M. Thompstone, Manchester; Harry Wade, Manchester; Louisa Wakeman-Newport, Tenbury; J. C. Warburg, London; H. Snowden Ward, F.R.P.S., Editor "The Photogram"; W. D. Welford, F.R.P.S., London and Prov. Photo. Association; Jeannie A. Welford, London; T. E. Corney Wilson, Liverpool Amateur Photo. Association; Eustace Young, London; J. C. Warburg, Hon. Sec. R.P.S. "Pictorial Wing" Movement.

To the Editors.

Gentlemen,—In reply to the letter of Mr. H. W. Bennett, in which he accuses of bias a small and perverted section of the Selection Committee, and inferentially charges the majority with being "led by the nose" by such minority, I do not feel the pages of a paper offer the best medium for dealing with such assertions, offering, as they do, no means of arriving at a definite issue.

If Mr. Bennett really believes a title of what he states, it appears to me to be his bounden duty to the R.P.S., of which he is a member, to bring his charges formally before the Council, who would no doubt afford him every opportunity of producing his evidence, which—probably by an oversight—is omitted from his letter.

This is purely a personal suggestion; but I am not aware of any reason why the Selection Committee, having nothing to conceal individually or collectively, would in any way object to meet their traducer face to face.

I therefore challenge him to adopt this course.—Yours, etc.,

J. PAGE CROFT.

P.S.—I may perhaps be permitted to mention that my exhibits to the Exhibition numbered nine in 1899, ten in 1900, and four in 1901, when, owing to pressure of business, I did practically no photography. My representation this year is thus 20 per cent. below the average of the past three years.

CRISTOID DEMONSTRATIONS.

To the Editors.

GENTLEMEN,—I am now giving demonstrations on the development of cristoid films on Mondays, Wednesdays, and Fridays, commencing at 7.30 p.m. I ask you if you will kindly insert this in the columns of your journal, so that any of your readers residing in the North of London who may like to know how the cristoid films are developed I shall be delighted to show them, at 159, Stroud Green Road, Stroud Green, London, N. Thanking you in anticipation—I am, Gentlemen, yours faithfully,

J. B. CAMP.

93 and 94, Chancery Lane, London, W.C., 21st Oct., 1902.

A LOST COOKE LENS.

To the Editors.

Gentlemen,—May we call the attention of photographic dealers generally, particularly of those who do business in second-hand lenses, to the fact that a 5½ in. Series 111 Focussing Cooke Lens, mounted in a 5 x 4 unicum shutter, has been stolen from the R.P.S. Exhibition some time during the afternoon of Thursday, the 16th inst. The number of the lens is 9.564, and its equivalent focus is 5.55 inches.

Should this instrument be offered for sale or exchange to any dealer we trust he will kindly communicate with us at once.—Thanking you in anticipation, we are, gentlemen, yours faithfully,

TAYLOR, TAYLOR AND HOBSON, LIMITED.

Stoughton Street Works, Leicester, October 17th, 1902.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

J. Moffat, 125, Princes Street, Edinburgh. Photograph of 1903 calendar.
D. Hedges and Sons, Clifton Square, Lytham. Photograph of Homing pigeon.
W. H. Fischer, 19, Egerton Crescent, Withington. Photograph of J. Scotson, M.A.
J. G. (Tregoney).—Better send us a print to see. From your description we can offer no opinion whatever.

SEAL PORTRAITS.—A.E.N.S. wishes to know the address of a firm that make a speciality of doing seal portraits for the trade.—In reply: We are unable to answer this query, as we know of no one who does seal portraits for the trade.

SPOTS ON COLLODIO PAPER.—MATTE SURFACE says: "I would be very much obliged if you would kindly inform me the cause of the spots on the enclosed pieces of C.C. matt surface paper."—In reply: The spots are caused by the paper having been splashed with some chemical—possibly an acid.

ORTHOCHROMATIC PHOTOGRAPHY.—ORTHOCHROMATIC asks: "Would you kindly tell me what advantages orthochromatic plates have over ordinary plates in every day use?"—In reply: The advantage is that they translate colours into monochrome better than ordinary plates do, particularly when they are employed with suitable colour screens.

THE P.P.A.—J. A. LONGFORD writes: "I have recently returned from the United States, and have purchased the above business. Can you inform me if there is any association in this country to which it might be desirable for a dealer to belong?"—In reply: The Professional Photographers' Association. Hon. secretary, Mr. Alfred Ellis, 51, Baker Street, London, W.

ACETYLENE IN THE STUDIO.—J. A. writes: "Will you inform me what success is being obtained by the use of acetylene gas for lighting studios for night work, and if consistent, please state a reliable make of apparatus, complete?"—In reply: Acetylene can be successfully employed for taking portraits at night. Messrs. Thorne and Hoddle, Victoria Street, S.W., make a speciality of an apparatus for studio work.

BLACK BACKING PAPER.—BLACK BACKING says: "I herewith enclose you a few samples. What I want to know is what is put on the backs of the enclosed bromides to make black—it will not rub off not even if you wet it? It is done after I know it has been developed and dried."—In reply: The little pieces sent are not bromide paper, but ordinary black paper with an adhesive on it—probably gelatine. But we may say your query is by no means clear.

COLOUR PHOTOGRAPHY.—W. W. GRANFIELD says: "I read in the 'Westminster Gazette,' a few weeks ago, an article on a new process of coloured photography called, I believe, the L.N.A. process, and I am writing to ask you if you would be so good as to let me know where I could obtain further information of this new process."—In reply: Write to the Lumiere N.A. Co., 4, Bloomsbury Street, W.C. You will see their advertisement in last week's JOURNAL.

FOREIGN ENCYCLOPÆDIA.—"Having a brother in Java who wishes me to obtain for him a copy of volume (as advertisement enclosed), I will feel greatly obliged if you will send me one that I may send him. If you will kindly let me know cost of same, I will remit

per return."—In reply: We do not supply books. You will have to get it direct from the publisher, or through one or other of the foreign booksellers. We regret that we do not, for the moment remember the price of the work.

STEREOSCOPIC PHOTOGRAPHY.—SILURIAN says: "I am thinking of taking up stereoscopic photography. (a) Would you advise me to buy a stereo camera? or (b) Would Brown's Stereo Transmitter, with its ordinary camera, act satisfactorily? (c) What are the disadvantages of the transmitter?"—In reply: (a) We should certainly advise you to get a stereoscopic camera. (b) We have seen good results that have been taken with it, but we prefer a bi-lens camera ourselves.

LANTERN SLIDES.—J. SEATTER says: "I wish to learn how to make photographic lantern slides from illustrations in magazines, engraving in books, etc. Would you kindly tell me what kind of a camera I should get for that purpose, also what instruction books I should get?"—In reply: Any ordinary camera will do for making the negatives. For the slides a lantern slide camera will be the most convenient to use. Any of the dealers will supply one. Or by using dry plates no camera is necessary, as the slides may be printed by contact. As you appear to be ignorant of photography "Abney's Instruction in Photography" will be a good work for you to get.

STAMP PORTRAITS.—BIGRIGG says: "I enclose a quarter-plate sheet of bromide prints. Will you please say what you think of them under the circumstances? They are flash-light portraits taken in our kitchen at night. I have designed the printing frame they are printed with, and I can print same as enclosed, or four larger, or sixteen smaller, on quarter-plate sheets, from a negative the fourth of a quarter plate in size. Could I have it protected?"—In reply: The portraits are fairly good—about the average of flash-light work. With regard to the printing frame, if there is anything in it superior to others that are in the market it might be worth your while to secure a patent for it. That is the only form of protection you can obtain.

NEGATIVE REDUCERS.—W. B. GOWLAND writes: "In reducing negatives please say what I am to avoid in the prevention of marks, which completely spoil for printing. The Almanac recommends Farmer's formula. Burton says if negative is dry soak in hypo—usual negative strength—take out and add a few drops red P. of P. (saturated solution). Another formula is, 30 grains ferric chloride in 3ozs. water. Allow solution to act, then wash and place in hypo. I used an old mixture of hypo not used before; negative was soaked in water first, then placed in hypo and red P. of P. bath. Result: Spoliation. The red P. of P. was not saturated, but rather weak."—In reply: All the formulae named are good if used with judgment. In future we should recommend you to employ the Howard Farmer formula, as you cannot well go wrong with that, and it is a good reducer.

LENSES.—STUDIO writes: 1. "Will you kindly tell me the angle of Goerz 12 x 10, Series 1 B. lens, double Anastigmat, the angle of Dallmeyer 12 x 10 rapid rectilinear, both lens without stops? 2. I have an unfinished studio requiring a sun shade on the top of ridge plate. What height should the shade be erected on the ridge, to cast a shadow over the glass on the midsummer day, when the sun is at its greatest zenith?"—In reply: 1. It is as we have often said before, strictly against our rule to make any comparison of different makers' apparatus. Better write to the manufacturers of the lenses. 2. The shade would have to be so high, to cast a shadow over so large an area as you desire when at its highest, that it would be very unsafe in windy weather, unless the studio was much more strongly built than the majority of studios are. Better deal with the sun by blinds.

* * Owing to pressure on our space, several letters, answers to correspondents, etc., are crowded out.

* * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published in December next. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The growth in popularity of the ALMANAC is evidenced by the remarkable rapidity of its sales.

The 1900 Edition (20,500 copies) was sold within three months after publication.

The 1901 Edition (20,500 copies) was sold a fortnight after publication.

The 1902 Edition (20,500 copies) was sold a fortnight before publication.

The widespread interest in the ALMANAC grows steadily year by year, and in order to supply the increasing home, foreign, and colonial demand, we have decided to enlarge the 1903 issue to

25,000 COPIES.

The great addition to the circulation of this most popular annual (over 20 per cent.) undoubtedly enhances its value as an advertising medium, and the issue of the large

number of extra copies will supply the wants of thousands of photographers, dealers and publishers who were unable to obtain the ALMANAC for the last three years.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

EX CATHEDRA.

Isochromatic Plates in Astronomical Photography.

It would seem to the casual observer that there could be little scope for the use of isochromatic plates and a colour screen for such objects as the starry vault presents. Yet, at the meeting of the astronomical section of subsection A of the British Association there were exhibited photographs of star clusters so taken, which, according to *Nature*, were the feature of the evening of September 16th. These pictures were taken at the Yerkes Observatory with the 40in. visual refractor, the colour screen being in contact with the plates. There were also shown photos of the same objects taken on ordinary plates without screen by the two-foot reflector. With the former the densest part of the clusters are beautifully resolved and measurable. The photographs of nebulae made with the two-foot are unsurpassed, and it is remarkable, says that authority, "how, though nearly all the detail they show can be found on the photos taken at Crowborough, and Daramona, and Greenwich, the general effect is quite different. It has been felt that astronomy was not sufficiently represented at the Association meetings, hence this particular subsection was formed at the Bradford meeting in 1900. The papers presented, however, were scarcely enough to justify its existence, so that cosmical physics were this year included." To a certain extent this was successful, but still it was felt that amendment was desirable. *Nature* suggests, with what seems like lightly-veiled sarcasm, that all papers in section A should be divided into "two classes—papers that are generally intelligible, and papers that are not. . . . It is not impossible that this might have beneficial results in more ways than one!"

* * *

Comet Perrine. Dr. Isaac Roberts has taken a successful photo of this object, and a reproduction appeared in *Nature* last week. The photo gives a striking record of the rate at which the planet is moving in regard to its place amongst the stars. It was taken with fifty-two minutes' exposure by his 20in. reflector. The comet was virtually kept stationary in the field of the telescope; yet, though the

exposure was under an hour the stars included in the field have moved relatively to the comet so much that each is represented by a long trail. The reproduction does not appear to be an excellent one, for the original, it is stated, has a multiple tail, two of comparatively large dimensions, and several smaller streamers. It would be difficult to detect them in the process-block print.

* * *

Solubility of Platinum. It is usually stated that metallic platinum is only soluble in aqua regia; but M. Camille Matignon has been making some experiments—recorded in *Comptes Rendus*—that go to disprove this belief. When the metal in the spongy form is placed in a concentrated solution of hydrochloric acid in contact with air at the ordinary temperature the metal goes into solution in the form of chloroplatinic acid. If the platinum is used in the form of foil no action takes place at the temperature of the atmosphere, but if the materials are placed in a sealed tube containing oxygen and heated for five hours at a temperature of 170deg the platinum is taken up. It would appear that platinum is, under the given circumstances, more soluble than gold, as we read that it needs a temperature of 10deg. higher to bring about solution of amorphous gold, which might be compared for physical condition to spongy platinum.

* * *

"Hypo" and Acids. Herr H. V. Attingen has been investigating the action of acids upon hyposulphite of soda, and the time taken before the precipitation of sulphur becomes visible. He finds that the time taken depends on the concentration of the hydrogen ions, and is the same for all isohydric solutions. An interesting portion of his communication will be found in his observation that when sulphite of soda is present along with hypo the time of precipitation suffers retardation. In applying a knowledge of these facts to the hypo-fixing bath it may be well to bear in mind the presence of the gelatine of the plate, for it is well known that the presence of this and other organic matters entirely inhibit many reactions which in the absence of these disturbing elements are very pronounced. An example of this is seen when a plate which shows urgent signs of pitting is placed direct into the alum bath, when it is evident that hypo must be retained in the body of the gelatine, and must there come into contact with the alum, yet no precipitate is produced, as would be the case after a while under ordinary conditions. An action in this direction whose explanation is not very clear has been brought under our notice by a well-known photographer. He tells us that when a newly-mixed acid hypo bath—made by adding acid to an excess of sulphite of soda solution, and putting a limited amount to the hypo solution, the whole being, and continuing, perfectly clear and free from turbidity—is first used for fixing plates, the latter when dry are so rough on the surface as to render fine retouching impossible. After being used a few times, however, this effect dies away. Meanwhile the bath has continued clear and translucent.

Death from Bichromate of Potash. Most photographers are familiar with the pernicious effects that some of the chemicals they employ have on the skins of some workers—metol, as used for development, and the bichromate of potash, as employed in carbon printing, to wit. These, like many other things, including our old friend "pyro," used in the art, are deadly poisons when taken internally. On Saturday last Mr. Coroner Drew held an inquest, at Hammersmith, on a woman who had committed suicide by

drinking a solution of bichromate of potash. This is the first suicide we have read of by this substance, though we know of a case in which death resulted from accidentally drinking a solution of it in mistake for beer. It is a little surprising that there are so few accidents from the poisons used in photography, seeing the way that the solutions of them are sometimes left about; and the vessels, often tumblers and the like, they are frequently contained in, are not always kept in the dark room. A solution of bichloride of mercury in a tumbler, for example, is very like a glass of water, and one of bichromate of potash in a similar vessel, as in the case just referred to, might easily be mistaken for beer—and the mistake not discovered until too late. When poisonous things, such, for instance, as bichromate of potash, are so largely employed for industrial purposes, familiarity with them seems to breed, if not contempt, a certain degree of carelessness in their handling and keeping. If by chance some bichromate is swallowed, medical aid should be at once summoned, and, in the meantime, an emetic should be administered. Then the best antidote would probably be magnesia or chalk.

* * *

Magnesium Flashlight. Monsieur Albert Londe, in a paper read before the Société Française de Photographie, gives the results of some experiments he has made, which are deserving of note by those who have occasion to use flashlight mixtures. As might be expected, the amount of powder used affects the length of the time of combustion. This is shown by the following results:—

Weight.	Time.
1 Gramme.	120 thousandths of a sec.
3 Gramme.	140 thousandths of a sec.
5 Gramme.	160 thousandths of a sec.

The mode of ignition also affects the time of combustion, and it is best done by electrical fusion of a very thin wire. The condition of the powder likewise affects ignition and it is best to use the mixture as fresh as possible. A sample which ignited with a loud report and burnt rapidly when fresh, after keeping some time, burnt four times slower and without noise. The duration of the flash was determined by a camera with 12 lenses, the shutter giving successive exposures of 1-100sec. The flash was photographed against a black background. If less than 12-100sec., ignition and extinction were comprised within the exposures. As the speed of the shutter could be regulated, adjustments for longer or shorter exposures could be made. Illustrations of the stages of a flash are given. A very interesting illustration is given, showing the time it takes for a sitter to close his eyes after the commencement of the flash. During the first 1-100sec. the eyes are open and natural in appearance, but at the seventh exposure representing 7-100sec., the eyes are completely closed. The maximum actinism of a flash appears to be attained in 1-50sec. and lasts about 5-100 to 6-100sec.

* * *

Sepia Platinotypes. Recalling his previous experiments, Hübl points out in "Eder's Jahrbuch" that the sepia image obtained by using a palladium salt in the sensitiser for platinotype paper is but a brown modification of pure platinum, and that he had assumed that when mercury was used the same thing occurred. Further experiments have proved, however, that such is not the case. In all probability the sepia image given with mercury is a compound of mercury and platinum, as concentrated nitric acid or cupric-chloride solution immediately destroy the mercury image, whilst leaving the palladium image untouched. If a platinotype paper is sensitised with a mercuric oxide salt, such as the citrate, it is probably

reduced to the ous state, and is then reduced by the developer with the platinum in the black-brown compound. With mercuric oxide salts this can be readily effected with a cold developer, but with mercuric chloride in the sensitising solution a hot developer must be used to obtain the brown compound. If the mercury salt is added to the developer and not to the sensitiser, the ferrous oxalate formed by the action of the light on the ferric oxalate reduces it to the metallic state and not to a mercurous salt. If Hübl is correct in his statements as to the nature of the sepia images obtained by the use of mercury salts, it is an open question whether the process is worth general adoption, as it would seem more than probable that such an image would not be so stable as one of pure platinum.

* * *

Separate versus Combined Baths.

The question as to the superiority of separate versus combined toning baths as regards permanency is likely to be always a vexed question. Adherents of the separate baths always point to the danger of sulphur toning and the consequent evanescent character of the prints. Advocates of the combined baths point out that one is quite sure that the tone obtained is not altered by any subsequent fixation, and further that at least one, if not two, operations are saved—namely, fixing and preliminary washing. Of all the arguments adduced for and against no one, so far as we are aware, has commented upon the quantity of gold deposited by each system; nor, for the matter of that, has it been established that an image containing a greater proportion of gold is the more stable. In this year's edition of Elder's "Jahrbuch," however, Herr Novak details his experiments in this direction, using albumen paper with a borax bath, and two collodio-chloride papers with the sulpho-cyanide and a combined bath. In each case a print was toned faintly, that is, to a brownish purple, and one also strongly toned to a blueish violet, and the ratio of gold to silver determined. For albumen this was 1:4.96 and 1:4.3. For the collodion paper A the ratio was 1:0.84 and 1:0.25. In the combined bath this paper gave 1:3.18 and 1:1.14; collodion paper B gave 1:3.2 and 1:0.85, and 1:4.7 and 1:2 for the separate and combined baths respectively. From these figures it is obvious that there is far more gold in the final image when the separate baths are used, although according to Herr Novak the appearance of the prints was the same. Of course, the total quantity of gold will vary with the composition of the silver emulsion, though from the experiments we have mentioned collodio-chloride papers require more gold than albumen, for the well-toned albumen prints contained 28 milligrammes of gold and 122 milligrammes of silver per square metre, whilst the collodion contained 122 milligrammes of gold and 31.2 milligrammes of silver per square metre.

Detective Photographs.

When quick plates first made the hand-camera possible, it was the fashion to call such instruments detective cameras, for it was imagined that every policeman would carry one under his cape to the terror of evildoers. This, however, was a dream only capable of realisation if criminals had been in the habit of prosecuting their nefarious schemes in broad daylight. It is only under very rare conditions that a picture which can be remotely described as a detective photograph is produced. We know of one case in which a defaulter's portrait was taken on a solicitor's door-step from a cab which had been hired for the purpose, and doubtless this is not an isolated case of detective photography. The matter came up in a strange way the other day in the

course of a law suit against the Great Northern and City Railway Company. The plaintiff, a waste-paper dealer, stated that owing to the construction of the defendants' railway tunnels damage had been done to one of his houses which had cost him £62 to repair, and cracks had appeared since the driving of the tunnels in another house of his. Having made this statement, the witness was confronted with a photograph which had been taken twelve months before the tunnels were made, and the picture showed a crack in front of one of the houses. His claim was finally demolished by Mr. Douglas Young, F.S.I., who stated that he acted for the company when the tunnels were about to be constructed, and, anticipating claims of this nature—oh! artful Mr. Young—he caused photographs to be taken of all houses on the line of route which showed cracks. The cracks shown in the picture were practically in the same condition now, and the work necessary to be done to the houses came entirely within the repairing clauses of the leases, and was not caused by the tunnels. Upon this evidence the jury returned a verdict for the defendant company, on the ground that the tunnels were quite innocent of causing any damage. Poor waste-paper dealer, the only satisfaction he will have will be that the various legal documents pertaining to the case will add somewhat to his stock in trade. How he must anathematise photography and all its works. Little did he dream of this child taking notes, and that the "prents" would take such a very inconvenient form. People who are about to make doubtful claims for damages will do well to ascertain first whether Mr. Douglas Young is retained by the other side.

Bichloride of Mercury used before Fixing.

An interesting abstract of a paper by Dr. R. A. Reiss upon the use of bichloride of mercury appears in *La Photographie Française*. The writer states that it differs in effect when used as an intensifier before and after fixing the image. If the plate is washed for five minutes after development, then bleached with bichloride of mercury, well washed, re-developed, it will be found that the intensified image is finer in grain than if the intensification had been done after fixing the image. The fact is interesting, and may be of use in special cases, but as the operations have to be carried out in the dark-room the process is not likely to be generally used. A slight modification, however, gives a different result. If the plate after exposure be treated with a slow developer and the action stopped by washing as soon as all fine details have appeared, a positive may be obtained by immersing the plate in a solution of bichloride of mercury for ten to fifteen minutes until the image has almost disappeared, and then, after rinsing, again immersing it in the developer. The plate, still charged with mercuric salts, veils uniformly and the image cannot be seen by transmitted light. When immersed in the fixing bath a reversed image may be obtained, those parts which were not reduced by the first development appearing yellowish brown, which intensifies in drying. The non-actinic quality of this image gives it the properties of a positive. Colson has pointed out that chloride of mercury in the dry state, when brought into contact with a bromide emulsion, destroys the latent image and renders the plate insensitive to subsequent exposure. Dr. Reiss, on the other hand, has found that a solution of chloride of mercury does not destroy the latent image, but merely slows the emulsion considerably. To make use of plates which have already been exposed or fagged, they should be placed in a 5 per cent. solution of bichloride of mercury for ten to fifteen minutes. Wash in running water for ten minutes, dip in a solution of amidol developer, and wash

the plates again. If the plate is used wet, immediately after the final rinsing, it will be found about 150 to 200 times slower than it was originally. The image is faintly visible and development proceeds slowly. In the *Photographisches Wochenblatt* we find a further note upon the subject, stating the Dr. Reiss has made practical use of his researches for another purpose, the restoration of exposed or fogged bromide paper. This he immerses in a 2 per cent. solution of bichloride of mercury for fifteen minutes, and after well washing and drying it, obtains a very slow contact paper of exceptionally fine quality. The requisite exposure is thirty minutes in diffused daylight under a negative of average quality. Plates may be treated in the same way for obtaining transparencies.

Journalistic Portraiture.

The man who distinguishes himself in any way is sure to find his portrait published in the newspapers, and from the persistence with which these pictures present themselves a few hours after the original has awakened to find himself famous one would think that editors kept the blocks ready made, and selected the most suitable to the case in hand. It cannot be said that the majority of these sketchy pictures are satisfactory, and it often happens that blocks supposed to represent the same individual, and appearing in different newspapers, have not the slightest resemblance to one another. Only a few days ago the portrait of the unfortunate Mr. Kensit appeared in a morning and in an evening journal on the same date, and while one represented a bald-headed man of about fifty, the other introduced us to a much younger man who still kept his hair intact. Now if portraits are not likenesses, what is the good of publishing them, unless there be an advantage in purveying that which is untrue? The competition in modern journalism is so stupendous that editors, we fear, are not always as particular as they might be with regard to accuracy, so long as the matter they print ministers to the desires, prejudices, and curiosity of their readers. Much the same thing happened in the long ago, when the making of a wood block was a serious business, and when photography was as yet unborn. It was common in those days for the same portrait to do duty over and over again for different persons. So it was, too, with the pictured "broadsides," the forerunners of the modern newspaper. Looking through a collection of these lately we found the same blocks appearing many times, on each occasion being labelled differently. They were mostly pictures of prize fighters, murderers, and hangings, and it was amusing to see how the same designs did duty for so many different individuals. Editors, nowadays, thanks to the cheap photo-process block, are not obliged to be so cheeseparing in the matter of pictures, and when they want a portrait they get a photograph, if possible, and have it turned into a line drawing. Failing the photograph, the artist draws as much upon his imagination as he does upon the cardboard upon which he works. The result is not always inspiring. A well-known professional man was, he told us, once on his way north to fulfil a lecturing engagement. When he arrived within a hundred miles of his destination he noticed, with some surprise, that his fellow travellers in the railway carriage stared at him as if there were something uncanny about him. It was the same when newcomers entered the carriage; their eyes left their newspapers, and were focussed on him. At last he found out what was the matter. One of the travellers left his paper on the seat of the carriage, and there, on the up-turned page, was the portrait of our professional friend. And an awful production it was. "I know I am not a beauty," said he to us, "nor am I very particular as to

my personal appearance, but if I was the hang-dog, cut-throat, hydrocephalous monster that that paper represented me to be, I should take a dose of prussic acid." He then asked us whether he would not be justified in prosecuting that northern editor for libel—to which query we gave the safe and sage reply that he had better consult a solicitor.

* * *

X-ray Examination. A most lamentable occurrence is reported from Cleveland, Ohio, which should act as a warning to those who are unaccustomed to interpret the readings of the X-rays. A certain Mr. Buettner, a wealthy contractor, awoke one morning with a sore throat, not by any means an uncommon experience with most of us. But at the same time he missed his false teeth, and at once jumped to the conclusion that he had swallowed them in his sleep, and that the pain in the throat was the result. A surgeon was sent for post haste, the X-rays were called into requisition, and by their aid he discovered, to his own satisfaction, the plate of teeth resting in the stomach. An immediate operation was recommended, and while it was in progress a relative of the patient found the missing teeth under his bed. She rushed to the hospital, but was too late. The patient died from the effects of the unnecessary operation. Now, it seems to us that in a case of this kind, the opinion of the surgeon should have been fortified by a radiograph before such a serious operation was ventured upon. With the X-ray apparatus at hand, the production of a negative would have been but a matter of a quarter of an hour or thereabouts, and such a picture would show clearly the plate and teeth if they had been there. If, on the other hand, as we presume was the method of procedure in the case adverted to, the examination is merely by fluorescent screen, there is ample opportunity for error. Such examination is often the only kind that can be made on the battlefield, but army surgeons are now so expert in the use of the rays, and a bullet is such an unmistakable "foreign body," that mistakes cannot easily occur. Any one who has had the opportunity of making an examination by screen will at once appreciate the difficulties surrounding it. A hand, a foot, or a leg, or an arm, are easy enough to examine, and there is no difficulty at all in noting all the bones and any abnormal appearance which they may present. But when we come to place the screen in front of the torso there are many organs covered with layers of thick muscle that it is extremely difficult even to an anatomist to recognise the masses of shadow for what they really are. And this is the case even if tube, coil, and battery are all working at their best and in harmony under a skilled operator. There are several X-ray pictures in the present exhibition at the New Gallery, one of which shows how plainly a hat pin, which has lodged itself by some unaccountable mishap in the stomach, can be revealed by radiograph. Another shows a collection of needles in a man's knee-cap. It is evident that in either of these cases the surgeon would be justified by the evidence afforded by the pictures in cutting down towards the intruding bodies. The radiographs leave no room for fancy, there are the articles which have found such a strange tenement, and the sooner they are evicted the better. If such a picture had been available in the case reported from Cleveland, the sacrifice of a life might have been obviated.

A COMPETITION of special interest to photographers is at present running through the pages of "The Sunday Magazine." Every month a micro-photograph of some familiar object is published, and readers are invited to state what the picture represents, £5 being awarded to the successful competitor.

THE CONTINUING ACTION OF LIGHT IN THE CARBON PROCESS.

At a Society meeting a few weeks ago, when the subject of carbon printing was under discussion, some doubt seems to have been expressed as to whether the action of light set up in an exposed carbon print could be continued in another piece of tissue kept pressed in contact with it. At another meeting, reported in our last issue, one of the members showed the result of an experiment which proved that such action did take place, although the image was very faint, and was said to be too flat to be of any practical use. The fact that the action of light set up in one bichromated gelatine film could be continued in another that had not been exposed by its being kept pressed in contact with it for a time was shown nearly thirty years ago, and also that good pictures could be produced in that way. This was practically demonstrated before the London Photographic Society, now the R.P.S., by the late M. A. Marion, nearly thirty years ago, a full report of which will be found on page 242 of our volume for 1873. In our issue for November 9th, 1900, Mr. E. W. Foxlee published the results of some experiments that he had recently been making with M. Marion's process—"Mariotype"—and how the time of keeping the two tissues in contact could be considerably shortened, from that necessary in the process published by M. Marion, from eight or ten, to two or three hours. Since then Mr. Foxlee has shown in our contemporary the *Photographic News* that the action of light set up in a bichromated gelatine film could be communicated to and continued in other colloid bodies, such as gum, for example. Also that the presence of free bichromate in either film was unnecessary, as that could be all washed away and the print dried and kept for weeks before the second colloid body is applied. Furthermore, he has proved that the initial print need not be made in bichromated gelatine at all, as other colloids will answer the same end. Paper, for example, may be coated with a starch—arrowroot, for instance—sensitised, printed, washed, dried, and at any subsequent time coated with pigmented gum containing an acid, and again dried. In this state the print can be kept for weeks, to be developed at any convenient time. In this method of working excellent pictures may be obtained; but, of course, it entails more trouble and time than that involved in working the ordinary carbon process, notwithstanding that the picture is obtained the "right way about" without transfer, and the fact that we have a visible image to begin with. Still, the system is interesting from a scientific point of view, as illustrating the persistent action of light in bichromated colloid substances.

THE Photograph of a Thought.—An elderly man in Cleveland ran in great suffering to a hospital, where he said that he had swallowed his false teeth. The X ray disclosed in his gullet a dark blotch that looked like the missing object, but when an incision was made no teeth were there. They had in fact fallen under the bed, where a servant later found them. The man had only dreamed of swallowing them. But what was the object which the X ray had photographed? That the doctors could not tell, unless "some psychological-physiological effect" was produced by the man's delusion which was actually visible through the fluoroscope. The belief that he had swallowed the teeth and that they had "stuck half way down" gave the patient such pain as the actual object would have done. Was that imagined object as real to another's sight as it was to the sufferer's own sense of feeling? If it was, here is an argument for those who hold that all pain, sight, hearing, and feeling are in the mind; though to the "man in the street" it is easier to suppose that the doctors were mistaken and saw neither teeth nor thought. At any rate, if X-raying a thought is possible, a photograph of the reflections of the patient's relatives on the whole affair would be interesting. For the subject of this absorbing inquiry died as the result of his needless operation.—"New York World."

TWO THOUSAND PHOTOGRAPHS.

HAVING taken part in the recent selection of pictures for the R.P.S. Exhibition, and having thereby received a lesson of considerable value, I feel that the knowledge of the experience there gained should prove equally valuable to exhibition workers generally.

The earliest feature to strike me was the extreme divergence of opinion of the Committee, which probably ranged pretty generally from one end to the other, and the feeling naturally followed that every so-called school was represented, thus ensuring recognition of every class of work.

At times when a picture of a controversial nature appeared, this difference of opinion was most markedly defined, but everyone, after vigorously and occasionally fiercely fighting for the principle which he felt was involved, accepted his victory or defeat with appropriate moderation, or good temper.

The usual plan was, of course, adopted of the frames being held on the table, and generally adjudicated upon in this way; but the smaller work was more closely inspected and passed along from hand to hand.

As hour after hour passed, and hundreds of the most ordinary, and even elementary, work passed along, anyone casting a momentary glance on the Committee at their task might be almost pardoned in concluding that the body was carrying out its work in a very lackadaisical and almost indifferent manner.

But the effect of the cry of "Rats!" to a drowsy terrier was not more electrical than the appearance of something out of the ordinary in the way of picture-making.

In a moment every member was on the war path, the picture was keenly discussed, argued and harangued, the appeal for the vote was promptly acted upon, the fate impartially settled, and the Committee again resumed its dreary task of picking the bits of coal from the ashes.

I say dreary advisedly, for, in the first place, it is not generally pleasing to sit in judgment on one's fellow man, and be compelled to condemn when it would be more gratifying to praise. One does not expect, and certainly would not desire, to see the undertaker conduct his operations with face wreathed in smiles, and can fully realise that the gentleman has probably not chosen his vocation for, vulgarly speaking, "the fun of the thing."

Consequently, it is not enlivening to return to obscurity that which has evidently given cause for much work and well-meant thought. As a proof, however, of the keenness which the Committee maintained right up to the finish, and the number to be adjudicated upon was very close upon two thousand, it may be mentioned that the keenest fight took place well after eight o'clock in the evening, when one might reasonably suppose there was not a kick left in the room.

For nearly a quarter-of-an-hour did the fight rage hot, members rising to address their fellows, or arguing the matter in twos or threes, with the greatest animation, before the particular point was finally decided.

However, I hold no brief for the Selection Committee, who neither desire nor require my advocacy; but the feature I want to press home is the lesson to be learned by the viewing of such a mass of work, and the remarks aforementioned are made rather to the probably some hundreds of disappointed exhibitors, to show the impartiality and thoroughness attempted. But all of us have been disappointed exhibitors at some time or other, and it is at such times that we are least amenable to reason.

'Tis not, therefore, so much the view of endeavouring to alleviate such disappointment, as by trying to give a few general

hints as to what appeared to appeal to the Committee, and what did not, and thus endeavour to avoid the recurrence of further disappointment. Selection Committees are but human, even if when they reject our pictures we think they are not humane, and are keenly anxious to pick out the best material at their command, to make as attractive a show as possible. Besides, their own reputations are at stake, as they will be subsequently judged by what they hang. One of their foremost desires is probably to relieve the exhibition from the ordinary; consequently anything removed from the beaten track, or suggesting novelty in idea or treatment, receives their closest study, and elicits their warmest interest. On the other hand, that which especially failed to appeal were the flat grey bromide prints of a generally commonplace subject—and there appeared to be acres upon acres of these, which repeated themselves with a persistency and monotony which was simply deadly. Of very little more interest was the good ordinary, clean, technical print, whose virtues lay entirely on the negative side, for which from their very number no one could raise sufficient enthusiasm to fight, and the best went into the “doubtfuls,” from which probably they never emerged, thus receiving recognition at about their approximate value.

Another point which prevented many really good things from being hung was the atrocity in framing and mounting, many showing such a violation of taste, the hanging of which would be a studious insult to all work in the vicinity. The prints of many would-be-exhibitors seemed to suggest that as soon as the authors knew how to decently develop a plate and make a tidy print, they were entitled to recognition by having such hung. Some sent as many as from twelve to twenty frames, and one could not fail to anticipate with regret the disappointment which the compulsory rejection must entail, while at the same time considering how different the result might be were so much labour and thought concentrated on to, say, one or two of the subjects.

Taking the whole couple of thousand prints collectively, one could not help but be more than ever impressed with the fact that what is needed and should be striven for by those anxious to exhibit, is some individuality, to lift them from the rut of the mass, and some feeling and motive in treatment to remove them from the commonplace. This would probably more easily be accomplished by the serious attempt to learn from all, while slavishly copying none, and by a close study of the art side of picture-making, and by a concentration of thought on to a little endeavour to do that little really well, rather than perpetuate that which has been done as well before and will be again, and which brings no lasting satisfaction or interest, even after its accomplishment.

J. PAGE CROFF.

THE Earth's Rotation.—The great pendulum which had been hung from the top of the dome of the Pantheon by the Astronomical Society of France to demonstrate by its oscillations the rotation of the globe, was last week set in movement at an inaugural ceremony, presided over by M. Chaumie, Minister of Public Instruction. The President of the Republic was represented by Commandant Roulet, and delegates from the Polytechnic and Normal School were also present. The official personages were received by M. Poincaré, member of the Institute and of the Bureau of Longitudes, and M. Camille Flammarion, President of the Astronomical Society. They were supported by numerous other *savants*, mathematicians, astronomers, etc. M. Camille Flammarion, after reminding his hearers that it was in 1661 that the demonstration was first made in Florence by Galileo, referred at considerable length to the memorable experiment made in France by Foucault half a century ago, and of which the present was a repetition. M. Chaumie commented on the technical explanations given by the astronomer, and then, by burning with a match the string which held it, freed the pendulum, which commenced its majestic oscillations, the stylet marking clearly its passage over the sand.—Paris correspondent of “The Standard.”

ON THE MOLECULAR STRAIN THEORY OF VISION AND OF PHOTOGRAPHIC ACTION.

(Presidential Address to the Photographic Society of Ireland, Delivered on Friday, 10th Oct., 1902.)

I HAVE felt a difficulty in selecting a subject on which to address you, because my knowledge of the processes of photography is limited to the ordinary routine of the amateur's work, but I have at various times studied scientific questions connected with photography, and I have thought it better that I should confine my remarks to a short account of a recent advance in photographic science which has come from an Indian scientist. I refer to Mr. Jagadis Chunder Bose, whose work has opened up a field of advance in photographic science, a field so promising that I think the members who are not already acquainted with it would be interested in an account of Mr. Bose's work.

You are, of course, aware that ever since the beginning of photographic science, as soon as chemists and physicists began to speculate upon what was going on in the photographic plate, it was recognised that the effects were partly chemical and partly physical.

Mr. Bose began his work a few years ago, in 1899, and, as in many other cases in science, he began working in an entirely different direction. You are, of course, aware of the leading principles of wireless telegraphy, and you no doubt know that, in order to carry out wireless telegraphy, one of the most important parts of the apparatus is, or till quite recently has been, the coherer. The coherer is, briefly, a little glass tube filled with iron filings. It is found that when such a tube is exposed to electric waves there is a variation in conductivity, and that in the case of iron filings the conductivity is increased, and it is by this increase of conductivity that it is possible to detect the waves.

In order to connect this matter with photography, I will remind you that these electric waves are identical with light waves, only that they are of greater length. Prof. Lodge suggested an hypothesis to explain the action of the coherer, and it was on the basis of his explanation that the term “coherer” became popular. He suggested that effects arising from the electric waves might cause the iron filings to become fused together at their minute points of contact, the idea being that the iron filings cohered, and in this way the resistance of the tube became diminished.

Mr. Bose, in experimenting with different metals, in 1899, discovered that there were some metals that did not increase in conductivity when the electric waves impinged upon them, but that they increased in resistance or diminished in conductivity. Now, if the coherer hypothesis was correct, every substance should show an increase of conductivity; but here Mr. Bose had found that some substances, instead of increasing, diminished in conductivity, therefore the coherer theory must, according to Mr. Bose, be abandoned. Mr. Bose named as “negative” those substances which diminished in conductivity under the action of electric radiation, and “positive” those which increased in conductivity, the substance being in a state of powder when its conductivity is being examined. Among the first class are the metals potassium and sodium; among the second, iron, magnesium, zinc, and cadmium. Silver, the substance that the photographer is continually dealing with, may be sometimes positive and sometimes negative under the influence of the electric waves.

Mr. Bose, in a subsequent paper, designates the peculiar phenomena he is studying “electric touch,” and expressed his belief that what he was observing was an allotropic modification of the substance under the influence of the electric radiation.

He suggests that such modifications are very general attendants on the activity of electric or luminous radiation; but only in special cases can their effects be observed during their continuance. Further observation revealed the fact that the same substance may sometimes react positively, sometimes negatively, towards electric radiation. It seemed partly to depend on the intensity of the electric radiation to which it was exposed. For instance, the substance arsenic is negative close to the radiator, but if removed a sufficient distance it becomes positive.

Substances exhibited also a phenomenon which he called "fatigue." This was, in short, a loss of sensitiveness to radiation. But before that state was reached a still more remarkable phenomenon became evident under continuous radiation: the substances may spontaneously reverse in sign. The radiation product may change from negative to positive, the action of radiation reversing the sign of the electric touch. This appeared to be distinct from the change of sign dependent on intensity of radiation, as the experiment in arsenic would indicate. The curve for the conductivity of such a substance as arsenic under continued radiation is a line alternately rising above and sinking below the level of mean or normal conductivity, and finally revealing the fatigue of the substance by the approximation of the curve to this level, the substance finally becoming almost inert and insensitive to electric radiation.

To account for these phenomena, Mr. Bose put forward a strain theory of such allotropic changes as he supposes to obtain in the substance under the influence of electric radiation. If the two forms of the substance be for clearness designated A and B, electric radiation in the first instance converts some of A to B. Now, if A is the + form, B is the — form of the substance. Further radiation to the substance must therefore be attended with lessened response, for A and B are acting antagonistically. There is, however, an "electric elasticity" attending the change, which may result in B rapidly reverting to A. This is "self-recovery." In this case a second trial may show the substance to possess its original sensitiveness. On the other hand, all may become B, and "reversal" result; or again, A + B may exist in such proportions as to lead to resultant insensitiveness or "fatigue." The conductivity curves of potassium, magnesium, and arsenic well illustrated these cases.

The audience would by this time perceive the connection between Mr. Bose's researches and photography. All are familiar with the phenomenon of solarisation. It was only necessary to photograph an arc light, giving an exposure of a few minutes, to get the reversals. In Mr. Bose's view these reversals were phenomena continuous with, or of the same physical nature as, those he dealt with in his experiments. The silver bromide molecule is "strained," and the strain-silver bromide responds to chemical actions differently to the unstrained molecule. The sensitiser's function is to retard the self-recovery from strain. Chemical action is in short a secondary phenomenon, and not a primary one attending exposure.

The successive phases of "solarisation" are represented in Mr. Bose's curves. When the curve of conductivity under the influence of radiation departs from the normal, the first negative is secured; but this conductivity cannot be continuously maintained. In the photographic plate the sensitiser forbids its annulment upon the mere stoppage of radiation. In the "coherer" tube, till fatigue or actual reversion occurs, there will be in general recovery (more or less complete) upon stoppage of radiation. But at length a point is reached when fresh exposure to radiation is attended with fatigue or reversal. The

passage from the one state to the other may be said to depict the photographic phenomenon of the first positive; for at some point in this transition the photographic effect causing the negative has been annulled. In Mr. Bose's experiment this passage may be attended with an interval of inertness towards radiation. (Reference was made to the case of Mr. Bose's specially prepared negative silver). After this the sign is reversed. Light, or radio-activity, involves a fresh strain; and the second negative is obtained, and so on. It would appear that a final state of fatigue or inertness attends on continual radiation to the "coherer." On the photographic plate the intervals lengthen, far more light being required to produce the second negative than the first. But this may not be the corresponding phenomenon to "fatigue." Is such fatigue finally reached in the photographic plate short of the appearance of a visible image?

Although it is difficult to correlate the two phenomena with exactness, there is much in the character of the observed changes of conductivity which may be paralleled with photographic actions, and when along with this it is taken into account that the agent inducing the surface changes in the particles in the tube is the same agent which affects the molecules or aggregates of silver bromide, one cannot help regarding the strain theory as most suggestive. That ultimate chemical decomposition may attend continuous light action may not be denied. Many instances can, of course, be cited, and, as I read Mr. Bose, he probably would not deny that light ultimately effects chemical decomposition of the silver haloid in the sensitive plate. But within the range of reversal phenomena the strain theory appears to lend itself in explanation of many effects only awkwardly explained by chemical actions. Chemists apparently do not like to admit merely loosened bonds; strains, on the other hand, may be reasonably supposed to exist in any degree short of disruption of molecular grouping, and, in the other direction, to the minutest beginnings.

Directly in harmony with a strain theory is the well-known fact that mechanically made impressions on the plate are developable. But perhaps the most striking fact supporting the strain theory is the continued sensitiveness of the plate at temperatures so reduced as to inhibit orthodox chemical actions. Readers of Professor Dewar's address to the British Association this year will recollect his reference to this phenomenon. At so low a temperature as that of liquid hydrogen, about 10 per cent. of the original sensitiveness remains. It is now many years ago since I photographed the spectrum on ordinary and isochromatic plates, backed by solid carbonic acid and ether. While the waves of low refrangibility in general had at this temperature lost much of their effect (the loss being most marked on the isochromatic plate), the rays of high refrangibility were little reduced in activity. The action of the dye appeared affected after the manner of chemical reaction, leaving the normal photographic sensitiveness of the plate, to the blue, violet, and ultra violet rays, almost unaffected. But this reminds me that I have more to say about Mr. Bose's work, and must not more digress from my original intention of placing a simple account of his experiment before you.

A photo-electric experiment of Mr. Bose's, analagous to those of Professor Minchen and others, revealing features in common with conductivity experiments, must claim our attention for a little. Two strips of silver which have been exposed to bromine vapour are immersed in a water-cell and examined as to their variations of electric potential under exposure to flashes of light and to continuous illumination. The phenomena of a maximum effect attending continuous illumination, of self-

recovery, of reversal, and even indications of fatigue are obtained. Other similarities in the forms of the curves are observable.

The connection here is evident. Potential differences will arise under molecular alterations; conversely, potential differences may be taken to indicate molecular strains or alterations. The experiments indicate, therefore, molecular effects similar in many features, arising under light action and arising under electric radiation. The resemblance of the course of events in each case is certainly striking.

The last experiments I have to tell you about were designed to connect the radiation effects with undoubted strain effects, and so support the hypothesis of the former being indeed purely of the nature of strain. In the "strain cell," a very interesting and simple piece of apparatus is presented to us. Two wires cut from the same length are stretched vertically between ebonite supports, and above are attached to binding screws; one of these is capable of being rotated. The "electrolyte" is water, and a sensitive galvanometer of D'Arsonval type is connected to the binding screws. Whatever P.D. there may be in the first instance between the wires at once becomes modified on applying a torque to one of the wires. It may be annulled or increased. A potential difference is, in fact, generated while twisting, and thus straining, one of the wires.

It was found that most of the metals become negative while under increasing strain—i.e., the current in the cell is from the strained to the unstrained wire. With successive turns the effect during each turn grows less. When the twisting is stopped there is recovery showing a time rate resembling the recovery from electric radiation and light radiation. It is remarkable that silver often exhibits an opposite electromotive effect to that generally shown by metals under twist.

Mr. Bose, finding that the electromotive effect is not dependent on the direction of twist, whether clockwise or counter-clockwise, arranged to produce continuous molecular disturbances by conferring a vibratory character to the twist—i.e., arranging so that the wire is twisted alternately through certain definite angles first in one direction and then in the other. This generated a P.D., the magnitude of which depended on the amplitude of twist. We now find in his curves—rapid recovery under a short stimulus, a maximum effect under continued vibration, followed by recovery; and reversal in some cases under intense stimulus or under long continued stimulus. These are the most important points.

The course of experiments is summarised in Mr. Bose's final paper on "The Strain Theory of Photographic Action."

I have not left myself time to touch on the chemists' side of the question, which, from my inability to speak with authority in that direction, I do not entirely regret. What is chemical and what is physical may well be asked. One answer would be that short of disunion and re-arrangement of atomic or molecular bonds between dissimilar substances, we agree to call atomic or molecular disturbances "physical." If this be assumed, there is much known about photographic actions which suggest that the light effect is at least primarily physical. The increased sensitiveness obtained by increasing the size of the silver bromide aggregates (ripening) can hardly be a mere resonance phenomenon. It more directly suggests the building of a system sensitive to molecular strain. So far as chemical action goes, the smallest and the largest aggregate are alike in chemical composition. The image in the silver iodide of the Daguerreotype film may be developed with water vapour.

Moser, and more recently Major-General Waterhouse, pro-

duced images directly visible or developable by mercury vapour on clean silver surfaces, exposed in contact with air; and the latter obtained an image developable by water vapour on a clean glass plate. Mere molecular strain effects are certainly suggested by such experiments; but it must not be lost sight of that oxygen and other gases of the atmosphere are present in these experiments. Nor can we entirely side with a strain theory of recurrent reversals till we get some explanation as to why the presence of atmospheric oxygen would appear to be a factor in the phenomenon of solarisation. Professor Meldola suggested that it acts upon the sensitiser, diminishing its halogen absorbing capacity. Those who favour a strain theory may argue that such a chemical alteration of the sensitiser may affect its influence on "self-recovery."

In this sort of obscurity we at present move. But Mr. Bose has conferred a service on photographic science by suggesting alternative views to those long held by many workers in this field. He has opened wide vistas of study, and this is always good, whether the pioneer's deductions are sustained or not. The most dangerous state is that of contentment—a frame of mind never meant for man, however much moralists may advocate its cultivation.

PROFESSOR JOHN JOLY, D.Sc., F.R.S.

COLOUR Photography.—On November 3rd, the Lumiere process will be illustrated by Mr. T. K. Grant at the meeting of the South London Photographic Society, held at Hanover Hall, Hanover Park, Peckham. Photographers interested are invited to the meeting, 8 p.m.

WOLVERHAMPTON Photographic Society.—A demonstration of platinotype printing was given by Mr. T. Henry Cox before the members on the 22nd inst. Prints were developed by several methods, including the employment of glycerine as a restrainer. Mr. Cox also dealt very fully with the chemical side of the process in a most entertaining manner.

DEVONPORT Camera Club met on Tuesday under the presidency of Mr. R. J. Lamb. Five new members were elected. A large number of excellent slides, lent by Messrs. A. J. Catford, J. F. Coombes, J. Trouern Trend, W. H. Lamb, and R. Maw, were shown. They dealt with marine subjects, Continental views, Dartmoor, Lynnmouth, and Ilfracombe. On November 4th Mr. J. Trouern Trend will give an "enlarging" demonstration.

MRS. CARRIE NATION Hoaxed.—The New York correspondent of "The Yorkshire Post" is responsible for the following:—Mrs. Carrie Nation, who has just concluded a visit to the Yale University for the purpose of inducing the students to give up drinking and cigarette smoking, was tumultuously received. At her lecture the Glee Club sang "Down with Alcohol, Drink it Down," and "Good morning, Carrie." The famous saloon-smasher yielded to importunities to sit for her picture, holding a glass of water in her hand as an emblem of teetotalism. In the resulting photograph Mrs. Nation is represented holding a glass which, owing to the mysteries of the dark room, is capped with a crown of foam. Around her are the students, one drinking from a whisky bottle, another lighting a pipe, others smoking cigarettes, and two apparently in the last stages of intoxication. Mrs. Nation intends to sue the University for libel.

"AFTERNOON Tea at a Photographer's."—Tuesday and Wednesday, Oct. 21st and 22nd, were the two days set apart as show days at the new photographic studio recently opened by Mr. J. W. Beaufort in Birmingham. The invitations were sent out in a neatly printed and artistic booklet, and many ladies and gentlemen called to view the suite of rooms and studios, where they were received by Mr. and Mrs. Beaufort, whilst the assistants, some dozen or more, conducted the visitors over the premises. Afternoon tea was served in the orthodox manner in the reception room, and on leaving, each visitor was presented with a souvenir, consisting of the first number of "Achievements," containing a portrait study by Mr. Beaufort, entitled "Contemplation," a charming effect, the subject being a well posed female figure, soft, well graded and modelled, and admirably translated in sepia carbon. Mr. Beaufort says in his elegant publication: "Picture making by photography, particularly when in relation to figure studies, is the most fascinating hobby for the patient photographer, providing, of course, the worker possesses the necessary skill and accomplishments. The work has a peculiar charm of its own. The sudden inspiration, the eagerness to secure the effects, the disappointments on developing to find some unnoticed object has taken upon itself certain prominence which destroys the value of the rest of the tones, all tend to lure the enthusiast on to achieve the ideal. For several years, in my old studio in Colmore Row, I tried in vain to secure certain effects which were almost impossible owing to the unsuitability of the studio. Now with a studio built to my own design, as my present one is, such effects in lighting and the true rendering of tone values are under absolute control." We congratulate Mr. Beaufort on a marked advancement in his aims, ideals, and work.

GLEANINGS FROM OLD LONDON DIRECTORIES.

AMONG the pleasures of life may be counted the perusal of old books. If the subjects or the places to which they refer appeal to the reader, the most prosaic of volumes acquire a fascinating interest. A duller volume than a London Directory can scarcely be imagined, yet time invests even such with a peculiar attractiveness. Three old Directories of the Metropolis recently passed through our hands. They were for the years 1798, 1839, and 1848, and a most interesting study they proved to be. Their relative size at once appealed to the imagination as suggestive of the expansion of this vast city. The oldest volume contained some 300 octavo pages, but in the year 1839 their number had increased to about 1,400, whilst the most recent volume of the three contained about 2,000 pages, of usual size, for the Commercial and Court sections. The oldest volume contained about 9,000 addresses, and we wandered through them instinctively, in search of opticians and others who may have been connected with that branch of industry. In 1798 we found Peter and John Dollond were located at 59, St. Paul's Churchyard. At 20, Cornhill, resided Edward Nairne, optician to the King. Dring and Fage were hydrometer makers at 6, Tooley Street, Southwark. Jesse Ramsden, a noted optician, whose name is still associated with eye-pieces, was established at 199, Piccadilly. From another source we gather that his connection with optics dated back to 1764, and that he married the daughter of John Dollond. William Cary, mathematical instrument maker, was at 182, Strand. John and Edward Troughton, also mathematical instrument makers, were in business at 136, Fleet Street. At 42, Lothbury, was John Lister, wine and brandy merchant, probably the father of Joseph Lister, who interested himself very much in the improvement of the microscope, whence the name of Lister Works, given to their factory by Messrs. R. and J. Beck, of Cornhill. The celebrated surgeon, Lord Lister, was son of Joseph Lister. Spencer, Browning, and Rust were mathematical instrument makers at 66, Wapping. In 1839 they were wholesale dealers in bunting for ships' colours also. Was the Browning here referred to the predecessor of the celebrated spectroscope maker of the Strand? Another interesting name, in a different sphere of life, was Benjamin D'Israeli, merchant, 26, Broad Street Buildings. We looked in vain for Newton and Co. in the oldest volume, but in 1839 there was a firm, Newton and Berry, globe makers and land surveyors, 66, Chancery Lane. In 1839 Andrew Ross was established as mathematical instrument maker at 15, St. John's Square, Clerkenwell; but in 1848 he was an optician at 2, Featherstone Buildings, High Holborn. Carpenter and Westley were located at the Microcosm, 24, Regent Street. Smith and Beck, in 1848, were opticians and microscope makers at 6, Coleman Street. In the same year Richard Beard was in business at the Photographic Portrait Rooms, Royal Polytechnic Institution, 309, Regent Street; 34, Parliament Street; 85, King William Street, City; and he also had a factory at 18½, Wharf Road, City Road. Whose names will appear a hundred years hence as links with the opticians and photographers of to-day?

LEICESTER Literary and Philosophical Society.—Messrs. Taylor, Taylor and Hobson most kindly invited the members of the photographic section to inspect their works in Stoughton Street on Thursday, October 23rd. A party of twenty-five ladies and gentlemen availed themselves of the offer, and were shown round by Mr. Smithies Taylor, and other members of the firm. The whole process of manufacture of a lens was explained, and the intricate machinery employed examined. The visit lasted two hours, and at its conclusion tea was kindly provided. Mr. Councillor Squire expressed the thanks of the visitors for the kind hospitality extended to them, and a most enjoyable afternoon was thus brought to a close.

THE BARD'S TRIBUTE TO HIS PHOTOGRAPHIC SOCIETY.

[We perceive by the October number of the Edinburgh Photographic Society's Transactions that one of its members, like Mr. Silas Wegg, has dropped into poetry. We append the lines, and congratulate the Society on having inspired such grateful emotions.—Eds. B.J.P.]

With mingled feelings I recall those days when forth I hied,
A novice, with my half-plate in a satchel by my side;
Resolved on "taking" somebody, or something, you may guess,
But, lackaday! I knew not then the good old E.P.S.

To drive the crowd of urchins back, who gathered quite in force,
Upset one, and the dark slide I forgot to draw, of course;
And oftentimes two exposures on one plate (which is excess)
Produced effects more wonderful than charming, I confess.

Sometimes the cap I would forget still firm upon the hood,
While, I, with air of one who knows (but inward trembling), stood;
And, watch in hand, the rubber ball most deftly would I press,
Then came a glad, expectant dream—words cannot here express.

'Twas in the dark-room vivid thoughts of latent gems would rise,
And phantom landscapes oft beguiled one's weary, watchful eyes;
'Till roused by some home critic—"What a horrid, splashy mess!
Why don't you learn from others. Go and join the E.P.S."

On progress bent, with firm resolve, and by a friend proposed,
I proudly was admitted *mem. con.* (that is, unopposed);
Now, while I live, I surely that auspicious day shall bless,
When I became a member of the good old E.P.S.

Here genial, kindred spirits one can meet with by the way,
And all his wrongs have righted, and made clear as an X-ray;
Those little peccadillos need no longer now distress,
For everything goes smiling when you've joined the E.P.S.

So now I sally forth, rare gems to gather as I go,
And e'en have ventured to exhibit at the Photo Show;
Success has crowned my efforts. If you'll call at my address,
You there can see my trophy—Bronze Medallion, E.P.S.

KARR BONNE.

THE Blairstown and District at their monthly meeting added three members to the roll. The "Hand Camera Work" competition (A class) was won by D. G. Monair; and B class by L. Falconer, junr. The R.P.S. lecture on "practical Landscape Photography" was read.

A MEETING of professional photographers will be held at the rooms of the Birmingham Photographic Society, Norwich Union Chambers, Congreve Street, on Thursday, November 6th, at 7.30 p.m., to consider the advisability of forming a local branch of the Professional Photographers' Association. Mr. Alfred Ellis, hon. secretary of the Association, and Mr. T. C. Turner, hon. secretary to Local Branches Committee, will be present. All professional photographers of the district are cordially invited to the meeting.

AN Historic Photograph Accepted by the King.—His Majesty the King has just accepted of Mr. Horace W. Nicholls, of Windsor, late of Johannesburg, South Africa, a panoramic carbon photograph of the great Peace Thanksgiving Service at Pretoria in June last. The King, in accepting the picture, commented on its interest. Viscount Kitchener has also sent Mr. Nicholls a letter in reference to the same subject, in which he states that it is quite the best photograph he has seen of the historic ceremony, showing so well the great mass of troops present. He requested Mr. Nicholls to send him some copies of it. The picture is rather remarkable from the fact that it shows over 7,000 troops, and is 36 inches long.

THE Glasgow Art Galleries.—The building in Kelvin Grove, Glasgow, which housed the fine art and the archaeological and historical collection during the recent international exhibition, was last week dedicated to its permanent purpose as the home of the collections of fine art and of natural scientific and industrial objects belonging to the corporation. The building is the outcome of the Glasgow Exhibition of 1888, the £40,000 surplus derived from that undertaking serving as a nucleus for its erection. To this amount a considerable sum was added by public subscription, but there is still a large balance of the £170,000 which the building has cost to be provided, no doubt out of the rates. As the galleries have been finally arranged sculpture occupies the great central hall. The eastern pavilions on the ground floor are devoted to natural history, science, zoology, and mineralogy, whilst industrial exhibits and historical memorials and remains are located in the Western Pavilions. The upper floor of the building is entirely devoted to pictures and objects of art, the latter being displayed in the balconies.

STATISTICS CONCERNING THE TRAINING OF CHEMISTS EMPLOYED IN ENGLISH CHEMICAL INDUSTRIES.*

(Reprinted from "The Chemical News")

THE Committee decided that the best method of obtaining the desired statistics concerning the training of the chemists employed in English chemical industries was to send a circular letter, with a form for reply enclosed, to all those members of the Society of Chemical Industry who, so far as could be judged from the designations given in the list of members, occupy a position as manager or chemist in a works. This method was adopted because the great majority of the chemists engaged in technological work in this country are members of that Society, and because no other means of obtaining the information seemed practicable. The result of the inquiry was that more than half of those addressed sent replies to the circular. It is probable that a considerable proportion of those who did not reply are not engaged in chemical works, and therefore the accompanying statistics may be considered to give a fair idea of the present position.

Information concerning their course of training was received from 502 managers and chemists employed in English chemical industries. Of these, 107, or 21 per cent. are graduates, and 395 have not taken a degree; 111, or 22 per cent. are Fellows or Associates of the Institute of Chemistry.

The following figures give more detailed information:—

Number of graduates of a British university	59
Number of graduates of both a British and a foreign university	16
Number of graduates of a foreign university	32 (a)
<hr/>	
	107
Number of non-graduates trained in a British university or university college	137 (b)
Number of non-graduates trained in a British technical college	165
Number of non-graduates trained in a foreign university or technical college	8
Number of non-graduates trained in evening classes, analysts' laboratories, works' laboratories, or otherwise	85
<hr/>	
	395

(a) Thirteen of whom studied also in a British university or technical college

(b) Twenty of whom studied also in a foreign university or technical college.

The distribution of the chemists among the principal industries is shown in the accompanying table:—

Industry.	Graduates—			Non-graduates, trained in—				Total.
	Of British university.	Of British and foreign university.	Of foreign university.	University or university college.	Technical college.	Foreign university or technical college.	Evening classes, &c.	
Acids, alkalis, inorganic salts	9	3	5	20	19	2	20	78
Metallurgical (various)	1	—	4	19	13	—	14	51
Explosives	6	—	1	4	28	1	6	46

* Report of the Committee, consisting of Professor W. H. Perkin (Chairman), Professor H. E. Armstrong, Mr. G. T. Bilby, and Professor G. G. Henderson (Secretary).

THE MANCHESTER SCHOOL OF TECHNOLOGY.

[Abridged from the "Times."]

THE school has been seven years in building, and represents an endowment of nearly £300,000, largely, but not entirely, of municipal origin. From one point of view, the school is the latest development of the Manchester Mechanics' Institute, founded in 1824, and in 1883 transformed into the Manchester Technical School. By 1883, Mr. Forster's Education Act of 1870 had wrought a diffusion of elementary knowledge which virtually superseded the voluntary effort of Birkbeck and Brougham, of their coadjutors and their disciples. The common-school system was giving the people the leaven of primary teaching, the want of which on their part had to a great degree rendered the offer of technical instruction at mechanics' institutes futile. Meantime, also, investigators, such as the late Mr. Slagg, Sir Henry Roscoe, and Sir William Mather, had traced to its root in foreign methods of technical teaching the growth of foreign industrial competition. It was in these circumstances that the Manchester Mechanics' Institute availed itself of the assistance of the City and Guilds of London for the establishment of specialised courses of instruction. In 1892, however, the local movement received an impulse beyond that of even the most munificent private benefaction. The Whitworth Institute of Art and Industry had been a projected supplement to the splendid gifts of the Whitworth legatees to Manchester; but in 1892 the promoters of that scheme joined forces with the municipality in the application of the ways and means for technical schooling which the Acts of 1889 and 1890 had put in municipal hands. Four thousand six hundred square yards of ground, formerly the site of the Whitworth Engineering Works, are included in the contribution of the Whitworth Trust, and to this area above 2,000 square yards have been added by the Corporation of the city. A sum of £44,000, representing the profits of the Jubilee Exhibition at Manchester in 1887, swells the composite subscription of Imperial, local, and philanthropic funds. The product is a School of Technology on a scale of equipment which qualified judges have said is unsurpassed.

Both day and evening classes are provided for in the syllabus of the school. The following are the day courses of study, together with the names of the heads of the departments:—Preparatory course, Mr. J. E. Holden; pure and applied mathematics, Professor J. P. Wrapson; mechanical engineering, Professor J. T. Nicolson; electrical engineering and technical physics, Professor A. Schwartz; sanitary engineering, Professor J. Radcliffe; pure and applied chemistry, Professor W. J. Pope; textile industries, Professor T. W. Fox; photographic and printing crafts, Mr. C. W. Gamble. The municipal school of art is in a separate building, and has a department for architecture, to which a lecturer, Mr. A. E. Corbett, has been appointed. There are also classes for German, dressmaking, and millinery, and other subjects.

The electrical and physics department is an important division of the school. The various rooms and laboratories spread over four floors. Dynamos and electric motors of many descriptions have been laid down, and there is a great abundance of testing and recording instruments. In the hands of Professor Schwartz and his staff we may hope that

this complete equipment will lead to the elucidation of many unsolved problems in the application of science to electrical industry. A special feature is an experimental tramcar truck, the wheels of which, being

driven by electric motors, can be run on rollers. The load can be varied, and other adjustments can be made for experimental purposes. There is also an arrangement for producing an artificial gradient. It will give an idea of the completeness of the arrangements in the electrical laboratory to state that current measurements can be made up to 4,000 amperes, and pressures up to 100,000 volts.

The chemistry department might be aptly described as a school in itself. There are lecture-rooms, laboratories, and offices of various kinds, all most completely fitted. The largest laboratory is one of the finest rooms in the building, and will accommodate 180 students. One detail of apparatus, amongst many, may be mentioned as showing the influence exerted on practice by researches which at first appear to have no bearing on a subject. The importance of distillation under very low barometric pressures is a prominent feature in modern chemical research, but the presence of aqueous vapour has been a difficulty which has given much trouble. In order to get over this, Professor Pope hit upon the ingenious expedient of causing his air pump to draw through a glass vessel cooled by immersion in boiling liquid air, thus freezing out the vapour.

It is the purpose of this article to describe only the school and its equipment, but in writing on the subject one cannot avoid speculating on the use to which all this elaborate and costly plant will be put. Reference has been made to research, but research is not exactly the same thing as teaching, although it should form an important element of higher technological education. It is a question for Manchester to decide whether the plant of the schools, and the time of the teaching staff, should be devoted chiefly to the instruction of the average student who does not soar to very great heights in the rarefied atmosphere of science, or whether it should be more especially utilised for the select few who are to become the leaders in applied science, the originators and inventors who will raise the industry of the country to a higher level—such men, in short, as the country cannot do without if it is to hold its own with other nations. To some extent, it may be possible to provide for both classes, but the combination is beset with difficulties. If research work, which involves the training of students who can play a useful and intelligent part in such work, is to be the main feature, it will result in the production of comparatively few—though perhaps sufficient—highly trained men, and will also be a most potent means of raising the industries of the district to a higher scientific level, directly through the medium of the work done in solving problems submitted by the manufacturers. If quantity rather than quality of output is to be the aim of the school, it may supply to the country a larger contingent of mediocre men who will be useful in their proper spheres, but whose function it will be to follow rather than to lead.

This problem appears to be the chief that technical educationists have now to solve; but, in any case, the chance should be given to every man or boy who has the ability to climb to reach the top. We cannot afford to waste a single grain of the talent which the country produces.

THE members of "The Linked Ring" were at home to their friends at the photographic salon, Dudley Gallery, Egyptian Hall, Piccadilly, on Tuesday evening last. The programme included "smoking, and its usual accessories; accompanied by a little music."

THE Goldsmiths' Institute Camera Club.—The Hon. Secretary writes: I beg leave to inform you that "The Goldsmiths' Institute Camera Club," which was established in 1893, has recently been reconstituted in one or two minor matters, and will in future be called "The Goldsmiths' Institute Photographic Society."

It is with great regret we ("Invention") chronicle the demise of Mr. Albert Alston, of Burnley, on the 6th inst. Deceased was the inventor (*sic*) of the popular and beautiful system of "crystoleum" painting, by means of which such artistic results are obtained in photographs.

WE regret to have to announce the death of Dr. E. C. Fincham, which took place on the 22nd inst. The deceased gentleman, who was 39 years old, was an accomplished amateur photographer. He took a leading part in the "reform movement" of the Royal Photographic Society last winter, and was elected a member of the Council in February of this year.

NATIONAL Photographic Record Association.—A meeting of the National Photographic Record Association will be held at the Midland Grand Hotel, St. Pancras, on Tuesday, November 4th. Afternoon tea will be served at 4 o'clock. A report of the work will be presented, and a discussion will be invited as to the best means of carrying on the work. A series of Sir J. Benjamin Stone's photographs of the Coronation ceremonies, and some other recent contributions, will be on exhibition.

MESSRS. Mawson and Swan offer the following prizes for competition by amateurs only for transparencies made on the Mawson "Lantern" plates which have been purchased since September 30th, 1902: One £5 5s., two £3 3s., one £2 2s., ten £1 1s. The transparencies to be sent in not later than February 1st, 1903. The awards will be issued about one week later. For further particulars apply to Messrs. Mawson and Swan, Mosley Street, Newcastle-on-Tyne, and 33, Soho Square, London.

New Books.

"Photographische Bibliothek." Vol. 14. "Die Architektur—Photographie." Hans Schmidt. Verlag von Gustav Schmidt, Berlin.

This volume on "Architectural Photography" is written by a well-known German amateur photographer of considerable skill, who has devoted much time to the study of optics. The instructions given as to selection of apparatus will be found reliable and sufficiently comprehensive to meet all requirements. The chapters on perspective, the use of the camera, and the necessary photographic manipulations will also be found very useful by those who are new to photographic work. A series of well executed illustrations exemplify the text and mostly represent well selected views of Germany's city of classic art—Munich. A very fine specimen of tele-photographic work is given on page 112, which shows the immense control of focal length the photographer has with a tele-photo lens.

"Artificial Light for Portrait Photography." Illustrated. Price 6d. Published by Human Limited, Newcastle-on-Tyne.

The half-tone reproductions in this little book supply a high testimonial to the practical efficiency of the Morgan system of electric lighting which the anonymous author briefly describes. The group and the portraits are faultless specimens of studio work. At this season of the year, when so many questions reach us on the subject of artificial lighting in the studio, we have pleasure in directing the attention of our readers to the book, the second part of which consists of a chapter entitled "A Study of how to make the most of Dry Plates for Portrait Photography." We append a brief description of the Morgan system, which the professional photographer would do well to study in its entirety. "The first and most important feature is the large area of illumination which is made available to the artist, ranging from 80 to 120 square feet—or even more—of equally illuminated surface. The next important feature in the system is the actinic quality of the light, which is rich in violet rays, making well exposed negatives possible with an exposure of less than half a second (lens at f. 3.), and groups perfectly covered in six seconds (lens at f. 7). The general appearance of the Morgan lamp is that of an ordinary daylight window, divided by the usual astragals, and glazed. There is no appearance of mechanism, and any person entering the studio while the light was in operation would be led to believe that he had entered a room lighted by soft diffused daylight. The size and angle of the apparent window is, moreover, such as one is accustomed to see in all daylight studios; and in the treatment of sitters for different effects of lighting, the usual blinds and screens used in daylight work are employed. Another important feature is the simplicity of manipulation. A switch is moved, and the room is instantly flooded with soft white light. Should more be required a lever is pushed forward, if less it is pulled backward. There is no noise, and the actinic value is registered by a graduated scale showing the quantity of electric current passing through the carbons in amperes. The economy of current—an important factor—has been carefully and fully considered, and waste has been reduced to the lowest point. The light is obtained from powerful arcs fed automatically, and where the current used is continuous, noiselessly. All the light, both direct and reflected, is utilised, but the direct light is so broken up by reflectors and diffusers that all the light, both direct and reflected, is thrown into the studio, and on to the subject, in a broad diffused mass the full size of the window aperture."

"The Science Teachers' Pocket Book and Diary, 1902-3." 100 pp. Price 1s. Published by James Woolley, Sons and Co., Victoria Bridge, Manchester.

Enumeration of the principal contents of this pocket book will show that it contains a mass of information likely to be of use for reference not merely to the student of chemistry and physics, but also to that comparatively rare personage, the scientific photographer. Here are the subjects:—Weights and Measures; Atomic Weights; Specific and Atomic Heats; Atomicity of the elements; Periodic Law; Specific Gravity Tables; Freezing Mixtures; Boiling Points; Fusing Points; Solubility of Salts; Precipitating Powers of Reagents; Various Useful Data (Chemistry); Various Useful Data (Electricity); Standard Wire Gauge; Lanternists' Reference Table; Common Names of some Chemical Substances; Directions for Making Test Solutions; Science Examinations, Evening; Science Examinations, Day; Scientific Societies. There is a list of scientific societies which might with advantage be lengthened in future editions of the pocket-book; and there are also spaces for diary records. We have found the book of assistance in refreshing our memory on many points of chemical nomenclature; and here and there it is interesting as indicating how greatly chemical theory in some of its aspects has been changed or altered. Thus, in our school days, heptads found no recognition in the valency of the elements.

MR. DOWNEY, M.V.O., of 10, Nevern Square, South Kensington, has had the honour of receiving the Coronation Medal from His Majesty the King.

New Apparatus, &c.

A New Double Transfer Paper. Manufactured by the Autotype Company, 74, New Oxford Street, and Ealing Dean.

Hitherto in carbon printing, if the picture is desired on a rough or matt paper, it has had to be made by the single transfer method, for which a reversed negative is required, unless one is content with a reversed (as regards right or left) image. The reason for this is the difficulty of getting perfect contact with the rough surface of the paper and the image, while on its temporary support in the final transfer. The Autotype Company, however, have just put upon the market a double transfer with a matt surface, with which this difficulty is avoided, and they have been good enough to send us a couple of samples—white and cream toned—which, upon trial, we find work admirably. The method of using it is similar to that of the ordinary smooth double transfer paper. Here are the directions issued with the paper:—

“Cut pieces, which should be a little larger than the prints, are soaked in clean cold water about an hour before they are required for use.

“The prints developed on temporary support, having been alumed and dried in the usual manner, are placed in a bath of warm water 70 degrees to 90 degrees Fahrenheit. Now remove a piece of the final support from the cold water and place it in the warm water until the coated surface becomes slimy to the touch. When this has occurred bring the coated surface in contact with the picture on temporary support, lift both out together and lay them, support upwards, on a level rigid surface, such as plate-glass or zinc-plate.

“A very light application of the squeegee suffices to remove excess of water and to secure absolute contact. Now hang them up, and when thoroughly dry they may be pulled apart.”

With the matt double transfer paper, the company send us a single transfer print on a “pyramid grained” paper, as well as an excellent photograph of their exhibit at the R.P.S. The pyramid paper seems to give great softness to the picture, with little or no loss of detail, and for this reason it will no doubt commend itself to many workers of the carbon process.

Commercial & Legal Intelligence

RE Frederick Thomas Harris, Photographer, 137, Whiteladies Road, Bristol.—The public examination of this debtor was held at the Bristol Bankruptcy Court on Friday last, before Mr. Registrar Harley. Full particulars have already been published in the BRITISH JOURNAL OF PHOTOGRAPHY. The examination was upon the application of Mr. Sloan, who appeared on behalf of the debtor, ordered to be closed.

AN adjourned inquest was held at Woolwich on Wednesday last week on the body of Thomas Lewis, a Woolwich Dockyard foreman, who died from the effects of injuries received in an explosion in Woolwich Dockyard on September 23rd. Captain Lapham, Army Service Corps, said that in consequence of waste in the shipment of gasoline to South Africa, used in making search lights, Lieut. Chase, with the approval of the dockyard authorities, decided to make some experiments with regard to the expansion of gasoline when shipped to hot climates. It was thought that the basement of the dockyard wine cellar was the most suitable place for testing the gasoline. A drum of the fluid was placed in hot water, and exploded. Lewis was so much injured that he died, and Lieut. Chase, who was conducting the experiment, and a labourer named Soloan were so severely burned as to be still in hospital, and unable to attend to give evidence. The authorities had no idea of the extreme inflammability and danger of gasoline, or they would not have sanctioned the experiment. The inquiry was adjourned for another month, in the hope that Lieut. Chase and Soloan will then be able to attend. We regret to learn that Lieut. Chase has since died. It seems strange indeed that the authorities at Woolwich were not aware of the great inflammability, and danger in the handling, of gasoline.

SEASON in Advertising.—Is it not questionable whether the unaided general advertiser always conducts his operations, or lays out his plan, with reference to season? A perhaps not unreasonable paraphrase of Lincoln's celebrated opinion would read thus: “You may sell your goods to some of the people all the time, and to all the people some of the time, but you won't sell all your goods to all the people all the time.” This points to the conclusion that the people are creatures of mood, and the facts prove that such mood is greatly the creature of season. Courageous modern continental philosophers incline to the belief that a man may so train himself by investigation of the trend of events in the past, as to be able to define, with tolerable accuracy, how the future will order itself. But the training would appear to be a large matter, necessitating the abandonment of most of the purposes of life. The

shrewd man of business, however, should have little difficulty in anticipating, well in advance, a substantial proportion of the wants of the season. And yet in the pages of the newspapers, the magazines and other advertising publications, are to be seen, year in year out, announcements modelled upon one unvarying method, conveying some colourless unconvincing intelligence, as wearisome as the fact that the earth is somewhat round in shape, or that water continues to persevere with dogged obstinacy in finding its level. Certain classes of goods may possess few but undoubted merits, and those well within the public knowledge. Perhaps, in such a case, the mere mention of the names of the goods may in an advertisement be all-sufficient to acquaint the people, year in year out, with the claims of such goods to patronage. But surely, it were wisdom to refresh the public occasionally by a reminder that, just at the moment, those goods have a peculiar and forcible demand upon the public recognition. If a food, a medicine, a beverage or a toilet preparation is suitable for use all the year round and in any climate, the mere repetition of the facts may soon weary the world into indifference. If any one of the mentioned commodities is useful in summer, winter, autumn and spring, then let the why and wherefore of its usefulness be told in reference to season. If a meat extract exhilarates, comforts and nourishes at a time when the vagaries of autumn unhinge the human mechanism, we shall be more impressed with the virtues of the speciality if we are told of them in connection with the season. It is, perhaps, not a fine stroke of prudence to wait for the rain before you advertise an umbrella. The clothier who put out the announcement, “Sooner or later it will rain and you'll want an overall,” told us a truism, but there was a certain touch of sly humour about his advice, suggesting the unwisdom of ignoring that should appeal to everyone. The old draper looked in June through the almanac for September, and when he was reminded that the partridge became uncomfortable about the first of that month, he set his wife and daughter down to knitting heather stockings. Let the advertiser constantly think over his present and prospective stock. Not confining his reflections to the time and the hour; but looking well ahead, for what will be wanted by and by, and let his announcements, wherever possible, be made with reference to the season and its demands.—“Practical Advertising.”

THE Patent Law Amendment Bill.—Last week, in the House of Commons, on consideration of this Bill as amended by the standing committee, Mr. Caldwell (Lanark, Mid) moved the following new clause:—“An invention covered by any patent granted on an application to which section one of this Act applies shall not be deemed to have been anticipated by reason only of its publication in a specification deposited in the Patent Office pursuant to an application made not less than 50 years before the date of the application for a patent therefor, or of its publication in a provisional specification of any date not followed by a complete specification.”—Mr. Gerald Balfour (Leeds, Central) accepted the clause, which was agreed to.—On Clause 2, Mr. Cawley (Lancashire, Prestwich) moved an amendment, the effect of which, he said, would be to enable the Board of Trade not only to dismiss petitions for patents or to refer them to the Judicial Committee of the Privy Council, but to grant them outright, a course which under the present law they were not empowered to take. His amendment was designed in the interests especially of the small manufacturers in the colour trade. That trade had been largely transferred to Germany mainly, he contended, owing to the operations of the Patent Laws of this country.—Mr. Brigg supported the amendment on the ground that anything that could be done to help the small inventor, so that the industry of the country might be promoted, deserved the consideration of the Board of Trade.—Mr. Gerald Balfour said the particular modification desired by the hon. member for Prestwich was very fully discussed in the committee upstairs and rejected, as he thought, for excellent reasons. What the Bill proposed was that applications should, in the first instance, be made to the Board of Trade, who could then act the part of conciliator between the patentee and those who were seeking for a licence. If the parties were unable to come to an agreement with the assistance of the Board of Trade, the Board of Trade might, if in its opinion there was a prima facie case, refer the petition to the Privy Council, and the Privy Council decide at once and for all. Until the petition was referred to the Privy Council no expense of any kind was involved upon either of the parties, but he imagined that, in the case of the small manufacturers of whom the hon. member spoke, it would be possible for the Board of Trade to bring the parties together in the majority of instances at all events. The effect of the hon. member's scheme, if it were carried, would be this. The Board of Trade would not accept the task of deciding upon matters in which very great pecuniary interests were constantly involved without referring them to a tribunal constituted ad hoc. There would be an arbitration, whose expenses would have to be paid, and there would be the expenses of counsel, and the result would be that, where a case was carried from the decision of the Board of Trade to the Privy Council, so far from the expenses being diminished, they would be doubled. The object of the amendments which the Government introduced into the Bill in committee was to diminish the expenses as far as possible, and with that view they had arranged that there should be only one trial of these matters before a Court, and that from that Court there should be no appeal. He believed they could not get a better Court for the purpose than the Privy Council, and it was for that reason the Government substituted the Privy Council for the High Court. His own belief was that under the procedure which the Bill now contemplated they would get at once the cheapest and most satisfactory procedure available.—Mr. Caldwell thought the Board of Trade should take upon itself the responsibility of giving a decision when there would be, if the necessity arose, an appeal to the Privy Council. The probability, however, was that the parties would come to an agreement before the Board of Trade.—The amendment was negatived without a division.—The Bill was then read a third time.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

NO.	Name of Society.	Subject.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 23RD.—Mr. W. G. Barker in the chair.

The meeting of the previous week was continued in reference to the administration of the "Henderson" award, and a resolution of the committee was read, to the effect that a list of eligible papers had been drawn up, but in the opinion of the committee some of these were deemed of sufficient merit. It was therefore proposed that a die should be struck which would cost about £5, so that if in the future any winner of the award should prefer a medal instead of cash, a suitable gold medal could be made to the value of the award, and, as £10 was already in hand, the balance could be held as a fund to defray any expenses in connection with the award, so as not to interfere with the funds of the Association. A lengthy discussion followed with numerous amendments and propositions. Eventually the original amendment of the committee was put to the vote and won by 11 for and 5 against, the amendment reading:—

That the £10 be treated as a special fund to be devoted to:—
1st. To providing a special die from which medals may be struck in gold, silver, or bronze.
2nd. To the future administration of the award for special postage and other expenses.

Mr. R. P. Drage proposed a very hearty vote of thanks be given to the chairman for the efficient manner in which the difficult meeting had been carried through. This was seconded by Mr. A. Mackie, and carried unanimously.

PHOTOGRAPHIC CLUB.

EDDINGTON, LTD., demonstrated their new developing machine for roll film on the 22nd inst. "Five minutes with the Company's standard developer, irrespective of temperature, was the time he gave the film for development, and he invariably obtained good all-round negatives," said the demonstrator. The No. O F.P.K. was also shown.

CAMERA CLUB.

The winter session, by which is meant the lecture season, has now commenced at the Camera Club, and the members met on Thursday last week to find the premises swept and garnished, several small attractions having been made in the appointment of the rooms to add to their comfort and convenience.

The lecture was by Mr. Hepworth, and was entitled "The Evolution of an Illustrated Newspaper," special attention being directed to the great revolution in block production, which has been brought about by the help of photography. The particular newspaper treated of was the "Daily Graphic," which can boast that it is the first illustrated daily newspaper established in this country, although we believe that attempts in the same direction had been made in America before its invention. The "Daily Graphic" office appears to be a most comprehensive place, for the whole of the work of production is carried on there. A large staff of artists is engaged in the studio, whose duty it is to produce all the pictures sent in to line form. These drawings then pass on to the photographic studio, when they are turned into reversed negatives, under the beneficent beams of the electric light, for it would never do to depend upon the fickle aid of Fleet Street daylight for work which must be produced with any regularity. The same light is employed to transfer the lines of the negative to the bichromatised zinc plate, after which the plate is etched in rocking baths, and finally mounted type high in metal blocks. The whole of this process was illustrated by lantern lectures from negatives taken by the lecturer at the office of the "Daily Graphic."

Another section of the lecture was devoted to the making of the paper

upon which the newspaper is printed, and here again explanation was much helped by a series of photographs taken at two different paper mills in the heart of Kent. One of these mills was of the old picturesque type, where a water wheel affords the motive power, and where paper is still made by hand. At the other mill, known as the Horton Kirby Paper Works, everything is done by machine, and the contrast between the old and the new methods is most interesting. In the time that it takes to make a single small sheet by the first process, several yards are reeled off by the second. And whereas rags form the staple material for the hand made paper, esparto grass and wood pulp are most largely used by the big mills. The process of making paper from rags is still employed for the finer descriptions of material, such as that used by artists, and for the finest book work, but had the paper maker no other source of supply than rags, his occupation would be almost gone, and we should have no cheap literature.

After removal from the machine upon which it is made and reeled, the paper is calendered so as to give it a smooth surface, after which it is cut into sheets, or wound by the mile upon reels according to the purpose for which it is destined. For finer descriptions of work, the sheet form is employed, and for newspapers the reel form is imperative. For such reels are attached to the printing machines, and are run through them automatically, the printed sheets being cut off and folded ready for delivery to the newsagents, as they pass through.

Not the least interesting portion of the lecture was that which illustrated the gradual evolution of the illustrated newspaper from those very roughly adorned sheets of news hawked about the streets at one time under the name of broadsides. Collections of these may be seen at the British Museum and elsewhere, and a strange feature about them is that they mostly deal with episodes of a morbid character. Any particularly atrocious murder was illustrated in this manner, and generally a rough portrait of the murderer added further zest to the lurid description of the crime. Another broadside would, at a later stage, minister to the popular love of the horrible by depicting the murderer hanging from the fatal beam, with the clergyman by his side, administering spiritual consolation to the unhappy man. Wood cuts were so difficult to procure in those days that the same pictures did duty over and over again for different criminals, and in order that they should have as wide an application as possible, the figure hanging on the scaffold was so clothed that it was quite impossible to say whether it represented a man or a woman. It thus served for a criminal of either sex.

The "Observer" was the journal which gave its readers the most frequent illustrations, and two of these were of interest in showing that the motor-car craze is not quite so new as some people would think. In 1827 Mr. Gurney's steam carriage was shown running in St. James's Park. The new vehicle excited such apprehensions that another picture was published showing the carriage in the act of blowing up and scattering its unfortunate passengers in fragments. A later wood cut in the same newspaper showed the house in Cato Street where the famous conspiracy was hatched, which aimed at general anarchy in London.

Mr. Hepworth's lecture closed with a brief reference to the work done by artists in time of war, and he showed how the necessarily rough sketches executed at the front were turned into presentable pictures by artists at home.

In the discussion which followed the lecture, various questions were raised as to the influence of the German school of wood engraving, as represented by Albert Durer, upon similar work in England, and with regard to technical matters in connection with block production. The usual vote of thanks closed the proceedings.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

The eighteenth winter session of the above society was opened on Wednesday, Oct. 22nd, by Mrs. Catherine Weed Ward with a lantern lecture entitled "Shakespeare at Home." Mrs. Ward is an American, and this accounts for the thorough manner in which she has photographed Stratford-on-Avon and district. No people enthuse so much over the "Immortal One" as do the Americans, and nothing of Shakespearean interest amenable to the camera has been too insignificant for Mrs. Ward, and he who would go to Stratford with the intention of doing one better has a tough task indeed. Much of the lecture might be more or less conjecture, but the pictures were very real and good, and that is the most interesting part to the members of a photographic society.

Songs were sung at intervals by Miss Edith Winn and Mr. James Trotter, and thus the winter's work of the L. and L.P.S. was fairly launched.

CROYDON CAMERA CLUB.

ON Wednesday, the 22nd inst., the members of this club, for the nonce abandoning matters photographic, gave a Cinderella dance and soiree, which went off with every indication of success.

Nearly two hundred members and friends assembled at the Small Public hall, where dancing was indulged in from eight p.m. to twelve, to the strains of Mackinnon's Orchestra. In addition to the dancing, various other attractions had been provided. The president (Mr. Hector Maclean, F.R.P.S.), in a commendably short speech, gracefully welcomed all, and indicated the general arrangements for the evening.

Mr. Chick recited in humorous fashion, Messrs. Aris, in the best burnt cork, and delightful "make-ups," sang, and looked so well, that it seemed almost a pity that the exigencies of everyday life should compel them to

alter their complexions and costumes. The hon. secretary conjured, and did all sorts of impossible things, which are expected from him on these occasions, and Mr. W. Best played the violin with such feeling and expression as to score a genuine success.

At one end of the hall an elaborate and most interesting installation of Messrs. Muirhead's beautifully finished instruments for working long submarine cables was shown in actual operation by Mr. R. W. Edgar, assisted by Mr. Sutton. In the annexe, Mr. H. E. Whittaker controlled a ping-pong tournament, and the indefatigable Mr. W. H. Smith gave startling electrical and chemical experiments, including X rays. Mr. Glanville was busy throughout the evening taking portraits, chiefly of ladies in festive attire, by the aid of the Platinotype Company's oxy-magnesium lamp, which proved admirably adapted for the purpose.

A hearty vote of congratulation must be tendered to the genial "general manager" (Mr. S. H. Wratten) for so skilfully arranging and piloting the entertainment through.

ISLE OF THANET PHOTOGRAPHIC SOCIETY.

THE following are extracts from the fourteenth annual report:—Commencing the year with a roll of 68 (one member who had sent in his resignation withdrawing it), 19 new members were elected, making a total of 87. Of this number 4 are in arrear and 3 have left the town, so that the year ends with an effective strength of 80, which is so far the record. Notices of resignation and removals will reduce this number by 10, so that the new session will open with a roll of 70. The number of members outside the town of Ramsgate is still very unsatisfactory. This may be partly accounted for by the wretched service on the local railways.

It is a matter of regret that it has been found impossible to hold the proposed exhibition of prints, or to organise any practical work during the summer season; but the committee hope to be able to arrange an excursion to the Photographic Exhibitions in London, as for the first time in the history of the Society a member's work has found a place therein. The committee feel sure that every member congratulates Mr. L. Longfield on his success in getting his work accepted at the R.P.S.

The annual lantern slide competition was very successful, no less than 42 sets being sent in, and the judge in his report says "They contain certainly a higher average of work than in those I have previously seen from the Society." The competition for the medal offered by Mr. Blower was not taken up with much heartiness, but the evening devoted to it was one of the most pleasant meetings of the whole session.

As will be seen by the balance-sheet, the year ends with a small balance in hand, but a glance at the figures and the items will at once show that it is a very serious question whether the Society is justified in continuing with such a nominal subscription. After eight years of ungrudging work for the Society, Mr. Forwalk finds himself unable to continue to occupy the post of hon. lanternist. His resignation at once raises the important question of apparatus and gas for efficiently carrying out the programme. Hitherto lantern, screen, and gas have been all provided by him without any expense to the Society, and it is therefore apparent that had it not been for his action the balance must have on the wrong side, and this is still more strongly shown by the fact that the annual lantern slide exhibition added no less than £4 6s. 10d. to the funds. This question ought to receive both immediate and careful consideration, and the committee trust that members will attend the annual meeting, when a proposal will be made to them on this point.

The library has been more used during the past session, but the committee regret that it is so little considered and that no additions have been made during the year. The red book has been issued for the third time and the affiliation committee have spared neither expense nor trouble in bringing out a book which it is hoped justifies its issue.

BOURNEVILLE CAMERA CLUB

On Wednesday, October 15th, the above club commenced its winter season with a visit by Mr. W. A. Sims, of the Rotary Photographic Co., Limited, London.

Mr. Sims gave a demonstration on the use of bromide papers.

During the evening he handed round specimens of the Rotograph Negative Paper, together with prints made from same. These were much admired by the members, several of whom expressed their intention of giving the negative paper a trial.

The demonstration given by Mr. Sims was much appreciated by the members, and at the conclusion he invited them to try their skill, two of whom availed themselves of the opportunity, and were much delighted with the ease with which good results were obtained in each instance.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

THE twenty-first annual meeting of the Newcastle-on-Tyne and Northern Counties' Photographic Association was held on the 27th inst., at the Y.M.C.A., Blakett Street. The following officers were elected for the

ensuing year:—President, W. E. Cowan; Vice-Presidents, C. E. Be J. S. B. Bell, C.E., T. M. Clague, W. S. Corder, J.P.; Council, Jas. Thomas Bulman, W. Dotchin, A. B. Gardiner, J. P. Gibson, Job Gibson, G. Hastings, Walter Scutt, Wm. Thompson, John Watson; Treasurer, Alex. Marshall; Hon. Secretary, J. H. Harbottle, 5, Ben Crescent, Newcastle-upon-Tyne; Hon. Assistant Secretary, F. Mill Hon. Lanternists, J. J. Kirkwood, E. G. Lee; Hon. Auditor, T. M. Cl The programme for the ensuing session promises to be very interesting and instructive. The next meeting will be held on November 11th, and will be of a social and musical character, with a lantern exhibition.

WOOLWICH PHOTOGRAPHIC SOCIETY.

THE tenth annual meeting of the Woolwich Photographic Society held on October 16th, when continued satisfactory progress was reported. The Society made a strong forward movement during the past year which added largely to its members. The winter meetings have commenced, and there is every promise of continued prosperity. Mr. Churchill, F.R.P.S., was re-elected president for the third time, supported by the following officers:—Vice-Presidents, W. H. Dawson, J. Desford, F. W. Machen, and J. Borthwick Panting, F.R.P.S.; Council, J. Cre A. E. Harris, S. Hughesdon, S. A. Saffron, W. F. Slater, F.R.P.S., H. G. Weekes; Librarian, Alex. Lees; Lanternist, G. W. Tapp; Secretary and Treasurer, W. H. Nichols, 30, Heavitree Road, Plumstead Common; Affiliation Delegates, Messrs. Churchill and Nichols.

News and Notes.

BATH Mutual Aid Photographic Club.—It has been arranged to start a photographic club in Bath on the principle of mutual aid. Those who are interested in the practice of photography as an art, and making it a hobby, are cordially invited to apply to the honorary secretary pro tem. (Mr. H. Roland Bateman, 9, Nelson Villas), who will be pleased to furnish them with all particulars as to the club and invitation to the next meeting. It is the intention to arrange for instruction to be given (free) in the various modes of printing, developing, etc., so to include enlarging and lantern slide making. For a nominal subscription a member will have the full use of all club property, and endeavour will be made to equip the club rooms with every requisite in the way of home photography. It is also intended to make the study of this fascinating art as pleasant as possible. Ladies are specially invited to join.

INDIVIDUALITY.—Individuality counts for a great deal in business. Just as there are lots of people who can talk fluently who cannot sit down to write anything without immediately becoming someone else and expressing thoughts, aims, and ideas that are entirely foreign to their true nature, so there are in the commercial world many who do not do themselves justice for the same reason. Every business that rises above the ordinary portrays in many of its features the individuality of the governing spirit, lack of it. Somebody connected with the business has not cared what other manufacturers or merchants in the same line thought about running such a business, but has followed his own best judgment with implicit confidence that if the result was not successful it would at least be such as to suit his ideas of how it should be conducted. The great trouble with the average man who copies the methods of others is that he very often gets poorer ideas in this way than he has himself, if he only sets his own mind in motion along the proper lines. After all, why should anyone copy after some other fellow when he can create methods for himself which are more appropriate, more natural; that are more a part of himself? Of course, it is well enough to look about you and try to learn by observation, but learning and copying are entirely different. Probably no manufacturer who copied the styles of another ever made such a good copy as the original was, and the great trouble is that, after all, it is only a copy, and as such advertises the goods of the originator of the style more than itself. There is room for originality in every department of business. What if somebody else or a whole army of people have been in the habit of doing things a certain way, that does not make it the right or only way, by any means. A business man should strive after correct originality as he would to find a priceless treasure, because it attracts the attention of the buying public as nothing else will. Originality in every sphere of life is at a premium, and though people may criticise it, they still pay homage to it. The men who have made great successes in business have been the originators. They have broken away from the shackles of conventionalism and have set themselves apart from the great mass of humanity who are followers and not leaders.

THE Prime Minister on Technical Education.—At the opening of the Manchester School of Technology, Mr. Balfour referred to the change from the pre-scientific to the scientific stage of industry. When England or Great Britain first obtained its great manufacturing monopoly, it was not too much to say that the relation between science and industry was of the feeblest character. There was always, of course, the closest connection between mechanical ingenuity and invention and the great growth of our industries, but the intimate correlation between the discoveries of the laboratory and the processes of the workshop was not in existence, and it was because we had been a little slow to discover

his country how intimately speculative research is connected with manufacturing progress that we were, in some branches of our work at events, behind our neighbours, who in this respect, although not in any others, had proved themselves more ready and more apt to learn a lesson than we had ourselves. And if anybody wanted a proof of truth of the proposition he was laying down they had only to recall kind of meaning which the average man attached only a few years to the phrase "technical instruction." In the phrase "technical instruction" there was, in the minds of the people of whom he spoke, a scientific tinge or flavour whatever, but some kind of knowledge of manual dexterity, some opportunity for learning the uses of machinery, and so forth. But the fact on which he was venturing to insist, and which the very existence and justification of an institution like that of Manchester depended, was that henceforth and evermore there would be a closer and closer connection between the most remote and abstract scientific study of the chemist, of the physicist, of the electrician in his laboratory, and the great industries of the community of which he was a member. He wished he could be quite sure that even now, and even in the more cultivated parts of the community, there was a more perfect appreciation of two capital facts which he would like to impress upon those who heard him. One was that education was, and must be, an organic growth, and that it was perfectly vain to spend vast sums upon buildings and equipments unless the student who went to those places went adequately prepared to learn the lesson they could teach. He had not the slightest intention of over-exalting or over-praising foreign nations at the expense of our own, but it must be admitted that they had grasped the truth more fully and much more firmly than the great truth on which he was insisting—namely, that a man really to profit by the scientific training which he could get in these institutions and to be able himself to turn the learning he acquired to the purpose of original discovery, it may be said original research of his own, had to go there, not a raw product, but at least events a half-prepared human product. He should go there, not only anxious to learn, but ready to learn. Another great truth was that, in general, the persons who were responsible for the manufactures of the country were the manufacturers. It was perfectly vain and useless to turn out highly-trained and capable servants if there were not to be employers for them when they were turned out. He did not in the least know whether in Germany, for instance, they might not have overdone the matter; he had not sufficient evidence on the point, but he was quite sure something must be very wrong when he saw the extraordinary preference in the practice of the great German and in some, at all events, in the English firms. He was speaking on a subject which he only knew at second hand to people who knew the whole thing at first hand; that, unless his information erred, they would find, if they went to Germany, at all events a few years ago, and studied the equipment of one of the great German industrial concerns, electrical, chemical, optical, or what not, a proportion of scientifically trained students in the German manufacturing enormously in excess of anything commonly thought necessary in this country. There was not the least use in the Manchester Corporation turning out competent students if those students were not to find employment when they were turned out. With the naturally conservative instincts of our nation, the tradition of the great manufacturing establishments would rather tend to make people say that the best place in which to learn was not in the lecture-room, but in the workshop, not at the feet of skilled professors, but actually among the artisans who were carrying on the industry, and he did not deny there was as a great deal of truth in that, and that probably we gained a great deal by our extreme anxiety to make industrial training a practical training. But he felt confident that they drove that truth too far, and now, however sound the instinct might be which lay at the bottom of it, they were working it too hard at the present time, and that, if they really did mean to turn the brains, and the muscles, and the enterprise, and the energy, and the inventive skill of their countrymen to its best purpose, it was absolutely necessary to place among the directors of the industry those who had not merely that admirable and necessary practical knowledge which consisted in seeing things done from day to day by the people who had to sell the article when it was finished, but, in addition, they must give that complete scientific training which had become more the basis of our whole industrial fabric.

LANTERN Slides on Process Plates.—Lantern slides from diagrams, maps, drawings, etc., are often required, and present many difficulties to those who are unaccustomed to prepare them. It sometimes seems quite impossible to get the lines dark enough without degrading the brilliancy of the whites. Of course, to the old collodion worker it is quite easy by means of redevelopment and intensification to produce a copy of a plan with sharp black lines (really black, not a dirty brown),

with perfectly clear glass spaces between them. But as the collodion worker scarcely exists outside conservative process block, or professional lantern slide makers, we need not consider him. The everyday photographer is often at a loss when he is asked to make such slides, and probably they give him so much trouble that he becomes discouraged. To such a man Ilford Process plates should be a "boon and a blessing," for they will help him to do the work with ease. In the first place, his negatives should be made on Process plates, the black lines should be clear glass and the white spaces nearly opaque. If the drawing to be copied is too weak to give an ideal negative, much can be done by intensification. The exposure for Process plates must be full, if good density is to be obtained; it is useless to give a short exposure and expect to get a vigorous result. In a good light, with $f/32$ the exposure will be from thirty seconds to a minute, the developer should be sparingly diluted with water, and should contain a fair proportion of bromide; but any developer which gives density will give good results. The image should begin to appear quickly, say within thirty seconds or less; development should be prolonged until the white parts of the drawing appear on the back of the plate, and if the dark lines are slightly veiled it does not matter. If on examination the dark lines appear much veiled in the negative, reduction with very weak ferricyanide reducer will clear them without, apparently, affecting the denser parts. If the plate has been over-exposed, or over-developed, the very fine lines will sometimes be blocked, and may even almost disappear; here again very weak ferricyanide will effect a cure. When the drawing is soiled or creased it is almost hopeless to obtain a negative which will give a good slide on a lantern plate; but by using a Process plate for making the slide excellent results can be secured from decidedly poor negatives. A hydroquinone developer should be used, and the slide may be slightly over-developed and cleared with very dilute ferricyanide and hypo. Most of the creases and dirt on the original drawing will be absent from a slide treated in this manner. In making the negative a full exposure must be given, under-exposure produces flat weak negatives. Title slides are often useful for a lantern evening, and it is more restful to the eyes if they are made with the letters showing light on a black ground. Slides with black or coloured letters on a clear glass ground are very trying to an audience if they come after a series of ordinary lantern slides. The former are easily prepared. The words should be written or printed in the deepest, dead black on a smooth white card; this card is then photographed on a Process plate $3\frac{1}{2}$ in. by $3\frac{1}{2}$ in., but the exposure must be under rather than over, as there must be no deposit of silver on the spaces representing the black letters. The slide should be developed carefully so as to obtain the fullest density in the spaces round the letters, but the letters themselves must be represented by "bare glass." It is almost impossible to get sufficient density in the background by development alone, and development must be stopped as soon as the letters show any sign of veiling, as it is more essential to have clear letters than to have a dense background. The exposure is of the greatest importance, as it must be sufficient to give fair density in the background, yet not enough to veil the letters. A perfect slide is scarcely ever obtained by development, so recourse must be had to intensification. After thorough washing, the slide must be bleached right through with mercury, and after another thorough washing, blackened with dilute ammonia. The slide should not be dried in spirit, as this tends to damage the clearness of the letters. When dry the letters may be tinted various colours. One method of doing this is to superimpose slips of coloured gelatine, but a better result is obtained by staining the film with the liquid colours sold for tinting photographs. Three colours will be sufficient, red, yellow, and blue. A special brush should be kept for each colour, and the red brush should never be put into the blue bottle, and so on. The colours may be washed right over the letters, as the background should be so dense as to be disregarded. Two or more coats may be necessary, and if it is desired to produce more than three colours, several other shades can be obtained by washing a word over with blue first, allowing the colour to be absorbed by the film, and become half dry, when a wash of yellow over it will produce green; red on blue will produce violet, while red and yellow will give scarlet or orange. Different greens and violets can be produced by using the two colours in different proportions. The colours should never be mixed together before putting them on the slide, but each colour should be washed on separately. If, for instance, green is desired, we may begin with a faint wash of yellow, followed after a few minutes with a wash of blue; this may be rather too blue, and a second wash of yellow can be laid on, or vice versa. Mixing the colours before applying them produces muddy, dirty results. The letters on the slide will be reversed, but this can, of course, be put right when it is placed in the lantern. It is not necessary that the dark parts of the slide should be absolutely opaque. These slides which show best on the screen, even when electric light is used for projection, are those in which the letters are quite clear, and the dark parts not dense enough to prevent showing where the colour has been washed over the letters when held in the hand; such a slide will show the letters quite bright on a pure black ground. A pretty title can be made by putting black letters over a landscape. This is done by writing or printing the title on smooth, pure white card, or Bristol board, using Stephens' Ebony stain for ink. A negative the proper size is made from this on a process plate in the usual way, and a slide also on a Process plate is made from it. A lantern slide of a suitable subject is then made, but it should be delicate in character, so that it may not obscure the black letters of the title, this slide is used as a cover-glass to the black letters. Another method, which scarcely comes within the scope of this article, is to make a bromide enlargement of a suitable subject and fasten upon it rustic letters made of moss-grown twigs. These may be attached to the enlargements with needle points such as are used by cabinet makers.—Harold Baker, in "Photographic Scrap."

KODAK, LIMITED, AND THE TRADE.

To the Editors.

Gentlemen,—For a long time I have followed, with wonder not unmixed with amusement, the bickerings between the Photographic Trade Association and Kodak, Limited, but have not till now been able to focus my attention on the arguments used by the two parties.

The latest development that meets our notice is a manifesto by a trade association, the ruling body of which is a number of men known in photographic circles as wholesalers, dealers, or rivals of Kodak, Limited. As I see from Kodak's letter that that firm has "ceased to use that channel for distribution of goods," the position of the wholesalers is plain enough. No less is the anger of the rival manufacturers easily understood. Why the ordinary dealer complains I do not understand, if what Kodak says about the terms to dealers is true, and that firm dare not make a statement of figures that, if false, could at once be disproved. Kodak says that dealers are at perfect liberty to sell whatever goods they please; that whatever goods the dealers sell Kodak still gives them what is certainly a handsome discount on such Kodak products as they may sell; and if they sell no other goods in certain lines, specially the province of Kodak, it gives still further discount.

Now, I am at a loss to conceive anything fairer than this. Surely any trading concern has a right to offer inducements, of an open and honest nature, to dealers, to give special, or even sole, attention to a line of goods which the trading concern has made its own speciality, at enormous cost of money and labour. I have not the fortune to be a trader or a dealer, but this seems to me sound sense. I notice that the association in its manifesto uses the word "profit," or "profits," throughout; they fight shy of the word "discount," no doubt, because discount is a voluntary allowance made by a vendor to a purchaser who is going to distribute to the public; its essence is its voluntariness. Discount is given to induce the distributor to take more goods, and if the manufacturer goes one better and offers extra discount for taking his goods only, and if it pays the dealer to accept this, I absolutely fail to see any reason against it, from the dealer's or the public's point of view, though less enterprising or less able manufacturers may not like it.

The next thing I do not understand is the cry of "monopoly." Apart from the fact that Kodak disclaims all intention of monopolising anything, I have as yet seen no signs of their wishing to do so, and it is no use for the Trade Association or anybody else crying out about what they say is going to happen. To point out with such innuendo that the Kodak Company in America has "acquired an interest in the manufacture of plates" is the most awful rubbish, for ever so many English platemakers have "acquired an interest" in the manufacture of films, printing papers, and who knows what else, without any outcry about monopoly.

If these tearful ones of the trade association would dry their eyes and start something of their own that would meet the public wants, as Kodak things do, it would be a vast deal more "British" than wringing their hands, or, still worse, flooding the market with apparatus deliberately and glaringly imitations of Kodak cameras and films. At the beginning of these complaints a great deal of nonsense was written about "un-English" methods, but what was un-English was the fact that every paper was full of figures of cameras hardly to be distinguished from Kodaks; and we have makers of film actually using spools made to fit Kodaks, and often called by names forestalled in their use by Kodak. If it is true, as asserted by Kodak, that other products are palmed off on customers as Kodak goods, when they are not Kodak, then the matter is ten times worse. No; this is not the best nor the highest way for the Trade Association to retrieve their position; the only true plan is to strike fresh wells, to do something original to catch the public, and to benefit themselves. British work and British workmen are quite as good as any that have ever come out of America. By the way, it is not fair to suggest that all Kodak goods are made in America, for I have seen a very large factory at Harrow, visible from the railway, and no doubt a great

amount of photographic products are made there, probably an enormous amount.

And as to monopoly! Kodak says it does not aim at monopoly, it did, what chance has it of getting it? When for centuries has it succeeded in establishing a monopoly? Why does the Trade Association stop short of chemicals? Why not extend the coming monopoly over lenses, shutters, light screens, microscopes, telescopes, may, clothes and boots to go photographing in? Kodak can effect a monopoly of photographic goods, and for my own part I see a grain of evidence that they wish to.

A weaker production than this manifesto of the Trade Association I never saw, and one thing which puzzles me, as it must puzzle every thinking member of the public, is that certain trade papers, viciously attacking Kodak, Limited, for its mythical crimes yet committed, should accept and display (for mere lucre) the pernicious advertisements of this malevolent monopoly. This is "running the hare and hunting with the hounds" with a vengeance.

This letter voices much of the sentiment that is quite commonly expressed by members of the public, amateur photographers, and the who probably do not think it worth while to protest against the noise of those who, instead of facing the battle, hold up the white flag and raise all sorts of imaginary bugbears to frighten those who are timid as themselves.—Yours,
October 27th, 1902.

To the Editors.

Gentlemen,—Referring to the reply of Kodak, Limited, to our letter kindly inserted by you in your last issue, the company state that they seek no monopoly. If this is so, why should they not withdraw the conditions by which they seek to induce the retail dealers to limit themselves to sell no competing article? Kodak, Ltd., also asserts that they intend to hold their own by good quality and good service, and that the only monopoly they seek is that which the public choose to give them, and further, that they rely upon the policy of good quality and fair prices to get the trade and the public to favour their products. Why, then, is it necessary for the company to bolster their cause by adopting a principle which, if successful, must lead to a monopoly, whether intended or not? We are told that it is to the benefit of the public, but the British public can generally be trusted to look after its own interests without the assistance of the best-intentioned philanthropic business house.

If, as Kodak, Ltd., state, the retailer is not bound by any engagement, why seek to get signatures to an agreement which practically binds the retailer for nine months unless he elects to lose part of his profit on his sales for the whole of that term? It is true that by sacrificing about half his profit on Kodak cameras and roll films, the photographic dealer may hold an independent position and sell anything which the public requires; but in doing so he renders himself liable to receive letters from Kodak, Ltd., of which the following extract is specimen:—

"We have always been glad to have your business, and think you will fully consider the matter you will admit that the conditions we lay down, although arbitrary—as all rules must necessarily be—are favourable to you. The agency for leading makes of plates and papers which are handled by you may in time pass into other hands. We feel sure that if you consider the question you will find that it is far more favourable for you to work with us."

We may safely leave the public to judge whether this is an attempt at monopoly or not.

Some of the "large and famous plate and paper makers" referred to by Kodak, Ltd., are represented on the council of this association and others are members. It is possible that it may shortly be proved to Kodak, Ltd., in an unmistakable manner, that the opposition to the present methods of trading has the entire support and sympathy of the whole of the plate and paper manufacturers.

The patent laws are specially framed to protect the rights of patentees, and, apart from such protection, there is nothing to prevent competition. That some of the so-called "flagrant imitators" and "parasites" have introduced improvements cannot be denied, and an open market provides the best means for still further advancement.

The question of using the registered names of Kodak, Ltd., forms, we believe, the subject of impending litigation. As the matter is, therefore, sub-judice, neither the company nor the association are in the position to pre-judge the question.

Whether or not the wholesaler is necessary is not a matter which will interest the public, but the fact that he exists in almost every branch of industry is sufficient proof that he is an important factor in trading.

It is scarcely likely that an association that represents the most important firms in the photographic trade should have been created

no other purpose than to work up animus against Kodak, Ltd., her would the members have taken up this question unless they had reasons to believe that Kodak, Ltd., were endeavouring to create a monopoly. At least, one half of the council of the association are Americans, and practically the whole trade is in full sympathy with the action of the council. The association was formed to watch over the interests of the trade, and abuse will not deter it from carrying out its object.

The assertion by Kodak, Ltd., that nearly three-quarters of the shareholders in their Corporation are British does not contradict the statement that Kodak, Ltd., is an American company, and that by far the largest portion of the capital is held by the minority of shareholders, who reside in America. Neither does it alter the fact that the company's roll film cameras and roll films, about which this controversy has arisen, are made in America. Did not the directors themselves say at the Cannon Street Hotel that by transferring the English concern to an American concern the major portion of the dividends would not be subject to income tax?

The photographic societies of Great Britain came forward about a year ago and assisted materially in getting the first restrictive terms of the Kodak, Limited, withdrawn, and they will doubtless lend their aid on the present occasion. The individual support of every photographer solicited in the endeavour to secure a free and open field for British productions.—We are, yours faithfully,

THE PHOTOGRAPHIC TRADE ASSOCIATION.

3, Farringdon Street, London, E.C.

October, 1902.

To the Editors.

Gentlemen,—In the note appended to the polemics of the Photographic Trade Association and Kodak, Limited, you invite expression of opinion by those, who may be interested in the controversy, as regards photographic material. I should be heartily in sympathy with the Trade Association but for the fact that the principle upon which they base their case is flagrantly violated by a number, if not all, of the members of the council of the association. If this be true, as I shall endeavour to show, the arguments of the association are characterised by more rhetoric than consistency. At the same time I must say that the policy by Kodak, Limited, notwithstanding its clever treatment, is equally unconvincing. The plea of the Trade Association is briefly put in the seventh paragraph of their letter: "The prevention of any monopoly; the giving a fair field and no favour; free trade for all. This is a sound English business principle, but is it practised by the photographic trade? Are the retailers of photographic material compelled to sign undertakings to charge certain fixed prices, and refused goods if they will not? Is this the prevention of monopoly? Is it a fair field and no favour? Is it free trade for all? It is true that Kodak, Ltd., also offers the trade in the same way, but it is futile for the Photographic Trade Association to appeal for the support of the public when they follow the practice of restriction of trade, of which the present action of Kodak, Ltd., is but another development. The battle, consequently, is one between tweedle-dum and tweedle-dee.

Kodak, Ltd., affirms that the cause of the present struggle is their dealing without the wholesale dealer. This may be so, but the public benefits nothing by the change, for there has been no reduction in the price of rollable film, nor of Kodaks.

For the past few years the retail photographic trade has had a fat and merry time. In proportion to the amount of capital requisite to carry on the business, the large establishments, such as the Army and Navy Stores, must have made enormous profits. The small man who has had a golden harvest, but those happy days are coming to an end. It requires little capital to start a small retail business, and we see shops for photographic material being opened in all directions. The trade is being scattered by the rush for the monopoly profits fostered by this policy. With such a band of weak-kneed persons, can the Photographic Trade Association hope to fight a well-organised business, which commands more capital than it needs? Their chance of success lies only in a compact band of strong, enterprising, retail traders, which can only be created by the removal of restrictions, which prevent the concentration of business in the hands of keen energetic men.

Some of the Kodak imitations must be good, else the firm would not be that "the get up of their appliances is closely imitated, and their goods, special and peculiar to themselves, are exactly and minutely imitated." If men were permitted to enter the trade and push these goods at competition prices, instead of big profits, the weakness of the policy of Kodak, Ltd., would soon manifest itself. At present Kodak, in opening shops, seeks the most commanding positions, but these shops would have to be multiplied, if the retailer offered similar goods at competitive prices, and it is a well-known fact that business

can only be extended at diminished profit. Increased expenses, or a reduction in prices, would absorb the exceptional profits of Kodak, Ltd., and a healthier state of the trade would be brought about.

Genuine free trade should be the policy of the Photographic Trade Association, and unless it is adopted Kodak, Ltd., will succeed. The public do not care a straw for a dispute between men who have combined to exploit them.—Truly yours,

X. Y. Z.

To the Editors.

Gentlemen,—As you open your pages to correspondence on the Kodak monopoly question, may I venture to offer one or two remarks on the letter from the Kodak Company, which appeared in your last issue.

If, as the company allege, others imitate the get-up and appearance of their goods in such a manner as to deceive a purchaser into the belief that he is buying Kodak goods, whereas he is buying other goods, the Kodak Company has a remedy at law; so, too, if their trade marks, or patents, or trade name, are used. But every person, no patent barring his way, has a right to sell the same class of goods provided he does not act as above described. It is this right which the Kodak Company seek to limit, in other words, the right of the trade to sell and the purchaser to buy goods, the manufacture of which infringes no private right. This I and others resent, and intend to resist. Accordingly, since this attempt was first made I have purchased no goods whatever emanating from the works of the Kodak Company, and until it is abandoned I shall observe this rule. My negatives and my prints have, I am glad to say, suffered no deterioration in consequence, and others who adopt my rule, will, I am sure, be as satisfied in this respect as your obedient servant,

AN AMATEUR.

"PHOTOGRAPHY AS A FINE ART."

To the Editors.

Gentlemen,—I read the article in last week's JOURNAL by the *Daily Mail* art critic with interest. A much more appropriate title for his subject would have been "The Limitations of Photography."

I certainly do not agree with him when he states that the nude is beyond the artist photographer. If delicately treated by a photographic artist, who takes the picture for the picture's sake and not for sale, I do not see any reason why the result should not be beautiful and free from any objectionable taint. Of course, I am taking for granted that he has a good model (he can get one for the paying), and understands artistic anatomy.

I may say that since last writing I have been further convinced in my opinion by hearing a painter, who employs photography to aid him in his painting, say, some of the photographic pictures he has seen, could only have been produced by artists, and that the mechanical must have been over-ruled to get results so beautiful and technically perfect. He further said that by his experience he should feel safe in calling photography an art. I was very pleased to hear the above opinion so frankly expressed by a painter.

There are certainly two remarks in which I agree with the *Daily Mail* art critic. That sacred subjects are, as yet, beyond the scope of the photographic artist, and that the excessive faking and indistinct results, so much in favour at present, cannot help or strengthen the "Art of Photography," but must have an opposite effect.—Yours faithfully,

HERBERT BALL.

THE R.P.S. EXHIBITION.

To the Editors.

Gentlemen,—The charge of favouring themselves and their friends that has been made against some of the members of the Selecting Committee is one of so serious a nature that it should not have been brought without incontestable evidence to support it. A much more charitable and reasonable way of accounting for the presence of so large a proportion of pictures, in which sentimentality is the only noticeable feature, is that these gentlemen are not sufficiently educated in art matters to recognise and appreciate those qualities which are necessary for pictorial effect. We may safely take the pictures exhibited by Messrs. Page Croft and J. C. Warburg as examples of what they admire. I mention these two names, as they are the two most directly pointed at in the course of this correspondence. If these eleven works are studied first and then attention is turned to the remainder of the exhibits, it will be found that the same characteristics are constantly present. The work is just of that type one finds in the members' classes of a small society which has just reached the stage of recognising that something is possible in photography beyond chance snapshotting. One could hardly find a more perfectly typical representative of the ordinary society members' exhibit than "The Park Palings," by Mr. Warburg. In our suburban shows during the next few months one

will be able to find dozens of photographs of a similar character—quite appropriate where they are, but not so on the walls of our representative exhibition. Then take Mr. Croft's gum attempts. If they were passed round at a society meeting to illustrate the difficulties of a process one could understand their seeing light, but where they are they proclaim the fact that, in Mr. Croft's opinion at least, they fairly represent his standard of pictorial photography. To suggest that these two gentlemen hung their own work, knowing it to be as bad as it is absurd. The only reasonable interpretation to put upon the matter is that they do not know any better. I prefer to think that they were perfectly honest, but mistaken. The society has to suffer for their mistakes, inasmuch as there is a general disappointment at the kind of work that has been selected as representative of that of the year, but no doubt greater care will be taken in the future to secure properly qualified men to fill the responsible posts.—I am, etc.,

P. P.

To the Editors.

Gentlemen.—Having confuted most of Mr. Bennett's allegations already, I need not follow him when he brings the same or other charges, even less courteously than before. There is, however, one little point I would like to advert to. I wrote: "The bona-fides of the committee should be obvious to even a rejected contributor," and Mr. Bennett promptly puts the cap on his own head, which, sooth to say, it would seem to fit admirably. I must however, disclaim any knowledge as to whether he sent up work or not; and if, as a member of the committee, I did know, I should certainly not divulge the fact in a newspaper.—Yours, etc.,

JOHN C. WARBURG.

21, Pembroke Gardens.

October 27th, 1902.

FOR THE P.P.A.

To the Editors.

Gentlemen.—I have received an order to copy a photograph taken by a London firm, which photograph is marked "Copyright."

On inquiry I find that the customer, whose portrait it is, visited the studio privately, and not by invitation; also, that he paid full price for, and obtained, one dozen copies.

As the word "copyright" was on the photograph I had refused the order.

But now I think the London firm had no right to mark "copyright" upon the photograph. Is this not so? Also, I would like to know your opinion of firms who thus send out photographs marked "copyright" when they are not so. Another item for the P.P.A.—I remain, yours, etc.,

J. C. RUDDOCK.

"Castle Studio," Bendgate, Alnwick.

October 24th, 1902.

THE RIGHT TO USE THE ROYAL ARMS.

To the Editors.

Gentlemen.—I notice the many inquiries to you respecting the use of the Royal Arms. Very few really seem to know that the right to use the same by any person can only be by those who have received, and still hold, the Royal warrant of appointment. In your article in last week's issue you state, which is quite correct, that anyone, even if called upon to photograph the King, Queen, or any member of the Royal Family, cannot style himself photographer to the King or use the Royal Arms. I have on various occasions photographed the King, Queen, and the late Queen Victoria; but, without holding the warrant, could not, as you say, do so. But you fall into an error—a very natural one—when you say that those who held the warrant to the late Queen, "of course, they are entitled to use the Royal Arms, and to say by appointment to the late Queen, etc." This they cannot do unless their warrant has been endorsed for use during the present reign. I received a notice from the Lord Chamberlain stating that my warrant would be void three months after the death of the Queen. This I regretted, as it was given me by special command of the Queen. Shortly afterwards I received a notice to return the warrant, that, by command of the King, it would be endorsed for use during the present reign. Usually at the demise of the Crown warrants become void, but owing to the exceptional length of the last reign many firms had been permitted to retain their warrants to her late Majesty, and to continue to use the Royal Arms, but not to fly the Royal standard during the present reign; but unless such warrants bear endorsement to that effect they are void, and the right to the use of the Royal Arms has elapsed, and the person using the same is liable to the penalty. My

endorsement says, "The persons named herein are permitted to use the Royal Arms, and to style themselves 'By Appointment to the late Queen.'" Many of the warrants have not been endorsed. I take a list of the first twenty names; thirteen of these held warrants to the late Queen in various trades, nine of these only have been endorsed. It may interest you to know that the total number of photographers holding warrants to the King, Queen, or late Queen is twenty-five, twenty-one of these in England, Ireland, Scotland, and Wales, and four on the Continent.—I remain, truly yours,

HORATIO NELSON KING

October 28th, 1902.

NEW YEAR'S ENTERTAINMENT TO LONDON CHILDREN

To the Editors.

Gentlemen.—Will you once again permit me to bring to the notice of your readers the fund which it is my privilege annually to raise a two-fold object, that of providing a New Year's entertainment about 1,200 poor children of the Ragged School Union in the Guildhall of the City of London, and the accompanying distribution of Christmas hampers to 4,000 or 5,000 little cripples?

His Majesty the King has for several years contributed to the list subscriptions, and this year I am again honoured by His Majesty's support.

General Sir Dighton Probyn, Keeper of His Majesty's Privy Purse writes me: "I am commanded by the King to send you the enclosed cheque for £10 10s., as a donation from His Majesty to the Poor Children and Cripples' Christmas and New Year's Entertainment Fund which you so kindly organise on their behalf."

The Court of Common Council have, as in previous years, accorded the use of the Guildhall, and many members of the Court warmly and actively assist me but as the poor and suffering children of the metropolis, as a whole, are participants, I confidently extend my appeal to London at large.

No one who has witnessed the reception by a home-tied cripple of a hamper at Christmas can over-estimate the good done by the time gift, and the Guildhall banquet is a source of never-failing pleasure.

Mr. W. H. Pannell, C.C., chartered accountant and honorary auditor has signed the balance sheet, which shows that last year £1,644 8s. 6d. was collected, and the list of donors indicates that the movement has lost none of its popularity.

Contributions, large or small, to the "Children's Fund" should be addressed to me at 69, Ludgate Hill, E.C.—I am, Sirs, yours truly,

W. P. TRELOAR, Alderman.

69, Ludgate Hill, E.C.

October 22nd, 1902.

KEEPING QUALITIES OF ALBUMENISED PAPER.

To the Editors.

Gentlemen.—Some week or two since my brother sent me the enclosed print, of which a description may have some interest to your readers. As you will see by his notes at back, the negative was taken upon a Liverpool plate in 1869, with an exposure of five minutes to a Ross wide-angle lens. A print was taken from this on August 18th, 1902, using some paper he had since 1869 or 1870 called "Garrier sensitised albumenised paper," and had been kept since he bought it in red blotting-paper. He bought from Solomon, then of Red Lion Square. "The toning bath is chloride gold, chloride ammonium, and water. Fixed as usual. Further, my brother adds, with regard to the paper, that, in toning, the picture nearly, or in some cases quite disappears, and then gradually re-appears. When the tone you desire appears, stop the toning and fix."—I am, gentlemen, yours truly,

W. T. F. M. INGALL, M.R.I.

THE FUNNY PART.

To the Editors.

Gentlemen.—On page 327, of the BRITISH JOURNAL OF PHOTOGRAPHY, you publish a letter after the heading of, "One of the advertisers in our ALMANAC writes, etc.," and you or he calls the letter very funny. Would you call me very inquisitive if I should ask you why this letter is very funny? Is it because of the writing to an advertiser in your ALMANAC, or is it that the proposal is in itself funny? If it is the answer itself I have nothing to say, as I do not know the advertisement to which the writer refers, but if it is the proposal itself I fail to see

the funny part of it. Of course, I admit in all this that the party is competent, and, knowing what he talks about, can take good lectures, as he gives references. Therefore, I cannot see the difference in a party asking an outfit of a certain value in exchange of his work and surrendering of valuable negatives; or the asking of a certain amount of money. To the contrary, it seems at first sight quite reasonable. The outfit, etc., would probably cost, if first class, £16 or £20, which, for 100 half-plate negatives, would make 3s. to 4s. each, which would consider cheap enough; of course, one can make good use of them, and which would make the proposal quite acceptable (always if the operator is good). The only funny part of the transaction would be that the party ordering the work to be done was obliged to pay in advance, and therefore obliged also to take the negatives at the price paid for, and not quarrel ultimately about price agreed upon on account of quality of work, etc., as is too often the case when no deposit is left as security of good faith in ordering the negatives. This case happens often enough, as your police courts and others can testify in your "News and Notes." I had this happen to me not long ago, with an English firm ordering views from Paris, and I have even now another one pending. Please tell me the funny part of it, and oblige, yours very truly,

ALBERT LEVY.

Asnières (Seine).

October 20th, 1902.

[Perhaps our original correspondent will tell Mons. Levy where the fun comes in.—Eds. B.J.P.]

THE COLUMBIA OPTICAL COMPANY.

To the Editors.

Gentlemen,—The photographic and optical business carried on by the Columbia Optical and Camera Company, at 42, Goswell Road, has now been entirely discontinued. We have to thank you for the many kindnesses in the way of notices and so forth during the continuance of this business, and inform you now of this change, so that you may strike our name off the list of papers for distribution. The photographic business is entirely given up, the stock having been sold off in several large deals, one to Messrs. Levi and Co., who bought all the Columbia sets; one to the City Sale and Exchange, who bought all the American folding cameras; "Pectos" and "Centuries," to Mr. W. E. Dunmore, of the Tella Camera Company, who bought a very large stock of sundries for his auction business, and other details too small to particularise.

The optical business, principally in American gold-filled and other goods, will be carried on under the direction and name of Mr. S. Pulzer, at 33, Holborn Viaduct, just opposite Hatton Garden, where he will continue his own agencies of the Philadelphia Watch Case Company, the United States Watch Company, the Standard Watch Company, and others, together with the optical agencies formerly held by the Columbia Company.

Once more for the very kind notices you have given our goods, our competitions, etc., we thank you.—Yours truly,

F. E. BUCKLAND,
Columbia Optical Company.

42, Goswell Road, London, E.C.

October 24th, 1902.

COPYRIGHT IN SOUTH AFRICA.

To the Editors.

Gentlemen,—I am forwarding herewith for your information a copy of a circular letter which we are sending to-day to a number of British publishers.—Yours very faithfully,

A. JAS. FULLER.

Hon. Sec.

Cape Town Photographic Society, P. O. Box 470.

Cape Town, 8th October, 1902.

Sir,—As you are most probably aware, there is at present no copyright protection in this colony for paintings, drawings, photographs, and works of fine art.

The only Copyright Act in existence here at present being one relating to books, and this is a very imperfect and unsatisfactory one.

This want has been felt to a very large degree, and has resulted in heavy pecuniary loss to artists and photographers generally. Quite a number of firms exist in the colony, which obtain their livelihood almost entirely by piracy, and quite a small army of hawkers are employed in carrying on the business.

The Cape Town Photographic Society took this matter up some three years ago, but owing to the outbreak of the war were not able to get

any measure introduced. The society, in combination with artists and photographers throughout the colony, are now making a very determined effort to induce the Government to bring in a Bill this session; the joint committee appointed have had a Bill drafted, which is now being considered by the Government, and there is some prospect of a move being made, and should the Bill not get through for want of time this session, there is every prospect of its going through next session.

Considerable expense has already been incurred, and it will, of course, be necessary to expend a much larger sum before the measure becomes law.

The committee feel that as you would no doubt be interested from a business point of view, in the passing of this Act, you might possibly like to forward a donation to the fund required in securing its passage through the Houses.

The committee have also had under consideration the advisability of forming a Copyright Union for protecting the interests of artists, photographers, and publishers, and I should be glad of an expression of your views on this matter, as it will depend to some extent upon the replies to this as to whether it is felt that it would be of sufficient value and help to British publishers to include that branch in the formation of such a union.—Yours very faithfully,

A. JAS. FULLER.

Hon. Sec.

P. O. Box 470.

SOUTHAMPTON, HOVE, AND SOUTHSEA EXHIBITIONS.

To the Editors.

Gentlemen,—As a slight misconception exists regarding the matter, may I say that, although exhibitors may enter for either of these exhibitions in the usual way, those exhibitors desiring to compete for the special award and to have their exhibits conveyed between the exhibition free of charge, must enter for all three exhibitions.

Entries close November 5th, and entry forms will be forwarded upon application to, yours faithfully,

S. G. KIMBER,

Hon. Sec. Southampton Camera Club.

Highfield, Southampton.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

UNRETURNED SPECIMENS.—H. MASON: We know nothing of the man. We should advise you, without delay, to write to the superintendent of police, Aberdeen, stating the case fully to him.

ADDRESS WANTED.—W. A. S. writes: "Please give me the name and address of makers of Royal Sovereign Camera half plates, their address is I believe in Jersey or Guernsey."—In reply: We do not know the address inquired for. Indeed we may say we have never heard of the plates. Possibly some readers may help our correspondent.

LECTURES ON LENSES.—H. R. BATEMAN writes: "Could you inform me of any names and addresses of firms who send out lectures to photographic societies, such as lectures on lenses, their making, etc., so that I could write them?"—In reply: Messrs. Beck, 68, Cornhill, and Messrs. Goerz, Holborn Circus, send out such lectures, we believe.

LENS QUERY.—J. B. SMITH asks: "Would you kindly answer this question. In order to take a quarter-plate size or carte de visite with half-plate camera, are you obliged to have a lens to cover the size required, or can the half-plate size be used if placed further back?"—In reply: A half-plate lens will do as well as a quarter-plate one, if the camera is taken further from the sitter. Indeed, it will do better, as the definition will be better towards the corners of the plate.

COPYRIGHT.—R. M. GORDON says: "I have made some negatives from prints in the possession of a friend. The prints are over a hundred

years old. Would I be safe in printing and selling copies of same? My friend has no objection to my doing so. Also could I get negatives registered?—In reply: As the prints are so old there is probably no copyright in them, in which case you will be quite safe in selling copies of them. You can also make your reproductions of them copyright.

INSTRUCTION IN RETURN FOR SERVICES.—**AMBITIOUS** writes: "I am in a high class photographer's shop as retoucher and finisher, but have no opportunity to learn operating; and as I wish to become an operator, do you think any good firm would have me in house and teach me operating in return for my services as retoucher and finisher in B. and W., for about six months?"—In reply: We should say that some houses would make such an arrangement. The best way would be for you to advertise stating what you desire.

PRINTS FOR PROCESS BLOCKS REGISTRATION.—**TERRANT** says: 1. "I am making some photos for a gentleman who tells me that he will be sending one away to have a process block made, and I would like to know what kind of printing paper would give the best result (matt or glossy, etc.). 2. I have two photos that I wish to have made copyright. Would you please let me know the cost, if sent to you?"—In reply: 1. Glossy prints will be the best for you to supply. 2. One shilling and sevenpence each. You must send us two prints of each subject.

FORMULA WANTED.—**FORMULA** asks: "Could you give me the formula for making the mixture that the enclosed tintype plates are coated with? If you cannot tell by the plates, perhaps you can from the printed directions for working the same, which I herewith send you. Kindly return 'printed directions,' for which I enclose stamped addressed envelope.—In reply: We cannot say, by merely seeing the plates and reading the directions for their use, how they were prepared. They are evidently coated with a collodion emulsion, and we can tell you nothing beyond that. The directions have been returned as requested.

TINTING EMULSION.—**A. D.** says: "I want to tint my chloride emulsion mauve and rose. What it is done with, and how to add it? Must it be added before the silver or after, and what quantity will it take?"—In reply: Any of the coal tar colours, soluble in spirit (we presume you refer to collodion emulsion) may be employed. The proportion of colour is dependent upon the depth of tint desired, which you will easily arrive at by experiment. We may tell you it is not usual to tint the emulsion. Better get some paper in which the baryta coating is tinted. That is what is used for all the emulsion papers.

BROKEN NEGATIVE.—**J. R. G.** writes: "I have cracked the glass of a $\frac{1}{4}$ plate negative, but the film is not broken. I cemented another glass on the back, but it has not dried even, so that to print it now would print markings. Can you tell me if you know of any one who could successfully remove the film and transfer it on another piece of glass without spoiling the film or damaging it?"—In reply: We should imagine that one or other of the professional photographers in your town would transfer the film to another plate for you. If not, we suggest that you communicate with the Autotype Company; they may perhaps undertake the work.

PORTRAIT WITH AUTOGRAPH.—**INVERTED** writes: "I herewith enclose a print with sitter's own signature printed in white with own portrait. Will you kindly let me have full particulars how to work this process, as I am desirous of adding same to my business? Of course the difficulty is to get the name on the right way."—In reply: There are different ways of doing the pictures. This appears to have been done by double printing. The negative is masked so that only the head is printed, the other portion of the paper remaining white. The autograph, written probably on thin paper, is then taken and used as a second negative, a mask being fixed on to it to protect the part already printed. The portrait has been returned.

MOUNTING CARBON PRINTS.—**W. H. STAPLEY** asks: "Can you tell me a method of mounting carbon, or other prints, on vellum mounts, so that they do not cockle up and crease when taken into a warm atmosphere? I have been in the habit of mounting carbon prints dry with starch paste; but in a few days they curl up, and pressure will not bring them back to their original flatness. I enclose sample of vellum."—In reply: It is very difficult to mount prints on such thin paper as the sample sent without their cockling. The best way is to cement the prints only by their edges to the paper. On page 1,092 of the ALMANAC you will find a formula for a mounting solution, that does not cause the prints to cockle. You should try that.

FACTORY ACT.—**INQUIRER** says: "One of His Majesty's inspectors has called upon me with a view of inspecting my workshops, contending that a mounting room and frame-making business (also retouching) brings me within the meaning of the Act. I should like an expression of opinion from you before admitting as much, as I told him I should so obtain it. He contended that in other towns photographers had been obliged to submit. Our hours of work: 9 to 6, mounting room and frame-making 8 to 7, Fridays only, 8 to 8."—In reply: We should say that your workshops decidedly come under the Factory Act, and that you will have to comply with it. You can get an abstract of the Act by writing to the office of the Factory Inspectors, London, S.W. That will give you all information.

CARBON PRINTING.—**ARTIST** asks: "Will you kindly answer following questions: 1. In what proportions shall I mix gelatine and chromate of

potash for carbon printing, to give the most hard, clear, and sharp results? 2. Are there any other substances used in sensitizing carbon paper than potash; if so, what are they? I wish to get, if possible, a 'hard' result, i.e., with great contrast, and outlines clearly and sharply defined, and shall be very much obliged if you will put me right."—In reply: 1. It is the bichromate, and not the chromate of potash, that is used for sensitising carbon tissue. The weaker the solution is the stronger will be the contrasts. If very strong contrasts are desired, use a bath of one or one and a half per cent. 2. The bichromate of ammonia may be used, but it offers no advantages over the potash salt.

COPYRIGHT QUERIES.—**PHOTO** asks: "Will you kindly answer me the following questions: (1) If I send you a P.O. (please say how much), can you find out if two photos of two different gents are made copyright? (2) If a person has been asked by a photographer to sit to him, and the photographer has given that person some photos for his trouble, if the said photo has not been made copyright, can I copy the said photo and make an enlargement, and sell it to the sitter's friends? Do I run any risk if the said photo is made copyright after such time as I have copied it?"—In reply: (1) We do not undertake to search the register to find out whether certain pictures are copyright or not; that would be quite without our province. (2) If the picture is not copyright you can copy it, but whether you would be acting honourably in doing so is another matter. If you copied it against the sitter's wish, he could, we surmise, restrain you from making any use of the picture for your benefit.

PREPARING POSTCARDS.—**POSTCARD** writes: "I shall esteem it a favour if you will help me out of a dilemma by answering the following queries: I have an order for a quantity of pictorial postcards from local views. In the B.J.P. ALMANAC for 1899, I read a formula for preparing postcards as follows: Use equal parts of a 9 per cent. solution of metabisulphite of potassium, and a 25 per cent. solution of ammonio citrate of iron. Queries: 1. Is this a sensitising solution? 2. Should it be kept in the dark? 3. Is it green ammonio citrate of iron that is meant? 4. Will the solutions keep well if mixed together, or must they be kept separate, and only mixed at the time of using?"—In reply: 1. Yes. 2 and 4. We should advise the solutions to be kept separate and mixed as required. 3. The ordinary will answer. As postcards, ready for printing, are now supplied at such a low price, we should recommend you to use them. They will yield better results than you will probably get on cards of your own preparation.

STUDIO BUILDING.—**E. L. F.** says: "I shall be glad of information on the following: 1. Am about to erect a portable studio 28ft. by 14ft. by 12ft. or so, $\frac{3}{4}$ span, as per enclosed diagram, to face N.E., for private study. Could I better this pattern or dimensions? Smaller size would suit pocket better. 2. Am about to erect in allotment in Borough. Will it be necessary to get consent from local authorities—and especially for wooden studios—seeing it will be what is called the portable class. And as I am not having water or gas at present, should I be liable to a rate for the structure? Rates very high here. 3. Could the landowner of whom I rent the garden have any claim whatever should I require to remove studio, if it was portable, and not fixed in the ground? 4. What book would you recommend on the studio pose? 5. Have got an offer of a studio, 30ft. by 10ft., 9ft. high, 8ft. back. Would this be good size?"—In reply: 1. The design and dimensions are good, but we should suggest that the glass be carried down to one foot nearer the floor. Four or five feet at either end may be as well made opaque. 2. We cannot say, as the bye-laws in different districts vary so. A local surveyor or builder will give you information on this point. 3. If the building is in no way fixed to the ground the landlord has no claim upon it. 5. Yes, but it will be rather narrow.

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOK-SELLERS.**—A *Contents Bill* is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published in December next. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The growth in popularity of the ALMANAC is evidenced by the remarkable rapidity of its sales.

The 1900 Edition (20,500 copies) was sold within three months after publication.

The 1901 Edition (20,500 copies) was sold a fortnight after publication.

The 1902 Edition (20,500 copies) was sold a fortnight before publication.

The widespread interest in the ALMANAC grows steadily year by year, and in order to supply the increasing home, foreign, and colonial demand, we have decided to enlarge the 1903 issue to

25,000 COPIES.

The great addition to the circulation of this most popular annual (over 20 per cent.) undoubtedly enhances its value as an advertising medium, and the issue of the large number of extra copies will supply the wants of thousands of photographers, dealers and publishers who were unable to obtain the ALMANAC for the last three years.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

EX CATHEDRA.

Uralite. The art of the photographer has now so many branches, that things seemingly quite outside his province are often of interest to him. And it was this train of thought which urged us to procure samples of a recently-introduced material known as "Uralite." This substance is now being manufactured at Higham, Kent, at the works of the British Uralite Company, and its principal use is as a fireproof material to take the place of wood in the construction of walls, ceilings, and roofs. It is a mixture of asbestos and other materials which, after being pulped, are formed into sheets in a machine like that used for the manufacture of paper. These sheets are afterwards treated with silicate of soda, and pressed together into thicker sheets. Uralite is made in two varieties, the one hard and looking very like china, and the other soft and flexible. Its price is about threepence per square foot, and it can be procured in sheets which measure 6 x 3 feet. From our examination of uralite we are inclined to think that the softer variety would be an admirable lining for the optical and other kinds of lantern; while the harder kind would prove valuable for the manufacture of large dishes for use in photography. Such dishes could, we imagine, be made for half the price of those made of celluloid or papier maché. There are a number of other uses to which uralite can be put, for it will take a nail, or a screw, just like wood, but will not split. It goes without saying that it would be invaluable in studio construction, for it is not only incombustible, but is a bad conductor of heat.

* * *

Drawing for Process. It is always interesting to hear from a good craftsman how he sets about the work which brings so much delight to his fellow mortals, and when that work happens to be pen and ink drawing, it is of special interest to photographers, for the usual fate of such a work is to be translated into a process block. Mr. Harry Furniss, in the current number of the *Magazine of Art*, takes us behind the scenes and tells us all about it. He gives us examples of the way in which a line should be drawn and in which it should not be drawn; of the

direful results of crossing lines while the ink on the under ones is still wet, and what much cleaner work results by waiting until that lower layer is dry. He even tells us how he maps out his drawing in outline, thus:—"First, with a few hieroglyphics I mark the size of the figure, its position, whether sitting or standing; long or short coat; style of tie, collar, etc.; and then I draw in the head completely and carefully in pen and ink." Then it is that the model comes upon the scene, and in a triplet of masterly sketches he shows the model—a very ordinary person—and how that individual is by an expanding process turned into Lord Salisbury, and by a shrinking method converted into the present Prime Minister. Mr. Furniss feelingly says that it is an easy matter to reproduce drawings, but quite another thing to print them. Of course he is safe enough when such a well-printed periodical as that in which he writes is concerned, but the rotary press, with its output of thousands per hour, plays havoc with a drawing, unless it is executed in the boldest possible manner. Mr. Furniss seldom uses a lead pencil in his work, and then only for the most sketchy outlines, for the rubbing out of such lines inures the fine surface of the Bristol board upon which the drawing is made, and the ink lines, too, are liable to be degraded in such rubbing. He uses water-proof Indian ink, and for fine lines, on the face, a crow-quill pen known as Gillott's No. 659, but for the rest of the drawing he employs the same pen as that with which he writes, namely, Perry and Co.'s No. 39 fine, which will under persuasive pressure make either very fine or very broad markings. We give these details in the hope that they may be useful to those of our readers who are wishful to vary their photographic pursuits with a little practice in pen and ink drawing. One curious comment Mr. Furniss makes in deprecating the method, common with many black and white artists, of making a correction by pasting over the faulty part a piece of plain paper, and redrawing. He writes:—"The sticking of paper is unwise, as the paper is on a different plane, although slight, to the rest of the drawing, and the camera, in photographing the drawing for reproduction, will not have the same focus equally all over." We presume, from this, that Mr. Furniss is more familiar with microscopic objectives than he is with photographic lenses.

* * *

Village Photography. There is something about "the village" that appeals to the imaginations and sympathies of most men. The attraction is probably in part instinctive, and due to blood and race. Affection for the village is characteristic of the English stock. The earliest accounts that we have of our distant ancestors, the German tribes of Tacitus, show them to have been fiercely jealous of the independence of the small village communities in which they lived. History proves the same feature to have been characteristic of the villages of Saxon and Mediæval England. The manorial village was a self-contained and self-ruling unit, and we are now instinctively returning to the same form of government, as far as we reasonably and safely can, with our rural and parish councils. But outside of this consideration, the calm and quiet of a village is so complete a contrast to the noise and bustle of the town, that we naturally turn to it and its suggestions as a restful foil to over-sensitive nerves and harassed minds. The attraction takes us to villages for our holidays, the pleasant remembrances of which still further tend to strengthen our regard. Everybody has a favourite, or

favourite type of, village. One is in love with the highly rural village with its low, grey church tower and bridge-spanned brook, its blacksmith's forge, wheelwright's shop, and cottages set in gay, sweet-scented gardens, built at varying angles to the road, the whole compactly and artistically packed together in a gentle turn of the smiling valley. Another prefers the high-lying village, more scattered and exposed, framed in ample spaces of gorse and heather, whilst a third will have the domination of the sea in his village, and the insignia of lordship in boat, net, and creel scattered here and there throughout it. He likes to lean against the capstan at the end of the breakwater, and chat with the brown-armed mariners in the evening.

* * *

The Value of Suggestion. In most cases where the liking is keen, there must be a desire to have a picture to suggest the pleasant spot at city, home-keeping times, and to act as a tonic to the spirits in dull seasons. The village as a whole is impossible in a photographic picture. It cannot be got into the compass of the plate. Even if it could, it would be a mistake to record it. It can only be suggested, but the suggestion can be made stronger than the full measure of the reality. The artist, although he may be able to paint the whole is far too wise to do so. He knows the value of suggestion and pictures a characteristic bit. So should the photographer. It resolves itself in a great measure into artistic feel. At the same time technical knowledge is necessary in picking what is photographable. The view must always be regarded with half the thought upon the camera and its limitations. The best view is useless unless it pass this qualification. If the fact were borne in mind there would be less disappointment as result, oftentimes, amongst artistic amateurs. Still there is plenty of room left for the highest photographic work. In the first essential place, a characteristic feature should be selected, and not a peculiar one. The more expressive the particular is of the general, of a type, the higher it ranks, and the more permanent and sustained will be the interest in it. The gentler, too, the emotions aroused in looking at a picture, the better. To take an instance to illustrate the two points, if it be the fishing village, a brown-sailed smack gently drifting down the harbour as a central object, will prove far more satisfactory in the long run than the launch of a lifeboat on a storm-beaten beach. We say nothing, of course, against pictures of the lifeboat and of storms, but they must be placed in other, and special, classes. The going out of the lifeboat is an occasional event, and the emotions aroused at seeing it, or a faithful and telling picture for the first time, cannot be called up each time the picture is looked at. The result is, that there is a sub-conscious sense of lack of proportion in some way or other, and the picture loses its force and attraction. The slow drift of the fishing boat, on the other hand, is a common-place event that can be seen every day, and the associations connected with it being softer, and making no strong drain upon the emotions, the response to its appeal and suggestion is fuller and more pleasurable. The instance chosen may, perhaps, be a little strong, for the lifeboat goes out but rarely, and when it does it is, as a rule, in a winter's storm, and at night, when the chances of successful photography are very poor. But the strength of the illustration may serve to impress its value, and it will apply in less or greater degree everywhere. A rippling sea is better than a smooth, or a stormy one, for it is the usual sea; a crowd in a village street lowers its pictorial suggestive value, because

it is so rarely that a village street is crowded. Even if there be an unusual building in a village it should not be included in the picture. Somebody's "Folly," whether ancient or modern, reduces the desired breadth of suggestion, and throws the picture further from the aim at being typical.

* * *

Treatment of the Subject.

It is impossible to indicate in any detail what to take in a rural, upland, or fishing village, but whatever it be it should be characteristic and common-place. It should also be treated as broadly as possible. It is of the utmost importance that there be as much space of sky, moor, or sea as possible shown. To this end the foreground should not be too pronounced. The artist can arrange his foreground as falsely, but as pleasingly, as he likes. Unfortunately the photographer cannot, apart from the picture as a whole. He must trust to wise selection and careful composition, judging his picture as a suggestive whole upon the screen. The best lens to use will be the one with the longest possible focus. When a telephoto lens with a wider angle of view, and permitting of a rapid exposure is evolved, it will be just the thing. If the conditions will admit of the use of the present telephoto lens with its limitations, it certainly should be used, for it gives far better proportion, and higher possibilities of an artistic setting, than the ordinary lens. The best time for working is undoubtedly either early in the morning, or as late as possible in the evening, for the sake of gaining the expressive long and soft shadows. Personally we prefer the evening, towards sunset, according to the season of the year. Our best results have been obtained with a plate of medium rapidity, and an exposure of a half to one second, at F/16. Finally, work should be done with plenty of time to spare, and an hour or two after a meal. Haste and an empty stomach have spoilt many a good picture. Rather prosaic, perhaps, the last condition, but things generally have a marvellous knack of turning out to be prosaic when analysed. However beautiful and elegant the edifice, the bricks that have gone to build it up are, after all, but small squares of baked clay.

* * *

Uniformity and Simplicity in Sizes.

Whatever may have been the origin of the various conventional sizes of plates and papers used for photographic purposes, there appears to be no fixed rule which governs their proportions, as the ratio of length to breadth varies considerably in different sizes, without at the same time offering in return much scope for choice of alternative shapes of about the same area. This becomes very apparent in the case of enlargements, where the sizes of printing paper are often found to have very different proportions to the negatives from which the enlargements are required, thus involving more or less waste. It is not perhaps very likely that these commercial standards will now be superseded by any more rational system, and it is, therefore, rather as an academic inquiry that we here present these suggestions for a more uniform plan of proportioning the various areas of paper plates and films. What appears to be a suitable form to adopt as a standard is one in which division by successive halving would result in smaller sizes retaining the same proportion of length to breadth. A simple, mathematical investigation will show that the object may be accomplished

by adopting a shape in which the ratio of length to breadth is as 1.414 (equal $\sqrt{2}$) to 1, the required length being divided, or the breadth multiplied, by the former figures, to obtain the respective breadth or length. Adopting, for instance, as a starting-point, a length of 24 inches—dividing this by 1.414, gives a corresponding breadth of 17 inches (neglecting small fractions). Division (across the breadth) of this area into two equal parts results in two pieces of 17 x 12, which will be found to possess the same relative proportions of length and breadth as the original area. Further, such divisions will lead to a series of diminishing sizes also bearing the same proportions, and we obtain the following list: 24 x 17, 17 x 12, 12 x $8\frac{1}{2}$, $8\frac{1}{2}$ x 6, 6 x $4\frac{1}{4}$, $4\frac{1}{4}$ x 3, 3 x $2\frac{1}{8}$; capable of extension to larger or smaller sizes. These figures give a good average shape for most purposes, and will be seen to correspond nearly with many of the old dimensions, but to have the advantage that each size may be cut without waste to a smaller one, and the latter be found to be of the same proportion as the other, so that an enlarged image will fit a sheet of larger size than the original without superfluous margins of length or breadth. If intermediate sizes are desired, they may be obtained in a similar way by beginning with a length of say 20 inches, the breadth corresponding to this will be found to be 14 inches, giving an additional list as follows:—20 x 14, 14 x 10, 10 x 7, 7 x 5, 5 x $3\frac{1}{2}$, $3\frac{1}{2}$ x $2\frac{1}{2}$, $2\frac{1}{2}$ x $1\frac{3}{4}$, etc., again varying little from sizes at present in use.

* * *

Simplification of Formulae.

Another department of photography in which a delivery from the burden of unnecessary complications is desirable is that of formulae for solutions, which are frequently given in such a way as to render an intricate calculation necessary to discover the actual proportions of the ingredients in any quantity of the solution except that mentioned. Many apparently differing formulae, also, contain practically unimportant variations in their ingredients. It would not be difficult to reduce to a small compass the innumerable formulae for developers, which occupy so much space in our photographic literature, and to adopt a uniform system of expression which would give a much clearer conception of the relative quantities and efficiency of the chemicals used. A friend of our acquaintance has, for instance, drawn up for his own use the following general formulae for some ordinary developers, principally obtained from analysis of those given in various books and journals. It is probably open to correction in some of the amounts mentioned, but will serve to show a method suitable for a clear view of the nature of the solutions, and for convenience in preparing and using different developers. A standard developer for ordinary purposes may be made as follows:—Water 1oz., sodium sulphite 1-20=24grs., sodium carbonate 1-20=24grs., or potassium carbonate 1-40=12grs., potassium bromide $\frac{1}{2}$ gr. To this add any of the usual developing substances, for instance:—Pyro, metol, hydrokinone, or ortol, 3grs.; eikonogen, 8grs.; amidol, $2\frac{1}{2}$ grs. per oz. (omitting for the last, the carbonate); or mixtures of two or more may be used. The developer may be made more concentrated if desired, or may be diluted, and the carbonate might be increased for very short exposures. It may be convenient to make up the carbonate in a separate solution, in which case each solution may be made double strength, and combined either in equal parts for ordinary purposes, or the relative proportions varied as desired. It would, perhaps, however, be best to use, in both solutions, sulphite in the

proportion of 1-20 as given above, and to double the other ingredients in the respective solutions; in this way the amount of sulphite per ounce in the mixed developer would remain constant for different amounts of carbonate, the proportion of pyro, etc., varying inversely as the carbonate; this would tend to correct results. A general formula of this description with a few special ones arranged in a similar form for some chemicals (as, for example, when a caustic alkali is desirable), and some notes as to the peculiarities and special uses of the various substances, would enable the photographer to use them intelligently, and with much more convenience than by the trial of a multitude of the ordinary formulae.

MOUNTING PHOTOGRAPHS ON THIN PAPER WITHOUT COCKLING.

If there is one subject in connection with photography that has been more written about than another it is, probably, the mounting of finished pictures. Still, correspondents are continually asking for further information upon it, at the same time detailing the difficulties that sometimes beset them under certain conditions. The most frequent queries have been with reference to mounting prints in albums or scrap books without their cockling the leaves. Since so many photographers have adopted Japanese, and vellum, papers as mounts for their work, the queries in this direction have increased proportionately. Last week a correspondent detailed his difficulty in mounting carbon pictures on the latter, by reason of the mounts cockling when they became dry, which after rolling did not overcome.

Only a short time ago we dealt with this question from a theoretical point of view, and pointed out that the cockling was due to the expansion of the paper by the aqueous nature of the mountants, a difficulty that could only be avoided by the employment of a cement that is entirely free from water. There is, unfortunately, no cement that fulfils this condition that can be successfully employed for mounting photographs. Many years ago a thin solution of indiarubber was introduced for mounting photographs with, and admirably it answered its purpose, as prints mounted with it, even if on thin paper, were perfectly free from cockling. Unfortunately, however, after a time, often a very short one, the rubber perished—became resinised—and the prints left the mounts. Alcoholic solutions of resins—shellac and the like—which, of course, are free from water, have from time to time been tried, but with little or no success.

The most successful mountant, as avoiding cockling of the mount, is the solution of a suitable gelatine in which alcohol is made, to a great extent, to take the place of water. A formula for this has appeared regularly in the ALMANAC for several years past. Although this is the best cement yet introduced for the purpose, it does not entirely get over the difficulty, even when thick mounts are used. It only ameliorates it, and reduces the cockling to a minimum. There is, it is true, the dry system of mounting, which was introduced by Mr. A. Cowan: some years ago. In this method the adhesive—starch or the like—is applied to the back of the print and allowed to dry. The mount is then slightly moistened with water, and the two passed through the rolling press, when perfect adhesion is secured. But it is manifest that this method cannot be applied to mounting prints in albums, unless the books are taken to pieces, and, after the prints are mounted, rebound. If this system were

adopted in mounting on some of the papers now used as mounts—Japanese or vellum, for example—the dampening of the paper would quite destroy the peculiar sheen on the surface, and this is one of its principal features, and no amount of after rolling or pressing would restore it to its pristine condition.

Here is a method we saw, a few years ago, in use in a large Continental house for mounting carbon pictures. The mounting of the print, and the India-paper on the plate-paper, as well as the titling of the picture, was done in a single operation, and without the slightest after cockling of the paper. The system is somewhat similar to that of Cowan. The back of the print is first coated with an adhesive—such as starch—and allowed to dry. It is then trimmed. The India-paper is very slightly damped between blotting paper. A steel, or copper, plate with the title engraved upon it is heated and inked up after the manner of copper-plate printing. The India-paper is then brushed on the back, as is done in printing on India-paper. The print is then laid on the heated plate, on that the India-paper, and on that the plate-paper mount. The whole is then passed through the copper plate press, with several thicknesses of blanketing between the plate and the roller. The work is then complete—the cemented print adheres to the damp India paper, and that, by reason of the brushing, adheres to the plate-paper the same as it does in ordinary copper plate printing. This method, however, is better suited to large establishments than to the requirements of the ordinary photographer.

Here is a method that will commend itself better to them when the prints are to be mounted on the thin papers now much in vogue. It is this. Only the edges of the print are attached to the mounts, and it is the plan that it is now generally followed by those who make a speciality of pictures on Japanese and similar papers. The trimmed print should first be rolled to get it perfectly flat. Then an adhesive, preferably that given on page 1092 of the ALMANAC, is applied for a quarter-of-an-inch round the edges, and the print placed down on the mount, and well pressed in contact. It may then be rolled or not as desired. When this method is employed the print can at any time be removed and another a trifle larger be substituted. This is a great advantage in the case of albums, also in the case of costly mounts, which can be used again if the first picture is not satisfactory. In the early days of photography, it may be mentioned, most large prints were only attached to the mounts at their edges.

There is one precaution that has to be taken, even in this method of mounting, if cockling is to be entirely avoided, namely, that the print and the mount should be as nearly as possible in the same hygroscopic condition. A little consideration will show that if the former is in a damp and expanded state when it is mounted it will contract as it dries, and that will drag the mount into a cockled condition. If the mounting be neatly done it will be difficult to detect that the picture is not entirely cemented to the mount, unless it be bent or doubled.

CAMERA Club for Watford.—A very successful meeting was held at the Watford Public Library on Saturday, the 18th ult., to discuss the advisability of forming a camera club for Watford, and after Mr. F. Roberts had explained what had been done in the matter and what were the proposed lines on which the club was to be constituted, it was unanimously resolved that the club be formed. Upwards of forty names of those desirous of becoming members were handed in, and it was decided to hold the next meeting at the Watford Public Library on Saturday, November 1st, at 8 p.m., to receive the names of new members and to elect officers, etc. Any further information can be obtained from Mr. Frank Roberts, "Winslade," Cassio Road, Watford.

BROMIDE PAPERS.

In most photographic establishments I believe it is the usual rule to look upon bromide printing as a very valuable ally in an emergency; a method, as it were, of competing against time where circumstances demand the quick delivery of orders. No doubt it does, in this respect, put into the photographer's hands a means of accepting contracts that would be absolutely impossible without it. In this it stands alone, and has no competitor—probably never will have. This point scarcely wants elaborating. I suppose there is no professional reader of this who has not taken advantage of it at one time or another, perhaps many times. When an urgent order comes in, his thoughts immediately and naturally fly to bromide paper. But, with the majority, at all other times the process seems to have no attractions. Unless there is a tearing rush for some prints in the quickest possible time, bromide paper is never thought of. Now, is this fair treatment for a really beautiful method of reproducing photographs? For, no matter how simple a process may be, there are always points in the working that need consideration to obtain best results.

Perhaps the neglect explains the neglect. This may read somewhat strangely, but it expresses my meaning tersely. Setting it out in fuller detail, I will instance the man who neglects bromide paper as a regular method of printing when it might hold a very important—perhaps even the very first—place among the processes he offers to the public. The urgent order comes in, and he utilises bromide, not because he finds it a very simple process to work; not because the results are beautiful, not because of its adaptability to all classes of subjects in the matter of surface, etc., not because of the permanence of the results; but purely and simply because of the great speed of production capable by its agency. This man completes his urgent order, and by reason of his very occasional and intermittent acquaintance with the process he, generally speaking, does not make the best possible results, and he therefore fails altogether to appreciate the advantages set out above, and in consequence he does not trouble further with it until another urgent case arises. The neglect in the first place causes second-rate work in the emergency, which in its turn causes further neglect.

Let us look at some of the advantages bromide paper printing possesses, and try to find out why the occasional worker just manages to miss them. The result may be to convert him into a habitual worker. Simple it certainly is. On the face of it, anyone who can expose and develop a plate coated with gelatino-bromide of silver, and thus make a good negative, can surely expose and develop a piece of paper coated with a similar emulsion, and thus make a good print. But—and it is a fairly big “but”—the conditions are not precisely the same. The two emulsions, although similar, are not identical. The plate is probably coated with a fairly rapid emulsion, and the paper with one much slower. The results desired in the two cases differ, hence the method of working must differ. The plate is developed with the idea of producing a negative image, the colour of which is an unimportant matter, to be used by transmitted light; whilst the paper positive, the colour of which is all-important, is to be judged entirely by reflected light.

It is well known that a slow emulsion allows of much greater error (sometimes wrongly called “latitude”) in exposure than a rapid emulsion, and here is a possible stumbling block. A bromide print may be greatly in error as to the exposure given, and yet be a passable print. But there is only one correct exposure for a given negative, and that is the exposure that gives the best possible result—anything short of this best is not worthy of a serious worker. The colour of the print is also

governed to some extent by the exposure, but is much more dependent on the developer used and the length of time development is continued. It is an easy matter to make constant the latter two conditions by selecting a suitable formula (the one given by the makers is probably the best for the particular brand of paper in use), and by deciding the time in which the surface image reaches full strength. This time will, of course, vary with the temperature of the solutions and surrounding atmosphere, but I take it that any photographer nowadays who is seriously endeavouring to do good work has already learned that lesson in other departments than bromide printing, and that as a natural course every precaution is taken to minimise the effects of our peculiar climate.

The limit of time that a bromide print should remain in the developer seems to be one that will include the point where there is no further development of surface detail or density, and at the same time will not include any chance of fog from protracted development. Herein lies the great difference between negative making and bromide printing. To get the best results as a negative development will of necessity be stopped at an earlier stage than the plate is capable of developing, and the least exposed portions (the shadows) should show appreciable light action under the developer. To get the best result out of bromide paper development must be pushed to the extreme in every case, whilst the least exposed portions (the high lights) must be absolutely clean and free from any apparent action of light. The makers of one popular bromide paper would seem to have this idea in mind when recommending the metol formula. They say: “Development will be completed in about two minutes.” Personally, I find three minutes a better time either with metol or amidol. It is probable that other developers may each have a time best suited to each one. In any case, no absolute rule can be given, because the amount of bromide present and the strength of the solution will both make a considerable difference. Each worker must find by experiment what time is best suited to his developer, and having decided this, it should be a fixed standard that every print shall have that amount of development. He will then have two unvarying factors in printing—the power of the light (artificial light, of course) and the duration of development.

These two items being standardised, only one remains to be considered in determining the correct exposure, viz., the character of the negative. And here all the judgment and experience of a photographer will only enable him to arrive at an approximate estimate. The printer whose everyday work is confined to P.O.P. and similar processes with a visible image would certainly be able to classify his negatives roughly as quick, medium, and slow printers. But ask him the exact proportion of difference between the amount of light action necessary for two negatives of different classes, or even two of the same class (particularly dense ones), and he will be entirely at sea. This is perfectly natural, because his work has never called for such discrimination. But even those with considerable experience with development papers will find it hard to form an exact judgment without verifying it by a trial exposure. I believe there are on the market contrivances for judging the exact printing strength of a negative, but even these cannot take into account the variations of colour in negatives, which materially influence the exposure required. To me, personally, looking through a negative is not a good method of estimating exposure. I find the best way is to lay the negative, film down, flat upon a piece of white paper, and from its appearance thus, by comparison with one of which the exposure is already known, I form something like an idea of how long to expose. A trial print is now made with three different times on

three portions of it—one the estimated exposure, one about 25 per cent. more, and one about 25 per cent. less. Development of this will usually settle the matter; if not, a further trial exposure is made. These trials are always made at one fixed distance from the illuminant, viz., 12in., and the negative is then marked with the number of seconds required at that distance.

It is usual to lay down a law in bromide printing that all exposures shall be made at one fixed distance. I find, in practice, that it is much more convenient to have a fixed time for the exposure—say 10 seconds—and to vary the distance from the illuminant. When printing from thin negatives, anything less than 10 seconds is somewhat difficult to manage with exactitude, and with dense negatives any longer exposure seems to be waste of time. Again, a thin negative will give a brighter print if removed further from the light, and the equivalent exposure given, whilst a dense negative will yield a softer result by the more brilliant illumination of a shorter distance and proportionately less exposure. Of course, you know the law of proportion in such cases—the exposure increases, or decreases, in the ratio of the squares of the distances. But such sums are not easily worked by mental arithmetic, and the dim, religious light of the dark-room always seems to add greater mystery to the problem. Hence I decided to mark out an exposing board measured in inches and half-inches, but marked with the equivalent exposures, as follows:—

4in. distance is marked	90
4½ „ „ „ „ „ „	72
5 „ „ „ „ „ „	58
5½ „ „ „ „ „ „	48
6 „ „ „ „ „ „	40
6½ „ „ „ „ „ „	34
7 „ „ „ „ „ „	29
8 „ „ „ „ „ „	22
9 „ „ „ „ „ „	18
10 „ „ „ „ „ „	14½
11 „ „ „ „ „ „	12
12 „ „ „ „ „ „	10
13 „ „ „ „ „ „	8½
14 „ „ „ „ „ „	7⅓
15 „ „ „ „ „ „	6⅓
16 „ „ „ „ „ „	5⅝
18 „ „ „ „ „ „	4½

These numbers approximately represent the equivalent exposures at the respective distances, giving in each case the standard exposure of 10 seconds.

The figures are not mathematically correct, decimals being ignored, but I find them practically correct, unless the flame of the illuminant is a very large one. It is only fair to state also that a reflector will upset the figures very much; in fact, with a true parabolic reflector and the light at its focus, Dr. Just has calculated that doubling the distance will increase the necessary exposure very little—in the proportion of 40 to 37 are his figures! The effect of doubling the distance without any reflector would necessitate an increased exposure in the proportion of 4 to 1.

The exposure made correctly, development should proceed mechanically, as previously suggested. The print is immersed in the developer for the standard time; if too dark or too light when fixed, the exposure is at fault, and nothing else should be altered.

A good bromide print is second to no other print (no matter what the process) in colour or gradation. The manufacturers have placed within our reach a marvellous choice of surface finish; for speed it is unrivalled; as to cost, it is very little

dearer than P.O.P. as far as materials are concerned; there is a considerable gain in time, and as "time is money," therefore it is probably the cheapest printing known, excluding ferro-prussiate; for permanence it is miles in front of P.O.P., and carefully made prints should rank with platinum and carbons. In fact, there seems so many advantages, that it is a puzzle to me why it is not more practised. It has been suggested before, and I would like to repeat the suggestion, that a professional might do much worse than make it his staple product, showing proofs to all sitters next day, and orders within three days.

I have made no mention here of gaslight papers. The results are much the same, the underlying principles of exposure and development are identical, although the formulæ differ. Gaslight papers are more convenient when large numbers are wanted, by avoiding any need for confinement in a dark-room, and although necessitating longer exposures, development of one print and exposure of another can proceed simultaneously, thus levelling up matters. Gaslight papers, however, give somewhat harsher prints than are desirable for portraiture, unless from suitable negatives. Probably the thoughtful worker will utilise both processes, thus reaping the advantages that either may offer under certain circumstances.

W. E. A. DRINKWATER.

PERSPECTIVE.

[Reprinted from "The Journal of The Camera Club,"]

My difficulty is to know how to go into the subject of "Perspective" in the short time allowed me. I shall suppose that you know nothing about it, and begin with the word itself, though it seems somewhat superfluous to talk about perspective to gentlemen who practise photography, seeing that their "perspective" is always so excellent—so perfect. "Perspective" means a seeing through, but perspective is not seen through a magnifying glass, but through a plane glass, and one of its conditions is that all straight lines remain straight in their perspective appearance, horizontal lines remain horizontal, and vertical lines remain vertical.

[Here Mr. Storey, by way of ocular demonstration, exhibited a rectangular frame, shown in Fig. 1, fitted with a pane of glass, and crossed, as shown, by two tightly-stretched strings, from the intersection of which depended two loose strings. This intersection represents the point of sight, or the point exactly opposite the eye of the spectator.]

Continuing, he said the piece of glass represents the picture; it is called the picture plane, and the front cross string is the horizontal line.

[Here Mr. Storey placed behind the glass a cube, and instructed gentlemen to take one of the loose strings, and hold it at right angles to the glass, and look along it. Then, with the other loose string in the other hand, by applying it to the glass, so as to coincide with the retreating lines of the cube, they would see that these same lines, being at right angles to the glass or picture plane, all converged to the point of sight.]

This was further explained by reference to a diagram, reproduced in Fig. 2, as to which he said, alluding to the two lines marked A S and B S: You see these two lines are going to a point. In perspective these two lines are parallel. You say parallels do not meet at a point, but they appear to do so. There is always at the other end of that perspective an infinitesimal representation of this line (the line A B in the diagram), and A B S is a very long parallelogram, the other end of which gets gradually smaller and smaller as it goes away into the distance.

The lecturer next measured off upon the horizontal line a

distance, S D, equal to the distance of the observer's eye in front of the perspective plane, and described the point D as the point of distance. Next, drawing the line A D, he drew from the point *d*, where it intersected the line B S, the horizontal line *c d*, and referring to the lines A *c*, *c d*, *d B*, and B A, he said:—These lines are the four sides of a square, and are

Now, I want to show you how it is that the diagonal of the square decides the point of distance. For this purpose take the following figure (Fig. 3), and assume that it shows a plan view of the top of the table on which the perspective frame stands, so that the line S D D represents the top edge of the frame seen from above. Then, if I place the square at any dis-

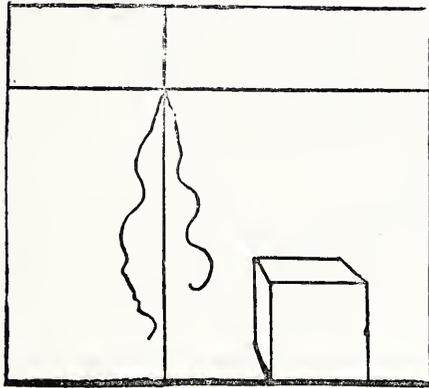

Fig. 1.

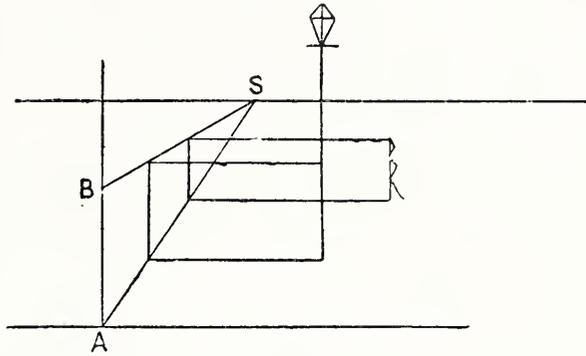

Fig. 2.

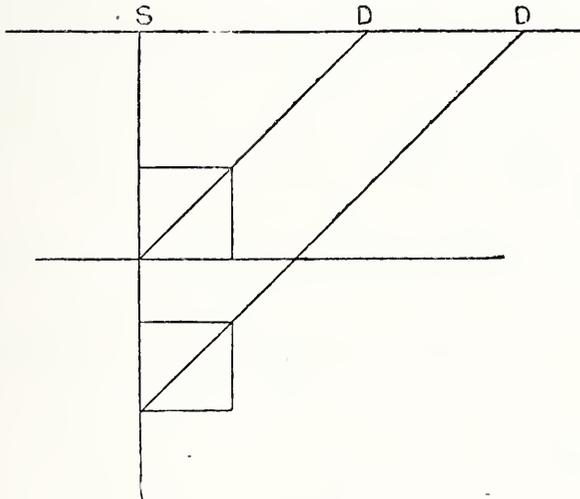

Fig. 3.

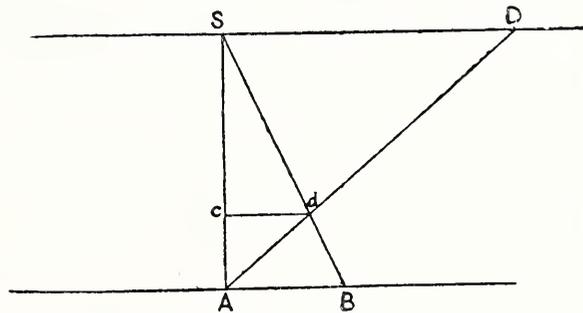

Fig. 4.

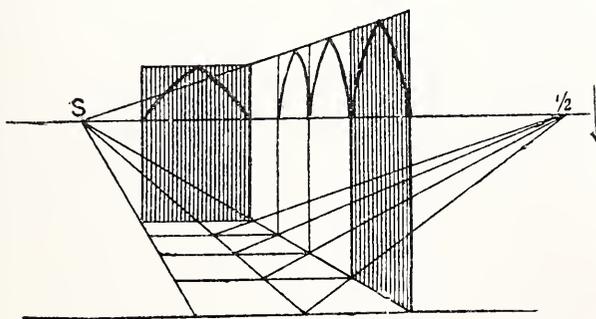

Fig. 5.

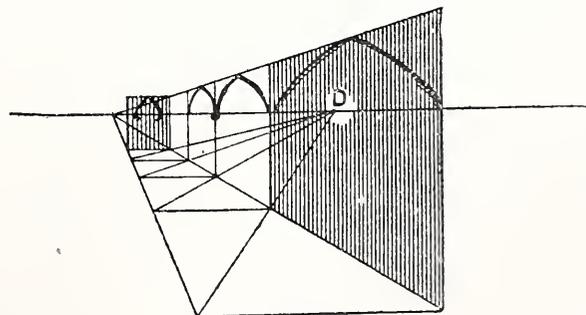

Fig. 6.

all equal. The four angles are right angles, and the line A *d* is the diagonal of the square. We learn from this that all lines of 45 degrees are drawn to the point of distance, and all lines which are at right angles to the base are drawn to the point of sight, and in these two very simple rules, we really have the great principle of perspective.

tance, as shown, in front of the plane, and with one edge pointing to the point of sight, and another edge parallel to the plane, and if, with the square in that position, I draw its diagonal, and prolong it until it meets the plane, the point D, in which it meets the plane, will always be distant from the point of sight by a distance equal to that of the forward edge of the

square from the plane. Hence, by measuring off a length upon the horizon line equal to the distance of the observer's eye from the perspective plane, we can at once determine, as in Fig. 2, the point of distance to which all lines must be drawn that make an angle of 45 degrees with the plane of the picture. The plane on which all these lines are drawn, and which extends from the lower edge of the picture to the horizon line, is called the perspective plane.

This perspective plane is perfectly even—as flat as any billiard table. But if it be desired to depict any erect objects upon it, that can easily be done. Fig. 4 shows how this may be done. Suppose, for example, that it is desired to delineate, somewhere in the midst of the perspective plane, a wall 4ft. high. From the point A upon the bottom edge of the picture we draw a perpendicular line, and set off the height, A B, say, 4ft., to scale. From A and B we draw straight lines to the point of sight, or any other point on the horizon, and thus obtain a measure of our 4ft. height in every part of the picture. The wall can now be introduced at any depth by simply drawing horizontal lines to meet the A S and B S at the desired position. Similarly, if we desire to introduce a lamp-post 15ft. high, it can be drawn by proportioning it according to the scale so found. In like manner, if I desire to measure a width instead of a height, I proceed in the same way: lay out the width to scale upon the bottom edge of the picture, and draw the perspective parallels to the point of sight. Thus I can measure the height and breadth of any object seen by these simple parallels.

In conclusion, Mr. Storey pointed out the bad effect upon perspective of the use of an excessively wide-angled lens, and illustrated his observations by Figs. 5 and 6. Fig. 5 represents the true perspective of an object seen through a plain sheet of glass. Fig. 6 shows the same object depicted by a wide-angled lens. The effect of the lens is to shorten the interval between the point of sight and the point of distance, thus bringing the spectator much nearer, as it were, to the plane of the picture, and proportionately exaggerating the change of scale due to perspective. It is for this reason that the moon and other distant objects come out so small in photography. In Fig. 5 the point marked $\frac{1}{2}$ represents, not the true point of distance, but a point half-way to the point of distance, to which lines drawn from the half of the base of square converge. The expedient of taking such a half-way point of distance as the point from which diagonals may be drawn is convenient, inasmuch as it shortens the length of horizon, which is included in the construction of the picture.

G. A. STOREY, A.R.A.

DISCUSSION.

The Chairman: This is a very interesting lecture, one which I am sure will be very useful to many in this very intelligent audience. We have many members who would like to discuss points.

Mr. Asbury Green: What does Mr. Storey consider the correct focal length of a lens?

Mr. Storey: I can tell you the angle—not the focal length—what is called the angle of vision. We see in a good many books on perspective the authors make that angle 90 degrees. They make it more than three times too wide to see anything with comfort; 28 degrees is a very good angle—i.e., 14 degrees on each side. An angle of 90 degrees is very much like trying to put a quart of wine into a pint bottle. The longer you make your point of distance, the flatter becomes your drawing; the floors look level, and the buildings look upright, and so forth. On the other hand, when the point of distance is too near, you

get distortion—you will acknowledge that this photograph [showing] does show distortion.

Captain Nash: I should like to express my extreme gratitude to the lecturer for his most concise and most interesting lecture. There must be many here who, like myself, take an interest not only in photography, but in sketching landscapes. I should like to ask Mr. Storey whether, if you have the measured details of your subject, that under these mathematical rules you can make a mistake in drawing the perspective? When you want to draw a tower, and do not know the height, how are you to use these rules for reproducing perspective in your picture?

Mr. Storey: If you want to draw an object at a certain distance, I will show you. There are means of finding out how far that object is away.

Captain Nash: But you must have the distance given or the height.

Mr. Storey: Yes, it is very difficult to find it out if you do not have it given. By means of a square on the foreground, you can find the point of distance and the horizontal line, so that you gradually construct the whole thing backwards.

Mr. T. C. Hepworth: One question—we may suppose that Turner understood these rules, and why, understanding them, did he draw the cliffs of Dover and of Hastings three or four times the height they ought to have been?

Mr. Storey: Because he thought they would look very much better. There is such a thing as idealising. Turner idealised everything. Turner's pictures are not supposed to be exact representations of everything he saw, but they are very beautiful ideals. That is the reason they do not appeal to our everyday sense of correctness and exact measurement. They appeal to the mind—to the far-extending imagination. They result in something that is beautiful. I went to Honfleur, having seen one of Turner's pictures. I thought what a dream of a place it must be—what a lovely place to be in—those trees towering up half a mile over the river, and the lighthouse shedding its lustre a hundred miles! I saw but a few squat trees and a squat lighthouse. The dream was gone, but I preferred Turner.

Mr. R. Inwards: One question—Mr. Storey was kind enough to tell us he thought 28 degrees or 30 degrees was a very good inclusive angle for a picture. To attempt to represent 90 degrees or 100 degrees in one picture is an enormous stretch. It is a very good thing for photographers to avoid these large angles. Mr. Storey told us the point of distance at which a picture would naturally be viewed. If you are dealing with 30 degrees, it would require a great length of camera. If there is a way of dispensing with this distant point, and using a nearer distance point, it would be a most useful rule.

Mr. Storey: This is very easy in perspective drawing, but I doubt if it can be done with the camera, unless you have a telescopic lens. Where a whole wall has to be decorated, the artist takes two, or even three, points of sight, and arranges his perspective so that it looks right, and as long as it looks right it is sufficient for all purposes. If you cannot see the whole of the picture as you move along, it is more reasonable to suppose that the point of sight might be shifted also. If you produce a cylindrical picture, such as a panorama, your station point is at the centre. The effect of that perspective is marvellous.

Mr. Smith Williams: If you take a wide-angle picture, and cut out a bit, giving a narrow angle, and enlarge that bit up to the size of your drawing, would that give you the same?

Mr. Storey: It would, to a certain extent.

Mr. Middleton: Mr. Storey asked me to bring an instrument here known as the centrolinead [showing]. If one of these forks is placed above the horizontal line, and the other an equal

distance below, it gives lines converging to a point very often far off your board. You can set this to any angle, and so obtain lines converging at any distance that you like.

Mr. H. E. Davis: If you had a battery of lenses costing several hundred pounds, perhaps the perspective would be quite as right as it is in the drawing.

The Chairman, in proposing a vote of thanks to the lecturer, said Mr. Storey started with the maxim that the essence of all good work was to act on the square in more ways than one. I presume the reason why our photographs do not look as truthful as they might is that we take our pictures with the photographic eye—i.e., the lens. If you take a wide-angle picture (and the wide-angle lens is a very good friend, after all), and look at it, putting your eye as far from the picture as your ground glass was from your lens, you will find that it does not look untruthful, a point which engravers recognised many years ago. Then there is our old friend the moon, in regard to the size of which artists very often take unwarrantable liberties, and make the moon twenty or thirty times the size it is. With regard to the converging of vertical lines. As to the reason why some of the old Greek workers made their pillars to bulge a little in the centre—it has been offered as a suggestion that two high vertical lines are not really seen as two quite parallel lines, but as they get higher or lower they would appear to be more or less curved.

Mr. Storey: I would like to add this—there is a certain amount of error in the estimation of sizes when you are dealing with brilliant objects, by the effect of irradiation. If an artist draws on his picture plane, let us say, 30 degrees, the size of his moon, and he takes a photograph with a lens of 30 in focal length, I venture to say the difference will not be very serious.

THE CONSTRUCTION OF ANASTIGMATS WITH NORMAL GLASSES.

[A Reply to the Article by Herr K. Martin.]

[Translated from the "Central Zeitung für Optik und Mechanik."]

As I have been travelling during my vacation, I have been prevented from giving an immediate reply to Herr Martin, but I now hasten to comply with his request.

Herr Martin does not appear to have grasped the full significance of the words "normal" and "abnormal," as applied to the glass of which an objective is constructed. In the protar patent specification No. 56,109, of the firm of Carl Zeiss, reference is only made to "normal and abnormal pairs of glasses," and not to normal and abnormal glasses in general. The normal glass pair is formed by the opposition of two glasses, one of which possesses higher dispersion and lower index of refraction. In the formation of an abnormal glass pair for the purposes of a photographic objective, a Baryta Crown with high index of refraction has hitherto been necessary, and this is still the case.

Herr Martin withdraws. He expressed himself incorrectly, but wished to say, with reference to the German patent specification 92,313, example No. 1, that anastigmats hitherto presupposed glass of the "new" Schott descriptions in general, instead of the new Baryta glasses. It is claimed that his anastigmat was the first computed with "old" varieties of glass.

This explanation is also beside the mark. In the first place, Herr Martin does not give any precise definition for the words "old and new," and it is not quite clear what should be understood by them.

For instance, the glasses used in example 1, Fig. 2, of the planar patent, No. 92,313, are not newer in a higher degree

than those used in the Martin anastigmat. In example 1 of the German patent specification No. 92,313, the following specimens of glass are used, and are thus described in Schott's catalogue:—

0.154.—Light silicate flint. Sold by other makers prior to Schott.

0.144.—Boro-silicate crown. Introduced by Schott in 1886.

0.608.—Crown with high dispersion. Introduced by Schott in 1888.

For the anastigmat by K. Martin, we have, according to the Austrian patent specification No. 8,364, 1902:—

0.802.—Boro-silicate crown. Introduced by Schott in "1892."

0.318.—Ordinary light flint. Made by other manufacturers prior to Schott.

If, by new glasses, those in general are understood, which Schott, since 1886, has placed at the disposal of opticians for the first time, it follows that Herr Martin has used a "new" glass of still more recent date than both the "new" glasses used in example 1 of the planar.

If, then, my colleague, Dr. von Rohr, says that the planar is a further example of the necessity of using the new Jena glasses for correction of Seidel's four aberrations of definition, it is evidently meant that the Baryta glasses are included in the "new" glasses, as this statement is made with reference to example 2, Fig. 3, patent No. 92,313, and not concerning example 1, of which alone I have spoken in reply to Herr Martin. To understand the words of Dr. von Rohr as meaning that an anastigmat could not be constructed with old varieties of glass implies an extraordinary faculty of imagination. The considerations put forward by Dr. von Rohr in the "Photographisches Central Blatt," vol. 6, No. 7, p. 146, refer to anastigmats of the doublet type, with halves consisting of two or more cemented elements, and Herr Martin has also recognised the necessity of glass with high refractive index and low dispersion for the construction of these. The objectives instanced by me in the communication to No. 14, vol. 23, of the "Central Zeitung für Optik und Mechanik,"* have, however, three and four components, separated from each other.

The reason why I have not utilised example No. 1 of patent No. 92,313, with its more limited means, as compared with example No. 2, must be clear to everyone who has not forgotten that the latter is four times more rapid than the former.

The aggressive remarks of Herr Martin also compel me to refer again to the relationship between the Clark lens, planar and Busch anastigmat.

Herr Martin has not been able to detract from my assertion that the Busch anastigmat does not differ materially from Clark's lens, excepting in the radii and thicknesses. He simply confines himself to the statement that the Busch anastigmat is better corrected for astigmatism. But if nothing more is done than carrying the correction of a lens a little further, what foundation is there for speaking of an epoch-making improvement? It is true that a well-known American firm ascribed extraordinary covering power to Clark's lens in their catalogue for 1890, and the same weight may be attached both to this and the analogous announcement of another firm of very recent date.

In making a comparison of the planar with Clark's lens, it will be seen that by its special means of achromatic correction, it has exceptional intensity, combined with particularly small residual errors of sphericity and astigmatism, and this is expressly emphasised in the patent specification No. 92,313. The planar claims a relative aperture of $f.3.6$, whilst Clark's lens

* See "British Journal of Photography," Aug. 1, 1902, p. 601.

has an aperture of $f.7.5$. The planar consequently has more than four times the rapidity of the Clark lens. The Busch anastigmat has the same aperture as the Clark lens, and Herr Martin has not exhibited a specimen yet with an aperture of $f.3.6$.

In the following examples the radii and thicknesses have been calculated proportionally, in such a manner that the three objectives are of the same value for r_1 (equivalent to r_1 of Clark's lens). It was impossible to correlate them to the same focus, as the data of the glass used in the Clark lens are not at my disposal, and the comparison would have suffered.

	Clark's Lens. U.S.P. 399499, 1889.	Planar. G.P. 92313. Example I.	Martin's Aust. Pat. 8364, 1902.
Radii	$r_1 = -2.4$	-2.4	-2.4
	$r_2 = -3.4$	-4.6	-4.56
	$r_3 = -6.3$	-33.3	-41.8
	$r_4 = -2.05$	-3.64	-3.6
Thicknesses	d 1, 2; unknown	0.66	0.65
	d 3, 4; unknown	0.81	0.61
	L 1, 2; perhaps 1.620	1.57	1.60
Kinds of glass	old	old	old
"D	L 3, 4; perhaps 1.510	1.51	1.49
	old	new	new

The radius r_3 , of the planar, which lies between r_2 and r_4 , is not given in these data. It has no perceptible effect upon chromatic correction, as affecting the goodness of the lens for ordinary purposes, since the spherical errors of the first order are not touched by it. The glasses cemented together at r_3 , are almost identical in their refractive indices (1.5116 and 1.5111), and therefore this contact has no perceptible refractive power.

All three objectives resemble each other in the form of the lenses of which they are constructed, as well as the order in which they are placed. The radii of the more recent planar and Busch anastigmat objectives differ from that of Clark's, but, on the other hand, the agreement between the former two in their radii and thicknesses strikes the eye immediately. The small difference in radii r_3 is explained by the fact of a small deviation in the difference between the refractive indices of the crown and flint glass used in these two objectives.

The improvement in the Clark lens, to which Herr Martin lays claim, was therefore already embodied in the planar, and the reason for my not having attached special value to it at the time is to be explained by the fact that a much more rapid lens than the Clark, with very small zones of spherical aberration, could be made by means of the peculiar method of chromatic correction and the use of the heavy Baryta Crown, referred to in the German patent specification No. 92,313, example 2.

The selection of the kinds of glass is left perfectly free in patent specification No. 92,313. They have only to comply with the conditions there laid down. If we refer to the catalogue of Schott and Gen for the purpose, we find a large number of suitable pairs of glass for the construction of a positive lens, with reduced chromatic error, in accordance with example 1 of the German patent No. 92,313, and amongst them some pairs composed of kinds of glass used before the year 1886. For example, we have:—

- 0.40, ordinary silicate crown.
- "D = 1.52, $n = 60.9$.
- 9 144 Chance Bros. soft crown.
- "D = 1.52, $n = 56.6$.

The only consequence of using this pair of glasses for L_2 , L_3 ,

in example 1 of the German patent No. 92,313, would be that radius r_3 , must have a stronger curve. In consequence of the refractive indices being the same, this has no effect upon spherical aberration. As an old variety of glass is used for L_1 , we should thus have a lens made of old kinds of glass, as defined above, if it were of consequence to attach any value to this incomprehensible condition. The collective lens, L_2 , L_3 , with diminished chromatic error, in example 1, German patent No. 92,313, is described by Herr Martin as a "hyperchromatic dispersive lens," and he thus gives us another drastic example of the thoroughness and reliability which characterise his remarks in No. 14 of this paper.*

The Taylor objective, without heavy Baryta Crown, to which I referred, has a relative aperture of $f.4$, and is consequently four times more rapid than the Busch anastigmat. Herr Martin is evidently not aware of the fact that the difficulty of obtaining anastigmatic flatness of field increases very rapidly with the relative aperture, for which the objective must be spherically corrected. So far as it may concern us, however, the degree to which definite correction has been accomplished is unimportant, as Herr Martin, so far as I am aware, has confined himself to general statement, and not given publicity, quantitatively, to any remarkable efficiency in his anastigmat. For all that, the Taylor lens referred to is very well corrected spherically, and has very good anastigmatic flatness of field up to an angle of 25 degrees.

I have only refuted the principal mistakes Herr Martin has made, and think this is quite sufficient to show that I have no reason to alter a single word of my remarks in No. 14, vol. 23, of the "Central Zeitung für Optik und Mechanik."

DR. P. RUDOLF, Jena.

MORE PERSONAL PARS AND NEWS NOTES.

Of course, I knew quite well that those sample Personal Pars would be a success, but still the electrical sensation which they created is none the less gratifying. Since they appeared I have mostly stayed indoors, but (with my usual temerity) I ventured to go to the R.P.S. soirée. Had it not been for the fiery false beard and green spectacles which I then wore, I think I should hardly have passed scatheless through the posse of notorieties who lay in wait for me beyond the turnstile. So effective, however, was my disguise that I was enabled to mingle with the throng uninjured, and had the pleasure of hearing—myself unnoticed—not a few comments on my own literary efforts. The tone of those comments (especially when they were made by personages referred to in the Personal Pars) left no room for doubt that the feature was the most successful which had appeared in any photographic journal for years past. Such being the case, I confidently take my pen in hand to write some more Personal Pars. (That any new ones could be more personal than the last is obviously impossible. But you all know what I mean.) So sit tight, and read on.

Of course, the absurd story which credits the design on the Salon plaques with being a compliment to the fair custodian of the gallery is wholly without foundation. This is only the second season of the desk-lady; not the tenth. Besides, Mr. Emanuel is above puns.

It is stated on good authority that the Linked Ring had to lay in a fresh store of red "sold" seals, Mr. Charles Job's picture, "Return of the Flock," having wholly used up the usual stock. By the way, so enormous were the sales at the Dudley Gallery that I am told that the lady who affixed the seals to the frames frequently went without lunch, the nourishment from the gummed side of the seals being sufficient for her wants.

* Vide "British Journal of Photography," Aug. 22, 1902, p. 672.

The wording of the invitation card to the Salon "smoker" was held in some quarters to be very significant: ". . . The Linked Ring will be at home at *their* photographic salon. . . ." and so on; which would seem to indicate that the said group of gentlemen desire no mistake to be made on the point of the ownership of the show. But they need have no fear. It certainly *is* theirs, and nobody else's. An inspection of the pictures would convince even the most sceptical that there is no mistaking the fact.

Further on, the card offered the inducement, "Smoking, and its usual accessories." What did this mean? Surely the Ring did not intend to provide such strong cigars that—? And could the "little music" mentioned next be a rude way of—? Banish the thought! Then did this obscure utterance refer to the sort of anecdotal conversation which is generally associated (in the vulgar mind) with the term "smoke-room?" Some experience of salon smokers places me in a position to absolutely negative both these repulsive theories. The "usual accessories" need never be feared—unless you've got a weak head and take a glass too much of them.

A rumour is going the rounds that there was some really good work at the Salon. Mr. Warburg and Mr. Bernard Moore are so far the only people who have seen it. A movement is on foot, I am glad to be able to say, to provide step ladders for the more average-sized members of the public.

The statement that the whole of the Linked Ring are going to start wearing Jaeger turn-down collars as a mode of expressing a delicate compliment, and, thanks to Mr. Bernard Shaw for his recent boom, is wholly without foundation. Nor is it true that Messrs. Cadby, Craigie, and Holland Day are about to open a studio in Bond Street under the name of Velasquez and Co

I was gratified to observe the same porter at the Camera Club two days running last week. This is surely a record length of time for that official to hold his post. I trust he received some testimonial in return for his constancy. Long periods of faithful service are too rare nowadays to be allowed to pass without due acknowledgment.

The Camera Club dining-room's renovation is now complete. The wall-paper meets with universal approbation. Several members have been overheard to remark that its severe straight-line pattern is—after dinner—an enormous improvement on the eye-irritating curls and leaves of the former paper.

I saw Mr. Harry Quilter at the R.P.S. soirée (I mean *the* Quilter of the "P.A.J.," not the mere art critic). He was conversing affably with all the leading lights of the photographic world. Behind his smiling face, however, was hidden quite a quantity of carking care. The tightness of money at the present moment and the criminal indifference of the public to the advantages offered by a certain company prospectus are heavy loads for any editor-cum-financier to bear. It is pleasant to be able to record, however, that somebody has at last begun to advertise in the "aesthetique" little paper, with the result that the "This space £2 10s." gaps have visibly diminished. Long may our friend H. Q.'s pen continue to dip in his poetic inkpot!

Dr. Grün's attempts to colour-snap the entertainment at a certain well-known music hall have been crowned with success, notwithstanding all difficulties. His three-colour process worked excellently, in spite of the fact that (owing to the nature of the subjects) blue predominated.

It is untrue that Mr. Cruwys Richards has disposed of his picture, "Anticipation," to a well-known firm of shaving soap makers. The charming old personage in the print is a lady—and not Barnum's bearded lady—so the notion that she is feeling the stubble on her chin in anticipation of its removal is quite off the mark.

To judge by the afore-mentioned run on Mr. Job's "Flock" picture, mutton is in demand at present. American meat, however, does not

seem to be finding a very ready purchase. Mr. Steichen may take *his sheep* to the market, but he cannot make them sell. At least, up to the time of writing, the red badge of courage had not yet blossomed on his frame. But perhaps a buyer has been awarded it for his temerity.

It has been suggested (and the idea is one well worth serious consideration) that a "fruit and fish" section should be inaugurated at next year's R.P.S. show, for the benefit of the Mattos Chemical Company. Mr. Bernard Shaw, who admired the said company's pictorial exhibits so much, would no doubt show his approval by taking a season ticket.

Mr. Warburg, I hear on good authority, has had the nib of his fountain pen renewed.

Dropping into a Strand A.B.C. shop recently, I discovered Mr. Snowden Ward and Mr. Brown indulging in the luxury of tea and a boiled egg apiece. They explained their conduct by stating that Mr. Robert Barr had bought the *Idler*. Congratulations to all parties concerned. I understand this is the first time anybody has bought the magazine in question since —. But Fleet Street gossip is out of place in a *causerie* such as this. Besides, those boiled eggs give the lie to all stammerous tales.

Mr. A. L. Henderson is on the wing again. This time his destination is Egypt. Three steamers have been chartered to take his cameras, lenses, and plates to the land of the Pharaohs. I hear a rumour that the keeper of the Mena House Hotel has refused to allow Mr. Henderson to stack his negatives in the neighbourhood, on the ground that they would dwarf the Pyramid.

Mr. Sandell, I am told, was horrified to find the other day that the shutter of his hand camera was open. The camera had evidently lain on his laboratory shelf in this condition for quite three weeks. Fortunately, however, one of the eminent inventor's own films was in the front carrier, and on development yielded a negative, showing less traces of over-exposure than some one-twentieth sec. snapshots taken on accompanying films in the same apartment.

The new Kodak daylight developing machine has had a large sale, and is, I understand, in use in nearly every photographic household's kitchen. As a blancmange shape it is unrivalled—so the wife of an eminent amateur tells me. Universal application is always the sign of a truly great invention.

Carping critics whisper that the celebrated writer in a contemporary on the use of a certain portrait lens for landscape work was ill-advised to entitle his effusion "Photography in a Wood," or, at any rate, ought not to have given tongue till he was out of it.

The exceedingly moderate price placed by Mrs. Carine Cadby upon her charming nasturtium leaf print at the Salon has attracted considerable attention. Envious personages have hinted that it is this moderation which has caused the work of art's large sale. Whether this is true or not, will be proved next year, for Mrs. Cadby is going to charge 7s. 6d. per leaf for her studies, and not 5s., as heretofore. Twigs will be counted as "leaves," but pine-needles will be reckoned per dozen.

Apropos of this, a circular has recently fallen into my hands advertising—in advance—the appearance of a volume, entitled "Dogs and a Doggerel," by the famed leaf-study lady, and her no less famed portraitist husband. The testimonials to their photographic efficiency, which accompany the prospectus, are weighty, both in number and matter. The *Sunday Times*, for September 27th, 1896, remarks (I notice) that "both these artists know how to coat a plate with brains." Comment is needless. If Mr. and Mrs. Cadby were already coating plates with brains as long ago as 1896, their stock of that all too rare commodity must be extraordinarily unexhaustible—even for Links.

. . . . Several persons armed with clubs are making such a noise

outside my house that I must stop writing. I shall go out for a walk (by the back door). In the meantime, au revoir from

SOLOMON SAGE.

Exhibition.

DONCASTER.

On Wednesday, the 29th ult., a photographic exhibition, promoted by the Wheatley Photographic Society, was opened by Mr. F. W. Fison, M.P., in the Dolphin Chambers, Doncaster. The show included pictures from all parts of the country, sixteen silver and bronze medals being awarded, the judges being Mr. Percy Lund, of the "Practical Photographer" and "Junior Photographer," and Mr. W. E. Tindall, R.B.A., of Leeds.

In opening the exhibition, Mr. Fison claimed acquaintance as a very old photographer, and said he had spent many happy years in the pursuit of the art. He related some interesting reminiscences of a journey made from the Baltic to Norway in the early days of photography, and remarked incidentally that he was the first Englishman to photograph those views of Norway with which they were all so familiar. He actually published the first series of lantern slides of Norway, and he believed there were some of them still on the market—no doubt being shown in some obscure out of the way place. Proceeding, he remarked on the spoliation of natural beauty and stated that the time would come when a man who possessed a beautiful estate and trees and pretty surroundings would not be allowed to cut them down and erect in their place telegraph and electric wire poles, but would have to show some respect for natural configuration of the landscape.

The following is the result of the adjudicator's awards:—Landscape and seascape (open): Silver medal, G. Whitehouse, Birmingham; bronze medal, A. D. Elliott, Ripon. Portraiture: L. A. Edmonds, Menston-in-Wharfedale, silver medal; E. W. Strong, Shipley, bronze medal. Architecture: W. R. Lathbury, Bristol, silver medal; F. J. Phillips, Brighton, bronze medal. Enlargements: E. Seymour, Watford, bronze medal. Champion class: Greystone Bird, Bath, silver gilt medal; Charles E. Walmsley, Ambleside, silver medal. Members only: J. Brooks, Doncaster, silver medal; Dr. F. B. Cormick, Wheatley, bronze medal; J. B. Beck, Doncaster, certificate.

New Books.

"Elementary Photo-micrography." By Walter Bagshaw. London: Iliffe and Sons. Illustrated. Price 1s.

If the term "elementary" applied to an instruction book can be taken to mean that the book contains just the information required by any one taking up the pursuit with which it deals for the first time, and put in the clearest language, we are bound to say that the little work under notice is not entirely satisfactory. There is evidence in its pages that the author is practically acquainted with the subject upon which he treats, and, as far as it goes, his advice appears sound; but he is evidently wanting in a faculty essential in a teacher—that of placing himself in the position occupied by the learner, and stating the facts of the subject in the sequence it is necessary to follow in order that their significance may be grasped by a fallow mind. About one-third of the book is devoted to photographic information which does not specially bear upon photo-micrography, but covers a wide field, including development, fixing, hypo. eliminators, storing negatives, clearing solutions, pinholes, intensification, reduction, printing in P.O.P., toning, the combined bath, bromide printing, platinum printing, spotting prints, albums, lantern slide making, etc. This is a wide range of subjects to attempt to treat usefully in a few pages, and the author would have done better by devoting the space to matters strictly germane to the subject, and referring his readers to the ordinary text-books for matters purely photographic.

Mr. J. T. SANDELL informs us that he has no longer any connection with Sandell Films and Plates, Ltd. His present address is 16, Whitworth Road, South Norwood, S.W. He is shortly placing a Sandell celluloid film on the market, in addition to Sandell plates.

The following advertisement was published in the "Times," this week:—"To Artists or Photographers.—The late Colonel de Cetto, late of Byculla, Norwood, is believed some years ago to have sent a portrait of his late father, Baron de Cetto, of 6, Hill Street, Berkeley Square, to some artist or photographer in London for the purpose of being copied. Any one having in his possession, or any knowledge of, the portrait is requested to communicate with Messrs. Walker, Martineau, and Co., 36, Theobald's Road, Gray's Inn, W.C."

New Apparatus, &c.

The Westendorp and Wehner Orthochromatic Plates. Manufactured by Westendorp and Wehner Actiengesellschaft, Cologne.

We have received a sample of these plates for trial from the manufacturers, who are now placing them upon the British market. As they are advertised for use without a yellow screen, we tested them in this manner, using flowers and various other coloured objects. We found very perceptible colour-sensitiveness for yellow, and likewise some for red, but we were more particularly struck by the subdued rendering of various shades of blue, and in this respect the plates stand in marked contrast with the ordinary photographic plate used for landscape purposes. Their green and yellow sensitiveness should make them specially valuable for this class of work. The plates are well coated with a liberal supply of emulsion. The speed is rapid and the grain remarkably fine. We used rodinal for the development, and obtained good density and gradation, with excellent printing quality.

The M. Q. Developers. Manufactured and sold by John J. Griffin and Sons, Limited, 20—26, Sardinia Street, Lincoln's Inn Fields, W.C.

Messrs. Griffin write: "We wish to draw your attention to a new line we have introduced in connection with the 'M. Q.' developer. We are now putting up three 'M. Q.' cartons in a neat and convenient box, selling at the popular price of 1s. We believe this will meet with favour amongst many of your readers who already know this developer, and will

no doubt be glad to have it in a more convenient form. We would take this opportunity of saying that owing to the many imitations of 'M. Q.' developers, some of our competitors even using the letters 'M. Q.' in a similar prominent manner to ourselves, we must warn our purchasers to look for our trade mark 'Gramme Standard,' on all boxes and packets, which alone designates the genuine article."

City and Guilds of London Institute.—The report of the department of technology in the City and Guilds of London Institute has been issued. In the different branches of technology the number of classes registered by the institute has increased from 2,222 to 2,320, and the number of students in attendance from 34,246 to 36,189. In the normal classes for manual training teachers the number of students has increased from 1,767 to 1,908. The total number of candidates for examination in Great Britain and Ireland was 16,580, showing an increase of 1,023 on the number presented in 1901. During the last ten years, particularly since the institute ceased to make payment on results, the volume of the work of the department has very much increased, and its scope has been enlarged. Besides the examination of candidates in different branches of technology, in manual training, and in domestic economy, the work includes the preparation of schemes of instruction, the registration of teachers, and the inspection of schools. The name of the department has accordingly been changed from the examinations department to the department of technology, as corresponding better with the character of the work undertaken by this branch of the institute. In their report of last year the committee referred to the appointment of a departmental committee by the then President of the Board of Education for co-ordinating the technological work to be undertaken by the Board with that conducted by the institute and other bodies. This year's report shows the relations that have been established between the Board of Education and the Institute for the Direction of Technological Instruction. As it was considered important that an effort should be made to strengthen the Board of Education as the central authority for all kinds of education, the institute desired to establish close relations with the Board, so that the work it had carried on for nearly 25 years might be brought under the aegis of the Board. From the report it can be seen that the Board of Education is now directly represented on the examination board, which is really the advisory committee of the department, and, failing the absolute transfer of the work of this department to the Board of Education, the arrangements agreed upon—which are set out fully in this report—are deemed satisfactory. From a letter from Sir Henry Craik, also given in the report, it appears that similar arrangements have been made with the Scotch Education Department, and from other papers that the institute is working in close relation with the Irish Department of Agriculture and Technical Instruction.

Commercial & Legal Intelligence

NOTICE of Removal.—Mr. J. L. Cox, wholesale photographic dealer, writes: Kindly note that on and after November 6th, my address will be Leda, Lawton Road, Heaton Chapel, near Stockport.

SYDNEY Photographers and Competition.—Competition is not always "the life of trade," as some would have us vainly believe; too frequently it is the death of all that is good and worth having. Fair and honest rivalry is helpful and acts as a stimulant, but what we know by competition nowadays means, not "the survival of the fittest," but rather "down with the other man at all costs." Competition has come to mean under-selling, and under-selling means loss and ruin. A good article and a fair charge suits all parties, whereas an indifferent article and a low price suits nobody. The public are prepared to pay a reasonable charge for good value, but they are not prepared to give more for a dozen pictures at the A studio if they can get the same number of equally good pictures at the B studio 25 per cent. cheaper. The public have not asked for this reduction. Then, does it not seem folly for the studios to adopt a policy which eventually must bring disaster to the profession? For years past we have been sorry to notice an increasing tendency with some photographers to cut down prices so low that the margin of profit is invisible. We are led to wonder how the establishment can be maintained. The photographer has to bring ability and training and artistic taste into his profession—he has to be up-to-date in all matters photographic. He has closely to watch the popular tastes—his studio has at all times to be a place of attraction, and he himself must be a man of many parts to win favour with his customers. Any appearance of niggardliness in the studio surroundings is soon detected by his visitors and he suffers loss. He cannot afford to get behind the times—he must keep well in step or go down. All this means expenditure, and his profits, consequently, must be such as to enable him to keep well in the front at all hazards. Not many days ago a meeting was convened by circular, and presided over by Mr. J. J. Rouse, of the firm of Baker and Rouse Proprietary, Ltd., at which all the leading photographers of Sydney were present. This meeting was called to consider the present outlook, and to take such steps as the meeting might decide to improve the status of the profession. All present manifested a deep interest in the questions discussed, and, after several adjournments, a resolution was submitted to the effect that "a combine" or "trust" should be formed. This proposition was well and thoroughly discussed from every standpoint. It was eventually decided not to take any action for the present, but wait for further developments. The majority evidently were in favour of a combine of some kind that the profession might be brought into closer touch and a better understanding among the studios established. The unmistakeable good feeling that pervaded the deliberations gives promise for a better condition of things than has hitherto existed.—"The Australasian Photographic Review."

A CORRESPONDENT writes:—In your article last week "Gleanings from Old London Directories," you ask if the John Browning, spectroscope maker, of the Strand, was related to the Browning, of Spence, Browning. He was son. The firm's last place of business was in the Minories. Goddard, the optician, was a workman of theirs at that time. He afterwards commenced business for himself at "Jesse Cottage," Isleworth, where I once visited him. Mr. Taylor had several lenses made by Goddard which he thought very much of. I have myself got two telescope lenses of his, and a pair of stereo-photographic lenses, six inches.

ROYAL Institution.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon (the 3rd inst.), Sir James Crichton-Browne, treasurer and vice-president, in the chair. The following were elected members: Mr. G. H. Baillie, Mr. W. D. Butcher, Mrs. A. R. Cox, Sir Archibald Campbell Lavrie, Mr. G. J. Morrison, and Mr. A. B. Tubini. The special thanks of the members were returned to Sir Andrew Noble, Bart., K.C.B., F.R.S., for his donation of £150, and to Dr. Ludwig Mond, F.R.S., for his donation of £200, to the fund for the promotion of experimental research at low temperatures.

ARTISTIC Copyright.—A meeting of artists and others interested in artistic copyright was held last week at 39b, Old Bond Street, for the purpose of considering a proposal to form a society for the protection of British artistic copyright at home, in the Colonies, and abroad. Mr. G. W. Agnew presided, and there was a good attendance. At the outset it was determined that the proceedings should be conducted in private. The circular convening the meeting bore the following names:—G. Agnew, L. Agnew, E. Bale, F. Bale, Sir Wyke Bayliss, G. Clausen, A. Clay, F. Dicksee, W. Dowdeswell, J. Farquharson, A.R.A., L. Fildes, R.A., A. Graves, J. F. Grundy, E. B. Haynes, J. MacWhirter, W. Q. Orchardson, J. B. Pratt, Sir W. B. Richmond, H. Scott-Bridgewater, Sir L. Alma-Tadema, D. Croal Thomson, and A. Tooth. The circular stated that it was being increasingly felt, in view of the constantly-expanding commercial value of artistic copyrights, that it was necessary to take active steps to form a society to afford protection to artists, collectors, publishers, and other owners of such copyrights. The success of the recent Act of Parliament controlling piracies of music emphasised what was possible to be done for artistic copyright by united and persistent action. Some months ago a society was formed for the protection of British fine art in the Colonies, but it was now recognised that the scope of this society was too limited to carry the general interest necessary to a successful movement. It was, therefore, to be proposed at the meeting to reconstruct this society and to enlarge it to one which might become of permanent utility.—"The Times."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Nov.	Name of Society.	Subject.
7.....	Leicester Literary	{ <i>Some Beauty Spots in the Isle of Man.</i> Mr. Walter Keig.
7.....	Borough Polytechnic.....	{ <i>Enlarging on Bromide Paper.</i> Mr. F. W. Bannister.
10.....	Oxford Camera Club	{ <i>How Photography was Discovered.</i> Mr. G. E. Brown. Illustrated with Slides.
10.....	Southampton Camera Club.....	{ The Exhibition Lantern Slides.
11.....	Leeds Photographic Society ...	{ <i>A Tour Round an Old Garden.</i> Mr. Alex. Keighley, F.R.P.S.
11.....	Wolverhampton Photographic	{ Lantern Evening. <i>Irish Slides.</i> With Descriptive Lecture. Mr. A. Eaton Painter.
11.....	Royal Photographic	{ Ordinary meeting. A paper will be read by Mr. Thomas K. Grant.
12.....	Croydon Camera Club	{ <i>A Popular Explanation and Demonstration of the Photographic Half-tone Process.</i> Mr. J. J. Waddington.
12.....	Leeds Camera Club	{ <i>The Dales and Coast of Yorkshire.</i> Mr. Godfrey Bingley.
12.....	Borough Polytechnic.....	{ <i>English Chapter Houses.</i> Mr. E. W. Harvey Piper.
12.....	North Middlesex Photographic	{ <i>Errors.</i> Mr. Chapman Jones, F.I.C. F.C.S., F.R.P.S.
12.....	Nottingham Camera Club	{ <i>A Simple Demonstration in the Development of Gum Bichromate Prints.</i> Mr. J. Page Croft (Birmingham).
12.....	Southport Photo. Society	{ Members' Lantern Night.
12.....	Photographic Club	{ <i>How a Lens is Made.</i> Mr. C. P. Goerz.
13.....	London and Provincial	{ <i>Collotype for Amateurs.</i> Mr. W. T. Wilkinson.
13.....	N.-W. London Photo. Society	{ Fireside Chat Upon Exposure, Development, and Retouching with Demonstrations. The President.
13.....	Goldsmiths' Institute Photo....	{ <i>Griffith's To the After-Supper Photographer.</i>
13.....	Liverpool Amateur Photo.	{ <i>The Focal Plane Shutter.</i> Illustrated. Mr. Eustace F. Wallis.

ROYAL PHOTOGRAPHIC SOCIETY.

TECHNICAL Meeting, October 28th.—Mr. Furley Lewis in the chair. Mr. Henry E. Davis exhibited and presented to the society a model of an ingenious little camera, constructed in the days when secret cameras, such as those in the scarf, the hat, and so forth, were in vogue. The designer was one Brin, but it appeared that he abandoned the patent. The plate used would be about the size of a florin. There was also an attachment which made a small telescope of the apparatus. The shutter was very cleverly contrived, and very simple. The curves of the trigger or handle corresponded with the curves on a fixed arm which, directly the lens was fully uncovered, carried the finger off the trigger, and so released the shutter without jar.

THE SINOP COLLOTYPE PROCESS.

Mr. William Gamble gave a demonstration of this variation of the collotype process proper, a variation which has claimed for it greater simplicity and reliability in working, with much saving of time. Mr. Gamble detailed for the sake of comparison the process known as collotype, which we will not enter into here, and then described the essential differences between it and Sinop. This name signifies nothing, and is a coined word to distinguish the process from any other. The tedious operations associated with collotype are largely overcome in Sinop. The prepared plates can be obtained commercially, and the apparatus or plant is of the simplest and cheapest description. The principle of the collotype process—that of the attraction and repulsion of printing ink by the gelatine image according to the varying degrees of its solubility when printed under a negative—is retained in the new process, but a new method of preparing the gelatine plate gives to it a much longer life in the sensitised state, and a much more durable printing surface. Briefly described, the operations are these: The special plate is exposed for some two to ten minutes under a negative, washed in water for ten minutes, drained, and soaked in glycerine for a quarter of an hour; the surplus moisture blotted off; the plate is attached to a printing bed, inked up with a printer's roller, and printed by means of an ordinary office letter-copying press. The process lends itself very well indeed to the production of illustrated postcards, Christmas and other cards, memo. and letter headings, and prints can be taken on paper, cardboard, silk, satin, leather, celluloid, etc. The three-colour process may also be applied to this printing method. The Sinop plate, with its image, may be stored for any length of time, and quickly prepared again for the printing of further copies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

OCTOBER 30TH.—Mr. J. E. Hodd in the chair. In drawing attention to the number of makes of P.O.P. now on the market, Mr. S. H. Fry passed round strips of seven different kinds, obtained commercially, which had all been printed from the same negative—they had all received identically the same treatment throughout, and there was extraordinarily little difference between them, and Mr. Fry had found practically no difference in the speed or in the working. Mr. W. Thomas gave a paper on "Suggestions." Touching on the subject of the Exhibitions and their use, it was pointed out that some of the

exhibits show us what to avoid, whilst others what to come up to. Mr. Thomas thought that what was really wanted was more study and retirement for work, with less rushing to the Exhibition walls. In regard to the selection of pictures to be hung, it was suggested that a quicker way, and a way that would do justice to everybody in this matter, would be for a select committee, previous to the final decision, to go through the various pictures, and classify each, according to its subject—all architecture in one pile, landscapes in another, portraits in another, and so on, then when the time came each pile could be taken and the similar subjects judged together. A picture of the interior of a cathedral cannot be judged alongside a portrait! whereas a portrait can be judged against a portrait, and in this way the cream of each set of subjects would find their way to the walls. Another matter of great importance is the effort of late years to decorate the walls by means of canvas, or coloured hangings, which do not harmonise with certain framing, and against these changes of decorations exhibitors have no chance whatever, and Mr. Thomas thought that exhibitors had a distinct right to receive previous notice of what colour the walls are intended to be. Passing on to individual work as a member of any society, it was suggested that one of the weakest points as applied to pictorial work is the untruthful rendering of colour value or tones, and to remedy this Mr. Thomas proposed that a monochrome or black and white drawing or painting should be made by a competent artist of some well-known local view, and then by photographic means and processes members could strive to obtain a like effect, as by this means a much fuller understanding of the meaning of colour values could be arrived at. Another useful suggestion to improve the work in societies was to have a standard negative, and from this have made by a first-class photographer an enlargement or print in bromide, and then loan out the negative for members to try and get as near a result as possible to the standard enlargement. Again, instead of wasting time on lantern lectures, or discussions as to the length of time one can use somebody's patent developers, why not set apart certain evenings for the reading of chapters from some standard work on pure photography, such as Abney's, which could then be discussed, and younger members of an association would in this way have a chance of learning something of practical advantage.

Mr. Thomas then showed several results of experiments in orthochromatic photography, showing very clearly how useful colour-sensitive plates really are, and concluded his remarks by showing on the screen reproductions from paintings of well-known artists, illustrating the arrangement of light and shade, and quoting the following rules by Clifton to the effect that: Shade defines form; every cloud is divided by light and shade; different shades express different distances or planes, and different planes express different shades and colours.

Mr. Teape proposed a very hearty vote of thanks to Mr. Thomas, which was seconded by Mr. A. Mackie and carried unanimously.

PHOTOGRAPHIC CLUB.

ON October 29th, Mr. L. Medland in the chair, a lecture lent by the "Photogram" was read by Mr. G. E. Brown, in the absence, through illness, of Mr. H. Snowden Ward.

The lecture was illustrated by some of Mr. Walter Kilbey's photographs of divers, jumping, etc., taken with the focal plane shutter in 1-1000sec. Then some flash-light exposures in a Cornish tin-mine; some of the Embankment and Leicester Square taken on a wet night with an exposure of an hour or so, and others taken in the theatre instantaneously by Dr. Grun with his fluid lens. Some of Mr. Reinhold Thiele's combination pictures of London as Venice, etc., were shown. Telephotography and colour photography examples brought the lecture to a close. A few slides by Mr. Wallis of Suffolk cottages and scenes were afterwards put through the lantern. Votes of thanks to, and condolence with Mr. H. Snowden Ward and Mr. Brown were passed unanimously.

CAMERA CLUB.

LAST week's lecture was by Mr. C. E. Keyser, a fellow of the Society of Antiquaries, who took for his subject "Norman Tympana." Possibly there may be many who have not dived sufficiently deeply into architectural terms to know the meaning of the word tympanum as applied to buildings, usually associated in their minds with a drum head, or with their own auditory apparatus. Be it known then, for their exclusive benefit, and not for the information of clever people who know everything that is to be known, that a tympan, or tympanum, is understood by architects to mean the semi-circular area, very often consisting of a single stone resting upon the lintel, which surmounts the doorway in many buildings. This tympanum is often richly ornamented with sculptures, and they may be found by those who care to search for them in many of the churches which are dotted about the hills and vales of England in rich profusion.

Mr. Keyser undertook, in the course of a couple of hours, to take his hearers tympanum hunting, and to show them, in the form of lantern slides, more than 200 examples which he had collected. He made a needless apology for the quality of some of the photographs, and explained that he was not himself a photographer, but had had to employ others to do the camera work for him. But he could appreciate the difficulties with which a photographer had to contend in dealing with these carvings, which were often situated in dark porches and other places difficult to get at. He did not hesitate to say that photographing tympana was one of the most difficult tasks that anyone could take up; but at the same time he must confess that the work was replete with interest.

These tympana belonged chiefly to the 12th century, and many of the examples represented a single stone covered with ornamental designs. He would begin with the most simple form of such ornament, and would show later on how elaborate carving gradually superseded mere incised

patterns. In the simplest forms of tympana it would be found that patterns were produced by the placing of stones diamond-wise, by covering a surface with small holes, by stars, or by bosses of rose form. A zig-zag pattern was very common, and small square panels, with perhaps a knob in the centre of each, were often met with. A fish-scale design, consisting of overlapping scallops, was also not uncommon, and had probably a Scandinavian origin. Various examples of these different patterns were shown on the screen in quick succession, and if a fault could be found with them it could only be in their superabundance. It would have been, perhaps, better if fewer pictures had been exhibited and a little more time devoted to the consideration of each. Much of the ornamentation was of a symbolical character, and many of these tympana were at the same time dedication stones, as was evidenced by the inscriptions which they bore. The lecturer was of the opinion that many of these stones served at one time as samples, or patterns, cut by a master hand for the guidance of inferior workers, and that subsequently they were incorporated into the buildings.

In most of the English Counties churches were to be found which afforded examples of these tympana, but there were exceptions to the rule. Thus in Norfolk he had not been able to discover a single specimen. In Gloucestershire, on the other hand, there were more examples than in any other county, while a great number occurred in Herefordshire.

Some of the sculptured figures of men and animals were of the rudest character, and one often had to guess at the genus of the creature represented. These quaint beings were generally shown doing homage to the cross, while the figure of Sargitarus, half man and half horse, St. George, or St. Michael and the Dragon, were very favourite subjects for the sculptor's art. A whole series of these tympana exhibited a tree as their chief feature, possibly emblematical of the tree of spiritual life and knowledge. Strange birds roosted in the branches, and griffins, dragons, and other fabulous monsters were shown devouring the fruit which grew there. At a later date, familiar bible stories were illustrated on these curious stones, and examples were shown of the episode of Elisha and the she bears, of the sacrifice of Isaac by Abraham, etc. In other cases the artist had been content to fill the space at his disposal with dragons, griffins, and other fearful wildfowl, which were perhaps intended to have a deterrent effect upon evil doers. Hunting scenes were not uncommon, and the frequent introduction into these compositions of the figure of a wild boar was probably due to the circumstance that at the time the animal was a familiar object in the adjacent woods. One curious example showed a boar and other animals taken by an abbot to do homage to the Agnus Dei, and in another a mermaid formed the principal figure. Another series of pictures were of New Testament subjects, the figure of Christ, or of the Virgin and Child, forming the centre piece.

Mr. Keyser had to leave rather hurriedly for another engagement, but before he went he expressed the hope that his paper would be productive of some discussion, and if any suggestions were made as to the meaning of some of these sculptures, which were rather obscure, he would be only too pleased to hear about it. He himself preferred a simple and straightforward interpretation rather than one which was strained and laboured.

Mr. Inwards said that it had struck him in looking at these pictures that a great many of the carved stones must have originally formed part of older buildings, and had later on been placed where they now were. They marked the time when superstition was being superseded by the teachings of Christianity. Some of the ruder sculptures recalled to his mind the roughly-wrought lions on the gate at Mycæne. He could not help remarking upon the vast amount of labour which the collection of these pictures must have entailed, and he quite envied the power of a memory which could retain so many names of churches and villages.

Mr. Lambert called special attention to one of the tympana shown, which he himself had photographed, and he gave an interesting description of the carvings thereon, and their interpretation.

Mr. Middleton, who occupied the chair, pointed out that these tympana were by no means peculiar to Britain, but were found in France of an even earlier date. They were probably introduced here by the Normans, although some were undoubtedly pre-Norman, and resembled in their execution the crude efforts of childhood. Those present would note that the earlier work is all incised; of the later work some is incised and some in relief. All work in relief is late, for the early workers did not know the use of the chisel. He was inclined to endorse the lecturer's opinion with regard to the use by the early workers of sample or pattern stones, for it was remarkable how the use of any particular design quickly spread over a large area, just as if they came from a common source. There were two distinct classes of ornament shown in the later examples, the one of Scandinavian origin and the other Roman. The Roman work would have been introduced here by masons from France and from the Rhine, where it is common.

WEST LONDON PHOTOGRAPHIC SOCIETY.

THE following is an abstract of the presidential address read before the Society on October 24th, 1902:—

What I would wish to impress most strongly on you is the importance of having some definite aim and keeping it steadily in view. If we spread our energies over too wide a range of subjects we shall not attain eminence in any of them, and the result will be a dead level of mediocrity. Most, if not all, of us have only a small amount of leisure that we can devote to photography, and it therefore behoves us to so utilise it as to obtain the greatest amount of satisfaction to ourselves. Now, this we shall never do if we take every interesting subject we come across, for there will be no time to do them justice, and the result will be a mass of prints, few, if any, of which reach the higher plane, and the contemplation of which leads to that feeling of dissatisfaction that so frequently ends in giving up photography altogether. One print of the

highest class is worth a thousand second-rate ones; and is a source of perennial pleasure and a stimulus to future work. Study and experiment are necessary to success in any class of subject, and I would suggest that you think out carefully in what class of photographic work your interest principally lies, and then concentrate all your energies upon it. To the great majority the pictorial side no doubt appeals most strongly; with some in portraiture or figure subjects, some in floral studies, and by far the larger number in landscape in its various forms. Now, in the latter the variety is far too great for anyone to successfully cover the whole, and that class of subject should be chosen which appeals most strongly to you. I may instance as distinct classes, mountain, woodland, river, moorland, fen and marsh, and marine, and one of these should be chosen and worked at until proficiency is attained. When you consider that a painter who devotes his whole time to his art and has been specially trained during the most susceptible years of youth, yet finds it necessary to limit himself to a certain class of subject, how is it possible to suppose that we who can only give a very limited amount of time can succeed in covering a wider range? Looking at the technical side alone, and considering that the development that will give the best results for any one of the kinds of subjects I have named differs for each of them, it is clear that the man who continually changes from one class of subject to another cannot expect to obtain such good results as he who confines himself to one. I know we are told that automatic development will give as good results as can be obtained by varying the developer with each subject, and no doubt it would if the exposure for all parts of the subject were the same, but in landscape work all exposure is a compromise, and therefore the development must also be a compromise, and must be adapted to suit the result we wish to obtain. Dwellers in London, and more especially in this part of it, enjoy almost unique advantages in the variety of subjects within easy reach, and I would strongly recommend to the novice, as the most satisfactory artistic training, that he should carefully select some subject that is easy of access to him, and set himself to carefully study it from all points of view and under all conditions of lighting, varying the exposure and development, printing from all the negatives, however bad they look, and taking prints on different kinds of paper and in different colours. Keep all the results, good or bad—particularly the latter. Make full and careful notes of every detail of exposure and development, then compare the results and think out why one is more pleasing than another. Test any ideas that may occur to you, and try if you can improve your results still further. Some will be better in one part than another, one perhaps in grouping, another in lighting, some more harmonious than others in relative subordination of the various parts to the whole. In some parts of the subject the details may be too pronounced, in others they may require accentuation, and attempts should be made to modify them. Familiarity with the subject will enable us to appreciate minute differences which otherwise would be almost certain to escape detection, and which are yet vital to the result. The difference between mediocrity and works of the greatest beauty is most often an aggregation, more or less extensive, of such minute differences. The way may be long and hard, and failures many, and success only attained after many struggles, but the pleasure resulting from such success will be in exact ratio to the difficulties of achievement. That you will succeed if you devote sufficient energy to it is certain, for in every man there is the germ of that artistic faculty which only needs proper cultivation to develop it. With some men it may be more easily developed than in others, owing to hereditary tendency; but that it is inherent in the human race is obvious to anyone who has studied the early history of man.

SOUTHAMPTON CAMERA CLUB.

THE members of the above club held a meeting on the 27th October, when Mr. G. Vivian presided. The chairman introduced Mr. F. C. Wardall (representative of Messrs. G. Houghton and Son), who gave a very entertaining lecture and demonstration on "The Possibilities of a Modern Camera." He ably described the many virtues and capabilities of the Sanderson camera, and fully satisfied the members of its great value as a photographic apparatus of the highest degree. The subject of telephotography was profusely enlarged on, and most valuable black-board sketches of a scientific nature, as to the construction of various lenses, were made; and the lecturer exemplified to the entire satisfaction of all, and with telling effect with numerous lantern slides, the great value of the use of the telephoto lens, and also the great advantage accruing from the use of the screen. Mr. Wardall was accorded a hearty vote of thanks for his most scientific and instructive discourse.

LEEDS CAMERA CLUB.

THE advisability of a change of quarters was strikingly demonstrated on Wednesday evening, October the 29th, when an audience of upwards of 100 attended at the rooms of the above club, Athenæum Buildings, Park Lane, to hear a lecture on "The Motor Car as an aid to Photography on various Tours," by that racy humorist, Mr. George Thistlethwaite, being one of the series of lectures promoted by the Yorkshire Photographic Union.

The president of the club, Mr. Charles B. Howdill, was in the chair, and in opening the proceedings stated that he disagreed with those people who held views that only matters purely photographic should find room on the club syllabus. A lecture of this character gave members an opportunity of asking ladies to join them and they would learn in that night what photography could do for them in knocking about the great county of Yorkshire. Mr. Thistlethwaite commenced by remarking that his first motor car had only two speeds, and in hilly country he had very often to get out and push the machine, which proved of little use to him in the country round Wharfedale, which was his "happy hunting ground." He might say, en passant, that he spent a good deal of time reading up

the subject, and fancied he knew a great deal of engineering, electricity, and gas engines, for a petrol motor car, which he favoured, was more or less worked simply on the gas engine principle; but he found with all these qualifications he had a lot to learn, and was learning still. He afterwards experimented a great deal on a 2½ motor, driven with a belt on the back wheel, and had three or four engines roughly knocked together, but as he humorously remarked, bits of the machine were constantly dropping off; and when you began motoring, why "rates" were nothing to the expense of a motor car. Finally he adopted a solid tyre motor car, which pleased him very well and had carried him some 3,000 miles so far, and he had no hesitation in setting off anywhere on a motor of this character. A car was very convenient for carrying photographic apparatus, and would be also useful for a geologist in taking home his specimens. That reminded him of a story that was told him when staying at Hawes. A certain Cambridge professor tarrying there for a fortnight geologizing, had gathered a fairly large stock of specimens of stones in this limestone district, and secured the services of a native to take them to the station. Unlike the Americans, there is no "hustle" in the native round Hawes, and when he was safely round the corner he got rid of them, filling up his sack again at a convenient spot near the station. The trip he would now take them began at the Manningham Park gateway, Bradford, through the Dales into Wharfedale, via, Bierley, Guiseley, Burnsall, to Linton, and covered the most pleasant part of the country; thence to Kettlewell, Hawes Arcrigg, down to Wensley, and after a stay there, back to Bradford.

The lecture was illustrated by numerous slides, elucidating various remarkable and exciting incidents of the tour, and showing most things of a topographical interest on the way, whilst the lecturer amused his audience in a racy and satirical manner with anecdotes, of which he had a plentiful stock. One of them will suffice, viz., the relation of an incident said to have happened in Barden church. During the temporary absence of the vicar, a budding and ambitious young man was left in charge of the parishioners, and took for his text on the Sunday "I am the light of the world." On entering the pulpit his nervousness left him without any recollection of the well-planned sermon, so to save himself from ignominy he kept repeating his text in a slow and measured manner some six or seven times, when the congregation were horrified to hear an old dame scream out: "If thou is the light of the world, thou wants snuffing." On the motion of Mr. Simpson, seconded by Mr. Ratcliffe, a hearty vote of thanks was tendered to Mr. Thistlethwaite for his evening's entertainment.

CROYDON CAMERA CLUB.

THE subject of last Wednesday's meeting was "The Universal Camera," as exemplified by the Sanderson hand camera.

The President, in introducing the lecturer, referred to the above camera, which, he stated, he himself and many other members of the club used, as a splendid example of British solidity. Mr. F. C. Wardall then gave his lecture upon the mechanics of camera construction, and in particular the optical principles involved in the Sanderson camera. He also explained other useful photographic apparatus, including the Ensign cameras, Dawson's Densitometer, and a cloud and lantern slide printing frame. A number of lantern slides were also shown in illustration of the demonstrator's remarks.

At the instance of the President, a hearty vote of thanks was accorded Mr. Wardall. He also announced that the sixth exhibition would be held in the spring, under the experienced secretaryship of Mr. W. H. Rogers. It should be added that Mr. F. W. Hicks will be associated with Mr. Rogers.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE seventh ordinary meeting of the present session of the Association was held on Thursday last week. There was a large attendance of members, with Mr. E. R. Dibdin in the chair. Mr. C. B. Howdill, A.R.I.B.A., of Leeds, gave a lecture on "Natural Colour Photography." He began with a few notes on the history of colour photography, and proceeded to give a most lucid description of the Joly and Sanger-Shepherd processes. Dealing first with the decomposition of light by means of a prism, the lecturer showed the spectrum colours, and gave an interesting description of their action on the photographic plate. In connection with the Sanger-Shepherd process, Mr. Howdill gave a full description of the apparatus used as well as practical instruction. Among the slides made by Mr. Howdill were some exceedingly fine fruit and flower studies, as well as splendid examples of stained glass windows. At the conclusion a hearty vote of thanks was passed to the lecturer on the motion of Mr. Paul Lange, seconded by Mr. Marples.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE following are abstracts from the presidential address, delivered at the first general meeting of the session:—

PURPOSELESS PHOTOGRAPHY.

In the early stages of our photographic career we are all keen and enthusiastic. The glamour of every phase of the production of a photograph absorbs all our energies, our leisure, and a great deal of our spare cash. This goes on for a long time, until, like the child and the toy, we look around for something fresh. Once we have got over being a nuisance to our own family circle and acquaintances, and perhaps still more so to the photographic dealer, whose life is not to be envied at times, judging by the inane questions he is asked about points which could be easily cleared up by buying and above all studying a shilling manual on photography, and also by the cool demands made on his time, as one of our members puts it, "for a pennyworth of hypo. and a shilling's worth of information," we then frequently feel photography beginning to pall.

Taking "the usual thing" does not interest us, snapping at everything is tiring. Particularly in developing and printing, which used to have such a delightful uncertainty about what kind of result would accrue as to fascinate us entirely, do we begin to find photography most monotonous; in short, we are losing interest. There are a few, no doubt, who never quite reach this stage, but remain nuisances for life, and try every one as well as every plate, every new developer, every new paper, and every other miscellaneous adjunct of photography devised for the special benefit of those who must have always something new. We can't help admiring the enthusiasm of this kind of photographer, and indeed we ought almost to feel grateful to him for bringing home to us the fact that even photography has its humorous aspect. However, it is with the more numerous contingent who are losing interest in photography that we have to do; and if they be caught at this stage, and their attention directed to the many phases of

SPECIALISATION IN PHOTOGRAPHY

open to them, much may be done to make them good and useful photographers if they be but persuaded to take up one phase or other and specialise. What a wide field is open for their energies. According to inclination and temperament, so will they select; but whatever it be, it may become much more than a mere hobby if they go into it with a heart and a will.

To begin to enumerate all the many aspects in which one could specialise is out of the question to-night, but a few may be briefly alluded to. On the purely scientific side of photography take photo-micrography; what an absorbing pursuit it may become if our interest in it be once awakened. Last session we were favoured with a most interesting paper on this phase of photography by Mr. Forgan. His knowledge of the subject was amazing, and he gave us a practical lesson of what "specialising" meant. His photo-micrographs of various natural objects, even of grains of sand, were a marvellous revelation of beauty, and a hint of what wondrous realms of knowledge lie hidden around us in the most trivial objects, yet ever there for the specialist to capture, not alone for himself, but to exhibit to others. All of us recollect the most excellent paper and demonstration given a year or two ago by Mr. Tudor Cundall on that most fascinating of photographic problems—colour photography. The results he showed us on that occasion were enough to force us to admit colour photography was something more than a mere dream. To treat or even attempt to deal with the subject in the fashion Mr. Cundall did would of course imply the necessity of a scientific training, but quite recently there has been put on the market more than one process of obtaining positives in natural colours that is within the reach and capacity of any level-headed photographer. Indeed, there has just been introduced one process which, at a very nominal cost for necessary materials, will enable any photographer who has already a camera to produce, with a little study, care, and patience, lantern slides in natural colours.

Many of us are familiar with the work done by the brothers Kearton, Lodge, and one or two of our own members in the field of portraying birds and their nests in their native haunts. Judging from the difficulties which the devotees of this side of photography face and encounter, and better still, overcome, in the quest after results portraying the haunts and habits of our wild birds, this phase of photography is one that may well occupy all the leisure anyone can give to photography. We may see almost everywhere examples of animal photography, the work of one of our own members, Mr. Charles Reid, of Wishaw, which could only have been obtained after long effort and untiring patience, but how splendid the results. What fields, then, are open ever in these two latter aspects of photography for the photographer to specialise.

Other fields of knowledge where the photographer might specialise and find absorbing work for a lifetime are astronomy and geology, but these must only be mentioned in passing, as they require considerable knowledge and training before hand to enable one to do satisfactory work.

The subject of architecture is one in which the photographer can easily specialise and acquire valuable knowledge as he goes along. It is a subject which furnishes material for portraying almost anywhere we like to go. Architecture has its difficulties, but it might well be more popular among photographers. We may not all be able to look with the eye of the architect on the many and varied forms of architecture, we may not all be able to appraise the value from an art point of view of every piece of architecture we see, but the subject is one of the grandest to which a photographer may devote his energies and skill. It is capable of being treated with the loftiest sentiment and poetical feeling, with the utmost breadth and in the most minute detail. Any old cathedral may furnish work for many years. In our city and neighbourhood architectural subjects, both ancient and modern, abound. Here is a wide field for any one to labour in photographically. Every day almost sees old landmarks hoary with age, historical associations, and romance, being swept away by the ruthless march of modern improvements. In many instances, such are being demolished without any record being in existence to hand down to future generations as to what they were like. Surely, then, even in

SURVEY WORK,

many photographers might find so much to do that would be of such incalculable value to posterity that the cry of "losing interest in photography" might well be dropped for many years to come. To those of you who affect no special phase of photography, as well as to those who do, let me appeal once more on behalf of our own Survey Section. During the past year it has made a little more progress than formerly, but **nothing like what it should or might have made.** It is astonishing the apathy members show regarding such a splendid scheme as this if it were only carried out in the spirit in which it was conceived. It is known generally in photographic circles that we have had such a scheme on hand for a year or two now. But what have we to show as results? So far, nothing very much. Visitors to our city see seemingly much better than

ourselves the wondrous beauty of our grand old buildings and our grey old town. We have our reputation, I sometimes think, at stake in connection with this matter of the Survey. To me personally it would be a lasting disgrace if a Society such as ours, with an honoured and unique history in the annals of photography, were to allow this scheme to fall through. Let us then be up and doing, let us realise that it is a work in which we should feel it a proud privilege to be allowed to take a share in. With the members individually rests the responsibility of the success of the scheme. I cannot bring myself to face the thought of its failure. Whatever arrangements, therefore, as are made by the Survey Committee during the current session ought and will, it is to be hoped, receive the heartiest support of every member. If this support be given, there can then be no question but the close of the session will see satisfactory progress made in furtherance of the work of the scheme.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—HULL BRANCH.

A MEETING was held at the Grosvenor Hotel, October 23th. Present, the Chairman (Mr. W. Barry), and Messrs. H. Abba, M. Boak, E. Cooper, C. Delf, W. H. Duncan, W. Fussey, C. Jones, A. J. Wellsted, and the hon Secretary.

The chairman welcomed the members after the interval of the summer months, in which meetings had not been called, and hoped that this second year of the Association's work in Hull would continue to be characterised by good fellowship and by many useful discussions on subjects of professional interest. He believed that these opportunities for friendly converse between photographers in business were of distinct benefit, and would tend to increase among them a feeling of pride in their profession as well as mutual respect.

The subjects on the agenda were "The permanency of collodio-chloride papers," and a matter referred to the branches from the London committee, viz., "The supply of electric current in the daytime at motor rates." Several prints in C.C. matte were then passed round, which illustrated the spots and markings commented upon by Mr. Lang Sims and others in letters to THE BRITISH JOURNAL OF PHOTOGRAPHY. It was generally agreed that collodio-chloride prints, toned with platinum, may as a rule be considered permanent, but that very occasionally the paper behaves badly, almost suggesting the presence of some impurity in the baryta basis.

Prints were shown which had been exposed to sunshine throughout the season, the mounts alone having changed colour, while other prints had spots and yellowish markings, which appeared in less than a month from the date of printing. One photographer stated that he had found this trouble occasionally, but that it had entirely disappeared with a change of the brand of paper in use.

Mr. Fussey said he could hardly believe the baryta base could be at fault, as the material was so cheap; but it was difficult to explain why the markings should appear on some samples of paper and not on others.

The chairman said that nearly all sensitive material was open to variation in quality, and all that we could hope for was the gradual rise to the perfection of manufacture which the majority of plate-makers had attained.

Messrs. Wellsted, Delf, Boak, and Cooper were of opinion that the silver image in collodion was more likely to be permanent when held in gelatine.

The hon. secretary thought the discussion pointed to the useful work which the branches might do in collecting information of this type, and comparing local experiences with those of London and the provincial members of the P.P.A. The water supply might not always be to blame for failures. The permanency of photographs was a matter of special interest to the profession, and this particular paper had undoubtedly come to stay. For small work some clients preferred it to platinotype, which itself was open to the risks of yellowing, if not actual fading, however careful the manipulation might be. He was of opinion that chemical decomposition of the paper itself might possibly be made accountable for fading troubles if the subject could be scientifically investigated.

The hon. secretary then read a paper on the supply of electric current as it affected Hull members of the P.P.A. He said:—

"It is safe to hazard the opinion that within a few years no professional studio will be considered complete in its working plant without an electric installation; indeed, at the present moment there are few businesses in the first rank which are deficient in this respect. It is therefore a good suggestion from the London committee that the matter of electrical supply should be brought before the branch meetings with the view of collecting information on the question of cost.

"Everyone is aware that the price for current varies with the purpose for which it is used, the distinction between motor and lighting consumers doubtless being made with the idea of increasing the demand for current in the daytime.

"But photographers for the most part use their studio installation between the hours of 10 a.m. and 6 p.m., and it is an anomaly to deny them the cheaper rate because they convert the current into light, instead of heat or mechanical energy. Hull photographers may heat their dark-rooms, or dressing-rooms, boil water for afternoon teas, ventilate the studio with fans, etc., at the cost of 2d. per unit, but directly the current is switched through lamps the price is raised to 4½d. per unit.

"Another matter for consideration is the serious waste of current which takes place in the large resistances which must be placed in circuit with any of the single arc lamps, and as the tendency is to raise the voltage on the mains for the sake of saving copper, this trouble will increase.

"Not long ago the Hull Municipal supply was raised from 110 to 220 volts, the effect in those studios using the single arc system being that

for the 45 volts actually utilised 175 is wasted in heating up the resistances. It is true this drawback does not apply to lighting by incandescent lamps as in the Adamson system, and it is obviated to a great extent by running arc lamps in series, as I believe Mr. Morgan, of Aberdeen, arranges; but the Pilsen single arc has been already established, and being worked with success in many studios, and these photographers are at considerable disadvantage in the matter of cost. At all events, their position provides an additional argument for urging the motor rate of charges as a more equitable thing.

"Probably any concession of this sort would not result in a loss to the supply companies, because photographers would be induced to burn their lamps more continuously, instead of switching them on for the brief periods of exposure. At present the temptation to save the current is necessarily strong, when a photographer using a 25 ampere lamp on a 220 volt circuit remembers it is costing about 2s. per hour, with the unit at 4½d. It can be worked economically by switching on and off for exposures, but it is not a comfortable practice, nor is it to the advantage of the supply company to have a somewhat heavy amperage drawing from the mains for brief periods only. It is not at all improbable that photographers may secure the motor rate if they can prove the demand for current in daylight hours is reasonably important. When we consider the wonderful success of municipal electric enterprise in our city, it is worth recalling the fact that the first customer of the Corporation in greater and modern Hull was a photographer, whose 50 ampere lamp was regarded as a nuisance by the switch board attendant. In those early days, whenever the lamps in the neighbouring shop windows or the club were inclined to be 'jumpy,' it was customary to find the excuse in 'that photographer again!'"

"Fortunately, with the immense and still growing central station at Sculcoates that absurd sensitiveness to varying pressure has ceased to trouble, and we can hope that with electricity in Hull relieving the rates this year to the extent of £25,000, the city can well afford to treat photographers as generously as printers, engineers, and other men of business who use the current in the daytime at 2d. per unit."

At the close of the paper it was ascertained that five photographers at present use arc lamps in Hull, and it was decided to write the city electrical engineer, and also to request the London committee to make a general representation on behalf of professional photographers. It was agreed (mem. con.) that the next six meetings should be held in the months of November, January, March, May, July, and October, and that the question of the reservation of copyright shall be fully discussed at the next meeting.

News and Notes.

THE Princess of Wales has honoured Mr. Richard N. Speaight by accepting a copy of his last work, "Children's Portraits," the frontispiece of which consists of his portrait of Prince Edward by special permission of the Prince of Wales.

THE Colours of Stars.—"The wide difference which there is between star and star as to brightness," says Mr. E. Walter Maunder, F.R.A.S., in "Knowledge," "is apparent on the very first glance towards the heavens: it requires a more careful scrutiny to realise that they differ also in their colour, and in the character of their shining. The ancients carried their discrimination of the difference of the brightnesses of stars so far as to recognise six magnitudes, but when it came to the question of colour they hardly noted any differences at all. The stars in general were described as yellow, six only being recorded as 'fiery.' Of these six we should class five as being distinctly orange or red—Antares, Betelgeuse, Aldebaran, Arcturus, and Pollux. The sixth, Sirius, is to us an intensely white star, and there have been many discussions as to whether it has changed its colour in the last 2,000 years, or whether the description given of it—'fiery red'—is due to some mistake in the record, or whether the excessive scintillation of the star may account for it. For, as we see it now when near the horizon, a momentary flash of vivid red flame shoots out from time to time, due to the irregular dispersion of its light in passing through the tremulous atmosphere. It is from this that Tennyson, most exact of all the poets in his scientific references, calls Sirius 'fiery' in the well-known passage from the 'Princess':—

'The fiery Sirius alters hue.

And bickers into red and emerald.'

Assuming that the light of any star is partly white and partly coloured, we may divide the stars into classes, depending entirely upon the depth of tint which it shows, and not upon its colour. A five-fold division suggests itself, something to the following effect:—(1) pure white, (2) tinted, (3) coloured, (4) fully coloured, (5) deeply coloured. After the question of the depth of tint which the stars show, comes the question of the colour of that tint. For naked-eye stars, the more refrangible colours do not come into consideration. The range is from orange-red up to yellowish green, or possibly in a single instance—that of Beta Libræ—to green. Alpha Lyrae, and possibly one or two other stars, have a distinct bluish tinge, but in general the stars not passed as white may be very well scheduled under one of the five following heads:—(1) reddish orange, (2) orange, (3) orange-yellow, (4) yellow, (5) yellowish green. In working upon star colours with the naked eye it is impossible to use any artificial standard of colour, but the wide field of view, and the ease and rapidity with which the attention can be turned from one part of the heavens to the other, will much more than make up for this deficiency. The stars must be compared one with another, the estimations of colour must be purely relative, and the method will be found much the most accurate possible." In Mr.

Maunder's forthcoming book on "Astronomy without a Telescope," the amateur observer of the manifold wonders and glories of the heavens will be led by a capable hand to a systematic study with the unaided sight of the ceaseless roll of the worlds around us.

THE Royal Society's Catalogue of Scientific Papers.—The Royal Society has been engaged continuously during the past forty years in cataloguing the various scientific papers which have been issued in all parts of the world since the beginning of the last century. The original scheme of the Catalogue of Scientific Papers provided that the papers should be catalogued only under the names of their respective authors, arranged alphabetically. This "Authors' Catalogue" has now been carried down to the end of 1883, and comprises twelve quarto volumes. More recently it has been decided to prepare also a subject index of the same papers—that is to say, a catalogue in which the papers are indexed according to the subject-matter of which they treat. Considerable progress has been made with this subject index, though nothing has as yet been published. The expense of this work has been very large, since, although a great amount of gratuitous labour has been readily given by Fellows of the society, it has been necessary to employ a considerable permanent salaried staff upon the preparation of the copy for the press. At first the printing and publication were undertaken by H.M. Stationery Office, the Treasury having determined that the catalogue should be printed at the public expense. In coming to this conclusion the Lords of the Treasury stated that they had regard "to the importance of the work with reference to the promotion of scientific knowledge generally, to the high authority of the source from whence it came, and to the labour gratuitously given by members of the Royal Society for its production." This arrangement, however, came to an end after the publication of the first eight volumes. The Treasury in 1889 informed the society that the catalogue could no longer be printed and published by the Stationery Office. The unsold volumes, were, however, handed over to the society, and Parliament voted a sum of £1,000 to assist the society in continuing the printing and publication. The four subsequent volumes have been printed and published by the Cambridge University Press, which has received subsidies from the society for this purpose, and receives the sums arising from sales. The total sum expended by the society upon the catalogue down to the end of June last has been £14,790 5s. 5d. Towards this expenditure a donation of £2,000 was made by Dr. Ludwig Mond in 1892. Sums amounting to £524 11s. 9d. have been received as the proceeds of sales of the volumes handed over to the Royal Society by the Stationery Office. As already stated, £1,000 has been received from the Treasury. The council has also hitherto devoted the income of the Handley Fund (which they have power to apply as they may deem best for the advancement of science) towards defraying the cost of producing the catalogue. The total sum received from this source has been £2,394 11s. 10d. A sum of £341 11s., arising from money invested until actually required, has also been available for the same purpose. These pecuniary aids amount in all to £6,260 14s. 7d. As will be seen, they have not been nearly sufficient to meet the whole cost, and the society has been compelled to make up the balance of £8,529 10s. 10d. out of its own general income. As it became obvious that to permanently continue to prepare and publish catalogues of the ever-increasing stream of scientific literature was wholly beyond the means of the society, the council took steps to obtain international co-operation in this great work. Such co-operation has happily been secured, and the cataloguing of the scientific literature of the present century is now in the hands of an international council. The Royal Society has, however, incurred large special responsibilities in connection with the matter, having undertaken, inter alia, to act as the publishers of the catalogue, and also to advance the capital required to start the enterprise. The International Catalogue is concerned only with the scientific literature appearing after the commencement of the present century. The Royal Society's Catalogue, as already stated, is at present carried down to the end of the year 1883 only, and the subject index for that period is but partially dealt with. The foreign delegates, assembled to consider the establishment of the International Council, expressed their sense of the great importance of the Royal Society's Catalogue, and of the obligations which men of science in all countries were under to the society for having undertaken it. They also expressed the hope that the society would complete the catalogue up to the close of the last century, so as to bring it into line with the International Catalogue. Indeed, it may be said that the International Council is proceeding on the assumption that this will be done. In order to complete the catalogue, it will be necessary to prepare and publish a catalogue of authors for the seventeen years 1883-1900, and to complete and publish the subject index for the whole of the past century. The Council of the Royal Society are satisfied that this work must be done, and have not felt justified in refusing to undertake it. They have accordingly commenced operations, and it is hoped that the copy may be produced ready for the press in about five years. Owing to the enormous increase in the number of scientific publications at the close of the last century, it is estimated that to complete the catalogue, and to subsidise a publisher for undertaking the printing and publication, he retaining the proceeds of the sale, will cost at least £12,000. The question now arises whether the funds of the Royal Society ought to continue to be burdened with any part of this expense. The activity and responsibilities of the society have greatly increased in recent years, and it is much straitened by its inability to increase its expenditure, either on its own establishment, or in other directions, owing to the incessant demands of the catalogue. The council consider that the time has now come for them to appeal to those who are in a position to afford substantial financial assistance, to enable them to complete this great undertaking without devoting any part of their funds, so sorely needed for other purposes, to this object. They are thankful to be able to announce that Dr. Ludwig Mond, F.R.S., has been so impressed with the importance of the catalogue, with the necessity for producing the

subject index of the scientific literature of the past century so far as possible in the same complete form as that adopted by the International Council for the literature of the present century, and with the justice of the view that the Royal Society ought for the future to be relieved of the cost of producing the catalogue, that he has most generously added to his previous gift of £2,000 the munificent donation of £6,000, payable in four annual instalments of £1,500. The president and council have also much pleasure in stating that Mr. Andrew Carnegie, fully appreciating the value of the society's undertaking, and the claims that it has on the liberality of those who, though not Fellows of the society, are interested in the promotion of natural knowledge, has contributed the handsome sum of £1,000 towards its accomplishment. They venture to hope that others may be willing to contribute towards a fund to provide for the total cost of this national work.

ENAMELLING SELF-TONING PAPERS.

To the Editors.

Gentlemen,—We have found a new method of enamelling our self-toning and other collodion paper. It is extremely simple, as you will see by the enclosed instructions. As the old method of laying down the print on collodionised glass was so troublesome, we feel sure that both professionals and amateurs will be interested to hear of this simple process.—Yours faithfully,

PAGET PRIZE PLATE COMPANY, LTD.

The Paget Prize Plate Company, Ltd., Watford.

October 29th, 1902.

GLAZING FRINTS.

If a highly glazed surface is desired, do not dry the prints after washing. Lay them, while wet, face downwards on a piece of well cleaned plate glass (which need not be French chalked or prepared in any way), roll the back firmly several times with a roller squeegee and leave to dry; or they may be dried by heat in a few minutes. When thoroughly dry, wet or well damp the back of the print in any way you please, and leave it for five minutes. Lift one corner of the print (if it is a large one, two adjacent corners are better), and pull steadily without stopping; the print will come off easily, and when dried again will have a highly glazed surface. This surface is not injured by wetting, which will be found to be a great advantage in mounting

KODAK, LIMITED, AND THE TRADE.

To the Editors.

Gentlemen,—The further statements made by the Photographic Trade Association in your last issue compel us to ask the equal favour of space in which to reply.

The Photographic Trade Association state that they are agitating this question because they have good reasons to believe that Kodak, Limited, are endeavouring to create a monopoly. "Reasons to believe." What a basis for a dispute, taking up so much valuable space in your columns! As a matter of fact, the Photographic Association was formed to excite and organise opposition to Kodak, the real aim being to create facilities for the marketing of imitations and piracies of our goods. The composition of its council proves this. The reports of its initial meetings prove it. The story can easily be read in print.

The association was formed at a time when the retailing dealers misunderstood our conditions. The case is very different now. Some of those on their own council even now refer to the Photographic Trade Association as "an association of Kodak haters." The association is led by wholesalers who are not now able to handle Kodak goods. We had to dispense with them because the intermediary of the middleman was found by us to be mischievous and useless. The manufacturer can get the goods to the dealers and to the public fresher and cheaper without him. Everyone knows that the aim of the middleman is to conceal the identity of the manufacturer and push out goods under his own name and brands.

All there is in this agitation is that certain of these wholesalers, not being able to handle Kodak goods, have induced German and English firms to produce imitations for them, and they seek to associate these imitations with the genuine articles as closely as possible, both in appearance and by crafty use of our special trade marks and names. The cry of monopoly is part of this scheme, and is adopted to confuse the real issue and excite animus against Kodak.

Our conditions are not aimed at, and cannot lead to any monopoly. Their object is to make sure that the thousands of purchasers who want Kodak goods shall be certain of having them in every town without fear of deception or confusion.

We, of course, mean to get all the business we can, and we offer those dealers who elect to concentrate on our goods better terms than to those who divide their interest between our goods and imitations of them. This is simply a business proposition.

If the imitators and wholesalers can make it worth the while of the dealers to handle their rollable film goods, it is open to them to do so, but for them to demand that we and all the trade should afford them every facility for marketing piracies in the channels that have been opened, and stand by and see our names and goods used as leaders and "call birds," without attempt to protect our customers from deception is beyond reason.

The cry of monopoly and coercion is a red herring across the trail. The Photographic Trade Association is merely seeking advertisement. Here is proof from their own lips that they have no other reason for this attempt at agitation. In their circular issued in September they state triumphantly that—

"Other rollable film apparatus and rollable films are being largely and successfully handled by the wholesale houses, and through these channels are finding a ready sale in retail dealers' establishments."

If this be true, our conditions of sale are evidently inoperative to secure monopoly. We think this will plainly expose the hollowness of this attempt to excite sympathy for the imitation goods by a cry of monopoly or coercion. The Photographic Trade Association, in other words, the wholesalers and imitation manufacturers, do not really think that we are attempting to secure or shall secure a monopoly. Their aim is solely to get hold of some of our trade, and they are looking for assistance from some who are jealous of the success of Kodak and of its great expansion. To say that superiority in goods should alone be relied on by manufacturers is absurd. It is notorious that some of the largest firms in the world find it necessary to spend large sums of money in protecting purchasers from flagrant imitations. Take the case of Burroughes and Wellcome, Bass and Co., Martell, Lee and Perrin, and many others, and there are none of them more afflicted with impudent attempts to steal trade than Kodak, Limited.

The tricks of the middleman and shoddy imitator and their abettors are many and wily. One has been to get hold of the Kodak reels which are stamped with the trade mark of the company, and wind imitation films upon them. Judgments against infringers of this kind have had to be obtained, both in Germany and in England. Further, a customer sends his Kodak to be loaded with a genuine spool, and an alien article is put in, with the result that the user winds it off upon the receiving reel, which in 99 cases out of 100, is a Kodak reel. Consequently, on development, if bad results appear, he thinks Kodak is to blame. There have been many cases of this kind.—Yours faithfully,

KODAK, LIMITED.

45, Clerkenwell Road, London, E.C.

November 3rd, 1902.

To the Editors.

Gentlemen,—The letter of your correspondent, "Briton," in the BRITISH JOURNAL, of October 31st, seems to me to try to evade the real point at issue in this matter.

Assuming, for instance, that it is, as he says, "fair," to offer conditional discounts, the question seems to be—is it expedient, in the interests of the photographic public, that a powerful corporation, like the Kodak Company, should induce retailers by such means, not so much to give their productions "special attention"—which in itself is no doubt fair—as to induce them to refrain altogether from selling any similar productions, even though they may be improvements, by giving "sole attention" to their productions, and in so doing create a monopoly, whether intentional or not?

Surely this cannot be expedient in the general interests, and why should not Kodak, Limited, rely—to use their own words—on "good terms, good quality, and fair prices," to keep up the demand for their goods?—Yours faithfully,

ANOTHER BRITON.

To the Editors.

Gentlemen,—My husband tells me that several hundred of the most important of the photographic manufacturers and shopkeepers say that they cannot compete with the Kodak Company, and want us to stop buying Kodak spools. I am quite sure that you would never get several hundred English ladies to acknowledge they could not hold their own against one American girl, even if she be up to date.

Besides, if these men cannot make any film that is any good, what would they have to sell, except the Kodak film? But I suppose the Kodak Company will not let them make any but those oiled tissue paper-looking imitations. Some men are such silly creatures, they just have what they call association dinners and smoke and talk what they are going to do, and then go home and do nothing, except, perhaps, sell things "made in Germany," or somewhere else. The only thing that I can see to be done is for us English ladies to go into the photographic business. An old lady friend of ours is quite enthusiastic about it; she is quite sure that we would not get into such

a muddle as these men have done, and even if we did we would not be so stupid as to say so.

I hope you will kindly publish the opinions of a

LADY AMATEUR.

THE PRESIDENT'S ADDRESS AT THE R.P.S.

A CORRECTION.

To the Editors.

Gentlemen,—

I regret very much to find that, in my presidential address, I made a statement with regard to the photomicrographs of the Lippmann heliochromes of the spectrum, that does an injustice to Dr. R. Neuhauss, and other investigators. I am reminded by the "Amateur Photographer," May 20, 1898, page 394, that the credit of the production of the first of these photomicrographs is due to Dr. R. Neuhauss, and in the society's exhibition of 1900, there was an exhibit, "356." Section through the picture surface of the red zone of a spectrum, prepared after Lippmann's interference method of colour photography, enlarged 4,000 diameters, by Dr. R. Neuhauss." This oversight is the more to be regretted, as the exhibit was made at our own exhibition. With regard to the exhibit sent by Mr. Edgar Senior, it appears that (1) Mr. Senior made the Lippmann photograph, stripped it from its glass support, and gave to Mr. T. A. O'Donohoe the red and blue parts from which to cut sections and make photomicrographs; (2) that Mr. O'Donohoe was the first investigator in England who saw the laminae under the microscope, and who produced photomicrographs showing most, though not all, of the strata; (3) that Mr. W. B. Randles, of the Royal College of Science, South Kensington, then made thinner sections on the microtome at the college; (4) that Mr. Randles took the photomicrograph of the blue part of the spectrum, which was sent to Professor Lippmann, and is now shown at the exhibition of R.P.S.; (5) that Mr. O'Donohoe produced the photomicrograph of the red part of the film with a magnification of 1,000 diameters, and this was the specimen Professor Lippmann pronounced to be strictly in accordance with theory, as the red actinic planes extend through the full thickness of the film; (6) that Mr. Senior's pictures, at present hanging in the photographic exhibition, are enlargements from the negatives taken by Mr. O'Donohoe and Mr. Randles.—Yours faithfully,

THOMAS R. DALLMEYER.

25, Newman Street, London, W.

October 30th, 1902.

A CORRECTION.

To the Editors.

Gentlemen,—We note in your issue of the 31st October, in your report on the double transfer carbon paper, that there is a slight error, which we would respectfully point out to you. You state that hitherto if a picture was desired on a matt paper by the carbon process it had to be made by the single transfer method, but we would point out to you that our gravure carbon tissue, which we introduced twelve months ago, was made for producing this very effect by double transfer, and it is now largely used by the leading photographers throughout the kingdom. We have supplied for twelve months matt papers, toned and white, with a special paste for rubbing the temporary support, and which gives a perfectly matt surface by the double transfer process. As we are the pioneers of this method, we trust in justice to us that you will kindly note this in your next issue, and, thanking you in anticipation and with compliments, we are, dear Sirs, yours faithfully,

THOMAS ILLINGWORTH AND CO., LTD.

Willesden Junction, London, N.W.

October 31st, 1902.

MR. ARTHUR MORTLOCK has sold for Mr. S. J. Porter (of Torquay, Paignton, and Exeter) the well-known high-class photographic business successfully carried on by him for the last fifteen years at "Maison Rouge," High Street, Ventnor. The purchaser is Mr. J. M. Allen, of Cirencester.

AN Appreciation of Sir J. Benjamin Stone.—In the last of his chatty series of articles "From Behind the Speaker's Chair," which appears in the November "Strand Magazine," Mr. Henry W. Lucy refers to Sir Benjamin Stone's photographic work in the following appreciative terms: A good deal is heard from time to time of Sir Benjamin Stone's collection of photographs relating to Parliamentary life. The photographs taken on the Terrace of the House of Commons, multitudinous as they are, form only a section of this unique collection. Like Ulysses, much has Sir Benjamin travelled, much of men and cities has he seen. Before he entered the House as member for East Birmingham he visited Japan, China, the Straits Settlements, Asia Minor, the West Indies, the Rocky Mountains, Vancouver, and the River Amazon, not to mention ordinary accomplishment in the way of historic places on the Continent of Europe. Wherever he went he carried with him his camera, bringing home photographs of whatever he saw. None are these of the ordinary snap-shot

character common to Cook's tourists. They are works of art, skilful use of the platinum process giving them the appearance rather of engravings than of photographs. The fact is, if Sir Benjamin had not been dazzled by the dignity of being five times Mayor of Sutton-Coldfield, he would have been—perhaps he is—the most successful photographer of the age. In addition to being an artistic photographer he is a practised writer, having recorded in several volumes his travels in Japan, Brazil, Spain, and Norway. His practice, extended over many years, has been that when he takes a photograph of a memorable scene or a distinguished person he writes a descriptive note, which is affixed to the picture when it is stored away and catalogued. The consequence is that his collection, which now numbers 25,000 separate plates, is an unparalleled pictorial history of the world. It is well to know that this rare achievement will not be lost to the public and to posterity. Sir Benjamin tells me he has bequeathed the collection to the care of trustees, with direction to take whatever steps they in their judgment think best calculated to add to the instruction and entertainment of the public. Whether the pictures, with personal notes or descriptions of scenery, shall be published in book form, or whether they shall be deposited in some public institution, is a matter Sir Benjamin leaves to the unfettered discretion of the trustees. Amongst the series of pictures of immediate home interest are photographs of every part of the interior of the structure of the Palace of Westminster. The Tower of London has been dealt with in the same minute and masterly fashion. One of the most beautiful and impressive among the multitudinous pictures is one of which I possess a cherished copy. It shows the last halt of Mr. Gladstone on his way to burial in Westminster Abbey. It was taken early on the morning of the 5th June, 1898. Westminster Hall is empty, save for the coffin set in its midst, on which the early morning light falls softly through the lofty windows set in their place when Richard II. was King. During the summer Session Sir Benjamin Stone had a rich harvest of celebrities in the foreign, Indian, and Colonial celebrities coming over for the Coronation. His studio is a portion of the Terrace belonging to the deserted section pertaining to the House of Lords. With quick artistic eye he discovered the usefulness of the accessory of a wrought-iron gateway opening on to the Terrace. With this background his subjects are posed. It is a memorable procession, including all the more famous past and present members who have held seats during the last seven years. In addition is the fringe of foreign notabilities who flock to the Lobby of the House of Commons. The latest photograph of Mr. Chamberlain was taken by Sir Benjamin on the day peace was signed at Pretoria.

PHOTOGRAPHY, Philosophy, and Humour.—The three were well combined in an interesting lecture delivered last Saturday night in the Fine Art Gallery, in the Leeds Municipal Buildings, by Mr. E. Rimbault Dibdin, a Liverpool journalist, who is president of that city's amateur photographic association and a past president of the Liverpool Artists' Club. Mr. W. Edwin Tindall, R.B.A. (secretary of the Yorkshire Union of Artists) was in the chair, and had the satisfaction of presiding over a crowded audience, a fact which was all the more gratifying when it was considered that only just across the street some five or six thousand people had gathered together with the fell design of waiting a couple of hours for the public declaration of the results of the municipal elections. The Saturday evenings at the Leeds Fine Art Gallery are usually devoted during the winter season to lectures on music and art of the brush-producing character, but last Saturday night the photographic people had an opportunity of showing to all and sundry that they too could claim to be endowed with the artistic feeling, and that they were moreover entitled to wear a nimbus which essentially is their own. Mr. Tindall in a sentence introduced the lecturer, remarking that Mr. Dibdin was not a stranger to most of them, and that he was known to be one of the best workers in the domain of photographic art in the kingdom. Mr. Dibdin said it was true that he was not an entire stranger to the city, as he could claim that an ancestor of his had the honour of entertaining the people by his songs as far back as the eighteenth century. The title of the lecture was the "Magic Carpet," but the old Arabian story was only utilised as an object lesson, and was in a sense treated allegorically. The lecturer sought to demonstrate his view of the proper treatment of a lantern lecture by making words and pictures interdependent on each other. Some people, he said, seemed to think that when they had made a lot of slides and obtained a lantern more or less effective their work was at an end, but as a matter of fact that was only the beginning, the best part being the lecturer's story which accompanied them. The lecture had been written for the purpose of showing his idea of how a miscellaneous collection of pictures might be made interesting alike to the spectator and the listener. There are few pictures that could not be turned to account as moral or other lessons, and adapted to the affairs of every-day life, as the fables of Æsop and La Fontaine might be. Having exhausted the story of the "Magic Carpet" Mr. Dibdin, in turns philosophic, sarcastic, and humorous, drew a parallel between the life of a child and of a river, and illustrated his story of development and progress by the aid of an excellent series of lantern slides. Several instances of the marvellous work of nature were depicted by slides of more than ordinary excellence, such as the effects of frost, heat, earthquakes, water, and air. A river, he claimed to be more than a symbol of human life, and strongly recommended the investigation of rivers, streams, mountains, and valleys to every student of life. Such an investigation could be made additionally interesting to the photographic student by reason of the fact that he could the better retain the impressions which had been made upon him, and could always revive them by looking at his pictures. The lecture seemed to be greatly enjoyed by the large audience, and Mr. Dibdin was frequently warmly applauded.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

WATER COLOURS.—S. W. asks: "Can you tell me where I can get colours from for photographic prints (water colours)."—In reply: The colours can be had of any of the artists' colourmen. It is the ordinary water colours that are used for colouring photographs.

COUNTY COURT CASE.—"I photographed a group on my own responsibility. I sent proof and the order was for ten copies. I sent same on and never received the money, which the people state was posted. Can I County Court them for same?"—In reply: You can sue in the County Court, but you will have to prove you never received the money. Then you will recover.

ENAMELLING PRINTS.—J. P. BAMBER asks: "Will you kindly give me formula for the mixing of emulsion for the enamelling of collodion-chloride prints?"—In reply: We do not understand what you mean by emulsion for enamelling C.C. prints. Collodion prints can be enamelled with gelatine and collodion, the same as any other prints. See reply to "Query."

REPAIR OF ENAMELLER.—C. SPENCE writes: "Do you know of any agent for the 'Globe enameller' in Britain, or other party that can put in order an 'enameller' that works with 'gasoline' not gas?"—In reply: Most of the large dealers supply "Globe enamellers," and no doubt the one who supplied yours, will get it repaired for you. Failing that, we imagine that any working engineer in your neighbourhood would do the needful.

COPYRIGHT QUERY.—A. W. SARGENT writes: "Kindly let me have your opinion of the following: A customer has asked me to make a negative of an old print out of a book published in 1725. Would there be any risk of infringing on any rights? Of course, the prints are not copyright at that date, but can I be prevented from making a photographic copy of them for reproduction?"—In reply: There being no copyright in the print there will be no risk in copying it for reproduction.

METALLINE PICTURES.—RETEP says: "I have recently been shown a photograph (presumably a carbon print) upon a square block (black), with silvered centre, and, I believe, lacquered over. Please inform me where the blocks may be obtained, and whether the idea is protected."—In reply: From the description we imagine that the picture is one that was produced by the "Metalline Company." If so, it is a carbon picture, but the Company make a secret of how they are produced. We cannot say where the blocks can be obtained, unless from the Company.

MARKING NEGATIVES.—MIDGET says: "Kindly inform me the best method of marking a negative so that it will print out the name and address the same time the picture is printed, in dark colour, for unmounted midgets printed on heavy bromide paper. Is there any appliance on the market for the purpose?"—In reply: The way to get the name and address to print black is to scratch it neatly out of the negative. There is no appliance on the market for the purpose, but there is for producing the lettering to print white. It may be had from Messrs. Richford, Snow Hill, E.C. Its name is "Namet."

A PROCESS QUERY.—W. C. EDMONDS asks: "Could you tell me what paper the enclosed print is. My employer says it is Velox special portrait but I cannot get the same rich effect with any slow gaslight paper. I believe it is C.C. matt, platinum toned. Should be very much obliged if you could say what paper, and if possible the brand, as we want to use it."—In reply: We see no reason to doubt what your employer says, as similar results can be produced on special "Velox" paper. We could not say for certain that the print is

not on a collodion paper without submitting it to such test as would damage it. The picture has been returned as desired.

COPYRIGHT COPY asks: 1. "Will you be kind enough to inform me whether a copyright photo is bound to have 'copyright' on same, or other means of making known the fact that the picture is copyrighted?" 2. Should I be doing right in copying a photograph without any 'copyright' or other words on? 3. If this print (half-plate) was from a copyright twelve by ten negative (that is part of the larger negative), would it be requisite for the word 'copyright' to appear on the smaller print?"—In reply: 1. A copyright photograph need not be marked as being copyright; 2. certainly not, if the photograph is a copyright one; 3. no, not at all necessary.

PHOTOGRAPHS ON JEWELLERY.—F. V. (Middlesbro') says: "I wish to transfer some photos on to a watch, and should be greatly obliged if you could give me the formula of the collodion mixture required for the process; also which kind of pasto for pasting down the print; and thirdly, where to obtain the patent varnish, I think it is called 'Zapona,' or similar."—In reply: Full working details for putting photographs on jewellery were published in our issue for July 19th of last year, to which we must refer our correspondent, as there is not space in this column to repeat them. Zapon varnish is supplied by the Crane Chemical Company, Newhall Street, Birmingham.

DUAL BUSINESS.—E. W. BALDWIN says: "I should like to hear your opinion upon a profession I have honourably upheld for the past fifteen years. When we see the following notice in a baker's shop, 'Photos taken daily from 2 p.m. to sunset; artistic mounts if desired,' it makes one think 'whatever is photography coming to.' Is it bakery going to the wall, or photography?"—In reply: We cannot answer our correspondent's query; but there is nothing to prevent the baker carrying on photography if he chooses, any more than there is to prevent a photographer adding another business to his own, which many do.

ENAMELLING PRINTS.—QUERY writes: "Will you kindly inform me as to which is the best method of glazing collodion-chloride and P.O.P. prints, and best way of mounting same in large quantities? I understand that to obtain a highly glazed effect, the prints must be coated with collodion or gelatine, and squeegeed on glass."—In reply: Prints are enamelled in this way—Take a perfectly clear glass plate, rub it well with French chalk, and coat it with enamel collodion. Allow to set, and then put into water to wash away the ether and alcohol. Immerse the print in a warm, dilute solution of gelatine, together with washed plate; bring both in contact, avoiding air bubbles. Remove and squeegee together, then allow to dry and strip off. "Backing paper" is sold by the dealers, which, if used according to the directions, will prevent any of the glass being destroyed when the prints are mounted.

STUDIO BUILDING.—SAXCULIE says: "I have a studio with a south-eastern light, and I am thinking of enlarging it and putting the side-light on the other side, and should like you to advise me if it would be best to make a ridge roof, with glass on both sides of roof, or if it would be best to make a lean-to roof. The studio is 10ft. wide, 27ft. long, and glass on the side about three parts of the length. Would it cast too heavy a shadow on the boarded side. If I build the side 14ft. and the other 6ft. 6in., and adopt the lean-to roof, how would it be to put a 6ft. by 4ft. section of glass in the side at the sitter's end as per sketch. I have a Suter's No. 5 landscape lens (12 by 10), and should like to know what the stops are; I mean, what are the apertures, in working with a Wynne's exposure meter."—In reply: It is quite a matter of personal opinion: both forms are good, one prefers one and another the other. If the lean-to form be adopted, the shadows, if necessary, could be softened by a reflector. The glass in the side would be useful, but we should advise its being put five or six feet nearer the middle than shown in the sketch. We have not one of the lenses mentioned by us, so cannot say what are the ratios of the stops.

* * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published in December next. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The growth in popularity of the ALMANAC is evidenced by the remarkable rapidity of its sales.

The 1900 Edition (20,500 copies) was sold within three months after publication.

The 1901 Edition (20,500 copies) was sold a fortnight after publication.

The 1902 Edition (20,500 copies) was sold a fortnight before publication.

The widespread interest in the ALMANAC grows steadily year by year, and in order to supply the increasing home, foreign, and colonial demand, we have decided to enlarge the 1903 issue to

25,000 COPIES.

The great addition to the circulation of this most popular annual (over 20 per cent.) undoubtedly enhances its value as an advertising medium, and the issue of the large number of extra copies will supply the wants of thousands

of photographers, dealers and publishers who were unable to obtain the ALMANAC for the last three years.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

EX CATHEDRA.

Aluminium. This metal promises to hold the public mind for some time to come, for the majority of scientific periodicals lately have contained references to and articles upon it, the exciting cause for this recrudescence of interest being probably the reading of a valuable and interesting paper on the subject by Professor Wilson, read before the British Association Meeting, the same topic having also been treated by him in a paper published in the *Journal of Electrical Engineers*. This metal, of prime importance in electrical work, has always had great attraction for what we might term photographic mechanics. It is not very far from half a century ago when its extreme lightness caused it to be used in the building up of a photographic objective, and almost as long ago it was employed as a substitute for wood in the construction of portable cameras, while at the present time in addition to these uses we find it subserving a variety of purposes, from the making of developing dishes onwards. In comparison with the familiar brass-work it has for some reason or other never had a great vogue for lens cases, the higher price of the aluminium mountings scarcely accounting for this in our opinion. The great drawback to its employment has been the greater difficulty of working it in the lathe; but the recent work of Professor Wilson will seem to show that some amelioration of these difficulties may be brought about by the adoption of certain alloys.

* * *

Aluminium Alloys. The occasional, or indeed, frequent brittleness of the metal for a long time

stood in the way of its utilisation for many purposes; but the product of the electric furnace is a vast improvement upon the substance obtained by the earlier modes, 99.5 per cent. being the rates of purity attained by this later method of production. By alloying it with a small proportion of other metals great gain in strength is obtained; thus, from a breaking strain of 64,000lbs. per square inch shown by pure copper we have 28,200lbs. only for the strength of aluminium, while with a little over 1 per cent. each of

copper and nickel this is increased to 49,500lbs. Again, the pure metal rapidly tarnishes in the air, though, really that is no great detriment to a lens fitting, as it is usually protected by a coating of lacquer, and if it does tarnish where the lacquer has been abraded the result is far less unsightly than the dirty colouration seen on brasswork under similar conditions. However, the increased purity of the latter-day samples of the metal tends to diminish the liability to alteration by atmospheric influences, and this liability is still further minimised by the addition of the small proportion of alloying metal referred to. A number of alloys of varying materials and proportions were, for over a year, placed on the roof of King's College and afterwards tested. It was found that the addition of copper and nickel gave a considerably increased corrosion-stability, but that an alloy with about one per cent. each of copper and nickel gave a considerably increased corrosive-resisting power.

* * *

Aluminium Two Thousand Years Ago.

Though our practical acquaintance with the metal covers a period of about half a century only (the French chemist, Deville, in 1855 demonstrated the possibility of its commercial production, and in 1860 its manufacture on a large scale was started in Newcastle by Sir I. Lowthian Bell), yet it is claimed that a metal which, from the description of its properties, can scarcely have been anything else, was discovered in the reign of the Emperor Tiberius 41 B.C. to 37 A.D. According to a writer in the *Globe* of August 19th, 1898, Pliny tells us that in that reign "A worker in metals presented a beautiful metal cup resembling silver, but lighter, to the Emperor, who questioned him, and learned that he had extracted the new metal from clay. The secret, he said, was known but to himself and the gods. The sage Tiberius reflecting that if this metal could be made from earth, it would lower the price of silver and gold, decapitated the artificer in order that his secret might remain with the gods, and so deprived the world of a most useful benefactor." A recent writer in the *Chemical News* wishes to be provided with name and page of the edition of Pliny's work referred to, and he goes on to say that for four reasons the white metal could have been none other than aluminium, for "(1) it was obtained from clay, (2) it resembled silver, (3) it was lighter than silver, and (4) it was capable of being wrought into a vessel." So far we have not seen any reply to this pertinent query, and it will be one of the most remarkable facts in chemical history if it should prove that the extract from Pliny is no figment but an actual fact.

* * *

Soldering Aluminium.

This necessary concomitant to the use of the metal has always formed the greatest difficulty in its practical economics, and innumerable have been the processes invented. The latest comes from the United States, on the authority of Mr. J. C. Webster, of Philadelphia, who has patented his invention. His solder consists of a mixture of tin, lead, aluminium, and zinc, the proportions being altered according to whether the work is of a heavy or light character, the tin being increased for the latter, thus giving a lower melting point. The inventor states that no flux or scraping of the aluminium is needed for removing the oxide, and that the oxide which forms during the soldering can be disregarded, as it does not affect the joining when the proper heat is applied.

* * *

Thiocarbamide Toning Bath. We have already noted the suggestion of the late M. Helain as to the use of an acid thiocarbamide toning bath for printing out emulsion

papers, and in the current number of the *Photographisch Correspondenz* Professor Valeuta reports most favourably upon it and strongly recommends it in preference to the ordinary sulphocyanide bath, and its advantages are that it is not poisonous, does not give rise to double toning does not attack the delicate details, and so far as his observations go it will keep well. Thiocarbamide is rather expensive, but as very small quantities are used, this need hardly be considered. The chemical formula for thiocarbamide is $CS(NH_2)_2$, and it forms with gold chlorides a colourless aurous salt $(CSN \cdot H)_2 Au Cl$, the gold in which is replaced by silver in the process of toning. The method of making the bath is as follows: Dissolve 1 gramme of thiocarbamide in 50cc. of water, and add sufficient of this solution to 25cc. of a 1 per cent solution of chloride of gold to dissolve the precipitate first formed (about 14 to 15cc. will be required), then add 0.5g. of citric acid and add sufficient water to make a litre, and then add 10g. of salt. The prints should be washed in water first, and also after toning, and then fixed in a 10 per cent. solution of hypo. We have been able to test this bath with two makes of P.O.P. and a collodio-chloride paper with excellent results, and found that toning takes place somewhat more quickly than with the sulphocyanide bath of normal constitution. The only point in its use to which we think attention need be called is the necessity for washing, after toning, as the toning bath being acid, there is, if this is not properly performed, danger of decomposition of the hypo, with possible sulphur toning.

* * *

No More Alkalies Required.

Of late years we have had several salts suggested as suitable substitutes for the alkalies in developers. Of these, possibly, lithium hydrate, sodium tribasic phosphate, and acetone are the only ones which have been practically used. Lumière and Seyewitz suggested trimethylamine, which was certainly the most promising, had it not been for its awful stench, which made even the most luxuriously appointed dark-room a room of horrors. Now the well-known colour manufacturers, formerly Meister, Lucius and Brüning, of Höchst a. Main, have patented the use of amidoacetate of soda. At a recent meeting of the Verein zur Pflege der Photographie at Frankfort, Dr. König described the use of this salt, and we gather that it is cheap, keeps well, and is without smell, and does not attack the skin nor the gelatine of the film, and further with pyro gives a developer of extraordinary rapidity and density, giving power with a good black image and absolute freedom from fog. Dr. König says: "It was not our endeavour to increase the number of commercial developers. We consider it far more important that we have succeeded in discovering a substance which can not only replace the alkalies with all organic developers, but which can so increase the reducing power of most of the developing agents to such a degree that developers of quite new qualities are the result." Probably this new preparation will shortly be placed on the English market, and we shall be able to practically try it, and we note that the above-mentioned firm have introduced a pyro developer, under the name of "Pinakol P," which contains pyro, amidoacetate of soda, and sulphate in suitable proportions.

* * *

The Permanency of C.C. Prints.

We are glad to see that the Hull branch of the P.P.A. discussed this important topic at their meeting, as reported in our last issue, and we would direct attention to one or two points which do not at present seem to have been noted. In the first place, it is essential to decide whether the

peculiar spots and markings that have been met with are due to the baryta paper or the image-bearing vehicle, and whether they are due to defective, though possibly unconsciously defective, working. It would be of interest if someone who has met with this particular trouble would dissolve the collodion film and see whether the baryta support itself were stained; further, it might be possible to strip the collodion film and compare the two. It would be interesting, too, if the same emulsion was coated on baryta paper and glass, the latter with and without a gelatine substratum, and submitted to various methods of treatment. Mercier, in his classic work "Virages et Fixage, 1893," points out that chloroplatinite of potash combines with free silver nitrate to form an insoluble salt which yellows under the action of light, and further it also forms an insoluble salt with hypo, which is also sensitive to light. Then again, all platinum toning baths are acid, and traces carried into the fixing bath may set up decomposition of the hypo and the incipient germs of fading. Chloroplatinite of potash coagulates gelatine, and may thus directly attack the baryta-bearing gelatine. The rational method of treating C.C. prints for platinum toning is obviously then to first immerse them in salt and water, so that no free silver salts, such as nitrate and citrate, are left in the paper, and then after toning to wash thoroughly, or else treat them to an alkaline salt bath and then fix in an alkaline hypo bath containing a little sulphite. If useful information is to be gathered from the members of the P.P.A. and others who use C.C. paper, as suggested by the hon. sec., specimen prints must be submitted with full working details, and we would suggest that when the spots are met with some of the same paper should be treated as we have suggested and compared under identical conditions with the defective prints.

* * *

Who was the Inventor?

When photographs in the colours of nature are firmly established among us, the question will some day arise as to who originated the method. Most persons would assert that the discovery or invention cannot be credited to one particular brain, but that, like many other inventions, it is the result of assiduous work upon the part of several individuals, Mr. F. E. Ives taking first place among them. But there is one name at least which should not be forgotten, although many have never heard of him. He was not a photographer, but an artist, and one of some distinction presumably, for he was painting master to the late Queen Victoria. His name was Henry Collen, and a full description of the process of colour photography which he suggested will be found in our volume for the year 1865. It is true that the method proposed would not have succeeded, for he based it upon the old theory that the spectrum was made up of the three so-called primary colours—red, blue, and yellow, but in it lies the germ of modern methods of working. He writes that if substances were discovered sensitive only to the three primaries, that is to say, one substance to each colour, it would be possible to obtain photographs in the tints of nature by some such means as the following:—Obtain a negative sensitive to the blue rays only, a second one sensitive to the red rays, and a third sensitive to the yellow rays only. Then he goes on to suggest that positives could be printed on the same kind of material as that used for the negatives so as to obtain three-coloured pictures, and that if these were superposed and laid on a white surface the colours of the original would be reproduced. To use his own words: "It will not be difficult to suppose that the effect would be not only the representation of the form of the object, but that of its colour also in all its compounds." These words, written

nearly forty years ago, seem to be strangely prophetic. It is true that the ideal substance which shall be sensitive in turn to each of the colour sensations has not yet been found, but we have now a very good substitute in the orthochromatic plate in conjunction with light filters. Henry Collen's suggestion was a most significant one, and if he had been a photographer he would at least have found a pedestal equal in height to that of Dr. Hauron, who published his method two or three years later. Indeed, the two methods are very much the same in principle, and both were based on a false theory of colour, but Collen's had the merit of priority.

* * *

The Colour Problem.

As will be seen by reference to our report of Mr. Sanger Shepherd's lecture to the Camera Club last week, that indefatigable worker promises us a process for producing coloured photographs on paper which, unless he is over sanguine, will mark a very forward step in the history of composite heliochromy. One might reasonably imagine, looking to Mr. Shepherd's successful work in the production of lantern slides in colour, that the new process would follow the same lines, with the superposition of three coloured films on a rigid support, the support in question being paper in lieu of glass. But he expressly repudiates such a method of procedure, and explains that the new method may be likened to a water-colour drawing in that pigments and pigments alone form the image. This would appear to be quite a new departure so far as the hand production of photographs is concerned, although such pigmental pictures have been produced from three different blocks in various methods of tri-colour printing—the Orloff, for example. But most attempts to produce a coloured image on paper have hitherto rung changes on the superposed film method. Such a process was produced a few years back, which gave excellent results, the films consisting of layers of collodion, but the cost, trouble, and uncertainty involved in producing a single picture made the commercial working of it impossible. Mr. Shepherd's process is simple, we are told, and cheap, the printing of a dozen quarter-plate pictures costing less than three halfpence apiece. One thing which he told his hearers, which does not appear in our necessarily abridged report, was that the new process would admit of all kinds of liberties being taken with the prints produced, from which we gather that the proportions of red, yellow, and blue in a picture can be varied at the sweet will of the operator. This opens up terrible possibilities for the future. We have lately seen how the comparative novice can distort nature when he has only black and white to do it with. What will be the result of placing in his remorseless hands a box of colours?

THE Thornton-Pickard 1902 Competition.—The following is a list of the prize winners in this competition:—Mr. J. N. Taylor, Christchurch, N.Z.; Mr. G. R. Ballance, St. Moritz Dorf; Mr. W. Wilkinson, Derby; Mr. W. E. Topping, Belfast; Miss Ella Tomlinson, Chichester (two prizes); Miss Agnes Tomlinson, Chichester; Mrs. Barton, Birmingham (three prizes); Mr. Paul Massia, Algiers; Mr. H. Beadnell, Redhill; Mlle. Celine Laguarde, Aix-provence; Mr. Graystone Bird, Bath; Lieut. A. W. McCombie, Woolwich; Mr. A. W. Sargent, Cardiff; Miss Sybil Aird, Eastbourne (two prizes); Mr. J. Cooke Smith, Champéry, Valois; Mr. W. J. Watson, Toronto; Mr. Andre Callier, Ghent; Mr. J. O. Samuels, Parkgate; Mr. R. W. Martin, Altrincham; Mrs. Mahony, Dalkey; Mr. A. Durn, Wotton-under-Edge; Mr. J. Field, Woodhall Spa; Mr. A. Macpherson, Stoke Newington, N.; Mr. T. Johnstone, Motherwell; Mr. J. Walker, Birkenhead; Mr. R. W. Dugdale, Gloucester; Mr. A. Compton, Sydenham; Mr. G. E. Low, Kingstown; Mr. A. W. M. Dickins, Bromley; Mr. Alphonse Cazal, Montpellier; Mr. W. Bratherton, Barrow-in-Furness; Mr. G. A. M. Baker, Harrow. The number of entries and in-prints sent in was considerably larger than last year, there being an increase of 138 of the former and 345 of the latter. The company are already organising another competition for the coming year, and are dividing the prizes into classes, including one for stereoscopic workers.

THE ELECTRIC CURRENT IN THE STUDIO.

SINCE the successful introduction many years ago, by Van derweyde, of electric-arc illumination for studio portraiture the use of electricity has been gradually but slowly gaining ground in the practice of the best portraitists. We say slowly, for, since the initial cost of an installation—where the current is already laid on, and the main lead is of sufficient capacity—does not necessarily exceed a score of pounds, the non-adoption of this means of lighting cannot well be due to financial causes, and it scarcely need be said that electrically lighted studios are the exception rather than the rule. A question, then, pertinent to the subject naturally arises, "Why this holding back?" We think we have discovered the cause. Recently we were in the company of a large number of what we might term representative professional photographers, when one of the number, apropos of the subject we are discussing, gave an opinion upon it which, to our surprise, was upheld by nearly all present. "Well," he said, "I have scrutinised a lot of portraits taken by electric light. I have never yet seen one equal to a good daylight picture." This opinion, as we say, was echoed by most of those present; yet, to our mind, it emphatically was not justified by the facts of the case. It is true that there are abroad a large number of badly lighted portraits taken with electric illumination; but to condemn the many because of the few is as bad in principle as it is in this case unjustified in practice. We have seen many portraits reflecting the highest credit upon their producers, who, having nothing but electricity to depend on for lighting the sitter, yet obtained results which no one could differentiate, by their appearance, from daylight photographs. When, as is evident to anyone who studies our "Answers to Correspondents" columns, we see so much ignorance upon the simple lighting of a studio by daylight, we ought not to be surprised at the inability of some men to so arrange their lighting with the electric current that the pictures taken by its aid should neither be inefficient as portraits nor unsuccessful as pictures.

It is obvious then that the schoolmaster needs to be abroad in matters of artistic lighting before its true principles are generally understood. There cannot possibly be anything in electric light *per se* that would prevent good portraits being taken; it is merely a question of its application. The chief difference between daylight and the best known forms of electric light illumination is that in the former the direction of the light and the area of what we might term the illuminating pencil is governed by the use of blinds, and is capable of being easily varied so as to obtain a pencil of light of any width, and directed upon the sitter from any angle. In the latter the illuminating area in the majority of forms of the lighting arrangement has a fixed width of illuminating pencil with a small maximum, and is equally capable of being directed from any angle.

The general tendency of inventors has been in the direction of modifications of the "umbrella" form of apparatus—that is, an arrangement shaped like an umbrella with a white reflecting under surface, the light itself being either a series of incandescent lamps directly lighting the sitter, or a central arc light or lights screened from the sitter and indirectly lighting him by reflection from the white inner surface of the umbrella. The incandescent type is almost always placed on a movable stand, while the arc form is used both in fixture and stand form. One great defect of many of the former kinds, and especially noticeable in foggy weather, is the transparent nature of the hemispherical reflector; this can, however, easily be remedied, and should be, as it nullifies one important advantage of the electric form of lighting in that it illumi-

nates the atmosphere between lens and sitter, and so does not utilise the great power possible of avoiding foggy negatives as would be the case if no illumination proceeded from the back of the arrangement. All this is avoided in the usual arc forms, as the umbrella has to be substantially built, so as to present a solid reflecting surface for its pure white lining of pigment or paper. It is obvious that by not making use of the direct light of the arc itself, the reflected light only being utilised, a great amount of light is actually thrown away, and we have long held the opinion that the true principle of construction should embrace the utilisation of both the direct and the reflected light from the arc. There are comparatively isolated instances of the adoption of such a principle, one adaptation of which was quite recently reviewed in these columns.

To carry out such a system in its most perfect form the light itself would be best placed entirely outside the studio windows. Internally half-silvered globes might be used, so as to be as independent of the rain as the usual public outdoor arc lamp. The next point then to consider would be the breaking up of the too dazzling effect upon the eyes that the close proximity of the arc would entail. This might be carried out either by translucent screens or other light diffusing media. A series of prismatic refracting or reflecting glasses could be put up; the "Luxfer prisms" described some little time ago by us could be utilised, or a series of small silvered reflectors at various angles according to the distance from the arc could be adopted. A hundred ways might be devised for obtaining the maximum of light and the minimum of glare, and we feel assured that in the construction of lighting arrangements of this type is to be found the extirpation of the belief of the inferiority of electric to solar lighting. Properly devised and carried out, the acting efficiency of the arc might also be increased to tenfold that of the arc lighted umbrella form.

THE RIGHT TO EXHIBIT SITTERS' PORTRAITS WITHOUT THEIR CONSENT.

It may be remembered that, about this time last year, we made some comments on two decisions—the one in Scotland and the other in England—with reference to the right of a photographer to exhibit portraits taken in the ordinary course of business, that were diametrically opposed to each other. So far back as 1888 it was ruled in the English Court of Chancery, in the case of Pollard versus the Photographic Company, that a photographer had no right whatever to exhibit, or use for his own purpose, portraits taken of his sitters. The case in the Scotch Court was this: Enlarged portraits of two daughters of the plaintiff—in Scotland termed the pursuer—were being shown as specimens at a photographer's, and he sought to restrain their exhibition. The case came before the Sheriff's substitute, who decided that the photographer had the right to exhibit them if he thought fit to do so, and he therefore refused to grant an injunction—or interdict. Just after this decision was given, another and similar case was brought in our Court of Chancery, before Mr. Justice Swinfen Eady, and here the decision was identical with that previously given here—namely, that the photographer has no right to exhibit, as was claimed by the defendant, against whom an injunction, with costs, was granted. We pointed out at the time that, although the forms of law in Scotland are different from what they are here, it was seldom that, in the main, the decisions were distinctly opposed to each other, but in these cases they were, for, while it was illegal to exhibit portraits in

England, it, according to the Sheriff Substitute's ruling, was legal to do so in Scotland.

This decision, however, was appealed against, and the Sheriff Principal recalled it, and sent the case back for proof. After hearing proof, the Sheriff Substitute granted interdict, saying in a note that he did so "out of deference to the opinion expressed by the Sheriff." But the matter did not rest at this, for this decision in turn was appealed against, but, according to the *Glasgow Herald*, the Sheriff Principal adhered to it, with costs against the photographers. It will now be seen that after about a year's litigation it has been decided that photographers in Scotland have no more right to exhibit portraits of their sitters without their permission than have photographers in England. We surmise that these decisions, alike in Scotland and England, will meet the approval of most persons. In delivering judgment in the case of Pollard v. the Photographic Company tried in 1888, Mr. Justice North clearly deals with the relations between the photographer and the sitter, when he said: "The customer who sits for the negative thus puts the power of reproducing the object in the hands of the photographer, and in my opinion the photographer who uses the negative to produce other copies for his own use without authority is abusing the power placed in his hands."

In the Scotch case there is a point worthy of note; the negatives were not actually taken by the defendants. They were taken by Miss Adamson, whose business, with the negatives, etc., eventually passed into the hands of Messrs. Crow and Co., who were the defendants in the action. Here it will be seen that the sitter has control over the negatives after they have left the hands of the one who took them. This recalls to mind a point we referred to a few years ago. It was this: In strolling through the Friday Market, in the Caledonian Road, we saw a number of finished carbon enlargements, 36in. by 30in., and under, for sale; also a large number of cabinet size negatives in envelopes, named and numbered. Curiosity induced us to look at some of them, and many, we noticed, bore the names of the elite of society. Evidently the negatives were part of the stock of a West End house that had, sometime before, "come to grief." Now it will seem from the recent decisions that sitters can prohibit their portraits from being exhibited anywhere, or by anyone, even though they may have changed hands. Hence, those who may have purchased the negatives in question could be prevented from making any use of them. This is as it should be, for it would be exceedingly annoying to sitters taken in a high-class studio, say at the West End, to find their portraits exhibited, for example, in Whitechapel, Westminster Bridge Road, and such-like localities.

"THE Platinotype Process" formed the subject of demonstration and discussion at the Chiswick Camera Club's meeting on Thursday week. Messrs. T. A. Coysh and A. Michaelsen demonstrated, and many of the members discussed.

THERE are more graves dug for colour-photography than for any other process, said Mr. T. K. Grant last Monday evening to the South London Photographic Society; and then after touching briefly on the history of colour-photography demonstrated the simplicity of the Lumiere N.A. process and the beauty of its results. Three screens, blue, yellow, and red, are required, and are fixed one at a time in front of the lens during exposure, which is made on three separate plates. Prints are then made on a mica sheet coated with gelatine emulsion sensitised with bichromate of potash giving a partially visible image. These three prints are developed by suspension in hot water at 150 F., and fixed in hypo-solution. The prints are then dried and dyed in aniline dyes, and afterwards carefully registered, giving a transparency in colour which is mounted between two sheets of glass like a lantern slide. Mr. T. K. Grant successfully developed and dyed several prints, and showed some excellent results on the screen. Emphasis was laid on the importance of keeping to one process of colour-photography right through, not using one make of plates with a different make of dye, etc.

THE HALF-TONE NEGATIVE UNDER THE MICROSCOPE

WHILE making photo-micrographs of pathological specimens some time ago, it occurred to the writer that an interesting series of studies might be made of the photographic negative in its various stages of production, and the results of a few investigations are given here.

The half-tone screen negative was selected, for various reasons, as the most suitable for examination. In the first place, half-tone negatives are usually wet collodion films, and a wet collodion photograph was a sine qua non for the high power objectives, on account of the silver in wet-plate negatives being deposited on the surface of the film, and the collodion, being free from granularity, does not impede the transmission of light. With gelatine dry plates the silver forming part of the emulsion renders it impossible to use a high power objective with any success, as the thickness of the gelatine film prevents the whole depth of the silver in the field of view being in focus at the same time.

There was another very important reason for using a screen negative, viz., the structure and size of the "dots," being practically the same all over the plate, providing a material of even texture is photographed (in this case a piece of white paper was used as the subject), the subsequent operations of intensifying can then be carried out with separate pieces of film, and the dots of each portion of film will have the same relative value. The half-tone dot makes a very convenient object for investigation, as its density varies from opacity in the centre to a few sparsely scattered grains at the edges. With the immersion lenses, the whole of the "dot" does not appear in the field of vision when under observation with the eyepiece, but when the inner tube and eyepiece of the microscope are removed, for photographic purposes, the increase of angle enlarges the field, and the whole of the dot comes easily into sight on the focussing glass.

Only one negative was used for the photo-micrographs of this article, to ensure identity of size and appearance in the screen points, and the camera remained in the same position for all objectives.

It will, perhaps, be best to give first the general effect of a screen negative under a low power. The following photograph (Fig. 1), taken with a $\frac{3}{4}$ in., will answer that purpose. The

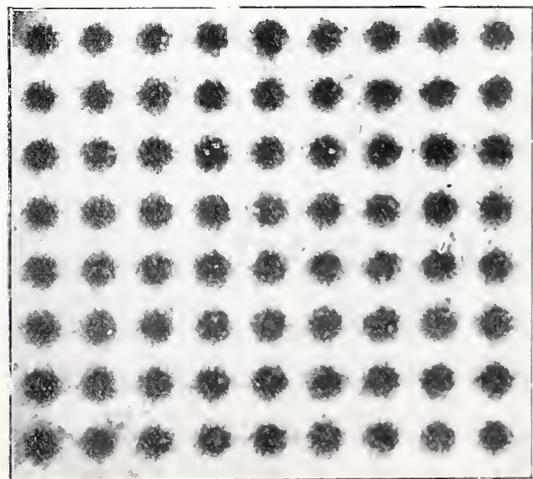

Fig. 1.—Object. plus 30 diameters.
Photo-micro. of screen negative.

film had been intensified with nitrate of lead. In this reproduction the dots appear as black patches, with ragged edges; the varying density of the silver deposit is not apparent till a higher power is used.

The next illustration (Fig. 2) shows the dot under a $\frac{1}{6}$ in. objective. The granules of silver, it will be observed, are here plainly visible; in the middle of each dot they are deposited in

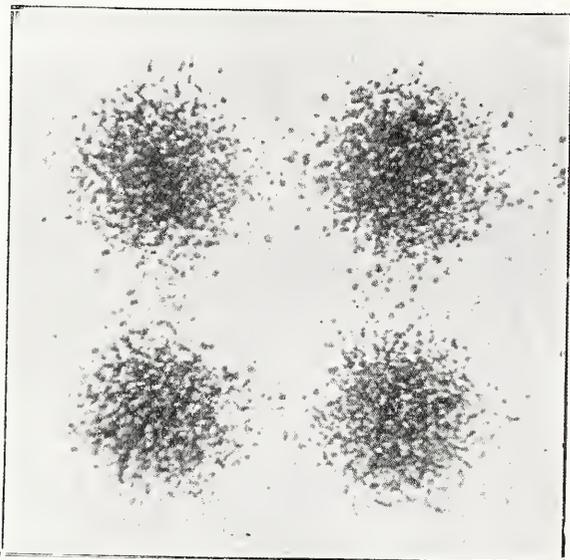

Fig. II.—Object. $\frac{1}{6}$ plus 170 diameters.
Photo.-micro. of half-tone dots (unintensified).

dense patches, with the light showing between the clusters. The deposit decreases towards the edges, till only a few isolated granules of silver are visible.

In another illustration (Fig. 4), in which the dot is photographed with an oil immersion objective, the silver deposit is shown still more clearly; but the lower power was required to show the characteristic way in which the particles of one dot merge into the adjoining screen points.

Our next photograph (Fig. 3) gives the appearance of the image after it has been intensified. For process work lead

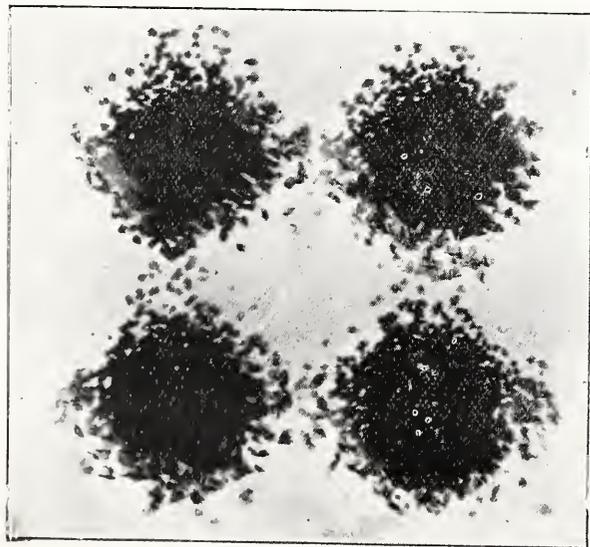

Fig. III.—Object. $\frac{1}{6}$ plus 170 diameters.
Photo.-micro. of dots, intensified with lead.

intensification is in general favour, on account of the dense black image resulting from its use. The film of Fig. 3 was intensified in this manner. It will be noticed that the lead has considerably increased the size of the dense portion of the image, which has spread nearly to the edges of the dot, and the light can no longer penetrate between the patches of black as in Fig. 2.

The foregoing photographs have been made with low power

objectives, in order that several dots may appear on the same plate. The following illustration (Fig. 4) gives the appearance

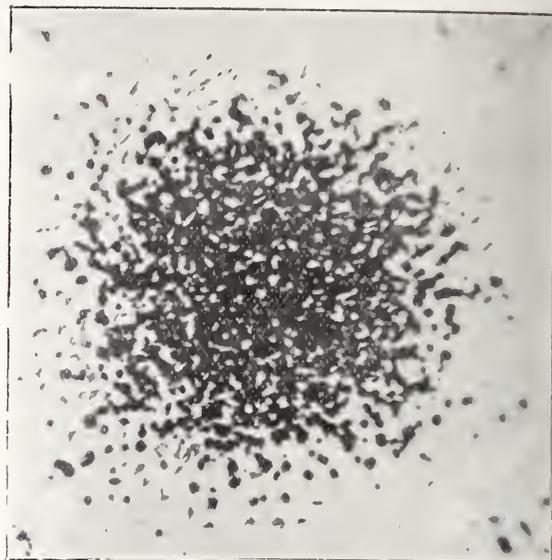

Fig. IV.—Object. $\frac{1}{12}$ plus 400 diameters.
Half-tone dot before intensification.

a half-tone dot presents under a high power. It was taken with an oil immersion, and shows the shape and distribution of the silver granules very clearly. The particles of silver do not assume any specific form, though many are of a circular shape. In the illustration the negative is shown as it appears after development and before the intensifier has been applied. Fig. 5 is the result of mercuric intensification.

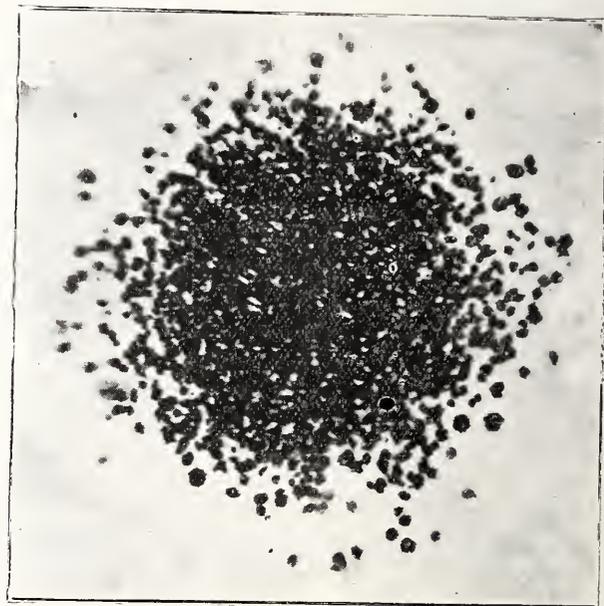

Fig. V.—Object. $\frac{1}{12}$ plus 400 diameters.
Showing appearance of dot after mercuric intensification.

The action of mercury, it will be seen, is not nearly so drastic as that of lead, and on this account it is rarely used in half-tone work, where density is the great desideratum; but as it is the chemical generally used by dry-plate workers to obtain contrast in flat negatives, the effect produced on the silver deposit by its use will be of interest.

It will be noticed that the silver granules have been considerably enlarged, and the light cannot penetrate through the centre of the dot in as many places. After being intensified with mercury, the image was not blackened by the application of am-

monia, as under the microscope the silver particles, after the use of mercury, remain opaque. In this respect mercury differs from lead, which gives an opalescent image under the objective, and requires the application of ammonia-hydrosulphuret to give the necessary opacity.

We now come to Fig. 6, in which the portion of film under observation has been intensified with lead, and blackened with am. hydrosulph. The appearance of the dot has been altered far more than when mercury was used to strengthen the image. The dot is practically opaque, except just round the edges, and even there the dark blotches are very much in evidence. It will be readily understood from this illustration what valuable assistance lead intensification gives to the half-tone operator, who requires excessive density in the lights and clear glass in the shadows for a perfect negative.

The operator who had only seen a screen negative through an ordinary magnifying glass would be surprised to find how little the dot has increased in actual size by the application of lead ;

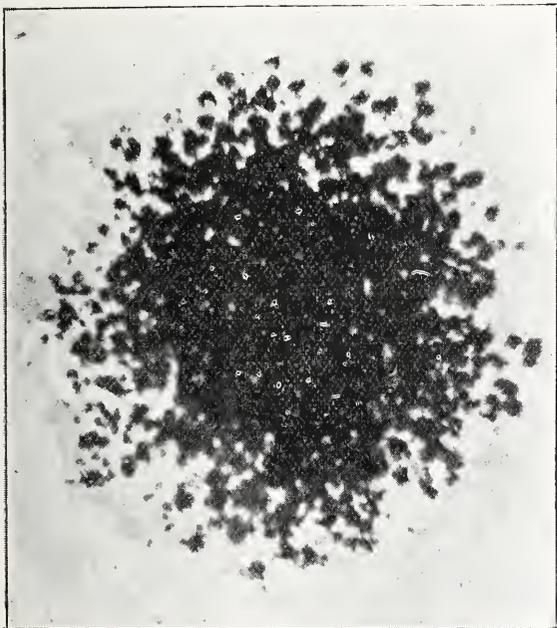

Fig. VI.—Object, $1/12$ plus 400 diameters.
Half-tone dot, intensified with lead.

with a strong magnifying glass the dots appear to increase considerably in size during intensification, and in the densest part of the negative to gradually overlap each other. There is really only an infinitesimal increase in the actual circumference of the dot, but the isolated grains of silver that were invisible to the magnifying glass (though easily detected by the microscope) become much larger by the action of the lead, and thus form part of the picture when viewed through the pocket lens.

Our next illustration (Fig. 7) is a reproduction of the dot as it appears after being intensified with lead, but before the crystals have been rendered opaque by am. hydrosulphuret.

The structure of the crystals can be plainly seen in many of the granules round the edges of the picture. Of course, the centre is out of focus, as the silver particles are piled up in the middle, and are consequently too near the objective ; in order to focus the edges of the image sharply, the detail of the densest deposit is lost.

The progress of lead intensification can be plainly seen under a high power. The writer found at first some little difficulty in accurately following the action of the intensifier, but after several failures in trying to find the best way of fixing the film to the glass, and applying the lead solution success was attained,

and the gradual increase in the size of the granules was easily observed. The change in the size and appearance of the silver grains makes a very interesting study, and is well worth the trouble involved in carrying out the necessary preparations.

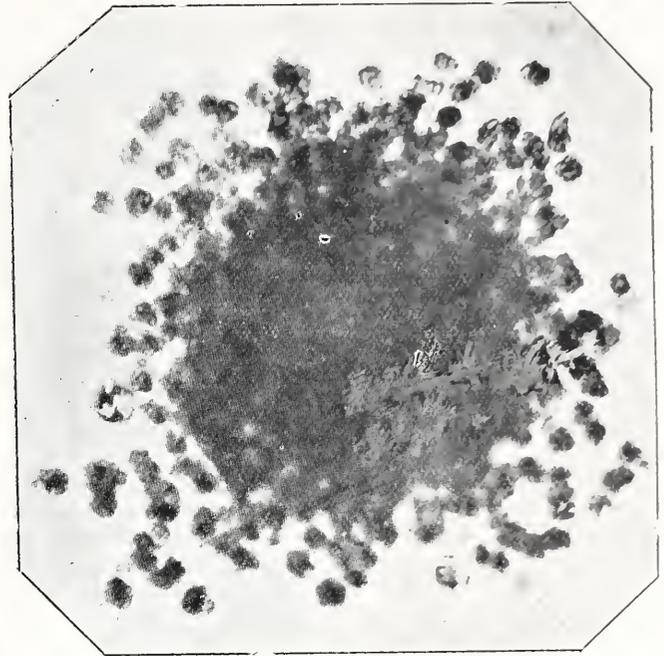

Fig. VII.—Object, $1/12$ plus 450 diameters.
Half-tone dot, intensified with lead, not rendered opaque by am. hydro. sulph.

The objective we found to give the best results was a $\frac{1}{2}$ in. Zeiss (dry) ; the higher power wet lenses for this purpose were not satisfactory.

A piece of wet film is placed on the slide and dried over the lamp ; it will then remain flat on the glass. The cover slip being placed over the film, a dot is moved into the field of view, and carefully focussed. The lead is applied to the edge

Fig. VIII.—Object, $1/12$ plus 300 diameters.
Photo.-micro of ordinary wet-plate negative.

of the cover slip by a camel-hair brush, and the solution flows, by capillary attraction, between the glasses and over the film. The entrance of the fluid throws the dot out of focus, and the objective must be brought away from the

cover slip by a turn of the fine adjustment screw. The action of the lead is at once apparent, and the crystals of silver begin to expand. It is best to fix the attention on a few granules that are lying near, but do not touch, each other; these will gradually increase in size, till the intervening spaces are closed, and the several grains have consolidated. It will be found that several applications of the brush will be required before full density is attained. The original diameter of the particles is doubled when the action of the lead ceases.

Of course, the actual amalgamation of the lead and silver cannot be followed, but the writer hoped, by the use of a 1-12th immersion, to observe at least some local disturbance of the water round the granules while intensification was in progress. This, however, did not occur; the particles enlarged, but no motion of any kind was perceptible, though a comparatively large amount of lead was being drawn from the water.

The only evidence of movement was given by some minute specks of insoluble matter that were by chance in the unfiltered lead solution. Several of these floated across the field of view, and whenever they came near a granule that was being intensified were thrown into a state of agitation, which did not cease till they were drawn by attraction to the crystals, or had passed beyond their influence. When first observed, it appears as if the silver grains remain quiescent, and the lead is precipitated upon them, and the appearance of granules, with dark spots in the centre, certainly justifies the impression; but on closer inspection it is evident that the silver is amalgamated with the lead. The unintensified silver of the dot is practically opaque under the microscope, while the nitrate of lead is opalescent. After intensification many of the crystals are semi-transparent in all parts, which proves that the silver has been distributed and rendered permeable to light by the action of the lead. To make certain of this, the grains were examined with a polariscope, in conjunction with the 1-12th immersion; but even that test failed to resolve the crystals. It is not clear what causes the silver to combine with lead to such a degree; whether the action is caused by the magnetic influence brought about by the conjunction of two metals, or is merely the result of chemical affinity.

If a zinc plate is immersed in an alkaline solution of sulphate of copper, a coating of copper is deposited on the zinc. This experiment seems to favour the magnetic theory, but in that case the lead should be deposited in its metallic form, whereas it is precipitated in crystals.

With mercuric intensification there is considerable difficulty in following the progress of amalgamation, as the grains remain practically opaque, and the increase in size of the deposit is so slight that there is not much chance of successfully observing it.

Bromide of copper is very much in vogue with wet-plate workers for intensification purposes, and would probably afford an interesting field for study. It comes between mercury and lead for density of deposit.

It may be mentioned in passing that the photograph of Fig. 7, which gives a very fair idea of the appearance of the silver deposit under a high power, was not obtained without some difficulty, owing to the opalescent nature of the subject; but by the use of a yellow screen and an exposure of half-an-hour a very fair result was obtained.

Our last photograph was taken from an ordinary wet-plate negative (landscape), and shows the irregular deposit of silver on the photographic plate; it was taken from a rather thin part of the negative. The high lights of the picture appear under the microscope as an almost solid mass of granules.

We may remark, in closing, that the screen used in taking the

negative for our experiments was ruled 150 lines to the inch consequently Fig. 7 shows the half-tone dot enlarged to over 200,000 times its original size.

J. I. PAGE.

"PICTORIAL SELECTION" COMMITTEES.

Few can have felt greater dissatisfaction with the work of the Royal Photographic Society's Pictorial Selection and Hanging Committee than I have; although, in response to the invitation of the Council, I accepted membership of that tribunal, and tried to be of service thereon.

I may as well acknowledge that the Editor of the *Photographic News* has correctly divined my reasons for lending my name to the "Pictorial Wing of the Royal Photographic Society" (see "Editorial Chat," No. 357, October 31st). It is probable that others were actuated by similar zeal, and have been as disappointed as I am.

Yet I knew enough of the leaders in that movement to have been aware—had I given the matter due thought—of the probable leaning of their sympathies. But I am one of the credulous and confiding British Public, which, prone to accept men at their own valuation, would no more think of questioning whether those who undertake to look after the interests of pictorial photography are qualified to do so than it would of inquiring whether "the butcher, the baker, and the candlestick maker," so anxious just at present to be entrusted with the safeguarding of the interests of National Education, are capable of even the crudest conception of what that term implies.

I see no reason why the motives of the "Wing" should be called in question. Our actions are another matter: their results are obvious, and are a legitimate subject of comment.

But please give us credit for purity of intention. Try to believe, for instance, that our leader, in sending in—let us say—"The Park Palings" for exhibition, was only philanthropically anxious that other photographers and the public generally should have the opportunity of seeing what he considers to be purely pictorial photography.

Try also to believe that those members of the "Wing" who formed the largest united party on the Selection Committee, and who voted so loyally for each other's work, were not moved by the petty vanity that burns to exhibit itself, but were consumed with similar devouring zeal for the æsthetic education of that photographer, amateur or professional, who merely "takes" beautiful things, people, and scenery, and whose work has only the commonplace characteristics of perfect technique and good taste, and no "personality" or other eccentricity whatever.

It is not wonderful that such benighted folk should fail of the lesson intended for them, and should even draw—from an exhibition notably rich in works that were quite beyond ordinary comprehension—conclusions prejudicial to that confidence which a committee so anxious for their improvement, and for the reputation of the Society, should beget.

It is time, however, to be serious. The inferences Mr. Bennett drew from matters of common knowledge and from personal observation are simply the conclusions at which any intelligent thinker would arrive. If not absolutely exact in every minute particular, he is very near the mark. His criticisms are perfectly justifiable.

No good purpose can be served by deprecating public comment on what is so largely of public interest. I think Mr. Bennett did well to write to the magazines. It is usually an effectual preliminary to further action, and I fancy we shall find that Mr. Page Croft's challenge to bring the matter before a meeting of the R.P.S. was unnecessary.

I have only one more reference to make to the correspondence that has arisen. Mr. Warburg's memory is at fault in one respect. There was not the unanimity he has implied in the voting on certain pictures. Several were passed on a majority of one vote, and in spite of strongly expressed dissent. This can be easily confirmed. Let us have daylight.

I am pressed for my "opinions" upon the whole matter. I will try to express them briefly.

1.—A large hanging committee is a mistake. The work is better done by four or five earnest and qualified men. But if it has been decreed that hanging committees of the R.P.S. shall consist of fifteen members, then let each committee organise itself, appoint a chairman, adopt rules of procedure, and do its work in decency and order. I was astonished to find, on my unavoidably late arrival, that no attempt had been made to establish routine or to secure decorum. One member kept up a constant shouting that made it a most difficult matter to address any connected remark to the others. A chairman was sorely needed.

2.—Some consistent standard of appraisalment should be, if possible, agreed upon for general guidance.

The best committee would be, I think, composed of five members—namely, two artists, two expert photographers, and a chairman, acquainted with both art and photography. (The others might also be qualified in both directions, but I am suggesting that two work as artists, etc.) The two artists should review the works, and pass all having a claim to be considered pictures. (Not merely pictorial, but pictures: there is no reason why anything imperfect should be accepted in photography.) Then the photographic experts should pass only those pictures which could claim to be excellent in technique.

But, if there must be fifteen, then let a section be delegated to pronounce on pictorial merits; a second on technique; and a third to ensure that no frames outrageous in themselves, or calculated to be an outrage to others in their proximity, be passed.

And if these three searching tests should leave but two hundred works for the exhibition walls, all the better for the quality of the exhibition, and for the benefit of those who go to see it.

3.—One way of raising the standard of the work would be to limit the number of entries. Nobody should be permitted to send in more than three works, or be entitled to have more than two hung.

A greater number of exhibitors would thus be represented, and new talent would have a chance of showing itself. And notable artists in photography would be precluded from "spoiling the sample." There were several cases, in the exhibition just closed, wherein if the artist had been represented by his one best work, he would have stood infinitely higher in popular estimation.

No hardship would be imposed by the limitation. Every man knows, within a little, his best dozen works during the year: in selecting the best three of these he may find a little difficulty, but will probably be right in his selection. And why should a selecting committee be charred to differentiate in such cases?

We had to deal with more than one instance of a whole series of studies from the same subject. It is ridiculous to suppose that a committee will hang a dozen studies of the same pretty girl in the same pretty hat; let the artist send the best trio, and spare the committee for more useful and less tedious work.

4.—But, above all, if the Royal Photographic Society would improve the pictorial quality of its exhibitions, let it do something to encourage the study of pictorial composition, par-

ticularly with the view of teaching wherein photography differs from the graphic arts—wherein it is inferior, and wherein it is superior—and how certain old conventions do not, while others do, apply to the genius of photography.

5.—And, finally, if we would improve our own work pictorially, let us have a little more masculinity in our methods, and in our talk about them. We are dealing with Photography, and a very fine and beautiful thing it is.

But there are certain rules just as applicable to our craft as ever they were to the graphic arts, because they are based upon aesthetic demands not very difficult to understand if thoughtfully studied, and calculated to be of the greatest assistance to the pictorial photographer.

But, alas, these rules and their foundations are far easier to talk and to write about than to understand, as every day proves in the amount of what a witty writer has lately called "flap-doodle" concerning art that magazines pour forth upon the amateur and the unwary.

Distrust the guide who, when you ask him for an opinion upon your first snap-shot at Scarborough Harbour, begins to talk to you of Velasquez, John Ruskin, and Poynter, and particularly of "individuality."

J. T. ASHBY, F.R.P.S.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION. FORMATION OF A BIRMINGHAM BRANCH.

A meeting of professional photographers of Birmingham and district was held at the rooms of the Birmingham Photographic Society, on Monday, November 6th, to consider the formation of a branch of the Professional Photographers' Association. Mr. H. J. Whitlock presided.

Mr. Harold Baker, who had undertaken the duties of hon. secretary *pro tem.*, read letters from photographers of Kidderminster, Leamington, Bilston, Cannock, Leicester, Bridgnorth, Ludlow, Hednesford, etc., regretting inability to attend, and expressing sympathy with the object of the meeting. A telegram was read from Mr. William Grove, President P.P.A., wishing the meeting success.
