Mr. Alfred Ellis, hon. sec. P.P.A., gave a short account of the formation of the Professional Photographers' Association in March, 1901, and of its progress to the present time. He said that approximately 550 photographers had joined, and that they had now a balance in hand of about £140, so that they were in a satisfactory position financially. The objects of the Association were: To promote the interests of its members in their professional work, by watching Parliamentary or public action affecting the interests of photographers, by dealing with matters affecting professional custom and practice, by co-operating with similar associations for the purpose of securing united action and mutual support in dealing with matters affecting the profession. As the Association was a newly-formed one, a considerable part of its first year's existence had naturally been spent in getting the machinery into working order, but still they had been able to do some good practical work. They had taken up the question of dealers' discounts to professional photographers, and had obtained some concessions, and undoubtedly would have been able to command still more had they been representing 5,000 instead of 500 photographers. The question of the premiums exacted by Fire Insurance Companies from professional photographers had been most successfully dealt with, and they were now in a position to get their members insured at a rate 20 per cent. less than they were paying heretofore. Mr. Ellis strongly urged each one present to join, and to bring in his friends in the profession. He pointed out that with a membership of four or five thousand they would have, at their present subscription of 5s., an income of at least £1,000 per annum. With such an income they would be able to have a permanent office and staff, and would be in a better position to assist their members in any difficulties they might encounter. As an example of what the Association was already doing, he might mention that he replied to about seventy letters a month, and that the advice of the committee was asked on questions so widely different as copyright insurance, lighting, and building studios, electric lighting, discounts, becoming dealers, price cutting, objectionable advertisements, exhibiting specimens, of private sitters, etc. In conclusion, he reminded his hearers that they should not expect to find that their subscription of 5s. brought an immediate and definite return. It should be looked upon as an investment for the benefit of the whole profession of which they were members. It was not only in this country that photographers had found the need of an association devoted to their interest. France had

a similar organisation, with which we were in friendly communication, with the object of mutual help.

Mr. Harold Baker, in urging the necessity of an Association for mutual protection, referred to a circumstance which had occurred in his own business, which clearly involved a question of importance to the whole profession.

Mr. T. C. Turner, hon. sec. of the local branches committee, who had journeyed from Hull in order to attend the meeting, moved a resolution that a local branch for the City of Birmingham and district be formed. Mr. Turner, in recommending the resolution to those present, explained the methods of working local branches, and gave an account of their work in Hull, where every photographer in the town, with two exceptions, had joined the branch. The result had been to put an end to the cutting of prices, as those photographers whose prices were low had asked the local branch to draw up a scale of minimum charges for certain work, and the members had agreed among themselves that work of a certain size, which had been done for 3s. 6d., should not be executed for less than 15s. Mr. Fletcher seconded the resolution, and in the discussion which followed Mr. J. W. Beaufort announced his intention of joining the Association, but expressed the fear that as there were photographers of such varied standing in the district it would be impossible to get them to work together for mutual protection. He also said that he was convinced that it was mistaken policy to charge low prices, as since he had raised his own he had done more business. Mr. Harold Baker thought the fact of there being so many different grades of photographers was the best argument in favour of combination, and pointed out that the best men in London, who had little or nothing to gain, had been most active in promoting the interests of an association whose object was to improve the position of all photographers, whatever their standing might be. Mr. Alfred Ellis then pointed out that the Association had no intention of interfering with any man's way of business, but sought to bring about a better state of things by mutual discussion and arrangement. The resolution was carried *nem. con.*

On the motion of Mr. H. J. Whitlock, seconded by Mr. McLucas, Mr. Harold Baker was elected branch hon. sec. Mr. Whitlock was elected chairman, on the motion of Mr. Baker, seconded by Mr. J. W. Beaufort. Votes of thanks were passed to the Birmingham Photographic Society for the use of their rooms for the meeting, and to Mr. Whitlock for presiding. After an excellent suggestion by Mr. Harry Whitlock, that each member should personally canvass all his neighbours, the meeting was brought to a close by every photographer present giving in his name as a member.

The following is a list of those who have been recommended by the President and Council of the Royal Society for election into the council for the year 1903, at the anniversary meeting on December 1st:—President, Sir William Huggins; treasurer, Mr. Alfred Bray Kempe; secretaries, Sir Michael Foster, M.P., and Dr. Joseph Larmor; foreign secretary, Dr. Thomas Edward Thorpe, C.B.; other members of the council, Mr. William Bateson, Mr. William Thomas Blandford, Professor Hugh Longbourne Callendar, Mr. Francis Darwin, Professor Harold Baily Dixon, Professor George Carey Foster, Sir John Gorst, M.P., Professor John Wesley Judd, C.B., Lord Lister, Professor George Downing Living, Professor Augustus Edward Hough Love, Professor Henry Alexander Miers, Professor Edward Albert Schafer, Captain Thomas Henry Tizard, R.N., C.B., Professor Herbert Hall Turner, and Sir John Wolfe-Barry.

CHEMISTS and the Kodak Policy.—An "M.P.S." writes to our contemporary, "The Pharmaceutical Journal" as to the "clear (?) statement" issued by the Photographic Trade Association, which body is endeavouring to enlist the sympathy and support of the public. What a failing cause theirs must be when they have to shout for the sympathy and support of the public. The chemist dealer of to-day knows on which side his bread is buttered, and wants none of that "open competition" which prevents him from obtaining a living profit on what he sells. The experience he has had of Blank's pills, etc., which have, time after time, been placed on the market at 1s. 1½d. and then cut through want of protection, until he got a beggarly profit of less than a farthing, has "cleared his eyesight," and he is not to be bamboozled or cajoled by the wriggling contortions of the middleman photographic dealer, who appears to think if he cannot obtain the sympathy and support of the retailer, he will cater for them from the public, whose interests, as many chemists know to their cost, do not always lie in the same channel as their own, especially if it comes to the question as to where it can most cheaply buy. How have co-operative stores obtained their supplies, except through the middleman? and some of them give checks which are worth as much as 1½d. in the 1s. to outsiders, although manufacturers may be doing their utmost to protect prices in order to secure to the dealer a remunerative profit, which, at the best, is not anything very abnormal. Such matters as this almost justify the passing of even the largest and most powerful of the middlemen, who appear to be unable to protect either titles or prices of goods on which they place their names, but do not manufacture. Now that they find that the dealer is not sufficiently affected by their sophistries, they must, forsooth, call for the help of the public. Let the dealer consider this: Whose interests are being considered in this desperate cry for help, those of the dealer, the public, or the middleman?

New Apparatus, &c.

Messrs. W. Howard and Co., of 116, Bishopsgate Street Without London, E.C., are issuing a new mountant for which the following properties and advantages are claimed: It is chemically pure, permanently sweet, will allow slipping on mount for adjustment, and will not cockle thick or thin mounts. It dries quickly, thus saving time. It will be found to hold down the thickest of papers with ease. A speciality is the fact of the mountant being supplied in tubes with a patent vegetable lining. The lining preserves contents from any corrosive action.

Hinto-Kinone Cartridges. Manufactured and sold by Hinton and Co., 33, Bedford Street, Strand, London, W.C.

These cartridges are issued in boxes of six. Each cartridge makes eight to ten ounces of developer ready for immediate use, or the contents of one cartridge may be dissolved in the bottle provided, forming a concentrated developer which will keep many months, and any quantity of which may be diluted as required for use. A bottle and a celluloid measuring glass are provided. In our time we have used pints of Hinto-Kinone, the convenience of which in cartridge form will, no doubt, be widely appreciated.

The "Junior" Todd-Forret Magnesium Lamp. Sold by A. H. Baird, Lothian Street, Edinburgh.

All the years we have heard of the Todd-Forret flash lamp this is the first time that one of the forms of the lamp have come under our

direct notice. The "Junior" here described is extremely simple of manipulation. The bellows being connected with the brass tube of the lamp, the cap and burner are removed and the chamber charged with magnesium. The burner having been replaced, the wick is saturated with methylated spirit. Then the little spring clip shown at the edge of the illustration is made to grip the india rubber, and the netted bladder fully inflated with air. All being ready for exposure the wick is lit and the magnesium discharged through the flame by pressure with the clip. Nothing could be simpler or more efficient in use. As this is the season of the year when flashlight work attracts the notice of photographers, we append some useful hints given by Mr. Baird for the successful use of the "Junior" Todd-Forret:—

The magnesium chamber and discharging tube must be dry. Test the action of the valve; it should rattle freely when the lamp is smartly shaken.

When not in use for any length of time, the bellows is liable to become hard (as is the case with all pure rubber goods), and must be carefully warmed till soft and elastic before the rubber ball is again inflated.

When the existing light is insufficient, the placing of the camera and the focussing of the picture are conveniently accomplished by the aid of one or more candles or tapers. While an assistant moves the light round the picture, the field included on the ground glass is determined by the operator; and the final adjustment is made by focussing some printed matter placed at that part of the picture requiring sharpest focus, and illuminating the type by a candle held a little in front of it.

In portraiture, the sudden brilliant illumination frequently causes the

sitter to start; and when the exposure is short, and commences with the firing of the lamp, the pupils of the eyes, being in process of contraction, lack that crispness in the negative so essential in successful portraiture. To combat these difficulties, it is advisable to burn a few inches of magnesium ribbon before exposing the plate.

When one lamp is used, the best position for it in most instances is on the top of the camera, or about three feet on either side. The height of the lamp can only be determined by the nature of the subject. It portraiture about eight feet high is recommended, while for interiors it will depend greatly upon the objects to be illuminated and the distance they are from the camera.

New Books.

"Jahrbuch für Photographie und Reproduktionstechnik, 1902." Edited by Dr. J. M. Eder. Published by Wilhelm Knapp, Halle a/S.

We have the pleasure once again to draw the attention of our readers to this valuable record of the progress of photography. The volume for the present year has just reached us, and we find it fully equal, if not superior in interest to any of the preceding fifteen volumes, which mark the life of the Jahrbuch. Its characteristic is a systematic collection of every item worth of note published in the photographic literature of the year. This, combined with an excellent index, makes the volume indispensable as a reference book to every serious student of photography. Amongst the numerous original contributions, one by Dr. J. Hartmann, of Potsdam, concerning the testing of lenses for focus, is of special interest. We are likewise glad to see the recent researches of Dr. Luppocramer included in the record. The volume commends itself especially to students of photo-mechanical processes, who will find it most useful. At the end of the book we find the usual collection of specimens of various photo-mechanical processes. They comprise some work of great merit, and amongst them we are glad to see Professor Miethe's highly successful three-colour portrait of the lady with the red sunshade.

"Merck's Index."

Mr. E. Merck, the well-known chemist of Darmstadt, has sent us through his London manager, a copy of the second edition of the Index to the preparations, drugs, minerals, etc., forming the scope of his business. It is a volume of 374 closely printed quarto pages, and might almost be called a chemical dictionary. The chief attention has been given to the needs of physicians and pharmacists, but the photographer has found due recognition under the headings of various chemicals used in his work. The information throughout has been collated in such a way that the reader is presented in one volume with facts which otherwise would have to be sought out at the expense of much time and trouble in a library of standard works. The Index is divided into six parts. The first comprises chemical bodies and definite principles, certain galenical preparations and organic extracts. The second, special solutions, and forms of substances used in analytical and microscopical work. The third, crude drugs. The fourth, minerals. The fifth, collections suitable to schools and museums. The sixth, sundries. We learn that the first edition of 10,000 copies, published five years ago, is exhausted. Judged by the useful information the volume contains, we think that the second will be as highly appreciated as the previous issue.

"Photograms of the Year, 1902." 192 pp.; illustrated; cloth, 3s. net. London: Published by Dawbarn and Ward, Ltd., 6, Farringdon Road, E.C.

Tempus fugit! This is the "eighth annual volume illustrating and criticising the pictorial photographic work of the year"—quoting from the publisher's note. The number of pictures reproduced is slightly larger than in former years, and by excluding the miniature views of the exhibition walls it has been possible to make the average size considerably greater. The twenty-eight pages of "Hints to Would-be Picture-makers" from the pen of the editor (H. Snowden Ward) have been based upon the queries and difficulties of numbers of amateurs who send their prints for criticism. In addition to the chief criticism by Mr. A. C. R. Carter, there is a French section by Robert Demachy; American, by Alfred Stieglitz; New Zealand, by Josiah Martin; German, by Ernst Juhl; Australian, by A. J. Hill-Griffiths. Here and there the reproductions are qualitatively disappointing, but on the whole the book is a capital one. A very fine and representative selection of modern photographic work, and some ably written essays and critiques make up a gift book, which for beauty and utility quite deservedly ranks high amongst the world's photographic publications. We would not be without "Photograms of the Year" for many times its price.

"Practical Landscape Photography." By G. T. Harris, F.R.P.S.; 119 pp., illustrated; 1s. net. London: Iliffe and Sons, Ltd.

Mr. Harris, in his prefatory note, observes:—"The information conveyed in these chapters is the result of some twenty years' varied experience in landscape photography, and an effort has been made to treat the subject upon broad and practical lines, rather than to embarrass the reader with a mass of formulæ and descriptions of apparatus that serve only to obscure essential points. The best office of a handbook like the present one is that of safely conveying the tyro until he has gained sufficient experience to formulate his own methods of work; and to enable him to pass through his novitiate with as few serious mistakes as possible." As we are personally aware that the author of this book is a most accomplished practical photographer. The teaching of the manual before us strikes us as perfectly sound, and the illustrations, amongst which are many stereos, could hardly be excelled in technique, although the half-tone process occasionally does the man injustice. It is one of the best beginner's books that has passed through our hands. In future editions

let us have Kinnear spelt with a capital "K." We wonder how many modern amateurs know who Kinnear was.

"Photography by Night with the Grun Lens." Dr. Edward F. Grun. Elmutt Clifton, Ltd., 157-9, Church Road, Hove, Sussex.

This pamphlet, with a collection of specimens of work done with the Grun lens, will doubtless be welcomed by all who have followed the interesting experiments upon which Dr. Grun has been engaged for a considerable time, in his endeavours to produce a more rapid lens. It is a remarkable fact that within the past few years there have been two distinct reversions in photographic optics, and that these two fresh departures are apparently contradictory. Dr. Grun returns to fluid media for use between crown and flint, to obtain larger apertures, and claims the special advantage of increased brilliancy, through the diminution of the reflecting surfaces. On the other hand, Dr. Rudolph, Dr. Steinheil, Herr von Hoegh, and others are using air spaces for obtaining improved correction and greater rapidity. But whilst the latter deem it essential to retain those qualities of fine definition which photographers usually demand in a lens, Dr. Grun is content to make some sacrifice to obtain an aperture, which may still give an image of sufficient sharpness for what we may term an impressionistic sketch, instead of a realistic picture. Some of the specimens of Dr. Grun's work are sufficiently well defined for portraiture of large size, but unfortunately we are unable to form an estimate of their value, in relation to the lens, as Dr. Grun does not specify the aperture at which any of these photographs were taken, although in many instances the duration of the exposure is given. The lens, which this pamphlet introduces to the market, has an aperture of f.2.5. If this be taken as the standard, it is not the most rapid lens at present obtainable. For instance, Dallmeyer's "Extra" quick-acting portrait lens (C) may be had with an aperture of f.2.2, nor is this the highest rapidity yet attained without the use of fluid media. We mention the fact because Dr. Grun, in laying stress upon the rapidity of the instrument he has constructed, seems to ignore what has already been done in this direction. Dr. Grun also appears to lay claim to greater depth of field for his lens, as compared with other lenses of large aperture. Perhaps he means greater depth, through roundness of field, which is a different thing. A disk may be of the same thickness as a bowl, but the surfaces lie in different planes. We think it would have been better had Dr. Grun refrained from discussing questions of practical optics, as it detracts much from the value of his booklet. For instance, the statement that "the varying composition of the best glasses of the same class renders it difficult, if not impossible, to construct a lens on purely mathematical bases" cannot fail to raise a smile on the lips of those who are familiar with the achievements in optics during the last decade, at least. With all its shortcomings, however, the pamphlet will do good in attracting attention to Dr. Grun's work, the tendency of which must be to spur opticians to give us lenses of the highest intensity, so that the camera may be used under almost any conditions of light. Where light is, photography should be possible also.

WE regret to learn of the death, on the 5th inst., of Mr. A. Rivot, of Willesden Green.

WITH the praiseworthy object of augmenting the funds of the committee of the Hadlow Ladies' Guild, and also the newly-formed reading-room and club, two musical monologues were given in the schools on Saturday afternoon and Monday evening last week by Mr. F. A. Bridge, assisted by Miss Muriel Gaze. Mr. Bridge was for many years a member of the Westminster Abbey choir, and has performed at the Crystal Palace and at the principal halls in all parts of the country. Saturday's matinee took the form of a musical monologue, entitled "Home, Sweet Home," or songs and stories of the fireside. Unfortunately the room on this occasion was somewhat thin, considering the splendid object for which the entertainment was given. Certainly one of the most useful village institutions at Hadlow is the Ladies' Guild, which, among other kind and charitable works, provides a village nurse. In many cases, and especially in the homes of the poor in times of sickness, the kindly and timely services of a trained and experienced nurse are simply invaluable, and have proved on many occasions in the village a perfect Godsend, bearing out the truth of Lord Methuen's happy phrase, at Bristol, on Monday last—equally applicable in times of peace in country villages or great towns—as to the soldier in time of war. His lordship then paid a tribute to what he described as "The most beautiful of God's gifts to the soldier on active service—the sisters and nurses who were with them." On Monday evening the subject of the entertainment was "Songs and ballads, quaint and humorous," for the benefit of the newly-formed reading-room and club, an institution which has long been wanted in the village. Both prices and programme were popular, and the room was much better filled. Mr. Bridge's rich deep baritone voice was perfectly fitted for what was evidently his own favourite ballads, and was well supported by Miss Gaze's full mezzo-soprano, a voice of much power and sweetness, of very long range, and in wonderful control for so young an artiste. The string of remarks, historical, quizzical, and occasionally satirical, by which Mr. Bridge introduced the many musical illustrations, was often broken by ripples of laughter and applause, and although it had been announced that no encores would be given, the audience absolutely demanded them after Miss Gaze's song, "Somebody," and at the close of the evening Miss Gaze responded with "Coming through the Rye"; after which the negro melody, "The old banjo," was spiritedly given as a duet. Mr. Bridge's selections covered the range of ballads from "London Larkpenny," of 1460, to some of Mr. Chevalier's latest coster triumphs. Miss Gaze, in addition to accompanying Mr. Bridge, sang "Near Woodstock Town," a minstrel ballad of the 17th century, and also "Good morrow, Gossip Jean," an early 18th century balad.—Tonbridge Free Press.

Commercial & Legal Intelligence

WE have received a list of photographs of Sandringham and royalty by Mr. F. Ralph, photographer, Dersingham, Norfolk.

At the low price of 1s. 6d. Mr. William Tylar, of 41, High Street, Aston, Birmingham, is issuing a box of folding Christmas and New Year's cards, with mottoes and envelopes. The designs are refined, and the package is both cheap and good.

MR. WILFRED EMERY, of High Road, Cricklewood, N.W., sends us samples of his original Christmas mounts for the coming season. He supplies them in 2s. packets, either assorted sizes or all one size, from midget to half-plate. Mr. Emery informs us that he is the actual manufacturer of these cards.

GEORGE A. WEALL AND CO., LIMITED.—The above-named company has been registered with a capital of £1,000 in £1 shares. The objects of the company are to carry on the business of chemists, druggists, manufacturers of photographic and scientific apparatus and materials, etc. No initial public issue. Registered without articles of association. Registered office: 20, Neal Street, Bradford.

MESSRS. MARION and Co., Ltd., of Soho Square, London, send us samples of some of their fancy mounts with Christmas and other mottoes. They are made to take various size prints, some to paste on and others to slip in. By an accompanying list we perceive that Messrs. Marion stock a large variety of patterns and sizes. The specimens submitted to us are beautiful and varied, and we recommend them to the attention of our readers, who should procure the special twelve page list, in which descriptions, sizes, and prices of them are given.

LORD KELVIN is the richest of British inventors. He is now receiving royalties on fourteen of his patent appliances which have been fitted on board the latest Japanese warship. He was the son of a small farmer and was apparently destined to till the soil, as his forbears had done for several generations. Chancing to wander one day through the village churchyard he came to an old and forgotten sundial, the strange marks of which were so interesting to him that he was unable to rest until finding out their meaning. This investigation, which took the country boy some little time, aroused his interest in matters scientific, with the result, as all the world knows, of producing the greatest all-round scientist of his age.—"Invention."

THE Instalment System.—At the Thetford County Court, before his honour Judge Eardley Willis, on Thursday last week, H. W. Boughton, of Thetford (Norfolk), sued E. L. Elias, to recover the price of a photographic camera. It appeared that plaintiff advertised cameras for sale on the instalment system, and the defendant had purchased one. No one appeared on behalf of the defendant, but a letter was received from his mother at Llandudno, stating that the boy was only 15 years of age, and in receipt of 15s. per week, which barely kept him in shoe leather. He was trying to learn watermaking. His honour said he did not consider a camera a necessary of life, but as he had signed an agreement to pay by instalments, he gave judgment for 15s. and costs, to be paid at the rate of 2s. per month.

MR. J. FALLOWFIELD, of 146, Charing Cross Road, London, W.C., is issuing a special illustrated price list of Motto mounts for Christmas and the New Year. He makes the following special offer to dealers and professional photographers:—To enable dealers and professional photographers to show to their customers a good variety of designs to select from, without keeping a very large stock, I will on receipt of trade card and a postal order for 5s., send post free to any address in the united Kingdom, a specially selected parcel of sample Christmas mounts, of all values (at list prices) for 7s. 6d. The samples will be of the newest and best designs. In ordering, the most suitable sizes should be stated, so that each parcel made be made up to suit customers' requirements. If desired the exact patterns may be specified, but only one of each pattern can be included.

INTERESTING Decision to Photographers.—Sheriff-Principal Berrv has issued an interlocutor, in which he adheres to the judgment of Sheriff Strachan, interdicting a firm from publishing, offering for sale, or exhibiting in their studio photographs of pursuer's children or enlargements thereof, in an action at the instance of Mr. Thomas McCosk, residing at Flores Villa, Burnside, Rutherglen, against Messrs. George Crow and Co., photographers, 136, Buchanan Street, Glasgow. It was averred by the pursuer that in the year 1893 he took his two children to be photographed by Messrs. Adamson Brothers, and ordered and received 18 cabinet photographs of each. Without any instructions from him, Messrs. Adamson made and exhibited in their studio an enlargement of said photos. The defenders, as successors to Messrs. Adamson, came into possession of the enlargements, and exhibited them in their studio to their customers and the public for the purposes of their trade, and refused to remove them, although requested to do so. Sheriff Strachan first refused interdict, but the decision was appealed to the Sheriff-Principal, who recalled the decision, and sent the case back for proof. Sheriff Strachan, after hearing proof, granted interdict as craved, remarking, in a "note," that he did so "out of deference to the opinion expressed by the Sheriff." This decision also was appealed against, but the Sheriff-Principal adhered to it, with expenses against the appellants. Sheriff Berrv, in the course of a "note," remarks that the photographs had passed through several hands since Mr. Adamson, who made the enlargements, sold them as part of his stock-in-trade. In 1894 the pursuer, when they were brought under his notice, desired to purchase them, but the parties differed as to price. If parties, however, could not agree as to the price, his Lordship could see nothing to prevent the pursuer from requiring that the pictures shall not be exhibited on the walls of the defenders' studio.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Nov.	Name of Society.	Subject.
14.....	Borough Polytechnic.....	{ Defects in Negatives—Prevention and Remedy. Mr. F. W. Bannister.
14.....	Photo. Society of Ireland.....	{ Camp Life in Connemara. Thos. Mason, Jun.
14.....	Croydon Natural History.....	{ Visit to Messrs. Waddington's Process Block Making Works.
18.....	Birmingham Photo. Society ...	{ A Demonstration of the use of the new Printing Paper "Chromatype." Mr. J. R. Gotz.
19.....	North Middlesex Photographic	{ The Making of Lantern Slides. A. Herbert Lisett.

20.....	London and Provincial	{ Convention Slides. Mr. H. C. Rapson
20.....	N.-W. London Photo. Society	{ Monthly Slide Competition.
20.....	Liverpool Amateur Photo.	{ Open meeting. Exhibition of Photographic Dodges, especially in relation to apparatus.

ROYAL PHOTOGRAPHIC SOCIETY.

PROCEEDINGS OF COUNCIL.

An Address to the King.—It was resolved at the first meeting since June that a message of sympathy with the King in his recent severe illness, and of congratulation upon his Coronation be addressed to his Majesty, the society's patron

The New Gallery.—The council received a report from the Finance Committee respecting future exhibitions, and recommending the renewal of the agreement with the proprietors of the New Gallery. Details in connection with the tenancy were considered, and it was resolved to take the New Gallery for a further period of three years.

The Permanent Collection.—The council received a report from the judges in the pictorial section of the exhibition recommending the acquisition of certain photographs for the society's collection. It was resolved that the society purchase the following works:—No. 69, "Where once the garden smiled," by J. M. Whitehead; No. 114, "Woodland Mists," by W. T. Greatbatch; No. 245, "The rose is sweetness," by William A. Stewart.

Metro-Photography.—The attention of the council having been drawn to the fact that metro-photography is languishing in England for want of efficient encouragement and support, it has been decided to appoint a committee with power to consult such authorities upon the subject as it may consider advisable, to give attention to the matter and report to council in due course.

The Metric System of Weights and Measures.—The council considered a communication received from the Decimal Association in which the request was made that the Royal Photographic Society should extend its approval and support to the association in its efforts to secure the adoption of the metric system throughout the British Empire. It was resolved that the president lay the matter before the next ordinary meeting, with an intimation that the council were in favour of the reform, and to ask the society to give its support to the objects of the Decimal Association.

A Photographic Studio.—The council have received a suggestion that it would be of great advantage to many members if the society could add to the existing facilities for the practice of photography at 66, Russell Square, by the provision of a properly fitted studio, which might be made self-supporting by a small charge to the members using it. The council have replied that a lack of funds prevented anything from being promised in the direction indicated, and that the question of making structural alterations to the house to permit of it constituted a very serious obstacle.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 6TH.—Mr. R. Beckett in the chair.
Mr. Alfred Bedding gave a very interesting lecture on the Tower of London, illustrated by a comprehensive and well-selected set of lantern views from his own photographs. Mr. Bedding's pictures included, of course, many general views, but the chief interest attached to the photographs of the small details, the old relics and the historical corners which abound in a place like the subject of the lecture. As an old State prison and a building associated with many a political conspiracy, with the imprisonment, torture, and subsequent execution of people who have played a great part in the country's history, and as the subject of more than one historical novel, the Tower of London enjoys a very remarkable reputation amongst sight-seers, however unenviable the method of the gaining. Mr. Bedding showed that the keen eye of the photographer, trained to detect at once the slightest point of interest from the picture-making point of view, was capable of making a visit to the Tower one of far more attraction than the usual guide book, which dilates upon the prominent features of its career at the expense of many a less important but equally absorbing incident. One could not help feeling that Mr.

Bedding had mastered his Tower of London as no guide book teaching would permit, and of his pictures the general feeling was that they threw a very interesting light upon a subject that must always exercise a fascination upon the visitor within its precincts.

PHOTOGRAPHIC CLUB.

The annual general meeting was held at Anderton's Hotel, Fleet Street, E.C., on Wednesday, November 5th, Mr. F. A. Bridge in the chair. The balance sheet was adopted, and the following officers were elected for the ensuing year:—Trustees, F. A. Bridge, H. Snowden Ward; committee, A. L. Bell, G. E. Brown, L. E. Cooke, E. W. Foxlee, A. Mackie, C. Wallis, G. Wynne, J. W. Zaehnsdorf; hon. curator and librarian, Hans Muller; hon. secretary and treasurer, T. W. Derrington, 85, Trinity Road, Wimbledon. Votes of thanks were passed to the retiring officers and auditors, and the meeting adjourned.

CAMERA CLUB.

Mr. Sanger Shepherd's lecture on recent advances in colour-photography naturally drew a good audience last week, for most photographers are interested in the question of casting off the sober livery of their pictures in favour of something more like nature. Mr. Cadett, who occupied the chair, introduced the lecturer as the greatest authority upon the subject, after which the members present settled down in a good listening mood.

After a few brief remarks as to what had been done in the past, Mr. Shepherd, who spoke without notes, said that he had nothing more to tell them with regard to orthochromatic plates. It now remained for the plate maker to make the next advance in that direction. We can never hope to produce an exact representation of the luminosity of nature, because our range of tones between black and white, that is to say distinct tones, number only thirty, while the tones in an open landscape ranging from the brightness of the sky to the deepest shadow are about ten times as many. We must observe the old rule of exposing for the shadows and letting the lights take care of themselves. In open landscape the light coming from the sky is so very much greater than that reflected from the dark portions of the subject that some means must be adopted of meeting the difficulty. This has been done to some extent by the use of shutters which cut off a large portion of the sky light. He might name Furnell's shutter as one of these. Another was invented by Colonel Durnford, which did excellent work, but it was somewhat complicated in use, and never came into general use. The lecturer himself had long been experimenting with a view to making a light filter which would act in the same way as one of these shutters, and he had produced a graduated screen which could be put either in front of the lens or in front of the plate. At first he used a graduated carbon tissue screen, but he had since obtained better results by the employment of a glass stained yellow and graduated. In this filter the sky portion was almost as deep in colour as the wellknown "Gilvus" filter, and the screen was oblong in form so as to compensate, to some extent, for a high or a low foreground.

The advantages of using a light filter and orthochromatic plates were many, and no words would convince anyone so well as this, as a demonstration of what this combination was capable. He therefore handed round three pictures recently taken in Burnham Beeches by Mr. Seyton Scott, of the same subject. One taken with an ordinary plate, one with a "Gilvus" filter, and one with an "Absolutus" filter. It would be noted that the ordinary plate showed the foliage all of one tone, and that there was much halation where the trees cut the sky. These faults were quite absent in the other two pictures, and he thought everyone would agree that the picture taken with the "Absolutus" filter was the most perfect.

With regard to the reproduction of colour in photographs, attempts to solve the problem have been varied. No one could be named as the discoverer, for so many had worked at it, but there was no question that we had now a satisfactory method of making transparencies, and a method which was well within the powers of the ordinary worker. Obtaining a colour record was one thing, and reproducing from that record presentable pictures was another thing, but we have now the means at hand of deceiving the eye sufficiently well by the blending of the three colours, red, yellow, and blue.

(Mr. Sanger Shepherd here described his process of transparency production, which is already familiar to our readers.)

He considered that a practically perfect representation of coloured objects was obtained by Ives in his Kromskop, which had often been shown at the Camera Club, but the instrument had not commanded the public attention which had been expected of it, and was now seldom seen. He thought, on the other hand, that the triple lantern slide, the production of which he had just described, had come to stay. The accuracy of the results mainly depended upon two factors:—1, The suitability of the light filters, and, 2, the efficiency of the three colours selected. If filters, screens, and plates were in harmonious combination a very close representation of the colours of the objects photographed should be the result of the operation.

An easy way to get the blue transparency was to employ an ordinary lantern plate, such as is used for black pictures. Develop it as usual, and change the black image into a blue one by treatment with ferricyanide and a salt of iron. Upon this, as a basis for the transparency, the pink and yellow images on celluloid could be superposed.

And now he would like to say something with regard to the production of coloured prints on paper. Practically he had solved this problem a year ago, but it was one thing to perfect a process in the laboratory and quite another to launch it upon the world in a form that everyone could use. During the last few months all difficulties had vanished, and he hoped in the course of two or three weeks to make the process public.

The old plan was to take white paper as a basis, and to superpose upon

it transparent coloured films of gelatine or other material. He did not care for a process of that kind, but maintained that a satisfactory method should, like a water colour drawing consist of layers of pigment only. Such is the process which he hopes to have ready for demonstration in about a fortnight's time. The prints on paper will contain colouring matter only, there will be no films, and the process is simple and permanent. Moreover, it can be worked at night, no daylight being necessary even for the printing, and the cost of making a dozen quarter plate prints will work out at something less than eightpence. Mr. Sanger Shepherd then brought his lecture to a close by an interesting exhibition of his lantern slides in colour, many of which were of great beauty.

The discussion was opened by Dr. Lyon, who said that to his eyes some of the pictures appeared too blue and others too red. It also occurred to him that the fundamental tints were truer to nature than the mixed tints. The lecturer at once answered these objections by stating that the artificial light used in the production of some of these slides was so different to daylight that discrepancies were likely to arise. The electric light used in the club lantern introduced another source of error. The accuracy of the colours must depend largely upon the negatives, if they are right the reproduction will then bear the strictest comparison with the original.

After a few desultory remarks from others, the chairman said that all of them would be interested in the new paper process which Mr. Shepherd had promised them. We cannot all carry lanterns about with us, and want to fill our albums with coloured prints. He then went into the question of possible improvements in plates, and said that if plates were sufficiently perfect no filters would be required. It would be easy to make a plate sensitive to all the rays of the spectrum, if the necessity did not arise of having some light to work by. If automatic machinery could be devised for coating, examining, and packing plates in complete darkness the thing could be done. He was of opinion that if people would give a good trial to orthochromatic plates they would never use any other.

In replying to the vote of thanks, Mr. Sanger Shepherd referred to the speed at which photographs in colour could now be produced. He had seen snapshots in colour which had had only half a second exposure, and one of a breaking wave taken in one-eighth of that time.

CROYDON CAMERA CLUB.

An unusually bright and instructive evening upon "The Holy Land" was spent on Wednesday, the 5th inst., the personally and pleasantly-conducted tour being under the guidance of Mr. Salmon, the editor of the "Photographic News."

In the course of his remarks, Mr. Salmon disclaimed any intention of giving a lecture. What he had to say was to be regarded in the light of a friendly chat. This turned out to be a distinction without a difference, for in the opinion of all present Mr. Salmon proved a most interesting and entertaining lecturer, with a genuine sense of humour which readily communicated itself to his audience. The subjects shown on the screen included nearly every important Biblical scene. Jerusalem, the Dead Sea, Tyre and Sidon, the Jordan, and the Cedars of Lebanon were, amongst many others, illustrated, and in imagination visited. To give an idea of the thoroughness with which Mr. Salmon carried through his work, it may be mentioned that in order to photograph the Cedars of Lebanon, a journey extending over eight days was necessary, during which the photographer had to pass uncomfortable nights amidst the snow on the mountains.

Considerably more than 5,000 stereoscopic negatives were taken altogether, and judging from the quality of the slides shown, very excellent and softly graduated negatives must have been obtained.

CROYDON SCIENTIFIC SOCIETY.

On Friday evening a very successful demonstration of the Lumiere N. A. process of colour photography was given by a representative of the Company. The history of the various attempts at colour photography was reviewed, beginning with Robert Hunt in 1843, but the scientific principles upon which the remarkable results now obtained owe their origin to Clerk Maxwell in 1861; by Mr. Ives in 1890, whose pictures were shown in 1894; and by numerous other experimenters. The Lumiere Company claim to have produced a simple and inexpensive process, all the necessary materials being obtainable for 25s. Three negatives have to be taken, through three colour screens, which are provided, i.e., the red, green, and blue. These negatives are all developed together, so as to give each an equal time. The blue may be examined by a red light, and if the exposure and development have been correct for that, then all are correct, there being a ratio between the different screens among themselves, and as regards to white light. Mica is employed instead of celluloid, and sensitised sheets of this material, 3¼ in. square, are supplied for the purpose.

From these negatives, the positives are made by being printed in, or stained, the complementary tints, thus:—

The red negative is printed in, or stained, blue.

The green negative is printed in, or stained, red,

The blue negative is printed in, or stained, yellow,

and this must be done from the back, like carbon work. The image is brought out by using hot water, the unaltered silver bromide dissolved by means of Farmer's solution, and then stained. This has to be judiciously done, care being taken not to over-stain. Should this happen, water will reduce the red, and also fairly well the yellow, but for the blue a weak solution of glue, say 2 per cent. has to be employed. The positives are then dried, carefully superposed to obtain a correct register, and bound up between two pieces of glass, just like an ordinary lantern slide. It is very necessary, in carrying out this process, to be very careful which print is stained; the negatives should therefore be marked in some

way, such as cutting off one or two corners, so that the prints from the red, green, and blue negatives may unfailingly be stained blue, red, and green respectively. The demonstration, which was very successful, was much appreciated by the members present.

SOUTHAMPTON CAMERA CLUB.

The members of the above club held a meeting on the 3rd inst., under the presidency of Mr. G. Vivian. After the election of new members, a lantern slide competition was conducted, the subject being "Landscape." After a close contest, Mr. W. H. Trigg was declared the winner, with a pair of very fine slides portraying scenes from Mansbridge. He was awarded the club's certificate of merit. The winner was very closely followed by Mr. Evans. A number of slides representing work executed by the Beck-Stenheil Orthostigmat and Telephoto lenses were then projected on the screen, showing remarkable capabilities.

News and Notes.

THE Professional Photographers' Association.—There will be a meeting of the General Committee at 51, Baker Street, W., on Friday, November 14th, at six.

MR. G. H. STANFORD, photographer, Boscombe, informs us that H.R.H. Princess Henry of Battenberg has been pleased to purchase three of his photographs of Her Royal Highness's recent visit to St. John's Church, Boscombe.

PHOTOGRAPHIC CLUB, Arderton's Hotel, Fleet Street, E.C.—Wednesday evening, November 19th, 1902, at eight o'clock, "Photographing from High Altitudes," by the Rev. J. M. Bacon. Visitors, including ladies, are specially welcomed on this evening.

ROTHERHAM Photographic Society.—On Tuesday, November 4th, Mr. C. P. Goerz's lecture on "What can be done with a hand camera" was read before a good meeting of the Rotherham Photographic Society. Six new members were elected.

GLASGOW North-Western Camera Club.—At the meeting held on November 6th, Mr. J. B. Haggart demonstrated the advantages of tentative development, developing under, correct, and over-exposed plates. There was a large turn out of members.

THE Traill Taylor Memorial Lecture.—The subject of the Traill Taylor memorial lecture to be delivered by Professor H. H. Turner, F.R.S., on Thursday, December 11th, at the rooms of the Royal Photographic Society, No. 66, Russell Square, London, W.C., is: "The Great Photographic Star Map."

LIVERPOOL Amateur Photographic Association.—The usual weekly meeting of the above association was held on Thursday last week at the rooms in Eberle Street, when Mr. P. Langc presided. The lecturer of the evening was Mr. F. Anyon, who demonstrated the working of the oxy-hydrogen lantern. He afterwards gave instruction in the best method of working the lantern, so as to obtain the greatest amount of light. A hearty vote of thanks was accorded to the lecturer.

ROYAL Institution.—The annual course of Christmas lectures, specially adapted to young people, at the Royal Institution, will be delivered by Professor H. S. Hele-Shaw, LL.D., F.R.S., Professor of Engineering in University College, Liverpool, whose subject is "Locomotion—On the Earth; through the Water; in the Air." The first lecture will take place on Saturday, December 27th, at three o'clock, and the remaining lectures will be delivered on December 30th, 1902, and on January 1st, 3rd, 6th, and 8th, 1903.

MEMBERS of the Longton and District Photographic Society owe a debt of gratitude to Mr. C. F. Inston, of Liverpool, for his enjoyable chatty lecture on "The possibilities of a Hand Camera," also for the privilege of inspecting some seventy of his charming prints, the majority of which were most fascinating, and showed the master hand in their general excellence, and it is to be hoped that all may profit by his advice and be encouraged by the sight of his beautiful examples to try more earnestly to reach the high standard set.

DEVONPORT Camera Club on November 4th heard at the Technical Schools a lecture on "Lantern-slide Making," by Mr. A. J. Catford (secretary). Mr. J. Trouern Trend was to have given a demonstration of enlarging, but through indisposition was unable to attend. Mr. Catford described the simple method of reducing slides by Baskett's reducer, and also the use of the compensating cover glass, and the method of cloud printing. The lecture was illustrated by numerous lantern slides. The president (Mr. R. J. Lamb) was chairman, and at the close a hearty vote of thanks was accorded the lecturer.

A SUGGESTION as to an Application of "Rotokon" Bromide Paper.—The convenience of "Rotokon" printing has impressed a reader of the "Bromide Monthly," who makes a suggestion to us which is certainly worth all the publicity we can give it in these pages. Our correspondent's idea concerns the use of Rotokon paper for the multiplication of the sketches and designs of students in art schools. The drawing is done in the first instance on a glass plate coated with a soft opaque varnish, the lines being made by scraping away the varnish with a fine stylus. A negative thus results from which any number of prints can be taken on Rotokon

in a very little time. We are not aware how far such multiplication of the work of students is desired in art schools, but we should say to a very limited extent. For private purposes, as for the preparation of Christmas cards and other forms of greeting, there may be a demand for such prepared plates; but the most likely sphere for this application of gaslight papers is in kindergarten schools. The copying of simple drawings by this means would fix the subject of the sketch in the child's mind as nothing else would, and it would not be difficult to instruct children of quite tender years to develop and fix the Rotokon prints. The New York kindergarten schools are in the habit of making use of ferropressiate paper for the very similar purpose of copying ferns and various patterns. Why should not the kindergarten teacher do the same independently of the weather by means of gaslight paper?—The "Bromide Monthly."

THE late Dr. Schroeder.—We regret to learn that Dr. Hugo Schroeder died at his residence at Balham on 31st October, in his sixty-eighth year. About a year ago he had a stroke of paralysis, which affected his left side and arm, and a recent second attack of the same kind proved fatal. During the sixties and seventies Dr. Schroeder acquired a European reputation as a constructor of telescopes and other high-class scientific instruments. In 1897 he came to London as mathematician and scientific adviser to Messrs. Ross and Co., with whom he remained in that capacity for the long period of fourteen years. During this time he carried out many important improvements in optical instruments, particularly in photographic lenses, being the first to produce a lens possessing anastigmatic properties, in 1838, the Ross Concentric being the forerunner of all other anastigmatic lenses. Dr. Schroeder was one of the first opticians in England to recognise the value for photographic purposes of the Jena glass on its introduction by Dr. Schott in 1886 and 1887, and he conducted extensive experiments with the new glasses which were then available. In 1894 Dr. Schroeder went to America to organise an optical establishment in that country, but returned to London about a year later, since which time he has been engaged in experimental work and calculations for Ross, Ltd., and other opticians. Dr. Schroeder was well known throughout Germany, where his reputation was first made, and where a number of his pupils have successful business establishments. In that country his death will be noticed and his work appreciated perhaps even more than in England.

NATIONAL Photographic Records.—A meeting of the National Photographic Record Association was held on Tuesday last week at the Midland Grand Hotel, St. Pancras. Sir J. Benjamin Stone, M.P., the president, occupied the chair, and among those present were Sir C. Purdon Clarke, Mr. John Spiller, Mr. T. Sebastian Davies, Mr. John Sterry, and Mr. C. Welch. Mr. George Scammell, the hon. secretary, read the annual report, in which the council congratulated the members on the steady progress of the work. Since the last report 593 prints had been received, and Sir J. Benjamin Stone had contributed a series of pictures of St. James's Palace, Sandringham Hall, Frogmore, and some of the old mansions of England. Sir J. Benjamin Stone, in moving the adoption of the report, said the work he had done he regarded as an example of what could be done throughout the country. His pictures of the Coronation, a large number of which, together with other subjects, were on view, would probably be the best historical record of that celebration for future times. He also produced a series of photos taken of the "Kern Baby," as a record of an ancient custom still in vogue at Walton, Northumberland; and of the ceremonies at the Welsh Eisteddfod. With regard to the official work of that association, it was very inexpensive, and they relied on the good will of photographers throughout the country to take records in connection with their own localities. Mr. C. Welch, librarian of the Guildhall library, seconded the adoption of the report, and recommended that librarians throughout the country should be asked to collect and preserve records. He announced that the Guildhall library authorities had agreed to accept a loan of the Coronation photographs for public exhibition. On the motion of Sir Caspar Purdon Clarke, seconded by Mr. Fincham, Sir J. Benjamin Stone was re-elected president, and the meeting then proceeded to elect the council and officers, after which an inspection of the numerous interesting photographs on exhibition took place.

Is a New System of Mounting a Large Telescope to be Adopted at Amherst?—The announcement in the August and September number of "Popular Astronomy" that Amherst is to have a new observatory and that Professor Todd has secured a first-class 18-inch objective for a new telescope was very gratifying to all interested in astronomy. From the account given it appears that the telescope is to be mounted in a dome 33 feet in diameter, and we are told that "Professor Todd, a year or two ago, spent several weeks in studying appliances and mechanism of Continental observatories, and will embody the results of his investigations, together with numerous inventions of his own." The last clause of this quotation is, to me, writes Mr. S. B. Elliott, in "Popular Astronomy," the most interesting part, for there was published in the "New York Tribune," some six or more months ago, an illustrated article descriptive of an unique mounting for a large telescope, and Professor Todd was credited with being its inventor, and only a few weeks ago Miss Mary Proctor gave, in the "Scientific American," a similar description, with illustrations, of Professor Todd's device. According to these accounts, this consists of a huge hollow metal sphere, out of which the object-glass end of the telescope protrudes one-half its length. The eye-piece end extends inwardly to near the opposite side of the shell where the observer will sit in a fixed comfortable seat. Of course a door, for his use, would lead to the interior. If desired, about one-half of the shell could be left open or covered with glass or sliding shutters. This big ball is to float in some fluid, water, oil, or mercury, and, of course, is to be properly balanced so that the telescope can be readily pointed to any part of the heavens—a sort of "ball joint." The tube, in addition to being firmly

fastened to the shell, is rigidly braced to prevent springing. This for the scheme looks fairly well on paper; but how is this big globe to be moved, how held in place after it is moved, and how made to accurately adjust itself to the rotation of the earth? Truc, there is shown in the illustrations a shaft with gears at one end and a crank at the other, but no device appears to connect these with the ball, and I confess my utter inability to conceive how this can be done in a way that will permit it to be moved in any direction required, nor how or where the hour and declination circles can be placed and the whole under the proper guidance of clock work. But suppose the difficulties I name can be overcome, there are still others which I think will have to be dealt with. To bring about accuracy of movement nearly one-half of the globe must be, that much of it, a perfect sphere, and how can such be constructed, or, if constructed, how kept so? The varying temperature that the exposed part will experience, and which cannot be promptly shared by the submerged portion, will most certainly so distort its form as to render the accurate adjustment of any instrument connected with it very unstable, for as the tube is rigidly fixed to the hollow sphere, it must partake of the same movements. Then, too, what will prevent the wind from causing such a tremor of the telescope as will be fatal to any observation? No shield for the outer end of the telescope can be provided, as there is the revolving dome, nor can the sphere itself—I think 50 feet was the diameter named—escape from the effects of even a very moderate breeze. All readings must be taken by the assistant who must necessarily, be posted on the outside of the shell, and where he will be placed is a wonder to me. However, this may not be one of the "numerous inventions" spoken of which Professor Todd proposes to adopt at Amherst. Yet the statement that the dome is to be 33 feet in diameter and the length of the tube 14 feet—this may be a typographical error—gives colouring to the supposition that a radical departure from usual methods is, somehow, to be made. I shall watch, with great interest any attempt—if it shall be made—to make a floating ball a satisfactory mounting for a large telescope—or a small one, for that matter.

PHOTOGRAPHY as Applied to Illustration and Printing.—Mr. Duncan C. Dallas writes to the "Journal of the Society of Arts": In one of the Cantor Lectures given by Mr. J. D. Geddes he describes the present methods of producing blocks by the use of the screen for trichromatic printing. Mr. Geddes mentions two methods of producing the screen negatives—the indirect and the direct. In the indirect the negatives are taken in the ordinary way, and with, of course, the necessary colour filters. From each of the negatives a transparency is made, and from this again a reversed negative, having the screen texture. There are thus three operations. The advantage is that the exposure for the original negatives is not lengthened as it would be by the interposition of the screen in front of the plate in the camera. There is, however, the important disadvantage of two extra operations, and a risk, not mentioned by Mr. Geddes, of deterioration of result in the screen negatives as compared with its original ones. There has been a copy of a copy of a copy for example in reproducing a painting, and although we know that skill can do a great deal in removing or modifying defects some deterioration will remain, especially in tone if not in detail. In the direct method the required reversed negatives are made with the screen in front of the plate in the camera. This, of course, saves the two extra operations of the indirect method, but has the disadvantage of lengthening the exposure. There is also a disadvantage not mentioned, by the lecturer, of having to take three reversed negatives through colour filters in combination with either a reversing prism or mirror. The necessity of reversing is of itself a disadvantage. In both the direct and indirect methods there is the necessity, as stated by Mr. Geddes, that the angle at which the screen is placed must be varied for each of the three negatives so that there shall be a progressive difference of 30deg. Thus, one is to be 15deg., the next 45deg., and the third 75deg. Mr. Geddes states two disadvantages which arise from not varying the angle of the screen. First, imperfect register, and second, the moiré antique effect. But there is a third, the necessity for very careful adjustment; and this not only in regard to the negatives but in two other respects not generally, if at all, considered, and in which the relationship of the angular conditions are probably never preserved. The first is the placing of the negatives to print by contact on the coated sensitised zinc or copper plates, and second, the perfectly accurate mounting and planing up after the etching and finishing. When all these points are considered, there is no question but that trichromatic work by screen-made photo-blocks is both complicated, expensive, and more or less imperfect—often indeed, very imperfect and unpleasing, not merely from the predominance of the red, but from muddiness of colour, due no doubt to the dots of each colour not properly registering, and therefore overlapping irregularly. The wonder is that any good work is done. The output of really presentable work is, up to the present, extremely scanty. Good results are decidedly the exception, not the rule, and are due greatly, there is little doubt, to highly-skilled engraver's work on the blocks. Compared with the complication of the screen trichromatic block method, and its uncertainties of result, the Dallastint natural grain trichromatic block method is simplicity itself and reliability. The natural grain, resembling, as it does, aquatint, not only lends itself to rendering gradations of colour without mechanical texture, but prevents slight imperfections in register from showing offensively. Indeed, a slight shifting of the register can be used in an effective manner if desired. As regards simplicity in the Dallastint method, it starts from the very foundation—the production of the negatives. With the exception of using the necessary colour filters the negatives are taken in the usual manner either on dry plates, collodion emulsion, or wet collodion. No reversed negatives are required for Dallastint blocks, except in the very rare case where the print has to

appear reversed. No expensive screen, prism, or reversing mirror is required, though the well-equipped taker of negatives for other purposes may find them useful. The advantage of being able to use the original unsophisticated negative—rectified blemishes excepted—is obviously preferable to having a negative to which instead of its natural gradation and correct rendering of the texture and detail of the original has been added a mechanical texture which skilful, wonderful, and worthy of all praise as has been the development of the production and use of the screen, can never have the same pleasing artistic effect in print, as a well selected natural grain. From the foundation simplicity obtained by using unsophisticated negatives the production of the Dallastint blocks is more simple also in the subsequent operations than by the methods more chiefly in use, whether for colour or monochrome. There is the same possibility of being able to work on the blocks as in the screen method and even with greater effect.

"**SPIRIT Photography.**"—It may be said at once that Mr. Podmore, in his two substantial volumes on "Modern Spiritualism," published last week by Messrs. Methuen, has not only given us the completest survey of the growth and nature of spiritualistic manifestations and beliefs which has so far been offered to the world, but that he has brought to his task a very rare faculty of intellectual detachment. The work has demanded great industry and scrupulous fairness, and the writer deserves to be congratulated in respect to both these qualities. It is not, indeed, easy to see how the book could have been better done, and it is not in any respect the author's fault that a thorough perusal of his pages, interesting as they are, leaves a certain weariness in the reader's mind. For Mr. Podmore is dealing with a theme which is probably more encrusted with humbug and credulity than any other in the world, and a prolonged survey of humbug and credulity is apt to sate the robustest inquirer. The writer has not set himself to pronounce judgment. He has made it his business to collect evidence on which a judgment may be formed. He says in effect, that if you believe the plaintiff you will find for the plaintiff, and if you believe the defendant you will find for the defendant. He is neither advocate nor jury. He is simply a scrupulously fair-minded and indefatigably industrious witness, and there is this rather striking peculiarity about his work—that it would be easy to build up from it, and from it alone, a very strong and plausible argument for either side. There is one encouragement which can hardly fail to present itself to the student's mind. The most striking thing in the earlier records of so-called spiritualistic manifestations is the absence of any real understanding of the nature of evidence. People of credit and repute were content to rely upon their eyes and ears. To see and hear is, of course, indubitable proof, of the thing seen and heard, but it is no proof whatever of the means by which the appearance and the sound were produced. There is a recorded case of a little child whose finger bore a witch-mark of a deep red colour and "about the bigness of a flea-bite." It is a hundred to one that the mark was there, but what an argument for the exercise of a malevolent supernatural power! We have left that sort of puerility behind us, and have learned that the observation of a simple fact is in itself of no importance whatever. The modern investigator asks for causes, and it is the safest of all rules in respect to this particular inquiry not to accept as supernormal anything whatever for which an explanation can be found in known natural means. Mr. Podmore, who cites almost every case of interest, deals, of course, with the exposure of Buguet, a Frenchman who was at one time famous for the production of spirit photographs. This man was watched by Mr. W. H. Harrison, and the identity of the plates he used was naturally the point at issue. Now M. Buguet, by way of establishing his bona fides, submitted a plate to Mr. Harrison which, on examination, was found not to have been tampered with in any way. He then broke off a fragment of glass, most obviously from a doctored plate which had not been inspected, and when the spirit negative was produced, "Mr. Harrison failed to detect any trickery in the operation." The test was a very good one if it had been properly applied. What ought to have been done was for the watcher to examine the plate and himself break off and retain the fragment. But this case of Buguet's constituted one of the most remarkable sensations of its time. The operator was put upon his trial for fraud, and made a clean breast of the whole business. He explained the methods he had practised, and produced the apparatus with which he had worked. Then it turned out that his dupes would not relinquish him. Many witnesses of high character, amongst them photographic experts and opticians, came to testify that they had watched the processes throughout, and were satisfied that the results were genuine. Stainton Moses averred that Buguet was obviously a genuine medium who had no doubt been bribed or terrorised to make a spurious confession and to fabricate a box of trick apparatus for exhibition at his own trial. William Howitt saw in the whole proceedings evidence of an organised conspiracy on the part of the Jesuits to overthrow spiritualism. The recorded facts cannot be held finally and definitely to prove that the whole pretence of spirit photography is fraudulent, and if Mr. Stainton Moses and Mr. William Howitt had been wise they would have contented themselves with that reflection. The proof of a fraud is the proof of a fraud, and there is an end of it. It is not a proof that a result apparently similar might not be produced by the most legitimate means. The truly intelligent modern spiritualist is far too discerning a man to put all his eggs in one basket in that fashion. He has permitted himself to be persuaded on what appears to him to be legitimate evidence that certain beliefs are true, that certain things not susceptible of explanation by commonly recognised causes do really happen. But he knows very well that many of these effects can be cunningly simulated, and, being a sensible man, he expects them to be simulated, whether by wholesale impostors who work for gain alone, or by genuine mediums who are tempted to pretend to powers which they do not possess.—"Merlin," in the "Referee."

Correspondence.

* * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* * * We do not undertake responsibility for the opinions expressed by our correspondents.

WHERE ARE WE DRIFTING?

To the Editors.

Gentlemen,—Where are we drifting? Is it towards the light, upwards, or down to the darkness? This idea has often occurred to me when reading various lectures and statements reported in our journal. At one time a speaker states that a knowledge of drawing is not necessary to good retouching. At another we are told that the best way to copy engravings is to photograph them through ground glass. Then another clever fellow attempts to explain the nature of a vignette by comparing it to a piece of land surrounded by water. Further on, we learn that a "multiplicity of glass and blinds" in the studio is an "abomination," etc. Now, as all this is diametrically opposed to the truth of facts and must tend to increase the dense cloud of ignorance through which we appear to be drifting, it is necessary that such statements should not be allowed to remain unquestioned. I will therefore break a lance with these champions of error, giving to each and all a flat denial and proceed to show wherein they err.

Mistake No. 1.—Is it possible for a retoucher to make good the imperfections and improve the expression of a face if he does not know the drawing of the features and their natural planes? Any authority will affirm that this is not possible.

Mistake No. 2.—Engravings are composed of dots and lines. It follows, then, that the better defined each dot and line is, the better will be the resulting copy. The ground glass suggested would certainly obscure these dots and lines, and therefore must impair the quality of the reproduction.

Mistake No. 3.—This is a matter of vital importance to all portrait photographers. The lecturer here, after making some slighting remarks on the construction of the studios of the early photographers, remarks which in no way commend his knowledge, designates a "multiplicity of glass and blinds" in the studio as an "abomination," and attempts to prove the needlessness of so much glass, by some childish experiments with blotting-paper reflectors.

One of these I will give as an example of this new teacher's system of photographic lighting. He says, "On the shade side of sitter place a big reflector, covered with clean blotting-paper, and take a photograph; you will now get a horribly flat picture. Now close in your direct window light, take another photograph, and brilliance is again recovered." But if so, where did the light come from? Not from the direct window, for that has been closed, nor from the reflector, for if the direct light is shut off the reflected light must go too. He then advises the abandonment of all top light, and recommends that all studios be built having side light only. More, he tells us that he has actually designed several such studios. Lord, help them! Now, all this is so obviously wrong that only the most uninformed could be misled thereby, but being as it is a subject of such great importance (for is not "light and shade" the great study of artists and photography's "all in all"), I will endeavour in a few sentences to refute the erroneous teaching of this glib orator.

To begin with, without top light, all power of concentration is lost, and concentration is essential to all pictorial art, also the perfect rounding of the head cannot be obtained without top light. Then the illumination of groups would be most unequal if lighted only from the side. I have seen many, too many, examples from studios with the side light, horrible one-sided faces they were, with the ear on the light side, showing preposterously large and white, errors of tonality hopelessly exaggerated, and altogether lop-sided atrocities; in fact, although suitable to some compositions of fine art, all side-lighted work in portraiture is unnatural, and therefore inartistic. Nature provides us with light from above, giving all objects their proper value in the scale of gradation, and from nature we may learn that we cannot have too much light at our disposal. The ideal studio will then be the lecturer's abomination, i.e., one with as much glass as possible, with shutters and blinds to cover every square, than with the aid of suitable screens and reflectors the artist could arrange the light to suit any subject.

A great authority now passed away once said that "Every picture in black and white was an arrangement in tone," and as this axiom applies to photographic work quite as much as to any other work, it is manifestly absurd to limit the power of the artist in his chief function by depriving him of his best means of light. I feel assured that all artists in photography will concur in this. In a studio of the above description, using a diffusion of focus lens, with a little supplementary art work on the negative, it would be quite possible to produce photographic portraits of such high artistic merit as would vie with the matchless work of the old engravers but to attain this desirable end we want more art and less chemistry. It is, I think, due to this want of artistic knowledge, as so often shown by these

irresponsible teachers, that we hear the parrot cry of the "limitations of photography." What are these limitations? Distortion, as seen in heads and extremities. This may be avoided by using lenses of greater focal length. Artists never think of drawing objects at a less distance than twenty feet; they know that if they did so, apparent distortion would result. False tonality. This can be corrected by art work on the negative, as want of colour has no reference to black and white it is not to be regarded as a limitation. Thus we find that there are practically no limitations in photography. Having written the above from a sense of common duty, which I think will not be misunderstood by artists, I will say, in conclusion, that I hope it may help to check the progress of error and assist in the discovery of light and truth.—Yours, etc.,

MICHAEL EDWARD BANGER.

TO OPERATORS.

To the Editors.

Gentlemen,—For many years there have been periodical complaints made by "operators" about their specimens being, to use a gentle expression, "kept up." Stolen, I think would be the word used if such cases came into the police-courts. However, operators, your troubles in this respect should now be at an end—if you do as I did. My specimens were being very much kept back. I wrote repeatedly for their immediate return, but got no reply—gave up all hope of ever seeing them again—when fortunately I noticed our Editor's advice to a correspondent—viz., "Write to the Chief of Police." I took the hint; and, lightning result, got specimens returned next day. So, Messrs. Operators, Retouchers, etc., don't trouble our poor Editor again. Just write to the Chief of Police.—Thanking the BRITISH JOURNAL for the hint, I am, etc.,

SATISFIED.

THE CHISWICK CAMERA CLUB.

To the Editors.

Gentlemen,—I feel that there must be many photographers in this neighbourhood who are not aware of the fact that there flourishes in their midst a club devoted to their hobby. I shall therefore esteem it a very great favour if you will allow me to use your valuable columns in order to bring the Chiswick Camera Club under their notice. The club has been in existence since 1896, is in a sound financial position, and its membership increases year by year. Meetings are held weekly, on Thursday evenings, in the Devonshire Room, at the Town Hall, Chiswick, for the discussion of matters photographic. Gentlemen interested in photography will be cordially welcomed at any of the ordinary meetings, notices of which are posted up outside the Town Hall, and various other places in the locality. Beginners have been specially catered for by meetings which will be held in the club's dark room; 344, High Road, Chiswick, such subjects as "The manipulation of a camera," exposure and development, printing and toning, etc., will be there dealt with in a practical manner, and in a way suited to the needs of such as require instruction. Such well-known gentlemen as John A. Hodges, Esq., F.R.P.S., Ernest Morgan, Esq., John Dollman, Esq., R.I., S. J. Beckett, Esq., F.R.P.S., etc., have kindly consented to attend in person and give the club the benefit of their services during the present session.

I shall be happy to furnish further particulars to anyone who cares to apply to me.

In conclusion, I will again call attention to the fact that gentlemen who are not members are invited to our ordinary meetings.—Thanking you in advance, I am, Gentlemen, yours faithfully,

J. MANN, Hon. Sec

344, High Road, Chiswick,

November 1st, 1902.

UTILITY OF THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

To the Editors.

Gentlemen,—It is very satisfactory to see that the P.P.A. is giving some attention to processes as well as to purely trade matters. At the last meeting of the Hull branch the question of the permanence of collodion-chloride pictures was discussed. Such subjects as the stability of his work is a matter of importance to every conscientious professional—he, for his credit sake, if not for that of photography itself, desires that his pictures should prove as permanent as the processes he works are capable of yielding. I hope that, as time goes on, the association will be able to devote some attention to the technical portion of the art its members follow. The general opinion of the meeting, as will be seen from the report given in your last issue, was that the silver image in collodion is more likely to be permanent than when it was held in gelatine. This is a point to which we have often made reference. This really beautiful process has been before the photographic world now nearly forty years, since 1864, and prints by it that were made about the time of its introduction are still intact. Although the process is so old, it seems strange that, until quite recently, it has been so little used by professional

photographers, and now complaints are being made as to the want of permanence of its results. At the Hull meeting the general opinion expressed was that the instability, when it arises, is due rather to the baryta coating than to the collodion emulsion. We have more than once pointed out that the insoluble sulphate of baryta, *per se*, may be considered an inert material, and that it is to the collodion body which cements it to the paper that the evil is really due. The free silver in the emulsion forms a compound with it, which is not dissolved out in the short time that is necessary to fix the collodion image. That such a compound is formed, and that it is sensitive to light, may be proved by removing the collodion film, when a faint image will be found in the baryta coating beneath. The emulsion employed in the early days of the process for the pictures that have withstood the test of time so well, was not materially different from that employed now, but the paper was entirely different. It had no so-called "baryta coating," it was the old "Saxe" or "Rims" paper, the camera was employed for albumenising, coated with arrowroot. A substratum of some kind of the paper is found, in practice, to be necessary, as the collodion does not adhere well to plain paper. Possibly some manufacturer will put upon the market a collodion paper prepared in this, the old, way. Or, as the emulsion is not difficult to prepare, some users of the paper may be induced to make some for themselves and compare it, for permanence, against the commercial article on the baryta coating. As the P.P.A., or the Hull branch of it, have given some attention to the question of permanence of C.C. prints, it may, perhaps, also go into that of the stability, or otherwise, of those made by other processes.—I am, yours, etc.,

PROFESSIONAL.

November 10th, 1902.

ON BEING APPRECIATED.

To the Editors.

Gentlemen,—That our work should be received with favour is a most vital point if we are to succeed, and therefore it becomes a very important matter of earnest study to find out the sort of work to turn out.

"That is the very best portrait ever taken of me, Mr. Focus. I cannot you tell how it has been admired; all my friends want one, and several of them say they shall get you to make good pictures of them." How it warms one to hear such a nice little speech, and makes us redouble our efforts to deserve such remarks. It is as good as a gold medal. Now, there are few callings in life which yield more opportunities of giving real pleasure than photography, as a true representation of a valued friend is a great treasure, and often the means of either commencing a friendship which may be lifelong, at least, or of cementing an engagement which is hanging on a thread.

Some there are who do not, or say they do not, care whether they exactly suit their clients' ideas or not—they have a notion that they must educate the public to like a certain sort of thing, which is, perhaps the only sort they care to make. This may be all very well if they are working simply for pleasure and not profit—and no doubt there have been cases where such a plan is a good one; but, as a general rule, we want the mill to grind us our bread, and so we must study the wind, and work accordingly.

Now, what do the public really want? "A correct likeness for sixpence" used to be the usual invitation when popular photography was young—and we who have had those "correct likenesses" to copy and enlarge in these modern days often open our eyes and wonder what our ancestors, and aunts and uncles, could have been really like if these were indeed "correct likenesses." But the invitation touched a chord that responded in those cases, or we should not have them before us now.

Then why is the invitation not repeated in some form at the present day by *high class houses*? Is a photographic likeness now so correct that it goes without saying?

Not exactly; retouching has proved itself a power for good or evil, as the case may be, and has much to answer for. In its early days it was often much overdone; and even now, in many cases, there is such an amount of scraping and patching that seeing cannot be believing by any means.

But let us return to our ideal of a "correct likeness," and see how our work may be generally "appreciated."

The first step is to *appreciate your sitter*. Get, if you can, an *excellent* idea of him into your own mind, and then set about expressing that idea so that all his friends shall not only *know* him by your picture, but also, as far as possible, they shall know his good qualities—his kind heart, or his firm decision, his thoughtful mind, or his studious habits. This must, as far as possible, be done by pose. You know him to have a kind heart, don't take him with an expression as if he might bite your camera. If he has a firm disposition give him a firm pose. If you know he is a great thinker do not let the eyes turn exactly with the head—some look slightly away, or up or down, to give expression to a passing thought. If he is a great student give him a book. If a man of business, show him writing, etc., etc.

Another important point is to fall in with your sitters' ideas if

possible. Many come to the studio with a very definite notion of the sort of picture they intend to make. Let this, therefore, be your first plate, as it will favour their feelings, and *possibly* be the best you will do as a likeness. It also gives you time and opportunity to get into their confidence and study what to do with your next plate. Then suggest a modification, and he will probably agree with the notion, and one position will grow out of another without a shock. On no account *complain* of your sitter. Don't say, "You are not easy to take a good picture of," as some do. Don't seem puzzled in posing, or find fault if an arm is looking stiff or awkward—see for yourself how it could be improved, and gently change it. Don't say, "Oh, full face won't suit you at all, your eyes are not alike," or "Your nose is crooked." If it is so it is your duty to get the best side, as one eye will be the happiest, and the nose will look better if taken the side it favours.

Most people enter a studio with a fairly good opinion of *themselves*. Take good care that when they leave they have formed a good opinion of *you*. They also come with their nerves very much on edge, so to speak, and they compare you with a dentist; let your manner have the effect of soothing and setting their feelings at rest as much as possible, and let them depart in peace, with a strong desire to bring all their friends, babies, and dogs, for these are the things that pay.

Then, as to that "fine-art" bit of photography—the *retouching*. Suit your pencil to your subject. If a lady wishes her face to appear like a bladder of lard let her have it; you need not put your name on her mounts. If that musical genius wishes the lines of the stave to remain clearly drawn across his forehead, with a clef by each eye, and a mouth the shape of a slur, why should he not have it so? He will be more likely to be pleased with the "expression" than if he is smoothed away into a face like a young shopman. But for freckles, marks of small-pox, scars of wounds (except in soldiers), the less they appear the better; and if you have a face with very strong, hard lines, let it turn towards the light, and take it with a Rembrandt effect, and hardly any retouching will be wanted.

And speak gently—gentleness is infectious. If a sitter comes shouting into your studio don't shout back, but speak quietly and firmly, as if he had not shouted to you, and he will soon drop his voice nearer to your tone. It is often the effect of excitement, and it will pass off. Don't be frightened; expose a plate as soon as you can, and get away into the dark-room and collect yourself, while he listens to the echoes of his own noise and gets into a more even frame of mind.

A word to all assistants. If you wish to be appreciated by the "Head," as boys say, make yourself indispensable; *fill* your place, and be a *personality*, so that when you return from your short holiday you may be greeted with "Oh, I am glad to see you again; it has been such a blank while you have been away."—I am, yours faithfully,

ALFRED SEELEY.

November 6th, 1902.

MATT CARBON PRINTS.

To the Editors.

Gentlemen,—In the BRITISH JOURNAL OF PHOTOGRAPHY of November 7th Messrs. Illingworth and Co. write in reference to your statement that hitherto "if a picture was desired on a matt. paper by the carbon process, it had to be made by the single transfer method" that they introduced a special tissue, etc., for producing prints by double transfer on matt paper twelve months ago, and that they are, therefore, pioneers of this method of working.

Without wishing to claim that I am a pioneer of such a method, I wish to call your attention to the fact that I published more than two years ago in the "British Journal Almanac," and also in your contemporary "Photography," a method of easily producing carbon prints by double transfer on any papers, even rough-surfaced varieties, and this method has been in constant use ever since for almost all my carbon work.

I enclose a print made by this method on Whatman's drawing-paper; you will see that in the matter of retaining the texture of the paper it closely resembles a single transfer print, and it is also exactly similar in another equally important respect, and that is that while there is a slight gloss on the deep shadow-work, the lighter tones are as free from gloss as the paper itself. Prints produced by this method have great depth and richness.—I am, gentlemen, yours truly,

November 11th, 1902.

HENRY W. BENNETT.

IRRITANT POISONING BY PHOTOGRAPHY.

To the Editors.

Gentlemen,—In your issue of August 28th there appears a letter on the above subject from a correspondent, who signs himself C., and to the letter is a footnote by yourself asking for the experience of others.

I have worked regularly as an amateur for the last nineteen years, and, except on one occasion, have never suffered from poisoning. On the occasion mentioned I was asked by a friend to come with him and assist to do some enlarging. The developer I used was metol, and the dish was one of wood with glass bottom, and unfortunately the carpenter who had made the dish had done his work very badly. Before

the development of each piece of bromide paper was complete, the dish was nearly empty of developer by leakage. The metal solution ran over my hands and between the fingers before it reached the sink. In a day or two afterwards I found my fingers red and itchy. I knew the cause, but not the remedy. However, walking in my garden I was struck instinctively to rub the affected parts with some dandelion flowers which I saw growing. I got relief at the time, and feeling the itchiness return next morning I again tried the same remedy, and, after that application had no more trouble. Although too late for your correspondent C., it might interest someone else, and if it prove efficacious to any person I should be glad to hear of it through your columns. The cure is at least easy and cheap.—I am, etc.,

W. L.

THE DELHI DURBAR.

To the Editors.

Gentlemen.—We think it may interest a number of your readers to know that the Viceroy has appointed us the official photographers to the Delhi Durbar Coronation, to be held in January next. We shall compile a book of all the eminent guests, native and foreign princes, who attend, with all interesting scenes. It will be on a costly and lavish scale. Their Excellencies the Viceroy and Lady Curzon have given us special sittings for this work.—Faithfully yours,

BOURNE AND SHEPHERD.

Calcutta.

October 16th, 1902.

To the Editors.

Gentlemen.—I shall be highly obliged if you will kindly recommend me to some illustrated paper or magazine publishers, some photo publishing firms, or lantern slide manufacturers, who would care to undertake to publish Delhi Durbar views. Of course, you must be knowing well that it is going to be a grand and unique affair of its kind in the history of India.

My charges are £9 9s. for one dozen negatives, with 10 per cent. discount. For orders exceeding two dozen, a discount of 25 per cent. will be allowed. All negatives guaranteed bona-fide and original. Each order should be accompanied by a certificate of appointment of me by them for the work.—Trusting to be favoured with an early reply, that should reach me not later than the mail that reaches this on the 12th of December next, I beg to remain, dear Sirs, yours faithfully,

MEHERWARYS, CAWASYS MODJ.

No. 37, Hornby Road, Fort, Bombay,

October 25th, 1902.

[We submit our correspondent's offer to our readers, in the hope that he may succeed in obtaining the commission he seeks.—Eds. B.J.P.]

KODAK, LIMITED, AND THE TRADE.

To the Editors.

Gentlemen,—I am reading with great interest, and I may say, with pleasure, the controversy between Kodak, Limited, and the Photographic Trade Association. Why the Photographic Trade Association goes with such energy for the Kodak, Limited, is a mystery. Has not Kodak, Limited, said repeatedly that they do not want a monopoly of photographic goods and instruments? Have we not had the testimony of a gentleman, about a year ago, showing the purity of Kodak, Limited's, designs on the photo. trade? Have they not now the assurances of "Briton" that monopoly was never thought of and will not be attempted? I do not exactly know or understand what "Lady Amateur" wants to prove in her letter; but I suppose she means to ask gents. to leave Kodak, Limited, alone. With all these assurances of no monopoly, what do you want more?

I understand that all Kodak, Limited, wants is to do all the business they can attend to, sell all their own instruments, instantaneous or otherwise, portable or not, their films and papers, plates and other outfits, etc., etc. To attain this end they offer good terms, and better ones to parties willing to exclude other goods (of course, much inferior ones always); but of monopoly there is no question whatever. If it were so they would reduce also their retail prices, but that is out of the question just now. They sell the best of all, and other goods are infringements. The only claim they make is superiority of quality, and if any film goes wrong it is that made by other manufacturers, and no mistake. *Prenez mon ours! Qui vivra verra!*—Yours very truly,

ANTI-MONOPOLIST

To the Editors.

Gentlemen,—It may interest "Kodak, Limited," who contend that they are not seeking a monopoly, to hear what an American professor has to say about the peculiar business methods which they are adopting. In a little work entitled "The Control of Trusts," published

by Macmillan and Co., Professor John Bates Clark, of Columbia University, describes the "factors' agreement" as one in common use by trusts, and defines it as either an absolute refusal on the part of the trust to sell to a merchant who buys goods from a competing establishment, or a refusal to give him necessary discounts (p. 34). This form of agreement, he contends, should be made illegal, as contrary to public policy. He is by no means uncompromisingly hostile to trusts, and recognises that the crushing out of independent competitors by the mere process of centralisation is "in a way legitimate; for it is an instance of the survival of the fittest." But the "factors' agreement," and some other forms of business effected by the trusts, he characterises as an attempt to "foul competitors, and disable them by an underhand blow," and as "actions that have in them the essence of robbery, though they lie altogether outside the scope of statutes heretofore enacted."

The author of this interesting little brochure has much to say on the inherent weakness of trusts, as well as on their connection with a protective tariff, and he proposes certain methods of dealing with them which are well worth consideration. For these your readers must consult the book

-Yours, etc.,

H. H. O'FARRELL.

Ealing, W.

To the Editors.

Gentlemen,—Having been away, I have only just received my copy of the JOURNAL, but I trust you will allow me to reply to X.Y.Z., as his letter consists of a series of inaccuracies.

He seems to be unaware of the exact signification of terms, and also of the conditions of the photographic trade in general. Asserting that there is nothing to choose between Kodak, Ltd., and the P.T.A. as both try to create a monopoly by keeping up prices; that it requires but a small capital to set up in the business; that the dealers have been having a merry time, the profits being very large; and that they have combined to "exploit the public."

A monopoly is a condition wherein a person (or persons) has an absolute control over the entire output, nature, quantity, quality, and price of an article. Now, how can the P.T.A. create a monopoly by fixing the prices of their articles? It is open for X.Y.Z. to flood the market with cheaper cameras as soon as he can get them ready, and no one could stop him.

There was never a time when more capital was required to set up than at the present moment. The large number of very high-priced cameras, the host of various makes and designs, the various brands of plates, papers, and films, and apparatus of all kinds, renders it increasingly difficult (except for those in a very large way of business) to keep up with the times.

The profits on a turnover of, say, £100 worth of cameras are no larger than those on the same quantity of beef, sugar, or any other article of trade; and if X.Y.Z. were a business man he would know that the cost of every undertaking must be borne by those who wish the undertaking carried on. He must be poor, indeed, at finance, who pockets the difference between buying and selling and calls it profit. Deterioration, consequent upon exposure to light and air; continual fingering, and opening and shutting of cameras to show enquirers; time occupied in making good defects in new cameras (nearly all are defective, even the high-priced ones); repairing machine after enquirer has damaged it; supersession of new patterns by still newer ones before one has had time to sell the former; a drop altogether in the sale of a certain class which went well a little while ago—all this comes out of that "huge" profit.

What does he mean by "exploiting the public?" I protest against both his remarks and those of many others who write, wherein they talk of two classes, retailers and the public. What are traders but part of the public? Who decreed that their sole aim should be for the benefit of the rest of the public? They, like, say, a bank clerk, lawyer, or government official, exist for their own benefit, and have just as much right to be properly paid for their work or occupation. Why should the optician sell a 1s. box of plates for 11d., which, when taking into account rent of storage room, time occupied in counting up, frequently, various makes, brands, rapidities, and sizes, to see he is not short (woe betide him if he be), time taken in ordering, heavy carriage, unpacking, storing away in order, stale stock of some brands after a time not asked for, salary of self or assistant while giving them out, etc.—is about what they cost, perhaps less.

The public benefit—or the greatest good to the greatest number—is not that one portion of it should live upon the other portion at cost price, but that each should have a wage or payment sufficient to enable him to carry on his calling and earn his living, to pay his accounts promptly, thereby allowing his creditors to settle their's, and so on; and, if a man in a town is, by reason of low prices, doing business at a loss, it is evident that those who are taking advantage of his services are not paying sufficiently to enable those services to be rendered.

If the optician's yearly income be no more than that of any other business man of the same standing—which it is not—he cannot be "exploiting the public," and it would be well to again remind X.Y.Z. and many others that those who trade do so for their own and the public

benefit in just the same measure as do those who sell by the hour, or the day, their writing, brains, or labour.—Yours faithfully,

A RETIRED DEALER.

To the Editors.

Gentlemen,—The Kodak letter in your issue of the 6th would imply that they were pioneers of daylight roll films and roll film cameras. Let me explain to your readers the history of daylight roll films and roll film cameras, so far as they concern this country.

The first daylight loading cameras and films were introduced by the European Blair Camera Co. in 1893; they were imported from America, but latterly they made first their film and then their cameras in this country. Two years later the Kodak Company put on this market a series of similar cameras and films, why then should Kodak take exception to others doing what they have done? If they had been the originators their case would be different. I can therefore only conclude that such terms so often used by them during this correspondence as "Shoddy Imitations," "Piracy," "Parasites," etc., are detrimental to their own products.

It will be seen that Kodak must have imitated, for, were the European Blair cameras not on the market two years before Kodak? Further, in 1895 I made folding pocket film cameras in two sizes, $3\frac{1}{2}$ by $2\frac{1}{2}$ and $4\frac{1}{4}$ by $3\frac{1}{4}$; they were similar to the present day loading ones, rather smaller if anything, and were taken off the market because of the difficulty at that time in getting good film. To the best of my knowledge, it was at least twelve months later before the folding daylight loading Kodaks appeared. Were they in design and size imitations or coincidence?

These statements can be substantiated by your readers referring to the "Amateur Photographer" or "Photography" for 1896, in which these folding pocket film cameras of my manufacture were advertised.

Kodak plate cameras were introduced this year, and attached to these is a folding focussing hood, which also serves to protect the ground glass. This arrangement was first applied to "Challenge" cameras when brought out seventeen years ago. Do Kodak Company then admit imitation on their part here?

Kodak Company have made a statement "that any dealer can retail their goods and is free to sell substitutes." I, as a dealer, have been refused to be supplied with their goods, and although I wrote them on the 11th June and on the 17th July for an explanation, it was only after my second letter that I got a verbal intimation from one of their officials that "acting on instructions from headquarters" I could not be supplied with their products, because I was pushing other makers' wares in preference to theirs.

In conclusion, I advocate free and fair trading, and that the public be the judge on the merits of the respective daylight roll film cameras and films.

J. LIZARS.

Glasgow, 9th November, 1902.

To the Editors.

Gentleman,—The question for the purchaser to consider is whether his (the customer's) interests are likely to be best served by the tied-house system. Evidently, many dealers have made up their minds that the exclusive policy serves their interest, and nobody can blame them for endeavouring to do the best they can for themselves. But it is not at all certain that the dealer will benefit in the long run by "concentrating" on Kodak goods. Anyway, if there were more competition in the manufacture of roll film, there would be a possibility of obtaining an efficient film at a cheaper price. At present it is too dear, particularly as affecting the larger sizes, in which the price is almost prohibitive, except to the wealthy dilettante. The Kodak Company's profits must be very considerable, or they would not be able to offer such handsome terms to the retail dealers. The purchaser does not benefit.

It is impossible for the makers of any successful invention to escape, more or less, imitation when the patent has expired. The Kodak Company make several things that they did not introduce. I wonder what would have happened if the Kodak Company had invented the dry plate.

Of course, the Kodak Company have every right to proceed against those who substitute other goods for theirs. Nobody would defend fraud. But I think it will be to the advantage of the customer if he claim to have an option of purchasing any of the roll film goods on the market. The question of quality and prices would then be deciding factors in the purchase. It is not expedient in the interests of the public that a powerful concern such as the Kodak Company should create anything like a continued monopoly, whether intentional or not.

Kodak, Limited, have themselves stated that, while dispensing with the services of the wholesale agents themselves—who I daresay have in the past done a good deal towards building up the Kodak

business, but who are now charged with having committed all manner of offences—"the agency for leading makes of plates and papers may in time pass into their hands." The Kodak Company have not yet seen fit to explain away that statement. Do they propose to use their control in the roll film goods line as a sort of lever by which they can influence the dealer in other directions; or, does the statement mean anything at all? If the wholesale dealer is useless in the sale and distribution of goods—according to the Kodak Company—why should Kodak, Limited, themselves propose to become wholesale dealers for the supply of leading makes of plates and papers? Perhaps the statement was only made to throw dust in the eyes of the retailer. But if there is any truth in the statement, the customer necessarily has to consider how, if the agency referred to was effected, it would affect him.

Of course, in the matter of roll film goods, the Kodak Company are entitled to credit for their enterprise. But if they held controlling patents, they had a free field, and their business has in no way been harassed in this country by tariffs. The writer has used a considerable quantity of the Kodak Company's film with satisfaction. Although the numbers from the protective cartridge paper sometimes affect the film, I assume that the percentage of negatives spoilt in this way is small. Still, the liability exists. There is a roll film on the market for which the makers claim that the markings referred to are impossible. If that be so, then it must be admitted there is an advance. But what many really want is an effective film at a cheaper price, and they are more likely to get it under the stimulation of competition. For that reason, the Kodak Company's exclusive policy is not desirable in the interests of the user.

I suppose it is very wicked for anybody to attempt to compete with them. That all depends upon the point of view. It is just as impossible for the Kodak Company to expect to retain a monopoly in the manufacture of roll film goods as it would be for the Dunlop Tyre Company to expect to retain the control of the manufacture of pneumatic tyres. In neither case, however, have the introducers and exploiters much occasion to grumble. In most cases inventions, when not of gradual evolution, are a matter of priority. If one person did not invent the thing, somebody else would. The Legislature gives the protection, and if it were a matter of public expediency it might be decided to curtail the period of protection after a reasonable time has elapsed, in regard to goods that are in almost universal demand.

I might add that I have no commercial interest in the matter whatever. I rather wish I had.—Yours truly,

J. A. REID.

Bedford, November 9, 1902.

To the Editors.

Gentlemen,—I was very much amused to see the appeal in a recent issue from the Photographic Trade Association.

Instead of sitting down and wringing their hands, if they are such "a thoroughly representative and influential" party as they make out, why do they not put their heads together, and see if they cannot invent an original "Photographic Trade Association Camera," with spools of special sizes and patterns that the Kodak spools will not fit?

The Kodak Company have alone worked out and made a practical success of film photography, with its special cameras, and all that these men seem able to do, or think of, is to make their cameras from the Kodak patterns (or, rather, to get some German firms to make them for them), and try to make imitation film on spools to fit the Kodak cameras.

If, instead of wanting to lay their eggs in another bird's nest in this way, how much better it would look had they followed the lessons that the success of the Kodak Company ought to have taught them by this time—viz. :—

1st. Have an original, go-ahead idea.

2nd. Lay down modern and scientific machinery.

3rd. Put the works in charge of practical analytical chemists and good business men.

There is no doubt that there would have been no 5s. or 10s. "Brownies" in the market had they been invented by a small English manufacturer. He would have been boycotted by the "Ring" for attempting to cut prices.—Yours faithfully,

HERBERT S. STARNES.

Myrtle Villa, Lion Road, Bexley Heath.

* * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

Answers to Correspondents.

- * * * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C."* Inattention to this ensures delay.
- * * * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * * * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.*

PHOTOGRAPHS REGISTERED:—

W. J. Reed, Arcade Studio, Old Christchurch Road, Bournemouth. *Photograph of Bournemouth Officials.*

A. Holborn, 25, Stokes Croft, Bristol. *Photograph of Esther McEwan as sailor boy.*

CLEANING DAGUERREOTYPES.—DAGO asks: "Will you oblige by giving me the address of an expert in restoring Daguerreotypes?"—In reply: Almost any old professional photographer would do the needful for you. We know of no one who makes a speciality of this work. The method of doing it has often been described in the JOURNAL.

COLLOTYPE PLATES.—E.J.M. asks: "Could you kindly inform me where the prepared colotype plates referred to by Mr. W. Gamble (in your last number) can be obtained commercially?"—In reply: Probably Messrs. Penrose and Co., Farringdon Rd., can supply them. If not we cannot say where they are to be obtained.

DEFINITION OF AMATEUR.—L. M. asks: "Is there any recognised definition of amateur and professional photographer? Can a so-called amateur recover for photographic work done under contract?"—There is really no recognition as to who is an amateur and who is a professional. Anyone, whether amateur or professional, can, of course, recover for work done under contract, whether it be photographic or otherwise.

ENLARGING.—BROMIDE writes: "As I am taking up enlarging, I should feel obliged if you would advise me on the following. (1) Are daylight enlargements better than gaslight enlargements? (2) Is a condenser used when enlarging by daylight?"—In reply: (1) There is practically no difference, provided the artificial light be skilfully used. (2) No; a condenser would be of no use at all in daylight enlarging.

POST CARDS—PROCESS BLOCKS.—F.W.W. asks: 1. Would you oblige by letting me know address of cheapest house for sensitised post-cards; 2. also best place for getting blocks made and printing done on post-cards?"—In reply: 1. We do not know which is the cheapest house; better get the price lists of the different makers. 2. Any of the process block makers will supply what you require. It is quite against our rule, as we have said many times before, to recommend any particular maker's goods.

STUDIO LIGHT.—J. M. writes: "I would esteem it a favour if you could recommend me to a book dealing with side-light studios, as mentioned in Mr. Howard Farmer's article, 'Some aspects of professional photography,' if there is one that treats the subject fully?"—In reply: You will find Robinson's "The Studio, and what to do in it," a useful work; also "Artistic lighting," by Jas. Inglis. There is no book published devoted to the professional aspects of photography.

BOOK WANTED.—SEEKER says: "I should be very pleased if you could give me the name and publisher of a reliable text-book on wet-plate photography, also the best hand-book to orthochromatic work?"—For the wet collodion process "Instruction in photography," by Abney; and "Wet Collodion photography," by Gamble. These books may be obtained through any of the dealers. Messrs. Cadett and Neal issue a pamphlet on orthochromatic photography, which you will find useful.

ARTIFICIAL LIGHT IN STUDIO.—W. H. asks: "Would you tell me anything about photos taken by night in studio, and the best means of doing it, and how to arrange the same for very short exposures? Do you know of the Electric Instanion?"—The best artificial light for the studio is the electric, either arc or incandescent. Flash light is very good for rapid exposures, but the former is preferable. Good results may be obtained with either; it is simply a matter of skill. We know nothing of the light mentioned.

HEAT OF ARC LIGHT.—LANTERNIST writes as under: "For projection purposes I use an electric arc lamp, but I find the heat from this very injurious to lantern slides, sometimes even cracking them. Do you know of any method whereby the heat could be reduced? I might say I have tried an alum bath, but I do not consider that at all satisfactory. I should be obliged for any hint."—In reply: We can suggest nothing better than the alum bath. Probably the one you have employed is not sufficiently thick to fulfil its purpose. Try a thicker one.

LACQUER.—NORMAN ASHTON says: "I should be glad if you could give formula for making tinted lacquer, for staining glass various colours for use with lime boxes. I believe that these tints are obtained by adding some kind of dye to lacquer, but do not know what kind. Should be glad if you could give me information?"—The manufacture of lacquers does not come within our province, as it in no way relates to photography. We may say, however, that they may be had in various tints from any of the polish and lacquer makers, and receipts for them are given in receipt books.

BUSINESS QUERIES.—REMBRANDT asks: "1. As operator in a certain studio can I supply magazines and compete in exhibitions with specimens of my own work in my own name? Can an employer copyright work taken by his assistant? 3. In the event of starting on my own could I trade under the name of "Rembrandt" or any such assumed name?"—In reply: 1. Yes, but probably your employer would object to your doing so and possibly terminate your engagement; 2. Yes, if the copyright is registered in the assistant's name as the author, but if he takes part in the work himself that is not necessary; 3. Yes.

JAPANESE MOUNTS.—FAN asks: "Would you kindly tell me where I can buy (wholesale) the Japanese paper (for mounts) mentioned in the article in current number BRITISH JOURNAL OF PHOTOGRAPHY, page 884, entitled 'Mounting Photos on Thin Paper without Cockling?'"—In reply: Japanese paper, no doubt, may be had, both wholesale and retail, from any of the large dealers, such as Marion's Houghton's, and the like. The importers of the paper only supply it in really wholesale quantities, and we surmise that you would not purchase several reams at a time, as the paper is somewhat expensive.

FOGGY NEGATIVES.—ZERO says: "I have been using extra rapid plates for snap-shots, and have been getting only weak and foggy-looking negatives from them. How can this be avoided? What is the best developer for under-exposed snap-shots?"—In reply: As the negatives are fogged, it is probable that the dark-room light is not safe for very rapid plates. If this should be the case, the remedy is obvious. Pyro is very good if the solution be well diluted, and contains a minimum of pyro and a good quantity of accelerator. The usual metol-hydrochinone developer, well diluted, is a good one for under-exposed plates.

REFLECTING STEREOSCOPE.—A.F.P. says: "I have a piece of apparatus which I have been told is a form of stereoscope, it consists of a grooved board in which slides an upright supporting two mirrors, there are also two other sliders fitting the same groove, apparently for supporting picture. I shall be very much obliged if you will kindly tell me if it really is a stereoscopic arrangement, and if so, how it is worked, for I confess I can make neither head nor tail of it?"—In reply: The description—and sketch—show that the apparatus is a Wheatstone's reflecting stereoscope. The pictures, about the whole plate size, were carried in the two slides. This form of stereoscope is quite obsolete, and has been for many years.

PANORAMIC PHOTOGRAPH.—CUPAR asks: "Would you kindly inform me how to correctly take panoramic views so that they join perfectly? I use 12 by 10 camera with wide-angle lens. I took a panorama on three plates by simply turning the camera on the tripod, the result being that my foreground was very distorted, the straight lines being very much curved, the centre part of picture joining correctly. I have also taken some by having the turntable screw in a line with the diaphragm of lens, but still have distortion, the camera in each case being levelled with spirit level."—In reply: With pictures taken with a wide-angle lens the perspective of the foreground is usually very violent, and the corners of the picture, as a rule, are not evenly illumined. We should advise our correspondent to use a lens including a moderate angle, and take the panorama in four or more sections instead of three.

VARIOUS QUERIES.—ANXIOUS asks: "(1) Can you inform me where Baryta paper is to be had, and whether it can be bought in small quantities? In sensitising plain salted paper, should I still have to first size it with arrow-root, or is the Baryta paper prepared for that? (2) Can you give me the address of any firm that sells life-size plaster heads, for practising how light and shade should fall on the face when photographing a person, and can you kindly mention about how much such heads would cost? (3) Also recommend a book on the above lighting and posing. I should prefer a good book, as cost is no object for this."—In reply: (1) Baryta paper may be had from Messrs. Otto Konig and Co., Cross Street, Finsbury, but whether they supply it in any but wholesale quantities we cannot say. Baryta paper is not suited for "salted paper" pictures. (2) The busts may be had from any of the plaster image makers, such as Bruciammi's, 4, Russell Street, Covent Garden. (3) "Artistic Lighting," by Jas. Inglis.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published in December next. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The growth in popularity of the ALMANAC is evidenced by the remarkable rapidity of its sales.

The 1900 Edition (20,500 copies) was sold within three months after publication.

The 1901 Edition (20,500 copies) was sold a fortnight after publication.

The 1902 Edition (20,500 copies) was sold a fortnight before publication.

The widespread interest in the ALMANAC grows steadily year by year, and in order to supply the increasing home, foreign, and colonial demand, we have decided to enlarge the 1903 issue to

25,000 COPIES.

The great addition to the circulation of this most popular annual (over 20 per cent.) undoubtedly enhances its value as an advertising medium, and the issue of the large number of extra copies will supply the wants of thousands

of photographers, dealers and publishers who were unable to obtain the ALMANAC for the last three years.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

EX CATHEDRA.

Affiliation of Scottish Societies. The proposed affiliation of Scottish societies seems a step in the right direction. The representatives of the societies that met in Dundee on Saturday did right in making no definite arrangements until all the societies in Scotland were consulted: the affiliation can then go forth as a united national body, and do much good work in the advancement of photography. The R.P.S. Affiliation has, somehow, never "caught on" in Scotland, and as the Scots are proverbially clannish, a Scottish affiliation should have a better chance of conserving the various photographic energies into a composite and harmonious whole. If the proposed affiliation comes into being, as we earnestly hope it will, there is nothing to prevent it having a working arrangement with the R.P.S. Affiliation, as is the case with the governing bodies of various pastimes on opposite sides of the Border. We commend the scheme to the earnest consideration of our Scottish readers.

* * *

Electricity, Gas, or Oil? In the latter part of the Nineteenth Century, Ely Place, Holborn, offered an example of a most singular anachronism. While the whole district around was one blaze of gas-lighting, any inquisitive visitor into that *cul de sac*, beloved of diamond merchants, would be astonished by seeing over the gateway in front of one of the houses, a little twinkling light, which proved on enquiry to be an old-fashioned oil lamp, religiously lighted every night, as a sort of silent protest of the aged tenant against the extravagant illumination that surrounded him. It formed an instructive comment upon the progress of less than a century in the matter of illumination. When the streets were as bright as day with gas-lights, and the photographer in his studio was able to rely upon a sufficiently brilliant artificial light to enable him to take portraits during London's fogs, this pathetic little twinkle showed us what our grandfathers were content with, and anyone who should have supported the possibility of a return to a liquid fuel as a source of public light would have been jeered at. Yet, at the beginning of this Twentieth Cen-

tury, such a suggestion is being realised, and, during the coming winter, anyone finding himself in Whitehall will see, between the Horse Guards and Bridge Street, a public installation of the Kitson-light, which will be tested against gas and electricity. It is true that there will be as much resemblance between the Kitson-light and the Ely Place oil lamp, as between the sun and a comet, still, the fact remains that, with the aid of compressed air, it is true oil as an illuminant, is to have a trial.

* * *

Artificial Light in the Studio.

The Whitehall experiment will possess considerable interest for the photographer, who, as we have said, is by no means wedded to electricity as a daylight substitute. Acetylene, for a time, seemed to promise an effectual supersession of all competitors; yet we do not hear of many studios where it is in regular use. The old pyrotechnic flare such as was used in, for example, the Moule's photogen of the middle of last century has given way to magnesium—as a flash-light or lamp—yet there is a steady band of workers who pin their trust to incandescent gas. All will be interested in the Whitehall experiments, as, though a successful street illuminant is by no means necessarily a success for the studio, it is still possible that a light may eventually be evolved suitable for either the photographer in his studio or the pedestrian in the street. The question of pounds, shillings, and pence is, naturally, one of prime importance in discussing this subject, and 's, perhaps, operative in many cases where electricity has not yet been employed. Hence the progress of a new patent incandescent gas burner, recently described in the *Scientific American*, and for which great economy is claimed, will be closely watched. Two patterns are made, one for rooms of limited size, and the other for street use. The main characteristics of these new burners seems to be an efficient method of mixing the air and gas, so as to utilise to the utmost the whole of the gas consumed in rendering the mantle incandescent. To this end a complete control over the quantity of air admitted is provided for by a series of comparatively simple arrangements. The larger burner has openings in its chimney to admit air to the outer surface of the mantle to insure high incandescence, though it may be stated that the more recent Welsbach burners have also a series of apertures in their glass chimneys designed for the same end. Our readers who are incandescent gas burners may be reminded that, especially in the older patterns, the maximum illumination is by no means coincident with the maximum amount of gas consumed. It is, in cases where the pressure is high, quite possible to more than double the intensity of the light by turning the gas down to a certain extent. Indeed, with these older burners, if it be desired to attain the very highest excellence of light, the exact point to which the gas should be turned off is a matter of very nice adjustment. We more particularly draw attention to this, not so much on the score of economy as in view of high efficiency, the main factor in the use of these Welsbach lights for portrait taking.

* * *

Photography through the Telephone.

It may be predicted, with a fair amount of safety, that if seeing by telephone should be rendered possible, it should be possible to photograph by the same agency, hence our readers will be interested to learn that a technical committee of the French Academy have under examination a new discovery relating to the possibility of seeing, at the receiving end of the telephone, the reflection of

persons at the operating end of the service; but it is not possible, the Secretary of the Academy states, to pronounce upon the real value of the discovery at this early stage. The only information available to the public is to the effect that a fresh contribution to the solution of the problem of vision through obstacles has been submitted to the Academy by an inventor whose name would be withheld until after the Committee had reported on the practicability of his invention. The leading idea of the plan is the utilisation of the well-known light sensitiveness of selenium in the circuit of the electric current, a problem which, in one form or another, has for many years occupied the attention of a large number of experimenters.

* * *

Is Pyro Excelled?

Even after the introduction of so many new developers, whose merits for cleanliness and rapidity of action have been so loudly sung, there still remain many photographers, mostly professional, who look upon pyrogallic acid as the developer par excellence for the gelatine dry plate. The rapid spread of amateur photography, and with it the desire for a developer free from that objectionable stain, which at one time might have served as a trade mark, has injured to some extent the reputation that pyro enjoyed so long. We have even heard the remark that its price has also been affected. Be his as it may, there seems some prospect that pyro may recover its old position. From a paper read at a Frankfort Photographic Society, we gather that the substitution of glycoll (amido-acetic acid) for the alkalis usually combined with pyro for development, adds greatly to its power, and places pyro in the front rank. It is said that the effect of the amido-acetic salts, in conjunction with sulphite of soda, is even greater with pyro than any other developer. By using, instead of carbonate of potash, only half the equivalent quantity of amido-acetate of soda, a remarkable gain in rapidity, pluck, and clearness is perceptible. Even if the solution be used as many as ten times in succession, the negatives are still of the stainless, pure, black type. The stock solution remains clear when kept, and the developer neither attacks the skin nor the film. With para-amidophinol, if the corresponding amount of amido-acetate of soda be substituted for the carbonate of potash generally used, the developer is an excellent one for bromide paper, and transparencies, the characteristics being greater rapidity and vigour, with exceptional purity of the high lights. The firm of Meister, Lucius, and Bruning, of Hoechst a/m., is bringing out a patent developer of this type, containing pyrogallic acid, an amido-acetate salt and sulphite of soda in suitable proportions. It is known as "Pinakol P."

* * *

Enlargement by the Radiometer.

The *Photographisches Wochenblatt* contains an article by Dr. H. Baurath describing an arrangement he has made for enlarging by day-light. As it is very simple, inexpensive, and practical, we give a description of the details. Dr. Baurath's dark-room has a sloping roof containing a window about 32 inches broad by 48 inches long, glazed with a stout, single sheet of glass. Beneath this, on a level with the lower edge of the window frame, is a shelf about 34 inches wide. The front and sides are closed with wood, and afford a convenient means of fastening the shelf to the window frame, or rafters. The shelf has an aperture of the size of the negative to be enlarged. Beneath it a camera may be fixed with the lens downwards, directed to the floor. Placed at some distance below the camera is a drawing-board supported on trestles, or a tripod. The

board carries the bromide paper, and it should be accurately levelled. The front of the structure enclosing the window is provided with a sliding door, through which the negative may be introduced and placed in the frame corresponding with the ground glass screen of the camera, which should be removed or turned back. In front of the edge of the negative, near the sliding door we have just described, is placed a Crookes' radiometer. Between the radiometer and the sliding door a tube, about 1½ in. in diameter, is introduced through the shelf. This tube is provided with elbows at both ends. The top one is turned towards the radiometer, and the bottom one towards the eye of the operator. Two small squares of looking-glass placed diagonally in the elbows, reflect the image of the radiometer through the tube to the eye of the operator, who is thus able to count the number of turns the radiometer makes, without permitting any light to pass into the dark-room. The rack and pinion of the camera are used for focussing the enlargement. As the radiometer is sensitive to heat as well as light, care should be taken to avoid exposure when making the enlargement. A trial will give the number of turns the radiometer should make for the exposure. Dr. Baurath has made experiments with the radiometer by exposing it to electric light, and has found it so reliable, that the speed at different distances varied almost with proportional exactitude. Only when the light was so weak that merely one or two revolutions per minute were made, did it give an incorrect reading. As an aid to counting the revolutions of the vane of the radiometer, one of the wings should be perforated with a round hole. This passes a flash of light at each revolution. Whether the light be dull or bright, the number of turns indicates the exposure that should be given, as they are more or less rapid according to the light intensity.

* * *

Acid Toning Baths.

In our issue of the 23rd May we drew attention to a new toning bath by Monsieur A. Helain, of which the following is the formula:—Two per cent. solution of sulpho-carbamide, 40c.c.; tartaric acid, ½ gramme; one per cent. solution of chloride of gold, 50c.c.; common salt, 20 grammes; water, according to toning quality of the paper, 1 to 2 litres. Professor Valenta has been induced to make a series of experiments with this bath, and speaks highly of it for uniformity and absence of double tones in the prints for which it is used. We refer our readers to page 402 of the current volume of *THE BRITISH JOURNAL OF PHOTOGRAPHY* for instructions concerning the bath. Professor Valenta attributes its action to the formation of a characteristic gold salt, by chloride of gold in the presence of an excess of sulpho-carbamide. The process by which the silver is converted by the bath may be expressed as follows:— $(\text{CSN}\cdot\text{H})_2 \text{ Au Cl} + \text{Ag} = (\text{CSN}\cdot\text{H})_2 \text{ Ag Cl} + \text{Au}$. The addition of organic acids assists toning considerably, and this is specially the case with tartaric and citric acids, the latter being of greater use with collodio chloride papers. Professor Valenta has found the bath of good keeping quality and likewise economical, the high price of thio-carbamide being compensated for by the small quantity used. As the bath does not attack the fine detail of the half-tones, and is not poisonous, Professor Valenta is of opinion that it should supersede the sulpho-cyanide bath.

INTENTION IN PHOTOGRAPHY.

WHEN we come to analyse the principal merits of any acceptedly excellent pictorial photograph, to sit in calm judgment, as it were, on all its superlative and minor beauties, what is it, after all, that finally contents and satisfies our artistic perception, and makes us admit that the picture's reputation is well deserved? In nine cases out of ten, probably, we shall come to the conclusion that it is the evident presence of what, for want of any better name, is called intention, the clear existence of a motive, and the more or less successful expression thereof. It is the possession or absence of this abstract good quality which makes all the difference between what may be a merely admirable technical result, and the work of art which demands and keeps our appreciative attention. Now of all things to be patiently aimed at in the pursuit of photographic excellence the successful expression of intention is, perhaps, the most difficult and most seldom achieved. Nor is it hard to understand why this should be so, considering the inevitably mechanical nature of the means and methods employed, which, except in the most skilful hands, are more apt to dominate their master than to move obediently at his dictation. The photographer, unlike his brother artists of the brush, pencil, chisel, or graving tool, does not always start his work with one clearly definite and settled object. Certainly, when he does, one would naturally expect that evidences of thought and intention would proceed to show themselves in his results as a coherent and necessary evolution. Sometimes, indeed, such is the case, more particularly in genre work and figure studies, some admirable examples of which may occur to us, that we know as a fact were the product of deliberate preparation and many trials before the pre-arranged imagination of the artist of the camera crystallised into the finished picture. More frequently, however, inspiration comes, so to speak, on the spur of the moment, on seeing what is felt to be a good subject for special and definite treatment. And it is wonderful how differently the same view or object may impress different workers, and how great may be the unlikeness of their individual renderings. For it would seem that there are four chief factors which go to the making of a pictorial photograph; the subject itself as it stands before the camera, the photographer's own impression and mental ideas of that subject, the way in which he tries to render it, and, lastly, the manner in which the mechanical powers and laws of his art will kindly allow him to render it. The successful worker is obviously the one who has not only his craft best under control, but he who knows best how to interpret and voice his own half intelligible thoughts and fancies in the concrete form of definite aim and intention; in a word, the man who not only feels, but understands his feelings, and the best method of compelling his material and tools to adequately translate them, so that his work may be understood of all.

Photography is admittedly very disappointing in the extent to which it allows its devotees to attain the results they so carefully aim at. Thought and care may be lavished liberally from start to finish, and yet, somehow, the wished-for sentiment and expression of the worker altogether fails to show itself in the finished print, be he never so expert and artistically right-minded. "It is pretty," he will say; "very pretty, but it's not what I meant!" This is one of the haunting draw-backs of the camera craft, which often causes a sense as of a broken melody, and tends to induce a gentle melancholy in the keenly photographic soul, and a resigned acceptance of the fact that, even at his best, he is striving after the unattainable that mockingly elusive beauty of outline, light, and

THE Southsea Exhibition.—Mr. F. J. Mortimer, the hon. sec., writes: "Our show this year promises to be another record. I shall be glad if you will kindly find room to mention that our last day for entries is December 3rd."

shade, whatever it be, that he feels so plainly, sees so truly, yet cannot grasp.

Nevertheless, our art has its compensations. How often it happens that, if we do not get what we intended, we come across rare treasure which we did not intend. It is nothing to boast of, perhaps, but if we would only admit it, how many an admired result has been the product of happy accident and sheer perversity! The plate that we think is going to yield a perfect negative proves a melancholy disappointment; the one we paid little attention to, and have slight expectations of, great is its success and plentiful its meed of admiration! "The last shall be first, and the first last!"

But, after all, "the print's the thing." Fortunate is it for the artist of the camera that so great a power of modification lies ready to his hand between the initial negative and the grand finale of his exhibition picture. Here he has it nearly all his own way. He can lighten this part, darken that; in a thousand ways which show the master hand he can impress his native individuality on his cherished productions. It was said of Michael Angelo that he could stand before a rough block of marble and see in his mind's eye the triumphant work of art which, with ready, unhesitating chisel, he shortly proceeded to bring forth. In like manner, it may be, some of us may have stored in our mental visions the beautiful photograph of the future, waiting but the suitable conjunction of circumstances to turn the ideal into reality. And, strictly and literally speaking, a photograph truly deserves its title of an artistic creation, only when it fulfils to the uttermost the original design and motive of its producer.

When all is said and done, it must not be forgotten that however successful the photographer may be in carrying out his primary intention and motive, he has, except as regards his own pleasure, utterly failed in his object unless his picture will convey to the minds of others the same sensations and impressions which he himself felt at the commencement. As that great authority on all matters artistic, Sir Joshua Reynolds, so well says:—"If the imagination be affected, the conclusion is fairly drawn; if it be not affected, the reasoning is erroneous, because the end is not obtained; the effect itself being the test, and the only test of the truth and efficacy of the means."

Many of the pictures we see that are attractive, yet unconvincing, are so simply because the original intention of their creator has not been successfully carried out. He has failed in getting what he wanted, knew he had failed, and yet rested content with something that fell short of his desires, and tried to make the best of it. Such results, attained in such a manner, can never be genuinely and permanently pleasing; the only road to that real success, which touches the mind and reaches the sympathy of others, is in loyal adherence to first impressions and purposes, and unshaken determination to render them, and nothing else, though it may cost many a futile trial and disappointment before the gratifying end is gained.

SOCIETY of Arts.—The Society of Arts is nearly half through its second century, for it commenced its 149th Session on the 19th of this month with a meeting at which an address was delivered by Sir William H. Preece, the Chairman of the Council, when the medals awarded by the Society during the past session were presented. At the next meeting, on November 26th, Dr. Goegg will read a paper in French on the Simplon Tunnel, and its effects on railway traffic to the East. At the other meetings before Christmas there are to be papers on "Photographic Development," by Mr. Watkins, on "French Education," by Mr. Brereton, and on the "Russian Iron Industry," by Mr. Head. There will also be a meeting of the Indian Section, at which a paper on "Domestic Life in Persia" will be read by Miss Ella Sykes, who, with her brother, Major Molesworth Sykes, has had so much experience of Persian travel. The Monday evenings up to Christmas will be devoted to a course of Cantor lectures on "Gas and Allied Illuminants," by Professor Vivian Lewes.

SOME NOTES ON COPYRIGHT.

PHOTOGRAPHERS in provincial towns, seaside resorts, etc., who publish views of local scenery, often feel aggrieved, and not altogether without reason, when they have issued a fresh series of pictures, to find that the enterprising, cheap view publisher comes along, purchases the prints, and reproduces them by collotype, or process block, as "albums," containing a dozen pictures, to sell at about the price that the photographer charges for a single print. Sometimes a fellow-townsmen, a stationer, buys the photographs and sends them away and has them reproduced in album form. In these circumstances the photographer, as we have just remarked, feels aggrieved, particularly when he finds that he has no redress against the pirates. But who is to blame for that? Only himself! The Copyright Act protects him if he would only avail himself of it by registering his pictures as soon as they are taken. But this he too often neglects to do, and then complains loudly if they are pirated. The cost of registration is but nominal—only one shilling for each picture—which cost would, in most cases, be covered by the sale of the first copy. As will have been noticed in the "Answers" column, we are frequently asked by correspondents if by registering the copyright after the piracies have been published they can restrain the publication and recover damages. There is an old saying that "it is no use locking the stable door after the steed is stolen." Subsequent copyright will not cover copyright in prints issued prior to registration, consequently that will give no redress, as most of the houses that publish these cheap albums of local views that do so much injury to the photographers who produce them, are substantial ones, heavy damages might often be recovered if the photographs had been registered in the first instance, and that they cannot be, is entirely the photographer's own fault. Subsequent registration is, however, sometimes of use in preventing future piracy. If there is a slight alteration made in the negative—say a few private marks put upon it, and a print from it is then registered, and any of those prints be pirated, the photographer can obtain redress as there will then be clear proof that the piracy was made *after* the picture had been registered. Some few years ago we were in Court where a case was being tried. It was this. A picture that was published on the Continent was pirated here, but as the copyright law of the country had not been complied with, there was no redress here. Subsequently, the artist who painted the picture made some slight alterations in it and fresh reproductions were made and published here. These were afterwards pirated by a well-known firm, as an advertisement in connection with their nostrums. An action for infringement was entered, and the owner of the copyright recovered substantial three figure damages, an injunction, and the forfeiture of all copies—many thousands—as well as the stones from which they were printed.

We are frequently asked by correspondents two questions. One is, if a photograph, the copyright of which has been registered, has to be marked "Copyright?" The other is, how is one to know whether such or such picture is copyright? The answer to the first query is in the negative. The photograph need not be so marked, and anyone who copies it has to take any risk he may incur in reproducing it. The reply to the second question is by searching the register at Stationers Hall. This may be done at any time between 10 and 4 o'clock, except on Saturday, when the hours are from 10 till 2. The fee for a search is one shilling for each subject. The names of the authors of the work are arranged alphabetically, so are the names of the assignees in the case of the copyright being

assigned by the author to a second party. So, it will be seen that it is easy for anyone to find out whether the copyright in any particular photograph has been registered or not; also who is the owner of the copyright for the time being. It is the custom with some photographers to mark pictures "Copyright" when the copyright in them has not been registered. This is certainly morally, if not legally, wrong, inasmuch as it implies a protection they are not legally entitled to. In the case of applying the term "patent" to anything that has not been patented, even if a provisional protection has been granted, incurs a heavy penalty which has more than once been enforced; though we do not know of a case where legal proceedings have been taken for falsely using the word "copyright" when the copyright has not been registered—still, such a case may arise.

DR. HEINRICH LUDWIG HUGO SCHROEDER.

IN announcing the death of Dr. Schroeder in our issue of last week, we only had the opportunity of briefly referring to the work of this distinguished optician, whose name commanded world-wide respect for learning and constructive ability. Not much information has been published concerning his career, and it is therefore difficult to give a detailed, comprehensive account of it. We gather from Dr. Moritz von Rohr's work on the "Theory and History of the Photographic Objective," that he served his apprenticeship, as a mechanic and optician with Moritz Meyerstein, Instrument Maker to the University of Göttingen. His study of optics was continued under J. B. Listing, of the same city, when he had completed his apprenticeship, and subsequently we find him in Hamburg as a maker of telescopes. In the latter part of the seventies he removed to Oberursel, near Frankfort-sur-Maine, but this change did not add to his business, and he relinquished it in 1882, to accept an invitation from the firm of Ross and Co., to take charge of the scientific work connected with their establishment. His knowledge of the optics of the telescope and microscope eminently qualified him for the position. It will be remembered that a few years after his arrival in this country, the discoveries of Dr. Schott, who was working in conjunction with Professor Abbé, revolutionised the manufacture of optical glass, and gave an enormous extension to the field for the optician's skill. Dr. Schroeder was one of the first to make use of the new possibilities, and led the van in photographic optics by inventing the concentric lens, the first photographic objective constructed with an abnormal pair of glasses. The lens is remarkable for its simplicity of construction, being symmetrical, with both halves, formed of a plano-convex cemented to a plano-concave element, possessing concentric surfaces. In adopting this construction, it was necessary to disregard the aberration of sphericity, and correct it by means of a diaphragm. The lens was consequently slow, and it was soon superseded by the more complex, but much more rapid objectives, invented by Continental opticians. It should, however, be remembered that the patent of this lens was applied for in 1888, and that its commercial introduction was delayed for some years by difficulty in obtaining the requisite glass. We may say, in recognition of the inventor's skill, that attempts were made by at least one other optician to construct a lens on similar lines, but without success. For the information of those unacquainted with the performance of the lens, it may be described as having a very flat anastigmatic field, and in this respect shows a great improvement, in comparison with the portable symmetrical type. In the year 1891 a controversy arose between Mr. T. R. Dall-

meyer and Dr. A. Miethe, as to priority in constructing a telephoto system of lenses. Like many other supposed inventions in photography, it was found to be ante-dated, and both disputants were denied the distinction. In a letter to THE BRITISH JOURNAL OF PHOTOGRAPHY, published on the 29th January, 1892, Dr. Schroeder pointed out that in 1869 to 1870 he was engaged upon the construction of a telescope for Baron von Bülow, and converted it to a telephoto system by using either a negative or a positive enlarging lens, according to the instructions given in the works of Sir John Herschel, Peter Barlow, and others. Photographs were taken with the instrument by Herr Höge, a Hamburg photographer. The late Editor of this paper, Mr. J. Traill Taylor, appended a footnote congratulating Dr. Schroeder upon the completeness of his researches, and stated that in the race for priority Dr. Schroeder must be held as coming in an easy first. It has, however, since been shown by Dr. von Rohr that Porro ante-dated Dr. Schroeder, having constructed a telephoto lens, with which he photographed an eclipse of the sun on the 28th July, 1851. Dr. Schroeder made use of the principle subsequently in a patent for a terrestrial telescope. The enlarging lens formed one of the components of the erector, and by a mechanical contrivance the eye-piece and the magnifying lens were so connected that the two could be simultaneously adjusted. In 1894 we find Dr. Schroeder's name associated with a patent for another photographic lens. This was an unsymmetrical doublet, in which the spherical aberration was corrected by one component and the chromatic aberration by the other. In the former the relative dispersions of the two glasses were as nearly as possible equal, whilst the difference of refraction was as great as possible. The converse was the case in the other component. Another photographic lens was also outlined by Dr. Schroeder, whilst engaged by the firm of Ross and Co. Dr. von Rohr describes it as a lens for astro-photography, resembling Sutton's triplet. The outer lenses were collective menisci, and the spherical and chromatic aberrations of the axial and oblique pencils were to be corrected by a middle compound lens. The construction does not appear to have been completed.

In 1894 Dr. Schroeder migrated to the United States, and entered the service of the Manhattan Optical Companies. Whilst there he invented and patented a photographic lens of very simple construction. The front lens was a combination of flint and crown, whilst the back lens was of flint only. Modern glass was used in its construction. In this lens we see Mr. Aldis's idea embodied, of constructing a doublet formed of only three elements. Considering the simplicity of the lens, very good results were obtained.

Dr. Schroeder returned to England in 1895, and since then has lived in retirement. Frequent articles from his pen have, however, appeared in the German press. Even as late as February, 1901, we find a patent taken out in his name for an improvement in photographic lenses. Whilst the former patents were marked by simplicity of construction, this last effort is of an opposite character. Two constructions are described and illustrated in the specification. Both have four elements in each component, and both objectives are unsymmetrical. Details of the indices, curves, and thicknesses are not given.

Dr. Schroeder's work on photographic optics, entitled, "Die Elemente der Photographischen Optik," was published in 1891, and forms one of the volumes of Dr. Vogel's "Handbook of Photography." The strength and originality of Dr. Schroeder's mind is visible throughout its pages.

By the death of Dr. Hugo Schroeder we lose an optician in the fullest sense of the word, for he combined great technical skill with scientific knowledge and inventive genius.

THE ACTION OF HYDROGEN PEROXIDE UPON PHOTOGRAPHIC PLATES IN THE RUSSELL EXPERIMENTS.

TRANSLATED FROM THE "PHOTOGRAPHISCHE CORRESPONDENZ."

DR. W. J. RUSSELL, in his important paper on "Hydrogen Peroxide as the Active Agent in Producing Pictures on a Photographic Plate in the Dark," shows that hydrogen peroxide, even in minute quantities, when it evaporates, strongly affects photographic dry plates. Dr. Russell has also found that various metals, like organic substances, affect the plate in the moist state, even if films of gelatine, celluloid, etc., be interposed, and he has established in a highly probable degree the cause of the action of these substances, in the intermediate formation of hydrogen peroxide. Le Roy,* in 1894, showed that a strongly alkaline solution of hydrogen peroxide would develop the latent image. This fact, as well as the action of an acid solution of hydrogen peroxide as a reducer, was thoroughly investigated by Dr. Andresen, in 1899.†

As the alkaline solution of hydrogen peroxide prepared by Dr. Andresen (100 c.c. of a 3 per cent. solution of H_2O_2 + 7 grammes of Na OH) possesses exceptional energy as a developer, we might be led to suppose that the action of hydrogen peroxide upon plates in the dark is likewise reduction of the silver.

A few experiments have shown me, however, that the nature of the action of H_2O_2 in the experiments undertaken by Dr. Russell, is quite different. The veiling action of hydrogen peroxide upon a dry plate may be studied in a more simple way than that of Dr. Russell by dipping it in a solution of H_2O_2 . If the plate be dipped for one minute in a solution of 100 c.c. of water and 5 c.c. of a 3 per cent. solution of commercial hydrogen peroxide‡, the film after washing will be completely blackened by any developer. But if a collodio-bromide plate be used instead of a gelatine plate, no action of the kind takes place. Even if the plate be left for some time in the 3 per cent. solution of H_2O_2 , without dilution, it will remain perfectly clear after the developer has been used. This experiment shows that the action upon gelatine dry plates, observed by Dr. Russell, has nothing to do with the reducing action of hydrogen peroxide, notwithstanding the fact that in alkaline solution it is a powerful developer for collodion plates. It is more probable that hydrogen peroxide belongs to those substances, which destroy the union evidently existing between bromide of silver and gelatine, by affecting the latter and thus bringing the silver bromide again into the reducible form exhibited by it in the precipitated state. This was shown by me some time ago§ in connection with nitric acid, sulphuric acid, and persulphate, and recently in connection with hydrochloric acid, citric acid, and gaseous nitrous acid.

As gelatine is dissolved, or decomposed, by hydrogen peroxide, the property of rendering emulsified bromide of silver amenable to development, in the absence of light action, is apparently a consequence, as in the case of the other substances we have mentioned.

It is not bromide of silver in the chemical sense, but "gelatino-bromide of silver," that is affected by the extremely delicate reaction of H_2O_2 , and this proves to us once more how easily "gelatino-bromide of silver" may be brought into the developable state without assuming previous reduction to have taken place. This may be important in the theory of the latent image. It is a remarkable peculiarity of hydrogen peroxide that the action exhibited in the Russell experiments is only exerted when the solution is in a more or less neutral state. There is no veiling of the image when the gelatine plate is developed with alkaline H_2O_2 , according to Andresen's formula. But if the plate is first dipped in neutral H_2O_2 , it will be completely veiled when developed with an alkaline H_2O_2 solution. The same behaviour is exhibited by gelatino-bromide of silver, when it is subsequently treated with the ordinary organic developers. If first subjected to neutral hydrogen peroxide, the plate fogs, but this is not the case if the preliminary bath of hydrogen peroxide be alkaline. These experiments clearly prove that there is no question, in the Russell experiments, of the action of H_2O_2 being a reduction of silver bromide, such as undoubtedly occurs in the forma-

tion of the latent image by the action of light. They prove that a true developer of great reductive power, such as alkaline hydrogen peroxide, does not produce fog, whilst neutral H_2O_2 does, although it has no capacity for development. Strongly acidified hydrogen peroxide also acts differently from neutral. If 1 c.c. of strongest sulphuric acid be added to 100 c.c. of a 3 per cent. solution of H_2O_2 , an exposed plate dipped in it for one minute, then washed and developed with an organic developer, will be found almost as clear as an undipped plate, although much of the latent image has been lost. My previous experiments have shown that dilute sulphuric acid of itself fogs a dry plate. A plate was therefore dipped in a 1 per cent. solution of sulphuric acid at the same time. It showed considerable fog, and it therefore follows that no kind of veiling action should be ascribed to H_2O_2 , even in the acid state.

PHENOMENA OF REVERSAL WITHOUT THE ACTION OF LIGHT.

Dr. Russell remarks in his treatise that reversal of the image occurs when the plate is subjected to the action of larger quantities of hydrogen peroxide. My experiments in this direction gave very remarkable results.

Strips of dry plate, 1c. broad by 9c. long, were placed in test tubes filled to a height of about 3c., with solutions of H_2O_2 , in ascending degrees of strength. They were kept in absolute darkness for two hours at a temperature of 20 degrees C. The strips were then washed and developed for three minutes with metol-soda

percentage of H_2O_2 contained in each solution.	
0.001.	The dipped end of the plate showed a slight deposit, but the upper (dry) end was unaffected.
0.003.	Considerably greater action. The top unaffected.
0.01.	Very strong action below. The top unaffected.
0.03.	Very strong action below. Perceptible action at the top.
0.1.	Somewhat stronger action below than in the previous case, and marked action above.
0.3.	Less dense below than in the previous case, and a much greater deposit above than below.
1.0.	Only slight reduction below. Complete reduction above.
3.—	Perfectly clear below. Complete reduction above.

With strengths between 0.03 and 1.1 per cent. the appearance of the plates resembles that of the "neutral condition" of solarisation by light. With 3 per cent. a complete reversal of the image occurs, that is to say, solarisation by chemical means. This phenomenon, exactly resembling solarisation by action of light|| acquires much interest from the fact mentioned at the beginning of this paper that the primary action of H_2O_2 upon the plate is not a direct reduction of the silver bromide, as in the case of exposure to light, since silver bromide emulsified in collodion is not affected by H_2O_2 . We would also remark that difference in the swelling of the gelatine, caused by difference in the diffusion of the developer at both extremities of the plates, or in the strips used with different quantities of hydrogen peroxide, cannot be looked upon as an explanation, as the entire surface of the plate is fixed with the equal rapidity in every instance. The phenomenon we have described might be explained by the peculiarity of hydrogen peroxide being a reducer as well as an oxidiser. In its

|| The statement recently put forward by Precht (Photo. Wochenblatt, 1902, p. 237) that solarisation is merely a phenomenon of development, is in my opinion, an entire misjudgement of the interesting phenomenon of the reversal of the latent image. My exhaustive examination of solarisation appears to have escaped Precht's notice, and I therefore take the liberty to refer him to my experiments concerning the action of Bromine and Nitric Acid upon solarised collodio-bromide plates (Photographische Correspondenz, 1901, p. 351, Luppö-Cramer: Wissenschaftliche Arbeiten; Knapp, Halle, 1902, p. 39). It has long been known that sulphite acts as a retarder, merely by counter-action of the alkali, and that the point at which reversal takes place may be set back by suitable development. Precht's researches, consequently, do not throw any fresh light upon the question. The use of acetone sulphite instead of bisulphite of potash, or even sulphuric acid, etc., for neutralizing alkalis, is also an innovation of very little importance. Professor Precht can ascertain for himself in very few minutes, that the same quantity of sulphuric acid will produce far more retarding action upon Edinol than can be obtained with Acetone sulphite, which he praises so inordinately for some incomprehensible reason. The phenolate developers, like Rodinal, contain a relatively small quantity of alkali, which can be counteracted by small additions of acid. With the carbonate developers it is of course preferable to use a small quantity of alkali for over exposure, instead of the inconvenient method of first taking a large quantity of alkali and then neutralizing it by a suitable acid body, such as Acetone sulphite, or sulphuric acid, which is much cheaper.

* "Bulletin de la Société Française," 1894, p. 23. See "Eder's Jahrbuch," 1896, p. 413.

† "Photographische Correspondenz," 1899, p. 260.

‡ It is immaterial, whether the ordinary, acid, commercial, hydrogen peroxide be neutralized or not. For further particulars see later on.

§ "Photographische Correspondenz, 1901, p. 159.

action upon the gelatine a substance may be formed which reduces a trace of the silver bromide, but when stronger solutions are used the "latent chemical image" is destroyed (oxidised). We find, in fact, that the latent image due to the action of light is considerably enfeebled by bathing a collodion plate for fifteen minutes in a 3 per cent. solution of H_2O_2 .

Ammonium persulphate, in different degrees of strength, acts upon a dry plate in precisely the same manner as hydrogen peroxide, excepting that it is slower and requires considerably more time to produce reversal. As persulphate does not evaporate, the part of the plate which is not immersed does not become affected, and the reversal is only to be judged by the diminished density of the immersed portion in proportion to the strength of the solution. We allowed the persulphate to act upon the plates for fifteen hours in 5, 3, 2, 1, and 0.5 per cent. solutions. Upon development, the 0.5 per cent. test showed the maximum of density, which diminished until 2 per cent. was reached. At this stage the density was still greater than the chemical fog originally present in the plate. With from 3 to 5 per cent., the dipped end was clearer than the other, and with 5 per cent. it was perfectly clear.

The action of persulphate might, with some effort, be similarly explained to that of H_2O_2 , as Lumière and Seyewetz endeavoured to interpret the process of reduction with persulphate, by oxidation and reduction proceeding simultaneously.

It is noteworthy that sulphuric acid was found to act similarly to hydrogen peroxide and persulphate. With solutions of higher strength, however (4 to 5 per cent. of H_2SO_4 , and four hours' immersion), the undipped part of the plate was likewise affected, but it is improbable that sulphuric acid evaporates at ordinary temperatures, and it may therefore be assumed that an impurity was the cause of this action. This appears probable from the fact that acid obtained from different sources, containing the same amount of H_2SO_4 , showed considerable difference in the time requisite to obtain reversal.

The action of sulphuric acid in other respects is the same as that of hydrogen peroxide, and it is open to doubt if traces of this substance may not be present in the acid, since the Russell experiments show by their extremely delicate photographic reaction how widely spread it is, and how easily it may be produced.

Unfortunately, it was impossible to obtain reversal with nitric acid, as the gelatine was dissolved by solutions exceeding 1 per cent. in strength, and the maximum of density was not reached. Citric acid also exerted a mechanical destructive action upon the medium before reversal could take place.

It is necessary to exercise great caution in formulating a hypothesis for these peculiar phenomena of reversal. The assumption of variable reduction, or secondary reoxidation by H_2O_2 and persulphate, according to strength of solution, seems very risky. In this case the action of sulphuric acid would have to be explained by the presence of H_2O_2 (or $H_2S_2O_8$?), an assumption which has not yet been proved. Above all, however, it seems impossible that the action of nitric acid upon gelatine should form a substance which could reduce bromide of silver in the presence of nitric acid. The action of nitric acid must consequently be considered in endeavouring to explain the cause of reversal by hydrogen peroxide, although reversal cannot be produced by its means.

DR. LUPPO-CRAMER.

Frankfort-on-Main. July, 1902.

P.S.—Dated September 16th, 1902.

Further close study of the nature of chemical fog, so-called, shows unquestionably that ordinary fog and the alteration in gelatino-bromide of silver caused by H_2O_2 and nitric acid, differ fundamentally from light action, and have nothing whatever to do with the very slight reduction of silver bromide produced by exposure. An account of this will shortly follow in the "Photographische Correspondenz."

THE AUTHOR.

In connection with the camera section of the Norwich Field Club, it is proposed to hold a three days' exhibition in January, 1903. In the open section there will be classes for (A) landscape, river and broads scenery; (B) Portraiture, figure and animal studies; (C) Architecture (interior and exterior) and survey work; (D) Field studies (animal, bird, and insect life photographed amid natural surroundings; (E) Instantaneous work (set of six). Silver and bronze medals will be awarded in each class. Full particulars, etc., will shortly be obtainable of the hon. secretary, Mr. J. H. Goreham, Ingleside, Lakenham, Norwich.

MOUNTS AND MOUNTING.

[A Paper read before the Edinburgh Photographic Society.]

THE territory of photography is undoubtedly a wide and increasing one, and the pioneers in its domain have ever something new and interesting to lay before you. Alas! I am no pioneer, and the field of the past has been so thoroughly surveyed, its lodes so accurately located, and its veins so persistently and successfully mined, that little is left one now but the opportunity to potter around about the "tailings," so to speak, in the small chance of turning to account some overlooked trifle, the contemplation of which in the absence of greater finds may serve to encourage us in our pursuit. It is just such a trifle I offer you to-night. It may repay your attention, or it may not, according to your previous experience and success; and while I can never hope to claim the attention of the advance guard, I may still be able to whisper advice to recruits in the ever-increasing army of our art-science. We are all ready enough to expose plates (a hand camera that carries less than a dozen is considered a drug on the market)—we are, as a rule, fairly eager to develop them; we may even exhibit anxiety occasionally about our printing; but from this stage enthusiasm rapidly evaporates, and he is indeed an amateur to be envied who possesses even an unmounted copy from each of his printable negatives. "Oh! mounting! that can be done later, at any odd moment—it's a small matter, almost beneath notice." Alas! it is too often considered beneath our thought; the notion that it is beyond it I shall endeavour to dispel. Whatever advantages the title of this discourse may claim—and I here acknowledge it provides a very wide scope—it has the disadvantage of possessing a certain sphinx-like quality, a feeling of the great unknown. As I have already alluded to the level I wish to reach, viz., that on which stand those having something to learn of mounting, I may be permitted to indicate the section I wish to work. This may be most rapidly done in a negative manner. I shall say nothing of the ordinary commercial cabinet; of the mounts selected to convey mementoes to our friends (unless special friends); of that article beloved of the lazy amateur, the "slip-in," "slip-about" mount. Neither shall I by implication or reference further the interest of any particular manufacturer of mounting compound, but assume that you have the means and ability to evenly apply a good adhesive to a good print, and spend all my time in trying to help you to decide on what you will place it. Notice, I say a good print. By that I mean a print which is the result of care in the preceding operations of selection, development, and printing—a print that contains some thought or feeling you would wish to convey to others; a print, in short, that holds part of yourself, and that, whatever others may think, you are not ashamed to be judged by.

In a large photographic society there are almost sure to be those who take up photography as a pastime or relaxation, and who are able to command the time of, and willing to relegate the trouble to, experts. Again there be those who belong to the great army of "snap-shooters" (I detest the word, but it is current), and who are quite content if they get say ten hits out of twelve shots, even supposing these are only "outers" in every sense of the word; while, on the other hand, there may be many who have attained and long since passed the limited range of my remarks. All of these, to quote the Duke of Plaza Toro, "may allow their attention to wander." I shall not interest them. But the real "amateurs," the "lovers" of our science—art—craft—call it what you will, may find something interesting or new here or there in what I say, and it is to these, as a brother amateur, I submit this lecture. "Addressing, then, the attentive gentlemen," to quote once more, why should

we mount our photographs? Well, this is a question that would have admitted a much simpler answer ten or twelve years ago. Mounting was a necessity then, and although a necessity, strange to say, there was less attention paid to the subject than now, when the needs are less clamant. Prints being for the most part on albumenised paper, had a tendency to retire upon themselves in a bashful but persistently irritating manner, unless closely attached to something that would supply sufficient "back-bone," so to speak, to meet the public gaze. Any good white or cream board, and plenty of it, was considered good enough for this; and as thoughts on mounting seemed to run to area, and white boards were fairly cheap, a speck of print was usually sailing on a sea of mount. This "unrelieved expanse of ocean's gleam" ultimately began to pall on some man with ideas, and he got to confining his cruises to one side the line, or rather series of lines. But this still left him plenty of sea-room. Someone else, recognising the improvement, "went one better," and taking up the ends of these lines, he crossed and re-crossed, tacked, and came about in the most complicated manœuvres, till the onlooker was as much at sea as the print. Then came the advent of the use of colour boards. If the mount-maker was lavish in line, he was positively prodigal in colour. Purple, maroon, green, and gold (especially gold), singly and in combination, matt on matt, he piled them up, and having experienced the scope for variety in line, he pressed that also to his service. Dome and square, oval and rectangle, not to mention fearful and wonderful shapes beyond the limits of a geometric vocabulary, all striving in strident tones, and producing an effect of barbaric splendour, which in its own medium outstripped anything "Tchkowsky" ever dreamed in his. One would have thought that such examples of misdirected genius were long since decently buried; but there may be found for sale at the present day a new mount which, while being pitched in a lower key and appealing in smoother harmonies, succeeds nevertheless in completely smothering the print in the embroidery of its themes. As a specimen of marquetry it might reach excellence; as a mount it is simply excess. The grey dawn of the bromide and platinotype period came in a restful change, and ushered in the day of the "plate-sunk" and "India-tint" mount. In these latter times, hypercritical people have, with and without reason, condemned the "plate-sunk" mount, and it may be interesting to speculate on the cause of its adoption and its long run of popularity. The first batch of prints in black-and-white, when shown to that ubiquitous and all-round critic, "the man in the street," drew from him the exclamation, "How unlike photographs"; and his hasty and ill-formed conclusion has been stereotyped and set in nearly every photographic art critique to the present day. Certainly they were unlike the photographs he had been accustomed to, and more like the familiar engravings, lithographs, or etchings of the printsellers'. This was also recognised by their producer, and he saw that different treatment would be required in mounting. Now photography in its art infancy has too often been tempted to imitate its elders, and while imitation is the sincerest form of flattery, that flattery is not to the imitator. Hence when the maker of mounts boldly annexed the idea of India-tint and plate-mark from the province of plate-produced impressions, he made two very grievous blunders. First, he aided and abetted the uninitiated in forming a false notion as to the nature of the prints; and secondly, he made the more flagrant but less-censured mistake of putting his plate-mark outside his tint. The effect of plate-mark and tint on a white mount or broad-margined impression is decidedly good; but as I will show later, it might have been arrived at in a manner which would have saved us for many years

from much adverse comment. But taking the much-maligned plate-sunk as it is, no one can deny it superiority for photographic purposes to its predecessors. Until recently, greys and grey-greens were the only shades to be had in this style of mount, but the infusion of art principles into photography, and the concomitant higher demands by the persistent amateur, have gradually changed all that, and at the present time no one can grumble at the paucity of tints in mounting boards, so that there can be no excuse for inharmonious mounting.

Having arrived at present-day conditions, at this stage the question may be repeated, why mount our photographs? Well, in many cases there is no reason why we should—and we do not. Photographs on heavy paper framed close up, and small prints on heavy paper with wide margin, such as may be got by printing in carbon, ozotype, gun, or platinotype, may with advantage be left unmounted. In two of the prints here shown the India-tint effect is obtained by legitimate photographic means. The prints (bromide or platinotype) are exposed in a frame with clear glass front and of sufficient size to take paper the full size of the finished picture. A mask is cut, showing size to be printed, and the part cut from this mask carefully laid aside. The mask is then laid on the clear glass front of printing frame, negative adjusted, and paper inserted to print. When printed, the mask is removed, and one with similar shape, but quarter to half inch larger, is inserted, the piece cut from original mask is carefully adjusted to cover the part already printed, the whole inserted once more in the frame, and a slight exposure given. This prints a band of selected width and varying depth all round the print, leaving the picture and white margin as before. A similar method was adopted with the bromide print, but the band was printed after the central part had been partially developed, to aid in accuracy of centring. The other unmounted examples are on platinotype C.C. paper, brush developed. But these means apart, prints are mounted, consciously or unconsciously, for three chief reasons:—(a) To isolate the print from its surroundings; (b) to enhance its good qualities; (c) to counteract its defects. I shall just say a word or two on the first reason, and deal with the second and third together. The amount of isolation a print requires depends a great deal on its surroundings. A print to be viewed in a room may not require such strong treatment as one for exhibition, where all the prints are adjacent, and each crying aloud for recognition. Hence heavy exhibition frames seldom appear to advantage unless in a large room, while portfolio prints admit of much daintier dressing. In this, as in many other points in mounting, a good deal depends on the point of view. The effect of a mount to enhance or mar a print may best be shown by experiment. Taking the two extremes, a white and a black mount, it will be noted that a grey print looks greyer on the white mount, but brightens up considerably on being placed on the black one. The selection will depend on the impression to be conveyed, always bearing in mind that there is a considerable range of mounting tints between white and black. There is nothing so easy to deceive as the human eye, and taking advantage of this, it will be seen that we have here, at one and the same time, a means of enhancing the qualities of our print, or of apparently removing some of its defects. But if we are to spend time on the isolating and enhancing properties of our mount, let us take care that we do not unduly burden it with the task. Has the print itself got good qualities, or negatively, not too many defects? Have we cut down all superfluities and disconcerting unnecessary? Have we isolated the print as much as possible in itself? A good way to find this out is to employ two pieces of neutral-tinted cardboard cut in the form of the letter L, and by moving them about over the print,

find out how much can be done without. How many pleasing pictures lie lurking unseen in the weary expanse of large prints. The lens does not discriminate. One may of necessity be tied to a certain size of plate and a fixed focus of lens, but not to one size of paper when there are trimming knives in existence. Better far an inch of interest than a foot of futility. If a twelve by ten print contains but a ten by two picture, let that same knife have free exercise.

But you may urge, how about mounts? A dealer can hardly be expected to stock such odd sizes? Well, hardly. The poor man has his own share of life's little worries at our hands, without increasing the burden. He may carry a wide range of boards, and a full stock of cut mounts, but these necessarily will be of well-known sizes, usually corresponding to the proportions of our plates. So it comes to this, either you must trim your print to suit your mount, or cut your mount to suit your print. Having made up your mind whether mount or print is of most importance, the answer is obvious. This brings us face to face with the fact that the man who wishes to preserve the individuality of his prints must make his own mounts, and having once begun, I can hardly fancy him returning to the old order. For he thus frees himself from the bonds of the mount-maker and the dealer's suave—"Very sorry, sir! Just out of that particular size at present. Expect them in every day, etc., etc."—these all become echoes of the past. He will have no difficulty in having his ideas carried out, and be saved many barren explanations. And lastly, if he prints in any of the permanent processes, as he is most likely to do, he will be able to use odd pieces of pulp or straw board, which will reduce his mount bill considerably. It is advisable to have always on hand a sheet or two of large board, say 25in. by 30in., and a few sheets of facing paper, and the amateur is equipped to meet the demand of odd sizes and delicate colours better than the largest stocked house in town. Now, assuming that the advantage of home-mounting is acknowledged, the selection of a suitable mount for a particular print will depend mainly on three things, viz., texture, tone, and tint. Though circumstances demand that we should consider each of these prints seriatim, they are closely allied and have a mutual effect, working together to a common end. By the texture of the mount is meant the comparative coarseness or fineness of surface, and on this matter I wish to call attention to two points only. First, rough and smooth are comparative terms, and vary, or seem to vary, like tones, according to the quality or tone of the immediate surroundings. Hence a smooth-surfaced print will appear by comparison smoother on a rough mount than on one with a "laid" surface; conversely, a rough-surfaced print on an ivory surface mount will appear much coarser than it does when viewed on a rough-faced mount. This power is often very valuable, and should weigh in selecting a texture for any particular print. Secondly, rough papers break up and scatter rather than reflect light; hence of two equal shades of grey, that on a rough paper will appear softer and lighter than the same shade on a calendered paper.

Having noted these points, we pass to the next consideration, that of tone. The terms tone and tint are sometimes used indiscriminately, so, to prevent confusion, I may say that here the word tone is used in a similar sense to "pitch"—that is, a high tone is one approaching the light or white end of the scale of colour, while a low tone belongs to the dark. Tone refers to depth—tint to colour. For example, a shade of red and a shade of green might be of the same tone, but could not be of the same tint. In our experiment with the grey prints on the black-and-white mounts, we saw in extreme the effect of tone in mounting. Between black and white there is a very

wide range of greys, and if we add colour or tint to our stock, an equally extensive range is available in each colour. On the white mount the greys appear dark and muddy, the high lights veiled, and the dark masses unduly dense. On the black, we improve the deep greys, banish the light ones, and cast a green-brown sheen on the shadows. Clearly we must find some medium tone if we would do the best we can for our print, and a trial or two on various shades of grey will probably give us what we require. The same method may be applied to colour prints, and I show you the effect of tone on a dark green and a dark blue carbon. The third consideration—that of tint—calls, perhaps, for somewhat fuller attention, as it is in this direction difficulties are most likely to arise. Let us first look at the general principle which underlies the whole question. Every photographic print has some dominant tint or colour, which varies according to the process employed in its production. Silver prints have usually the brown, brownish purple, or purple-black tints predominating; bromide and platinum papers range through the greys; while prints in carbon, ozotype, and gum bichromate allow the photographer some limited scope in the field of bright colour. In any single print, however, there is but one ruling tint, and the proper mount for that particular print—to be truly satisfactory—must either continue and harmonise with it or, on the other hand, contrast with it under the laws of complementary colour. To mount harmoniously is much more easy than to mount in contrast, as the principles underlying the one are less complicated than those which govern the other. In harmonious mounting, the prevailing tint of the photograph should at once indicate the colour to be employed; considerations of tone and texture coming after. Yet how often do we find grey prints on green or brown mounts, showing either that this principle is not recognised, that considerations of tint have been sacrificed to tone, or (and this is much more likely) that the commercial range available in that size was limited. Now at the present time there is no excuse—save want of knowledge—for a continued perpetration of such mistakes. There is no dearth of material ready to hand. Several shades of so-called "crayon" paper, to be obtained from the artists' colourmen, are very suitable, while from the same source the stock may be enriched with sheets of "Whatman" in various grades; Michallet, vellum, and Japanese papers. Good shades are sometimes to be picked up at the printers' or paper-makers', in the line they call "cover papers," while many tints of homely wrapping-paper are not to be despised. In fact, there is nothing so far removed from the usual photographic sphere in papers that cannot now and again be pressed into service. You may doubtless remember the rage a year or so ago for brown-paper mounts. It was a swing of the pendulum, and like most movements started with a jerk, went too far. Brown-paper mounts were considered the salvation of every print mounted thereon, and hardly an exhibition lacked its patch of packing-paper. The demand got so persistent that makers made, and dealers took to stocking, brown-paper mounts, and the average amateur was for the moment happy. We have got over that now, and no man did more for the general upward tendency of mounts at this stage than Mr. Percy Lund, of Bradford. His "Nature Series" of mounting papers came—if I may safely annex the phrase in Edinburgh—as "boons and blessings" to the aspiring photographer. The range in this series is extensive and open to addition, and with, perhaps, one or two extra tones of grey, would meet all the demands we would be likely to make, till the advent of such time as colour photography enables us to emulate the example of the elder arts, and exhibit our productions in heavy gilt frames. Another firm catering for the wants of the artistic mounter is the publishers of the "Photographic

Art Journal," Leicester. They issue for 1s. 6d. a sample set of papers, from which one may make a large selection, there being over eighty different grades and shades in the sample packet. The sheets size about 20in. by 25in., and cost about 2d. per sheet. Some of these papers, and all of the "Nature Series," admit of scrap mounting for portfolio use, without any backing of cardboard. These same stores are available for mounting in contrast; but I approach this part of the subject with diffidence, as it is delicate ground, and presupposes a knowledge of the theory of complementary colour not usually possessed by every amateur. The appreciation of colour effects and values is largely a matter of temperament and training, but there are certain laws that influence results, whether or not we may be conscious of their working. Briefly, it may be said that colours in juxtaposition act upon each other. For example, a white patch on a green mount will assume a reddish tinge, while if mounted on a purple it will seem tinged with yellow. The same applies to prints on strongly-coloured mounts—it exists, but in a subtler form, in the tertiary colours also—and the amateur may best be advised to judge by experiment. If his attempt at colour contrast looks well—in the print, I mean, not the mount—then it may be successful; it will entirely depend, as does so much more in this branch of mounting, on the feeling or effect to be conveyed. But a word of warning may be given in this connection. Do not waste time hunting for colour contrasts to black-and-white prints, as no colour contrast to either exists. Black and white will contrast and harmonise with each other, and between the deep tone of the one and the high tone of the other lies the whole gamut of greys.

Having so far considered, in some of its phases, the theory of artistic mounting, let us now pass to the practice; and as example is better than precept, I may be allowed to submit to you some specimens, showing the methods of applying our knowledge to our work, asking you, however, to bear in mind that it is the method the specimens are meant to show, not the mount, and much less the print. We saw in casting about for the suitable tone of our grey print that a grey board fulfilled the conditions as to tone; but in some cases we may find that, while its general effect may be good, it may seem to lack something to connect the print and mount, and destroy the "stuck-on" appearance. This may be supplied in a variety of ways, such as the printing in of a matt, as explained; in saving a border of the original paper (if tinted), and so arriving at what is equivalent to the India-tint without being, as the mount-makers say, "laid on"; or by masking a border to print white, and trimming so as to leave a narrow margin of this between print and a darker mount. Care should be taken, however, that the print is amenable to this treatment, or the border may get lost in a white sky. Another method is to lay the print first on one tint or tone, trim to show a margin of that, and then place the whole on another tint or tone. This may even be repeated with care, showing two tones, or a combination of matted border and applied tint be used successfully. This method is much used by our American friends, and sometimes, in fact, we find this called the American method of mounting. It may be easily overdone, however. An example is given of this treatment on the lines of contrast. But this breaking or connecting effect may be got in another way, viz., by what is known as the French method. This style, when neatly done, is very effective for delicate prints, and consists of a series of lines drawn about the print, of varying widths, at irregular intervals, with perhaps one or more of these intervals filled in with a wash of a pale tone in correct tint. I have already spoken of the plate-mark, and acknowledged its use in breaking up the space between the impression and the edge of the margin. As we have no impression, and hence no plate-mark, to

mark a mount with a blank plate or card, and then paste on a photograph, is undoubtedly trying to sail under false colours, and although few could be taken in with the deception, let us be true to our own flag. The same effect may be obtained by indents made with any stylate instrument or the edge of a paper-knife. This is very effective on a paper of good substance, such as Whatman "not."

In mounting on straw boards, all of the foregoing methods are available; but if cut openings, either plain or bevel, be desired, a white board must be used, as the edge shows. This white edge may take the place of the white matt if the board be thick and the bevel deep; in which case, if a tint also is employed, the tint should be laid down first and the opening cut afterwards. The cutting of bevel mounts is not a difficult matter, all that is required being a bevel rule with a bevel about 45 deg., a good flat knife or chisel, a cutting board or glass, and an obliging friend or a clamp. Of the latter perhaps the clamp is to be preferred, as you can put on the screw with less compunction. Having marked the desired opening, the bevel rule is placed sufficiently back from the line to allow the knife to get just on it when placed on the angle, the further end clamped to the bench, board, or table, and the cut or cuts made. It is desirable that if more than one cut is made in the one line, the second be a true continuation of the first, or ragged edges will result. The full effect of matts is obtained with a deep bevel on a double or triple board, but in this case the facing-paper is better laid over the bevel as well. A word about the size of the mount in relation to that of the print. Small prints require relatively larger mounts than large prints, therefore it follows that the larger the print the smaller relatively the mount, till in large sizes the mount may be dispensed with altogether. If the mount be too large, it dwarfs the print. If the margin of mount visible is equal to or more than the width of the print, the latter looks insignificant. In trimming a mount, which I usually do after rather than before the other operations, there are one or two little points to be observed. The diagonals of mount and print should never coincide. If the composition has a vertical tendency, dignity will be added by leaving the margin at top and bottom greater than that at the sides; while if the composition be horizontal, repose will be gained by the greater margin being at the ends. This refers, of course, to rectangular prints; circles and ovals require special treatment. The circle is a difficult figure to fill in a good decorative manner, and the oval more so, there being very few subjects that suit it; but if it is desired to trim to such shapes, a circular wheel trimmer and circle or oval metal forms are almost an absolute necessity, unless more elaborate and expensive apparatus be employed. Do not be led away by fad or fashion to adopt one style of mounting for everything. Let individuality enter into this as in other portions of your work, but do not mistake eccentricity for genius. With the knowledge of the effects of texture, tone, tint, and size on your print, employ that which will best express your idea. Art ceases to be art and becomes science when hemmed in by rules or laws, and so in artistic mounting it does not become one to dogmatise or lay down rules which, if blindly followed, would rob the result of all artistic quality; but rather I have attempted to indicate some of the lines along which the intelligent worker may proceed, remembering always that the only true rule of art is study, experiment, liberty, and personal feeling.

J. W. EADIE.

Those who are interested in the prosperity of the Photographic Association of 16, Brook Street will be glad to hear that the newly elected board of directors are strengthening its financial position by a considerable issue of debentures at 6 per cent., most of which have already been allotted.

Exhibitions.

HACKNEY PHOTOGRAPHIC SOCIETY.

The annual exhibition of the Hackney Photographic Society was held at Morley Hall, Hackney, on the 12th, 13th, and 14th inst.

The fact that the Hackney exhibition immediately follows the great photographic exhibitions of the year places the unselected work of the members of a suburban society in direct comparison with the pick of nearly three thousand photographs from all over the world. That, in such a competition, the Hackney Society is beaten is inevitable. That it is possible even to suggest the comparison shows that the little photographic community which forgathers week by week in the east of our city consists of able instructors and apt pupils, that the technical and pictorial aspects of photographic practice are equally matters of serious study, and that in spite of the individual spirit of emulation which must necessarily exist where there are prizes to be competed for, the members as a body are united in their efforts for the honour of their society. The exhibition that has just closed was indeed worthy of unstinted praise. It did not consist entirely of masterpieces—no exhibition ever did, but there was so much that reached the level of the best photographic work of the present day, and so little that fell immeasurably below it that as a whole it constituted perhaps the best society's exhibition that has been held within the London district. We have been referring to the members' classes, but the Hackney Society has always attracted some of the best work of the year to its open classes, and this year there was no falling off, perhaps an improvement.

The society is not very fortunate in the accommodation which it has for holding its exhibitions. The Morley Hall, though suitable enough for a concert or lecture hall, is certainly not an ideal exhibition gallery. It is insufficiently lighted, and the wall space available does not allow the pictures to be displayed to their best advantage. These are difficulties the society cannot overcome unaided, and it is to be hoped that at no distant time the educational value of such an exhibition as this will be recognised, and that, instead of an exhibition open for three days, under municipal encouragement, it will be open free for a sufficiently long period to allow all who are interested to view it.

The judges were Messrs. Reginald W. Craigie, A. Horsley Hinton, and Rev. F. C. Lambert. It may be a mere coincidence, but while on the members' side only one award was made to a picture accepted at the Royal or the Salon, several were made to pictures rejected by one or the other. On the open side there were two of the medalled pictures from the New Gallery; one was passed over and the other received a bronze medal. There is something very wrong somewhere. The fact that three, or really four, sets of authorities can create such hopeless confusion as to the merits of the same pictures is not a hopeful sign of the times.

THE AWARDS.

MEMBERS' CLASSES.

Best Picture in Members' Classes.—Gold medal, F. E. Roofe.

Class A.—Portraiture and Figure Studies.—Silver medal, W. A. I. Hensler; bronze medal, G. Parks; certificate, F. E. Roofe.

Class B.—Landscape, Seascape, and River Subjects.—Gold centre medal, E. J. Hunt; silver medal, W. Selfe; bronze medal, W. A. I. Hensler; certificates, W. F. Fenton-Jones and W. Selfe.

Class C.—Animal Studies.—Silver medal, W. Selfe; bronze medal, J. L. Smith.

Class D.—Architecture.—Silver medal, F. E. Roofe; certificates, Dr. Roland Smith.

Class E.—Lantern Slides.—Silver medal, F. E. Roofe; bronze medal, A. W. Cook; certificate, W. Selfe.

OPEN CLASSES.

Best Picture in Open Classes.—Gold medal, W. Scutt.

Class F.—Portraiture and Figure Studies.—Silver medal, Miss A. B. Warburg; bronze medal, J. D. Shields.

Class G.—Landscape, etc.—Silver medal, V. G. Barford; bronze medal, J. M. Whitehead; certificate, W. A. I. Hensler.

Class H.—Architecture.—Silver medal, Rev. H. R. Champion; bronze medal, W. R. Lathbury.

Class I.—Still Life, Animals, etc.—Silver medal, W. Selfe; bronze medal, O. G. Pike.

Class J.—Stereoscopic.—Silver medal, L. S. Wilks; bronze medal, W. Harvey.

Class K.—Lantern Slides.—Silver medal, J. W. Hodges; bronze medal, J. W. Hodges; certificate, W. J. Shelley.

TRADE SECTION.

Best Exhibit.—Silver medal, G. Houghton and Sons.

Most Useful Photographic Novelty.—Bronze medal, J. Ashford.

We have already indicated our opinion of the general progress the society has made since the last exhibition, but particularly is improvement to be found in the class for portraiture and figure studies.

This class of subject at Hackney, as with most societies appears, until recently to have received only occasional and desultory attention, with the result that at the exhibitions the class contained hardly anything worth looking at. The impetus in the Hackney Society seems to have been given by Mr. Snowden Ward, who invited the members to spend a summer day at his place at Tonbridge, provided a few graceful models, and stimulated efforts by the offer of prizes for the best figure studies made on the occasion. The result has been that the class contains several extremely good pictures, obviously taken at the Tonbridge excursion, and further that some of the members have realised that success in this branch of photography is quite within their reach if the same serious study be given to the essential conditions that, applied to field work, has won them eminence. The president of the society, Mr. Wm. Rawlings, who marks all his work "Not for Competition," has produced a most successful version of his Tonbridge model, and has imbued his picture with the refinement which characterises all his work. W. A. I. Hensler's "Musician," for which he has evidently been his own model, was also an entirely satisfactory work, and it was perhaps an unavoidable feature of the surroundings that robbed F. E. Roofe's "Blind News Seller" of something more than ordinary distinction. G. Parks, W. Selfe, H. W. Lane, and F. W. Gosling deserve a good word, and several others showed work that was more than passable.

The landscape class, which has always been at Hackney an echo of the fashions of the day, showed signs of a breaking away from the ordinary conventional subjects, treated in the conventional way. When mud puddles were the rage, Hackney revelled in mud and mist, but it must be confessed it was good mud and mist, though there was too much of it. One would have thought the members lived in a poetical atmosphere of gloom and melancholy, though they are usually as sunny a set of fellows as one would wish to meet; then came a period of woodland glades and forest paths, and the pensive charms of sylvan solitude was the all pervading sentiment. Since then experience has taught them to be more catholic, and if they are now prone to choose less romantic materials and more homely aspects of life, such as the dust cart, a fire engine station in Cloth Fair, Ludgate Hill from St. Paul's, etc., it is due to them to say that they are not unsuccessful in treating their subjects with that feeling for what is picturesque in them that characterises the works of the old Dutch masters when dealing with similar themes. But we do not wish to convey the impression that this kind of subject was more than pleasantly in evidence. There was plenty of spring, summer, autumn, and winter, and, indeed, a wonderfully good variety, and hardly a photograph that did not deserve its place on the wall. There were too many good things to refer to individually, without unduly trespassing on our space.

The architecture class, and that for animals, etc., were not so well filled as usual, but some very fair work was to be found amongst that shown.

The open classes were quite as well supported as usual. At this exhibition the classes are always greatly helped by contributions from members of the society, for it is considered a great thing to win a medal in an open class. Last year a member succeeded in capturing the gold medal. This year the society has not been so fortunate, but two silver medals and a certificate have been its share. Among the best known exhibitors in the open classes are H. Quilter, A. and F. Read, W. Scutt, Graystone Bird, Miss A. B. Warburg, E. A. Morgan, Jas. Auld, W. A. Stewart, C. Sweet, A. Tauxe, W. Kilbey, Jas. Gale, J. G. Barford, W. A. I. Hensler, G. H. Capper, W. J. Shelley, W. R. Lathbury, J. M. Whitehead, O. G. Pike, G. T. Harris, J. T. French, S. C. Stean, Rev. H. R. Champion, H. W. Bennett, W. Selfe, C. E. Walmsley, L. S. Wilks, and J. W. Hodges.

The trade exhibitors were Messrs. J. Ashford, Birmingham; R. and J. Beck, Cornhill, E.C.; Burroughes, Wellcome, and Co., F. F. Dadd and Son, Hackney; G. Houghton and Sons, T. Illingworth and Co., Ltd., the Kodak Company, J. Lizars, Sanders and Crowhurst, Shaftesbury Avenue; the Warwick Dry Plate Company, and S. J. Beckett, Baker Street, W.

In addition to the ordinary attractions of the exhibition, each evening there were concerts, lantern entertainments, and demonstrations of stereoscopic radiography, and wireless telegraphy.

SOUTHAMPTON CAMERA CLUB.

[FROM A CORRESPONDENT.]

THE Southampton Camera Club is to be congratulated on the initial effort in proving its capabilities in running a big open exhibition. This year's show places it at once in the front rank with other prominent Southern societies of the calibre of Southsea and Hove; and the most captious critic can find no fault with either the organisation of the show itself or the quality of the work sent in; indeed it is all of a very high standard. The Society has the good fortune to possess the desirable components—a hard-working, enthusiastic hon. secretary, and a competent committee. The Exhibition's success is due undoubtedly in a great measure, if not entirely, to the unremitting efforts of Mr. S. G. Kimber, the hon. secretary. The members of the committee have helped conscientiously throughout,

and it is a significant sign of the vitality of the Club that out of a membership of about eighty, nearly 50 have contributed specimens of their work to the Exhibition. Who can say after this fresh proof that Southern societies are moribund?

The idea of running the three Exhibitions of Southampton, Hove, and Southsea consecutively, and so save the cost of carriage between the shows, has undoubtedly had a big effect in bringing a great amount of good work to Southampton, and if the idea is as well carried out in future years, there is no reason to think otherwise than that these three societies will be the pick of the English exhibitions.

The Southampton catalogue, which is a well got up production, and should be a profitable source of income to the Exhibition, shows 582 entries. Of these 136 are contributed by members of the Club, and the remainder are in the open classes. The Rev. F. C. Lambert, M.A., and Mr. Walter D. Weiford, F.R.P.S., were the judges, and they expressed themselves well pleased with the high standard of work shown throughout all the classes, indeed the judging was anything but an enviable task.

Dealing with the members' classes first, the awards are (Class K.) Landscapes, etc.):—Silver medal—F. Thomson, for a quiet toned little platinum print: a river scene, entitled "Summer Time." Much of its beauty, however, is lost by contrast with its shocking frame of brilliant silvered wood and wide blue-grey mount. With one or two notable exceptions, unsuitable mounting and framing seem the shoal on which many members of the Club have wrecked their ship of success. The true comprehension of a suitable environment for their prints will be more than quickened by a glance at the framing in the open classes, which should prove an education in itself to these members. Bronze medal—E. Harrington, for "Autumn Haze," strikes one as being a trifle spotty about the sky; and certificate—S. G. Kimber, for a crisp little toned platinum print, entitled "On Chilworth Common."

Notable in this class are:—15, a dyed bromide print, "Evening, Hamble River," by F. Thomson, which has a most striking effect, although the means of obtaining it are questionable; 11, "Early Morning, Quimper," by Rev. J. Cairns, which, with its smoky haze rising from the housetops below, gives a fine suggestion of breakfast; 8, "My Remedy is an Absolute Cure," by the same worker, is one of the most vigorous bits of pure hand camera snap-shot work in the show; 13, W. J. Goatcher's "In the Stubble," a pleasing sheep study, which might, however, be improved by more judicious trimming; 26, Arthur Gibbings's "On the Ockment, Dartmoor," a little gem, full of life, and showing high technical qualities; 10, E. Max-Mills's "A Light Breeze," a good yachting study; 25, a vigorous landscape by G. R. Johnson, "Through the Woods," the true value of which is rather marred by its light mount; 24, "At Bosham," showing good selective abilities on the part of the worker, Geo. Vialls, although sky a trifle overdone. C. C. Cook also shows several good things in this class, all remarkable for careful selection, clean work and suitable framing. S. G. Kimber's other contributions are also noteworthy, and some carbon prints by A. E. Henley show that at future exhibitions the worker will take high rank. In Class L. (Portraiture, Figure, and Animals), Ed. Max-Mills secures the first award with a clever animal study, "Red Deer," evidently a bromide enlargement rather unevenly toned. C. C. Cook takes second place with a charming figure study *en plein air*, entitled "Meadow Sweet," while the third award is withheld, although Nos. 27, "Mischiefs," by Arthur Gibbings; 61, "Her Daily Toil," by Rev. J. Cairns; 57, "A Snack," by R. E. Jurd; 70, "Harrowing," by R. E. Jurd; and 66, "Old Dave," by S. G. Kimber, seem worthy of attention.

In the Architectural Class, M., C. C. Cook again scores, and takes the silver medal for 97, "Old Houses, Dinan," a good representation of a street in this old world town, showing careful selection on the part of its producer; 108, "To the Nave, Winchester Cathedral," by S. G. Kimber, is worthily awarded the bronze medal; and the certificate goes to H. R. Northover, for his little print, "Old Steps, West Gate Tower, Southampton," which is nearly spoilt by being overframed. Other exhibits specially worthy of note in this class are 109, "Interior Tudor House," G. T. Vivian, and 84, "North Aisle Steps, Winchester," by the same worker; 96, "Norman Arches, Winchester," C. C. Cook; 103, "Behind the Choir, Winchester," G. R. Johnson; 111, by C. C. Cook. This is a very strong class and shows good thoughtful work throughout, and also contains the only contribution of a lady member—110, "A Studio Exhibition," Miss Lydia Powell.

In the open classes some remarkably good work is shown in Class I., "For amateurs who have never won an award in any exhibition," and which proves that there is "as good fish in the sea as ever came out of it." Gilbert Watson takes the premier award (bronze medal) for a stirring landscape 124, "Sand Dunes," which shows a good mastery of technique, although perhaps the clouds are a trifle overdone, and 130, "Auld Reekie, a Study of Factory Chimneys and Fog," by Dr. Fred B. Jefferies, is awarded the second place, although there are many better things in the class, notably 128, 137, and 148, three

good compositions representing ice-bound stream scenes, with pleasing touches of sunlight and shade, by F. Parkinson; 123, "What of the Weather," by Lewis Longfield; 163, "Sunlight on a Cottage Floor," by E. S. Tardrew; 151, "Portrait of a Sailor," a quaintly lit but distinctly pleasing figure study, by J. H. Greville; 149, "In the Crypt D'Aquilon," a successful architectural bit by A. De Silva; 144, "An Organ Grinder," an effective portrait study, by E. Boyer Brown; 145, "An Echo of Caldecot's," is also a good attempt, rather spoilt by the wall paper background.

Coming now to Class A. (Landscape River Scenery and Marine), open to all—the strongest class in the show, containing no less than 145 exhibits—Charles E. Etches is awarded the silver medal for a representative example of the advanced fuzzy school, "A Derbyshire Dale," which, in justice to its latent pictorial possibilities, rather suffers by close contact with the bright gold slip of the frame. 213, "Homewards," a delicately rendered boat scene, teeming with light and atmosphere and conveying an idea of breadth and distance distinctly pleasing, secures the bronze medal, Gilbert Watson. And 224, "A Winter's Day," which well carries out the title, gets the certificate, G. H. Capper. This class contains many fine things, which must have run the winners very close indeed for an award. Dr. C. F. Grindrod's contributions are remarkable for strength and vigorous lighting, particularly 168, "A Worcestershire River," with a printed grain, evidently made with bolting cloth, and very atmospheric in effect; and 197, "Carting Trowse." 180 is a crisp little picture, entitled "Drying the Sails," by Miss Edith Thompson. 191, "Nature's Graces," W. A. Hubbard; 193, "The Cooling Stream," James Higson, are also both good. 196, "Sunshine," a well rendered effect of sun amongst tree trunks, by Augustus Fenn. 206, "Summer in the Woods," by D. Deely, is also a fine rendering of a similar subject. 210 gives a beautiful rendering of snow, and is entitled "Winter," Miss M. M. Eames. 219, "Sunrise," by Charles E. Etches, carries out the idea of the title perfectly. 202, "Reapers," is a work of important size, by Augustus Fenn, which fails somewhat in the matter of composition, the placing of the figures producing a spotty effect. 178 is a beautiful little reaping scene by E. Wood, who would have scored higher if more attention had been paid to the relative lighting of sky and figure. 187 is a pretty little cloud study by H. S. Sidebotham. 167, "The Harvest Moon," is a good example of the "What is it school?" and calls for attention only by the absurd length to which its author, F. M. Andrews, has carried fuzziness.

172, "After a Storm on the Thames," by Colonel W. F. Noverre, is just the opposite, and a rather pleasing subject is spoilt by the excessive lack of atmosphere and unnaturally heavy clouds. 211 and 212 are a couple of quaint pictures on silk by A. Tauxe. Graystone Bird contributes many examples of his excellent work, 216, "Summer Idleness," being very pleasing, although the figures are a trifle "posey." 243, "The Silent Watch," is a cleverly conceived and well carried out idea of moonlight amongst ruins; and 252, "Meadow Sweet," is a good figure study. 249, "The Glitter of the Sun," by A. R. F. Evershed, is a little gem, but suggestive more of the glitter of the moon. 228, "A Snowy Shore," by Miss A. Bird, is rather uneven, but very delicate and pretty. 226, "Thames Barges," by A. R. F. Evershed, is very striking, but the mounting is reminiscent of the American school at its worst. 246, "Harvest," by W. B. Summers, is a breezy little thing. 247, "Becalmed," shows thoughtful work, by G. H. Capper. 255, "Sunny Moon," a study of birches by Dan Dunlop, is good, straight-forward work, although the subject is rather hackneyed. 256, "A Dweller in the Wilderness," is a striking sheep study which gives an effect of solitary grandeur. 248 is a strong cattle study by R. Thomson. Mr. Hofer contributes many fine landscape subjects, which, however, arrived too late for judging. And other pictures in this class worthy of note are 233, "An Old World Fishing Town," Graystone Bird; 235, "Pastures," W. H. Max-Mills; 240, "A Forest Path," by the same worker; 242, "Misty December," by W. T. Marriott; and 309, "Industry," a fine rendering of smoke rolling from factory chimneys, by A. Nicholson.

A. L. Spiller, Syd. A. Pitcher, D. Fuller England, Captain F. Young, Fred Judge also sent noteworthy examples of their work.

In Class B. (Portraiture, Figure, Animals, etc.), which is also a very strong class, the silver medal goes to Miss Bessie Stanford for 392, "Shadows of departing Day," a carefully thought out and cleverly executed "genre" subject, with a pathetic character all its own: an aged countryman bends over an old sundial, peering at the fleeting shadow cast by the evening sun. Andrew Paterson takes the bronze medal for "The Plotter," 318, a sinister-looking individual in Cromwellian costume and a pose very suggestive of Steichen's "Solitude." It is a pity, however, that the print, a bromide, is of such poor quality. Drummond Shiel's "Old Spinner," 370, takes third place and undoubtedly deserves it, as it is a beautiful little picture of high technical and pictorial quality. No. 310, "Lady with Hat," by A. Tauxe, commands attention by its powerful light and shade, and stands out as one of the strongest things in the show. 313, "In the Highlands," is a clever cattle study, by Colonel W. L. Noverre, and

orks almost like a copy of a painting. 316, "My Old Sun Bonnet," an effective portrait study, by Miss Maud Shelley. Dr. C. F. Grindrod's "Village Scholar," 321, is immense, and quite in this ever worker's best vein. Ed. Norton Collins' fine figure studies, 322 and 341, are splendid examples of high technical knowledge well applied. John H. Coath contributes some excellent "straight" work, though 326, "A Copper, Please," suffers somewhat for want of liming. 337, "Portrait of a Clergyman," by R. M. Scott, is original in treatment. 342, "I Saw a Ship A-sailing," by F. A. McMichael, is a first-rate rendering of flesh. Miss Johnson's two portraits, 348 and 349 are delicate in execution and show a complete mastery of pose and lighting. 350, "Pleasance," is a striking portrait "Ozotype," by C. J. West; and C. Skelton Tyler is well represented by his two charmingly unconventional figure studies, "Daddy's Pet," 352, and "The Skein of Wool," 363. Graystone Bird's delightful title figure study, "Good-morning," should be as successful as his popular "Good-night," which is saying a great deal. A. Tauxe's exhibits are characterised throughout the exhibition by their originality and forcefulness, and 357, "Study of An Old Man" on "Mattos," another good example, and also is 359, "Little Raphael." And 378, 379, and 380, "Mineur" — strong semi-nude figure study — John Chaffin and Son's exhibits, in their curious frames, attract much attention and are withal good work. 388, "The Glove," by H. Wild, cleverly lit, and 420, by the same worker, is also well done. 415e is a striking portrait study by S. A. Pitcher, and 383, "The Forge," shows good technical work again, by W. B. Summers.

In Class C. (Architecture), W. A. Max-Mills, a member of the Southampton Club, takes the first award with 426, "The Montague Chantry, Christchurch," a noble picture and a clever representation of a difficult subject, both as regard lighting and selection. W. R. Rathbury, who contributes several first-class examples of architectural work, takes the bronze medal for 436, "As Day Steals on Night: Melting the Darkness"; and W. Kilbey secures the certificate for 438, "A Norman Crypt." The Rev. H. R. Campion's work in this class shows difficult subjects overcome in a masterly way, and Alfred Bedding, Syd. A. Pitcher, A. L. Spiller, and E. F. Harmer also show notable pictures. A. Nicholson's frames unfortunately arrived too late for judging.

Class D. (Flowers, Fruit, Still Life, Natural History, etc.) has brought together a good collection of artistic work, and the silver medal is taken again by Mr. Max-Mills for a beautiful photograph of "Apple Blossom," 455, which is almost stereoscopic in effect. A. Tauxe secures the bronze medal for his curiously coloured "Mattos" print, "Still Life," and certificates are awarded to both Douglas English for his always interesting photographs of "Old English Black Rat," and Mrs. Alice Dumas for "White Clematis," which has the effect of being almost in relief. Mrs. R. M. King's "Short Life and Merry" is a good study of butterflies, and Miss Mary C. James' "Chrysanthemums," are as delightfully done as most of this clever lady's work. Miss E. L. Turner's natural history photographs are distinctly clever, and J. C. H. Wallgrove is another exhibitor whose work is always praiseworthy. Dan Dunlop's "Daffodils" are also good.

The Champion Class—for pictures that have previously taken an exhibition award—concludes the pictorial part of the show, and contains many old friends, and it must have been a difficult task indeed to judge them. The gold medal, however, falls to Dr. C. F. Grindrod's "Woodcutters"; the silver medal to Ed. Strong's "At Midnight"; the bronze medal to Ed. Norton Collins' "The Old General"; and the certificate to James Burns' "The Wind Bloweth from the Sea." It must be said, however, in justice to Thomas Wright's magnificent landscape, "Winter," that it arrived too late to be judged.

The lantern slide entries are exceptionally heavy, and include much good work. The awards are:—

Class F. (Landscape, River Scenery, and Marine), bronze medal presented by H. Wilson), V. E. Morris; certificate, W. A. Clark.

Class G. (Portraiture and Figure Studies), bronze medal (presented by P. O. B. Hartnoll), Harry Wade; certificates, A. Warden Harvey and Graystone Bird.

Class H. (Architecture and other subject not included in F. and G.), bronze medal (presented by A. H. Marsack), A. Bailey; certificate, W. A. Max-Mills.

Class J. (Any Subject for Amateurs who have never won an Exhibition Award), bronze medal (presented by H. Wilson), F. Parkinson; certificate, A. Black.

The "A.P." special silver medal (presented by A. Horsley Hinton, Esq., editor of the "Amateur Photographer," to the best set of slides in Classes F., G., and H.), V. E. Morris.

Class N. (Members' Class, any subject), silver medal (presented by G. R. Johnson), E. G. Rose; bronze medal (presented by P. O. B. Hartnoll), W. J. Goatcher; certificate, F. W. Winzar.

Two fine portraits, one of the president, Mr. Burroughs Hill, F.S.I., and the other of the hon. secretary, S. G. Kimber, attract much attention, and have generously been presented to the Club by their exhibitor, Mr. Max-Mills.

The entire Exhibition is arranged in tasteful fashion in the admirably lit main hall of the Southampton Art School, Marland Place, and the show is attracting great attention locally.

Mr. Martin, of Southampton, has on view in the centre of the room a stall of the latest photographic novelties, and the lantern slides were shown at the Club Rooms, Philharmonic Hall.

FRENCH AND ENGLISH PROFESSIONAL PHOTOGRAPHERS.

THE following is a condensed translation of a letter addressed to Mr. Alfred Ellis, hon. secretary of the Professional Photographers' Association, by Monsieur Paul Nadar, President of the *Chambre Syndicale de Photographie et de ses applications*, of Paris:—

*Chambre Syndicale de la Photographie
et de ses applications,
Paris, 27th October, 1902.*

My dear Mr. Ellis,—

I have to thank you for sending me your last two little books containing information on the Professional Photographers' Association. I have had them translated, and probably we shall insert an article about your association in one of our reports.

As you desire, I have much pleasure in sending you the Statutes of our "*Chambre Syndicale*." I also send you, in the name of the French photographers whom we represent, an account of the National Congress of Professional Photographers of 1900, the organisation of which will perhaps interest some of your members; at the same time they will find therein the different questions that were treated.

Our "*Chambre Syndicale*" represents, as you know, the corporation of French professional photographers, and its mission is to watch their interests and support their rights. It includes not only commercial photographers taking portraits, landscapes, monuments, reproductions, enlargements, etc., but also photomechanical industries in all processes.

These are all admitted to our association as active members. We also receive as honorary members inventors, manufacturers, dealers in apparatus, instruments, and photographic accessories, but the latter, though entitled to be present at the meetings and take part in the discussions, have no right to vote. This regulation is made to prevent the association from diverging from its original intention, that of protecting the interests of professional photographers.

We also admit as honorary members foreign photographers, whether of our own nationality or not. You will see also in Article 6 that one of our objects is to establish and keep up relations with all French and foreign societies having a similar aim to ours. In our thoughts and intentions we would wish that the development and progress that can be obtained in many cases of fraternal understanding on various questions for our mutual interests could be internationally spread.

We do not ignore the obstacles that prevent us realising this golden age of photography, but we depend at least on the cordiality and understanding between photographers of different countries to render mutual assistance.

At this moment I am occupied with the important preparations for our next congress, which takes place on the 25th, 26th, and 27th November. The congress is to have the support of Government, and has as honorary presidents the Minister of Commerce and Industry, and the Minister of Public Instruction and Fine Arts. It has been very important to us that in 1900 the Minister of Fine Arts patronised our congress, and it is equally a matter for congratulation to be accorded the same protection this year, as heretofore photography has never been officially classified with the fine arts. I point out these details to you, as probably you have found the same difficulties and undergone the same struggles that we have.

We have instituted a competition to instruct photographers in the best systems of lighting, whether by electricity, magnesium, or acetylene, for portraiture, enlargements, and photomechanical processes.

I beg of you to read either the whole or part of this letter to your colleagues, and to present the cordial salutations to your new society from the "*Chambre Syndicale Française de la Photographie*," to which I am proud to belong, and accept from myself a hearty shake of the hand.

P. NADAR.

THE Newcastle-upon-Tyne and Northern Counties Photographic Association held the first meeting of the session in the Connaught Hall Y.M.C.A., Newcastle-upon-Tyne, on the 11th inst. The meeting partook more of the nature of a social entertainment than of the ordinary society meeting. The president, Mr. W. E. Cowan, opened the proceedings with a genial little speech, in which he gave many good reasons why photographers should join the association. An exhibition of high-class lantern slides by some of the foremost workers in the north followed; Mr. J. P. Gibson's Tyne scenery, and Mr. W. E. Cowan's night photographs of Glasgow Exhibition being especially fine. After the lantern slides had been duly admired, and refreshments were partaken of, the members and their friends settled down to listen to an excellent concert. The enthusiasm displayed augurs well for the success of the remainder of the session.

Commercial & Legal Intelligence

MESSRS. FUERST BROS. have engaged Mr. Walter D. Welford to demonstrate their "Axe" brand specialties before the various photographic societies. The title of his lecture is "Photographic Flexibilities."

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for current month has been awarded to Mr. Harold Moore, Quinta, Sidcup, for his negative, "An Old Gateway, Glastonbury."

ALWYNE DYSON, Ltd.—The above-named company has been registered with a capital of £2,000 in £1 shares. The objects of the company are to carry on the business of photographers, manufacturers of and dealers in photographic materials and apparatus, pictures, prints, engravings, and works of art, printers, etc. Registered office: 67, Grainger Street, Newcastle-on-Tyne.

THE Bausch and Lomb Competitions.—Messrs. A. E. Staley and Co., of 35, Aldermanbury, E.C., write: "Messrs. Bausch and Lomb have advised us of an extension of the time for the receipt of the pictures for their 3,000 dollar prize competition, which was originally announced to close on January 1st, 1903, but owing to the desire of their friends in European countries, they have extended the time till October 1st, 1903. We shall be pleased to supply booklets of the competition to applicants, if they will favour us with their names and addresses."

AFFILIATION OF SCOTTISH SOCIETIES.—At a meeting of the district societies held in Dundee on Saturday, it was decided to form an affiliation of photographic societies for their mutual benefit, but before taking any active steps in the actual formation it was decided to ask all the societies in Scotland to join and so make the movement national in its scope. Mr. John B. Maclachlan, Blairgowrie, was appointed to write to the secretaries of all the societies appearing in the "BRITISH JOURNAL Almanac," but any omitted will oblige by communicating with him.

W. A. WHARRAM, Limited.—The above-named company has been registered by Jordan and Sons, Limited, 120, Chancery Lane, W.C., with a capital of £10,000 in £1 shares (5,000 preference). The objects of the company are to carry on the business of chemists, wine, beer, and spirit merchants, distillers, importers of aerated mineral and artificial waters, manufacturers of photographic and scientific apparatus and materials, etc., and to take over the business carried on at 49, St. Paul's Street, Leeds, as W. A. Wharram. No initial public issue. The first directors (to number not less than two nor more than five) are W. A. Wharram, T. B. Wharram, and W. Brown (all permanent). Qualification £100. Registered office, North Street, Leeds.

THE Photographer and his Apprentices.—At the last sitting of the Gloucester County Court, before his Honour Judge Ellicott, two actions against Edwin Debenham, photographer, of Newquay, and formerly of Gloucester, were heard. They were brought to recover £50 in each case for alleged breach of contract to teach Alfred Samuel Lyde and Elsie Webb the art of photography, and application was also made to cancel the indentures. It appeared from the evidence that defendant sold his business at Gloucester and went to Newquay without making any arrangement for his apprentices, though it appeared that subsequently he offered to transfer the apprentices to his successors, or to provide for them at Newquay. Judgment was given for plaintiffs for £25 in Lyde's case and for £15 in Webb's case, each with costs, the indentures to be cancelled.

AN Injunction Granted.—At the Wakefield County Court on Wednesday last, George Henry Pycock, photographer, Normanton, sued A. I. Hart, also a photographer, of Normanton, to recover £3 7s. 6d., moneys over-paid on commission, and £10 10s. damages through breach of agreement. Plaintiff also sought for an injunction restraining defendant from carrying on business at Normanton. On April 19th, defendant entered plaintiff's employment as canvasser on commission, and signed an agreement not to commence business on his own account or canvass for others within three miles of Normanton for two years. Afterwards defendant ceased to canvass for plaintiff, and it was alleged that he had since started business on his own account at Normanton, though professedly in his son's name. He had also, it was alleged, been paid commission on orders which were not bona fide. Defendant denied this latter allegation, and said he thought the agreement only related to canvassing. His Honour granted an injunction, and awarded plaintiff £2 2s. damages.

ILFORD, Limited.—The following is an extract from the Directors' report for the year ended October 31st, 1902:—The Directors have the pleasure to report that after payment of working expenses, directors' fees, income tax, etc., and making provision for doubtful debts, the net profit for the year's trading is £51,507 15s. 3d. This amount, with £4,407 3s. 8d. brought forward from last year, gives £55,914 18s. 11d. for appropriation. The directors have paid an interim dividend on the ordinary share capital for the half-year ended April 30th, 1902, at the rate of 8 per cent. per annum, absorbing £7,600, and for the same period they have paid the dividend on the six per cent. preference shares, amounting to £5,700. Since then the second dividend on the six per cent. preference shares has been paid. From the balance, the directors recommend that on the ordinary share capital, a dividend be paid for the half-year ended October 31st, 1902, at the rate of 12 per cent. per annum, and in addition a bonus of 2½ per cent., making with the above interim dividend, a distribution of 12½ per cent. for the year. This will absorb £16,150. On the profit sharing scheme £843 16s. 7d., more or less, will be paid as bonus to the employees. Of the balance, £19,921 2s. 4d., the directors recommend that £8,000 be written off goodwill, processes, etc., that £9,000 be placed to reserve, and the balance, £2,921 2s. 4d., carried forward. The business continues to show satisfactory progress, and notwithstanding the very unseasonable weather throughout the summer, the sales are only a small fraction less than

last year. During the past year the Hon. Derek W. G. Keppel resigned his seat at the board. One director, Mr. Charles J. Cox, retired this year from the board, and being eligible, offers himself for re-election. The auditors, Messrs. Turquand, Youngs, Bishop and Clarke, now retired and being eligible, offer themselves for re-election.

THE Watson Enlarger Prize Competition.—W. Watson and Sons, 313, High Holborn, W.C., announce an enlarger competition, in connection with which they offer 28 cash prizes of from £2 2s. to 10s. 6d. for the two best enlargements in each division of the various classes named below. The prizes will be awarded by judges selected by Messrs. Watson. Each class will be in two divisions, namely, landscape and portrait, and two prizes will be awarded in each division. Class I., enlargement made from No. 1 or 2 Brownie negative, in Watson enlarger for Brownie cameras, 1st prize £1 1s.; 2nd prize 10s. 6d. Class II., enlargement made from Pocket Kodak negative, in Watson enlarger for Pocket Kodak, 1st prize £1 1s.; 2nd prize 10s. 6d. Class III., enlargement made from Folding Pocket Kodak negative, No. 1 or No. 1a, in Watson's enlarger for these cameras, 1st prize £1 10s. 6d.; 2nd prize 15s. Class IV., enlargement made from Kodak negative sizes Folding Pocket No. 2, Bull's-eye No. 2, Special Bull's-eye No. 2, or Plico, in Watson's enlarger for these cameras, 1st prize £1 10s.; 2nd prize 15s. Class V., enlargement made from F.O.P. Freena or No. Scout negative, in Watson's enlarger for these cameras, 1st prize £1 1s.; 2nd prize 10s. 6d. Class VI., enlargement made from ¼-plate negative in Watson's ¼-plate enlarger, 1st prize £2 2s.; 2nd prize £1 1s. Class VII., enlargement made from 5 by 4 negative, in Watson's 5 by 4 enlarger, 1st prize £2 2s.; 2nd prize £1 1s. The following are the rules of the competition:—1. The competition is for amateur photographers only. 2. All enlargements must be sent in, postage paid, by January 20th, 1903. 3. The enlargements must be made with Watson's patent enlarger, and each competitor will be required to furnish the name and address of the dealer from whom the enlarger was purchased. 4. The enlargements selected for prizes, and the negatives from which they are made, become the absolute property of W. Watson and Sons, who will acquire the sole right of reproduction for advertisement, or other purposes. 5. Any competitor may enter for one or more of the classes, but not more than one enlargement in each division. 6. No name or address of competitor shall appear on any enlargement. 7. It shall be at the option of any prize winner to take the value of the prize, plus 25 per cent., in any article manufactured by W. Watson and Sons. 8. The enlargements, with the exception of spotting, shall have no hand work upon them, and must be mounted on a plain cardboard. 9. Enlargements other than those awarded prizes will be returned to competitors on payment of postage. 10. Competitors must fill in the form of entry which will be provided, and can be obtained from their local photo dealer, or direct from Messrs. W. Watson and Sons, 313, High Holborn, London, and 16, Forrest Road, Edinburgh.

DISPUTE about a Dark Room.—At the Clerkenwell County Court on Thursday last, Harvey Ernest Walker, 89, York Road, Islington, sued A. Butcher to recover £10 16s. in respect of work done and materials supplied. Defendant had paid £5 into Court. Mr. Beckmore, counsel for plaintiff, said defendant wished to have a dark room for photographic purposes erected in his garden, and towards the end of July he employed plaintiff to construct it. He wanted something nice looking, and had certain ideas of his own about erecting the house, so that it could be taken to pieces, and also that it should not be an eyesore to his garden. Plaintiff, who was a painter, employed a carpenter and plumber to carry on the work, he himself doing the painting. In addition to being made portable, it had also to be made light-tight. No estimate was asked for, and nothing was said about the price. When the account was sent in defendant declared the price to be excessive, and offered £5, at the same time asking for a detailed account to be sent in. Plaintiff said the size of the building was 4ft. 6in. by 4ft. 4in., and 7ft. high. Defendant supplied the wood, but on examining it the carpenter said that inch matchboard would be preferable, and would come out much cheaper than the wood supplied by defendant, as this would involve much labour in properly working up. Defendant, however, insisted that his own wood should be used. He (plaintiff) painted the structure inside and out, and used three coats of paint. Defendant questioned plaintiff as to a number of items in the account, and elicited the fact that a charge had been made over and above what was customary in respect of the men's time. Peter Peterson, the carpenter, said the wood supplied by defendant was in a very bad state, and required a lot of labour in ploughing and tonguing. Mr. Atkinson, a builder of eighteen years' experience, said he had examined the building and measured it. He concluded that the charges were fair and reasonable. Defendant said his contention was that everything had been done in the most expensive way. The Judge: You find every tradesman does that when there is no estimate, making what he calls a "good job" of it. Defendant: But that is not fair to a client. The Judge: Then you should take care to have an estimate. Mr. Smith, a builder, said he had measured and valued the building, and thought that at the very utmost it would not be worth more than £5 to £6. All the wood had been grooved and tongued by hand, and this cost three times more than wood that had been already grooved and tongued by machinery. Evidence was given by another builder, who estimated the value at about £6. The Judge said it was perfectly clear that at the time defendant gave the order he had purchased some timber, and thought it would be cheaper to use that than follow the advice of the carpenter and obtain wood already grooved and tongued. Very often when a man did that sort of thing he was launched in much heavy and extra expense, and that seemed to be the state of affairs in this case. As far as the other items were concerned, he thought the charges were higher than they ought to be, and as to the extra charge respecting the men, that ought not to be down at all. His verdict would be for plaintiff for £11, including costs.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Nov.	Name of Society.	Subject.
1.	Croydon Natural History.....	<i>The Ozotype Process.</i> Illustrated by Lantern Slides. By Mr. T. Manley.
1.	West London Photo. Society....	<i>Intensification and Reduction.</i> Mr. J. Brown.
1.	Borough Polytechnic.....	<i>Developers—Their Use and Abuse.</i> Mr. Ernest Human.
4.	Southampton Camera Club.....	Affiliation Lecture.
4.	Society of Arts	<i>The Future of Coal Gas and Allied Illuminants.</i> Professor Vivian B. Lewes.

7.	Woolwich Photo. Society	Lantern Lecture. <i>A Journey through Spain.</i> Mr. Jas. A. Sinclair.
		<i>Lumière Process of Colour Photography.</i> Mr. T. K. Grant.

ROYAL PHOTOGRAPHIC SOCIETY.

ORDINARY MEETING, November 11th.—Mr. J. C. S. Mummery in the chair.

NEW MEMBERS.

Nominations in favour of eight candidates for membership were read, and forty candidates were elected by ballot members of the Society.

PRESENTS.

A portrait of Scott Archer, one of the pioneers of photography, was announced as received from Mr. Henry Cade, of Ipswich. It was a glass positive taken in 1875, and in excellent condition. A vote of thanks was passed to the donor of this present, as well as to Mr. Henry E. Davis, for his present of Brin's patent snap-shot camera, shown and described at a previous meeting.

AFFILIATION.

The Nottingham Mechanics' Institute Photographic Society and the Marple and District Photographic Society were announced as newly admitted to affiliation.

Mr. Thomas K. Grant read a paper on "The Fading of Positive Photographic Prints printed on Chloro-citrate of Silver Paper, toned and fixed in one operation," by Messrs. Lumiere and Seyewetz. The paper shows that the principal cause of the fading of chloro-citrate of silver prints is the presence of hyposulphite of soda incompletely eliminated, but that the fading of the image only takes place in the presence of moisture. The authors continue to point out that fading takes place in gold-toned images containing hyposulphite of soda, even if the toning occur in a neutral medium, as in the case where toning and fixing are separate operations. The absence of all traces of hyposulphite of soda in the print is a guarantee of its keeping in humid air, even if the image does not contain gold, and if it be constituted of either sulphide of silver, silver only, or silver and lead. It appears that the yellowish appearance of faded prints is not therefore due to the presence of sulphide of silver or lead, but perhaps to that of very finely divided sulphur, resulting from the decomposition of the soda hyposulphite. The authors do not consider the supposed drawbacks of combined toning and fixing methods to be well founded. On the other hand, prints toned and fixed separately fade as readily as those toned and fixed at a single operation, if they have been incompletely washed and exposed to damp air. The complete elimination of the hyposulphite of soda is therefore the only preventive of the fading of toned prints.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 13TH.—Mr. W. Thomas in the chair.

Mr. J. W. Collings gave a demonstration of

THE SINOP COLLOTYPE PROCESS.

The process was briefly introduced by Mr. W. T. Wilkinson, who shared with Mr. Collings the burden of the demonstration. The Sinop

process is a simplified form of the well-known but, to the amateur, little used process of colotype, a process of reproduction which yields very beautiful results. In the ordinary way, the colotype plates can only be prepared as wanted, and certain expensive apparatus is required by the process. The operator also requires considerable skill and experience. On the other hand, Sinop calls for practically no special knowledge. Plates may be obtained commercially, which only need sensitising in the bichromate solution, thus doing away with a great initial trouble attaching to the old process. The plates are of good keeping quality, both in the insensitive and sensitive state. The prepared plate is sensitised and dried, and exposed in a printing frame under the negative for from two to ten minutes at most; it is then washed with water for a further ten minutes, and soaked in glycerine for a quarter of an hour. The plate is then attached to a printing bed and inked with a printer's roller. When the inking has been thoroughly effected, prints may be taken with the aid of an ordinary office letter-copying press. Sinop thus depends upon exactly the same principles as does the colotype process. The plates are quicker than the colotype plates—a fact that was emphasised by the inking of a plate that had been exposed by Mr. Wilkinson that day, which showed marked over-exposure. Mr. Collings succeeded in pulling a number of excellent prints from plates previously exposed, and a portfolio containing a large number of examples was passed round. The Sinop plates may, after an addition has been pulled, be stored away for any length of time, and no difficulty presents itself when at some future time it is desired to take off further copies. The process is useful for the printing of postcards from negatives, Christmas cards, etc. It should be borne in mind that the image is a reversed one. This, of course, does not matter in many cases, but occasionally it will be necessary to have a reversed negative. Thin film negatives may be used without reversal, however, there being no noticeable loss of definition when they are printed from the reverse side.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at 51, Baker Street, W., on Monday, 14th inst., Mr. William Grove, president, in the chair.

The hon. secretary announced the death of Mr. H. J. Dalby, of Woolwich, a member of the committee. A letter of condolence, in the name of the committee, had been written to Mrs. Dalby, and her reply was read. The fact that Mr. H. Walter Barnett, a vice-president of the association, had been confined to his house for some time through illness, having been referred to, the hon. secretary was instructed to express to Mr. Barnett the regret of the committee at the cause of his absence.

The following gentlemen were accepted as members:—Percy Claude Byron (Byron New York), 63, West Thirty-second Street, New York, U.S.A.; Howard Cooper, 19, Bearwood Road, Smethwick; William Edwin Foster, 17, Bennett's Hill, Birmingham; William G. Hutt, 374, Dudley Road, Birmingham; Mark Edward Mitchell, Princes Colonnade, Princes Street, Harrogate; Sydney Charles Mote, 28, Breakspear Road, St. John's, S.E.; Frederick Charles Strate, Castibury Studio, Stafford; W. Alanson Varley, The Polygon, Bowdon, Cheshire.

The hon. secretary reported that since the last meeting of the committee, meetings had been held by branches of the Association at Edinburgh, Liverpool and Hull, and reports had been published in the BRITISH JOURNAL OF PHOTOGRAPHY. He also reported that Mr. T. C. Turner, hon. secretary of the Branch Organising Sub-Committee, and he had attended a meeting of photographers at Birmingham, held for the purpose of establishing a branch for the locality (the proceedings of the meeting were published in last week's B.J.). The meeting resulted in all present who were not already members of the P.P.A. agreeing to join, and the prospect of the branch becoming large and influential appeared most promising. Votes of thanks were passed to Messrs. Ellis and Turner for attending the meeting, and to Mr. Harold Baker for his services in connection therewith.

Letters from members relating to insurance copyright, etc., were read, and the hon. secretary instructed thereon.

A letter was read from Mons. Paul, Nadar, President of the Chambre Syndicate de la Photographie of Paris, explaining that the organisation had a basis similar to that of the P.P.A., and asking support for the forthcoming "Congres Nationale de la Photographie Professionnelle" to be held in Paris on the 25th, 26th, and 27th inst. The hon. secretary was directed to reply regretting that the date being so near the Association could do little with regard to the Congress, but assuring him of its fraternal sympathy and hoping that means could be found of bringing the two organisations into closer relationship.

The hon. secretary announced that four members of the committee had attended a meeting of artists and others interested in artistic copyright, held at Messrs. Agnew's gallery, Bond Street, W., which resulted in the formation of a new society having for its object the protection of the interests of owners of copyright in works of art, etc. Arrangements were made that the P.P.A. should be represented.

A letter was read from the Photographic Trade Association, asking the sympathy and support of the P.P.A. in their protest against the trade regulations of the Kodak Co. It was resolved that the Association should adopt a position of strict neutrality.

Letters and other communications respecting instances of price cutting, objectionable advertisements, and similar matters were read. These were dealt with.

The question of holding an exhibition of members' work was discussed, and the hon. secretary was instructed to make certain enquiries and report at the next meeting. It was decided that on the date of the next dinner a reception room at the place of holding the dinner should be open all the afternoon for the purpose of affording members, especially those from the provinces, the opportunity of discussing matters of mutual interest in a friendly and informal way.

LEEDS CAMERA CLUB.

THE presence of Mr. Godfrey Bingley at the rooms of the above Club, Athenæum Buildings, Park Lane, on Wednesday, Nov. 12th, drew together one of the largest audiences of the session, when close upon 150 members and friends attended to hear a lecture on "The Dales and Coast of Yorkshire."

The lecture was illustrated by a series of close upon 250 lantern slides of as fine a class as it has ever been our lot to witness, and during the course of the lecture, round after round of applause greeted the appearance of the fine specimens of the lecturer's work upon the screen.

The president, Mr. Howdill, by the way of introducing Mr. Bingley referred to the large attendance and to the evident attraction the lecture had to the fair sex. They all know Mr. Bingley's position and the work he had done as a lantern slide maker, in which he was such a past master, and if they could not make something as good, at any rate they had something to aim for.

Mr. Bingley, rising to address the meeting, thought the president had raised their expectations too high—some of the slides were not so very good, either technically or pictorially, but they had to be included to carry out the story. He remarked that by the aid of photography he hoped to be able to show them some of the natural beauty and places of interest in the County of Yorkshire, and a brief history would not be altogether out of place. At the date of the Roman Invasion the Celts occupied the County, their capital being at Boroughbridge, whilst York was at the time the chief City of Northern Britain. In the year 410 the Roman Legions withdrew in consequence of trouble of their own, and York subsequently became the capital of the Danish Kingdom. Through succeeding years Yorkshire was the scene of many historical events too numerous to go into that evening, and further, it was with the scenery and not with the history they would be occupied that evening. The scenery of Yorkshire was more varied than that of any other County in England. The coast line was full of beauties with its indented bays, fishing fleets, and numerous watering places, and perhaps no place could be found showing so many different features as along the seaboard of Yorkshire. The Tees formed the northern boundary, and was the only river of any size which did not empty its waters into the Humber. In the western part of the county the mountains formed the backbone, and divided the watershed east and west. At the time of the dissolution of the monasteries of York there were no less than twenty-eight abbeys and 128 convent buildings in the county. Going from Leeds to the Craven district was the River Aire, known to all of them by its perfumes rather than its beauty, but at its source intensely interesting, taking its rise about Malham. About three miles from the village on the moors was Malham Tarn, the greatest of our Yorkshire lakes, and where what was known as the water sinks appeared. Standing on the top of Malham Tarn a fine view of the dry valley of the Aire was obtained. From the water at the Tarn sinks, known as Aire Head, Malham Cove, and the stream called Gordale Beck, the River Aire was formed.

Mr. Bingley next proceeded to describe the experiments made to trace the source of the River Aire; then went on to Malham Church, where is shown the signature of Oliver Cromwell on the marriage certificate of a certain John Lambert. Then on to Settle and Giggleswick, and going back to the river valley we get to Catterick Force, the scenery round which was exceedingly pretty, and afforded many pictures for photographers, the views shown having been taken on one of the Yorkshire Union excursions to the neighbourhood.

Ripley Valley was next dealt with and the "hot holes" described, which are approached by Horton in Ribblesdale. Across the Pennine Chain next, to Ingleboro', famous for its seventeen falls. Over Ingleboro' to Gaping Hill hole, the first exploration of which was due to a Frenchman, M. Martell. Proceeding, the lecturer touched lightly upon Skipton, Towtonfield, then on to Boston Spa in the Washburn Valley, Bolton Hall, Bolton Abbey, Grassington, and Grass Woods to Conistone. The coast was touched at Saltburn, Brunswick, Sandend, Whitby, Filey, Scarborough, Bridlington, Hull, and returning to York, where the tour ended—one of the most interesting and instructive lectures delivered before the society.

On the motion of Mr. Howdill, seconded by Mr. Emmott, a most hearty vote of thanks was accorded to Mr. Bingley for his valuable lecture.

PHYSICAL SOCIETY.

At a meeting of the Physical Society on October 31st, Dr. Silvanus P. Thompson, F.R.S., president, in the chair, a paper on "The Size of Atoms" was read by Mr. H. V. Ridout. This investigation deals with the size of dissociated atoms, or ions, and the results obtained refer to a dissociated atom as the smallest quantity of matter which can take part in an electrolytic action. The element chosen is hydrogen, and the author concludes that, in round numbers, $114\frac{1}{2}$ million atoms are necessary to form a line 1 cm. long. The method employed consists in finding a pair of spheres which would be charged by the quantity of electricity known to be necessary to electrolyse a given quantity of the body under examination—in this case water—to the known difference of potential of its ions. From this the size of the atoms is deduced, subject to certain assumptions enumerated and discussed in the paper. The atoms are regarded as spherical and closely packed. To facilitate the calculations, the packing is assumed to be such that the centre of any sphere is immediately above the centre of the sphere upon which it rests. Under these circumstances the total volume of spheres necessary to fill a given cube is equal to that of the single sphere about which the cube is described. The electrical capacities of isolated spheres being proportional to their diameters, it follows that the total capacity of any

number of such spheres is equal to the capacity of a single sphere, the diameter of which is equal to the sum of the diameters of the small spheres. Using these two propositions, the size of the atoms is easily deduced from the pair of spheres already determined. The author points out that the method fixes both the superior and the inferior size of the atoms, and gives, therefore, the true value.

Lord Kelvin remarked that he had often concerned himself with the size of atoms, and pointed out that the value obtained by the author for the diameter of a hydrogen ion was almost exactly one-half of that which he had obtained for the diameter of a molecule of hydrogen. The fact, however, might be a coincidence. He had dealt with a sphere which would have the same effect as a double atom of hydrogen. While avoiding the assumption that atoms are hard and spherical, it was usual to treat them as such for purposes of calculation. The paper was an important one, but there were many assumptions which required looking into. Lord Kelvin said that in dealing with the subject of atoms it was necessary to consider the atoms of electricity. The atomic theory of electricity, now almost universally accepted, had been thought of by Faraday and Clerk-Maxwell and definitely proposed by Helmholtz. The atoms of electricity were very much smaller than the atoms of matter, and permeated freely through the spaces occupied by these greater atoms and also freely through space not occupied by them. An atom of electricity in the interior of an atom of matter experienced electric force towards the centre of the atom. We were forced to conclude that every kind of matter had electricity in it, and Lorenz had named electricity as the moving thing in atomic vibrations. If the electrons, or atoms of electricity, succeeded in getting out of the atoms of matter, they proceeded with the velocity of light, and the body was radioactive. It was, therefore, not surprising that some bodies showed radioactive properties, but rather surprising that such properties were not shown by all forms of matter. Our knowledge of this subject, which originated with the discovery of the Becquerel rays, had been greatly advanced by the experiments carried out at the Cavendish Laboratory, and he had no doubt that in the next two or three years much light would be thrown upon this important matter.

Professor Everett asked why the author had taken the specific inductive capacity of water equal to 2.

The author said that the latest determinations of the constant approximated to that number.

HILLSBRO' AND DISTRICT PHOTOGRAPHIC SOCIETY.

LANTERN-SLIDE making was the subject of a practical demonstration given by Mr. T. G. Hibbert to the members of the Hillsbro' and District Photographic Society, Sheffield, on the 12th inst. By the use of an exposure meter, and the developing of negatives strictly to time, good results are sure to follow, said the lecturer, which he proved to the satisfaction of his audience. Thus, if the high lights in a negative begin to show in half a minute, it will take three minutes to properly develop the same, or six times the factor.

CROYDON CAMERA CLUB.

NEARLY forty members of this club on Wednesday, the 12th inst., in response to a kind invitation, paid a visit to Mr. T. T. Waddington's works at London Road, Croydon, a popular and thoroughly practical demonstration of the "half-tone process" being afforded them.

Mr. Waddington first lucidly explained the process, and afterwards conducted the members over the workshops of the company, every step from the preparation of the collodion wet plate, to the ultimate etched block, being shown in actual operation.

Broadly speaking, the process, as explained by Mr. Waddington, may be outlined as follows:—A glass screen with minute opaque crossed rulings is placed in front of the plate in the camera, and a negative taken in the usual way. On development, this negative, if closely inspected under a powerful glass, will be found to possess, in a sense, no half-tone at all, the tints being represented by a series of dots and cross hatchings of varying degrees of frequency. A copper plate is next taken, coated with an exceedingly thin film of gum arabic, white of egg, fish glue, and ammonium bichromate in suitable proportions, and placed behind the negative, great pressure being used to secure absolute contact. An exposure for a few minutes to an arc lamp is sufficient to render those parts of the film, immediately behind the clear spaces in the negative, insoluble. The film is then developed in manner familiar to carbon workers, dyed so that exposure may be judged, and dried at a high temperature. At this stage we have a visible positive image composed of what is termed "resist." A solution of perchloride of iron is then flowed over the plate, which attacks the copper where not protected by the resist, and the necessary relief is obtained. The plate is then proofed, and if satisfactory, trimmed and mounted type high ready for printing.

THE Dangers of Celluloid. An evening contemporary is responsible for the following:—A remarkable and painful experience befel M. Leon Godefroy in the Boulevard St. Michel, in Paris. M. Godefroy once had the misfortune to be involved in a street row, the result being that his nose was smashed, and he had to secure an artificial nasal appendix. He was walking on the boulevard, and stopped to light a cigarette. Suddenly his nose burst into flames, which spread to his beard. M. Godefroy danced with pain until some policemen took him to a chemist's shop, where his burns were treated. An examination of the nose showed that it was made of celluloid, the unscrupulous dealer who sold it having foisted it on to his client instead of the horn nose which had been prescribed.

News and Notes.

THE Earl of Crawford, F.R.S., who is about to take a winter tour round the world in his famous steam yacht *Valhalla*, has invited Mr. J. Nicoll, a member of the British Ornithologists' Union, to accompany him as naturalist. After passing through the Straits of Magellan, the *Valhalla* will visit the principal island groups of the South Pacific, where its naturalist will have ample opportunities for collecting and observing birds and other animals. The return will be made by the Indian Ocean and Suez Canal.

CORRECTLY exposed platinotypes can be over-developed, in spite of the usual belief to the contrary, said Mr. W. H. Smith to the South London Photographic Society on Monday evening, by using the glycerine method of development, owing to none of the salts being dissolved by the developer, and therefore prints should not be left unfixed. Mr. Frank Goddard, hon. secretary to the South London Photographic Society, has resigned that position, and Mr. W. Calder Marshall, 41, Henton Road, S.E., has been appointed to succeed him.

MR. E. MERCK, 16, Jewry Street, E.C., writes: "In handing you herewith a sample of Merck's Pyro Developer in cartridge form, I would like to draw your attention to an innovation which I have made in the get-up of my photographic cartridges. Hitherto the alkalies and developer have been separated in the cartridges by a thin layer of specially prepared paper, but I found that this was not sufficient protection, and I am now supplying cartridges where the chemicals are separated by a glass partition. As both ends are hermetically sealed, there is no risk of oxidation, and on the other hand, owing to the glass, there is now no danger of interaction between the chemicals. I think it would interest your readers to know of this improvement."

STONEHENGE.—A meeting of the Stonehenge Committee, consisting of Lord Dillon, the Bishop of Bristol, Mr. Thackeray Turner, Mr. John Carruthers, the Rev. E. H. Goddard, Mr. N. Story Maskelyne, Mr. W. Gowland, and Mr. C. H. Read, representing the Society of Antiquaries of London, the Wilts Archaeological Society, and the Society for the Protection of Ancient Buildings, was held at Burlington House last week. The committee received a report of the operations that had taken place under its advice, with the sanction and at the cost of Sir Edmund Antrobus, expressed approval of the steps already taken towards ensuring the safety of Stonehenge, and repeated its resolve that further steps must be guided by the determination to do as little as possible in order to save the monument for posterity. The committee is anxiously conscious of the fact that in the present state of Stonehenge there is grave danger of further accident. To meet the dangers of the present winter it has now recommended the immediate application of wooden props to the stones about which the chief anxiety is felt.

"A New and Lucrative Profession."—Mr. Hector Maclean, F.G.S., takes upon himself the serious responsibility of the following paragraph in last Saturday's "Morning Post":—"It falls to my lot during the year to address a good many assemblages of amateurs, and once in each year I am called on for what is called a presidential address, the which is meant to arouse enthusiasm amongst the members of the society. I mention this because during the last of these addresses, recently given, among topics which I touched on was one which certainly arrested attention beyond all others. It was a relation of the comparative affluence to which a very large number of humble, or not well-to-do, individuals have attained through joining local photographic societies. I could mention one instance of a gentleman now receiving a "four-figure" income entirely through taking up amateur photography and attending photographic society meetings. The number of those who through similar means have risen from positions of a few shillings a week to distinguished appointments of from £500 to £1,000 per annum are too numerous to mention.

THE Royal Society.—The following is a list of those to whom the Royal Society has this year awarded medals. The awards of the Royal medals have received the King's gracious approval:—The Copley Medal to Lord Lister in recognition of the value of his physiological and pathological researches in regard to their influence on the modern practice of surgery. The Rumford Medal to the Hon. Charles Algernon Parsons for his success in the application of the steam turbine to industrial purposes and for its recent extension to navigation. A Royal medal to Professor Horace Lamb for his investigations in mathematical physics. A Royal medal to Professor Edward Albert Schafer for his researches into the functions and minute structure of the central nervous system, especially with regard to the motor and sensory functions of the cortex of the brain. The Davy Medal to Professor Svante August Arrhenius for the application of the theory of dissociation to the explanation of chemical change. The Darwin Medal to Mr. Francis Galton for his numerous contributions to the exact study of heredity and variation contained in "Hereditary Genius," "Natural Inheritance," and other writings. The Buchanan Medal to Dr. Sydney A. Monckton Copeman for his experimental investigations into the bacteriology and comparative pathology of vaccination. The Hughes Medal to Professor Joseph John Thomson for his numerous contributions to electric science, especially in reference to the phenomena of electric discharge in gases.

INFLAMMABLE Spirits.—The danger of handling spirits that give off inflammable vapours at low temperatures by those who do not understand their properties, was exemplified at Woolwich dockyard a few weeks ago, when two persons lost their lives and another was seriously injured while experimenting with gasoline, the vapour from which became ignited. We cull the following from the "Standard" of Saturday last, as illustrating still further this danger:—"A case was heard before the Oxford magistrates yesterday in which the chemist of the Christ Church laboratory was charged with having handed to the Great Western Railway,

for conveyance, a consignment falsely declared as ordinary petroleum, but which really consisted of petroleum spirit, giving off a vapour inflammable in a temperature below zero (Fahr.), also with not having observed the Government regulations in regard to packing traffic of such a highly dangerous character. During transit, when a member of the company's staff was carrying a lighted lamp through a yard, the vapour given off by the petroleum spirit became ignited, and if the efforts which were made to extinguish the fire had not been successful the result would have been disastrous. The magistrates commented upon the serious nature of the offence, but, as the defendant pleaded ignorance of the regulations, only a small fine of 20s. and costs was inflicted."

ART Lecture in Leeds.—The Lecture Hall of the Leeds Institute was well filled on Wednesday evening last, on the occasion of a lecture delivered by Mr. Whitworth Wallis, F.S.A., on the "Art of Lord Leighton." Commencing, the lecturer paid the late President of the Academy a gracious tribute in saying that no artist during the Victorian era had accomplished better and purer work than he did. Lord Leighton was a veritable "Crichton" among artists, combining with his knowledge and talent for art the gift of sculpture, the powers of a linguist, and also the accomplishment of a musician. Such training as Leighton received in his youth had perhaps been the privilege of no other artist. He studied successively and successfully at Rome, Berlin, Munich, and Frankfurt. His entrance to the school at Berlin was obtained by means of a "wicked misrepresentation." The age limit was fifteen, and the future peer had to state that he was a year older than he actually was at the time, before he could be taken in as a pupil. Whilst staying at Rome, and at ten years of age, Leighton decided to become an artist, much against the wishes of his father, who was a doctor, but who did not press his objections to this profession. About this time, the novelist Thackeray encountered the youthful painter. Returning to England, the author of "Vanity Fair" came across John Millais, who was then about twenty years old. He told him that he had met at Rome a young artist who "will some day run you very close for the Presidency of the Royal Academy." This prophecy was so true that so close did these two artists run each other for the honour, that Leighton actually achieved it first. Leighton became an Associate of the Academy in 1864, and was admitted as a member five years later. The lecturer then exhibited several views of Lord Leighton's past work, which without them would have rendered the lecture unenlivening. One cannot conceive of few more difficult tasks than that of keeping a mixed audience interested in descriptions of paintings; but Mr. Wallis's analysis of the qualities that enabled the great artist to make an enduring mark on the art of the age were not without value and interest, and in the occasional employment of human touches did Mr. Wallis find salvation.

GREENWICH Observatory.—The report of the Astronomer Royal to the Board of Visitors, Greenwich Observatory, read at the annual visitation in June last, has just been issued as a Parliamentary Paper. It relates to the year ended on May 10th last, and says that the sun, moon, planets, and fundamental stars had been regularly observed on the meridian as in previous years. The number of observations made was as follows:—Transits, the separate limbs being counted as one observation, 11,135; determinations of collimation error, 303; determinations of level error, 663; circle observations, 9,666; determinations of nadir point (included in the number of circle observations), 681; reflexion observations of stars (similarly included), 505. The number of stars observed in 1901 was 4,327. The progress made in the observations of the reference stars for the astrographic plates, for which 10,000 stars are to be observed three times above and twice below pole—with the exception of about 1,000 stars fainter than the ninth magnitude, which cannot be observed below pole—is shown in a table. These stars include all the stars down to the ninth magnitude of the "Bonn Durchmusterung," and fainter stars which have been added to the list recently, so that there will in no case be fewer than twelve reference stars on a plate, the average number being 22.4. The observations of these stars were commenced at the beginning of 1897, and as more than half of the observations required have already been secured, it may be confidently anticipated that the full number of observations will be obtained for the new Ten Year Catalogue, 1897 to 1906. During the year photographs of the sun were taken on 178 days. The Dallmeyer photoheliograph was in use till September 19th, when the Thompson photoheliograph, which had been taken to Sumatra for the eclipse, was mounted in its place. Of the Greenwich photographs, 344, taken on 171 days, have been selected for preservation, besides 18 with double images of the sun for the determination of zero of position angles. Supplementary photographs have been received from India and Mauritius to January 18th last. For the year 1901 Greenwich photographs were selected for measurement on 149 days and photographs from India and Mauritius (filling up gaps in the series) on 210 days, making a total of 359 days out of 365 on which photographs are at present available. The proportion of days upon which the sun was entirely free from spots was 80 per cent. for the year 1901, and about the same proportion for 1902 to May 31st. But the appearance of two considerable groups this year, and the high latitudes of the spots generally, are, Mr. Christie thinks, indications that the actual minimum is passed. The report states that in the year ending May 10th, 1902, the average daily number of chronometers and deck-watches being rated was 557; the total number received was 1,253, the total number issued was 1,183, and the number sent for repair 570. These include 35 box chronometers and two pocket chronometers for the Indian Government. During the year there have been on trial for purchase by the Indian Government eight box chronometers, of which three have been selected for purchase. Two pocket chronometers have also been purchased for the Indian Government. The Greenwich time-ball was not raised on two days during the year, owing to the violence of the wind. On June 18th the ball did not drop at 13h., owing to an interruption in the electric connections. The automatic signals from the Westminster clock were received throughout the year except on five days, when the

signal failed. The apparent error of the clock was not greater than 0s.5 on 28 per cent. of the days of observation; not greater than 1s.0 on 56 per cent., not greater than 2s.0 on 88 per cent., not greater than 3s.0 on 97 per cent., and exceeded 4s.0 on twelve occasions. The first stage of the re-determination of the Greenwich-Paris longitude, referred to in the last report, was, after consultation with M. Lœwy, deferred to the spring of this year, in order to allow more time for preparation and testing of the instruments, after Mr. Dyson's return from the Eclipse Expedition to Sumatra. Mr. Christie adds:—"The observations were made in three groups of three, six, and three full nights (or their equivalents in half-nights), the observers with their instruments being interchanged between the first and second, and again between the second and third groups. The English observers were Mr. Dyson and Mr. Hollis throughout, and the French M. Bigourdan and M. Renan during the first group. Unfortunately, at the end of this group, M. Renan was taken seriously ill, and it was necessary to replace him by another observer, M. Lancelin, and to recommence the work of the French observers, which is still in progress. It is proposed to carry out the second stage of the observations in the autumn. For these operations the Post-office authorities have courteously given the use of the telegraph line and the services of a telegraphist."—"Standard"

KODAK, LIMITED, AND THE TRADE.

To the Editors.

Gentlemen,—May I trouble you again in regard to the above, though you must be rather tired of the subject? I think there must be many, including myself, who were somewhat in the dark as to what the Kodak Company had a right to claim in regard to the manufacture of roll film goods. From the letter of Mr. J. Lizars, published in your Journal last week, it seems that both the European Blair Camera Company and Mr. Lizars made folding pocket daylight loading cameras similar to those on the market to-day several years ago. And presumably, any other manufacturer could have done the same, from which it must be gathered that the Kodak Company had no controlling patent for the manufacture of roll film goods, though I see from an old advertisement that the Kodak Company, then the Eastman Company, were selling roll film cameras (not daylight loading, I assume) in this country in 1890, and possibly a short time previous. The Kodak Company then claimed to have the only practical system of roll holder photography. There can be no doubt that from the first they had great faith in the roll film principle. Mr. Lizars, however, states that the first daylight roll films and roll film cameras were introduced into this country by the European Blair Camera Company. A detailed history of the subject would be interesting. Most people would be willing to give credit to whom credit is due. Whoever made the first efficient roll film, no doubt they were indebted to the investigations of those who did not succeed, though it is those who make a commercial success of a new thing who get the most credit. But the point I wish to emphasise is that, in view of the statements made by Mr. Lizars, it is evident that the Kodak Company did not possess a controlling patent. I was under the impression, and I have no doubt many others were, too, that they did. I do not profess to understand why other British manufacturers did not give attention to the matter long ago, which would probably have prevented the present difficulties.

I do not see how it can be made illegal for any of the retail dealers to "concentrate" on any particular firm's goods, as suggested by one of your correspondents. It is an interesting question, but I suppose the retailer has a right to please himself, though he may be obliged, by public demand, to stock other goods in the same line. Many of them would probably not at all object if the Kodak Company did secure the complete control of the photographic trade, as they may consider that it would simplify matters for them. Whether it would be beneficial to the customer is another matter. If the dealer decides to concentrate on any one firm's goods, the customer may concentrate elsewhere.

—Yours truly,
Kincaid, Cutcliffe Grove, Bedford.
November 15th, 1902.

To the Editors.

Gentlemen,—I hope "A Retired Dealer" finds himself in comfortable circumstances, if not affluence, through success in business, otherwise his fossilised notions of trade leave small hope for his future. It is a common expedient, in defending a bad case, to set up an arbitrary definition, and to dance and whoop around the imaginary corpse, after having scalped it in the most satisfactory manner. "A Retired Dealer" formulates his own definition of monopoly. You may infer

the rest. I prefer to take the common, accepted meaning, as shown by the following definition, taken from a standard dictionary:—"The exclusive possession of anything, as a commodity or a market; the sole right of selling."

Let us now turn to the facts. Kodak, Limited, are exclusive owners of certain articles and refuse to supply the trade, but upon certain conditions of sale. The P.T.A., collectively, are exclusive owners of certain articles, and refuse to supply the trade but upon certain conditions of sale. You may fill in the names of the articles and the terms for each particular case, but it is evident the principle is the same for all. What I ask for is, that the retailer should be free to fix his prices as he pleases, and not as "the Ring" dictates. This is the only policy by which you will succeed in defeating a business undertaking, organised on the lines of Kodak, Limited. Large profits have enabled it to obtain the control of the market for certain articles. Until you cut down those profits by competition, or scatter them by forcing the company to open a large number of shops, your efforts will be futile, and you may continue to snivel and drivel to an unsympathetic public.

I am not so ignorant of the photographic trade as "A Retired Dealer" imagines, and can inform him it is a fact that in one large photographic business, where prices had to be raised at the dictation of "the Ring," the net profits for the year reached 60 per cent. upon the capital invested. The profits upon a large number of photographic articles are much too heavy where business is transacted upon cash terms. I could name one that a small dealer would decline to stock and only supply to order. Yet for the small service of taking the order and handing the article to the purchaser, he receives the handsome remuneration of 35 per cent. of the price, or 50 per cent. on his outlay. In many cases the profit amounts to pounds. The P.T.A. refuses to supply men who would be content to serve the public upon reasonable terms. Whilst it does so, it cannot expect to receive the support of the public in fighting an organisation, managed on similar lines. "The Ring" is an organisation of manufacturers and retailers formed for the exploitation of the public. The outcome of the large retail profits must be a needless extension of the number of shops opened by men who will fritter away the profits until they touch the ordinary level of a shopkeeper's standard of living. When they have reached that stage their defence can be very ably undertaken by men of the stamp of "A Retired Dealer."—Yours truly,
X. Y. Z.

To the Editors.

Gentlemen,—In his letter in your issue of November 14th, Mr. H. H. O'Farrell suggests that Kodak, Limited, imposes factors' agreements upon dealers and refuses dealers' "necessary" discounts. This is a mistake. They do not refuse dealers' discounts, and do not ask them to enter into any factors' agreements. The Kodak Company gives a trade discount, varying from about 15 per cent. to 25 per cent., to all dealers alike.

If some of them like to earn more by under certain conditions that is for them to decide, and they claim further discounts for electing to handle only Kodak's rollable film goods, and they are not bound in any way for a moment longer than they elect. Mr. H. H. O'Farrell does not state what the "factors' agreements" are which Professor J. B. Clarke, of Columbia University, discusses. He assumes that they are the same as the conditions of sale of the Kodak Company. In this I believe he is in error. Who is to decide what are "necessary discounts?"
A SUBURBAN DEALER.

November 18th, 1902.

To the Editors.

Gentlemen,—The letter, signed "J. Lizars," appearing in your issue of the 14th inst., is a delightful instance of suppression of facts and suggestion of fictions. It is an attempt to justify imitations, among which Mr. Lizars' own products figure, and seeks to mislead your readers into the belief that the Kodak Companies have not been the pioneers of the roll film industry.

The Kodak Companies have been almost exclusively responsible from the outset for creating the vast trade that now exists in rollable film goods.

Films and roll holders were made by experimenters in very early days, but the Eastman Company introduced and acquired inventions and improvements (and this without any competition to speak of), and made these goods commercially successful in every stage.

The history of the progress of rollable film appliances is the history of the Eastman Companies, and this is common knowledge. First, paper films, then stripping films, then transparent films: none other than the Eastman Company has had any appreciable share in the making of the trade.

As regards daylight loading appliances, Mr. Lizars finds it convenient to suppress the fact that the apparatus stated by him to have been introduced here in 1893 was obtained from a company, which was afterwards merged in the Eastman Company, and all of whose patent rights were purchased at considerable cost. It may be added that the patents

covering essential features in the existing daylight loading camera system were bought up by the Eastman Company, and are still their property, wherever any such rights exist.

Mr. Lizars makes the mistake of saying we complain of imitations. It is not we who complain. It is the imitators themselves, who are crying out for assistance and sympathy, because all possible facilities for substitution practices are not afforded by the trade.

We do not complain of imitations, but when appliances are pushed forward by competitors which are similar to ours in outward appearance, and in which our gauges are minutely and exactly measured and copied, it is time to protect the public against "piracies" and "parasites," and to take precautionary measures against would-be purchasers of Kodak goods being deceived. We do not waste our breath in taking exception; we take proper business measures to encourage honest and pushful service from the dealers. That is all there is in it.

The competing manufacturers appear to be so poverty stricken in invention. If they want to make honest and original trade for themselves in rollable film goods, why do they not produce cameras and spools of their own design, and in the standard popular English sizes, $\frac{1}{4}$ plate, 5 by 4, and $\frac{1}{2}$ plate, instead of imitating our models and measuring up and copying all the new gauges we have introduced, which are in no case the standard sizes, but are special and peculiar to our introductions? Your readers ought to know why this little device of adopting our gauges is resorted to. It is that these special designs and sizes are associated with our world renowned trade names, "Kodak," "Brownie," "Bull's-Eye," etc., and the imitators desire such conditions as will help them to steal some benefit from our trade and make substitution as easy as possible. Not only have our Kodak reels—which are stamped with the trade mark of the company—been wound up with alien films upon them by imitation manufacturers, but purchasers who ask for spools under our trade mark names have passed off upon them, or put into their cameras without explanation, some one or other of the imitations made up like Kodak spools for use in Kodak cameras. As long as patents are not infringed we do not complain, but such tricks have to be met by giving better terms to those dealers who give us the best and most honest service.

We should have thought that Mr. Lizars would have kept discreetly silent concerning the fact that he is not now being supplied with Kodak goods for his shops. We on our part cannot, however, at the present time say more than that the real reason will be known sufficiently soon, when the legal proceedings, which we have had to take against Mr. Lizars, come to a hearing.

The suggestion made by Mr. Lizars that the Kodak Company has imitated sizes previously made by himself is as amusing as it is untrue, and, like the rest of the letter, is evidently put forward in the hope that the mis-statement will get a useful start of the contradiction.—We are, yours faithfully,
KODAK, LIMITED.

THE CHEMISTRY OF THE LEAD INTENSIFIER.

To the Editors.

Gentlemen,—In the interesting article, entitled "The Half-Tone Negative Under the Microscope," by Mr. J. I. Pigg, in your last issue, he seems to be under some misapprehension as to lead intensification.

It is quite unnecessary to call into explanation any "magnetic influence brought about by the conjunction of two metals," when we can explain the process, very simply, from a chemical point of view, thus: On mixing nitrate of lead and potassium ferricyanide, we get lead ferricyanide and nitrate of potash, as shown in the following equation:—

in contact with metallic silver, the lead ferricyanide is reduced to ferrocyanide, silver ferrocyanide being at the same time formed, both of which are much less opaque than metallic silver; the equation representing this reaction is—

and both these ferrocyanides are reduced by the ammonium sulphide to the corresponding lead and silver salts, thus—

—Yours faithfully,

CHEMICUS.

THE ELECTRIC LIGHT IN THE STUDIO.

To the Editors.

Gentlemen,—I was pleased to read your article on "Electric Light in the Studio," in last week's issue. It seems a rather hard matter to estimate the value in candle power of the light needed, but I believe that nothing short of 3,000 candle power will give the necessary brightness required for short exposures in the studio.

Arc lamps give about 900 candle power, when used without shades, but if worked with reflected light only, it is questionable if much more than 600 candle power is available. On that basis five lamps are required instead of three, as sometimes, and one as often used by photographers; the greater diffusion of the light will not be found so trying by the sitter, and will enable better negatives to be produced.

Incandescent lights are more easily managed, a group of 15 200 candle power lights being quite portable, even when placed inside a reflector, and, to my mind, the light is more comfortable to a sitter, which is a great point in making that style of lighting popular.

In regard to the working cost, it depends whether the light is only switched on during exposure, or burnt all the while the sitter is in the studio. The short lighting makes the cost about even, but five arc lamps only consume about three units per hour, against over ten for the incandescent.

The electric companies might reduce the cost if photographers did not switch on and off, but it is now well known that they do not appreciate the heavy load for such a short while.—Yours, sincerely,
ALF. H. CADE.

Cade's Popular Studio, Cornhill, Ipswich.

SPIRIT PHOTOGRAPHY.

To the Editors.

Gentlemen,—Referring to spirit photography, as per paragraph in your last number, there is in West London an old gentleman, now aged seventy, who is taking photos of spirits and of pictures made by spirits since 1895. He is naturally clairvoyant, or double sighted, and can see spirits. His daughter, who died some ten years ago, had the same gift, and acted as a medium for years. He is a photographer since 30 years back, in the same shop and studio. He is convinced that if his neighbours knew that he photographs ghosts he would lose his business and living, consequently he ties a veil of timid secrecy over the spiritual department of his establishment by never referring to it, and in other ways, and refusing to entertain applications from the Press lest his name as spirit photographer, with his address, should appear in print; his excellent but giftless wife is a strongly prejudiced anti-spiritualist, though converted.

I myself, who am an amateur medium, qualified "to call up spirits from the vasty deep," was the innocent cause of his becoming a spirit photographer in 1895. I went to him to have cabinet photos of myself to send to my son in India. He operated at the camera, and, being double sighted, saw a young woman, a spirit, by my side, when all was ready to take me. That was his first spirit photograph. I went to him frequently in the next ensuing two years, and had over forty photos of spirits taken—male and female, old and young-looking. I bought all the negatives (cabinet size photos) of him. They were described in "Borderland" (14 pages), October, 1895, and other publications. I expected to recoup my disbursements by selling copies of the photographs, but the public can only think they are spurious, because they refuse to believe, despite our bristling spires all over the country, that the dead revive in a new garment of flesh; and if they don't, why have we any religion in the land?—a dead letter, without that immortality that it promises! Any of your readers can have a spirit photo from me for a shilling, post paid. Money returned, if desired, on receipt of returned photo.—Yours truly,

J. STARLING.

62, Abercrombie Street, S.W.

WHERE ARE WE DRIFTING?

To the Editors.

Gentlemen,—"Where are we drifting?" Forsooth! Towards the light, surely, but not all top light. I think, like Mr. Farmer, that the studio of the future will be minus top light. I myself am taking portraits in an ordinary room (with two ordinary house windows on one side, about six feet apart), which I opened about three years ago, as a photographic studio, and find no difficulty in obtaining results, far from lop-sided atrocities; in fact, I often hear remarks, such as: "How very natural," "Quite artistic," "Looks as though he were about to speak," etc., etc. After reading Mr. Banger's letter I must consider my sitters an awfully ignorant lot, and not feel at all surprised if some were to develop large ears. To say that "Nature gives us light from above" is quite true, and if concentrated through the sky-light gives a most angelic beam; then all that is necessary to make a complete picture by the said light is a sitter with an expression to correspond. But it matters not whether the light is concentrated through the top, side, or through a keyhole, so long as the desired result is obtained. I am also afraid that midget or carte de visite full length portraits, taken with Mr. B.'s ideal lens, would require a vast amount of supplementary something on them, before one got paid for same.—I remain, yours, etc.,
SIDE LIGHT.

THE CARE OF APPARATUS WHEN OUT OF USE.

To the Editors.

Gentlemen,—The season has now arrived when outdoor photography with many, particularly with the users of hand cameras, will be a thing of the past, until next year. Too often the apparatus is relegated to the lumber room without any consideration as to the state it will be found in when next required for use, with the result that when it is, it is frequently found unusable until certain repairs have been done. This state of things might easily have been avoided if a little

care had been bestowed upon the apparatus before it was stowed away, and if it had been kept under other conditions, "lumber rooms," if at the top of the house, where the majority of them are situated, are, as a rule, none too dry, and as a consequence apparatus stored therein is often found in quite a different state from what it was when put away. The leather portions may have become mouldy, and the metal parts rusted or oxydised, things that, by a little care, might easily have been avoided. Here are a few hints that may be useful to many. Suppose it be a hand camera. All parts should be thoroughly freed from dust, and if it is supplied with metal sheaths it is a good plan to give them a coating of black varnish as a protection against rust. The leather cover may also be very slightly oiled with good olive oil; this will often prevent mildew. When this is all done the camera should be securely wrapped in brown paper, if it has not a leather case, to prevent access to dust, etc. In the case of cameras with leather bellows it is a good plan, after thoroughly dusting all parts, to rub the bellows over with French chalk, to prevent the gussets from sticking together, and pulling off the surface when they are again taken into use. With bellows body cameras it is a good precaution to open them two or three times during the storage, and expand the bellows, and, if any tendency to sticking is found, the French chalk treatment should be repeated. With regard to the place in which the apparatus is stored, it should be dry, but not abnormally so, as the wood with which the cheaper forms of modern apparatus are constructed is not too well seasoned, and an abnormally dry and warm place may do almost as much harm as a moderately damp one. However, if a little consideration be given in storing the apparatus it will always be found in as good working condition when next required for use as when it was put away. There is an old aphorism, "Safe bind safe find," and that well applies to photographic apparatus when not in constant use. Hence these seasonable hints.—I am, yours, etc.

DARK SLIDE.

November 16th, 1902.

Answers to Correspondents.

- * * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C."* Inattention to this ensures delay.
- * * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C*

PHOTOGRAPHS REGISTERED:—

- E. J. W. Beech, The Studio, The Cotteridge, King's Norton. *Photograph of St. Nicholas Parish Church and Old Grammar School.*
- R. P. Gregson, 37, Church Road, Lytham. *Two photographs of W. Farnworth, Esq.*
- H. Barney, 26, Bourne Street, Dudley. *Photograph of Dudley Town Prize Band.*

"SINOP."—J. D. STOKOE writes: "I shall feel indebted if you will inform me where I can get to know particulars of the process "Sinop" as mentioned in your Journal of November 7th inst."—In reply: See reply to "Sinop" below.

ADDRESSES WANTED.—FRANK THOMAS asks: "Could you oblige me by giving names and addresses of photographic view publishers?"—In reply: Messrs. Valentine and Son, Dundee; Frith and Co., Reigate; G. W. Wilson and Co., Aberdeen, are all publishers of photographic views.

CHRISTMAS CARDS.—A. FRASER asks: "Where can I get mounts for Christmas cards with mottoes, such as some professional photographers are now making such a feature of?"—In reply: Surely our correspondent cannot look at our advertisement pages or he would not need to ask this question.

BREMER ARC LAMP.—PHOTOPHIL says: "I should be obliged by information about the Bremer arc lamp, and where to procure it in Paris or in London. Is it of dimensions suitable for a magic lantern?"—In reply: We, unfortunately, do not know the lamp mentioned. Perhaps some reader may be able to give our correspondent the desired information.

J. P. BAMBER.—Your queries are so "mixed" between emulsions and enamel that we really do not understand what you require. If it is information on making collodio-chloride paper, you cannot do better than get Abney's book on "Photography with Emulsions." That gives formulae for collodio-chloride emulsions. You ask for your queries to be answered in the "text portion" of the JOURNAL. Correspondents are only replied to in this column.

DETERIORATION OF PLATES.—W. J. HORNER says: "If I keep plates in my magazine camera more than two or three days I find when I develop that they are often fogged or covered with patches, or go black all over. I feel satisfied that the camera is light tight and the dark room all right. Can you suggest a reason, and do plates generally spoil quicker if they are kept in the camera? Imperial, special rapid I use."—In reply: If the camera is light tight and the dark room light safe, the deterioration must be due to the camera—

probably from some exhalations from the wood or the blacking of the inside. Dry plates deteriorate rapidly if kept long in some dark slides from the same cause.

LOAN OF SLIDES.—MR. PERCY J. ASHFIELD writes as under: "Can you give me any information as to the best means of obtaining the addresses of lantern and photographic societies. The Rhyll Town and Improvement Association have a set of over sixty lantern slides of Rhyll and district, with a descriptive lecture they are willing to loan free of charge, hence my desire for above information?"—In reply: A list of different photographic societies and clubs in the United Kingdom is given on Pages 623-664 of the "Almanac" for the current year. Should any society desire the loan of the slides mentioned they had better communicate with Mr. Ashfield. His address is 66, High Street, Rhyll.

DRYING MACHINE FOR PLATES.—H. C. F. says: "I should be much obliged if you would let me know your opinion on the following—(1) Is there any demand for negative drying machines? (2) Are there many at present on market? (3) Would it be worth while taking up one of following detail—Will dry negative in six minutes (about) without treatment in further baths or application of spirits; adaptable to dry several at once; cost not to exceed five shillings?"—In reply: (1) We do not imagine that there is any great demand for the machines. (2) There are not many on the market. (3) We think, perhaps, it would, as the price is moderate, if the apparatus were well-exploited, but without seeing the machine we could give no decided opinion.

OBSTRUCTED LIGHT.—"TROUBLED" writes: "Five years ago I bought a piece of freehold land on which I have built a house and a studio on the garden at the back. Now the owner of the next house, built since mine, is putting up large workshops on his garden that will block out all my north side light, which is all the light I get. Will you kindly advise me as to what steps I must take to stop the building, which is at present only eight or ten feet high?"—In reply: Unfortunately you cannot stop the erection of the building, as your neighbour has as much right to put up what he likes on his ground, the same as you had on yours. As your studio has only been in existence for five years you cannot claim "ancient lights," consequently, you can do nothing in the matter—unfortunately for you.

COLLOTYPE.—"SINOP" writes: "(1) In the BRITISH JOURNAL OF PHOTOGRAPHY, November 7th, there appears a report of a demonstration given by Mr. William Gamble at the Royal Photographic Society on a process for printing known as Sinop. I should be obliged if you could help me in finding an address where I could obtain the prepared plates which he (Mr. Gamble) says can be obtained commercially? (2) Would the same be exposed under a negative or a positive so as to make a negative in relief? (3) Where can I obtain the rollers and ink for this process?"—In reply: (1) The plates, we believe, are supplied by Messrs. Penrose and Co., Farringdon Road. (2) A negative, but it must be a reversed one in order to have the image the "right way about." (3) Messrs. Penrose and Co. supply all the necessary materials for colotype work.

CHOICE OF APPARATUS.—"CASSIO" says: "I am going to take up photography for experimental purposes, such as the testing of the speed and quality of plates under all conditions. I am anxious to have the best apparatus, but I am somewhat in doubt as to the best form of lens and camera suitable for the purpose, whether the double anastigmat type of lens and a folding camera, or a good rapid symmetrical and a double extension camera. I favour the former type, but I am not quite certain whether it would be really adaptable for all purposes. Also I should be greatly obliged if you would tell me where to obtain a 'Sanger Shepherd' plate tester and the price?"—In reply: If the apparatus is only required for the purpose named almost any camera or lens will answer, supposing the apparatus is perfectly light tight. Both the systems mentioned are good and reliable. The plate tester named may be had from Messrs. Sanger-Shepherd and Co., Grays Inn Passage, Red Lion Street, Holborn, W.C.

* * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

THE forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published in December next. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The growth in popularity of the ALMANAC is evidenced by the remarkable rapidity of its sales.

The 1900 Edition (20,500 copies) was sold within three months after publication.

The 1901 Edition (20,500 copies) was sold a fortnight after publication.

The 1902 Edition (20,500 copies) was sold a fortnight before publication.

The widespread interest in the ALMANAC grows steadily year by year, and in order to supply the increasing home, foreign, and colonial demand, we have decided to enlarge the 1903 issue to

25,000 COPIES.

The great addition to the circulation of this most popular annual (over 20 per cent.) undoubtedly enhances its value as an advertising medium, and the issue of the large

number of extra copies will supply the wants of thousands of photographers, dealers and publishers who were unable to obtain the ALMANAC for the last three years.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

EX CATHEDRA.

Travellers' Tales.

As by an unfortunate *contretemps* the Camera Club was last week deprived of its customary lecture, the members made the best of the mishap and organised an informal discussion upon travelling experiences. The talk turned out to be of a rather desultory, as well as discursive character, but it was far from being uninteresting, for a number of points were considered by men who had visited most parts of the habitable globe. But there was common agreement among them upon one matter, and that was with regard to Custom House practice. It was maintained that although we enjoy the blessings of free trade to such an extent that duty is now levied on very few articles, there is far more trouble to the traveller in getting clear of the Customs officials at our own ports than in any other country under the sun. One member plaintively recounted his experiences in landing from France, his luggage being mercilessly overhauled in spite of his reiterated protest that he "had nothing to declare." But what he seemed to feel more acutely than anything else was the presumption that he might have concealed among his things any Gallic cigars. "As if anyone in his senses would burden himself with that awful form of tobacco represented by a French cigar." It is perfectly true that during the past twelve months the English tourist from abroad has been put to unusual inconveniences in passing the Customs, and we ourselves can testify to this. We believe the reason to be that instructions have been issued to the officials to keep a sharp look-out for smuggled saccharin. Since the war duty was placed on sugar, there has been a temptation to smuggle this sweet compound into the country. It is mostly made in Germany, and owing to the fact that it is some hundred times sweeter than sugar, and that a comparatively small quantity of it would be equal in sweetening power to a ton of the best Demerara, a duty of one sovereign per lb. has been put upon it. Those inclined to smuggle have not had such a good chance for many years of making a dishonest penny, and our readers will call to mind many recent instances in which individuals have

been heavily fined for the illegal possession of saccharin upon which no duty had been paid. It would certainly be hard on photographic tourists if packets of undeveloped plates were exposed to light in the search for saccharin, but such an accident is quite likely to occur unless the traveller is on the alert, and insists that the examination be conducted under red light. At most Custom-houses a dark-room is available for the purpose of examining packages said to contain photographic materials which for any cause come under suspicion of containing goods liable to duty.

* * *

German Industrial Methods.

We have, on more than one occasion, referred to the organisation of labour which is being carried out by the State in Germany, and we give the following extract from the *Allgemeine Photographen Zeitung*, which shows that the interference of the government with labour may not be an unmixed blessing. The balance sheet of the labour organisation for the district of Düsseldorf for the year 1902 deals with a total of 88,990 marks (about £4,300). Of this sum it is affirmed that only a few hundred marks were directly applied to the improvement of the workmen. The income appears to have been devoted principally to the payment of salaried officials, travelling expenses, delegates' charges, diet, and allowances. The seven master workmen, who occupy positions as presidents of the various departments, received together a sum of 17,600 marks for their attendances, etc., at congresses, although their positions are considered honorary. In addition to this, there are a number of officials receiving salaries varying between 3,000 to 4,800 marks per annum. Their personal expenses figure for an additional few thousand marks. Thus there were only a few hundred marks remaining for the apparently minor purpose of instructing master workmen and apprentices. Things are done so much better abroad!

* * *

Colour Protection.

A few weeks ago we commented upon the circumstance that the Admiralty authorities had determined to give our battleships a coat of grey paint, with the idea that this tint would so match the sea and sky that the vessels would be less visible to the eye of an enemy than if they retained the deeper colour which they have hitherto assumed. And we pointed out that photographers would be the first to note that the efficacy of the new dress would depend upon the conditions of lighting. "With a bright sky at their back," we wrote, "they will look under certain conditions quite black; while, should the sky be murky and the light full upon them, they will stand out almost white in tone." We now learn that our surmise was correct. H.M.S. *Devastation* is the first ship that has been submitted experimentally to the new treatment, and a picture of her, contrasted with another picture of the ship as she appeared before the pigmentary transformation, is published in last week's *Illustrated London News*. A note informs us that the new paint is composed of white 11ozs., and black 6ozs., but the particular kind of pigments, a very important point, is not given. The statement in which we are more interested is to the effect that there is a clear gain in invisibility by day, but that under the search-light the grey has been found more conspicuous than black. If our warships could be endowed with the power of the chameleon, to change their colour according to surroundings, it would be a gain indeed, but we can never hope for such protective value in one fixed tint. The steam banner from a tall

chimney shaft will look as black as Erebus against a sunset sky, but it will appear as white as snow if the morning sunlight falls upon it.

* * *

Line Drawing. There are comparatively few artists of note who can be said to be thorough masters of line. The introduction of the zinc block, which was the first step towards the suppression of wood engraving, naturally attracted many to that mode of artistic expression; but the fact still remains that for every one who can make a good line drawing, i.e., a pen and ink sketch, there are hundreds who can work with pencil and brush. Some of the most skilled of our line draughtsmen have been on the staff of *Punch*, and the names of Leech, Charles Keene, and Du Maurier naturally occur to one in connection with the past history of that popular periodical, just as to-day it is associated with the names of Linley Sambourne, Bernard Partridge, Phil May, and others. The wonderful command of line which these artists possess has given them their reputation. We have observed of late that a new method of illustration has found its way into the Conservative pages of the "London Charivari." Last week, for example, Mr. Lucy's amusing article on the doings of Parliament was illustrated by four half-tone blocks reproduced from pencil sketches. We were glad to see this because it is a sign that the pages of *Punch* will be thrown open to those who, while possessing the power of humorous expression, are not at their best when handling a pen and ink to give utterance to it. There was a rumour recently to the effect that *Punch* was to be confronted with a formidable rival, to contend with it in its own peculiar field of literature and art. Many attempts at such rivalry will be remembered by those who are approaching middle age, for success always leads to imitation, and the position of *Punch* has again and again been assailed. Students of comic literature could, without much difficulty, compile a list of at least fifty publications which have aimed at assuming the cap and bells worn so long by the genial hunchback, and a few of these have been conducted with so much ability that it is a matter for wonder that their existence was so ephemeral.

* * *

The Encyclopædia Britannica.

The supplementary volumes of this stupendous literary production differ from those which have preceded them in the circumstance that they are partly illustrated by half-tone process blocks. This is a most welcome innovation, and we consider that it adds considerably to the value of the work as a whole. Taking one of the first articles as an example, that on agriculture, we find it well illustrated by pictures of prize animals of different breeds—cattle, horses, pigs, and sheep. Such pictures may not be necessary for the information of the bucolic mind, but there are thousands of persons bred in towns whose knowledge of sheep and cattle is confined to the mutton and beef which they eat at their meals. By reference to the new volumes of the "Encyclopædia" they will now be able to distinguish between the many varieties of these animals which are so important to the welfare of man, and will be able to take an intelligent interest in them. The photographs are good, and have been excellently reproduced. To turn to another subject, and to show the up-to-date character of the work, we may mention that two half-tone pictures are given of M. Santos Dumont's dirigible balloon: one taken in Paris showing the gigantic aërostat resting in its shed, and the other taken instantaneously at Nice showing the balloon high in the air. A page is devoted to the life

and work of Sir L. Alma-Tadema, and another is given to a reproduction of one of his chief pictures "The Roses of Heliogabalus." Two paintings by Rosa Bonheur occupy another page, while, curiously enough, Lord Beaconsfield is dismissed with a small woodcut portrait. The article on "Caricature" is illustrated by three pages of specimens, but full page cartoons from *Punch* are not improved by being contracted to three inches in height. We are of opinion that half-tone blocks might have been introduced far more lavishly than they have been. For instance, the article on "Bacteriology" has nothing but wood blocks, and, of course, photographs of these organisms would have been much more convincing. Their omission is still more felt in the article on "Astronomy," which has merely a few geometrical diagrams. When we call to mind the immense revolution in astronomical methods which has been brought about by the wedding of the telescope with the camera, it seems surprising that no photographic examples are furnished to illustrate this article. The fact that a photographic chart of the heavens is now in progress would alone have furnished a plea for inserting some of these interesting pictures. It may be in contemplation to use such photographs in connection with other articles to come, and we hope that this may be the case. An encyclopædia is a work which, by its nature can never be finished, for by the time the last volume is completed, the first one requires amendment. We may feel certain that, eventually, the photographic illustrations to the work will supersede all others.

An Improved Carbon Process.

The *Deutsche Photographen Zeitung* informs its readers that Herr Carl Zink will shortly introduce an improved carbon process. Specimens have been submitted to the editor, who expresses a very favourable opinion upon the process for portraits of large size. The following are the advantages claimed by Herr Zink for his process:—
 1. Disuse of the photometer. 2. A visible image. 3. No transposition from right to left. 4. No transfer. 5. Abolition of the safe edge. 6. No necessity for a second, or reversed negative. 7. No blisters in development, even if boiling water be used. 8. A film that cannot be damaged in development. 9. In using an enlarged negative, the absence of the characteristics of an enlargement combined with perfect similarity to the original negative. It is also said that the process lends itself to the effects obtained with gum-bichromate. In referring to these various points the *Deutsche Photographen Zeitung* remarks that No. 1 and 2 are practically identical, since the image must be visible if the photometer is to be dispensed with. Moreover, if a large number of identical points are required, the retention of the photometer might be desirable. It is pointed out that No. 4 is discounted by the fact that the paper has to pass through a similar process before exposure, and that the carbon process may be worked without transfer by spreading the pigment with a brush. A large number of prints upon opal glass were produced in this way. Point No. 6 does not apply when double transfer is used in carbon printing. Nos. 7 and 8 may be looked upon as one and the same. No. 9 may depend to some extent upon the process of enlargement. There is, however, an unquestionable advantage in No. 3, and it may be of sufficient importance to make the process valuable. As the Editor of the *Deutsche Photographen Zeitung* does not know the details of the process, only its general outline, he abstains from expressing a definite opinion upon it. In our opinion the wiser course for photographers would also be to suspend

their judgment until more is known. The process is not to be placed upon the market in a concrete form, but as a formula for which subscribers have to pay 35 marks. Experience has often been unfavourable where processes have been introduced in such a way, but we say this without prejudice in the present instance. The firm of Haacke and Albers, Frankfort O M., has taken up the matter and will send the formula to subscribers in the course of the month of January.

* * *

Silvering Mirrors.

The following method of silvering, given by M. Izarn in the "Comptes rendus de l'Académie des Sciences," should be of great value to users of mirrors, as the author appears to have been uniformly successful with it. The process is a modification of that of M. Lumière, but as their account of it was very brief, M. Izarn had to ascertain the best conditions by experiment. The surface to be silvered should be scrupulously clean. Prepare it by rubbing it well with a wad of cotton wool, first using acid and then ammonia. Polish with a little finest rouge, and finally rinse well under the tap. The dish in which the mirror is silvered should also be perfectly clean. A 1 per cent. solution of silver nitrate should be prepared and converted with pure ammonia in the usual way. Take the quantity of solution required for the mirror and place it in a measure. In another measure take a certain quantity of formol, counting the number of drops from a dropping-flask. The determination of the quantity will be afterwards described. Pour the silver solution into the measure containing the formol, then back again into the original measure, and finally into the silvering dish. This should be done very quickly, so that the change which takes place in the colour of the solution may not begin until the dish is filled. Rock the dish well until the silvering is finished. The process takes scarcely more than a minute. The quantity of commercial formol (40 per cent.) to be used, should be ascertained in the following manner. Take a white porcelain dish, clean it well, pour a little ammonia into it, and finally rinse it thoroughly under the tap. Pour into the dish 15 c.c. of the ammonio-nitrate of silver solution and add successively seven drops of formol, rocking the dish well meanwhile. The solution rapidly assumes a rose-violet tint, which deepens in colour. This is quickly followed by an irregular deposit upon the surface of the dish. The deposit passes through various shades of colour from rose to violet, blue and iron-grey, and finally forms a film of bright silver, of yellowish tinge. The solution, meanwhile, clears and becomes coated with patches of fine metallic lustre, giving it an oily appearance. The dropping-flask determines, to some extent, the number of drops of formol. That used by M. Izarn gave a reading of 5 grammes for 100 drops. The silvering is complete when the solution clears and becomes charged with a flocculent precipitate. Insufficiency of formol is indicated by muddiness of the solution, whilst an excess will work too quickly and fail to give a deposit, or one too tender to be of use. When the solution is correctly adjusted the film, after well rinsing under the tap, will withstand hard rubbing. M. Izarn prepared glass plates in this way for daguerreotype. After the mirror has been well washed under the tap and finally rinsed with distilled water, it may be polished with soft washleather and finest rouge, as soon as it is dry. As the film becomes very hard, if it is intended to be used as a resist for engraving with hydro-fluoric acid, the work should be done as soon as the film is dry.

LIGHT IN DEVELOPING.

LATELY there has been brought under our notice a rather singular phase of photographer versus plate-maker. A certain dealer was rather surprised to have a letter from an old and expert customer complaining of a batch of plates he had just received being difficult to develop up to the right density. Seeing that a large number of plates out of the same batch had been sent out and no other complaint made, it was felt that some mistake must have occurred somewhere, for even yet makers often have at times to wade through a sea of correspondence describing the defects their plates are exhibiting, though they know full well that inexperience will almost certainly prove to be the explanation of all the so-called defects and deficiencies. Upon investigation into the particulars of the case in question a perfect explanation was found. The photographer admitted that he had written on the spur of the moment in a fit of anger as soon as he had finished development and placed his plates in the hypo, and without waiting to examine them after fixing; for when he had a little further experience with the objectionable plates he found himself getting all his negatives too dense. It appeared that the incandescent electric light, which he always used for development, had after a temporary disarrangement, been replaced much nearer the coloured glass of the lamp, which was covered with yellow fabric, so that the lamp itself was not visible. The result was, of course, that a much larger amount of actinic light passed through than when the light was placed further away; we need scarcely remind our readers that the intensity of the illumination on the fabric, etc., would increase in inverse proportion to the square of that distance, so that if, for example, the ordinary position of the light was four inches from the screening glass and the new position left only an inch of space, there would be a sixteen times more powerful light energy at work trying to penetrate the coloured lamp screen, and, of course, this increased intensity of illumination not having been discovered, the unfixed negatives would naturally look less dense than under the former conditions of lighting. Equally naturally, of course, the fixed negatives examined by daylight would be too dense.

This incident leads to a consideration of many nice points in dark-room work. For some time past there has been a growing tendency to abandon the use of daylight as a dark-room illuminant on account of its variability, and to adopt gas or electric light, either of which provides illumination that, for all practical purposes, may be looked upon as constant and uniform. It is beyond discussion that the greater the uniformity that can be made to attach to all dark-room operations and conditions the greater will be the attendant success.

We have lately had the opportunity of examining the dark-room arrangements of many studios, and it has been very instructive to note the great variety of illumination adopted, from the dim glow of a double thickness of ruby glass, through "cathedral green" to yellow, any of which may be safe or unsafe according to the conditions. It is now well understood that there is no such thing as a "safe" light, it is simply a question of time as to whether a plate will be fogged or not when exposed to any light, and if this fact were sufficiently appreciated much greater comfort might obtain in many dark-rooms. A careful operator when arranging his illumination will, perhaps, experiment on a partially-screened plate exposed at a certain distance to his light for a while and developed. It is evident that this exposure, if sufficiently prolonged, is bound, sooner or later, to show the effect of light action upon development. Hence the logical deduction is to decide first as to the length of time which it is considered

a plate under average developing conditions will be exposed to the light; secondly, as to which of available light screens will give a maximum amount of illumination with maximum approach to safety in that time. That such a simple principle of selection is not generally adopted seems in the examples we have had the opportunity of observing to be beyond doubt, for we have seen in some places developing carried on under conditions that are absolutely painful in comparison with those prevailing in other studios. We do not think the cause is far to seek. In the earlier days of dry-plate work it was soon discovered that a light safe for wet-plate conditions was not so for gelatino bromide, and the immediate effect was a reduction in amount of illumination, rather than an improvement in its light-obstructing power. Ruby glass was mentioned; it was adopted by most of the pioneers; and when it was found that gelatine had come to stay, almost every dark-room lamp put on the market was provided with ruby glass. After a time a little variation was introduced; but to this day if it is required to hunt out in a dealer's catalogue a dark-room lamp it may be safely looked for under the heading "Ruby Lamps." So much hold has this idea obtained that the word ruby seems almost in danger of losing (in photographic language) its true meaning and becoming accepted as a synonym for what is termed "non-actinic," an objectionable term, which has come to be adopted in opposition to etymological considerations like so many others that have obtained a footing in our language on false pretences. Some thirty or more years ago it was proposed, we believe, by the late R. W. Thomas, that the word adiacinic should be adopted (the word is to be found in the "New English Dictionary," but with no reference earlier than 1880), but it has not found favour, and "non-actinic" still holds the field.

It may be queried, Where is the objection to ruby glass? using the word in its true sense. The reply is that it offers a minimum of light with a maximum of danger, for unless it be of such light obstructive power as to give most feeble illumination, ruby glass permits a large proportion of the light from the most refrangible region of the spectrum to pass, and so causes fog after a comparatively short exposure. We cannot beyond this cautionary dealing with this particular glass give more space for the subject, though on a later occasion we may be able to give it further consideration.

WINTER TROUBLES IN PHOTOGRAPHY.

THE inclement weather we have already experienced has been sufficient to bring trouble and discomfort to many photographers. Although the temperature here has been exceedingly low for November, it has been some 15 to 20 degrees colder at some places on the Continent—Paris, Berlin, Munich, for example. It is rarely such extreme cold is experienced so early in the winter, and it is for this reason, perhaps, that some "weather-wise" prophets are predicting a long and very severe one. A Continental one even goes so far as to say that the forthcoming will be the most severe winter for the last fifty years. Most, nowadays, know how much or how little dependence is to be placed upon the predictions of weather prophets, who profess to foretell the weather some months in advance. Still the recent spells of cold have been sufficient to unpleasantly remind us that winter, with its photographic inconveniences, is at hand, and it may be asked, How many at the time it set in were fully prepared for it?

The troubles brought about by a very low temperature are often not at first fully realised by many photographers, even professionals, while with novices more often than not they remain for a time quite unsuspected. What is often

really due to a depressed temperature in the dark-room is frequently put down to under-exposure. As the image is slow in making its appearance, and takes a long time in the development, and in the end is thin and feeble, it is not altogether surprising that novices do suspect insufficient exposure as being the cause, rather than the low temperature. Sometimes, however, the trouble is ascribed to the plates; it is so easy to put blame on plates when things go wrong. In cold weather it is frequently recommended to heat the developer and the developing-dish to 65 or 70deg. That will certainly mend matters to some extent, but a little consideration will show that much of the advantage thus gained is considerably discounted if the manipulations are carried on in a dark-room the temperature of which is some twenty degrees lower. The temperature of many dark-rooms last week, unless they were artificially heated, did not exceed 45deg., and it is clear that if the development was commenced at the higher temperature the developing solution as well as the dish would cool down before the development was complete, and as a consequence the resulting negatives may be lacking in printing vigour, so that they frequently have to be afterwards intensified. Here, not infrequently, a further trouble is met with.

At a low temperature all chemical actions are slow, and the fixing of the image, unless the hypo solution is warmed, takes a long time and, too often, the plate is not allowed to remain in it long enough to (after the bromide of silver has disappeared) bring the hypo salts of silver into the freely soluble in water condition, with the result that when the image is attempted to be intensified stains are in evidence, and the negative is often spoilt. Again, supposing that the plate is left in the hypo long enough to perfectly fix it, the fact should be kept in mind that the water as it comes from the tap at, perhaps, but a few degrees above freezing point, has not the same solvent action as when it is, say, 20 degrees warmer, hence a much longer washing becomes necessary to ensure complete removal of the hypo. Unless that is done, stains may be expected if the negatives be intensified; or it may become stained with silver in the paper if that be at all damp when it is printed.

In the case of negatives the result of a depressed temperature is more directly manifest than it is in the case of paper prints. In the former the disappearance of the bromide of silver from the film while in the fixing bath is some guide as to its fixation. In the case of a paper print there is no such guide, and, too frequently, prints made in cold weather are not only imperfectly fixed, but also insufficiently washed, and as a consequence, they quickly change, developing yellow stains, spots, etc. We have long noticed that we hear far more complaints of these and similar defects during the winter months than at any other period of the year, and in the majority of instances the cause of the trouble is not far to seek.

In all well-appointed photographic establishments there are heating appliances to keep the dark-rooms, printing, and work-rooms, at an equable temperature. But even that does not effect the water supply, that still remains cold. With albumen or collodion papers warm water may be used for freeing the prints from the hypo. But the majority of gelatine papers will not permit of such treatment; hence a more prolonged washing becomes imperative to rid the prints from the last traces of hypo in very cold weather than when it is milder. The dark-rooms of many amateurs are little more than cupboards—often in the basement, or at the top of the house, with no direct means of heating them. Yet they may be brought to a comfortable working temperature by a cheap paraffin stove—one of these with a four, or four and a half, inch wick, will keep a small room at a comfortable working

temperature, even when that outside may be almost at the freezing point. A common paraffin lamp with an inch wick, left burning all night, with the door shut, will keep the room, the solution, dishes, etc., at a temperature suitable for working with in the morning. Objection may be raised to this mode of heating on account of the smell, but as a matter of fact there need not be any, provided the lamp, or stove, be kept scrupulously clean, and the wicks properly trimmed and adjusted. Even if from neglect of these conditions unpleasant fumes are given off they will have no injurious action whatever on photographic work of any kind.

A STRAY CONVERSATION.

"BUT, my dear fellow, I cannot conceive how you can doubt it. Do you really want me to believe that you refute the existence of personality? I have always thought of you as an egoist, and from your contributions to the press I had no hesitation in classing you as a disciple of metaphysical doctrines. And now you would scatter this belief to the fair winds; in a fit of what I can only imagine to be ironical humour you declare yourself to be a positivist; you place yourself on the side of Mill and Lewes, avowing the principles of psychology as your fundamental basis. Are you unable to realise the truth of *Tà μετὰ τὰ δαιμόνια*? or do you sink lower still, and declare yourself at once to be a materialist?"

"Yes and no; I hardly sufficiently explained myself. We commenced our conversation on the eternal topic of art photography, you at once branching off into the domain of portraiture; and here we are, less than half-an-hour from the time we started, involved in far deeper philosophy than I usually contemplate. I do not think I quite recognise the bearing it has on the subject."

"Why not? You think pretty deeply as a rule, and you admitted to me once that your success as a portraitist was chiefly due to intuition; now you try to convince me that anyone with your knowledge of technique would do just as well if they had a little studio experience. I will not believe you are serious. I regard it as an unthinkable absurdity that anyone in his senses can deny the existence of personality in an artist."

"That is of course true, and I do not wish to dispute the hypothesis; but I have often thought that after all is said and done our art is purely imitative. Quatremère de Quincy says the object of imitation is 'To produce the resemblance of a thing, but in some other thing which becomes the image of it.' Well, my dear fellow, that seems to fit our case. As portraitists, we try to turn out pictures which produce in the minds of the observers the resemblance of the original subject."

"That is exactly what I complain of—you are content with allowing your art to be imitative. If you would but exert yourself more, it would be possible to advance much further, and make it substitutive and suggestive. This, perhaps, wants a little explanation: the greatest of all arts, poetry, is substitutive and suggestive, employing, as it does, words not images; and I do not at all agree with those who say that words raise images in our minds. Thus Hegel tells us that the name has the same value as the representation, and supplies its place in memory. Pronounce the name of a lion, and there is no need of the image of a lion, the name being the intellectual existence of the thing. Thus, I think, if we can do it, it is our duty to invest our work with some of the attributes of poetry, so that, suppose for instance someone was looking at my portrait, he would not only say 'Oh! that's very good of him,' but would somehow find himself gazing at it, conscious of being struck with some abstract thought, and forgetting about the mere image of the subject. If you can do that, I say that your work is sug-

gestive and substitutive—suggestive because it has aroused an abstract idea, substitutive because it is through the medium of a virtual image that this emotion has been awakened.”

“Ah! if we could only be sure of being able to do that, we could at once class ourselves as artists; but I think there are very few of us who can do so. It must be admitted that the methods of our work are all against succeeding on such ambitious grounds—don't you think so?”

“Indeed I do; but then, I do not see why someone should not be more honest than the general mass, and if he claims to be an artist prove himself one, not only by the superiority of his work, but also by the originality of his methods.”

“But, my dear fellow, he would soon be a beggar—”

“No, no; I don't think so at all. A little capital would, of course, be necessary, but his vastly superior work would be bound to win its own reward. People would quickly recognise the artist, and be bound to patronise him. You must recollect his expenses would be very low indeed. The work would be done altogether by himself, and the personal tastes of such a man as I mean are always most economical. It would be necessary for him to adopt exactly the same methods as his brothers of the brush, and if possible live among them. His would be a life devoted to art, devoid of all those ugly barriers that make portraiture as practised by our present-day professional photographers such a mechanical method of reproduction. There would be time for the infusion of his personal genius into his work. Undoubtedly he would be considered more or less insane by other photographers, but the insanity would be altogether on their side and not on his—”

“You mean to say that by his mode of living and his methods of work he would be warmly fostering all the possibilities of art in his craft?”

“That's it exactly; he would. How the majority of our present-day professionals have the courage to call themselves artists I cannot understand. I can only conclude that they must be exceedingly thick-skinned and very ignorant of all art matters. What a very interesting thing it would be if they had to attend an examination, and answer ten questions on the philosophy of art. I think the answers would be a fitting memorial to their ignorance. And yet I do not see how any progress of a real value can be made until the fundamental principles are thoroughly understood. The fault of photography from the artist's standpoint is that it does too much for the operator. Don't you think so?”

“Yes, I do indeed. If the camera only did one quarter the work it does at present, we should have two things happen. Firstly, there would be one quarter, at least, of the number of photographers we have now. Secondly, they would be far better men. As practised nowadays, it is a sort of “*dernier ressort*” of the man who has failed in everything else; and, in this respect, shares the field with the wine business. It is probably on account of this that our profession does not occupy the position in society we would like it to. It is not, I think, because of the work itself, but because of the poverty of intellect and education which is so very apparent among the rank and file. They know so little that they are cruelly jealous of each other, and can hardly be got together in a friendly meeting. And yet as each year goes on fresh discoveries and further improvements bring greater opportunities for personal feelings being displayed in our work; but if these are to be taken full advantage of they must be employed by the intellectually endowed individual, and not by the merely mechanically accurate man.”

“Of course. It is the difference between the artist and the artisan. I fear the majority of us belong to the latter class;

our work is done on a commercial basis, and the longer we stick at it the more does this spirit of trade become the main factor in our efforts. There are some who, I believe, think that if the print is made in carbon or platinotype, or some crude method which they call ‘Rembrandt’—but which would make that master have a fit could he but see it—be adopted for the lighting, their work is at once a work of art. There are others who claim the same distinction, because they arrange the folds of a skirt or a piece of drapery gracefully, or place the hands in some fantastical position, which invariably looks most unnatural.”

“Yes, old chap; the amateurs are the best on the whole, I think. They work on truer art lines, and their failings are those which can generally be soon put right with more experience. If they stick at it till they reach the top of the tree, they will probably be far better qualified to speak on the subject than a professional man, because the chances are they have made a far more careful and exhaustive study of it, especially theoretically, than the other can do under the existing trade customs. They have greater freedom of action, more chances of suiting their own fancies, and realising their own ideas—”

“In other words, my friend, of displaying their personality. Aha! I knew you would be bound to come down to it sooner or later. How delightful!—you admit that nowadays the master amateur does work more entitled to be called art work than does his brother professional; further, you agree that the reason of this is that he is working on truer artistic lines, and, therefore, giving greater scope to his personality. The ‘*a priori*’ truth is consequently personality. ‘*Cogito ergo sum*’—it is necessary that I who think should be somewhat. Thought is inconceivable without a thinker, but the philosophy of the subject by no means stops there. But I am delighted that you can distinguish the difference between sensation and neural process. Tyndall said:—‘We have not an organ, nor apparently the rudiments of an organ, by which to apprehend how a motion in the brain becomes a sensation in consciousness.’ And yet the eye is the all powerful source of the artist. The great difference in the way the same thing affects different people is due to its subtle agency; and if this real spirit is strongly within anyone, it is bound to manifest itself in his work. The artist and the poet are men who can extract inner truths from what they see, where ordinary folk merely observe an external reality. Just hand me down that little book of verses by Henley, will you, please? Thanks; now listen to this:—

’Tis the spring,
Earth has conceived, and her bosom,
Teeming with summer, is glad.

There you have the expressed thoughts of a poet. No ordinary man ever drew such a comparison or offered such a fitting explanation of the buoyant energy and new life which seems to be in the air in springtime.”

“Ah! my dear friend, I think, though, you go too far. Your enthusiasm runs away with you, and your ideals are, I fear, too beautiful to be realised. I only wish such a man, endowed with the gifts you have mentioned, would do as you want him to. What do you think would be the result?”

“I think he would succeed.”

“Do you think he would be understood?”

“Undoubtedly; but only by those who were themselves animated by the spirit of pure art.”

“He would want to be a man of very superior education and refinement, and such men devote their lives to more intellectual spheres, as a rule, and would hardly be content with photography.”

“Why? There are immense possibilities before such a man. I will not admit his failure for a moment, though I believe he

would be laughed at by those he was brought up with, as being fanatic in his ideas. He would live his life like other artists, and while being subject to the limitations of his methods, would nevertheless have ample scope for the display of his personality. My pretty dream may never be realised; it may always remain the offspring of a diseased mind, as many would say; but I would give much to see the experiment tried. Meanwhile, we must wait until Dame Fortune sees fit to grant our wishes. In the words of our old school song:—

Concinamus ad Pinates!
Vox et audiatur:
Phosphore! quid jubar.
Segnius emicans,
Gaudia nostra moratur?"

A. V. K.

INTERFERENCE IN THIN FILMS — A GRAPHICAL TREATMENT.

[Reprinted from the "Physical Review."]

WHEN light falls upon a thin film of a transparent substance, interference fringes are observed in the portions of light reflected from the two surfaces. These fringes, under given conditions, appear to be localised at a particular place, so that they are not seen distinctly with a telescope unless it is focussed upon a point at a particular distance from the film. This feature of the phenomenon of interference due to thin films has seemed rather difficult of explanation.

Michelson* has given a mathematical solution of the problem for the cases which arise in the form of interferometer devised by him, in which the light is always incident normally or nearly so; and Feussner† has given an elaborate treatment of the general case of light incident at any angle upon a film whose plane surfaces make a small angle with each other. More recently H. A. Pocklington‡ has proposed a method of analysis which is much simpler and clearer than that of Feussner.

It has seemed to the writer that it might be an aid to clearness of thought with regard to the whole phenomenon if it could be treated in a graphical way, by which the wave surfaces could be constructed and the interference effects obtained by the intersections of these surfaces.

The method is often used in making clear some simple cases of interference, as, for instance, the effects which are seen when a distant arc light is viewed through two pinholes close together in a card which is held just in front of the eye. In this case each pinhole becomes effectively a source of light, sending out disturbances in the form of spherical waves into the region behind the card. The waves in the two sets are similar in every respect, having come from the same actual source, and so are able to produce definite interference effects.

In Fig. 1, A and B represent these two effective sources, and the circular arcs represent a series of corresponding wave-fronts of the two systems of waves. Any point in which a wave-front of system A intersects one of system B is evidently a point of maximum disturbance; and as the wave-fronts move outward, all points on the loci of these intersections will be points of maximum disturbance continuously. These loci are obviously portions of a system of hyperbolas, having A and B as foci; but within the region considered their curvature is so small that they may be well enough represented by straight lines. If a screen be placed within this region, so that the light passing through the two pinholes falls upon it, there will be a maximum of intensity at each point where it is cut by one of these lines. In this case the fringes have no definite focus.

Consider next a thin film of air enclosed between two glass plates, with the light from a sodium burner falling upon the film at any angle, and being reflected from its two surfaces. The figures are plane sections perpendicular to the surfaces of the film, and passing through the source of light and the eye of the observer. The desired simplicity of treatment can only be attained by considering a somewhat ideal case, in which the effect due to refraction in the upper glass plate is neglected. But the two portions of light which come by reflection from the two surfaces of the film are refracted by this plate in almost identical fashion, so that any relations which exist between them will not be appreciably changed thereby.

In Fig. 2, the two surfaces of the film are taken parallel. A is a particular point in the sodium flame which serves as the source of light, A' its image formed by reflection at the upper surface of the film, A'' that formed at the lower surface. The two reflected portions of light will then diverge from these two points as virtual sources. Finding the loci of the points of maximum disturbance as in Fig. 1, a_1 may represent the locus of points whose difference in distance from A' and A'' is four wave-lengths, a_2 the similar locus for a difference in path of three wave-lengths. In this and the following figures, the loci are constructed by locating two points on a chosen hyperbola, and drawing a straight line through them.

This construction is next carried out for two other points, B and C, on the luminous source, giving the loci b_1, c_1 , and b_2, c_2 . The three lines in each set are evidently parallel. There is actually a continuous series of luminous points across the source where it is intersected by the plane of the figure, and the loci for all of these points will similarly be parallel in each set. But for some point on the source, a locus of maximum disturbance will lie midway between a_1 and a_2 , which will be the locus of minimum disturbance for the point A on the source. This overlapping of maxima and minima on a screen placed in the path of reflected light will evidently prevent the formation of any definite interference effect. But if a portion of this reflected light enter the eye, the observer will see a maximum illumination coming apparently along the path a_1 and all paths parallel to it, and therefore coming apparently from the point where these parts intersect, at infinity. Looking along a direction midway between a_1 and a_2 , he will similarly see a minimum effect coming along a set of parallel paths. The interference fringes will then be clearly seen by the eye, or in a telescope, only when it is focussed for parallel light.

It is, of course, to be noted that definite interference cannot occur between portions of light coming from two different points, A and B, on the source, but only between different portions of the light which originally came from a single point on the source.

There are other portions of the light from A which will emerge from the film after multiple reflection within it, and interference may occur among any two of these portions. The locus for one such case is shown by the dotted line in the figure; and it is evident that they will all be parallel to those already found.

In Fig. 3 the same construction is applied to a wedge-shaped film. The two lines a_1 here represent two portions of the same hyperbola, in one case the light being reflected towards the angle of the wedge, in the other away from it. The two loci a_1 and b_1 now intersect at various points near the film. This means physically that at such a point of intersection there is a maximum of intensity in the illumination due to the point A on the source, and also in that due to B. It means, also, that the eye will see a maximum illumination coming along the two directions a_1 and b_1 , which will consequently seem to be localised at their intersection, and so a sharply-defined bright fringe will be seen in a telescope focussed upon this point.

‡ Proc. Camb. Phil. Soc., XI., 2, p. 105, April, 1901.

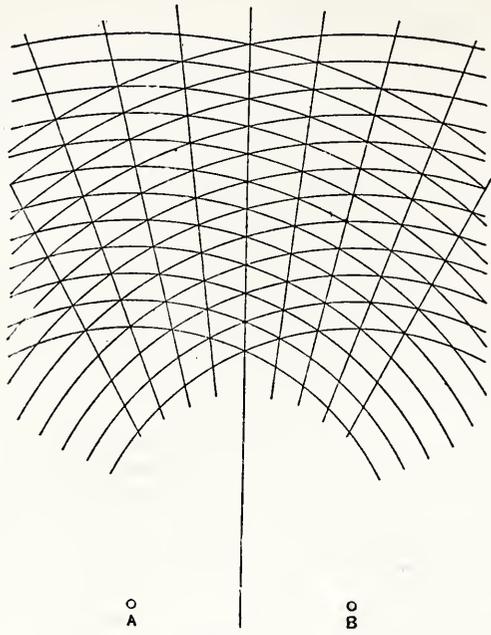

Fig. 1.

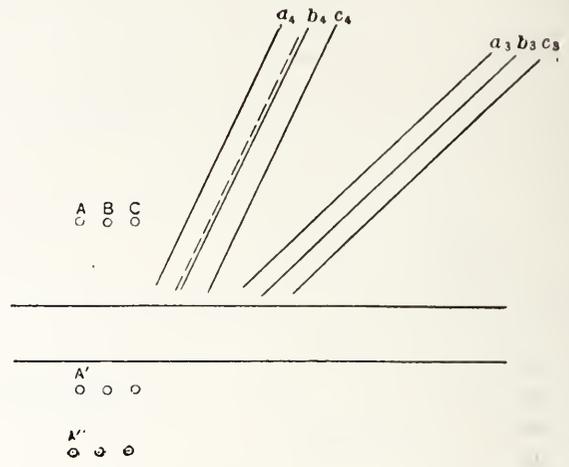

Fig. 2.

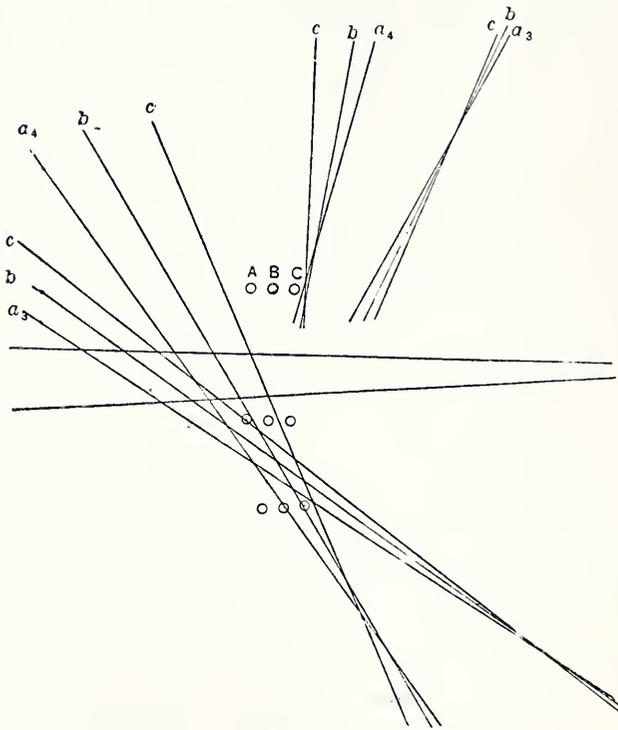

Fig. 3.

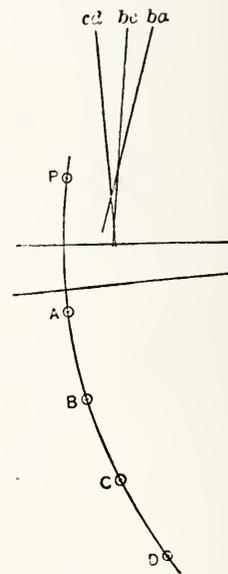

Fig. 4.

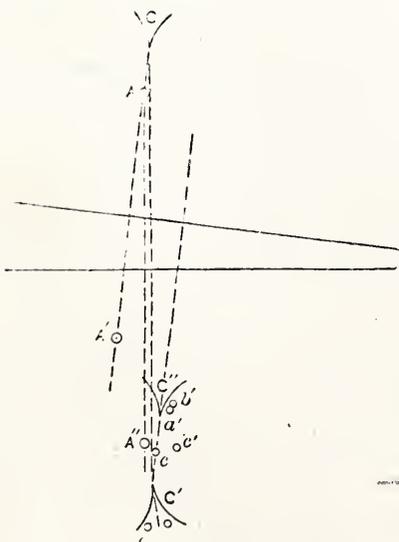

Fig. 5.

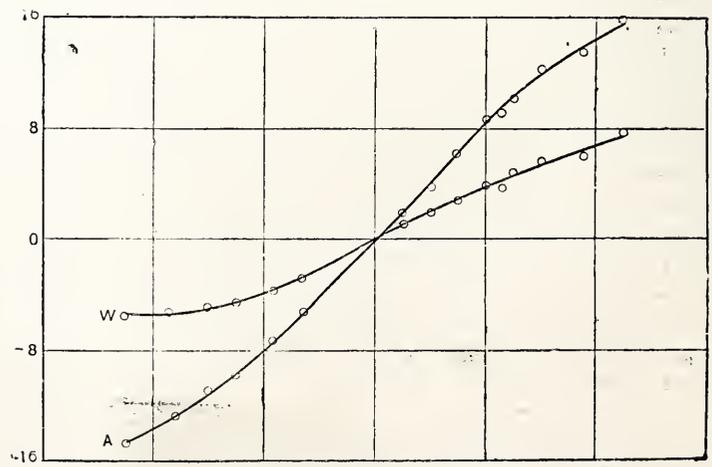

Fig. 6.

The construction shows that any three loci do not in general intersect in a point. It is quite suggestive of the similar construction for the wave-normals of light obliquely refracted at a plane surface.

The distance of the fringes from the film varies with the angle of incidence, becoming zero, and changing sign, with it. The distance also varies with the thickness of the film; for if the film, imagined extended beyond the vertex, be moved toward the left, keeping the angle of incidence fixed, the fringes will pass through the film as the vertex, where the thickness is zero, passes the point of incidence. It is also evident that the distance will vary inversely with the angle of the film, for the distance becomes infinite when the angle becomes zero.

Fig. 4 shows the effect of multiple reflection within the film. A, B, C, D are four successive images of the single point P on the source. The three loci obtained by taking these images successively in pairs intersect in a way very similar to those in the corresponding position in Fig. 3.

If the film be composed of a refracting medium, as water, instead of air, the light reflected from the lower surface of the film will appear to come, not from a point, but from a caustic surface; or, for a small pencil in any particular direction, from the circle of least confusion midway between two focal lines. Fig. 5 is an attempt to realise this condition graphically. The caustic C represents the image of the point A on the source, formed by refraction at the upper surface of the film, and C' is its reflected image at the lower surface. For small angles of incidence, the effective image is quite near the cusp of the caustic, and the light which finally emerges from the film will then appear to come from points quite near the cusp of the caustic C''.

The substitution of water for air has thus moved the second image of A from A'' to the cusp of the caustic C'', which could also have been done by making the air film thinner, and of greater angle. Both of these changes would bring the fringes nearer to the film, for the same angle of incidence. The ratio of tangents of angles of film, multiplied by the ratio of thickness, deduced from the figure, is approximately one-half. For small angles of incidence then the fringes should be about half as far from a water-film as from an air-film under similar conditions.

For a large angle of incidence, a and b may represent the effective images of A after reflection at the lower surface, for equal positive and negative values of the angle. For these two cases the cusp of the caustic C'' would be placed at c and c' respectively, and the final effective images of A, for light emerging from the upper surface, would be a' and b' . By the same reasoning that was used in the last paragraph, this shows that with the increasing angle of incidence the distance of the water-fringes from the film does not increase so fast as that of the air-fringes. Also that the distance does not increase quite so fast for negative as for positive angles of incidence, negative angles being those for which the light is reflected away from the angle of the film. The drawing is hardly exact enough to show this last point with certainty, although the others are quite clear.

All these conditions were verified by a series of observations on a film enclosed between glass plates about 4 cm. long, in contact at one end, and separated by two layers of tin-foil at the other. Small drops of water distributed irregularly in the film made it possible to observe the fringes in air and water, on either side of a boundary line, by merely changing the focus of the observing microscope without moving it laterally. The observations are plotted in Fig. 6, the curve A representing the results for the air-fringes and W for the water-fringes. Ordinates are distances in millimeters measured along the line of sight from film to fringes, and abscissæ are corresponding

angles of incidence. It will be noted that for angles of incidence less than 20 deg. the ratio of ordinates to the two curves is very nearly one-half.

For angles of incidence greater than 45 deg. the aberration becomes so great that measurements cannot be made with any accuracy.

It may be well to add that, for the sake of avoiding confusion, the phase difference of a half period introduced by the reflection within the glass, at the upper surface of the film, has been disregarded throughout.

E. R. DREW.

A VOICE FROM INDIA.

THE season is fast approaching when the ubiquitous globe-trotters and Murrayers are expected to come in large numbers to India from all parts of Europe and America with hand-cameras in hand of all shapes and description. A voice from India, from an Indian, may not be out of place if it can give them any help in their cameratic expedition.

From November to February 8 a.m. to 4 p.m. may be advantageously occupied in photography, but beginning half an hour later and closing half an hour earlier is necessary for snap-shotting and instantaneous work generally.

In full sunlight $f.12$ with 1-10th of a second exposure on Ilford "Special Rapid" and Wratten's "Instantaneous" plates may fairly be employed without any appreciable risk of under exposure, provided the landscape is sufficiently free from large and bushy trees. In India the trees "that are leafless" are an exception rather than a rule, even in the winter season; and the heat of the greater part of the year has made Nature to provide the country with an abundance of these trees, which are rich in foliage, and spacious in their umbrage giving dimensions.

I have mentioned Ilford and Wratten plates. I do not mean to disparage the other brands, but those are the two brands of dry plates that are always available in the Indian market. The others are rare, and if available, are in many cases of doubtful freshness. For tripod cameras and for time exposures the "ordinary" rapidity of both the above two brands are by far the best, but Ilford "Empress" and Wratten's "Instantaneous" are good for all-round general work. A hand-camerist does not require faster plates than Ilford "Special Rapid" or Wratten's "Instantaneous." Plates faster than these (other things being equal) are not only not necessary, but not suitable for their requirements.

In India architecture is the special feature for photography. The photographer should not, therefore, forget his wide-angle lens, with the aperture capable of working at $f.12$ if not larger. But one should not forget that the architects in Old India were seldom cramped for space and foreground; compound and gardens were inseparable companions of architecture. The necessity for the wide-angle lens was not conceived of by those royal builders, though they "designed like Titans and finished like jewellers." It is the modern greed for land that has killed space and frontage in some cases, and has brought into existence an unwholesome and unsightly neighbourhood—much to the detriment of long and ordinary focus lenses.

Pyro-soda and pyro-ammonia are the ruling developers in India. But locomotion in the country being generally not very smooth the various sorts of liver-squeezing conveyances that are brought into requisition transgress the wildest dreams of Europeans. The tourist should keep down his luggage as much as possible, and make them as little fragile as practicable under the circumstances. Tabloids, therefore, are much in requisition, though the cost is a bit high. Twelve annas to

the shilling, or 1s. 4d. to the rupee—the statutory rate of exchange in India—is seldom respected by the tradesmen here, not to speak of the photographic dealers.

Speaking for myself personally, I prefer Rodinal as the best result-producing, handy developer in India. Being a one-solution developer in a very concentrated form, it is particularly suited for touring. Its detail-giving, density-making, and quick-developing properties are the special features. But it has always been a matter of surprise to me that the recipe given by the maker for its use has always been fraught with disastrous results in my hands. The following has been the proportion which would give very satisfactory results, producing brilliant negatives of excellent printing qualities:—

Rodinal	1 dram.
Potassium bromide	36 grains.
Water up to	4 oz.

I first of all pour out one dram of Rodinal, then add to it 3 drams of a 20 per cent. bromide solution (there being 12 grains in each dram), or 6 drams of a 10 per cent. bromide solution (there being 6 grains in 1 dram, or 60 minims), and add water to the above up to 4 ounces.

In developing half-plates, I use the whole of the 4-ounce solution at once. The solution remains strong enough to develop the first and second plate. For each subsequent plate I go on adding 10 minims of Rodinal for each plate. This is for Ilford plates. Wratten's plates want a bit more Rodinal; and after the development of the first cabinet-size plate I would go on adding 10 to 15 minims of Rodinal for each of the subsequent plates.

No more bromide of potassium is necessary to be added even if two dozen or more are developed with the same developer. In fact, by the process of development the bromide, freed from the silver-bromide of the plate, and forming hydro-bromic acid, goes on strengthening the action of the bromide as the development proceeds.

One is likely to think that 36 grains of bromide of potassium is rather high. I should say that with Rodinal, Amidol, and other quick developers heroic doses of bromide of potassium are necessary to control the action of the developer, watch its progress by prolonging the development, and to obtain requisite density with a freedom from fog.

With Rodinal no frilling need be feared. Therefore, no alum solution is necessary. But if not otherwise inconvenient, alum solution may be used with advantage for Ilford plates. For Wratten's plates alum is altogether unnecessary.

Fixing is done as usual. A simple solution of Hypo is quite enough.

SARAT C. BASU.

THE STEREOSCOPE IN THE SCHOOLROOM.

[Reprinted from "The Stereoscopic Photograph."]

THE autocratic Doctor Johnson pronounces:—

Let observation with extensive view
Survey mankind from China to Peru,

the impressiveness of which dictum is a little diminished by someone's witty paraphrase, "Let observation with extensive observation observe mankind extensively." Tautological the doctor's lines may be, but the art of a good writer often lies in his skill in concealing tautology; and even in the paraphrast's grinning version, in which he swears he uses "no art at all," the admonition is still emphatic, "observe mankind," which is doubtless the point the good doctor desired to enforce.

"Observe mankind extensively" is certainly good advice, but the learned versifier omitted to indicate the ways and means. If a fellow has never been to China or Peru, how can he carry on the prescribed observations? How would Dr. Johnson him-

self have done so? for his farthest journey was into that Scotland where, according to his well-remembered sneer, they feed men on oats, which in England is fodder for horses. Is it not likely that Dr. Johnson's own observations on China or Peru must have been rather insubstantial, wide of the truth—in fact, grotesque? For in his day, at least, there were but poor substitutes for travel. There were no photographs, no process illustrations. To be sure, there were books of travel; but seeing through other men's eyes is a poor sort of observation at best. It is seeing through a glass darkly; and where are the books of the travellers who have seen clearly, sympathetically, understandingly, without prejudices to twist and ignorances to blind their vision? The great and peculiar value of travelling is that we see for ourselves, we see with emotional sight, we see what appeals to our interest and can be clutched by our apprehension (no one can really see anything else), and so we store up for all our future years a great fund of concrete images to be called on at occasion.

It cannot be too often urged upon those who carry on the work of education that the mind of the child is nourished and enriched mainly through its receiving abundance of concrete impressions. Minds must be brought into contact with realities. A dozen pedagogical maxims enforce this truth. The mind cannot grow upon itself. It must be fed. We cannot think unless we have things to think about, and the more we have seen and experienced, the more valuable and probably correct will be our conclusions. "Nihil in intellectu quod non prius in sensu." Hence the modern condemnation of "book-learning," "rote-teaching," "words before ideas," "signs without the things signified," and so on. Hence the modern demand for visualisation in teaching—storing the growing mind with realities—through the laboratory method in teaching science, business usages, and so on; through the use of concrete illustrations in arithmetic; through field-work in geography and history; through the reading of literature itself, instead of books about literature. The mind rests when it deals first hand with reality. The concrete is the basis of mental life.

In a way, this truth has always been more or less recognised. Men's esteem of literary works, for instance, has in a great degree depended upon the amount of concreteness, sense of reality, contained in the pages read. In early times poetry was the literature of the people, because it was vivid with the actual, it was "simple, sensuous, passionate." And from the time of Robinson Crusoe on to our own day fiction has been in the ascendant, because it is concrete, it deals with definite men and women in definite situations. The only other form of prose literature equally concrete is biography, and to this day a good piece of biography grips us as firmly as any novel; more firmly, in a way, for we know it to deal not only with the definite, but with the actual. Hence, when a man sick of speculations, abstruse studies, or routine labours, has sought in vain for relief in the froth of fiction, let him have recourse to a good autobiography—such as old Villehardouin's account of the crusade he assisted in, or Benvenuto Cellini's story of his remarkable life, or Pepys' naive diary, or, to take more recent examples, Ruskin's "Preterita," or Stillman's "Autobiography of a Journalist." These are real books, and it may be said of each of them, as Walt Whitman said of his unique "Leaves of Grass," that "he who touches this book touches a man." It is recorded by Trelawney, in his "Recollections of the Last Days of Byron and Shelley," that almost the only kind of reading Byron really cared for was autobiography. Indeed, it is in this sort of book that we get as near as we ever may, outside of ourselves, to the mystery of the inner life of a man.

But when all is said we come at reality in books only through

interpreting word symbols by the power of our imagination and through the illumination afforded by our personal experiences. Books cannot furnish us with new perceptions of realities. They can remind us, recall to us, suggest to us what we have seen or experienced, and with their aid the imagination may construct, using the materials it has, more or less correct notions of what we have never beheld. We are brought a great step nearer the actual by pictures. It is a mistake to suppose that mere amusement or entertainment explains our love of pictures. They go far to satisfy our desire for actuality, with the information the mind craves. Hence the importance of abundant illustrations in school work can hardly be exaggerated. Children learn more from the pictures in their geographies than from the text. So the modern school-book in almost all subjects abounds in illustrations, and is thereby not so much embellished merely, as enriched in power to convey instruction.

But in late years has been perfected something that, in my judgment, goes ahead of pictures, and quenches the mind's thirst for the concrete almost as completely as the very object before the bodily sight. I refer to the stereograph. The art of illustration, as we all know, has been marvellously improved in recent years. Our commonest school-books to-day have process illustrations that for accuracy, delicacy, and beauty, are greatly superior to the best of sixty years since. Our ten-cent magazines are familiar miracles of picture-books. Certainly the human mind has been vastly enriched by this cheapening and perfecting of processes of illustration. But even the best pictures we still feel to be but pictures; they do not create the illusions of reality, solidity, depth. "The best in this kind are but shadows." But with the stereoscope the wonder of photography is brought to its culmination. Man is a two-eyed animal, and the stereoscope, with its two lenses that blend two pictures into one, is like a pair of omnipresent human eyes, at the command of everyone.

Omnipresent eyes! The magic carpet we read of in the "Arabian Nights" was not so swift a transporter, nor to such remote and various regions. Goldsmith's "Traveller," who amid foreign scenes could sigh,

My heart, untravell'd, fondly turns to thee!

would (one is tempted to say) have been spared the pangs of homesickness had he travelled by the favour of the stereoscope. He could have an excellent substitute for going "to the uttermost parts of the earth," and still retained the satisfactions of the man in the popular song who "never cared to wander from his own fireside." One may imagine that the late Henry George, who taught that the earth is rightly the heritage and property of all, might have seen in the stereoscope at least a secondary means of bestowing upon disinherited men their God-given earth. For to see a thing with understanding and appreciation is about as much as to own it. I think it was Ruskin who said that if he looked upon a nobleman's parks or jewels with a more appreciative eye than the nobleman's, he really possessed them the more truly. "Finders is havens," shouts the small boy when looking for something that has been lost. This may or may not be a great truth; but it comes near being one, that seeing is having; and therein lies the value of travel. But the stereoscope gives us many of the most prized effects of travel, without the inconveniences and worries. Of course, some travellers relish the little annoyances and mishaps of a journey, as giving flavour to the experience; but it is still for most persons no small advantage to be able at will to reach China or Peru (or to have in good degree the feeling of being there) without seasickness, delays, ticket-buying, and weariness. Besides, the most of even us grown-ups cannot afford to travel widely anyway. Yet armed with the stereoscope, as Ancient

Pistol was with his sword, we like him can exult, "The world is mine oyster!"

Yet the most remarkable thing about the stereoscopic view is not that it transports us to so many quarters of the great round earth, but that it does it so completely. We look upon strange peoples and unknown lands with our own eyes, not with another's. We have a feeling that we are gazing upon reality. The tree-trunks are not lines upon a canvas or a printed page; they are solid, separate, growing. The objects we see take their positions in space, the scene has depth, vista, atmosphere, it is the real thing, and it stays for us as long as we desire to look. These Esquimaux, for example, are so real that one is almost embarrassed in scrutinising them so closely. It seems impolite to observe the dull earnestness of the man, the unlighted curiosity of the woman in her dirty sheepskins, and the more intelligent look of the one in the background. Like Whitman, observing a mother and child, "we study them long and long." They are human documents. One moment, and we likewise are gazing unabashed upon the dignitaries of President McKinley's Cabinet, and at very short range. Another moment, and we are seeing how pineapples and girls grow in Porto Rico; the next, and far in the frozen north, we discern a great hill of crumbly snow rising from the waveless ice-gorged sea. Thus, turn by turn, the burning tropics, the snow-draped peaks of the Alps, the wonders of the Yellowstone, the strange scenes of far India, and the cosy cottages of rural England, come before us—not as mere pictures, but rather as realities.

The problem of enriching the minds of children with a manifold contact with the actual is solved by the stereoscope. Illustrations in books, as I have said, are good, and have contributed much to the great work of giving real knowledge, a store of visualised impressions for the mind to work with. But with the stereoscope in the schoolchild's hands, he may range the inexhaustible world almost as if on actual travel, because with a much keener feeling of self-transference than is possible with any other means short of the impossible travel itself. Is he to study history? He may be present at Secretary Hay's eulogy on McKinley. Is it geography? He may behold all the lands and peoples of the earth; he may look upon Pelée's eruptions or the work of the Mer de Glace, or, by the aid of specially-prepared maps, he may come to know in detail the city of Rome as it is. Is it nature study? Here is how bananas grow in Hawaii, or there is how the great trees of California reach heavenward. Is it commerce? Here is the hurrying traffic of the East River, or there a vast log-raft on the wide Columbia. Is it art? Behold the marbles of Michael Angelo and Phidias. Is it literature? Here is the home of Irving, or here the village of Grand Pré.

One other striking advantage of the stereoscope is that by the use of it children may be trained to see. We are always surrounded by the concrete, but familiarity has staled its interest for us. The eager curiosity of the fast-learning infant is thus too soon lost. And as interest lessens, attention lags. If a boy is to be trained to see accurately, his interest must be engaged by that to which he is directed. It is because of the interest born of novelty that we observe so vividly and remember so well what we see when travelling. But precisely this interest may be aroused and kept alive by the stereoscopic views; so we can attain through them the first requisite in training the powers of observations—sustained attention. This gained, the teacher may by proper questions gradually lead the child to see, whether in the scientist's way, analytically, or in the artist's way, synthetically. It is hard to say which way the stereoscope lends itself to the more readily and admirably. In this connection, too, no teacher needs to

be told how valuable the stereoscope could be made in relation to language work and composition. For the great trouble in these exercises is that too often the child has nothing to say, no fresh impressions to record that seem to him worth setting down; and unless what he has seen and is told to describe or tell about seems worth while, he has no interest in the matter, and the exercise is savourless, a failure.

May we not conclude, then, that the general introduction of the stereoscope into the schools would be of incalculable value in almost all lines of school work? Notably it would put new life and interest into the geography, the nature study, the language work, while enriching the children's minds with varied preceptions in many realms, which would remain part of their equipment and a source of their enjoyment for as long as they live. This newer, vivid appeal to the desire of the concrete is in line with the tendencies and aims of modern education, it accords with the teachings of psychology, and it has the sanction of the universal experience that the world is interesting and eternally worth knowing about. When Mahomet found that the mountain would not come to him, he went to it. But modern science has worked more miracles than could Mahomet's prayers. As our children cannot themselves go out into the world in body, to see and possess it, let us nevertheless take them to the world, not in words only, or even in pictures only, but in the most vivid and satisfying way available, in stereoscopic photographs. G. J. SMITH, Ph.D.

THE "SINOP" COLLOTYPE PROCESS.

[Abstract of a pamphlet published by Messrs. Penrose and Co., 109, Farringdon Road, E.C.]

THE routine of the process is that a plate is taken from the box, exposed in the printing frame under a negative for from two to ten minutes at most, then placed under the water tap for ten minutes, drained and soaked in glycerine for fifteen minutes, all surplus water blotted off, fixed to a printing bed, and inked up with a printer's roller in about another ten minutes, and then printed from, the impression being taken in an ordinary letter-copying press. The colour of the ink, the strength of the image, the nature of the paper, the size of the margins, are all matters under the control of the operator, who thus has it in his power to produce artistic effects such as no other process is capable of yielding. Post-cards, memos, Christmas cards, letter headings, etc., can be prepared, and prints may be done on paper, cardboard, silk, satin, leather, celluloid, etc. The three-colour process can be applied to this method of printing with the most charming results, and with greater ease than with any other process, because the pure white ground of the "Sinop" film enables the inking to be exactly judged.

The "Sinop" patented process consists essentially of the "Sinop" plates and the special iron bed plate and frisket for printing. The iron bed has hinged to it an iron frame to support the frisket sheet, which is cut out in the centre to a size suitable for the picture, so as to form a clean margin.

To save expense, beginners are advised to use a letter-copying press for the impressions. Sometimes either the bed or the iron plate which gives the pressure is wanting in flatness. In such case the impression would be bad, and the print accordingly grey and patchy. This defect can be quite easily remedied by having the platen of the press replaned. Any local engineer would attend to this for a moderate charge.

The various accessories contained in the "Sinop" outfit are:—1, the "Sinop" bed plate; 2, indiarubber pad for pressure; 3, inking board; 4, inking roller; 5, trimming knife; 6, indiarubber flat squeegee; 7, three tins of inks; 8, a bottle of glycerine; 9, a bottle of turpentine; 10, bottle of sensitising solution; 11, jar of crystals for making sensitising solution; 12, a soft sponge; 13, ink knife; 14, box of 1½ dozen "Sinop" plates; 15, portfolio, containing six sheets of frisket paper, 12 sheets black masking paper, strips of paraffin paper for margins, blotting paper, gelatine paper for fixing the plate to the bed, various papers for printing.

HINTS ON MAKING REVERSED NEGATIVES FOR THE "SINOP" COLLOTYPE PROCESS.

As with all photo-mechanical processes, where the printing surface is applied directly to the photographic negative, a reversed image is required, otherwise the final print would be reversed in relation to left and right.

Reversed negatives can be obtained in various ways.

The most satisfactory method when copying indoors in to have a reflecting mirror or prism attached before or behind the lens.

A simple method is to reverse the plate in the dark slide, so that the image has to pass through the glass to the back of the film. In this case the glass side should be carefully cleaned and the film side protected from contact with the spring by means of a sheet of black paper. A slight alteration of focus is made by this method, and must be allowed for by reversing the ground glass in its frame. With hand cameras there need be no trouble about the focus. Thin celluloid films can generally be printed from the reverse side without disadvantage.

Some dry-plate makers supply stripping plates. These are exposed and developed in the usual manner. When the negative is dry, the film is cut through to the glass with a sharp knife at about ¼-inch from the edges. The film can then be stripped from the glass with the greatest ease, and such film can be printed from either side.

Another way which is capable of dealing with any negatives already in existence is to immerse the plate (which must be unvarnished) in a bath of formaline for about ten minutes. It is then drained and dried over a spirit lamp. The film is now cut through a sharp knife about ¼-inch from the edges. Then it is immersed in a solution of 5 per cent. hydrochloric acid for five to ten minutes, drained, and dipped immediately in a solution of carbonate of soda 5 per cent. strength. Small bubbles are evolved, and the film will come off the glass easily. It can then be transferred the other side up on the glass. To avoid tearing the film in squeezing it down, a sheet of damp paper is placed over it.

PRELIMINARY PREPARATIONS.

Whilst it has been found possible to keep the "Sinop" collotype plates for several months in the sensitised state, and still obtain good results from them, there is the possible disadvantage that a gradually increased exposure and lengthened time of washing is required the longer the plates are kept.

As it would be impossible to forecast the time the plates would remain in the hands of agents and dealers before reaching the user, the manufacturers feel that the process might be seriously compromised by old plates being sent out, and they have accordingly decided to send out the plates plain-coated with the "Sinop" emulsion, leaving the simple process of sensitising to be performed by the user.

This sensitising simply consists in immersing the plate for three minutes in a 2 per cent. bath of bichromate, placing it in a draining rack and allowing it to dry. No drying box is required. The plates are simply allowed to stand over-night in a dark room, cupboard, or ordinary room darkened, and will be found ready for use next morning. They have been found to keep well for two months, with the usual precautions against light and moisture.

WORKING INSTRUCTIONS.

All manipulations of the "Sinop" plate can be done in an ordinary dark room, lighted by artificial light of any kind (except the electric arc), or in a photographic dark room illuminated with plenty of yellow light.

The preparation of the "Sinop" plate may be considered as divided into four stages—viz.:—1. Exposure under the negative. 2. Washing out the plate and damping. 3. Fixing the plate to the bed and preparing the frisket. 4. Inking up and printing.

I.—EXPOSURE.

A mask should be cut out of black paper the full size of the printing frame, the opening in the centre being cut out to suit the picture. This mask is laid on the front glass of the printing frame, and the negative laid squarely over the opening, taking care that only the desired picture is unprotected by the mask, and that the margins are symmetrical. Put down the "Sinop" plate gently with its emulsion side in contact with the gelatine side of the negative, care being taken to get the picture in the centre of the plate. The frame is closed up and its front exposed to diffused daylight. For an ordinary negative without stain or veil and with good gradation, two minutes will be sufficient time. One may see how the exposure is progressing on opening one half of the back of the frame, laid on a table in a dimly lighted room, and inspecting the back of the "Sinop" plate. When the image is faintly seen as a light grey positive, the shadows being scarcely distinguishable from the high lights and the whole without detail, the exposure must be stopped. A little practice will soon guide one giving the correct exposure.

II.—WASHING AND DAMPING.

The "Sinop" plate is removed from the frame in the dark room, and should show a positive image of a reddish colour similar to an underprinted proof on P.O.P. paper. If the image is complete in all its gradations the final result will be good. The plate is immersed in a dish full of water several times changed until it becomes quite white, the yellow colour being washed away, and the reddish image almost entirely disappearing. This operation requires about ten to fifteen minutes, according to the weather and the temperature of the water. It is better to wash thoroughly, and the operator can without

risk allow the plate to remain one or two hours in cold water. Once the plate is immersed in water it is no longer sensitive to light.

When the plate is sufficiently washed, it is drained and immersed in the following solution:—Glycerine, 75 parts; water, 25 parts. The plate must be quite covered with this solution, and should remain in it about fifteen minutes as a rule, though, if one desires to obtain only five or six prints, eight or ten minutes' damping will be quite sufficient. Should one wish to pull a greater number, say, 30, 40, 100, or more, it is advisable to let the plate remain a longer time, in order that it may retain its dampness during the printing.

N.B.—Always use the same dishes for washing and damping, in order to avoid contamination of the "Sinop" plate with foreign matter, which might be prejudicial to its successful working. Hypo, alum, pyro, and ammonia are especially to be guarded against.

III.—FIXING THE PLATE ON THE BED AND MAKING THE MASK.

Place the bed on the table with the frisket frame laid back to the left of the operator. Take a sheet of ordinary stiff paper (sample of which will be found in envelope A of the outfit), cut the exact size of the "Sinop" plate. Dip this paper in water so as to wet both sides evenly, and lay it down quite wet in the middle of the bed in accordance with the guide marks, applying the squeegee to force out all surplus moisture. Next take a sheet of the green-coloured gelatine-coated paper, wet it, and lay it down over the first sheet. Being larger, it projects over the edges and adheres by the margins. The squeegee must be used to spread it out quite flat.

The "Sinop" plate is now drained slightly, and the back wiped perfectly clean. Any speck of dust or grit might cause the plate to be cracked when the pressure is applied. The plate must be laid exactly over the under sheet, the edges corresponding. A light pressure with the fingers on the edges of the plate will be sufficient to make the plate adhere until the first squeeze in the press, which will finally fix it.

The surplus moisture is removed from the surface of the plate with a soft sponge, followed by blotting paper (see sample in envelope B of the outfit), and finally the drying is completed with a soft piece of clean linen.

The plate should now appear with a polished surface, without water-markings, and in the centre of it the picture will be seen like a fine engraving.

IV.—INKING-UP AND PRINTING.

Those who have never handled a printer's roller will probably anticipate great difficulty in the inking. Nothing, however, is easier, and a few hours' practice will soon render the novice skilful in this part of the process.

A small portion of ink, not larger than the size of a pea, is taken on the point of the palette knife, and smeared smoothly on the inking board at the end nearest the operator in a strip equal to the length of the roller.

The roller is taken in the right hand and pushed forward, starting on the ink which has been laid. On reaching the other end of the board it is lifted off, brought back to the starting point, and pushed forward again. This is repeated over and over again, quickly or slowly, until the ink is spread evenly and thinly all over the board and upon the roller. Should the roller not appear sufficiently charged with ink, a little more is added and distributed as before.

The roller, after thus being well charged with ink, is gently rolled backward and forward on the plate, so as to cover the whole image each time. One must begin slowly, and then gradually go more quickly. The image begins to come out, and we note that the more slowly we roll the more heavily and uniformly the plate is inked, whilst as we roll quickly the high lights and half tones are developed. The operator can therefore control his subject at will, according as he rolls more quickly or slowly.

A little practice will teach more than further explanation. After having used two or three plates the operator will understand exactly how to treat each subject properly.

When the plate has been sufficiently inked, the frisket is pulled down and a sheet of paper laid over the image. Pencil marks on the frisket serve as guide for the margins and centring. The rubber pad is laid on and the bed put in the press. A strong pull should be given without overdoing the pressure. Here, again, a little practice will teach best.

The iron bed is removed from the press, the sheet gently taken off, and the frisket lifted.

The inking is repeated, and operations go along in the same way until the requisite number of proofs is obtained.

Generally 25 to 40 proofs can be pulled without stopping to re-damp. The exact number will depend on the state of the plate.

When the proofs become grey, the plate is cleaned up by pulling one or two sheets without inking. Glycerine is then poured on, and allowed to remain five or ten minutes, after which the printing is resumed.

V.—FAILURES AND REMEDIES.

Here are a few hints concerning the usual causes of failure in the printing:—

1. Image comes out with a grey, mottled, granular appearance, and

small white spots in parts.—Insufficient pressure or grain of paper is too coarse. Try pulling more heavily until the image is even.

2. Image very hard with little half tone.—Too long exposure. By inking slowly with plenty of ink tolerable proofs can be obtained; nevertheless, the printing is difficult.

3. Grey image without brilliancy.—Insufficient damping or negative poor and flat.

4. Image refuses to ink up.—Plate underexposed or too damp, or roller has become affected by dampness, or ink has dried up. Run up the roller briskly on the inking board; apply a little fresh ink if necessary; dry off the plate a little with a sheet or two of paper.

5. Whites refuse to clean up, and image becomes flat and grey.—Plate becoming too dry or too much ink on roller. Pull off the ink on waste sheets and pour on the glycerine solution, spreading with the finger. Allow glycerine to remain on ten to fifteen minutes. Run the roller on a clean slab to take off some of the ink, or wash off with turps.

6. Streaks and markings.—Due to not covering the image with the full width of the roller and to stoppages in rolling; also from scum from the damping solution.

7. Ink pulls off the image.—Too quick rolling or roller too tacky. In the last case, clean ink off roller and sponge with a saturated solution of alum. (N.B.—Don't use this sponge afterwards on the "Sinop" plate.)

VI.—CLEANING UP THE PLATE.

When the printing is done, it is necessary to clean it, so that it can be used at any subsequent time. A plate that has been handled with care is capable of supplying a considerable number of prints; up to 300 have been taken off one plate without showing any deterioration.

The ink should be removed by pouring on the plate a quantity of turpentine sufficient for diluting the ink, spreading the turpentine all over the plate either with the finger or with a soft linen rag. When so diluted with turpentine the ink can be readily washed away with a sponge and water until no traces remain. Wash the sponge carefully after this operation.

The plate is afterwards immersed in water for one or two hours, and is then allowed to drain and dry. When the plate is dry there is no longer any trace of the image. In this state the plate will keep good for years if preserved from damp. When required for use again, the "Sinop" plate is wetted by soaking in the water and flowing glycerine on, in the same way as for a new plate. It will then give equally as good results as the latter will yield.

It is recommended that the roller and inking board be cleaned up each time with turpentine after the printing is finished, otherwise the roller and ink cannot be relied upon to be in condition for the next plate.

Tidiness and cleanliness in performing the operations go a long way towards securing successful results. The instructions must also be carefully adhered to.

THE NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION. OFFICIAL REPORT.

REPORT OF MEETING HELD AT THE MIDLAND GRAND HOTEL.

A meeting of the National Photographic Record Association was held by the invitation of the president, Sir J. B. Stone, M.P., at the Midland Grand Hotel, Tuesday, November 4th, 1902, which was well attended by members and friends. The president exhibited a series of prints of the Coronation ceremonies, the Welsh Eistedfodd, the Kern Baby Celebration at Whalton, Northumberland, and the Installation of the Master of one of the City Livery Companies—the "Girdlers"; and other prints were shown by Mr. H. W. Fincham, Capt. G. W. Cosens, and by the hon. secretary.

The Hon. Secretary (Mr. George Scamell) read the following report: The council have again much pleasure in presenting their annual report, and to congratulate the members on the steady progress of the work, not only of collecting prints for the British Museum, but also on account of the general interest that is being taken in the object of the association throughout the country.

Since our last report 593 prints have been received, Sir J. Benjamin Stone has contributed a series of St. James's Palace, Sandringham Hall, Frogmore, and of some of the old mansions of England, including Hatfield House, Houghton, Norfolk, built by Sir Robert Walpole, Hunstanton Hall, Holkham, Lynedon, Charlecote, Warwick, the home of the Lucys, Ashby St. Ledgers manor house, Catesby's house, and a series of prints of the Tynwald Day ceremonies of the Isle of Man. Mr. Diveri has again favoured us with sixty prints from his valuable Scotch collection, including views of the Royal Palace, Linlithgow, Castle of the Boyne, Craigmillar, and Ballindallock Castle, and some of the old Incised Stones; Mr. Fincham has sent in a very fine series of St. John's Gate, Clerkenwell, and some of the old courts of that neighbourhood, and of St. John's Crypt, the remains of St. John's Priory; from Mr. A. Victor Haslam we have received a set from Iona, of the Cathedral, and some of the Monuments; from Mr. Armytage, some views of Buildwas Abbey, and some old bits of Pembridge,

Herefordshire; Mr. H. W. Smith forwarded views of Kirkstall Abbey and the Cloisters, Chester; to Mr. E. J. Felce we are again indebted for some of his fine examples of old Northampton work, some of the Carved Panels in Abington Abbey; Mr. Cecil Gethin, hon. secretary of the Herefordshire Survey Society, has favoured us with a set from Hereford Cathedral: from Mrs. Gandy some views of Wingfield Manor, Derby; Mr. Parkinson has forwarded a complete set of that most interesting monument, the Eastern Sepulchre, at Navenby, Lincoln; Mr. A. J. Loughton, Carvings of the Caps of the North Pier, Southwell Minster, Notts; we also have to acknowledge prints of interest from Miss Beedham, Mrs. Muriel, and Mrs. F. G. Emler, A. J. Loughton, F. Littledale, G. W. Cosens, G. W. H. Tyndall, and a series of the Churches of Herefordshire from the hon. secretary, Mr. G. Scamell.

The association have again to thank Mr. Horsley Hinton and the proprietors of "The Amateur Photographer" for having promoted a competition for record work. A large number of prints were sent in and prizes awarded. A selection was made and 132 prints were presented to the association. This year they are again promoting a competition on a larger scale, and in addition to offering medals for private work, a valuable prize is offered for the best collection of work of a photographic society.

Photographic survey work is now being seriously carried on in many districts, and since our last meeting a public meeting has been held in the Town Hall, Croydon, for the purpose of starting a survey society for the county of Surrey, when a strong committee was elected, with Mr. H. D. Gower as hon. secretary; and the Croydon Camera Club, Mr. Hector Maclean, president, have also joined in the movement, and have offered medals to their members for the best record prints. The Photographic Survey of Shropshire is making considerable progress. Mr. F. R. Armytage has arranged with the Corporation of Shrewsbury, and they have undertaken to mount suitable prints to be preserved in the Free Library. An exhibition of prints has been held in the Camera Club's rooms and at the School of Art, which was attended by a large number of the leading inhabitants. The survey of Leicestershire has been taken up in a thorough systematic way and gives promise of doing valuable work under the guidance of a strong committee, with Mr. H. A. Roehling as hon. secretary. Efforts are also being made to commence work in the Isle of Thanet, and in connection with the Hampshire Archaeological Society. Many of the librarians of the public libraries are also interesting themselves in the collection of records of their particular neighbourhood, and we have been in communication with the librarians at Edmonton and other places. No doubt all these various fresh centres coming into existence will interfere to a certain extent with our own collection, as many prints will be added to the local museums instead of the British Museum collection, and although we may regret this, at the same time it must be a source of gratification that prints are being collected and preserved by responsible bodies for public reference.

A representative collection of Sir J. Benjamin Stone's record work has been arranged by Sir C. Purdon Clarke, which has been on exhibition at the Imperial Institute. Since then the prints have been put into circulation and have been on view at various local museums in connection with South Kensington, and are now being exhibited in the West of England.

The thanks of the association are due to the council of the Royal Institute of British Architects, who kindly lent their rooms in March last for a small exhibition of record photographs. Sir J. Benjamin Stone attended and opened the exhibition by an address, which was fully reported in the journal of the Institute of March 8th, and the hon. secretary attended and gave a short account of the work of the association to the Architectural Association.

Whilst thanking their numerous friends for their contributions the council would again appeal, first for further contributions to the funds, as, when in a position to do so, they can obtain many valuable prints from negatives held by the professional photographer at a very moderate cost, and they would also ask the amateurs to look through their stock of negatives, as there must be an immense number of negatives in their hands from which prints of great value to our collection could be produced.

Sir J. Benjamin Stone was warmly greeted on rising to move the adoption of the report. He asked those present to excuse the fact of his being so palpably present amongst them, in so many parcels of photographs, whole plates and enlargements. What he had tried to do and show them was simply to be taken as an example of what could be done all over the country. Those before them were simply what he had done himself. Yet they exhibited in a pictorial form better than any printed description could convey what the incidents accompanying the Coronation were like, and these would carry the living presentation of the ceremony to all future times. (Applause.) There were in all about 300, and they included not only the street pageant attending the Coronation, but also the representation of the erections—such as the annexe to the Abbey, the appearance within the Abbey, the Coronation Chairs of the King and Queen, the appearance of the altar, the decoration of the streets on every part of the route, as well as the Royal progress through the City; but also the detachments of Colonial

soldiers, the Royal guests, and many portraits of eminent men and women who were in London at the time of the Coronation (Applause.) Then, besides these, he had visited different parts of the country and photographed some of the quaint customs which still survived from ancient times. Amongst these they would find a collection taken at the meeting of the Eistedfodd, in Wales, which would preserve the details of that ancient and interesting ceremony, and the portraits of those who took part on the occasion. Another interesting series consisted of the incidents attending the Kern Baby celebration in Whalton, in a remote corner of Northumberland. This was possibly one of the most ancient rites which existed, and descended from the festival of Ceres, established by the Romans during their occupation of Britain. In Whalton a sheaf of corn was arrayed in the white dress of a woman, the ears of corn forming the fingers, and the ears in a great bunch making up the head. This was borne to church on Harvest Sunday, and on the Monday was carried through the village on a pole, and finally set up at the Harvest Festival rejoicings. They had to acknowledge with thanks the presentation of a large number of gifts from different parts of the country, and he sincerely believed that the object for which the association was formed was being slowly but surely realised. (Applause.) Before resuming his seat he wished to bear testimony to the good services rendered the association by their hon. secretary, Mr. G. Scamell.

Mr. C. Welch seconded the adoption of the report, and congratulated the association on their work, and had no doubt of the advantages of having one leading record association to keep in touch with the various local survey societies, to be the means of communication, and so, to a certain extent, to centralise the work. As librarian of the Corporation Library of the City of London he was glad to find librarians generally were interesting themselves in making local collections. He had found the value of record work, and that it was now being appreciated was shown by the number of applications he had had from various gentlemen to search the City records, when preparing the lectures to be given (with photographic illustrations) at the board schools. The library committee of the City Corporation were arranging for an exhibition of Sir J. Benjamin Stone's Coronation ceremonies at the Guildhall.

The motion was adopted by acclamation.

The Rev. J. O. Bevan proposed a vote of thanks to the council and officers of the N.P.R.A. He did not agree with Sir J. Benjamin Stone, as he did not consider a society having such important ends could be an unimportant society; the work they were carrying on could no longer be considered of a local nature, but national. In the preservation of buildings, monuments, customs, etc., time was not on our side, in fact both nature and man are against us, so much the more necessary it is that a systematic effort should be made to retain records. In Ireland the old monuments have been much better preserved than in this country, and such a piece of vandalism as has taken place at Dartmoor, where an old stone circle has been removed, and used to make a road, could not have happened in the Sister Isle.

Mr. A. P. Graves seconded the motion. He said the first inception of the society was due to Sir J. B. Stone. As an Irishman he quite agreed with the Rev. J. O. Bevan, but still much remains to be done if we are to prevent interesting remains from being put to agricultural uses. As an inspector of schools he strongly urged the greater use of photography in schools, and now that most of the board schools have good halls he should like to see them hung with photographs of local and other views which might be turned to good account in the training of the scholars.

The motion was carried unanimously.

Sir C. Purdon Clarke moved the re-election of Sir J. Benjamin Stone as president for the year ensuing. After referring to the work already accomplished, he said he well knew the value of photographs, having some 160,000 under his charge at the Kensington Museum. He wished to draw particular attention to one set of photographs on the table—viz., the ceremony of the installation of the master of the Girdlers' Company, and trusted Sir J. Benjamin Stone would follow it up by obtaining records of similar ceremonies of some of the other lively companies of the City of London. He would also draw attention to the value of records of passing events, particularly on account of the costume, as that is often the only means of fixing the date of other events by comparison of costume.

Mr. H. W. Fincham seconded the motion, and trusted when funds would allow the association would prepare lists of all prints in their collection, so that workers might know what had been done, and so prevent duplication.

The Hon. Secretary replied he had already indexes of all prints, one of the subjects, and one grouped in counties, and would be at all times ready to supply any information regarding the collection to any one upon application.

The motion was then carried.

Sir J. Benjamin Stone thanked the meeting for his re-election, and then moved the following list of council and officers for the year ensuing: The Right Hon. the Earl of Crawford, K.T., Sir E. Maunde Thompson, K.C.B., D.C.L., Sir H. Trueman Wood, M.A., Harold Baker, C. E. Fagan, L. Fletcher, F.R.S., A. V. Haslam, A. Horsley

Hinton, St. John Hope, F.S.A., B. E. Lawrence, LL.D., A. Mackie, J. W. Marchant, Dr. H. R. Mill, Ralph Nevill, P. Norman, F.S.A., N. B. Stone, H. Snowden Ward, Mrs. Catharine Weed Ward, H. B. Weatley; hon. treasurer, Alexander Graham, F.S.A.; hon. secretary, George Scamell; which was carried, and the meeting terminated.

Exhibition.

EDINBURGH PHOTOGRAPHIC SOCIETY'S.

Last year, or rather last season, for it was in the spring of this year, this society experimented. It abolished classification and gave only one class of medal, a bronze; but two sections were retained, one open, and one confined to members who had never gained a medal at the exhibitions of the society. This latter class is not exactly a novice class, as we have members exhibiting in it who have gained medals elsewhere. This season the same course is adopted, but the date of the exhibition is altered from Feb.—March to Nov.—Dec. The entries number in all 279, of which 141 are in "open" class. But even in the "open" class the very large majority of the work is by members, with the exception of two frames from E. G. Boon, Alasio, Italy, all the work is British, with a largely predominating flavour of E.P.S. The exhibition can, therefore, hardly be called representative, but it shows that the E.P.S. has in its 500 members not a few who are quite qualified to exhibit in any company, although the percentage of members' wins (i.e., medals won), two out of five, is lower than last year, when it was four out of five. The judges were Messrs. G. Ogilvy Reid, R.S.A., Edinburgh; Harold Baker, Birmingham; and Charles Sweet, Rothesay.

The need of a proper hall for their exhibitions is still very evident, but it is pleasing to know from the address of the energetic president, Mr. Burns, that the acquirement of larger and more suitable premises is a goal for which the society is unceasingly striving.

Following the catalogue, we find that W. J. Byrne, Richmond, gains one of the coveted medals with "Study of a Head" (2), much the superior of the two works he has submitted to the judges; the veteran he has had as a model has a magnificent head with a wealth of silver hair, and the strong, virile characteristics of the old gentleman have lost nothing at Mr. Byrne's hands; the clothing and background are subdued and the spectators gaze is riveted on the head. Not only is it pictorial, but we feel sure it is a good likeness; here we have that rare combination of studio and exhibition work in one picture. R. S. Webster has several good pictures hung, but none better than his small, full-length portrait of "Mrs. Argyll Robertson" (17), in which that lady is charmingly posed and lighted; it may have been done in the studio, but it has a quite "at home" look, and "at home" work in its best sense is associated with Mr. Webster. "Woodcutter" (21), by Charles F. Grindrod, next claims attention. It is nearly, but not quite, a replica of his medalled "Woodcutters" of last year, the theme and treatment are similar. W. J. Croall gains a medal with "Bulldogs" (24), a picture we drew attention to at the Dundee Exhibition, where it took a "first" medal; it is a striking work, marred by a white dog in the foreground, which is not only obtrusive, but does not aid the picture in the slightest; with that blemish absent we could have a photographic "Landseer"; two landscapes and a large "Head of the King's Lion, Sultan," complete Mr. Croall's exhibit. "A Masterpiece" (25), by James Patrick, represents one of Scotland's well-known painters, but his best exhibit is "When Love Laughs in her E'e" (111), where he gives a telling interpretation of a rural scene; the composition is at once simple and complete—the various items combining to form a harmonious whole. Well might he be called, as one visitor was overheard baptising him, the Scottish H. P. Robinson. W. R. Lathbury, Bristol, has three good architectural pictures, the finest, perhaps, being "As Day Steals on Night, Melting the Darkness" (27), which has been medalled elsewhere. "Marcistee, Mich., U.S.A." (37), by W. Drummond Young, jun., gains a medal, it is a sand-dune picture, a symphony in tones; the other pictures he shows, with one exception, are unfortunately so inferior that one wonders he exhibited them. "A Scottish Professor" (40), is a breezy and life-like picture of Edinburgh's pet, Professor Blackie; his "John McWhirter, R.A." (95) is also strongly limned, while he has treated "Portrait of a Lady" (121) with reverence and presented a picture of a typical old Scots lady. "The Triforium Staircase" (50), by Vanessa C. Baird, is an architectural "bit," redeemed from the commonplace, in fact, made by a gleam of light in the distance, which at once gives the picture depth and character, it is a real *multum in parvo*. Graystone Bird in "Good Morning" (52) and "Fair Innocence" (53) gives us examples of what dainty work we have come to associate with his name. "A Beech Study" (45), by G. G. Boon, is a strong bit of character drawing while the title of his other work, "Reflections" (70) sufficiently describes it. There is rare quality in "Portrait Study" (57), by T. Pursey, while "Study" (58), by Charles M. Wane, is a sample of studio work sufficiently out of the ordinary grouping to command

attention. "Feeding the Sheep" (71), by Charles E. Walmsley, gains a medal, but probably no award in the exhibition has been more adversely criticised; the scene is evidently one hill-top, the arrangement of the sheep and pony are good, but the man is very evidently posed, and the picture foreground, distant hill and clouds, seem all on one plane; and yet we are informed it has been sold to an eminent artist—there must be something in it that we are unable to decipher. "Iris" (81), by John M. Whitehead, seems too cramped and his "Honesty and Apples" (120) is too hard and metallic, but his other contributions are in his best manner; general surprise was expressed that his R.P.S. medalled picture had been unnoticed by the judges; the more study given it the more the wonder grew; it is probably as fine a rendering of the lines which give it its title as could be imagined, and yet—. "By Banks o' Fleet" (82), by R. M. Readdie, is a delicate little work with a fine suggestion of atmosphere. "The Lonely Moor" (94) is a fine landscape, carrying out its title well, but marred by a sky.

A number of the members whose work we have had the pleasure of favourably reviewing at former exhibitions seem to have fallen from their high estate, at least the work they submit is not nearly up to the standard they have led us to expect.

Section II., taken all over, is weak, with good work scattered through it; we were surprised that the delightful work of Mrs. M. L. Herdman Newton did not gain recognition, her "Gossip" (259) being a lovely example of that class of work identified with the late H. P. Robinson, and considered by several to be the best thing in the section.

The following is a detailed list of awards:—

Open Section.—Medals—"Study of a Head" (2), W. J. Byrne, Richmond; "Bulldogs" (24), W. J. Croall, Edinburgh; "Marcistee, Mich., U.S.A." (37), W. Drummond Young, jun., Edinburgh; "The Triforium Staircase" (50), Vanessa C. Baird, Broughty Ferry; "Feeding Sheep" (71) Charles E. Walmsley, Ambleside.

Section II. (Members).—Medals—"A Misty Morning—Glasgow Exhibition" (209), J. A. Trevelyan Sturrock; "Ploughing" (233), John R. Sandilands; "The Evening Chapter" (259), J. Drummond Shiels; "A Lowland River" (247), Fawcett Clapperton; "An April Evening" (248), Robert Lees. Honourable Mention: "Thistles" (190), Ewen Kennedy; "Off the North of Ireland" (205), Professor D. W. Finlay, M.D.; "Portrait Study" (211), Mrs. Mary Cooper; "In the Cathedral, Amalfi" (274), Mrs. Mary Cooper.

The medals were distributed at the opening ceremony on Saturday. To-morrow Mr. Alfred A. Murray, LL.B., W.S., will deliver a lantern lecture entitled "By Stockholm to Lapland": the following Saturday there will be a smoking concert arranged by Mr. John Anderson.

New Books.

"Photographische Bibliothek." Verlag von Gustav Schmidt. Vol. I. Vogel-Hanneke. Das Pigment Verfahren.

This is the fourth edition of the late Dr. H. W. Vogel's treatise on carbon printing, revised and brought up to date by Paul Hanneke. The principles of carbon printing are dealt with in the opening chapter, and in those which follow we have a detailed account of the various manipulations and the recent modifications of the process known under the names of Gum-bichromate printing, the Artigue process, and Ozotype. The text is well illustrated, and the frontispiece is a charming study of a child, upon paper manufactured by the Autotype Company.

Vol. XV. Fritz Loescher. Vergrössern und Kopieren auf Bromsilberpapier.

The use of the hand camera and the tendency during the last few years to still smaller negatives than the quarter-plate size, have given bromide printing by enlargement a great impetus. The advantages gained by using a small camera are so evident, that we have little doubt amateur photographers will give much more attention to bromide enlargement than they have even hitherto done. The volume before us will be found a very complete guide, and we can recommend it with confidence to those who wish for information in this branch of photography.

A SUBSTITUTE for Celluloid.—The extensive commercial use of celluloid has caused many people to seek for substitutions or imitations of it. In Germany, in the vicinity of Coburg, an imitation has been made by dissolving in 16 parts—by weight—of glacial acetic acid, 1.8 parts of nitro-cellulose, and adding 5 parts of gelatine. Gentle heating and stirring are necessary. After the mass has swollen, it is mixed with 7.5 parts of alcohol, and stirring is continued. The resulting product is poured into moulds, or after further dilution may be spread in thin layers on glass. Consul-General Hughes, of Coburg, is of opinion that "as an underlay for sensitive photographic films, the material has important advantages, not the least being that it remains flat in developing."—*Journal of the Society of Arts.*

Commercial & Legal Intelligence

PATENT Law Amendment.—Last week, in the House of Lords, Lord Wolverton moved the second reading of the Patent Law Amendment Bill. His lordship said the President of the Board of Trade had long recognised the necessity for amendment in the patent laws of this country, firstly, because patents were often granted by the Patent Office and proved to be practically valueless, as that office at present had no charge upon them to enquire whether such applications had not been already allowed; and, secondly, because very frequently patents were taken in this country by foreigners and others who had no intention whatever of working them here, or of granting licenses to British manufacturers to use them. The proposed changes had been based upon the report of a strong committee, presided over by Sir E. Fry. Provision was made in the measure for a limited official enquiry into applications for patents, with a view to ascertaining whether they had been anticipated during the past 50 years. It also provided for the transfer to the Judicial Committee of the powers of the Board of Trade in respect to the granting of compulsory licenses. This would give a patentee some security, and would modify the amount of the fees. With increased business, the office would still be self-supporting. Already the Bill had passed its stages in another House, and obtained the approval of the trade communities. The Board of Trade felt sure it would effect a great amendment in the existing law.

OBTAINING a Camera by Fraud.—William Philip Dabbs, 23, commission agent, of Ringcroft Street, Holloway, was charged on remand, at the North London Police Court on Thursday last, for fraudulently obtaining a variety of articles from persons in various parts of London and the provinces. Mr. Gordon Cuming Whadcoat defended the prisoner. Detective-sergeant Jennings, of the Y division, said that the prisoner, under the aliases of G. White, A. Skipper, G. Walters, J. Robinson, and A. Shepherd answered advertisements in the "Exchange and Mart" newspaper, and thereby obtained a camera from Liverpool, a watch from Sheffield, etc. The cases of the camera and the watch were only now gone into, and Mr. Henry Norwood, of Yew Tree Road, Liverpool, and Mr. E. Harrison, of Fitzalon Street, Sheffield, deposed to sending these articles on the prisoner's assurance that he would at once remit the cash. Neither of these witnesses had seen the prisoner before, but letters and pawnbrokers' duplicates found in his possession showed that the property (now produced) had come into his possession. Henry Spencer (one of the aeronauts) was called by the police to speak to the prisoner's handwriting, but he could not say that the writing now produced was the prisoner's. From the cross-examination, it was gathered that the prisoner had been on one of the balloon expeditions, and had nearly become asphyxiated by the gas. There were several other cameras, opera glasses, and other articles found in the prisoner's room, as well as fifteen pawntickets, but the prisoner said that the tickets relating to a gold watch, chain, and pin were his own property. Mr. Whadcoat intimated that his defence was that the prisoner's senses had been dulled by his partial asphyxiation mentioned, and he added that the prisoner had given the police every assistance. Detective Jennings said he considered the prisoner remarkably acute, but as he had about a thousand letters to go through, he would like another remand. Formal evidence was given of the prisoner receiving letters and parcels addressed to him respectively at the shop of Mrs. Bateman, tobacconist, of New North Road, and Mr. Robert Thomas Wigmore, newsagent, of Gray's Inn Road, which addresses were those to which the watch and camera were respectively addressed. Mr. Fordham granted the remand, and on a question of bail said he would consider it next time. He would, however, require two sureties of £100 each.

Re George Francis Readwin, artist and photographer, Pelham Road, New Catton, and carrying on business at 131a, Magdalen Street, Norwich.—The first meeting of the creditors interested under this failure took place at the offices of the Official Receiver, Norwich, on Friday last, before Mr. H. P. Gould (Official Receiver). The statement of affairs filed by the debtor disclosed liabilities amounting to £180 ls. 9d., and assets estimated to produce £121 5s. 4d. He alleges as the cause of his failure "doctor's bills in connection with the ailments of my wife, bad trade, and ill health." The Official Receiver, in his observations, says that the proceedings were instituted by the debtor on his own petition in consequence of pressure from creditors. The debtor commenced business as a travelling photographer about 1892 without capital. Since September, 1899, he has carried on business as a photographer. There was no quorum of creditors present, and the Official Receiver remains trustee in the bankruptcy.

Re George Alfred Woodfield, photographer, New Brompton, Kent, formerly carrying on business in Hard Street and Week Street, Maidstone.—This debtor made an application for his discharge at the Maidstone Bankruptcy Court, before his honour Judge Emden, on Thursday last week. It appeared from the Official Receiver's report on the case, that the receiving order was made in January, 1899. The statement of affairs filed by the debtor discloses liabilities amounting to £134 2s. 4d., and assets estimated to produce £50 2s. 6d. In reply to questions, put by the Official Receiver, the debtor stated that his earnings now amounted to between 25s. and 35s. per week. He had two in family. Mr. Ellis, who appeared on behalf of the debtor, stated that the debtor's business rapidly declined in consequence of the severe epidemic in Maidstone a few years ago. The Official Receiver had alleged in his report that the debtor had committed an offence

under the Bankruptcy Act by not paying his unsecured creditors a dividend of 10s. in the £. He, of course, could not dispute that, and unfortunately it was quite impossible for the debtor to make the dividend up to 10s. in the £, and so obtain an immediate discharge. He submitted, however, that this was a case of misfortune, and he hoped his honour would deal leniently with the debtor. His honour said it was one of those cases in which, if he had the power, he would grant an immediate discharge; but he was bound by the Act of Parliament to suspend the discharge for at least two years. He should therefore suspend the discharge for the minimum period allowed by the Act, viz., two years.

Re Francis Albert Woodcock, photographer, Douglas Head Road, and 15, Lodge Lane, Liverpool.—The above-named debtor appeared for his public examination at the Liverpool Bankruptcy Court on Thursday last, before Mr. Registrar Bellringer. The statement of affairs filed by the debtor disclosed liabilities amounting to £174, and net assets estimated to produce £12 8s. The bankrupt attributed his bankruptcy to "the failure of the recent Isle of Man season." In reply to questions put by the Official Receiver, debtor stated that he had been a photographer in Douglas Head Road for about twenty years, and his father had been in the same line of business before him. He had lost about £250 the last two years owing to bad seasons and opposition, but before that he had made plenty of money and had banked plenty. Last year his earnings were not more than £40 a week during the busy season, which was from the end of July to the beginning of September. The whole season was from Whit week to September, 12 or 14 weeks usually, but a good portion of that time he lost money owing to bad weather and the visitors leaving. The best week was usually "Scotch week," or the last week in July, when the Scotch people took their holidays and came over in great numbers. That they termed the "Glasgow Fair," and was generally the best week in the season. If they had wet weather then, they (photographers), generally lost £100.—The Official Receiver: Do you mean that you get the Scotsmen to have their photographs taken over there?—The Bankrupt: Well, when they go to the Isle of Man they go to enjoy themselves, and they like to have their photos taken with the donkeys, or in boats with drowning scenes. (Laughter.) They spend their money freely in Scotch week, and if it is bad weather we have a bad time all through the season.—The Official Receiver: But there are other weeks that the weather is good?—The Bankrupt: Yes; but they are not there to spend their money. In reply to further questions, the bankrupt stated that he took about £250 last season, and a little more the year before, but they were both bad seasons, and the net profits would not be more than £50 on that amount after paying rent of ground, labour and materials. In a busy time he paid £18 a week in wages. His effects in the Isle of Man at the present time would not be worth more than 30s., and his Lodge Lane place was merely his home and winter studio. A place he had had at 91a, Great George Street, Liverpool, did not pay, and he was turned out for arrears of rent. He had also had a travelling wagon, but it did not pay, and he sold it twelve months ago. The examination was adjourned for further information.

CINEMATOGRAPH Profits and Losses.—At the London Bankruptcy Court on Tuesday a sitting was held, before Registrar Linklater, for the public examination of A. Duncan Thomas, of Manchester, Sheffield, Colwyn Bay, Edinburgh, and elsewhere, cinematograph operator. The receiving order was made on a creditor's petition in May last, the debtor now applying to pass his public examination on accounts showing gross debts of £9,472, of which £8,959 was unsecured, and assets £372. In examination by Mr. Boyle, Assistant Receiver, the debtor stated that for some years he was engaged in farming in Devonshire, with a relative. On the death of the relative in 1893 he purchased a phonograph, and went on tour with it until 1897, when he purchased one of Edison's projectoscope machines, and exhibited at the London halls. He exhibited the Spanish-American war pictures, which were also taken on tour on the Continent. He afterwards purchased other machines, and toured with them under management throughout the country. He had an exhibition in Edinburgh, which he afterwards handed over to his wife. At Colwyn Bay he used to show in a tent, and one windy night the tent was blown into the sea and most of his stock was lost. Just prior to that—in 1899—he sold his machines, which cost £1,000, to his brother-in-law, who had been his manager, for £200, and his brother-in-law completed the tours which were then open. In 1900 he opened at Newcastle on a large scale, and cleared £900 in three weeks. He extended his business to six shows, which he conducted with managers. The business increased, and in 1901 he had fourteen shows running. It was during that year that a proposal was made to turn the business into a limited company—the Thomas-Edison Animated Pictures Company, Limited, with a capital of £100,000. He was to be managing director. The prospectus was not sent out to the public. Towards the end of 1901 the shows began to fall off owing to the approaching end of the Boer war. Early in 1902 he was introduced to a Mr. Turner, who was forming a limited company to acquire and work cinematographs. The name was the British Bioscope Company, Limited, the capital being £50,000. He was to be manager. His profits on his prior working shows were put down at over £10,000. He was not aware that his stock was valued at £13,000. That he believed was the cost price of it. The company was not floated. It was after February last that his machines began to be sold for rent, and he estimated such loss and the depreciation on machine films, etc., at £6,706. The liability he was under in connection with the halls at Manchester and Sheffield was £894. He had received from his wife sums amounting in the aggregate to £900. The

money was not sent to him as the takings of the Edinburgh business. It was money lent. The Edinburgh business he gave to his wife in 1900, since which time he had had nothing to do with it. Acting on his advice, she agreed to sell it to the company for £2,000, half of which was to be in cash, but the company was not floated, and the business still belonged to her. She was not proving against him for the £900. The examination was ordered to be concluded.—“Morning Post.”

PHOTOGRAPHIC INSTRUCTION IN AUSTRALIA.—We are unable at the present moment to note what is being done in the Commonwealth with the object of placing photography within the reach of the increasing army of young folk. In New South Wales, however, outside of the Government Technical Colleges, whatever movements have been made in this direction are almost entirely the result of the energy and enterprise of the firm of Messrs. Harrington and Co., Limited. We have previously referred, with pleasure, to the establishment by this firm of mid-day classes of free instruction to all and sundry who wish to make a more rapid advance than would be probable without advice. We have ourselves become associated somewhat with the management of these classes, and have recently, at the instigation of Messrs. Harrington and Co., approached the teachers and governing bodies of our public and private schools, with a view to giving free instruction to classes of the scholars. The result has been most encouraging. The masters and leaders have received the proposals with enthusiasm, and the result is an arrangement to carry on a series of lectures and demonstrations for the benefit of all those young people interested in photography. And they are many. Such schools as the Sydney Grammar School and the Fort Street Public School have eagerly seized the opportunity offered, and many of the lesser schools are equally enthusiastic. The masters are generally quite in accord with the view we have expressed—that photography ought to be placed in the school curriculum, but, so far as the public schools are concerned, this innovation cannot be introduced at once. The boys' classes, which have already been established, have quickly proved most successful, and encouragement has been given to the learners by several of the schools having notified their intention of holding competitions and awarding prizes periodically, and at the “breaking-up” for holiday time—“Australian Photographic Journal.”

THE POSITION OF ART IN EDUCATION.—A deputation from the Society of Art Masters waited on Lord Londonderry, the President of the Board of Education, last week. Mr. W. F. Lawrence, M.P., who introduced the deputation, explained that its members were headmasters of schools of art in the country, who wished to point out that the actual teaching side of the subject of art education was under present circumstances improperly represented. Mr. Stevenson and other members of the deputation then spoke. They complained of the insufficient qualifications of inspectors in art schools, and argued that art masters and experts should have a place on the advisory council for art purposes, and advocated co-ordination of study in elementary schools and institutions giving advanced art instruction. The whole of art subjects and technological subjects related to art should be kept absolutely separate from science, and be placed under the control of qualified art masters only. Although for convenience sake art and science schools might be carried on in the same building, the two subjects should be taught in separate schools. The present was considered an opportune time to bring the matter forward, as the Government Education Bill was before Parliament. In several cases science inspectors had ventured to report on art instruction in the schools. They contended that art teaching was just as important in elementary schools as science or anything else in view of the many industries in which knowledge of art in some of its branches was a necessity. Lord Londonderry, in reply, said that he understood that the deputation's opinion was that in view of the recent introduction of the block grant which created the necessity for more complete inspection, the inspectors in schools of art, art classes, polytechnics, secondary and elementary schools must be experts in art instruction. A detailed inspection at long intervals had been arranged for. The Board also had at their disposal the services of occasional inspectors, whose qualifications had been looked upon as of the most valuable kind; and steps had been, and were now being, taken to extend their operations to other schools, in addition to schools of art. As to the suggestion that it was desirable to co-ordinate the instruction in drawing and art in primary schools with that given in schools of art, he agreed that this was a very important point; but for the present it was necessarily mainly a matter for local arrangement. The Board of Education had encouraged such co-ordination and the employment of art masters in connection with it. In Birmingham, Leicester, and Burslem co-ordinated schemes were successfully working, and other localities would doubtless be encouraged to adopt similar schemes. The deputation had suggested that the age limit of inspectors, at present fixed at 35, be removed, as it deprived the Board of the services of the best qualified men. This age limit, however, was in force in other departments of the State as well as the Board of Education, and was in the interests of the public service. But where it was thought necessary to obtain the services of gentlemen of more mature age, it seemed better to utilise them in a temporary capacity. The Board had done this in the past, and intended to do so in the future. Respecting the deputation's desire for representation on the Teachers' Representation Council and on the Council of Advice for Art, he said that the regulations governing the matter were under the consideration of the consultative committee, and the recommendation of the deputation to include the Royal College of Art on the same lines as the Royal College of Science should be submitted to it.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

ROYAL PHOTOGRAPHIC SOCIETY.

NOVEMBER 18TH.—Mr. J. C. S. Mummery in the chair.

The first lantern meeting of the present winter session was the occasion of the delivery of a most interesting lecture by Mr. John Gunston upon the beauties of

CHAMONIX.

Chamonix is a centre offering great opportunities to the photographer, and that Mr. Gunston has fully grasped these the slides form ample evidence. His pictures of glaciers and the kind of mountaineering that it is within the power of the ordinary tourist to accomplish are probably second to none. There is a fine technical and pictorial quality about them that is too often missed by photographers working under similar circumstances, and this, added to his intimate knowledge of the country, which was obvious from his remarks, lent additional charm to the lecture.

A hearty vote of thanks was passed to Mr. Gunston for his entertainment.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 20TH.—Mr. A. Mackie in the chair.

Mr. R. P. Drage passed round two or three prints toned some ten years before with a combined toning and fixing bath. They did not appear to have perished or suffered in that time, and were not yellower than when produced. Mr. Drage also mentioned a difficulty he had experienced in preventing the cockling of certain negative films after stripping the paper support.

The Chairman said that if Mr. Drage mounted the negative, before stripping, on a piece of cardboard, paper support to the cardboard, and stripped when quite dry, there would be no trouble. Mr. Drage added that the film often stripped quite flat, but cockled in the printing frame.

THE CONVENTION SLIDES.

Mr. H. C. Rapson gave an interesting discourse upon the places visited this year by members of the Photographic Convention of the

United Kingdom. After making a progressive tour of the colleges and places of interest within the city of Cambridge, and explaining at length their features, he took his audience to Bury St. Edmunds, Lavenham, Milford, and other attractive places in the neighbourhood. The photographs and the accompanying descriptive notes were much appreciated.

CROYDON NATURAL HISTORY AND SCIENTIFIC SOCIETY.

WHEN invited by the executive of this Society to lecture to the members on the subject of "Process Block Printing," Mr. J. J. Waddington realised that such a lecture would in itself be incomplete, and hit upon the happy idea of inviting the members to witness a practical demonstration at his works, 49, London Road, Croydon, on Friday evening. After welcoming his guests, Mr. Waddington gave a general description of the process, from the moment that the original picture is handed to him until the finished block, mounted type high, is ready for delivery to the publisher for whom it has been prepared. Mr. Waddington is a past master in the art of engraving, every detail of which he has at his fingers' ends, and, what is more, he possesses to a very high degree the ability to describe the intricacies and technicalities of the process in such a lucid style that even the most uninitiated of his hearers can follow and thoroughly understand him. The visitors were taken through every department of the works, and witnessed every incident and detail in the preparation of a process block in actual operation, accompanied by a running explanation or commentary, either by Mr. Waddington himself, or by members of his experienced staff of workers. They were greatly surprised to see how many delicate processes a plain plate of copper has to go through before it becomes a process block, and, interested as they were by the able description given at the outset, this feeling was as nothing compared with the rapt fascination with which they watched the process being actually worked out until they saw one of those beautifully-finished plates which have won the firm of J. J. Waddington, Ltd., a leading place among the illustrators of our high-class magazines. The visitors could not fail to be struck with the immense strides that have been made in this art in recent years, and it is largely due to Mr. Waddington, who is an enthusiast in his work, and others that England has maintained that pride of place which the Americans at one time threatened to take from us—if, indeed, they did not actually do so for a short time—in the production of process blocks. At the conclusion of the demonstration the delighted visitors cordially thanked Mr. Waddington for his lecture, and for the kindness which had prompted him to keep every department of his works going until so late an hour for their edification and instruction.—"Croydon Advertiser."

CROYDON CAMERA CLUB.

CROWDED attendances have been the rule since the opening of the winter session, and Wednesday, the 19th inst., proved no exception, the members assembling in force to hear Mr. P. Leuthardt lecture on a new printing-out paper called "Mattos," the invention of a Mr. Tauxe, of Switzerland.

Its method of manufacture was stated to be a secret, but from what could be gathered it appeared that the paper is sensitised with an emulsion of albumen and a silver salt, and another metal not named, in conjunction with barium sulphate, and that several distinct operations are necessary to reach the finished article. That barium sulphate has the power of precipitating colloids has long been known to chemists, and apparently the inventor has turned this fact to good account. Be this as it may, Mattos paper produces vigorous prints of great beauty, and with an absolutely matte surface, but without the sunk-in appearance sometimes characteristic of plain salted papers. So fine indeed is the coating, that the sensitised side is indistinguishable from the back, the latter being marked to identify it.

The emulsion is coated on various grades of rough, smooth, white, and tinted papers, and can also be applied to fabrics, including silks, satins, and gauze. Even wood can be brought into requisition. Its applicability is therefore extensive. An opaline paper is deserving of separate notice. Thin and semi-transparent, colouring can be applied to the back, and in skilful hands with charming effects. Practically grainless, it would also seem a suitable medium for making a negative by contact from an enlarged positive; several small paper negatives were shown, together with excellent prints therefrom.

The tones obtainable range from red browns, through fine sepias, to a pleasing warm black. A lactic acid platinum bath is recommended in preference to others, and here a word of caution may not be out of place, for the lactic acid of commerce is of very uncertain quality, and of much under strength might materially affect results. The toning bath, Mr. Leuthardt said, need not be thrown away after use, but could be returned to a stock bottle and employed again and again, and if necessary replenished. He also stated that the papers required no special type of negative, and kept for a considerable time both before and after printing. Prints made from papers eight months old, and carelessly stored, showed not the slightest alteration. Exposure for 48 hours to nitrous hydrochloric acid vapours also failed to effect any change.

Mr. Leuthardt ascribed the "ill repute" of silver papers entirely to the use of gelatine, which he regarded as unsuitable for an emulsion. It was impossible, he said, to entirely remove the hyposulphite from gelatine, and in consequence supplementary sulphuration took place, which showed itself by yellow spots and blisters. This is an entirely new explanation of "blisters," and with all due deference to Mr. Leuthardt or Mr. Tauxe, the case made out against gelatine must be considered as distinctly "not proven."

Correspondence.

* * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* * * We do not undertake responsibility for the opinions expressed by our correspondents.

SPIRIT PHOTOGRAPHY.

To the Editors.

Gentlemen.—The letter of Mr. Starling in your last week's issue, reviving the neglected subject of spirit photography, suggests a field of unlimited promise for those enterprising gentlemen to whom we already owe so much regarding the photography of colour.

In a standard work* on ghosts by Mrs. Crowe, it is laid down that an apparition when occurring after dark is always manifested by a sort of electric bluish flame, accompanied by a peculiar earthy and offensive odour.

I do not wish them to reproduce the odour; but why not an absolutely correct and scientifically-tested light-filter, which would transmit only that region of the spectrum represented by those blue rays? It would no doubt be in the form of a curve. Said colour curve could be sealed hermetically and without chance of escape between two pieces of plano-parallel and homogeneous glass, thus enabling every possessor of a quarter-plate camera to take up at a small cost this fascinating branch.

Then there would be the only "safe light" for the dark-room, the special plates, the gifted clairvoyant operator, in fact, everything necessary to make business hum during the coming hard winter.

Would the R. P. S. Process section take the matter in hand?—
Yours faithfully,
S. TALLON.

57, London Road, Derby.

November 22nd, 1902.

A LETTER FROM EGYPT.

To the Editors.

Gentlemen.—It has been said that a statement to be of any value should be correct. I don't want your readers to think that I require the proverbial operation performed. On the contrary, I verily believe that the Englishmen of the Sydney Smith period could not see that he meant sarcasm, and that they themselves required the operation. I still live in spite of the attack of cachinnation induced by "Solomon Sage." Now for the correction. Instead of my chartering three steamers I have chartered four, one N. D. L. 20,000 tonner, and three Cook's special Nile steamers to the Second Cataract. This gentleman takes first place in Egypt, Lord Cromer second, and the Khedive third. My negatives have already reached the summit of the Sphinx and the two largest pyramids. Egypt is fast becoming Anglicised. I have no difficulty with the language. Cairo is the most cosmopolitan place I have ever visited. The English and others are well catered for (vide a prospectus enclosed of a new restaurant) in four languages—viz., French, Arabic, Greek, and English. If you do not see me any more you must conclude that I have patronised the said restaurant.—
I am yours faithfully,
A. L. HENDERSON.

THE SOUTHSEA EXHIBITION.

To the Editors.

Gentlemen.—I shall esteem it a favour if you can kindly find space in your next issue to correct a misconception that seems to exist (as many exhibitors have written me on the matter) that it is necessary to have entered for the Southampton and Hove Exhibitions to also compete at the forthcoming Southsea Exhibition in December. This is quite a mistake, as the Southsea Exhibition is an entirely distinct organisation as regards all the fourteen open classes, and it is only in respect of a special award offered by the three societies that exhibitors need enter for all three. Entries for the Southsea Exhibition can, therefore, still be made until December 3rd, and I shall be pleased to forward full particulars on application to my address.—
Yours faithfully,
F. J. MORTIMER, Hon. Sec.

Pembroke Road, Portsmouth.

WHERE ARE WE DRIFTING?

To the Editors

Gentlemen.—Your correspondent "Side Light" is correct in supposing that a concentrated light can be obtained from ordinary windows, in fact it is all concentration, but of the wrong sort. Yet tolerable work may be done with it in some cases; nevertheless, if two windows are used double lights in the eyes and double shadows everywhere must result.

He is also to be congratulated upon his sitters, who, if they have not yet developed the "large ears" he speaks of, must certainly be possessed of the other attributes; but he may find with longer experience that all patrons are not so indiscriminating, and regret that he ever confined himself to his keyhole, etc.

"Side Light" is, however, wide of the mark in speaking of my ideal lens; it was the ideal studio I mentioned. I recommended:

* "The Night Side of Nature."

lens, that of the diffusion of the focus type patented by the elder Dallmeyer, as being the best suited to the requirements of artistic portraiture, but suppose that he is not acquainted with it.

Happily for our profession there are men with nobler aims than "Side Light" and less easily satisfied, as I know by numerous letters which I have received on this subject. I can, therefore, calmly leave this nameless one to the serene enjoyment of his natural productions.—Yours, etc.,
MICHAEL E. BANGER.

November 23rd, 1902.

INTENSIFICATION.

To the Editors.

Gentlemen,—The account of the action of the intensifier on the silver given by "Chemicus" is a statement of facts rather than an explanation of causes. The results of several experiments give me reason to think the suggestion was not altogether unreasonable, and I believe that it can be proved that electricity bears some part in the combination of the metals.—Yours truly,
J. S. PIGG.

November 24th, 1902.

A CORRECTION.

To the Editors.

Gentlemen,—Kindly correct the statement in your journal of last week. I am reported to have left my apprentices unprovided for. This is not the fact. I arranged for their transfer to my successors before completing any agreement. The agreement itself bears witness to this fact.

I am sure you will not be a party to any misrepresentation of the truth, so I feel certain you will publish this correction.—And oblige, yours faithfully,
EDWIN DEBENHAM.

3, Victoria Parade, Newquay,
November 25th, 1902.

KODAK, LIMITED, AND THE TRADE.

To the Editors.

Gentlemen,—I have read with interest the correspondence between the Photographic Trade Association and Kodak, Ltd., and also the comments of many others regarding the attempts of the Americans to create a monopoly in the photographic trade.

It seems to me that Kodak, Ltd., are playing the roll of the petted and injured child when they cry out so loudly about piracies, parasites, etc. They state in their letter of October 25th that it is absurd to contend that they have desired a monopoly in the photographic trade. Look for a moment at the conditions issued by them some time ago, and you will see that monopoly is what they sought. Evidently, having failed, however, they have since issued a new set of conditions.

Here is an extract from the conditions referred to:—"Our Kodaks, Kodak roll holders, and Kodak films are sold to you as a dealer and discount allowed thereon on condition that no other rollable film cameras and roll holders, and no other rollable films than those of our manufacture are sold by you." Yet they state they never wanted monopoly, but their own conditions give a direct negative to this contention.

I do not blame them for desiring to create a monopoly, but, on the other hand, I admire their adversaries, the British dealers, for teaching them a lesson. Also in the letter of October 25th Kodak, Ltd., say that others have copied the "get-up and outward appearance" of their goods so as to foist them on an innocent public as "just as good." This strikes me as being a poor cry when everyone knows that they have copied many designs in outward and inward appearance for printing frames, stands, stereoscopes, and many goods pertaining to the photographic trade.

Kodak, Ltd., ask why British manufacturers have copied their special sizes, but, on the other hand, I would like to ask why Kodak, Ltd., have copied, pushed, and advertised, the British sizes, namely $\frac{1}{4}$ -plate and 5 by 4, and at the same time it should be remembered that $\frac{1}{4}$ -plate is to-day the size which is most used and sells in the largest quantity.

If it is wrong for the British manufacturer to copy American sizes, surely it is equally wrong for the Americans to copy the British sizes. Kodak, Ltd., should not lower their dignity by accusing others of faults which they themselves commit. I think Messrs. Wellington and Ward and Edwards have as much right as Kodak, Ltd., to ask why Kodak reels are taken advantage of in winding on films, but, with reference to this, my answer to Kodak is as previous films of Kodak make were unsatisfactory the amateur is now exposing newer and better films and making use of old Kodak reels for receiving, hence the reason they sometimes get other films on Kodak reels. This is my answer to Kodak's query why they are receiving films of other manufacturers wound round the reels of Kodak manufacture.

It cannot be denied that Kodak, Ltd., among many others, have done a great deal to popularise amateur photography, but the childish cry of accusation against the British trader for "stealing" their roll films, reels, sizes, etc., is of no avail when we see now that they are "stealing" and pushing designs for printing frames, stands, stereoscopes, and sizes, etc., which were introduced many years ago by British and other manufacturers and long before Kodak, Ltd., existed.

It is evident that Kodak, Ltd., are feeling the competition of the

British dealer more to-day than at any previous time, and therefore they resort to crying like a petted and injured child.—Yours, etc.,

THISTLE.

To the Editors.

Gentlemen,—Kindly allow me to say a few last words with reference to the reply of "X. Y. Z."

His first paragraph consists of sarcasm, which argues nothing and has no place in a discussion. His definition of monopoly is identical with mine, but in other words—exclusive control. But as I stated that he could flood the market and supply every dealer in the kingdom with photographic materials, as far as the P.T.A. is concerned there is no monopoly. Dealers are not restricted to P.T.A. goods, and the P.T.A. has no exclusive control, therefore there can be no monopoly. I regret having to labour this self-evident point.

"X. Y. Z." carefully avoids controverting my plain statement of fact as to the amount of dealers' profits, but contents himself with a re-statement, in different words, of his previous fallacy, bringing forward two cases; the first indicating nothing to the general public, the second being an argument from the special to the general—a fallacious method of reasoning. He pleads that a firm made 65 per cent. upon its capital. What is intended to be inferred from this it is impossible to say, but it has nothing to do with the question of profits. If two men each invest £5 in a cwt. of tea, the one selling his cwt. during the week for £6 (a small gross profit), repeating the operation each week for a year, while the other takes twelve months to get rid of his for the same amount at the same profit, one will have made £52, or a 1,000 per cent. upon his capital, whilst the other only £1, or 20 per cent. The question at issue was of gross profits, not as to how many times one or two fortunate people were able to turn over their capital. Had I £100 of stock, and should, after working nine or ten hours a day, in my shop, only succeed in making £65 at the end of the year I should realise, take a week off, and go in for a "rise" as junior assistant behind the counter without any responsibility.

With regard to the special article which bore 35 per cent., it is most probable that the cost of procuring it came to quite that; I have known it so, frequently. Dealers are not subsidised out of the rates to act as distributors of goods at cost price.

Ignoring that I stated that the profits are no greater upon photographic goods than upon any other article of trade, "X. Y. Z." again begs the whole question by repeating that dealers should sell at a reasonable profit. Repetition without argument is unconvincing; and personally, I am unable to find any reason why that which is a reasonable profit on, say, beef or sugar, should be upon our goods a wholly unreasonable one, and an exploitation of the public.

Of course, I do not affect not to understand the state of things that many like to see, namely, that all dealers should be undercutting one another (euphemistically termed "competition"); struggling from hand to mouth—as did many chemists—until absorbed or wiped out by some firm with a large amount of capital, "X. Y. Z." and others meanwhile taking advantage of the low and unremunerative prices obtaining, forgetting entirely that such is only another form of sweating. This is the alternative to foregoing these gigantic (?) profits, and is not for the benefit of the public as a whole.—Yours faithfully,
A RETIRED DEALER.

November 22nd, 1902.

To the Editors.

Gentlemen,—With reference to the letter of Kodak, Limited, in reply to Mr. Lizars, may I be permitted to ask for a reply from the company to the following questions: (1) Are there reliable films and special cameras now protected by existing patents? (2) If not what is the objection, legal or moral, to the purchase of rollable film or cameras of a like design by the public? (3) Assuming that I possess a Kodak camera and wish to use in it a film not made by the Kodak company, which, rightly or wrongly, I prefer, either because it is of higher speed, or, say, because it is isochromatic, what is the objection, legal or moral, to my doing so? (I am aware that no isochromatic rollable film is on the market at present.) I may say that I shall not be surprised if Kodak Co. ignore these inconvenient questions.—I am, sirs, yours faithfully,
AN AMATEUR.

[It is time, we think, that the closure should be applied to this correspondence, in the course of which every aspect of the controversy has been exhibited to our readers.—Eds. B.J.P.]

MR. BENNETT CLARK, of Ivydene, Penn Fields, Wolverhampton, writes:—It is with deep regret that I have to tell you of the death of my father, Mr. William Clark, of 37, Park Street, Bristol, at the age of 68, which took place on Saturday, the 22nd inst., at his residence at Bristol, after a painful illness of two months. He was one of the earliest members of our profession, having been 47½ years engaged in it, and was very well known and respected in Bristol, where he had been in business for nearly forty years in the same premises. He learnt his profession with a firm in Regent Street, London; at that time there were only three or four licensees of the Daguerreotype process in the Midlands and West of England. Although one of the oldest practitioners, he was wonderfully active till the time of his illness, and the careful production and high quality of his work had always gained him a foremost place amongst the photographers in his city.

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W. C." Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W. C.

PHOTOGRAPHS REGISTERED:—

- J. W. Clapperton, 23, Albert Place, Galashiels, N.B. Photograph of Rev. R. Small.
- H. H. Wragg, 27, Railway Road, Leigh, Lancs. Two photographs of J. Bates.
- E. Gray, 39, Wide Bargate, Boston. Photograph of "The Stocks" Boston.
- W. A. Searle, Royal Military Avenue, Cheriton, Folkestone. Photograph of an old recruiting poster of 1st R.D.
- H. Bown, 31, Jamaica Road, Bermondsey, S.E. Photograph of 1 Officer and 49 N.C.O. of 3rd V.B.R.W.S.

LENS QUERY.—J. M. says: "I have a cabinet lens, branded with letter 'V,' etc. Can you tell me who is the maker?"—In reply: The lens is of French make, but by whom we cannot say for certain. We think, probably, the maker may be Vallentin.

BUSINESS AGENT.—A. G. PUGH asks: "Can you kindly give me the address of a reliable firm who undertake the sale and disposal of photographers' businesses, on commission?"—In reply: Mr. Arthur Mortlock, Venner Road, Sydenham, is an agent for the disposal of photographic businesses.

ROYAL ARMS.—SUBSCRIBER writes he would like to know if he would be allowed to use on his mounts coats of arms, if not appointed by Royalty; he is not sure if this is the true one.—In reply: Certainly not, as by doing so you would incur a heavy penalty. Neither must you use a colourable imitation of the Royal Arms.

STAMP PHOTOGRAPHS.—STAMPS asks: "Can you give us the address of a firm who do stamp photographs? They are just the size of stamps, and are in a sheet perforated ready to tear off, as you do stamps."—In reply: Messrs. Firman and Co., Gloucester Road, Peckham, advertise that they do stamp portraits. Others also do them; see the advertisement columns.

BOOK WANTED.—H. S. COUSENS says: "I should be much obliged if you would state what book you could most recommend on miniature painting."—In reply: We know of no book, at present in print, devoted entirely to miniature painting. Johnson's book, "Art of Retouching Negatives, and Finishing and Colouring Photographs," published by Marion and Co., will give you some information on the subject.

TONING BATH.—J. ANDERSON says: "Please say if enclosed formula, which I have copied from a book, is any good. How long would prints require to be fixed? Would they be permanent? No gold combined bath; hypo., 6ozs.; washing soda, 4oz; lead acetate, 1/2oz.; water, 1 quart."—In reply: The prints should be fixed in about a quarter of an hour. We cannot say if the prints will be permanent, but we should very much doubt it, seeing that there is no gold used in the bath.

MOUNTING COLOURED PHOTOGRAPHS.—P. G. C. writes: "As I have got a few hundred Japanese coloured photographs to mount, I would be very pleased if you would kindly inform me through the JOURNAL which would be the best way to mount same. Also which mountant you would think best to use. They are printed on albuminised paper, and coloured with water colours as far as I am aware, so I am afraid to soak them before mounting, as it might take away the colour."—In reply: The photographs must certainly be mounted dry, and starch or other mountant may be employed. In the JOURNAL of November 7th you will find an article on mounting on Japanese paper, if the prints are required on that

FLASH LIGHT PHOTOGRAPH.—E. CARVER writes: "I am going to try a few flash light photographs, having one of Maloni's patent ball-room flash lamps; but I am really in doubt as to getting focus. For instance, say I wanted to take a view of a decorated ball-room, or a dinner party, how should I get a good all-round focus? If I focus one spot and stop down to get everything sharp, I shall require too long an exposure."—In reply: The only way to obtain objects in different planes in focus is by stopping down the lens. All we can suggest is that you adjust the focus so as to get the best general sharpness you can with the largest stop you can do it with. We do not reply to queries by post.

QUESTION OF CHARGES.—LANC writes: "Last month I was asked by a gentleman to go out about eleven miles to take views. I took eight different views, 12 by 10, and occupied (with the journeys) the whole day securing the negatives; and I then supplied sixteen platinotype photographs, i.e., two from each view, and sent in my bill £6 6s. Result, objects to the charge, saying 'inasmuch as the amount of £6 6s. is quite unreasonable for the sixteen photographs.' The work was acknowledged to be first class, and the small number ordered was sufficient as they were for a law case. Do you think the charge reasonable?"—In reply:

Yes, we think the charges very reasonable. Indeed, they are less than most photographers would have charged under the circumstances.

FAULTY NEGATIVE.—AGFA says: "Kindly criticise enclosed print, and inform me reason of (1) such a dark sky and (2) general blurring towards sides of picture. The photo was taken with one of _____'s cameras (hand; fixed focus). I have some prints here which do not show the blurring taken with the same camera. The plate used in this instance was Imperial Special Rapid, and exposed for about 1-30sec. I do not wish the pinholes and torn film to be taken into account. (3) Kindly let me know, also, how I am to use the intensifier known as 'Agfa.'"—In reply: (1) The picture is much over-exposed, and the negative seems to be fogged. (2) Probably the camera was moved during the exposure, as no part of the picture is really sharp. (3) Directions for use are supplied with the intensifier.

STUDIO QUERIES.—SEMPER FIDELIS puts the following questions: "(1) I have built a studio of the lean-to design, with top and front lights; length of lights, 14ft. front by 3ft. length; top lights four in number, 4ft. wide by 7ft. long. The top lights I intend covering over with white calico stretched on frames, instead of ground glass. What I ask for (the studio facing south, with full sun on the top lights, but no direct sun on the front lights) is your advice re blinds. What colour, and how many would you recommend for top and front?—I intend running them on wires as suggested by Mr. Bolas. (2) Also, my studio is 24ft. long by 12ft. 6in. wide, with an additional 8ft. required in waiting room. What lenses would you recommend for cabinet, carte-de-visite, and also one for full length and group work. I mean to say, what length focus would be required for each of these conditions?"—In reply: (1) As the studio has a south light, we should recommend a tolerably dark green for the top blinds, and a similar colour for the sides. (2) For cabinet pictures a lens of from 11in. to 12in. focus will be suitable. The same lens will also do for cartes and three-quarter figure, but for full lengths one of shorter focus will be required. The size of the group picture is not stated, so that we are unable to answer this query.

RICHMOND Camera Club.—The meetings of the club will in future be held at the premises of the Freemason's club, Sheen Road, Richmond, Surrey.

NATURE Study in Yorkshire.—Last week an important conference of teachers and school managers from all parts of the East Riding was held in the Assembly Rooms, Beverley. Lord Harris, chairman of the Technical Education Committee of the East Riding County Council, presided, and amongst those who took part in the proceedings were Professor Miall, Mr. Loftus T. Monro, and Mr. E. H. Howard, His Majesty's inspectors of schools, and the Rev. Canon Nolloth. About 600 teachers and managers were present. After the chairman and others had spoken, Professor Miall delivered an address, and said that the good teacher questioned his class perpetually, and was not eager to pour out information. He did not seek merely to cultivate the memory, but tried to improve the reasoning powers, and to train the eye and hand. There was no possible substitute for a teacher who himself observed well, and it was unfortunate that a regular industry had been organised for the supply of ready-made object-lessons and lantern-slides. He advised his hearers not to use stuffed animals and dried plants in the class-room, but wherever possible to study living animals and plants. It was not wise at present to look to public bodies for guidance, as they already had too much work on hand. If they could only afford one hour a week for nature study they might as well let it alone, for three hours was the minimum for it to be of any use. Mr. E. H. Howard said much had already been done in nature study in a quiet way. In one school he knew the study was the means of securing good attendance. A representative committee to promote nature study in the East Riding and Hull was elected.

* * NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOK-SELLERS.—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1903.

Edited by THOMAS BEDDING, F.R.P.S.

The forty-second annual issue of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC will be published during the present month. This year's ALMANAC reached a total of 1,560 pages, and the entire edition of 20,500 copies was sold out a fortnight before publication. Of no other photographic book ever issued can two such unique facts be recorded.

The growth in popularity of the ALMANAC is evidenced by the remarkable rapidity of its sales.

The 1900 Edition (20,500 copies) was sold within three months after publication.

The 1901 Edition (20,500 copies) was sold a fortnight after publication.

The 1902 Edition (20,500 copies) was sold a fortnight before publication.

The widespread interest in the ALMANAC grows steadily year by year, and in order to supply the increasing home, foreign, and colonial demand, we have decided to enlarge the 1903 issue to

25,000 COPIES.

The great addition to the circulation of this most popular annual (over 20 per cent.) undoubtedly enhances its

value as an advertising medium, and the issue of the large number of extra copies will supply the wants of thousands of photographers, dealers and publishers who were unable to obtain the ALMANAC for the last three years.

The ALMANAC for 1903 will appeal to photographers all the world over as a daily reference guide in practical work. The standard matter and formulæ will be revised and added to where necessary, and the latest departures in theory and practice will be chronicled. The year's advances will be recorded, and wherever practicable new features of an informative nature will be added.

EX CATHEDRA.

Photographic Chemicals in Analysis. The range of chemicals made use of in photographic technique has of late years become so widely extended that it now embraces quite a large number of chemicals that are almost a necessity for the laboratory shelves. For a long time we have had work in the ferro and ferricyanides, so valuable in testing for iron, though the sulphocyanides are still more delicate when testing for ferric compounds. For example, a drop of perchloride of iron solution being placed in a test tube filled with water, the liquid emptied out and the tube refilled with water, a distinct red colouration will be brought about upon a drop of sulphocyanide solution being added. Then we have oxalate of potash as a test for lime, platinum chloride for potassium, nitrate of silver for chlorine, and so on. But quite the latest addition to the list are the mutual reactions of formalin and amidol. For some time past the germicidal properties of formalin have been made use of in putting a check on the practice of some of the milk dealers and the meat jelly manufacturers. A very small quantity is sufficient for preservative purposes, but is contrary to law and public morality to make use of it for such purposes. It is recommended when the presence of formalin is suspected in a sample of milk to lightly powder the surface with amidol, or amido-phenol, and leave it for some moments. Normal milk, or milk treated with boric acid, develops a salmon colour, but if a trace of formalin be present the colour is yellow. When testing meat jelly the chemical is mixed up with it. It turns yellow if formalin has been added, and a dirty yellow upon the further addition of a drop of another photographic chemical ammonia solution. When the suspected adulterant is absent the colours produced are brownish rose colour and blue respectively. This photographic method is quicker and more sensitive than the usual, which requires a preliminary distillation of the substance under examination.

Photography and Aëronautics.

Photography and aëronautics have been closely allied for a long time; the name of Glaisher and the greatest height attained will always be linked together, the ascent when the record was made being historical. We have had since then many ascents in which the photographing of the country below has been the main cause of the aërial journey, as recent pictures in several of the illustrated monthlies would show. We believe photographic apparatus formed part of the personal luggage of Mr. Santos Dumont when his machine collapsed, and he and his camera fell ignominiously into the sea. So popular has the mania for flying machines and navigable balloons become that the various aëronautical societies of the kingdom are to be asked to consider a scheme for preventing fatal accidents, such as have already of late befallen quite a number of aërial travellers. The suggestion is similar to that made for application to motorists—viz., that every would-be balloonist should be first examined as to his experience and ability with ordinary balloons before being allowed a certificate. Then every navigable balloon, flying machine, or airship, should be examined by a committee of experts before it left the ground; if passed as being safe and a certificated aëronaut accompanied it, the journey or flight might be made. Next, the permission was to be dependent on certain limitations as to height and speed being observed; if these were not observed, or if examination of the machine were refused, a criminal prosecution should lie in case of accident. If anyone made an ascent in a machine pronounced by the experts to be impracticable and certain to come to grief he was to be liable to be dealt with as an ordinary homicidal or suicidal lunatic.

* * *

The present Price of Silver.

Although photographers are dependent upon silver in the majority of the processes they employ, they are at present but very little interested in its market price until it becomes a question of the sum they obtain for the residues sent to the refiner. The value of the metal has been gradually decreasing for some years past. One day last week its price was quoted at 21 11-16d per ounce, with a downward tendency. Standard silver at less than one shilling and ninepence three farthings an ounce, is, we believe, a record price. More than once we have alluded to record prices of the metal, but this beats them all up to the present. Some forty years or so ago the market price of standard silver exceeded five shillings the ounce—for some time it was quoted as high as 62d., nearly three times its present value. Now, when it is considered that in the processes now in vogue so little silver is used in comparison with what was the case in the wet collodion days, and when photographers sensitised their own papers and strong baths had to be employed for the purpose, it will be seen that the residues nowadays necessarily contain but very little silver as compared with what they did in the past. Added to this, the ashes from the papers—gelatine and collodion—are much heavier than they were from the old albumen paper, by reason of their being surfaced with the heavy sulphate of baryta and the paper itself being considerably thicker. Hence, say ten pounds of carefully-treated residue now may contain less silver than did a third, or less, that weight some years ago; and when it is considered that, when the metal is recovered, it is not worth much more than a third what it used to be, the small returns now made by refiners are fully accounted for. If nitrate of silver is received in return for the residues, the discrepancy does not seem so great, as its price is governed by the price of the metal; but it is when cash is

returned instead that it seems the greater. Taking all these facts into consideration, it is a question whether it is worth the while of workers on a small scale—such as amateurs—to take any trouble at all about their silver wastes, seeing how little they will get in return for them after the cost of reducing them is deducted.

* * *

Stained Negatives in Cold Weather.

In an article last week, "Winter Troubles in Photography," we alluded to the fact that complaints of stains, etc., on negatives and prints were far more prevalent during the winter months than at other seasons of the year. The trouble to which we are now referring might easily be avoided if photographers would only take the precaution to varnish their negatives. It would not be altogether a wild speculation to say that nine-tenths of amateurs at the present time do not varnish their negatives, or that a very large percentage of professionals do not varnish theirs. They take exceeding pains in getting the best results they can—intensifying, reducing, and retouching them, for example—and afterwards, for the sake of a little additional trouble, expose them to risks that may result in their practical destruction, which might otherwise have been avoided, the reason being, simply, that gelatine negatives may be printed from without mechanical injury. Collodion negatives cannot be, hence they are always varnished, and for this reason they are free from the risk we are now dealing with. Most workers are cognisant of the fact that if a gelatine negative is printed from while it is damp, or the paper is damp, stains are the almost inevitable result. In the winter, if the weather is fine, the printing is usually done in the open air; consequently the negatives, the frames, and the pads become exceedingly cold. Then they are taken into a warm room for the paper to be changed, and moisture at once condenses upon them, in the same way as it does upon cold glasses when they are taken into a warm room, or a lens is dimmed when it is attempted to be used in such a place as a warm conservatory, unless it has been previously warmed. Now this condensation is not manifest on the film side of the negative, though it is generally palpable on the glass side, but it is there all the same. This moisture is then absorbed, either by the film of the negative, or by that of the paper—probably by both—with the result that, after several printings, the negatives become stained with silver. These may possibly not make themselves manifest at once, but after they have been stored away for a time they show themselves, often to the surprise of the owners, and the real cause is but little suspected. But had the simple precaution been taken to varnish the negatives before they were printed from no such injury would have arisen, for in this case no moisture would have been absorbed by the negative, and that taken up by the paper would have been of no moment. It is, as we have more than once said before, surprising that photographers—professional and amateur—should expend so much time and care in the production of their negatives and then begrudge the little trouble of varnishing them as a means for their preservation afterwards.

* * *

Curious Actinic Power of Diamonds with Radium.

Shortly after the remarkable discovery by Röntgen of the invisible opacity-penetrating rays from the vacuum tube there was brought before the scientific world another set of invisible actinic rays, somewhat analogous to those emitted by uranium and other bodies. These latter radiators have been investigated by a number of acute scientific workers with results of the highest interest; indeed, it is difficult to say what limit can be fixed upon their ultimate bearing on the most abstruse

problems dealing with the constitution of matter. New metals have been discovered in the course of these investigations, and entirely new and unexpected properties found to be possessed by some of the long known elements. One of these new metals, polonium, has the property of emitting certain radiations, some of whose properties—the electric—are foreign to the purposes of our journal; others have special photographic interest. Dr. Otto Rosenheim, writing from King's College, London, describes his experiment in the *Chemical News* in abstract somewhat as follows: If a diamond rendered phosphorescent by exposure be placed upon a dry plate and left there for twenty-four hours, no developable effect is produced. If a bar of polonium be placed on such a plate covered with a piece of tissue paper, no effect is shown on development. If, however, the polonium is placed in contact with the diamond a distinct impression is developed under the diamond, but not under the polonium. If the paper be removed, there issue from each object radiations that affect the plate. If the diamond and the polonium be kept in contact, but away from the plate, for a considerable time, the diamond has no action upon the plate. The diamond radiations (when it is in contact with polonium) are capable of passing through thin films of paper, celluloid, gutta percha, and glass, while these films are entirely opaque to the companion polonium radiations. No special deductions have been drawn from these phenomena, nor can they be said to have a practical photographic bearing; but it is highly desirable that they should be placed on record in these pages, as also any further results in the same direction when they are published, and this our readers may rely upon our doing

* * *

The Smoke Nuisance.

Practical photographers have often been amused at the remark very often made by ladies in their admiration for portraits taken on the Continent. They say, "You see the air is so much clearer over there." For the practical man knows well enough that as good photographic work is done in London as anywhere else, and that although November does bring us fog and mist, when daylight work is out of the question, there are plenty of times when work of the highest quality can be safely counted upon. Yet it seems hard that with all the protests which have been made, with the legislation against smoky furnaces, and all the other attempts to deal with the evil which have been pushed forward, we should still have the fog fiend in our midst. Simple white fog we can never hope to banish, for it is a natural produce of our island home; it is the yellow, sulphur-impregnated abomination that we want to kill. We look with envious eyes to most of the large Continental cities, which by some means or another manage to keep their atmospheres clean, and are prone to ask why they manage so much better than we do in England. Some light is thrown upon the question, so far as Germany is concerned, by a recent report of the United States Consul-General in Berlin, who tells how coal fires are largely superceded there by the use of briquettes, which are made of lignite, peat, and the dust and waste of coal mines, mixed with a certain proportion of mineral pitch. These briquettes are easy to handle, and to store; they burn with a clear, intense flame, and make practically no smoke. Their manufacture represents a very large industry, the output during the past year amounting to more than one and a half million tons. This form of fuel is used in private houses, in workshops, and in factories, and as a result Berlin is one of the cleanest cities in the world. The Consul attributes this cleanliness to three main causes:—(1) The use of this smokeless fuel, (2) the skilful, scientific construction of boiler furnaces

and chimneys; and (3) the skill that is taught and enforced among firemen who stoke the furnaces for manufacturing purposes. He says, on this last point, "It is not every strapping labourer who can shovel coal who is permitted to stoke a boiler furnace in this country. Before he can assume such a charge he must be taught the theory and practice of economical, scientific firing, by which the fuel is distributed in such manner and quantity over the grate surface as to secure the most perfect combustion of the volatile elements." The English plan is to allow the volatile elements to escape up the chimney, and gradually form a pall over their chief cities, which brings widespread discomfort and loss to thousands. Among these photographers are the first to suffer, for the veil of smoke keeps light from entering their studios, and visitors from entering their doors.

* * *

The Sins of Celluloid.

When the introduction of celluloid made the cinematograph a practical success, there were many prognostications of the disasters which must occur from the inflammability of that material. A few such episodes did happen, happily without any grave results, and these could be traced to the imperfect apparatus then in use, or to the foolhardiness, or the ignorance, of inexperienced operators. The London County Council took alarm, and ruled that no machine for exhibiting animated photographs should be employed in any of the halls under their jurisdiction, unless apparatus and operator were shut up in an iron box, where they were completely isolated from the spectators, and where they could frizzle away at their own sweet will. But if all the accidents arising from the inflammability of celluloid could be tabulated, we have no doubt that the majority would prove to be in connection with the use of that material other than as a support for the photographic film. There have been accidents, for example, from celluloid collars catching fire and inflicting terrible burns upon the wearers' necks. And there is no great reason to wonder at this, for tens of thousands of such collars must be in daily use—a silent protest against the destruction wrought in linen by the modern laundress. Combs, and other fancy articles made of celluloid, are responsible for several more accidents, and we have even heard of a billiard ball made of the material catching fire and deflagrating violently, to the utter ruin of the green cloth upon which it rested. But perhaps the most remarkable episode of the kind yet reported is that described by the Paris correspondent of the *Daily Telegraph* last week. A certain gentleman had, by an unkind turn of fortune, lost his nose, and as he considered that the absence of this very necessary appendage to a complete countenance might excite remark, he hied him to the surgical instrument shop and purchased an artificial olfactory organ. It was supposed to be made of horn, but sophistication enters into the composition of artificial noses as it does into that of most other commercial products, and the thing supplied to him for horn was really celluloid. He did not become aware of this until chancing to light a cigarette, the flame from the match set fire to his newly-acquired nasal organ, and in a moment he was running about with a small volcanic eruption coming from his face. We earnestly trust that the poor fellow was not badly burned, but while we sympathise with him in his misfortune we cannot help feeling glad that the accident was quite unconnected with the use of celluloid in photography. Those who use films of celluloid, either in the flat form or in the roll holder, are, we need hardly point out, running no more risk than if they were handling glass plates, for the necessary care exercised in keeping the material from access of light involves protection from fire as well.

HINTS ON WORKING VELOX PAPERS.

THE following method of working Velox paper has given such excellent results, and with such a minimum of trouble, that it has always been a matter of surprise not to have seen it more than suggested, much less reduced to a system. The chief feature is the use of magnesium wire for the exposing light, and depends on the fact that an equal length of ribbon at the same distance from the negative will always give the same result. Besides, the time taken in exposing is so short that the total time required to produce a dozen or more prints is materially lessened, as compared with lamp or gas light. The requirements are very few. The long, narrow table which is usually found in the dark-room is best, on which are arranged, in the following order:—First, at one end a candle or gas jet, in the flame of which the magnesium ribbon may be conveniently lit, then a space of, say, four feet marked off every six inches, so that the printing frame may be quickly set up any distance from the light. Next, the dish for the developer, then one for the hypo, and next to this a large washing tray; some sheets of white, clean blotting paper and a roller squeegee will also be very useful.

Now to classify: Velox may be had in grades which will suit almost any negative, and give results to satisfy any taste in the matter of surface, tone, or contrast. First, we have the regular or Carbon Velox, which will give contrasty results from ordinary negatives, and which will enable us to get good prints from negatives which are so flat that we are almost inclined to throw them away. This is made in rough, smooth, and glossy, and gives tones from jet black to red, according to exposure and developing. Then, if our negatives are too contrasty, we have the Special Velox, for giving soft effects. These papers are more rapid than the regular, and require perfectly fresh and pure developer to give good results. We should therefore carefully examine the negatives we propose to print from and classify them, first according to their density, and then to their contrast. We will find that Velox gives such latitude of exposure that three classes of negatives would be sufficient—that is, first, negatives of average density; second, those that are below; and, third, those much above the average. There will naturally be many that would come between these, but we should soon find that, having three known factors (that is, speed of paper, strength of developer, and intensity of light) always the same, the only other factor (distance of printing frame from the light, depending of course on the density of the negative) would be such an easy matter to judge, especially with the densitometers now on the market, that we will hardly ever make an error.

The method adopted is this:—A negative of ordinary density is placed in the frame with a piece of Carbon Velox. This is set up on end, exactly three feet from the light (note the appearance of the paper under the negative by reflected light, as this is one of the best guides to the density of the negative). All the magnesium ribbon is cut into lengths of exactly one inch. If pyro-stained negatives are used, the standard will have to be two or three inches, according to colour of negatives. One of these lengths of wire is taken in a pair of pliers, or on the end of a long hat pin, and held in the flame of the candle; as soon as it has burnt out the Velox is taken from the frame and placed into the developer without previous immersion into water, care being taken to flood the whole print and to avoid air bubbles. Now watch carefully, and the moment the whole picture is faintly up it is withdrawn by one corner on to a clean sheet of glass, and held so that all the developer runs off at once. It can now be held quite close to the candle

light, and allowed to finish developing, while you examine it carefully. The moment it is quite to your fancy it is plunged into the acid hypo, which stops all action. If preferred, it can be plunged into clean water instead, and then examined more carefully, when, if not quite enough developed, it can be returned to the developer, or a drop of the developer may be applied with the tip of the finger to any spot requiring it; the amount of water on the paper preventing the too rapid action of the developer. The secret, however, is to withdraw it from the developer before it is quite finished and allow it to finish on the glass; if you have taken it out too soon, it is easy to replace it; on the other hand, you can stop it at the moment you like if it is over-exposed, and the chance of a spoilt print is very small after a little practice. As soon as a print is in the hypo the next can be exposed without risk of spoiling it, so that in a very short time a dozen or more will be in the hypo dish, from which they go to the washing water, where, if they are kept for ten minutes, and then squeegeed between sheets of white blotting paper, again placed in clean water, and once or twice again squeegeed, they will be quite free from hypo and dry in a very short time.

Any tone-finished print may be obtained by remembering the following:—A short, full exposure and strong developer give normal black and white results; the weaker and more restrained the developer the longer the exposure must be, but the further over to red tones the result will be. If upon development it is found that the exposure—i.e., the distance in inches of the negative from the burning wire, was exactly right, that distance is minutely marked in one corner of the negative—in this instance say 36in.—and this number will in any future exposure of the same negative convey the fact that the normal exposure—i.e., to get black results with normal developer, will be one inch of magnesium ribbon at a distance of 36in on Carbon Velox, and on Special Velox will have to be one half, or once again as far, as it is about three or four times as rapid; and likewise by exposing the same print at 36in. to two, three, or more inches of wire consecutively, and correspondingly restraining the developer, we can get any tone always repeated from that negative. If, on the other hand, the exposure had proved too much or too little on developing, we should alter the distance for the next print, and when the correct distance is once obtained it is scratched on the negative in the form of a single figure, which will at any future time give the correct distances in inches. Of course your developer must be as known a quantity as your light, paper, and distance if the best results are to be obtained; and nothing is better than the amidol tabloids in this respect; all that is required is the stock bottle of soda sulphite solution, from which the required amount is poured each time a batch of prints is developed, and into which are crushed two grains of tabloids, according to formula, and you have a perfectly reliable and fresh developer to work with each time, which will be specially appreciated when working with the Special Velox. It will be found, however, that greater control will be obtained by making the developer half the strength recommended on the package and regulating the exposure thereto. To sum up:—First, use plenty of light to work by; candles are best and safest. Second, remove print from developer before quite finished, and allow to finish on a glass plate. Third, alternate squeegeeing between blotting paper and placing into clean water gives quickest way of removing hypo, and a final squeegeeing in blotting paper leaves a print which will be dry in a few minutes. Fourth, always use fresh developer. By following the above we have a process which gives prints which cannot be beaten for beauty, and one which becomes a pleasure instead of a task to perform.

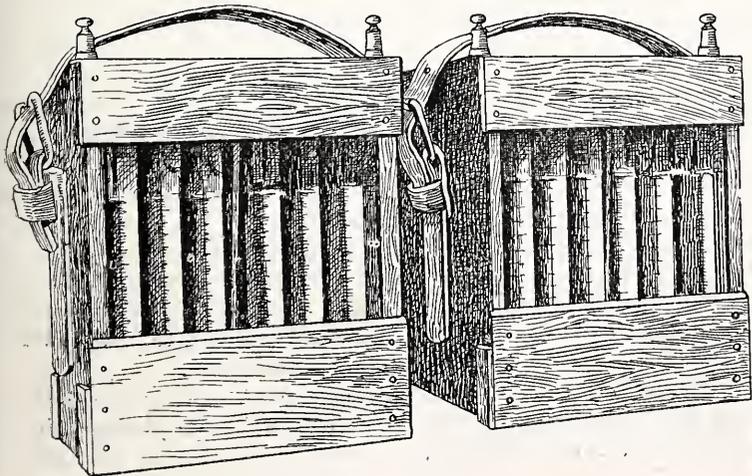

BATTERIES AND ACCUMULATORS FOR PHOTOGRAPHIC AND OTHER PURPOSES.

By THE AMATEUR OPTICIAN.

AN experience extending to some years—more particularly since the application of electric lighting to our business premises—confirms me in the view that accumulators or storage batteries are, and may be made by most persons, very convenient and of general utility for a variety of purposes. A small electric light is extremely useful, safely enclosed in ruby paper, to develop by; a cluster of lamps mounted in the bottom of a box, the lid or cover of which is a printing frame, serves as a good uniform, healthy, and economical illuminant in exposing lantern plates; when working the induction coil for X-ray work, I have the range of a set of batteries, and can couple up any number of cells, from one to ten—i.e., two to twenty volts.; in the purely domestic region, two or three batteries are in constant use, not to mention a night light which is only in occasional use to ascertain the time in the “wee, sma’ hours,” a light which can be switched on at the head of one’s bed to read by, is a luxury not to be sneered at—clean, safe, and inodorous.

The cost of accumulators is a serious consideration; one suitable for working a 4in. coil will cost almost half as much as the coil itself; then the weight is somewhat of a nuisance, and the risk of breakage and damage by irresponsible porters and workmen is such that nothing but great and sustained enthusiasm will enable one to carry on the work. My first accumulator cost me nearly cent. per cent. more than the initial invoice price for repairs, the damage, consisting of such items as fused connections and cracked cells, being done by persons to whom the battery had been entrusted for recharging and by porters. Now, all that is at an end. I make my own, at a cost which is less than half that of a bought article. I make the weight such that I can do my own portage, and, what is of supreme importance, the batteries are as effective as anyone could desire. Amateurs sometimes essay this work *ab initio*—i.e., they make models of, and cast their own “grids,” fill them with the usual lead peroxide and spongy lead, and so on. It means no end of trouble, much needless cost, mess, and objectionable smell, and as a result a battery of cells which, weight for weight, is not to be compared for effectiveness to such cells, say, as the E.P.S. type. I write from personal and practical experience. No, in making accumulators, of all things electrical, attempt nothing beyond the putting together or building up of the parts, and you are safe. Take the chief essential, the “grids,” positive and negative. No amateur living can model, cast, and turn out ready for “forming,” grids equal in capacity, finish, and quality to those which can be purchased at less money, ready for use.

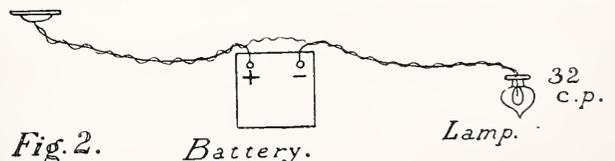

Below is a photograph of two four-volt. batteries, replicas of

others which I have made and used for some time past, their cost, exclusive of labour, works out for the two at 21s. 10l. They weigh approximately 15lb. each, which means that one can be carried to and fro without undue fatigue; if you have them heavier, of greater capacity, they become unwieldy, and you have to employ others to carry them, and then come the risks and the expenses. In short, look after them yourself, and they are no trouble and small expense beyond the original cost. The first question, however, is, has the reader access to an electrical installation?

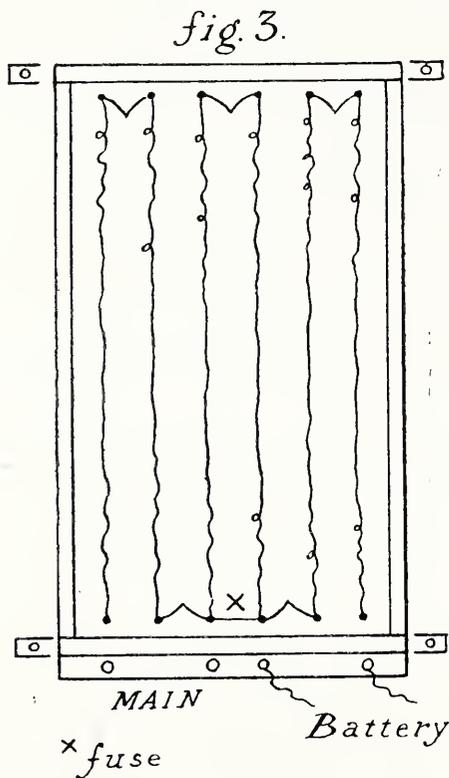

Before, therefore, giving the necessary instructions for making and fitting, a few practical suggestions will not be out of place relative to the “charging” of the accumulators when made. Obviously, this is a question of main importance.

Accumulators may be charged from primary batteries, e.g., chloride cells, Daniells’, and so on; from dynamos, small or large, and part of one’s installation; or from the corporation supply, which, however, must be continuous current. The first method I shall not consider on account of the cost, mess, and trouble; the owner of a private installation will know all about it already; the third, from a main supply, direct current, at a pressure of 100 to 200 volts., only need be commented upon here. Now, presuming we have a small pocket accumulator, two or four volts—i.e., one or two cells, each cell being equivalent to two volts—the method of charging this will be as follows:—Select any convenient lamp near a table, bench, or mantelpiece; find also, or lay open to view, the twin silk-covered wire which conveys the current to the said lamp, take one strand of this twin wire—which one does not matter—cut the wire, and bare the ends for about 1in. We have to find now which bared end is positive and which negative. To do this in the safest and easiest manner—an electrician would use “pole-finding” paper—I recommend the method following:—Place the two bared ends one on each side of a phial cork, and tie with string; let the ends project over the end of the cork, and be about $\frac{1}{2}$ in. apart; holding the wires by means of the cork, immerse the bared ends into a glass of water, and switch on the current. Bubbles of gas will be seen, more or less freely, proceeding from the negative wire; a drop of acid (lemon juice will do) greatly facilitates the formation of the bubbles. Now, to save trouble next time by having to repeat this operation, mark the positive wire with a piece of red sealing-wax, the usual custom being to paint the positive terminal red and the negative black. All that is necessary now to “charge” is to connect the negative bared wire to the negative (marked —) terminal of the accumulator, and the positive wire to the positive (marked +) terminal. Substitute a 32 c.p. lamp for the 16 c.p. on circuit, and more current will pass. Arrange to do this when the lamps are in use, and the cost of charging is trifling, while the candle power of the lamp is not greatly decreased. The figure shows this clearly, remembering that the wires must be tested for polarity before being attached to the terminals of the accumulator.

For charging accumulators of larger size, such as those to be described, it will be found more convenient to have a “resistance frame” made by a professional expert; the cost should not greatly exceed a guinea. A frame to step down a 200 volt. current is figured below (Fig. 3). It consists of half-a-dozen lengths of suitable platinoid wire arranged in spirals, and properly attached and connected to a stout iron frame.

From this we get a current of about three ampères, and can safely charge even the comparatively small batteries dealt with in this article, and in a reasonable space of time. In the case of the resistance frame figured, a length of the best silk and rubber-covered twin wire is first attached to the terminals, to be found on one of the porcelain pots through which come the branch wires, supplying four or five lamps; the other two ends of the twin wire are connected to the two "main" terminals on the resistance board (marked "main" on the figure). Attach another length of twin wire to the other two terminals, and test the polarities of the bared ends of this wire as before described; the wire which is found to be negative is attached to the negative terminal of battery, and the positive wire to the positive terminal as in the previous arrangement. If there are any spare terminals on the main switch-board, the connections might be made here; but the services of a competent electrician ought to be called in before making any such alteration, as a 200 volt. circuit is not to be played with. My own board is, however, fixed and at-

tached, as required, to one of the "pots" mentioned, and by putting in fuse wire between accumulator and main wires, accident is reduced to a minimum. Now that I see how simple a matter it is to properly charge accumulators in this way from one's own supply, I wonder at my own timidity and innocence in paying, time after time, fees for recharging my batteries, fees, too, which may be reasonable enough, but still eighty per cent. above the cost when done at home!

The beginner must first master the rudiments of "soldering." This is a small art, easy of acquirement, and one which at times comes in very handy. Purchase a soldering iron of fair size, with a copper "bitt" at right angles to the handle; buy also some soft solder, resin, and some pieces of sheet lead; cut the latter into strips, and practise with them, soldering pieces together until able to make good joints. We want a clean "bitt," and just at the right heat, for making the lead joint. The heat required is not that required for brass soldering, and the only real difficulty will be the finding of the right temperature, and that is easily acquired. When able to make a good job with the pieces or strips of lead, one may safely tackle the

putting together of a storage battery. Glass cells of suitable size (6 by 4 by 2 full, inside) cost 1s. 2d. each; these will comfortably take five "grids," 4 by 4, bought ready made and formed, at the price of 8d. each for the negative, and 9d. each for the positive. For the two cells we want six negative and four positive. Next we require six pieces of hard vulcanised fibre or vulcanite, $\frac{1}{2}$ in. wide, $\frac{1}{4}$ in. thick, and 2 in., or the exact width of the cell, long. These pieces are required, two at the bottom and one at the top, to hold the grids in position, and keep them at a uniform distance of $\frac{1}{4}$ in. apart; they have, therefore, to be cut to the following figure (Fig. 4).

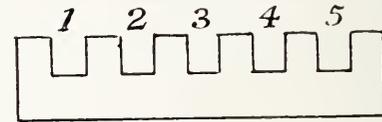

Fig. 4.

Having ruled off the distances, saw down to, say, $\frac{1}{4}$ in., then use a small fretsaw to cut out the squares. Having prepared these, and tried them in the cell—they should fit easily—we now proceed to solder strips of sheet lead to the lugs with which the grids are provided; the length of the strip is not material, but the connection made should be well and neatly done. The negative grids are a trifle thinner than the positive, and grey in colour. The positive being chocolate, commence with a negative, and having fitted it with the strip of lead—lengthened its lug, that is—set it up to the left in two of the vulcanite separators; next lengthen the lug of a positive grid, and set this up, with the lug on the other side, next to the negative. The negatives occupy the grooves 1, 3, and 5, with their lugs all on one side, and the positives 2 and 4, with their lugs parallel.

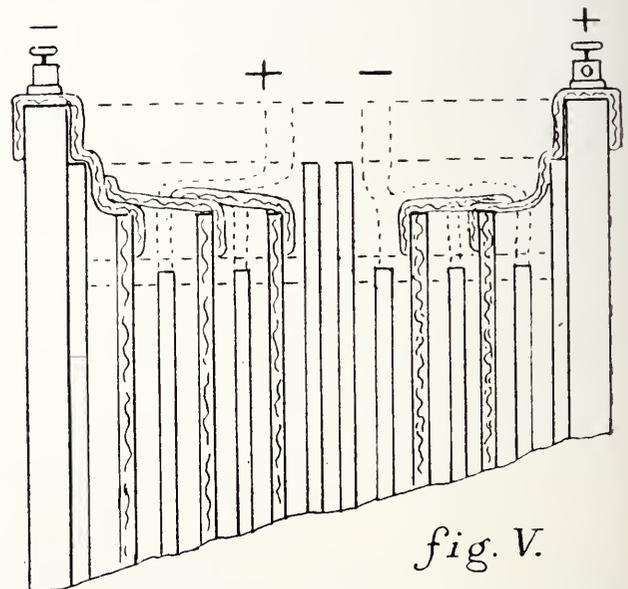

fig. 5.

Fig. 5 shows a vertical section of the cells in outside case, looking at them from the front. Fig. 6 gives the arrangement as viewed from the top.

I invariably put a touch of seccotine into the ebonite grooves before setting up the grids, therefore by the time we have finished soldering the lugs and coupling them to complete the cell, the set of five may be lifted without all colliding. Double up a piece of string, pass the loop under the set of grids, and make a sort of sling by which the whole can be lifted and lowered into the cell, drawing out the string afterwards.

Having completed the fitting of the cells, they are encased in stout frames substantially, as shown in the photograph. I separate the cells slightly, by inserting a piece of good corru-

gated paper (rubber would be better), and practically build up the frame round the cells. The back and front are designedly left open, and you have consequently a clear view through each cell. In case of a "short circuit," or mishap by the falling out of any of the lead paste, which would lodge between the grids, you can at once see the mischief and remedy it when charging; also I like to see that each plate is "gassing" freely, thus demonstrating that all the connections have been properly made. All the wood casing, as well as the cover to be finally fitted and let in at the top, should receive several coats of shellac varnish. The battery is finished by screwing on a stout leather strap. I get the suitable article at 6l. each, very stout and strong, but whether it is all leather I could not say.

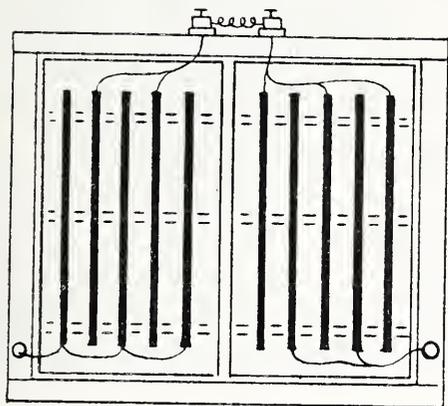

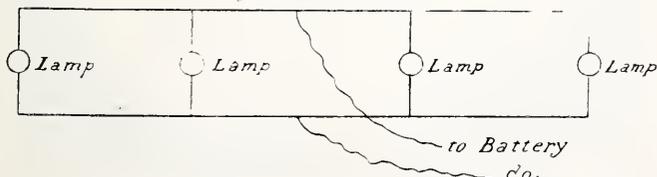

fig. VI.

The battery is now ready for charging. Prepare a solution (called the electrolyte) of the best strong sulphuric acid, 5 parts, to water, 21 parts. The acid should be added to the water gradually, and the solution should be cold before pouring into the cells; enough solution should be put in to just cover the grids. We may now proceed at once to connect the battery to the wires, as described. The wires comprising the resistance will get hot, but should not get above a dull red, and after a couple of hours or so, the cells will begin to "gas" and spray—they should be covered with a piece of glass—and they may be allowed to go on like this for two or three hours for the first charge (better too much than not enough), and will take no harm, provided the terminals show no signs of getting too warm; but unless a very strong current is passing, this would not be likely to happen. In any case, the safety fuses would show it long before this. My own method, on a 200 volt circuit, is precisely as described, and I have never experienced any trouble. The battery just made will light a 4 volt h.e. lamp for several hours; it is well to get the best h.e. (high efficiency) lamps, as they last longer than the cheaper kind. It will also light four 3½ or 4 volt lamps, for a shorter time, if they are placed in parallel, i.e. :—

Arranged in a cluster, these serve splendidly for contact printing, lantern slide making, etc., and being switched on for a few seconds only at a time, will last a long time. As shown in Fig. 5, the batteries are made so that one or two cells or more can be coupled together, to suit one's requirements. As a rule, however, the two cells are always connected positive and negative at the back, and usually two complete batteries would be "charged" together.

THE PHOTOGRAPHY OF THE INFINITELY LITTLE.

[Reprinted from the "Journal of the Photographic Society of India."]

"Photo-micrography is simply Photography applied to the Microscopic Image."
—PRINGLE.

PHOTOGRAPHY has been called the recording pencil of science in all its branches; and perhaps its most signal services have been rendered in the domain of microscopical research. It would almost seem as if the sensitised plate and the developing solution were the predestined and natural allies of the improved achromatic compound microscope. The two run well in double harness. Without the addition of any special lens the microscope is its own camera. It faithfully projects on the ground glass, or on the sensitised plate, the images formed by its own system of lenses. It leaves the operator nothing to do but to develop, in the ordinary methods, the latent picture which itself has traced of the marvels of that world of the infinitely little which are its own special revelation.

Previous to the application of photography the observer was not without means of preserving a record of his work. Before the discoveries of Niépce and Daguerre were announced, Dr. Wollaston, who died in 1828, had perfected his camera lucida, or grapho-prism, by means of which drawings could be executed of objects under microscopic observation. Amici's camera lucida, the steel disc, or mirror, of Sömmering, Beale's simple neutral tinted glass, the Zeichenprisma of Zeiss, the excellent vertical camera lucida of Beck, and numerous other appliances, enable the working microscopist to sketch with precision the minute details of the different objects which pass across the field of his instrument. We cannot yet afford to forget Dr. Goring's drawings, while the contributions of Tuffen West are absolutely accurate marvels of graphic art. The splendid plates which illustrate Smith's "Synopsis of the British Diatomaceæ" (1853), Wolle's "Diatomaceæ of North America," Pritchard's "Infusoria," the "Micrographic Dictionary," Kent's "Manuel of the Infusoria," and other standard works are conclusive proof of the scientific reliability of the hand-drawings of students whose hearts were in their work. For my own part, I have always held that for compelling an observer to look thoroughly into a microscopic object, sketching with the aid of a camera lucida possesses a higher educational value than photo-micrography. Moreover, the draftsman has it in his power to confine his attention to one particular feature, or class of features, in the field under observation; while the indiscriminate and non-selective accuracy of photographic methods often leads to the sensitive plate recording the debris and waste to be found in all but the best mounted slides. It has also to be admitted that the portability of the camera lucida is a distinct recommendation. On the other hand, we must recognise that sketching with any form of camera lucida is a distinct strain on the eyes, while the process is necessarily slow and tedious. On the whole we are forced to the conclusion that while hand-drawing was suited to a time, not long past, when life had some heritage of leisure, and graphic art was still a desideratum, photomicrography is thoroughly well up to date. It combines scientific accuracy with rapidity of execution; and it enables the observer to reproduce great numbers of his pictures at a comparatively small cost. Moreover, from the same negatives he can make those increasingly popular lantern slides which, when projected on the screen, will acquaint a roomful of people with the intricate elaboration of details to be found in the diatom-valve, or the "terrifically minute" organisations displayed in the structure of the eye of the house-fly or the bee.

Some interest having been evinced in the photomicrographs exhibited at one or two of our lantern evenings, I purpose in this paper to explain how they were taken. The apparatus employed in the process consists essentially of two parts—a

microscope and some kind of carriage. The selection of both these instruments must to a large extent be determined by the amount which the amateur photographer is able or willing to expend. The price of an achromatic microscope will range from about five guineas to upwards of £100. A costly microscope is

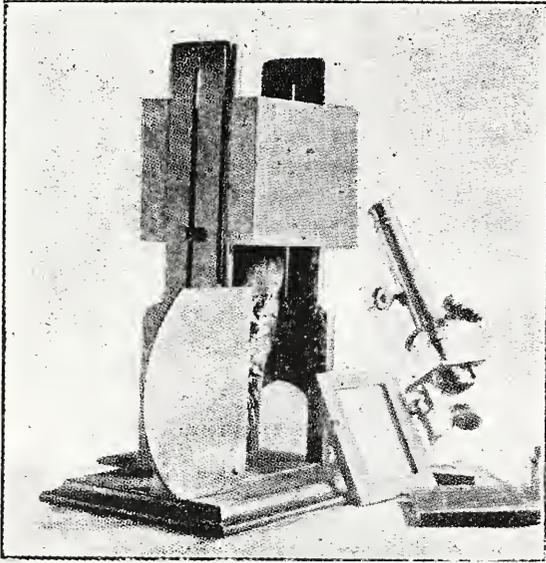

Fig. 1.

not, however, indispensably necessary. An intelligent worker will turn out better results with a reliable student's microscope than a dilettante bungler will achieve with one costing twenty times as much. Brains and perseverance count for a great deal in this matter, as in every other. Where all the leading opticians offer really excellent microscopes, it would be invidious to name any one of them as being better than the rest. My own work has been mainly done with Beck's bacteriological "Star" microscope, which is supplied with two eyepieces, an inch and one-sixth inch objectives, and an Abbe condenser, for some seven guineas. Absolutely reliable scientific observations can

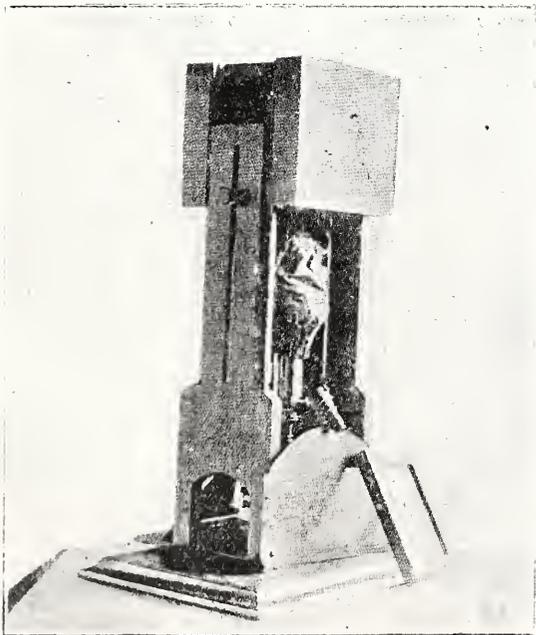

Fig. 2.

be prosecuted with its help, apart altogether from its suitability to our present purposes. Zeiss, Seibert, and Reichert sell excellent objectives which can, if desired, be substituted for those supplied by the English maker of the stand; many of my own best photomicrographs have been taken with German

objectives. For the one-inch, half-inch, and quarter-inch object glasses a condenser may be dispensed with; but it must be used with the higher powers. When used with a low power, such as the one-inch, the upper lens of the Abbe condenser should be screwed off; and whenever used the condenser should

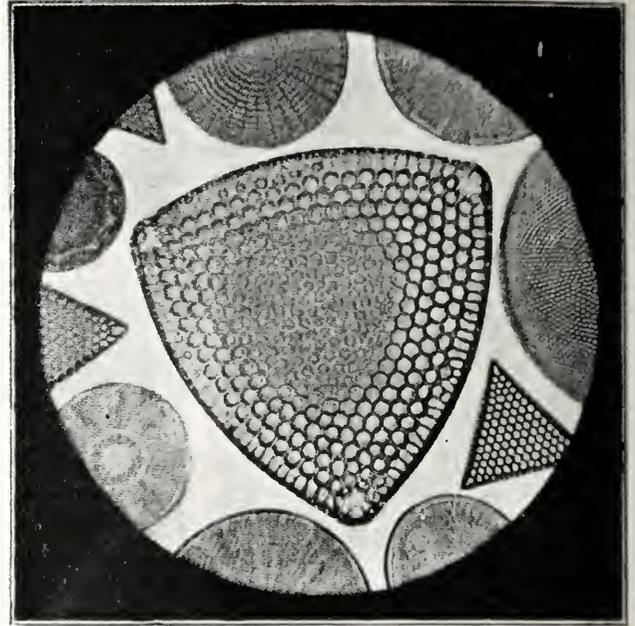

Fig. 3.

be focussed. The books on the microscope will teach you how to do this, and indeed you must learn the uses of the different parts of the microscope, and be able to apply them to advantage, if you want to turn out good work.

At starting the beginner is likely to experience some difficulty in securing an evenly lighted field. In this connection experience and repeated experiments will be necessary; the distance of the flame from the mirror, its height above the table,

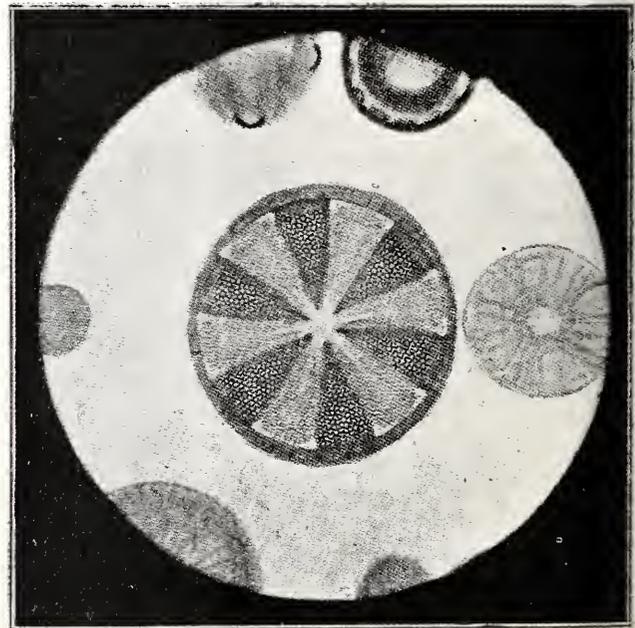

Fig. 4.

the angle of incidence, the position of the lamp (whether directly in front, or just a little to one side) are determining factors, and will have to be attended to. When successful results are secured, make a note of the exact positions and distances for future guidance. A notebook in which to record these matters

is a valuable help in photomicrography. All my own work has had to be done out of business hours, and at night, and beyond observing that daylight exposures are much shorter than those given to night work, I shall at once proceed to say that a Hinks' double-wick wall lamp, or, better still, one of Ditmar's little central draught "Favourites," is all that is necessary for an illuminant. My own experience does not lead me to recommend the electric light for microscopic purposes. You should not rely too much on Tulsī bearer's methods and honesty; but if you would work successfully, you will see yourself to the cutting of the lamp wick, the purity of the mineral oil used, and the general cleanliness of the air tubes, etc. To increase the whiteness of the light, add a little camphor to the kerosene oil, and do not fill the oil holder to excess when you have done so. I got this "tip" from a professional magic lantern exhibitor some years ago, and have found it useful as well for photomicrographical purposes as for the optical lantern or the enlarging apparatus. Both lamp and microscope must be placed on a firm table; remember the microscope magnifies motion as well as linear dimensions. Before I pass on to deal with the camera, let me say a word as to the exposure necessary for securing a good negative. It will depend on the power of your objective, the brightness of your light, the colour, and degree of transparency of the object you are photographing, the rapidity of your plate, and so on. A high power objective may necessitate an exposure of several minutes, while a few seconds suffice for a low power. Red and yellow objects require a much longer exposure than those of a bluish or violet tint. A section of rock, such as limestone, or basalt, or of wood-tissue, will require a considerably longer exposure than the wing of an insect, or any other transparent object. It is useful to bear this in mind when photographing a stained section, and your difficulties reach a maximum when you are dealing with a tissue stained in two colours, blue and red. This leads me to refer to the plates to be used; rapid plates are not necessary, while isochromatic plates are a distinct advantage. The Ilford Empress and chromatic plates are those I generally use, and good negatives can be obtained with the Ilford ordinary. In the matter of exposure the operator will find experience to be the best of teachers, provided he keeps a note of each object photographed, and of the exposure which secures the best results. Such note should include particulars of the plate used, the distance of the source of light from the mirror, its height above the table, etc. In no branch of photography is a systematic record of procedure and results more necessary than in the one dealt with in this paper.

I have next to deal with the camera. An ordinary quarter-plate camera may be used for our purpose, the camera lens being itself removed from its mount. The microscope should be laid in the horizontal position, and the eyepiece end of the body inserted into the lens mount of the camera. An outer sleeve of double black twill should cover the lens mount and part of the microscope, and it should be securely fastened to both by tape or rubber bands. Any leakage of light is fatal to success. Both the microscope and camera must be clamped, or otherwise secured to a stand, or table; and this must be done in such a way as not to interfere with the bellows and focussing adjustments; and the stage of the microscope must be parallel to the ground glass of the camera. If a microscopic object is now placed on the stage, its image will be seen projected on the focussing screen of the camera. Obviously what remains to be done is familiar to every photographer. I do not, however, recommend this method of taking a photomicrograph; and would advise all who wish to become proficient by regular work in the art to get some form of vertical camera, specially de-

signed for photomicrography. And here again prices will be found to have a wide range—such an instrument may be purchased for £5 or £100. The vertical camera with which my own work is done was designed by Mr. S. J. Leslie, since deceased, and who, I believe, patented it under the Indian law. He got mine constructed for me, by a native "mistry" in a back verandah, at a cost of a few rupees. Messrs. Brees and Co. used to make and sell Leslie's camera for a little over thirty rupees. Its form, etc., will be best understood by reference to Figs. 1 and 2. As will be seen, it is a light wooden box, about 6in. square, working between two wooden uprights, about 17in. high, which are firmly fixed to a base-board measuring 9in. by 13in. At the bottom of the box a circular aperture is cut, to which is fitted a sleeve of black velvet or twill, lined with black or red twill so as to make it light-tight. This sleeve is shown in the illustrations as hanging from the bottom of the box, between the two uprights. When in use the tube, or body, of the microscope is inserted into the sleeve, the lower, or free, end of which is tied tightly to the body of the microscope. At the top of the box is a groove for receiving the focussing screen or the dark slide. Two clamping screws, one on each side of the box, work in slits cut in the uprights, and enable the operator to raise or lower the box, and thus increase or diminish the size of the microscopic image projected on the ground glass. The image can be thus roughly focussed, the focussing heads attached to the microscope being resorted to for securing a properly and sharply-defined picture. A thin plank is fixed to the bottom of one of the uprights; let us call it the cap-screen, as by its help light is cut off from the lamp. In Fig. 1 the several parts are shown separately. The ground glass, or focussing screen, is resting against the further upright. Immediately in front of it is the dark slide. The cap-screen is thrown to one side, disclosing the empty sleeve which is hanging between the uprights. The microscope—Beck's "Star"—stands to the right, with a double nose-piece attachment, a very useful, but not indispensable accessory; while the condenser and mirror are seen beneath the stage. In Fig. 2 the microscope, etc., are in position for taking a photograph. The microscope stands between the uprights, with the sleeve drawn over it. The camera has been raised almost to the top of the uprights, thus securing a circular field about 2 4-5in. in diameter; and the dark slide (not shown in the illustration) rests in the grooves at the top of the box. The cap-screen when the actual exposure is being made has to be thrown to the side, as in Fig. 1. In Fig. 2 the cap-screen is in the position it should be before and after exposure. Every photographer has the appliances required for the development of the latent image left on the sensitised plate after exposure. Though the favourite developer, pyro and soda, is suited to photomicrographical work, I prefer one of the quinol or quinol and metol combinations. At any rate, my readers would do well to give each a fair trial (by which I do not mean just two or three plates), and then adopt the developer which gives the best result in his hands. To revert to the apparatus above described very briefly before passing on, I use a roll of dead-black paper in the tube of the microscope; and I would note lastly that many prefer to use the microscope without its eyepiece.

So much for what I trust will be found an intelligible and practical description of the working appliances employed in photomicrography. If the exhibitor of lantern slides made from negatives taken with the help of the microscope would be a successful all-round man, he must read up something about his objects. It is useless to project a diatom on the screen, unless you can tell your audience what it is; or to show them a fly's eye without being able to call attention to the different parts of that organ.

It will serve the two-fold purpose of showing what can be done with the jungly-looking apparatus figured above, and of giving interest to the two illustrations which follow, if I briefly describe them. In Fig. 3 we have a photomicrograph of a triangular diatom—*Triceratium Favus*; and in Fig. 4 of a circular, or disc-like, diatom—*Actinoptychus heliopelta*. Around each of these may be seen portions of other diatoms, which suffice to show how varied are the forms and patterns on the valves of these interesting objects. Diatoms are vegetable organisms. They are found all the world over, and in both salt and fresh water. Typically they may be compared to a pill-box, the upper and lower valves of the diatom corresponding to the lid and bottom of the pill-box, which in the diatom are connected or bound together by a hoop or ring. They consist essentially of an outer siliceous covering, enclosing a protoplasmic mass, or endochrome. Their remains as fossils form deposits, many feet in thickness, and several miles in extent; cities stand upon them. Their pedigree, as diatoms, dates further back than ours as human beings. They have been found in volcanic ejecta; and to bring the matter nearer home to ourselves, they abound in the tanks, "jheels" and creeks of Bengal. One of my own favourite hunting grounds for specimens of living diatoms has been the tank known as General's Tank, at the head of Park Street, within a stone's throw from our Club rooms. Some species are fixed by stipes to objects in the water, while others are free; of these last many are motile. It is difficult to realise at the outset that many of the motile forms of organisms revealed to us by the microscope are vegetable and not animal in their nature; but one of the early lessons which the microscope teaches us is to abandon the idea that motility is characteristic of the animal kingdom. In the case of the Diatomaceæ the way in which locomotion is effected is a moot point. Some hold that the endochrome streams through the orifices in the flinty covering (frustule) in the form of cilia; others that motion is due to endosmotic changes, that is, to the transmission of fluids from without; others, again, attribute the movements to the action of a delicate layer of protoplasm which invests the frustule. The ordinary mode of propagation obtaining amongst these minute objects is by cell division, or fission, a process not peculiar to diatoms, and which they share with all other vegetable cells, though the Diatomaceæ get their name from it ("dia" through, and "tomé" a cutting). They also multiply by conjugation, a true sexual act, which has been observed in several species. Probably, after going through many generations by fission, conjugation occurs as a recuperative act preceding another series of generations by the simpler method of fission. While all these biological processes are of fascinating interest to anyone who will take up the study of these simple life-forms, it must be confessed that what chiefly attracts the ordinary observer is the rare and chaste beauty of the markings on the siliceous coat of the diatom. No photographic method can give any adequate idea of the real appearance of a well-illuminated group of diatoms. The markings on the valves not only vary in mere pattern, but their investigation discloses a marvellous elaboration of detail. With a low power nothing but lines (striæ) are visible. A higher power breaks these lines up into rows of hexagonal dots or apertures; and in many cases a still higher power shows that behind the hexagonal dots is another and still more minute system of punctures, which perforate an underlying film of silica. Fig. 3 will give some idea of what I mean. Owing to the valves of *Triceratium* not being flat, but bearing a boss in their central area, we are easily able to focus the lower siliceous stratum for the boss simultaneously with the surface of its margins for the hexagonal apertures. We can thus see, or photograph, both

at once. As test-objects for the microscope, diatoms have done more than any other to develop and perfect objectives; and a lens which can project such an image as is reproduced in Fig. 3 is reliable for all scientific or photographic purposes. My readers have now got some idea of the complex structure of a diatom, apart altogether from its beauty. To proceed:—In Fig. 4 we have a fluted valve, and for this reason the surface of the rayed convexities of *Actinoptychus heliopelta* will be in focus simultaneously with an underlying siliceous coat of the concave rays. This I consider is the correct interpretation of the appearance of the diatom as a whole. Members who have seen the lantern slide printed from the same negative projected at our meetings, giving a diameter of about 3ft. to the disc of *A. heliopelta*, will recollect that it makes a most effective object. The actual diameter of *Triceratium* figured above is not more than 1-240th of an inch, while that of *A. heliopelta* is even less.

It may seem that all this is leading on to branches of science which in no way concern the Photographic Society of India. Perhaps, therefore, it would be well for me in closing to explain myself. I hold that photography is only an illustrative art; a means to an end, but not an end in itself. Mere proficiency in negative-making, and in the subsequent printing processes, should not be the be-all and end-all of any photographer's studies. If he works at landscapes, he should aim at the pictorial representation of scenery, or the preservation of a record of some view which has a tale to tell. If portraits be his speciality, he quite as much as the painter in oils, should study effective posing, and possess some knowledge of art. So, too, if he would take up with photomicrography; beyond the necessary acquisition of technical proficiency, he must endeavour to learn the lessons which his objects have to teach, and be able to at least popularise the tale they tell. Only those of my readers who are willing to do this need carry their pursuit of photomicrography beyond the restricted limits of this paper. But, let me add, if they will take the trouble to work up the subject in the way indicated they will never have reason to regret it. An extract from Mr. Pringle's "Photomicrography" heads this paper. An extract from another recognised authority on the subject may appropriately close it. Mr. Jennings, in his book entitled "How to Photograph Microscopic Objects," says:—"To become a skilful photomicrographer it is first necessary to be a skilful microscopist; for if the operator does not know how to display an object to the best advantage, his photographs will be useless." W. J. SIMMONS.

ROYAL Photographic Society ordinary meeting, Tuesday, December 9th, 1902. Dr. R. Norris Wolfenden will read a paper on "Photography applied to marine zoology."

MR. LATHBURY informs us that the publication of "The Pilot" (a weekly review of politics, literature, and learning), price 3d., will be resumed on Saturday, December 6th.

THE SCOTCH Affiliation.—There is every prospect of the affiliation of Scottish photographic societies becoming a reality. The majority of the societies seem to be taking up the matter with enthusiasm, and a goodly attendance may now safely be prophesied for the first meeting.

MR. W. CALDER MARSHALL, F.C.A., 41, Glenton Road, Lee, S.E., hon. secretary of the South London Photographic Society, writes:—Our 14th annual exhibition will be held from 7th to 14th March, 1903 (both dates inclusive), at the Public Baths, Camberwell. The open class entry forms are now in the press, and will be sent in response to a postcard addressed to me.

THE Nottingham Camera Club 1903 exhibition will be held in the Mechanics' Lecture Hall, Nottingham, on Thursday, Friday, and Saturday, February 12th, 13th, and 14th, 1903. The judges are Messrs. W. R. Bland, F.R.P.S., Saml. Bourne, J.P., and C. Barrow Keene, F.R.P.S. The following are the open classes:—(a) Champion class, any subject which has been previously medalled in open exhibition (previous awards to be stated on entry form); (b) landscape, seascape, and river scenery; (c) portraiture, figure studies, animals, and still life; (d) architecture, and any subject other than above; (e) stereoscopic work (sets of four prints); (f) lantern slides (set of four, any subject). Further information and entry forms may be obtained of Mr. Arthur Black, 9, Bowers Avenue, Nottingham.

PHOTOGRAPHIC SURVEY AND RECORD OF SURREY.

We have received the following circular:—

The work of the society is divided into sections, each being under the direction of a committee.

The whole collection will be housed at the Public Library, Town Hall, Croydon. It is hoped that, later on, local collections will be similarly deposited in other centres.

Members of the Survey and all others interested are earnestly invited to help the work by communicating with the hon. secs., and particularly by sending in photographs of objects as classified below.

CONDITIONS.

All photographs are subject to approval by the Council of the Survey; must be sent in trimmed but unmounted, preferably of whole plate; half-plate, or quarter-plate size, but larger sizes will not be excluded; preferably in platinotype or carbon, although under exceptional circumstances, untuned bromides may be admissible; must be accompanied by the following particulars, written on a separate slip:—(a) Subject; (b) Date of negative; (c) Compass point where known; (d) Name and address of contributor; (e) Brief description; (f) Process. Printed slips will be provided on application. It is desirable to indicate in some manner the scale of pictures.

CLASSIFICATION OF SUBJECTS.

Architecture Section.—All buildings of interest, whether ancient or modern. Churches, including monuments and all church furniture. Public buildings and dwelling houses, exteriors and interiors. Street architecture, illustrating the relative positions of houses and boundaries at the present time. Engineering works. Ruins.

Art and Literature Section.—Art: 1. Paintings, drawings, and engravings. 2. Sculpture and carvings (not architectural). 3. Art work in metals. 4. Pottery and glass. 5. Tapestry, lace, and other fabrics. 6. Art furniture and other objects of art. Literature: 1. Printed books, when old, curious, or rare. 2. Manuscripts. 3. Maps and plans.

Note.—The committee will be glad to receive information of the existence of objects of interest falling within their province, since a great deal that is most valuable is in private hands, and may otherwise remain unknown to them.

Anthropology Section.—Antiquities. Prehistoric and historic (non-architectural). Physical anthropology. Folk lore: 1. Material objects. 2. Ceremonial. 3. Traditions (games, holy wells, social, and religious subjects).

Geology Section.—Land contours. River courses. Sections.

Note.—It is advisable that a geologist be present when a geological photograph is taken.

Natural History Section.—Zoology: 1. Mammals—(a) Rare species; (b) Habits; (c) Homes and young. 2. Birds—(a) Rare species; (b) Habits; (c) Homes and young; (d) Migration. 3. Reptiles. 4. Fishes. 5. Insects (including economical entomology). 6. Pond life.

Botany.—1. Trees, peculiarities of growth. 2. Shrubs and herbaceous plants. (a) Habitat; (b) Peculiarities of flowering; (c) Galls and other forms of parasitism.

Meteorology.—Halos. Remarkable cloud appearances. Hailstones and frost effects. Lightning. Auroræ.

Photo-Micrography.

Astronomy.—Eclipses. Comets. Meteors, etc.

Scenery and Passing Events Section.—Scenery: 1. Landscapes. 2. Views of places of special beauty or interest, other than architectural.

Passing Events.—1. Scenes of every day life. 2. Processions. 3. Carnivals. 4. Bonfires, etc.

Hon. Secretaries.—General: J. M. Hobson, M.D., B.Sc., 1, Morland Road, Croydon. Survey: H. D. Gower, 55, Benson Road, Croydon, to whom all photographs should be sent.

LIVERPOOL Amateur Photographic Association.—The ordinary monthly meeting of the above association was held in the clubrooms, Eberle Street, on Thursday week, when a crowded attendance of members and friends assembled to welcome Mr. James A. Sinclair, who lectured on "A Journey through Spain." Mr. E. R. Dibdin (president) occupied the chair. Mr. Sinclair, in the course of his remarks, mentioned that he visited Burgos, Madrid, Toledo, Cordova, Seville, Granada with the wondrous beauties of the Alhambra, Ronda, and finally Gibraltar. The lecture was illustrated by upwards of 130 slides of the highest order taken by the lecturer. A hearty vote of thanks was accorded Mr. Sinclair at the close.

THE Glasgow Southern Photographic Association's Exhibition.—The hon. secretaries write from 28, Bank Street, Hillhead, Glasgow:—Our second annual open exhibition is to be held from 24th March to 7th April, 1903. There are to be nine open classes, in addition to four for members and one for the trade, and the hall we have secured this year is much larger than the one we had last year, and is well suited for the purposes of an exhibition. We trust that your readers will give us the same kind support this year as they gave us last year. The prospectus will be issued as early next month as possible, but, in the meantime, any further information will be gladly given on application being made to us.

THE CAT AND THE COBRA.

AN Indian correspondent writes:—I enclose you a little print of my cat playing with a cobra. This was taken with a cheap hand camera, and the print done with rodinal. With a reading glass it

will be seen that the cobra is just raising his hood. Cats will generally kill a cobra if they have him in the open: they simply worry him to death, and are very sharp at avoiding a bite.

THE ROYAL SOCIETY AND MODERN EDUCATION.

In the course of his annual address to the Royal Society on Monday last, the president said that since the last anniversary the society had lost by death nine Fellows and two foreign members. The deceased Fellows were Sir Joseph Gilbert, died December 25, 1901, aged 84; the Marquis of Dufferin and Ava, died February 12, aged 75; Maxwell Simpson, died February 25, aged 86; Sir Richard Temple, died March 15, aged 76; George F. Wilson, died March 28, aged 80; Sir Frederick A. Abel, died September 6, aged 75; Dr. John Hall Gladstone, died October 6, aged 75; William Henry Barlow, died November 12, aged 90; Sir William C. Roberts-Austen, K.C.B., died November 22, aged 59. The foreign members were Alfred Cornu, died April 12, aged 61; Rudolf Virchow, died September 5, aged 80.

France lost in Alfred Cornu one of the most distinguished of her men of science. Possessed of rare perspicacity of intellect and of resourcefulness in experiment, by his numerous researches, especially in the domain of optics, he had won no mean place as an original contributor to science. On his part, Mme. Cornu wrote in a private letter that he especially appreciated and reciprocated the friendship and sympathy of his English colleagues. Cornu was born in 1841; he was elected a foreign member of this society in 1884; he received the honorary degree of Doctor of Science from the University of Cambridge in 1899; and died, in the spring of this year, mourned and deeply regretted by the whole scientific world. It was with deep regret that he recorded the loss which the society had sustained by the decease of Sir Frederick Abel, who held for many years a conspicuous position in the world of science, and in public life, in connection with technical education and the Imperial Institute. His services were recognised by a baronetcy, by K.C.B., and by the G.C.V.O. In 1887 he was awarded a Royal medal by the Council. They had also to record with sorrow the death of Sir Henry Gilbert, the fellow-worker with the late Sir John Bennet Lawes in the famous agricultural experiments carried on for a long series of years by them at Rothamsted. Dr. Gladstone's work was remarkable for its varied nature, and he was among the first to labour in the borderland between chemistry and physics. He was awarded the Davy medal in 1897. He was the first president of the Physical Society, and later president of the Chemical Society, and he served on two Royal Commissions. They bade a hearty welcome to the new society which had recently received a Royal Charter for the organisation and promotion of those branches of learning which, in foreign academies, were usually included in the philosophico-historical section. This new body, under its adopted title of "The British Academy for the Promotion of Historical, Philosophical, and Philological Studies," would, they sincerely trusted, take a worthy place by the side of the older and very distinguished institutions, the Royal Society and the Royal Academy, in representing the intellectual activities of the kingdom, though, in accordance with the sentiments and habits of the national character, each society retained its complete independence, and was in no way subservient to the State. The present council having reaffirmed the view taken by the council of last year that it would not be desirable to attempt to include the studies

undertaken by the newly-formed body as an integral part of the work of the Royal Society, they might rejoice that they would now be cared for by an independent society. Though the words of the charter granted by Charles II. were wide enough legally to include historical and philosophical studies, yet, as a matter of fact, with some few exceptions in early days, the work of the Royal Society had been confined for two centuries and a half to the studies with which it was now occupied. It would be their pleasant duty, as the Acting Academy of the International Association of Academies, to recommend the new society for admission into the "Association of Academies" as the body representing philosophico-historical science in the United Kingdom. After referring to the National Antarctic Expedition, and the arrival of the "Morning" in New Zealand, which place she was leaving this month in search of the "Discovery," the president referred to the establishment of a National Physical Laboratory, the opening of which had taken place since the last anniversary. He then described the work of the Physikalisch-technische Reichsanstalt, of Berlin, which was largely due to the scientific foresight of von Helmholtz. The original cost of the institute was over £200,000, and its yearly maintenance was not less than £17,000. During the five years that it had been at work its influence upon the science and the manufacturing interests of Germany had been most remarkable. It was, therefore, with feelings of high satisfaction that he had to record the opening in March last of a similar national institution in this country. The sum voted by the Government for the physical laboratory, an institution second to none in its national importance, was the very modest one of £13,000 for the buildings and equipment, and an annual grant of £4,000 for five years in aid of the expenses of conducting the work of the institution. It was, therefore, "to the liberality of the public," as the Prince of Wales at the opening pointed out, "that we must look, not only for money, but also for presents of machinery and other appliances." The supreme necessity in this country of a more systematic application of scientific methods, both in theory and in practice, to our manufactures and industries, which was so wisely insisted upon by the Prince of Wales on the occasion of his admission to the Fellowship of the society, and again in his address at the opening of the National Laboratory, had since been confirmed and enforced in a remarkable way by the individual testimonies of thirteen Fellows of this society, in the evidence which they recently gave from their own knowledge and experience, either as teachers of science or as leaders and technical advisers in manufactories or commercial undertakings, before a committee of the London Technical Board. The evidence seemed clear that the present inappreciative attitude of our public men, and of the influential classes of society generally, towards scientific knowledge and methods of thought must be attributed to the too close adherence of our older universities, and through them of our public schools, and all other schools in the country downwards, to the traditional methods of teaching of mediæval times. With the experience of Germany and the United States before us, the direction in which we should look for a remedy for this state of things would seem to be for both the teacher and the student to be less shackled by the hampering fetters of examinal restrictions, and so for the professor to have greater freedom as to what he should teach, and the student greater freedom as to what line of study and research he might select as being best suited to his tastes and powers. In the United States the candidate for the highest degree, Ph.D., must spend at least two years, after obtaining his bachelor degree, in carrying out an investigation in the field of his main object of study, and then submit the dissertation which embodied the results of his research. One way of bringing about reform in this direction would be to make individual research an indispensable condition of proceeding to degrees higher than the B.A. The first steps in the direction of true reform must be taken by the universities in the relaxation to some extent of the established methods and subjects of their examinations, which had been carried down with but little change from the Middle Ages. It was some satisfaction to know that a new section of the British Association for the Advancement of Science had been formed for the consideration and discussion in detail of the reforms which were needed in the educational methods of the country.

Mr. W. BARRY, of Hull, writes re our article on judging the light by Crooke's radiometer:—Nigh on twenty years ago the idea occurred to me to use this instrument for this purpose, and I gave it an exhaustive and fair trial, but found it of little use, if any at all, as in practice it registers more heat than actinic value of light. Its fate was destruction by the studio cat (? biped or quadruped). However, the idea is again revived, and I shall watch its evolution with interest.

At the Grantham Industrial and Fine Art Exhibition, to be held at the Exchange Hall, Grantham, on January 14th, 15th, and 16th, 1903, Section J (photography) will be open to amateurs in the United Kingdom: 45. Landscapes, Seascapes, and Interiors, in sets not exceeding six pictures; 46. Portrait and animal studies, in sets not exceeding six pictures (each picture judged separately); 47. Collection of framed photographs, any size (open to the radius), for amateurs only; 48. Bromide enlargements (open to the radius), for amateurs only. The general manager of the exhibition is Mr. George Jackson, Launder Terrace, Grantham, to whom all communications should be addressed.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION: LIVERPOOL BRANCH.—ANNUAL DINNER.

A MEETING was held at headquarters, Alexander Hotel, Dale Street, on Friday, November 14th, 1902. Present—Messrs. G. Watmough Webster, E. T. Vanderbilt, F. S. Bains, A. Priestley, H. Dowden, R. H. Waite, S. M. Heberd, W. T. Smith, W. Warrington, Thos. Foulds, W. Saronie, Joseph Cooper, W. N. Cooper, A. F. Mowll. Mr. G. Watmough Webster occupied the chair.

The final arrangements were made for the first annual dinner of the branch. An advertisement appearing in a Birkenhead newspaper offering free photographs, the photographer, being a member of the branch, having been referred to the branch by the central committee, a lively discussion took place. It was the general opinion that the free portrait system was derogatory to the dignity and inimical to the interests of the photographic profession, but it was an evil which had a tendency to provide its own remedy. The member whose name appeared on the advertisement frankly stated that although he had honestly supplied his best work, the venture was a complete failure.

Mr. H. Dowden gave the particulars of a claim he was making against the Post Office for a negative broken in transit by parcel post. It was decided to submit the matter to the central committee.

The first annual dinner of the branch was held on Monday, November 21st, at the Alexander Hotel. Mr. G. Watmough Webster, chairman of the branch, occupied the chair. The dinner was admirably served. The toasts, loyal and general, including the Professional Photographers' Association and the Liverpool Branch, were duly honoured. The after-dinner entertainment, musical and otherwise, was capital, and it was altogether a complete success.

The following letter was read, in the course of the dinner, from Mr. T. C. Turner, of Hull:—I have the greatest faith in the future of the P.P.A. It must necessarily be a slow progression, because photographers as a body have for so long been accustomed to read in the Press that their capacity for union is non-existent, that they have grown to believe it. We have this to break down, not any surly, unwise determination to live in solitary disunion. The time is ripe for the successful development of the movement if we are content to achieve results in patience, and not imagine that the nominal subscription of 5s. is sufficient to make a powerful machine of our association.

What we urgently require at this moment is personal enthusiasm in backing up the work in each local centre as it is formed. I believe that, could we but persuade a dozen men in Liverpool, Edinburgh, Birmingham, Hull, and Aberdeen—the branches already working, in fact—to discuss professional matters fearlessly and report the discussions fully, we should soon carry the whole country with us. At present too many good fellows are waiting for something to be done for them, by some one else! It is a mistake, because the improvement of photography as a profession, can only be achieved by the efforts of the live men in harness at the moment.

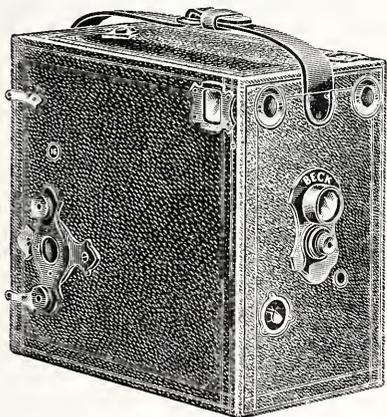

I have been struck by the wonderful growth of influence which even our little group of local members shows. We are but a fraction of the photographic body, but because we are united and interested sufficiently to meet and discuss professional subjects, these discussions assume an importance quite out of proportion to our numerical strength, and, who knows, they may have a modest share in shaping a general agreement as to business procedure in many directions. Now, only consider the effect if the association could rely upon the country, providing the London committee with a true reflection of professional opinion on the difficult questions arising in the conduct of perhaps the most harassing calling known to modern man! I believe that in three or four years the public recognition of it as a business would be completely altered. It should be possible, too, for if men are clever enough to make money at photography they are clever enough to see this association made fruitful of good results. There are men who keenly feel the sting of the sneers thrown at the professional, men who only want the encouragement of their fellows, the powerful "moral" support of members behind them, and in agreement with them, to take up this work with zest and purposeful vigour. And, after all, the desire to lift up one's own head in the world and at the same time help the business confrères to do the same is no ignoble aim.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon (the 1st inst.), Sir James Crichton-Browne, treasurer and vice-president, in the chair. The following were elected members: Edward Divers, M.D., Miss Amy French, Winifred Lady Howard of Glossop, and Mr. J. H. Whitehorn. The special thanks of the members were returned to Mrs. Hickman for her donation of £21, and to Dr. Frank McClean, F.R.S., for his donation of £40 to the fund for the promotion of experimental research at low temperatures.

New Apparatus, &c.

The Frena Max Camera. Manufactured and sold by R. and J. Beck, Limited, 68, Cornhill, E.C.

The Frena Max is a development of the long familiar Frena. The instrument before us takes either forty cut films or twelve glass plates in sheaths. Using the former, the well-known alternate notch system is availed of; so, too, with regard to the plate sheaths. Messrs Beck evidently aim to reduce the use of the hand camera to its utmost simplicity. They very properly remind photographers that in the Frena system three manipulations repeated for each exposure are all that is actually required of the operator: (1) Wind the shutter; (2) expose by setting off the shutter; (3) change the film by turning a handle.

We may enumerate the principal features of the Frena Max: It has two "Cornex" brilliant view finders; a rectilinear lens; four adjustable diaphragms; an automatic counter to register the number of plates used; two tripod sockets; one movement of the handle changes the film and makes ready for the next exposure. The film is changed with the camera in the same position as it is when the photograph is taken. The instrument measures $3\frac{1}{2}$ in. by $9\frac{1}{2}$ in. by $4\frac{1}{4}$ in., and it is well and strongly made. Upon testing the various movements we find them simple and reliable. Indeed, nothing could be more effective than the changing system, which is controlled by the lever at the side. One merely pushes it to and fro and *voilà tout*.

The "Velox" Folding Enlarger. Sold by John J. Griffin and Sons, Ltd., 20-26, Sardinia Street, Lincoln's Inn Fields, W.C.

This compact and easily mastered piece of apparatus appears at a time of year when enlarging is a favourite evening recreation with amateur workers. It is of the collapsible kind, and packs into a small space. The sample submitted to us struck us as exceedingly simple to set up. A reference to the illustration will show the instrument in actual use. Messrs. Griffin's own description may be quoted to more fully emphasise the ready manner in which it may be availed of:—

To open the enlarger, release the three spring catches which hold the parts together, and extend the folding base-board. Then pull out bellows and attach the lens and negative supports to the base by means of the thumb-screws. See that the holders are vertical and well screwed down. The negative must be placed in the grooves at the small end,

film side inwards. If films are to be enlarged, place the same between the two pieces of glass supplied and insert as you would a glass negative. To charge the enlarger with the sensitive paper, remove the wooden back and insert a piece of Velox or bromide paper, sensitive or film side towards the glass. Then replace back and turn the hold-fast spring until held by the supports. Exposure: Carry the enlarger out into

daylight—an even, diffused light is essential—if sunlight cannot be avoided, cover the negative with a piece of ground glass or fine tissue paper—and place on the ground with the negative pointing to the sky. The length of exposure varies according to the time of year, of day, and condition of negative. The following may assist as a guide, the figures being for good, bright negatives, with almost clear glass in the shadow, and Special Velox as the sensitive medium:—Feb.-April: 11 a.m. to 2 p.m., $1\frac{1}{2}$ minutes; 2 to 4 p.m., $3\frac{1}{2}$ minutes. May-July: 11 a.m. to 2 p.m., $\frac{3}{4}$ minute; 2 to 4 p.m., 1 minute; 4 to 6 p.m., $1\frac{1}{2}$ minutes. Aug.-Oct.: 11 a.m. to 2 p.m., $1\frac{1}{4}$ minutes; 2 to 4 p.m., $2\frac{1}{2}$ minutes; 4 to 6 p.m., $3\frac{1}{2}$ minutes. Nov.-Jan.: 11 a.m. to 2 p.m., 2 minutes; 2 to 4 p.m., 5 minutes.

Payne's Exposure Calculator. Issued by Mawson and Swan, Mosley Street, Newcastle-on-Tyne.

This exposure calculator avails itself of the slide rule principle, and the data are printed on both sides of a cardboard slip, which in its case may be comfortably carried in the pocket. Quoting from the descriptive particulars, this calculator is based upon the principle that the light is always the same on the corresponding days in each year. The atmospheric conditions, however, differ, and the alterations in the quality of the light thus produced are arranged for in the calculator by dividing this possible variation into three kinds—mean, very bright, and very dull. "Mean" is accepted as that quantity of light which is present when the sun is just casting a shadow. "Very bright" is readily appreciated by every photographer. "Very dull" is understood to be that quantity of light which is present when it is only just possible to take a photograph. The slide rule is divided so as to give a direct answer when exposing upon an ordinary landscape and using a lens working at f/8 during the months of May, June, July, and August. An ordinary landscape is taken as one in which there are no heavy shadows in the immediate foreground. Any variations from these conditions may be readily met by multiplying the exposure which is first found for the standard conditions by the requisite exposure factors which are given at the back of the slide rule. Example: To find the exposure for an ordinary landscape, "Castle" plate, lens f/8, time 10 a.m. June, light "very bright." Adjust the slide rule until the division marked "Very bright" is opposite to the division marked "Castle," and then, as 10 a.m. is between 9 a.m. and 3 p.m. against the division marked 9 to 3 will be found the exposure, which is 1-40th. of a second. If it be desired to use f/16 instead of f/8, from the list of exposure factors on the back of the rule, the multiplying factor for this stop is found to be 4, and 1-40th of a second multiplied by 4 gives 1-10th of a second as the answer. Knowing that the exposure for a "Castle Plate" with f/16 upon an ordinary landscape is 1-10th second, it is easy to calculate the exposure for "Shipping," which will be 1-30th second, or "Clouds," which is 1-100th second under similar conditions. In the cases of the exposure being made in January or December, it is necessary to multiply them by 4, in February or November by 3, in March or October by 2, and in April or September by $1\frac{1}{2}$.

The intelligent use of this little device should, as Messrs. Mawson and Swan claim, convert it into a useful plate saver.

THE Kodak Sensitised Post Card Competition.—The following is a list of the prize winners:—Class A, portraiture and figure subjects: 1st prize, Miss A. M. Walters, Forthampton Vicarage, Tewkesbury; 2nd prize, Mr. A. Ashe, 27, Elm Grove Road, Barnes, Surrey; 3rd prize, Mrs. Turnbull, 11, Slitrig Crescent, Hawick, N.B.; 4th prize, Mr. J. Peat Millar, Braehead, Beith, N.B.; 5th prize, Mr. J. A. Wilson, B.A., Westminster College, Cambridge; 6th prize, Miss M. J. Adnams, 71, Newborough, Scarborough; 7th prize, Mr. H. Montgomerie, Laigh Croft, Kilmaurs, Ayrshire, N.B.; 8th prize, Mr. A. M. Scott, 2, Woodville Gardens, Langside, Glasgow; 9th prize, Miss E. Wheelwright, 18, Grosvenor Road, Watford, Herts; 10th prize, Mr. F. E. Huson, 53, Gleneagle Road, Streatham, S.W.; 11th prize, Mr. R. Burnie, 162, Cambridge Drive, Kelvinside North, Glasgow; 12th prize, M. Le Maillot, Vice-President of the Photographic Society of St. Malo. Class B, landscape and seascape: 1st prize, M. Le Maillot, Vice-President of the Photographic Society of St. Malo; 2nd prize, Mr. R. Burnie, 162, Cambridge Drive, Kelvinside North, Glasgow; 3rd prize, Miss E. A. Burton, 21, Finsbury Square, London, E.C.; 4th prize, M. G. Herwig, Onderwijzer, Oude Pekeld, Holland; 5th prize, Mrs. J. Anley, 39, De Parys Avenue, Bedford; 6th prize, Mr. C. Ponting, 26, Hill Top Mount, Roundhay, Road, Leeds; 7th prize, Mr. F. W. Beken, Blenheim House, Cowes, I.W.; 8th prize, Mr. H. G. Ayers, 110, Sunny Hill Road, Streatham, S.W.; 9th prize, Mr. W. E. Blackstone, 2, Olive Villas, Kimberley Street, Hull; 10th prize, Mr. A. E. Relph, 43, Aberdare Gardens, West Hampstead; 11th prize, Mr. R. Booker, 6, Alexandra Terrace, Bognor; 12th prize, M. J. Dantine, Imprimeur, Skee, Hainault. Class C, architecture, interiors and exteriors, street scenes, and other subjects not included in classes A and B: 1st prize, Mr. E. R. Bull, 53, Bovill Road, Forest Hill, S.E.; 2nd prize, Mr. J. H. Pratt, 21, Finsbury Square, London, E.C.; 3rd prize, Mr. J. R. Jewson, Virginia Cottage, South Street, Epsom; 4th prize, Mr. J. Peat Millar, Braehead, Beith, N.B.; 5th prize, Fleet-Surgeon S. T. O'Grady, R.N., Royal Naval Hospital, Great Yarmouth; 6th prize, M. J. Jacobs, Rue des Bogards 83, Louvain, Belgium; 7th prize, M. G. Marie, Le Puys; 8th prize, M. E. Leveng, 50, Rue Tronchet, Lyons; 9th prize, Miss Mills, Elm Lea, Old Windsor; 10th prize, Mr. C. A. Gandy, Arcot, Margate Road, Herne Bay; 11th prize, Mr. J. W. Smith, 66, Sarah Street, Darwen; 12th prize, Mr. H. R. Flanders, 85, Tavistock Street, Bedford. The judges were Sir H. Trueman Wood, M.A., and Mr. Thomas Bedding, F.R.P.S.

Commercial & Legal Intelligence

Messrs Lindsay, Hemery and Co., of Regent House, Brockley Road, S.E., write:—We are retail agents for the "Tea" Christmas Cards, and forward boxes of same—also descriptive circular—post free to any address. Probably many of your readers in out-of-the-way places would be glad of the information.

A RECEIVER Appointed.—In the Chancery Division of the High Court on Friday last, an application was made by Mr. Parker to Mr. Justice Byrne in the matter of an action in which the Automatic Photo Printing Syndicate were concerned, for the appointment of a receiver. There was no opposition. Counsel stated that he applied on behalf of Sir George Newnes, who owned nearly half the amount of the £12,000 capital of the company which was issued. There was a clause to the effect that the whole principal money should become due if the company stopped payment. There was evidence that the company had drawn cheques which were dishonoured, and there was really no money to go on with. His Lordship appointed Mr. Geere, accountant, of Cockspur Street, S.W.

The Select Committee which has been considering the sale of articles containing poison used in agriculture and horticulture has, the "Field" understands, almost completed its labours. A draft report has been prepared and practically approved. This, it is understood, will recommend the addition of a third schedule to the Pharmacy Act, by which persons other than those authorised by the Pharmacy Acts will be licensed to sell articles containing poisons that are used in agriculture and horticulture, subject to regulations to be drawn up by the Privy Council. These regulations, it is expected, will provide that the articles shall be in special bottles and have special labels, and their general effect will be that articles like sheep dip and insecticides will be free from some of the restrictions that now exist.

At the Marylebone County Court (London), on Monday, before Judge Stonor, Mr. George Garett-Charles, photographic artist, 49, Acacia Road, Regent's Park, W., brought an action against Mr. John F. Levinger, 3, Church Passage, Guildhall, E.C., receiver and liquidator for "Press, Limited," claiming £13 13s. in respect of photographs said to have been lent with a view to their reproduction and publication. Mr. J. Scott, counsel, appeared for plaintiff, and Mr. A. Koe, counsel, defended. Mr. E. Morant, in the service of plaintiff, stated that he had called upon the editor of "The Candid Friend," which publication had been connected with "Press, Limited," and left certain 8in. by 6in. photographs. He was requested to leave the pictures, it being clearly understood that the charge to be made for permission to reproduce and publish them would be a guinea each.—The Judge: You say it was understood that the charge would be a guinea each?—The witness: It is the custom of the trade to charge a guinea each for the first use of the pictures. In answer to further questions, the witness said that he had several times called for the pictures, thirteen of which had never been returned. Counsel for the defendant submitted that there was no proper contract on the part of the editor to use at least certain of the photographs. It appeared also that at least one of the photographs had not been used for publication.—The Judge: It appears to be the custom of the trade to charge a guinea each for these pictures. I find for the plaintiff for twelve guineas, with costs.

Mr. George Francis Readwin, artist and photographer, of 7, Felham Road, New Catton, and carrying on business at 131a, Magdalen Street, Norwich.—The above-named debtor appeared for his public examination at the Norwich Bankruptcy Court on Friday last, before the Registrar. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £180 1s. 9d., and a surplus of £32 7s. 9d. Mr. W. J. Sadd for the debtor. In reply to questions put by the Official Receiver, debtor stated that he had been in the employ of Singer and of Brand and Co., Dereham Road, photographers. He had no capital when he started, and was not in debt. For a short time previously he had been in partnership with Mr. Quinton, a travelling photographer, but that was dissolved. He had never been bankrupt before. He had never kept any books of account. The business had always been a small one, and lately it had been very slow. In August, 1901, his wife died of cancer after a long and expensive illness, and debtor had himself been in bad health. He had been compelled to pawn his large lens, for which he received £5, and this had gone in rent and living expenses. He consulted Mr. Bracey, and later on Mr. W. J. Sadd (Sadd and Bacon). He had an interest under his grandfather's will in which a life tenant aged 84 or 85 had a life interest. It amounted to about £100, but he had mortgaged it to Mr. Wilson Gilbert for £30. Consequently, instead of there being a surplus, as he had estimated, there would be a deficiency of £50 or so. His drawings from the business amounted to about 30s. or £2 a week. The examination was closed.

ILFORD, Limited.—The sixth ordinary general meeting of the shareholders of Ilford, Limited, was held on Thursday week, at Winchester House, Old Broad Street, E.C. Major-General G. F. Blake (chairman of the company), who presided, said:—The first matter to which I invite your attention is an item on the balance-sheet under the heading "Freehold land, buildings, plant, etc." You will see that that item shows an increase of £9,000 beyond the amount that that particular entry showed last year. No inconsiderable portion of this expenditure was for effecting a very important improvement in one of our factories at Ilford. Further, we have found it necessary to build another factory. A very advantageous freehold site has been secured at Warley, and on it is being erected an auxiliary factory of a most important description for the work we have in hand. This improvement at Ilford, and the new factory, we are confident will tend to the development of our business, and, of course, that improvement and the additional factory will materi-

ally increase the value of our assets. Notwithstanding the outlay upon these works, I am glad to call your attention to our list of investments, which show practically the same amount of money invested as was invested last year. (Applause.) As to sundry debtors, they show an increase of rather over £2,000 on the amount shown last year, but that is explained in a manner which will be satisfactory to you. Our sales during the month of October, the last month of the year we are reviewing, were very considerable. The next item is stock, and it is put in our accounts at a valuation which possibly conveys a wrong and unjust impression. The stock there is our largest item—it is £26,000 odd, or some £7,000 more than last year. It is, however, only put down at actual prime cost; but as you can readily understand, the value is unquestionably more than it appears in the balance-sheet. It is significant, and a significance which should be pleasing to you, that, although our stock is more than £7,000 in excess of what we really had at this time last year, yet our creditors are more than £700 less. Referring back to our freehold land and buildings, I ought to call attention to the fact that we have again this year made an ample and liberal depreciation on our property. As a matter of fact, I have not the slightest doubt that our property is just as valuable as it was; in fact, some portions of it are more valuable to us than they were last year. In this matter of depreciation we have met with the cordial approval of our searching auditors. On the matter of sundry debtors, I may say that we have thousands of customers, and an immense number of open accounts. That the year under review should have passed without incurring a single bad debt is due to the unceasing vigilance of our managers. This is a testimony and proof of the sound principles on which your business is being conducted. In our report there is a feature that I must deal with, and that is, that, although and in spite of antagonistic circumstances which seemed to be unpleasant—I mean bad weather—our sales have been practically the same as last year. Our net profits may be less proportionately—rather less than an infinitesimal reduction—but when we consider the amount of business we do, that need scarcely be taken into consideration. However, we do not wish to be unnecessarily optimistic by putting before you pleasing things and glossing over others. As to our commercial manager, I am glad to tell you that we are in every way satisfied with the efficient manner in which he carried out his onerous and responsible duties. Acting a good deal on his advice, but after careful consideration, we came to the conclusion that it would be expedient to incur a larger outlay in certain matters, notably advertising. We have incurred a certain amount of expense which has lessened our net profits, but I can confidently assure you that we shall reap the benefit in the near future. As to the report, I feel that you will welcome our dividend again of 10 per cent., and also the bonus which we declare. This year we felt it right to give you a bonus, rather than write off a larger sum than £3,000 for goodwill. We have thought it better rather to increase the amount we put to reserve by an additional £1,000, bringing the amount this year up to £9,000, instead of £8,000 as last year. I hope that will meet with your cordial approval. (Applause.) At this point I feel it right, at the end of our fifth year, to review a little the satisfactory position which this company now occupies. In our prospectus, it will be remembered, it was set out there that the average profits for four years previous to the taking over of the business by the company, was some £46,000—the net profits I mean. In each of the past five years we have considerably exceeded that amount; in fact, the average for the five years comes out at £53,010. That is satisfactory, but in addition to that we have built up a reserve of £41,000, written off £61,000 from the goodwill, and depreciated the property by over £10,000. (Loud applause.) I have now a further piece of information to give you, which I am sure will be received with gratification, and that is that both our managing director and our colleague, Mr. Hughes, whose excellent work it would be invidious for me to mention in their presence, have consented to renew their agreement with us for another five years. (Renewed applause.) I have also another piece of information to give which will also be exceedingly gratifying to you. I am exceedingly glad to be able to tell you that a few days ago Mr. Harman, the founder of the original company—the Britannia Company—has agreed to accept a position on the Board of the company. From the year 1830 up to the time that this company was formed Mr. Harman presided over the affairs of the first company with signal success, and now he has consented to join our Board. (Applause.) That is a matter for congratulation, as his presence with us means enormous strength being given to our counsels by his vast experience, not only as a photographer, but as an expert in our business. When Lord Crawford could no longer hold the chairmanship of this company, an attempt was made to induce Mr. Harman to take his place, but that gentleman declined the honour, though urged by Mr. Knobel and myself. Now, at the end of our fifth year, Mr. Harman, finding our affairs so satisfactory, has come back to his old love, and to support the Board by his valuable counsel. I now beg to move: "That the annual statement of accounts and balance-sheet, and the reports of the directors and auditors, be and they are hereby adopted, and that the dividend declared and the bonus be paid in accordance therewith." Mr. Charles J. Cox (deputy chairman) said he had great pleasure in seconding this motion. Mr. Lee Smith congratulated the directors on the admirable result of their working during the past year. It was exceedingly gratifying to hear that the founder of the company was about to join the Board. It was known that in their trade there was much competition, and therefore the acquisition of Mr. Harman was of vast importance in the guidance and counsel which he would be able to afford the Board. He proceeded to refer to the position of the preference shares on the Stock Exchange, stating that he could scarcely comprehend how it was that they stood at the present figure, more especially when they had in liquid assets £190,000, in buildings £46,000, in investments £92,783, in stocks £6,836, and with other items making

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Dec.	Name of Society.	Subject.
5.....	West London Photo. Society..	{ Show of Work done at Outdoor Meet- ings, and Miscellaneous.
5.....	Leicester Literary	{ Exhibition of Photography Prize Lan- tern Slides for 1902.
5.....	Borough Polytechnic.....	{ Lantern Slide Making by Reduction Mr. F. W. Gregg.
8.....	Oxford Camera Club	{ Demonstrations by Mr. H. Minn.
8.....	Southampton Camera Club	{ Demonstration of the Lumière Process of Colour Photography.
8.....	Society of Arts	{ The Future of Coal Gas and Allied Inventions. Professor Vivian B Lewes.
9.....	Leeds Photographic Society ..	{ Selections from a Year's Lantern Slide Work. Mr. Godfrey Pingley.
9.....	Isle of Thanet Photo. Society	{ Club Competition: Lantern Slide Making. Prize, Silver Medal pre- sented by Mr. P. F. Weeks.
9.....	Roy. Photo. Soc. of Gt. Britain	{ Photography in Marine Zoology. Dr. R. Norris Wolfenden.
9.....	Birmingham Photo. Society ...	{ Birmingham Markets and Fairs. By Mr. Walter Barrow.
9.....	Brentford Photo. Society	{ Colour Photographer by the Lumière Process. Demonstration by Mr. Turner.
10.....	Ashton-under-Lyne Photo.	{ Discussion on Winter Photography in its Various Aspects.
10.....	Leeds Camera Club	{ Yorkshire Photographic Union Port- folio (Members' Work).
10.....	Borough Polytechnic.....	{ Practical Enlarging. Mr. J. H. Gear, F.R.P.S.
10.....	North Middlesex Photographic	{ A Trip to Eastern Ireland. Mr. C. H. Oakden, F.R.P.S.
10.....	Nottingham Camera Club	{ The Two Rivers. Mr. S. Bourne.
10.....	Southport Photo. Society	{ Practical Working of Rotograph Papers, &c. Mr. W. A. Sims.
10.....	Photographic Club	{ Demonstration. G. Houghton & Son.
10.....	Society of Arts	{ French Rural Education and its Lessons for England. Mr. Cloudesley Bre- erton.
10.....	Southsea Photographic Society	{ Animated Photographs. Mr. Luther Dyer.
11.....	Roy. Photo. Soc. of Gt. Britain	{ The Great Photographic Star Map. Professor H. H. Turner.
11.....	Society of Arts	{ Domestic Life in Persia. Miss Ella C. Sykes.
11.....	London and Provincial	{ Exhibition of competing pictures.
11.....	N.-W. London Photo. Society	{ A Ramble Round the Tower of London. A. Bedding.
11.....	Goldsmiths' Institute Photo ...	{ Welford's Photographie Flexibilities.
11.....	Liverpool Amateur Photo.	{ Lantern Lecture. Bridgnorth. Mr. Joseph Marples.
11.....	Woolwich Photo. Society	{ Camera Notes by an Amateur Field Naturalist. Mr. Douglas English, B.A.
11.....	Richmond Camera Club	{ Night Photography. By Mr. Ellis Kelsey.

ROYAL PHOTOGRAPHIC SOCIETY.

TECHNICAL Meeting, November 25th.—Mr. Leslie Selby in the chair.

A frame of photographic enamels, for the presentation of which the Society is indebted to Mr. A. L. Henderson, who made them in 1866, was passed round for examination.

In the absence of the author through indisposition, the secretary read a paper on "Halation," by Mr. Harold Holcroft, M.A., F.C.S. The paper was in some respects supplementary to one read before the Birmingham Photographic Society, and published by us in our issue for January 31st of the current year. The present paper points to the necessity for further investigation into the cure of halation, and with this view, the importance of isolating each of the causes. The effects upon an unbacked plate, classed as halation, are complex, and attributable to various causes. The author refers to three separate principal forms of halation:—(1) That due to lateral spreading of light in the film; (2) that due to reflection from the back internal surface of the glass plate; and (3) that due to reflection from the separating division of the dark slide. Considering what takes place in the case of an unbacked plate when a bright spot of light is focussed in the centre of an otherwise black field, and the possibility of accurately accounting for the destination of the whole of the rays proceeding from the bright spot, one should include all the separate causes of halation. Some are radiated forward, and are absorbed by the black interior of the camera; some radiate laterally into the substance of the film, and produce a ring of what is called lateral halation round the spot. This lateral halation will be chiefly in the upper parts of the film. Other rays will radiate into the glass plate, and some of them will be reflected from the internal back surface of the glass, and produce a ring of halation on the inner surface of the film. The extent of the halation will depend upon the intensity of the light, the thickness of the glass, the physical condition of the film, the length of exposure, etc. The author describes the method adopted for measuring the area of the lateral halation and the reflected halation, and in the course of these remarks develops the possibility of a further cause of halation due to the lens itself. It has been assumed that the lens projects a clean image of the spot on the black field, and the possibility that it

a total of £168,619. He could only understand the position of these preference shares by the fact that in the market preference shares in industrial companies were mere shuttlecocks. Mr. Lyall also congratulated the directors on the successful year they had had. They were quite prepared, owing to the recent bad summer, to hear of a smaller turnover, but he saw that the Ilford company had increased their business. Considering the great advance of film photography, he hoped the Board would make arrangements for the introduction of this branch. The resolution was then put to the meeting and agreed to. The chairman then moved that Mr. Charles J. Cox, the retiring director, be re-elected. Mr. Knobel, in seconding the motion, said that competition had been referred to, and he might say that such competition was a very good thing for them. (Hear, hear.) It kept the whole of their staff up to the mark, and it was very necessary that all members connected with the management of this company should be vigilant in every department, whether relating to the trading of the company or in the manufacture of their articles. In the balance-sheet they would notice they had a reserve fund of several thousand pounds sterling; but he might tell them that at Ilford they had another reserve of skill and energy which the directors could draw upon to meet any demand that might be made. The resolution was agreed to. The auditors, Messrs. Turquand, Youngs, Bishop, and Clarke were re-appointed on the motion of Mr. Helby, seconded by Mr. Lockhart. A vote of thanks to the chairman, the directors, and staff having been passed, the chairman returned thanks, and proceeded to say that they had placed on the market this year two new photographic papers, and the result had been, as far as they had gone, most satisfactory to them. Late in the season they had introduced an excellent camera, of patented designs. The result as yet had not been very pronounced. It was so late in the season when they produced it; but they were not without confidence that that would also materially affect the prosperity of their business.

THE Christmas number of "Photography" (published by Messrs. Iliffe and Sons, Limited, 3, St. Bride Street, London, E.C.) contains reproductions of well-selected "photographs of the year," with accompanying letterpress of an appreciative and critical nature. The book makes a handsome present, and should lead the novice to aspire to the production of good photographs.

Use of Photographs as Evidence.—Ever since its inception, photography has rendered valuable assistance to justice by the popular nature of the data it is capable of producing. One of its earliest services along this line was the improvement of the various "rogues' Galleries" scattered throughout the country, writes Mr. James G. McCurdy, in "The Scientific American," where efforts were being made to keep a record of portraits of leading lawbreakers. Prior to the advent of photography, likenesses of criminals, as sketched by the artist and reproduced by the wood engraver, offered but little aid to the officers of the law for purposes of identification. The camera, however, capable of catching each facial characteristic and fleeting expression, together with the ease with which its results could be duplicated without loss of any essential qualities, proved a most effectual help in the detection of criminals. The United States government endeavoured for many years to perfect a system of identification by description merely, in the matter of Chinese certificates. But so many frauds were perpetrated that at last Congress was compelled to adopt the amendment of November 3rd, 1893, requiring every such certificate to have attached to its face the photograph of the person applying for the same. This clause in the exclusion Bill was very distasteful to the Chinese, who fought it with great energy throughout the country, but without avail. When at last the Chinese found that they must comply with the new regulation or suffer deportation, the photographers of the Pacific Coast could hardly meet the demands of the excited Celestials, all of whom had become very anxious to be photographed before the expiration of the time limit. Certificate photographs are not retouched, and any scar or other prominent marking upon the face is made as conspicuous as possible, to aid identification. The effect of the new law was most salutary, and while frauds are still occasionally attempted, they are rarely successful. When the foregoing facts are taken into consideration, it is not at all surprising that the camera is held in wholesome respect by those who would seek to break or evade the law. This point was emphasised last winter during the great teamsters' strike in Boston, where policemen riding with the drivers found cameras more formidable weapons than firearms would have been. Somehow, when those bent on mischief realised that any act of violence on their part would be duly recorded by the all-seeing lenses, to be brought up against them later, the very boldest among them shrank from making a demonstration. Although the photograph has been used for years as a means of identification, it is still looked upon in many courts with a degree of suspicion, when submitted in general evidence. This is largely due to the fact that photographic negatives, in the hands of skilful manipulators, are capable of much "doctoring," and can readily be made to bear witness to untruths. Yet realising that all evidence is open to question and must be thoroughly sifted, and trusting to photographic experts to unearth attempted fraud, the photograph is being admitted in courts of justice as evidence more extensively each year. Finding by experience that a well-taken, untouched photograph bearing upon a case in point often makes valuable evidence, many railroads, steamship companies, and other corporations are making it a practice to keep cameras within easy reach of their employees, to be used when necessity arises.

is a factor in halation comes as a surprise. A photographic lens usually consists of several distinct lenses, bounded by surfaces of varying radii; the lens not only transmits, but reflects, light at each surface. Flare spot is caused by light reflected from one of the back surfaces and reflected again at one of the front surfaces, being brought more or less to a focus upon the centre of the plate. The correction of flare spot is brought about by such an adjustment of the curves and the position of the stop that the spot is enlarged and distributed over the whole surface of the plate with reduced intensity. There are other reflecting surfaces, however, in addition to the principal surface to which the flare spot just discussed is due, and these cause what the author describes as secondary and tertiary flare spots, which are likely to manifest themselves under critical conditions. Mr. Holcroft sees little possibility of correcting this form of halation if it is rightly ascribed to the lens, seeing what a wonderful compromise of conflicting conditions the modern lens already is. The author sets himself the following programme: (1) To resolve halation into its constituent parts, and to determine the exact part played by the lens; (2) to ascertain the amount of lateral spreading of light in the film under varying conditions; (3) to examine the distribution of halation in the film by preparing cross sections of the film for the microscope. Variable factors, many in number, have to be considered—the actinic intensity of the light, the stop valve, speed of film, exposure, the developer (its strength, temperature, and penetrating power), physical constitution of the film, its thickness and colour, thickness of the plate, the actinic absorptive power of the glass, etc. It is also necessary to work under standard conditions, which the author also details. The experiments are still proceeding.

A long discussion ensued, which it is understood will be submitted to the author for his consideration and reply.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

NOVEMBER 27TH.—Mr. A. E. Smith in the chair.

Mr. J. W. Hodges read a paper on "The Photography of Architecture." At the outset, he made a strong plea for more specialising in photographic work, pointing to the greater pleasure to be obtained by the thorough mastery of one subject than the superficial knowledge of many. His own speciality lay in the study of architecture and its photographic rendering. Throughout the lecture the meeting had ample opportunity for appreciating the extent to which Mr. Hodges has carried his specialising, in the shape of numerous splendid examples of architectural slides. An elementary knowledge of the history of Gothic architecture gives to the beginner in architectural photography a strong inducement to acquire more, and greatly increases his chances of quickly acquiring a knowledge of the photographic treatment of the wealth of subjects which abound in this country. Mr. Hodges discussed the use of backed plates, the best forms of camera for the work, the utility of rising and cross fronts, levelling devices, slow versus fast plates, the use of the actinometer, etc. Full exposure is a sine qua non, and exposure meters appear to be of little value in the dark buildings. He advocated the employment of two cameras, especially in places where very long exposures are called for, the second being devoted to the photographing of details, which offer an ever-ready excuse for an exposure. As the slides were shown, Mr. Hodges gave interesting data about them and their originals, and it was generally agreed that his paper and illustrations had afforded a valuable series of hints to those thinking of pursuing the subject further.

THE SOUTHAMPTON CAMERA CLUB.

A MEETING of the Southampton Camera Club was held at the club-room, Philharmonic Hall, on Monday evening, November 24th, under the presidency of Mr. W. Burrough Hill, who takes a paternal interest in the club, which, under good officership, is making pleasing and satisfactory progress. At the outset of the proceedings 100 slides of Canadian scenery, lent by the Royal Photographic Society, to which the club is affiliated, were thrown on the screen by Mr. Vivian; and Mr. S. G. Kimber, the energetic hon. secretary, added to the enjoyment of the entertainment by making a few concise descriptive remarks as the slides "passed through." Subsequently, at the invitation of Mr. Hill, who presided in the absence of the Mayor (Mr. H. I. Sanders), the hon. secretary gave a brief history of the club, which, he said, was started six years ago in an underground kitchen at Northam with a membership of eight. To-day they could boast a membership of over 100, and could honestly lay claim to being one of the strongest clubs in the South of England. (Hear, hear.) Speaking of the recent exhibition, held in the Art Society's Gallery, Marland Place, in behalf of the club he tendered their heartiest thanks to all who contributed to the success of their annual venture, and congratulated the members on the excellent photographs exhibited by them, which earned the encomiums of the judges. There was no doubt, he added, when the accounts were gone into they would have a balance of £20 on the exhibition, and the committee proposed to spend this amount on the purchase of apparatus for the use of the members. (Applause.) The president complimented the club on the successful exhibition, which, he said, was the most perfect of its kind he had ever attended. Mr. Hill subsequently presented the medals and certificates won by the members at the exhibition.

A vote of thanks to the president concluded the proceedings.

The members met on the 1st inst., at their headquarters, Philharmonic Hall, under the presidency of Mr. G. Vivian, and after the election of new members, Mr. Harry Wade, representing Messrs. Wellington and Ward, gave demonstrations on the specialities of the firm. The utility of the film and paper negatives was explained. The slow contact paper

could not lie; but the first three slides proved that it could lie artistic-

The paper can be safely worked by gaslight, and exposure made by any artificial light, or very short exposure in daylight. A new method of procuring warm tones on slow contact paper by development was shown. The developer used being edinol and hydroquinone, well restrained with potassium bromide, and the tones obtained ranged from sepia to red chalk, according to the exposure given, a long one being necessary. The results were highly appreciated. Mr. Wade then showed the process of carbon printing by both single and double transfer, and was given a hearty vote of thanks for his interesting and instructive demonstrations.

CROYDON CAMERA CLUB.

THE meeting on Wednesday, the 28th ult., was devoted to lantern slides, a selection being made for the seventieth lantern show to be held at the Art Gallery, on December 10th. It was announced that an interesting series of Paul's animatographs would also be displayed.

During the evening a demonstration of Messrs. Butcher and Sons' Maxlite generator, and four burner acetylene lamp, was given by Mr. W. H. Smith. The lamp burned with great steadiness, without smell or smoke, and gave a brilliant disc of good colour. The general opinion of all present was, that when the limelight or electric arc was not available, the Maxlite formed a most efficient substitute.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

MR. J. PAGE CROFT, one of the most original and best abused workers of the day, was announced to lecture before the above society on Wednesday last. He demonstrated the gum-bichromate process, and remarked as follows: "Photographic technique has been mastered, the future progress in photography will come from the artistic workers, and gum is the ideal process for the photo-artist. It is also the simplest process under the sun; a touch of the brush here, the finger there, a dash of hot water somewhere else, and there you are: just the effect you want and just what no other process will yield. For latitude no other process equals it; you can have enough rope to hang both in the Salon and Royal. If you tire in developing a gum print, dry it, put it away, and start again when you feel inclined." Mr. Croft is a practical preacher, his efforts were just incomplete enough to make a man want to try for himself, and as an encouragement he offered a guinea's worth of apparatus for the most artistic bi-gum print by any of the members.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.

ON November 25th, Mr. A. B. Gardiner, a well-known local photographer, gave a lecture and demonstration before this association. Mr. Gardiner is a firm believer in the merits of modern gelatine dry plates, expressing the opinion that the man for whom a first-class gelatine slide was not good enough must be hard indeed to please. The lecturer explained the manner in which slides can be made by contact, and also by reduction in the camera, the former method being usual in the case of small negatives or where a small portion only of a large negative was required, while the reduction method is absolutely necessary where it is required to make a slide from the whole of a large negative. The lecturer recommended beginners to commence with strong plucky negatives, as it is easier to judge the exposure from them than it is from softer negatives, although no accurate rules can be given on this head. As conditions vary so widely, such as density of negative, source, strength, and distance of light and effect required; Mr. Gardiner said the secret of doing good work lay in choosing a suitable negative, full exposure and tentative development carried far enough. With regard to development, he said that to get the best results in all cases the maker's formulæ should be used, and condemned the indiscriminate publication of formulæ by persons lacking scientific knowledge. The Howard-Farmer reducer was recommended for clearing off fog and generally adding brilliancy to the finished transparency. Many useful hints as to binding, spotting, increasing and decreasing, contrast by the use of different sources of light and the interposition of various coloured glasses between the light and the negative, and many other matters were given by the lecturer. Mr. Gardiner exposed some plates, developed, fixed, cleared, washed, and finally put them through the lantern, demonstrating in an interesting manner an absorbing branch of photographic work.

LONGTON AND DISTRICT PHOTOGRAPHIC SOCIETY.

MR. F. W. PILDITCH, of Birmingham, entertained a fair number of members of the Longton and District Photographic Society with a lecture at the Court House, recently, entitled "Stories of Dartmoor." Mr. Pilditch had many interesting and amusing stories to tell, and he spoke in warm praise of the charming physical beauties of the county which Baring Gould describes in "Uriah." The lecture was very enjoyable, and was illustrated by a number of splendid lantern slides, by means of which the audience were able to appreciate the irresistible picturesque-ness of Devonshire scenery. At the close of the lecture a series of members' slides were tested through the lantern.

DEVONPORT CAMERA CLUB.

BEFORE the Devonport Camera Club recently, Mr. W. D. Welford delivered a lecture on "Photographic flexibilities, in the camera, the developer, the printing process, and in general work." The lecture was of a practical character, and was rendered additionally interesting by demonstrations and the exhibition of a large series of photographs. A splendid set of slides was also shown with the lantern. Among some people, the lecturer remarked, there was an idea that the camera could not lie; but the first three slides proved that it could lie artistic-

ly. A fine set of night pictures, taken in New York, and a number taken in the course of a week in camp in "Shakespeare country" were also much appreciated. Mr. R. J. Lamb presided, and announced that a conversazione and exhibition of members' work would be held in January. Two new members were elected.

BLAIRGOWRIE AND DISTRICT.

At the monthly meeting, in the club room, recently, Mr. Jas. Richardson, V.P., presided, and Mr. MacLachlan gave in a report on the meeting at Dundee to consider the question of affiliation amongst the societies. The action of the delegates—Messrs. Richardson and MacLachlan—met the approval of the meeting. The result of last month's competition—wild birds' nests, in situ—was announced as follows: 1, D. G. Monair; 2, J. W. Petrie; 3, Jas. Richardson. Mr. J. W. Petrie then gave a paper on "Gum Bichromate Printing," wherein he advocated that process for bold work where broad effects were aimed at. He demonstrated the method of sensitising and coating the paper, and was bombarded with questions from the members present, which resolved itself into an animated discussion.

News and Notes.

THE telegraphic and cable address of the Imperial Dry Plate Co., Limited, of Cricklewood, London, N.W., is now "Impeople, London."

"Dogs and Doggerel."—Mrs. Carine Cadby writes:—"We were very much amused at your wag's humorous remarks about our little pamphlet. We just had enough brains left from our plate coating to produce this little book I am enclosing. Perhaps it may inspire that wag to further witticisms." The little book is published by the Art Record Press, 144, Fleet Street, London, E.C., price sixpence. The "doggerel" concerns itself with the doings of a couple of Airedale pups, who appear to have a very good time indeed. The nine photographs are extremely well done, and, with the lines, further testify to the remarkable versatility of those accomplished photographers, Mr. and Mrs. Cadby.

THE year book of the Gateshead Camera Club is a capital production. Here are some of its contents:—A frontispiece; list of officers and council; rules; syllabus; an open letter from F. M. Sutcliffe; local spots of interest; exposure guides; finding due south; notes on the construction of a picture; weights and measures; development; formulæ; general hints; federation of Northumberland and Durham photographic societies; and a list of members who offer special help. Well done, Editor Hewitt!

MESSRS. MARION AND Co., Limited, of Soho Square, London, W., are issuing a series of negative masks for printing Christmas, new year, and birthday mottoes on photographic papers. The masks are on translucent cloth, and the positive is in dark pigment. A set of six different designs is obtainable for one shilling and sixpence.

PHOTOGRAPHIC Society for Bowes Park.—A meeting was held at the Collegiate School, 111, Myddleton Road, Bowes Park, on Wednesday, the 26th ult., for the purpose of forming a photographic society for the district, fifteen gentlemen being present, and a number of others having signified their intention of becoming members. Mr. Craston having been voted to the chair, it was proposed and unanimously agreed that a photographic society be formed for the district, to be called the Bowes Park and District Photographic Society. The following gentlemen were appointed to form a committee to draw up the rules of the society: Messrs. Cob, Duncan, H. C. Bird, A. J. Craston, Hornsey, Richardson, and Young. Mr. A. Kerwin was elected hon. secretary pro tem. It was agreed that the fee for adult members be 5s. per annum, and junior members, under 18 years, be 2s. 6d. per annum, no entrance fee being charged to members joining during remainder of the present year. It was also agreed that ladies be admitted to membership.

A GOOD many more of our readers know of Mr. F. C. Tilney than think they do. Amongst photographic critics he is one of the most active, although his name is not usually found at the foot of his articles. We are now in a position to criticise him on his own ground, which is that of art, for he sends us a pack of Shakespearean playing cards, designed and schemed throughout by himself. All the kings, queens, and knaves are taken from Shakespeare's plays, with appropriate quotations. He claims that the usual objections to fancy cards have been entirely avoided, for the kings are instantaneously distinguishable from the Jacks, both by their dignified appearance and by the crowns on their heads. The Jacks look unmistakably the knaves they are. The quotations have evidently been chosen with great care, and very happily give the cue to the character depicted, of whose utterances they consist, and bear a metaphorical allusion also to the vicissitudes of card playing. The cards are undoubtedly the most artistic ever yet produced, and for 2s. 6d. make a capital present for Christmas time. The Queen has graciously accepted a pack. Altogether, we heartily congratulate Mr. Tilney on his artistic success, and wish him a financial extension of it.

THE Bausch and Lomb Competitions.—A new booklet relating to these competitions has been issued by Messrs. A. E. Staley and Co., 35, Aldermanbury, London, E.C., of whom copies may be obtained. We extract the objects of the competition:—The main object of this competition is to demonstrate the possibilities of our photographic lenses from the optical standpoint, that is, under the most trying conditions optically. The properties of a lens which we seek to obtain in the highest degree in our lenses are freedom from astigmatism, defining power, depth of focus, flatness of field, and speed, combined with proper focal length to give the best pictorial results. Photographs demonstrating these qualities in the highest degree will have preference over those of equal

pictorial excellence in which such qualities are not so clearly demonstrated. Interesting subjects should be selected. A photograph may show perfect lens work, artistic composition, proper lighting, and have all the qualities that go to make up a picture, without exciting the least interest in the beholder. Photographs should appeal in some way strongly to those who have no knowledge of the particular subjects or incidents depicted.

EXHIBITION at Leith.—The second annual exhibition of the work of members of the Leith Photographic Association was opened on Tuesday week in the Wilson's Hall, Hope Street, Leith. The exhibition is most interesting for its examples of what photography is capable of giving us. All the work on view, some 110 frames in number, evidences a distinct appreciation of the pictorial on the part of the exhibitors, generally combined with a very high technical ability. The attendance of the public has been extremely gratifying, and goes to show the place photographic art is making for itself. Mr. J. Gibson is a prominent exhibitor, and his works seem to us to point to the deep sympathy that exists between him and his subjects. This is very strikingly suggested by his "Early Spring," where we have a splendid rendering of that singular feeling we are all so apt to experience on its advent. So, similarly, with "Sunset," another very successful contribution. Mr. Wm. Duncan, S.S.C., the hon. secretary, has been wonderfully successful with his picture of the woodyard fire. It must be reckoned an especial success. "Stacking Hay" is another good thing, this time from the camera of Mr. T. Wilson. As a transcript of country life it will be hard to beat. This also applies to the "Haymaking" of Mr. W. J. Melville. "Mirth," by Mr. G. B. Massie, shows a masterly treatment, and the print is of a rare quality. Other workers whose contributions should on no account be passed without notice are Messrs. Robertson, Hayes, Clark, Laycock, Ewart, and Oliver. To the visitor who is interested in lantern slides and stereoscopic work, the exhibits in this section must prove interesting, they are of so high quality generally. Altogether, the exhibition as a whole is marvellously good, and full of interest to all who have an outlook in photographic practice.

HOVE Camera Club Exhibition.—The following is the award list:—Open classes: Class A, landscape, river scenery, and marine, silver medal, No. 32, A. Fenn; bronze medals, No. 19, C. E. Etches; No. 66, D. Deeley. Class B, figure, portraiture, and animal studies, silver medal, No. 297, H. Lawrence; bronze medals, No. 257, Douglas English, F.R.P.S.; No. 172, Mrs. R. M. King. Class C, architecture—interior and exterior, silver medal, No. 323, Rev. H. R. Campion; bronze medal, No. 339, W. A. Clark; certificate, No. 341, S. A. Pitcher. Class D, flowers, fruit, still life, etc., silver medal, No. 379, H. Lawrence; bronze medal, No. 375, A. Tauxe; certificate, No. 367, Mrs. Alice Dumas. Class F, lantern slides—landscape and marine, silver medal, No. 391, W. A. Clarke; bronze medal, No. 384, F. Parkinson; certificate, No. 385, Ellis Kelsey. Class G, lantern slides—portraiture and animal studies, silver medal, No. 414, H. Wade; bronze medal, No. 408, D. J. Gadsby; certificate, No. 426, Grun. Class H, lantern slides—architecture, etc., silver medal, No. 432a, H. Wade; bronze medal, No. 420, D. J. Gadsby; certificate, No. 426, W. Harvey. Club classes: Challenge silver, "Gladys," No. 509, F. R. Richardson. Class J, landscape, silver medal, No. 465, Victor E. Morris; bronze medal, No. 459, R. C. Ryan; certificate, No. 480, A. R. Sargeant. Class K, marine, silver medal, No. 489, Victor E. Morris; bronze medal, No. 488, F. J. Phillips; certificate, No. 492, C. Berrington-Stoner. Class L, portraiture, silver medal, No. 509, F. R. Richardson; bronze medal, No. 513, C. Berrington-Stoner; certificate, No. 523, H. Lawrence. Class M, architecture, silver medal, No. 533, F. J. Phillips; bronze medal, No. 529, D. J. Gadsby; certificate, No. 526, W. Bailey. Class N, lantern slides (any subjects), silver medal, No. 551, Victor Morris; bronze medal, No. 553, Capt. Davidson; certificate, No. 547, F. R. Richardson. Class O, novices (in sets of three), bronze medal, Nos. 575-577, F. Northern; certificate, Nos. 565-567, W. A. Ellington. Class P, lantern slides (novices), bronze medal, No. 588, W. Bailey; certificate, No. 586, H. W. Bailey.

THE View from Richmond Hill.—The Parks Committee of the London County Council have issued a report in connection with the negotiations with Sir Whittaker Ellis for preserving the amenities of the view from Richmond Hill. The committee point out that the properties at Twickenham, known as Cambridge Park Gardens and Haversham Grange, which are within the view from Richmond Hill, are at present owned by Sir Whittaker Ellis. Recently the Cambridge Park Gardens property was offered for sale by auction, but was bought in. The owners of these two properties and of Meadowbank adjoining to the westward are under covenant each with the other not to build in advance of a certain line. It was the desire of the committee that an agreement embodying this covenant should be scheduled to the Act of Parliament authorising the purchase of Marble Hill; but they were not able to obtain the consent of the owners of the properties to this course in sufficient time to enable this to be done in the Bill then before Parliament. In October, 1901, Sir Whittaker Ellis wrote, forwarding a plan showing the line above referred to so far as his properties were concerned, and stating that he would undertake not to build below that line provided the Marble Hill property were retained as an open space. He afterwards wrote stating that if the Marble Hill estate and such other adjoining properties were secured by the London County Council as would, in their opinion, preserve the view from Richmond Hill, he would be quite willing to give such undertaking as the Council might desire that the land he held on the opposite side of the river, being Cambridge Park Gardens and Haversham Grange, should not be further built upon than at present, except conservatories or other buildings of that nature for garden purposes. When, however, Cambridge Park Gardens were recently offered for sale, there was no reference in the conditions of sale to restriction of building other than the covenant with the adjoining owner. On Sir Whittaker Ellis's being asked to cause an announcement to be made in the auction room that the property

would be sold subject to the undertaking he had given not to build upon it, he replied, "I certainly never contemplated binding the property in other hands than my own, and of course it will now be for any purchaser of the property to deal with the question." The committee are advised that Sir Whittaker Ellis can be required to enter into the undertaking indicated by his letter, and accordingly recommend the Council to pass a resolution to the effect that such steps as may be necessary be at once taken for the enforcement of the promise, and generally for the protection of the Council's interests in relation to the view.—"The Times."

Correspondence.

THE UNIVERSAL EXPOSITION, ST. LOUIS, 1904.

To the Editors.

Gentlemen,—After the formal acceptance, by the British Government, of the invitation to take part in the Universal Exposition, it was thought desirable to prepare some special descriptive literature for the guidance of intending exhibitors and visitors from the United Kingdom.

In pursuance of this purpose, I forward, for your information and with my compliments, the accompanying illustrated pamphlet. An attempt has been made to set forth, with all possible brevity, but with completeness, the scope and plan of the Exposition, estimates of the men, and the historic events to be commemorated, descriptions of the grounds and buildings, a comprehensive review of the various exhibits, notices of the organisation, the work, and the financial resources available, and the relations which foreign countries, the Government of the United States, and the States of the Union, bear to it.

It is believed that readers may thus obtain a fair idea of the scheme, its aims, and its progress, in all of which the people of the foreign countries accepting invitations have an interest scarcely less vital than those of the United States themselves.—I am, yours very truly,

GEORGE F. PARKER.

Sanctuary House, Tothill Street, Westminster, S.W.

November 27th, 1902.

[In the interesting pamphlet sent by Mr. Parker photography is classed with the liberal arts.—Eds. B.J.P.]

THE GOERZ COMPETITION.

To the Editors.

Gentlemen,—May I ask you to kindly inform your readers that, at the request of numerous photographers in the British Colonies, the latest date for receiving prints for my £300 competition has been extended from December 31st, 1902, to June 30th, 1903.—I am, dear Sirs, yours faithfully,

C. P. GOERZ.

4 and 5, Holborn Circus, London, E.C.

November 27th, 1902.

THE TRAILL-TAYLOR MEMORIAL LECTURE.

To the Editors.

Gentlemen,—I shall be much obliged to you if you will permit me to remind your readers that the fifth Traill-Taylor Memorial Lecture will be delivered at the rooms of the Royal Photographic Society, 66, Russell Square, W.C., on Thursday evening, the 11th December, at 8 o'clock, by Professor H. H. Turner, F.R.S., of Oxford Observatory. The subject of the lecture is "The Great Photographic Star Map." The president of the Royal Photographic Society, Mr. T. R. Dallmeyer, has kindly consented to preside.

Admission tickets were sent by me last week to all the London and suburban photographic societies, but if it should be found inconvenient to obtain them through these channels, I shall be happy to send others to anyone upon receipt of a stamped addressed envelope.—Yours truly,

P. EVERITT, Hon. Sec.

88, Evering Road, London, N.

December 1st, 1902.

STILL DRIFTING.

To the Editors.

Gentlemen,—This is a melancholy fact as may be seen by the hyperbolic effusion signed by one A. V. K. The unparalleled presumption of this writer is on a par with the ignorance he displays on the essential points of his subject matter, and I, writing in the cause of our art, will endeavour to check the one and correct the other. I will admit that A. V. K. is well venerated and highly polished, and writes with a certain easy grace, but it is the flimsy grace of a fop, rather than the solid grace of strength, in fact, I think under his panoply of words and quotations, may be discerned the amateur. It is to be hoped this is so for his own sake as it is a

bad bird that would so foul its own nest. I will pass over the elegant platitudes with which he commences his paper and will come at once to his first error, this is fundamental, and proves that he is wanting in logic and perception; I allude to his statement that the "Art of poetry is the greatest of all arts," let me correct him here. The art of writing or composing poetry cannot claim a higher plane than other fine arts, as it is merely a different means of expressing the same thing. On the other hand, poesy is the divinity of every art and the cachet of all that is beautiful. His mistake here consists in confounding poetry with poesy, and the error must be obvious to all.

Photography also is an exquisite means of expression and thus stands on the same plane as the monochromes of the painters, for it matters not how a work of art is made if the result be good. It is said that there is but a fractional division between the sublime and the ridiculous, and when A. V. K. after soaring in the mental ether of mythical abstracts concludes that the "Amateur is the best on the whole," he reaches his climax, and inextinguishable laughter shakes the skies. Could greater ignorance be displayed than he shows here? We will, however, examine this statement which is large and lofty, and quite in the writer's vein. The amateur as we know him is generally a pleasant fellow and goes forth merrily in the morning with his kidnapper slung on his shoulder and feeling like Alexander, seeks new worlds (of art) to conquer, and then returning to his portable dark tent at even, what raptures are his on finding something on his plate, and how sincerely do we all envy him! But put him for one day in a studio with ten or twenty sitters to photograph, and what havoc he would create. But we must give the devil his due, and acknowledge that in landscape work he excels, but the excellence is more due to his lenses than anything else, and his merits cease here. Let us, however, suppose that after long experience and tuition by some competent professional he should reach the top of the tree (he is a long way off yet), he would then discover that the best work he was capable of would be no better than what had been done thirty or forty years before he commenced to learn. The crass ignorance of this writer on matters of photographic art will be enlightened when I tell him that perfect gems of portrait art have been produced by photographic means more than thirty years ago. There was one artist at Hastings, a miniaturist, who did such exquisite work that he obtained a guinea for each cart. vig. picture; later on Mr. Van der Weyde charmed the world with the exquisite portraits he produced with the "Van der Weyde light," portraits whose perfect beauty could not be excelled by work of any kind. There were of course many others who did excellent work in those days, and this I think rather knocks the bottom out of A. V. K.'s hypothetical amateur who we may suppose to be living (in the near future) in a tub, gnawing bones to save expenses in the pursuit of this writer's ideal of art.

And now we will consider the most serious portion of A. V. K.'s offence, I mean his tirade on the imperfect knowledge of art shown by a section of our fraternity, this, however just or unjust it may be, is quite inexcusable in the pages of our journal and is wholly uncalled for, as precisely the same condemnation might be pronounced upon some members in all ranks of art, for the same relative degrees of knowledge or want of knowledge may be found in all the arts, witness for instance the indifferent and sometimes atrocious work occasionally turned out by painters who are not artists, even the great masters themselves fail miserably at times and they know it. But it is not the place of such men as A. V. K. to pronounce judgment in these matters, and before he presumes to do so he should see that he is fitted for the task. We have so many of these ready writers and scholarly know nothings flooding the pages of our literature with their crude imaginings and learned twiddle twaddle that the air grows thick and obscure.

We want more daylight, as someone has said, and I think in order to preserve our professional status it is time we instituted a Guild of Art Photography having power to award diplomas of art to all who pass the examinations, and providing competent teachers in all departments of our portrait art. We can leave the landscapes to the amateurs. There would then be an end to all these peripatetic philosophers, and we should stand in the broad light of art proudly conscious of the dignity of our profession.—Yours, etc.,

MICHAEL E. BANGER.

WHERE ARE WE DRIFTING?

To the Editors.

Gentlemen,—I have read with interest the letters published in your columns, re "Where are we Drifting?" and should like to say that I agree with Mr. Banger's views on the matter. I have seen some of these "side light" photographs, and can only say that if the public are going to choose this style of picture against the "Banger" style they have a very poor idea of art. Some of these "side lighters" take a portrait, giving very exaggerated shadows and high lights, and call them "Rembrandts." Why, they are enough to make that great artist turn in his grave. Again, how is a man going to treat all subjects with this "side light?" Why, it would be impossible to take

a large group in this style. While disapproving of this mode of photographing, I will say it is possible to do some really beautiful work with "side light" only, but these cases are few and far between, and at the same time, require such an assortment of reflectors that the light in the eyes must be false, and therefore give an unnatural expression in most cases; therefore, I think it would be much more sensible to adhere to the top and side light system and work with a more reliable light.—I am, gentlemen, yours faithfully,

F. VIGOUREUX-CHILDERSTONE.

55, Mervan Road, Brixton, S.W.

To the Editors.

Gentlemen,—Any person who attempts to take a portrait in a studio without the usual window in the roof has less "noble aims" than our friend, Mr. Banger. "Happily for our profession," there are men who are not so narrow-minded. Apparently he has not studied light and shade thoroughly, though in his own mind he is an adept, else he would not have been so emphatic and conclusive respecting the side light studio. It will, perhaps, surprise him that, although I use both windows, there is only one light on the face, and not the slightest suspicion of a double shadow. He should read the article which set me thinking—viz., "A Chat with W. J. Anckorn," in the "Photogram," August, 1894, who states that "the studio is not nearly so much wanted as it used to be," for almost any lighting can be obtained in a drawing-room." He also says that, respecting at-home work, "the great advantage of this work is that it gives the operator a splendid variety of opportunities for artistic lighting and posing." No two persons who are photographed have features exactly alike, therefore each should be treated separately; there can be no fixed rule for lighting, a certain light may bring into prominence good points in one face, the same light would disgrace another. I should like to know how Mr. Banger lights his "interior" portraits, seeing that he clings so tenaciously to nature. I presume he will have sittings where indoor furniture is used, which, if lighted from above, cannot be called a natural lighting. If he cares to forward me a sample of his "nature" bit photographs unretouched, I have every confidence in being able to supply the same style of lighting with my two windows.—I remain, yours truly,

SIDE LIGHT.

December 1st, 1902.

THE STEREOSCOPE IN THE SCHOOLROOM.

To the Editors.

Gentlemen,—Your interesting article on the "Stereoscope in the Schoolroom" omits to mention another valuable use of the stereoscope for instructive purposes—viz., the substitution of stereoscopic slides for solid models in the study of such branches of physics as the polarisation of light. The diagrams of the text books are often difficult of realisation, and some time ago I completed a set of stereoscopic drawings, illustrating a number of such diagrams, in a way that makes the student see and understand the laws of reflection, refraction, etc., as clearly as if he could handle the very rays. Many of these stereoscopic diagrams are unpublished, but those on the polarisation of light are issued by Messrs. Newton and Co., of Fleet Street.—Yours faithfully,

CHARLES E. BENHAM.

"Essex County Standard" Office, Colchester.

November 29th, 1902.

THE GEM DRY PLATE COMPANY'S DEMONSTRATIONS.

To the Editors.

Gentlemen,—I should be much obliged if you will kindly inform your readers that I am now prepared to give demonstrations of the "Gem" Duplex paper, if secretaries of societies care to communicate with me.—Yours faithfully,

T. THORNE BAKER.

The "Gem" Dry Plate Company, Ltd., 92A, Villiers Road, Willesden Green, N.W.

November 29th, 1902.

AN IMPROVEMENT IN CARBON PRINTING.

To the Editors.

Gentlemen,—In "Ex Cathedra" last week you alluded to a statement, in the "Deutsche Photographen Zeitung," that an improved carbon process is shortly to be introduced by a Herr Carl Zink. The process is to be exploited as a secret one, and the charge for one formula is to be 35 marks, equal to as many shillings English; not a large sum. It is true, although, as you said last week, past experience has not often been quite satisfactory where processes have been introduced in such a way. Nine special claims are made for Herr Zink's process, and if the formula supplied meets them, the introducer will have kept faith with the purchasers. But when reading through these nine claims it seems to me that all of them are fulfilled with several other methods that have already been published. Did not the first carbon process—that of Pouncey, now called the gum-bichromate process? Did not the "Mariotype," and Mr. Foxlee's modification of it? Does not the Ozotype process? Also the starch-gum process of Mr. Foxlee,

alluded to in your issue of October 31st, in connection with the continuing action of light in carbon printing? Still, Herr Zink's may be something quite different from anything that has been done before, or it may be an improvement on existing methods. It is a little noteworthy that, practically, the present method of working the carbon process in everyday work is the same as when it was first introduced by Mr. Swan nearly forty years ago. Improvements and modifications have been made in other printing processes, but, to all intents and purposes, the carbon process remains as it was, with, perhaps, improvements in the manufacture of the material employed. No photographic process can be looked upon as being so perfect that it cannot be improved, and it cannot be claimed that the carbon process is an exception.—I am, yours, etc.,

A CARBON PRINTER.

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

M. Baker, 10 Horncastle Road, Boston, Lincs. Photograph of the "Sham Ruins," Boston.

C. H. Skillman, 22 Uxbridge Road, Shepherd's Bush, W. Photograph of Mr. Commissioner Kerr.

ANXIOUS.—Better communicate with the local superintendent of police.

ARTISTIC LIGHTING.—"FAN" asks: "Could you tell me the publisher and price of "Artistic Lighting," by J. Inglis?"—In reply: The price of the work is 4s. 6d. Any photographic dealer will procure it for you.

PHOTOGRAPHIC MOUNTS.—C. J. writes: "I should be glad if you could let me know where I can purchase photo mounts of every description wholesale, but not at fancy prices?"—In reply: Surely our correspondent is not a reader of the advertisement columns of the JOURNAL, or he would not need to put such a query as this. We refer him to them.

STUDIO QUERY.—"PUZZLED": So far as we can judge from the sketches the studio will be (as the only light is from the roof with the sun on it all day) a rather awkward one to work, particularly as it is so short. We should advise you to have the roof glazed to within three feet of either end, and to as near the eaves as possible. The glass need not be carried more than two-thirds to the ridge. You can utilize the little side window as opportunity occurs.

LEAD INTENSIFIER.—G. BARKER writes: "Re formula for the lead and hydrosulphuret intensifier used by Mr. J. I. Pigg, as per his experiments referred to in the issue of November 14th, 1902. I shall esteem it a favour if you will give me the above formula."—In reply: Immerse the negative in nitrate of lead 20 grains, ferrid-cyanide of potassium 30 grains, water 1 ounce; thoroughly wash, and then pour over ammonium sulphide one part to ten parts of water.

TAKING GROUP AT NIGHT.—WALTER SMITH asks: "Will you please give me instructions or advice as to whom I should apply to, to come down to Spalding, at a date I should be able to fix, and bring apparatus (flash light) and take me a negative of a dinner in a large public hall, some one thoroughly reliable, and able to guarantee good negative? It would be at seven o'clock at night."—We do not know of anyone who would undertake the work. Most photographers do it for themselves. Probably if you inserted an advertisement in our columns you would obtain what you require.

LEGAL POINTS.—ORIENT asks: "(1) If A (trading under an assumed name) sells his business, with goodwill, etc., to B, and has not given any undertaking not to start in business in the same town, is A (in his own name) justified in making a start in the same line of business there? Has B any reparation against A? (2) Are agreements between masters and servants and employers and apprentices wherein the employees agree not to start in business in opposition according to law binding?"—In reply: (1) All will depend upon the terms of sale as to the legality; but, apart from that, it would be very dishonourable for A to do so after selling his business to B. (2) Certainly.

GLAZING PRINTS.—GLAZING asks: "Would you be so good as to tell me, through your valuable paper, what I have tried and tried to find out? It is this: What is the word or name of the spirit or acid that is used to pour on glass for glazing prints, instead of using French chalk? I know there is such a thing used, for I have and do know people who use it, but they cannot tell me the word or speak it."—In reply: We are not quite sure

that we clearly understand this query; but if it is for a substitute for French chalk in the preparing glass for stripping films from a solution of beeswax, five grains to the ounce of benzol, is what is generally used. The solution is first rubbed on and then polished off with flannel.

RECOVERY OF DEPT.—C. D. V. says: "About three years ago I photographed for the tenant his house and supplied him with photos, etc., to the value of 11s. 4d. He has since left the place and gone clear away, leaving me in debt the above sum. His parents are in this neighbourhood, and I have, of course, made repeated applications for his address to them. And the reply I got the last time I asked was that he was leaving his place and going to another, and they did not know his address. I know he was seeing them a few days back with his wife, but did not hear until afterwards. So how am I to obtain his address and the money?—In reply: We can only suggest that you find out the man's address, and then summon him in the County Court. It is obviously impossible for us to tell you how to find his address.

SALE OF POISONS.—O. P. SUISSE says: "Cyanide of potassium and all metallic cyanides and their preparations belong to the scheduled poisons. One chemist says that sulpho-cyanide of ammonium is not a scheduled poison (sulphur is no metal), and the other is positive that it is a scheduled poison. Similar ideas exist in the case of red prussiate of potash. Can you inform me which is right? Here is another query: That I as a dealer (I am a dealer now) can buy unquestioned cyanide of potassium, etc., in small bottles and resell single bottles to bona fide photographers, that is to the trade (quasi wholesale), so long as I do not touch the original packing or sealing, put on the bottle by the manufacturer?"—In reply: (1) There is no restriction of the sale of sulpho-cyanide of ammonium in England. (2) What you propose would be quite illegal; cyanide of potassium can only be vended by pharmaceutical chemists, whether in bottles or not.

PHOTOGRAPHING MIRRORS.—"FURNITURE" says: In my work I have a large number of mirrors to photograph. Could you kindly give me any advice as to the best way of treating these. I have tried soaping them and also whitening and water, but these cannot be put on evenly. I would like to know of something that will stop the reflection, and also prevent halation? Trusting you may be able to give me a reply?"—In reply: In place of coating the glass with anything we should prefer to arrange the mirrors so that the light falls upon them at an angle—say of 45 deg.—so that any reflection from them will be away from the lens. Care must, of course, be taken that there are no objects so situated in the studio as to be reflected in the glass as to be seen by the lens. Putty dabbed on the glass will avoid reflections, and if carefully done, will not be patchy. Halation may be avoided by backing the plates.

SPOTTY PRINTS.—"TONING" writes: "I am sending two cabinet prints for your inspection. You will observe some grey mottled spots on them; you would be doing me the greatest favour if you will tell me the cause. I toned about 100 cabinets and 12 by 10 on Thursday; they were all quite free from the marks on Friday; they did not show till Saturday morning, being mounted Friday afternoon. There are twenty cabinets marked in this way, and the others appear to be quite free from the spots. My opinion is that they were not washed long enough, but our manager gave me orders to dry them at once as he said they had washed enough. I am printer and he is operator, and he knows when a thing is right. He says the prints were not fixed, but I timed them fifteen minutes in hypo; 16 pints, hypo 50ozs.?"—In reply: The spots appear to us to be due to air bubbles adhering to the surface of the prints while they were in the fixing bath. We think the washing had nothing to do with them.

PRECIPITATING RESIDUE PLATINOTYPE.—G. LANGTON asks: "Would you be good enough to inform me (1) What proportion of liver of sulphide is required to 'throw down' the residue of 'hypo' which has been used for prints? Also, what is the tests used to ascertain when the operation is complete? (2) Recently, while developing platinum with the cold-bath process, and working exactly as usual, immediately on floating a print, a dark-coloured discharge came from it. This happened to each print, but does not appear to have had any subsequent effect upon them."—In reply: (1) The quantity of sulphide required is, of course, dependent upon the quantity of silver the solution contains. The test is when no more silver is thrown down on a further addition of the sulphide. (2) We think that some extraneous matter must be present in the developer or on the surface of the paper. But the mere statement of "a dark-coloured discharge" is not sufficient data to form a definite opinion as to what it was, if you were working exactly as usual.

BRITISH Association Geological Photographs.—Probably no instrument—not including the bicycle—has more facilitated the labours of the geologist than the photographic camera, which has for some time past become almost as necessary a part of his outfit as the indispensable hammer. Professional and amateur workers alike carry it, and photographs of geological features do increasingly abound. This was already true in 1888, when the happy idea occurred to Mr. Osmund W. Jeffs of forming a public collection of geological photographs, which should be lodged in some central and readily accessible place. As he rightly pointed out, "photographic records of sections and other geological features . . . are not only invaluable aids to geological instruction, but serve also to preserve for future reference the details of many

exposures of strata and other landscape features, which in course of time . . . are in danger of becoming obliterated." At Mr. Jeffs's suggestion, a Committee of the British Association was appointed at the Bath meeting, charged with the duty of obtaining geological photographs, which were to be duly preserved, catalogued, dated and described. The Committee commenced its labours by inviting contributions from all British geologists, and its appeal met with a most generous response. Photographs at once began to flow in, and have continued to do so ever since, so that a vast mass of valuable material is now accumulated in the Museum of Geology, Jermyn Street, which was selected as the home of the collection. The usefulness of the collection has now been largely increased by the action of the Committee in resolving to publish a selected number of its best photographs, and geologists are greatly indebted to the secretary of the Committee, Prof. W. W. Watts, for the admirable manner in which he has carried this resolution into effect. The success of his efforts is witnessed by the first issue, now before us. It comprises twenty-two photographs, contained in a neat portfolio case; each is accompanied by descriptive letterpress, the date when it was taken, and the name of the photographer. The descriptions are terse and to the point, as might be expected when it is added that they are all contributed by well-known geologists; among others, we notice the names of Sir Archibald Geikie, Prof. Bouney, Mr. J. E. Marr and Prof. Watts himself. To show how thoughtfully even smaller matters have been attended to, we may point out that a duplicate copy of the letterpress is provided, printed on one side of the paper only, and gummed on the other, so that when mounted each photograph may bear its own description secured to it. Further, in addition to the paper prints, which are platinotype and therefore permanent, there is another issue in the form of lantern slides, which should prove of great value in the lecture room. The issue is the first of three, the second of which may be expected to appear before the end of the current year. The price of these photographs is so small that they are sure to be much used in museums, colleges, and schools for teaching purposes. The subscription list is nominally closed, but we understand that subscribers will still be admitted on the original terms until the end of November. In congratulating the Committee of the British Association and its secretary on this admirable piece of work, the hope may be expressed that now the way has been shown, foreign societies, if they have not already done so, may follow suit; the subject is one that might well be brought before the notice of the International Geological Congress at its meeting next year in Vienna.—"Nature."

TRICHROMATICS ON PAPER.—In view of the interest excited by the various announcements that have been made with regard to the adaptation of trichromatics to the production of paper prints, our readers will no doubt be interested to learn that shortly before this number of the JOURNAL went to press, some interesting specimens by a modified process were placed before us. These we examined with very great interest. The subjects were fruit studies and a copy of a painting; and a careful scrutiny of the colours satisfied us that the process constitutes a great advance on anything of the kind that has hitherto been placed before us. We are not at liberty to divulge details of the manipulations of this modified system, but it has evidently reduced colour photography on paper to such a simple form that it is placed within the capacity of all photographers to successfully practice. We may say that this trichromatic paper process has been worked out in the laboratories of the Lumière North American Company.

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854.

PUBLISHED EVERY FRIDAY.

PRICE TWOPENCE.

TERMS OF SUBSCRIPTION, Post Free

(UNITED KINGDOM AND THE CHANNEL ISLES).

EX CATHEDRA.

Novel Method of Remedying Coloured Fringes in Telescopic Images. Mr. T. Thorp, famous for his diffraction gratings, has recently described in the "English Mechanic," an ingenious, simple, and novel method of attaining this object. He says "It may not be generally known that the coloured fringes to telescopic objects due to atmospheric refraction, and which so greatly affect definition, may be got rid of in a very simple manner, although in this case again, the device is only a makeshift. . . . All one has to do is to bring, in front of the eye-lens, another lens, say of 6-in. focus (a spectacle lens either convex or concave will do very well), and re-focus. Upon now moving this lens across the eye-lens a point will be found where the chromatic aberration has entirely vanished."

* * *

Photographs in Law Suits. Some judges have refused to receive photographic portraits as evidence of identity, and rightly too, in some instances. In the evidence in a sensational divorce suit a photograph was, last week, shown to one of the witnesses, and the learned judge asked to see it, with these remarks:

"I ask to see it because I often find photographs are a very slight representation of the person concerned." The learned judge was quite right in his remark. Many portraits are but a slight resemblance to the persons depicted, but where does the fault lie? certainly not in the photograph pure and simple. Photographers have to please their sitters, and have to look to the "bread and butter" side of photography, and, as a rule, the more they flatter their sitters the better are they pleased with their portraits, although the likeness may, and often does, suffer. Retouching, particularly bad retouching, has done much, it must be confessed, to throw doubt on the veracity of photography. An anecdote occurs to us of a Chinese artist who was called upon to paint a miniature of an English lady, and he, with the idea of pleasing, blandly asked the lady in the best English he could command: "Ladee likee likee, or likee prettee?" Most photographers need not put this honest Chinaman's query, for they assume what the answer would be if they did, and act accordingly.

Pure Anhydrous Peroxide of Hydrogen.

Peroxide of Hydrogen, though not a common occupant of the photographic laboratory shelves, has yet a distinct place in photography. Among other things it has been recommended as a hypo-eliminator, but its price has been against its use for that purpose, if indeed, a hypo-eliminator is any use at all. Hitherto it has been sold in 10 volume and 20 volume and 30 per cent. strength, and not stronger. A communication, however, has been made to a foreign technical journal by Wilhelm Stadel, to the effect that he has succeeded in making the chemical in a crystallised form at a low temperature, when, of course, it is evident that melting of the crystals should give a very pure sample. Herr Stadel finds that, contrary to recent assertions, peroxide of hydrogen readily crystallises and in a very distinct manner. He first obtains solid crystals of the chemical and then drops a small portion into a strong solution—at 8° or 10°—how prepared he does not say, but this communication was only of a preliminary nature, and immediately the whole mass is permeated with crystals. Repeating this process with these crystals obtained from another liquor and re-melted he obtained peroxide of hydrogen free from water. It will be interesting to await further developments with details of cost, etc.

* * *

Electrical Thermometers. An article in the "Chemical News" last week shadows forth a far-reaching improvement in the means of measuring temperatures.

Mercurial thermometers of great accuracy are obtainable almost anywhere and at a low cost, and there is no reason why every photographer should not have one in the various apartments he uses. Certainly one each in his dark room, his studio, and his printing rooms; and, indeed, wherever the temperature is subject to fluctuations a thermometer is a most useful aid to his work. But if a busy man had these views presented to him he would probably reply, "I trust to my operator, or my printer, to see that things are comfortable, I can't go running about the place looking after thermometers," and so on. But the new plan would prevent the possibility of such a reply. The Cambridge Scientific Instrument Company working upon the lines of electrical thermometers devised by Professor H. L. Callendar, and Dr. E. H. Griffiths, and endeavouring to render them capable of withstanding the rough treatment of commercial work without sacrificing their well-known scientific accuracy, have succeeded in producing thermometers fulfilling all these requirements, and not only these but others of a startling character. These new electrical thermometers are of two kinds, the second the thermo-electrical, being most germane to our remarks. These may be placed almost anywhere, and in positions where it would be absolutely impossible to use or read a mercurial one, and any one might sit on his office stool and by means of a switchboard can read on the indicator in front of him the temperature of any one or a number of the thermo-electric thermometers about his premises. Various other advantages possessed by these instruments are set forth in the "Chronicle News" as follows: "They can be used for the measurement of very high or very low temperatures, their indications can be read at a considerable distance without appreciable error. In conjunction with a Callendar recorder they will give a complete record of the temperature for a day or a week." Judging from mere description we should say the new instrument promises to be epoch making as regards temperature indicators.

* * *

Pyro Redivivus. Pyro was for so many years the standard developer for professional work that many an old worker notwithstanding the introduction of the newer developers, still swears by his own particular formula. The discovery of the use of amidoacetate of soda and the improved action of pyro, will, though at present unconfirmed, have therefore rejoiced the hearts of these old conservative workers, and now Professor Valenta, of Vienna, announces in the current number of the "Photographische Correspondenz," yet another fact in connection with pyro, which may possibly induce many who have abandoned its use to again revert to it. In early dry-plate days plain pyro-ammonia with bromide was the accepted best form of using this reagent, and then probably due to the inconstant strength of the ammonia solution and the smell which was said to be extremely unpleasant in its action on some people, the fixed alkalis gradually came into favour, and in amateur circles the use of Beach's developer was so great that one journal had a standing announcement that the formula for the same would be found on certain pages. With the use of the fixed alkalis, increasing quantities of sulphite were taken, and finally, pyro-soda without bromide was widely adopted as a standard developer for plate speed testing and other experiments. The use of caustic alkalis was never general, for their action on the skin and the gelatine were not beneficial, and even with sodium sulphite the developer could not be used for more than one or two plates, rarely more than

one, because of the deep stain produced by the oxidation of the pyro. Valenta points out that pyrogallol is a triatomic phenol of the formula

C. H. OH and that in the presence of excess of

caustic alkali, the hydrogen atom of each hydroxyl group OH, can be replaced by one of the fixed alkalis, sodium, potassium, or lithium, and the formula would therefore be

C. H. ONa or K or Li, but if only sufficient

alkali be added to saturate one or two of these hydroxyl groups, we may have mono—or di-phenolates or pyrogallol, as in the formula

C. H. OH

and

C. H. ONa or K or Li

He therefore made a series of experiments and found that the sodium and potassium monophenolates of pyrogallol gave developers, which were $3\frac{1}{2}$ and $3\frac{2}{3}$ respectively more rapid than a normal pyro-soda, and further, that the solution remained colourless, so that three negatives could be successively developed in the same solution without any loss of gradation, and without any staining, the developer being far more like one of the newer developers than a normal pyro developer. The actual formula used was as follows:—Stock solutions: A., crystallised sodium sulphite, 160g.; pyrogallol, 25g.; water, to 1,000c.c. B., caustic potash, 11.5g., or caustic soda, 8g.; water, to 1,000c.c. For use, mix 1 part of A, 1 part of B., and add 1 part of water.

* * *

Suburban London. It is an idiosyncrasy of our human nature that we should pass over the attractions which may be found in our immediate vicinity, in our endeavour to seek imaginary ones at a distance. The country at the other side of the hill is, to us, although we know little or nothing of it, a land of promise which must be visited. This was the text of a pleasant discourse by Mr. Henry Davis last week at the Camera Club, who illustrated his remarks with a variety of photographs taken on the borderland of the Metropolis, a veritable *terra incognita* to most of his hearers. He pleaded for a little more photographic recognition of the various outlying villages, some of them possessing features of no small artistic value, and he pointed out that in those places adjacent to the metropolis no time should be lost in taking a camera there, for the jerry builder is at work, and is fast doing his best to extinguish all relics of the past sleepy-hollow kind of life, and to replace them by buildings with all the advantages of modern sanitation, and as ugly as sin. That some picturesqueness still hangs about these outskirts of our teeming city, Mr. Davis proved by the exhibition of a number of pictures, taken chiefly in the North-west of the metropolis, and he expressed the hope that others would find an opportunity to go to similar places and secure photographic records of suburban London before the country undergoes a complete change. What would we not give now to have photographs, had such

pictures been possible, of Islington when it was a village quite detached from London; of Marylebone, when it was surrounded by fields, or of Primrose Hill, when it justified its name? In the same way a few decades hence people will value pictures of places which have now a rural character, but will then be the centre of a brick-bound population. Most of the photographs illustrating lectures at the Camera Club, complained the speaker, were of places abroad, and the members were too fond, he thought, of leaving the beauties of their own country undiscovered, because unsought for. There is, of course, a good deal to be said on the other side. A man, most of whose time is spent in the pursuit of his business, or profession, is anxious, when holiday time comes round, to go somewhere which presents such a thorough change of scene, of people, and even of language, that he is for a time in a new world, where manners and customs, and even eatables and drinkables, are different to what he is accustomed to. All this means a change of ideas, and the mind is refreshed at the same time that the body gains health. Such benefits could hardly accrue to the man who contented himself with a holiday in the home counties. Still, we sympathise with the aims of Mr. Davis, and think that when opportunity presents itself for a day's, or perhaps two or three day's, outing, a most enjoyable time might be spent, and useful work prosecuted in carrying a camera round suburban London. Although he confined his attentions almost exclusively to the north and west of the metropolis, there is a fine field for photographic work in the south, especially if the camera bearer extends his walks far into Surrey. It is, as he reminded his hearers, often a case of "Eyes and no eyes"; one man will see and garner much, while another with better opportunities will reap little.

* * *

Daylight Development. A few weeks ago we were invited to witness the demonstration of a photographic process, the nature of which was not stated, but we were told that it was associated with a discovery that would work a revolution in the method of negative production, and that it represented generally one of the greatest advances in photographic procedure, which had been brought forward for many years. We were further told that this mysterious process had been highly extolled by some of the first experts in Germany, and that it had already been protected by patents in all countries. Full of anticipations as to what this wonderful thing might be, anticipations which, we must confess, were tempered by a few years' experience of, so-called, secret processes, we went to the rendezvous named in the letter of invitation, and witnessed the demonstration. A plate was exposed in a camera, in a special form of single back; this back was held over a dish of exactly the same size, a spring was touched, and the plate dropped into a bath of dark coloured liquid. In this bath the film was stained a dark red, an operation which occupied about a minute, when it was transferred to the developing dish, the whole of these manipulations being conducted in daylight. In a word, the much vaunted process was a method of developing plates in ordinary light. Upon being asked to give a candid opinion of the process, we were constrained to say that there was no novelty in it, and nothing, in our opinion, that would warrant its protection by patent. Moreover, we were able to refer its promoters to a little pamphlet published more than twenty years ago, by Mr. Morgan, of Greenwich, before he went into partnership with Mr. Kidd, and started the well-known works at Richmond, in which a somewhat similar, but more simple, process was described. In this

old method the exposed plate was dipped in water, and then plunged in a developing bath of ferrous oxalate, covered with a layer of paraffin, to preserve it from the action of the air, the red colour of the developer permitting the dish to be carried into unfiltered daylight, and that the progress of development might be watched without the usual restrictions of the dark room. Now, if there had been any notable advantage in this method of procedure we may be quite sure that it would have been improved and generally adopted years ago. But, as a matter of fact, it is easier to develop a plate with one of the almost water-white developers in common use, by the liberal light allowed in a properly furnished dark room, than it is to watch its progress through a necessarily dark dye. We were requested not to make public any details of the recent German experiments, but as we see that the matter has already found its way into print, in last Friday's "Westminster Gazette," the seal of secrecy is removed, and we publish this short account of the process as a specimen of a novelty which is not new.

* * *

Pictures by Telegraph. It is to be hoped that the Bill for the amendment of the law relating to patents, which is now before Parliament, will pass, for it provides for an official search of existing specifications, which will for the future prevent the same idea being protected (?) over and over again. The system has been proved to work well in America and other countries, and it has been long needed here. As an instance of the way in which time and money have been wasted in the past by inventors following the same path, we might instance the many contrivances which have been produced for the transmission of pictures by telegraph. Three of these inventions will be sufficient for our purpose. The first was Bakewell's, in which the message, or picture, was drawn in resinous ink on tinfoil, the tinfoil being afterwards attached to a cylinder, which, as it rotated, was touched by a stylus attached to a screw, like the tool-holder of a screw-cutting lathe. This stylus would therefore traverse every part of the foil as the cylinder turned. A similar cylinder at the receiving end of the circuit was covered by a chemically prepared paper, also touched by a stylus in the same way as the transmitting cylinder, and so long as an electric current flowed through the point it would make a stain on the prepared paper. But when the current was broken by the resinous ink on the tinfoil at the transmitting station, no mark was made. The resulting picture, therefore, was a kind of negative image, white on a background of coloured lines. This telegraph of Bakewell's was invented in 1850, and it found many imitators. The best of these was the apparatus of d'Arlincourt, and here again we have pictures produced in parallel lines, by means of the interruptions caused by the introduction of a non-conducting substance. This invention appeared, if we remember rightly, in 1880—or thereabouts. We now find illustrated, in a recent number of the "Scientific American," what is described as an improved electrograph, which really differs little in principle from Bakewell's contrivance of more than half a century back, although its performance is certainly better, judging from the specimens shown. In this case the transmitting agent consists of a zinc plate, bearing a photographic image, the shadows of the picture being filled in with an insulating compound. This plate is bent, so as to fit upon a cylinder, where it is traversed by a stylus. At the receiving end is a cylinder covered with paper, upon which acts a drawing pen, the pen being lifted from the paper by the passage of the stylus over the insulating material

at the other end of the line. The speed at which a picture can be "wired" by this means is about the same as that involved in telegraphing words which would cover, when in type, the same space. The result is a line drawing, which can very quickly be turned into a printing block. But, granting that the apparatus works well, of what use is it? In these days a block can be duplicated and sent from place to place very quickly, and a big business is done in stereotypes and electros. Would this telegraphing of pictures help in such a business? We think not, for if the demand had existed we may feel quite sure that Bakewell's telegraph, which showed so suggestively how the thing might be done, would long ago have been at work producing such pictures. It is sad to see so much ingenuity exercised in vain, and the new provisions of the patent law will help to cure the evil.

* * *

A Novel Bath.

It has often occurred to us, when listening to a lecture by a traveller, that some of the most interesting items are left to verbal description only, pictorial illustration being conspicuous by its absence. Very often an excuse is made that that particular negative went wrong, or, unfortunately, it was a very wet day, or something else happened to prevent a photograph being taken. There was an instance of the kind in the course of Mr. Cutcliffe Hyne's lecture, at the Camera Club last week, on "Arctic Lapland," the lecturer having been one of the very few people who have carried a camera into that inhospitable region. He describes the peculiar way in which the Lapps cleanse themselves, and a few photographs of the operations would have been most interesting. Possibly he took pictures, and did not like to show them, forgetful of the national motto, "Honi soit," etc. At any rate, his hearers had to content themselves with a verbal description, which perhaps would have been thought rather exaggerated had there not been other travellers to corroborate him. Sophus Tromholt, for one, the man whom we believe was the very first to introduce photography to the Lapps, gives a full description of the process—but even he, amid a host of other pictures, does not give any of this particular function, which has a strange similitude to the Turkish bath, as known to Europeans. There is a common bath room, known as the Savna, attached to every farm, and every Saturday this bathroom is used by the whole family, the servants of the farm, and any visitors desirous of joining. A beehive arrangement of bricks, or stones, in the middle of the room, has a fire lighted within it, and when the stones are red hot water is poured on them, so as to fill the place with steam. Then the bathers, of both sexes, and all ages, in the primitive costume of our first parents, proceed to the Savna—although the temperature may be many degrees below zero, and disport themselves round the hot stones, and belabour each other with birch twigs, until they are all in a profuse state of perspiration. Then they go outside, roll in the snow, and finally betake themselves homeward in the same "clothing" in which they came. If the scene in the hot chamber were not photographable, the final roll in the snow would, at any rate, have made an amusing picture. Some will possibly remember the sketch in "Punch," by the late Mr. du Maurier, in which a couple of men were shown, stewing in a hot room of a Turkish bath. One was giving a dinner invitation to the other, with the words, "No ceremony, come just as you are." So that we really have a good precedent for the picture we are suggesting. A series of photographic illustrations of bathing customs all the world over would, if such a col-

lection could be made, be of very great interest. We have seen pictures of the natives indulging in "mixed bathing" in the hot springs of New Zealand, and have also been shown similar pictures of the public baths at Japan. But the land of the chrysanthemum is becoming far too modern in its ideas for these old customs to remain long. Even already in some places the edict has gone forth that the sexes should be separated whilst bathing, the separation being carried out by stretching a piece of string across the surface of the water. Before such customs entirely disappear every opportunity should be seized to obtain photographic records of them. Had photographs been possible in the past, the contemptuous term, "Traveller's tales," would never have been invented, and the "Adventures of Baron Munchausen," which was written in order to cover travellers with ridicule, would have lost its point. The camera stands as sponsor for the tales told by modern travellers, and no man can impeach its evidence.

PHOTOGRAPHERS' WINTER TROUBLES.

WHEN writing, a fortnight back, on some of the troubles that photographers meet with, just as a sudden snap of cold weather sets in, we alluded more particularly to such as were also unsuspected. There is another trouble that is often met with. It is one that is at once palpable, though often not readily overcome, namely a frozen water supply, although, in most instances, it might easily have been avoided had a few timely precautions been taken. The inconvenience caused by the water supply being stopped is always great, but it is sometimes added to in the shape of burst pipes, flooded rooms, damaged ceilings, etc., when the thaw sets in. In nine cases out of ten, these troubles would not have arisen had a little care been taken at the advent of the cold weather. At most ironmongers there is now sold a material, "hair felt," three or four thicknesses of which, if bound round or nailed over exposed pipes will prevent their freezing; so will the straw bands with which trusses of hay are secured. When the supply pipe from the street main to the house is laid near the surface, as is too often the case, it will require protection. If, say, six inches of stable manure be laid on the ground above, and well trodden down, that portion of the pipe will be well protected. When these precautions have been taken, if the taps at night be left just dribbling, there will be little risk of a frozen water supply. Of course, the water companies will not approve of this latter procedure, unless indeed, the water is supplied by meter, but we suspect they do not always know what takes place in photographic establishments? Should, however, timely precaution not have been taken, and the pipes get frozen, the next thing is to avert further trouble, such as would arise from burst pipes. The pipes, when they are found to be frozen, should be examined throughout their length to see if they have burst anywhere. That is easily seen by the pipe being swollen at that point, caused by the expansion of the water at the time of freezing, and the aid of a plumber should be sought without delay and the fracture repaired. The services of the plumber can be more easily obtained while the frost lasts than when the thaw sets in—then so many are requisitioning his aid. If, however, a burst pipe is not discovered until its presence is made painfully manifest, and the place is being flooded with water, the best and the quickest way of dealing with it is to with a hammer batter up the pipe a few inches from the fracture. This, of course,

entails the plumber having to make two joints instead of one; but the little extra cost it involves is more than compensated for in saving damaged ceilings, soaked walls and floors, that may take even months to dry. When the working supply of water is taken from a cistern the pipes, if they are much exposed, may freeze. This may be avoided if the precaution is taken to empty them when the day's work is done—as they never freeze while the water is continually being used. The most convenient arrangement for doing this is to have a cock fixed just below the cistern and, below that, a small air cock, then, when the former is shut off, and the latter opened, and all the taps are left open, the pipes will be emptied, and there will be nothing in them to freeze. An extemporised arrangement that fulfils the same end, may be made in this way—get a piece of gas pipe, say "iron barrel," smaller than the outlet from the cistern, and a few inches larger than its depth. Next wind some rag round the end, and plug the pipe with it; then, if the lower taps are opened, the pipes will be emptied by reason of the air admitted by the plugging pipe.

S N O W .

Snow has an attraction to most people. The first fall of the light swirling flakes begets an agreeable feeling whether the observer sees them against a dead wall twenty feet distant through the office window, against the cathedral across the Close through an oriel window, or with tall elms as a background through the leaded panes of an old farmhouse window. The pleasure is characterised by a sense of vagueness due to the factors that generate it. The multitudinous moving flakes produce a soothing physical effect. The eye gives up as vain its usual effort to determine size and position, the optic nerve drifts into a kind of quiescent, mesmeric condition, and the brain as a whole accepts with relief the resulting temporary reduction of demand in attention and action upon it. When the snow has fallen and lies a white carpet upon the ground, the eye, and through it the mind, still experiences a holiday feeling of relief in the lack of need for taking in the usual petty detail of the face of the world. A man's thoughts take a broader cast when looking out over a snowy landscape than over the sweetest summer scene. The same is the case in looking out over broad reaches of sand, and for the same reason, there is no distraction due to a sub-conscious recognition of detail. This quality being physical, and acting unconsciously, is responded to by all men. Other factors, such as the comparative unusualness of snow, its suggestion of purity, and the alteration it produces in the appearance of a landscape, appeal with more or less force according to peculiarities of temperament and training. But it can be safely stated as a broad fact, that snow, at its first appearance anyway, is pleasing and suggestive. The former quality should be sufficient to determine the taking of a picture, and the latter its kind.

From a technical point of view there is no reason why a photograph of snow, even on a dull day, should not prove a success. Using a landscape lens, four seconds exposure, at F/16, upon a rustic gate in a country lane on a dull November day, with the snow falling fast, gave a capital result. The tendency is to be deceived by the prevailing whiteness and under expose. The light shading on the surface of the snow that indicates form and contour is what should be aimed at, and this needs a fairly

long exposure. Otherwise the picture is certain to be flat and expressionless. A slight over exposure is less important in a snow scene than under normal conditions. But there is less risk of failure on the technical side than in the selection of the best type of picture. In determining the latter an important consideration to be borne in mind is, that if snow is itself vaguely suggestive, the picture should tend to produce the same effect. It would, for instance, be better vignettted gently off than square sided. Indeed it is extremely difficult to gain a snow picture to fill in the full, orthodox demands of "a picture." The detail that is so valuable in ordinary composition is absent. We grumble, it is true, at its excess ordinarily, but anyone who has tried to compose a picture on his screen with snow well on the ground will be ready to admit that it is better to have over much detail than none at all. Blank white spaces do not make effective elements in pictures, and it is not snow, as snow that we need so much, as snow in its modifying effects upon ordinary scenes and life. The usual way out of the difficulty is to take a scene after a fall light enough to have reduced, but not altogether obliterated, detail. This is very well as far as it goes, but it is not often practicable to be on hand at the right time. Snow does not give notice of its exact time of coming, and bread and cheese must be worked for, snow or no snow. Even if successfully taken, the result is apt to show too clearly the conditions under which it was gained. It looks what it was, a sprinkling of snow, and not "snow." The only way out of the difficulty, and it is a good one, is not to aim at a picture, but a scrap in which there is no doubt as to the amount of snow, and which in its frankly acknowledged incompleteness as a picture, allows the imagination to fill in the full scene for itself. The porch with a figure warmly clad coming out will do, so will the waggon or market cart, with their wheel tracks in the lane, the cathedral tower, or the elms—preferably from a distance with a telephoto lens. However heavy the fall may have been, there are always objects, a steep-pitched pinnacle or roof, tree trunks, rails of gates, and so on, on which snow cannot lodge to the extent of full obliteration. The darker bit of detail is what is needed to give contrast, and that touch of crispness instinctively craved for where all lines and contours are so soft, wavy and fleecy. The subject will naturally vary in different parts of the country, for each has its own peculiar winter scene, as characteristic under snow as without it. The typical should always be selected, and treated less as a formal orthodox picture than a soft, sketchy suggestion of a piece with the evanescent character of snow. One drawback to any extended taking of snow scenes, beyond the slight physical discomfort of the actual work, is the chilly suggestion they give. In our country and climate suggestions of warmth and sunshine are most humanly attractive and agreeable. Snow scenes would be more effective, psychologically, hung upon the walls of a bungalow in the tropics. Still, apart from merits in such other directions as those already touched upon, there are occasionally piping hot days in an English summer when the coming suddenly across a good snow scene in turning over the leaves of an album, gives a strong feeling of pleasure in its grateful suggestion of coolness. The philosophic worker should hold himself ready for the opportunities—probably not far distant at this time of the year—for gaining the material for such pleasure. He will gain more out of photography, and help to lighten the dullest season of the year in so doing. It is far better than following the usual plan of

laying by the camera in the late autumn until the following spring. Life is short, and its pleasures should be heightened and increased as much as possible. Catching artistic suggestions of the fleeting beauties of snow is one means to that desirable end.

PHOTOGRAPHERS AND APPRENTICES.

PHOTOGRAPHERS who take apprentices are under more obligations to them than many seem to be aware of. A case bearing on this point was reported in our columns a few weeks back. Briefly, the case, as stated in the report, was to recover the sum of £50 on behalf of each of two apprentices for alleged breach of contract to teach them the art of photography, and for the indentures to be cancelled. It appeared, from the evidence, that the defendant sold his business at Gloucester and went to Newquay without making any arrangement for his apprentices. This, however, was confuted, by the defendant, in our next issue, for he there says that "I arranged for their transfer to my successors before completing any agreement." In the end, however, judgment was given for the plaintiffs for £25 in one case, and £15 in the other, each with costs, and the indentures were to be cancelled. Now this case illustrates more than one interesting point in connection with those who take apprentices with premiums, and also to those who apprentice them. One is this. When a heavy premium, or a premium at all, is paid to an experienced, and say a well-known, photographer, to teach an apprentice his trade, and he sells his business to a less skilful man, and possibly one less known, is he fulfilling his undertaking when he transfers the apprentice to his successor? Higher premiums are paid to high-class photographers than to those of lesser status; therefore, is it fair to the apprentices to transfer them to others—or to expect them to go a hundred miles or more, from the place, or the establishment to which they were bound, apprentices?

The object with some photographers seems to be to obtain a premium, or the services of apprentices at a nominal rate for a term of years, rather than to teach them their trade. We have frequently received letters from apprentices, when out of their time, complaining that they have been taught nothing practically, of studio work, and asking how they can acquire knowledge in that direction. Now, such cases should not arise, neither would they if the master had fulfilled his contract—namely, to teach the apprentice his trade, or at least so far as he was capable of doing so; for it should be borne in mind that there are some who are carrying on business who know very little indeed of it themselves—either theoretically or practically—sometimes nothing at all, but are simply carrying on the business through a manager or operator. Such men, it is obvious, are quite incapable of teaching apprentices their trade, though according to the indentures, they undertake to do so. Therefore it behoves parents or guardians to satisfy themselves as to the ability of those to whom they bind their charges to fulfil their part of the contract—willing as they may be to do so. We are sometimes asked by parents what is a fair premium to be paid in the apprentice of a youth to be taught the trade of a photographer. This is a difficult question to answer, seeing that all will depend upon the status and class of business carried on by the master. It is manifest that in a high-class business, with a *recherche clientèle*, a much

higher premium is demanded—and is well given—than in a second or third-rate one. However, whatever class business it may be, the owner of it is bound to teach his apprentices their trade, and if he fails to do so, the law will give redress, and this must be kept in mind by all who take apprentices.

ON THINGS IN GENERAL.

The question of the possible connection between photography and fine art is, like the poor, "always with us," and though it is late in the day to refer to it, it is worth while saying a few words regarding the utterances of the *Daily Mail* on this burning topic. Now, although it is impossible to argue with any prospect of satisfaction upon any thesis whatever without the admission of some postulates, or the adhesion to some axioms, yet it is usually the case when this eternal subject comes into prominence that each disputant either argues in a circle, begs the question, or propounds a theory of his own, generally illogical, and often too amusing to be taken seriously. The *Daily Mail* critic's dicta will be classed by any well-balanced mind under the latter heading. He founds his argument on an imaginary principle which he, in the usual manner, proceeds to demolish. Here are his words: "Not even an indignant enthusiast like Mr. Ball will maintain that the camera can idealise." Did ever any one credit the camera with that gift of the gods—imagination? Great Britain is the home of the highest class of camera making, and I have seen some of its finest examples, yet never one that had any imagination worth speaking of, though I have met many camera owners with very exalted, not to say vivid, imaginations, most frequently exercised, perhaps, in their accounts of the number of first-class negatives they obtained from a given number of plates, a proportion frequently figuring out at ninety-nine and a fraction per cent. The *Daily Mail* critic will, perhaps, argue that this is mere trifling, so I will shift my ground and speak of artistic imagination, and not of fish stories. There, I have done it—"artistic imagination"—at the outset I use a debatable term. Let us for once try to set out our premises with precision. Who shall be our authority? The "New English Dictionary" will be accepted, perhaps, as the highest possible work of reference, for upon a question of meanings, as of spellings, a dictionary cannot be termed an authority—it is merely a mirror in which are reflected the practice and the etymological usage of eminent men whom all would recognise as authorities. Under the word "Art" we find, in paragraph 6: "The application of skill to the arts of imitation and design, painting, engraving, sculpture, architecture; the cultivation of these in its principles, practice, and results; the skilful production of the beautiful in visible forms. This is the most usual modern sense of 'art' when used without any qualification. It does not occur in any English Dictionary before 1880, and seems to have been chiefly used by painters, and writers upon painting until the present" (the nineteenth) "century." Mr. Gladstone is quoted: "By the term Art, I understand the production of beauty in material forms palpable; whether associated with industrial forms or not." So far we are on sure ground: a photograph may be capable of classification under any of these descriptions. But, it may be argued, it is "Fine Art," not "Art," that is in question. Let us turn over the page and see what is said in this direction: "Fine arts, those in which the mind and imagination are chiefly concerned." The most apt of the quotations under this heading is that of Ruskin, who, writing in 1854, in his "Two Paths," says: "Fine art is that in which the hand, the head, and the heart of man go together." Can any one not blinded by partisanship or polemical obliquity

deny the possibility of producing by purely photographic processes results in which evidence of hand, heart, and head working together are shown? The strongest argument ever employed in this connection is that photographs are mechanical. True, many are; but it could not be gainsaid that if, say, the President of the Royal Academy were an expert mechanical user of a camera, he could put into a purely photographic print enough of his heart, head, and hand to differentiate his photograph entirely from the work of a mere mechanic. There have been photographs produced which, apart from mere questions of imitative technique, no one could say were not reproductions of paintings, so much did they appeal to the imagination and the idealisation of form or beauty. But—and here is the true crux of the whole question—such works are the exception, and the most powerful exponent of Fine Art requirements has never got beyond the point of differentiating photography and Fine Art merely by the tools used in each style of work. Put in their baldest form, such arguments approaching those of *Daily Mail* critic may be expressed thus: "A painting is a work of Fine Art because pigments and brush are used; a photograph is not a work of Fine Art because a camera is used, and a camera cannot think." Can a brush and palette think? Is the Bear's Paw or the Bull's Head that attracts the wayfarer with alcoholic thirst a work of Fine Art? The possibilities in this direction are extremely limited; but the argument has not yet been penned which logically proves that a photograph can never be a work of Fine Art, which is very different from claiming that it is necessarily such.

The true artist is supposed to disdain such sordid considerations as filthy lucre, hence a leaning towards the pecuniary aspect of his work might, on *a priori* grounds, incline the purist to deny the application of this much-abused term to the protégés of Mr. Hector Maclean, who, writing in the *Morning Post*, paints such a glowing picture of the commercial possibilities of photography, as will arouse the envy of nearly every trade in the country. His statements are quoted in THE BRITISH JOURNAL OF PHOTOGRAPHY for November 21st, and some of them I here reproduce: "...the comparative affluence to which a very large number of humble, or not well-to-do individuals have attained through joining local photographic societies. I could mention one instance of a gentleman now receiving a 'four-figure' income entirely through taking up amateur photography and attending photographic societies' meetings. The number of those who, through similar means, have risen from positions of a few shillings a week to distinguished appointments of from £500 to £1,000 per annum are too numerous to mention." Talleyrand said that words were given us to conceal our thoughts, and truly Mr. Maclean's words must have been employed with a similar object, for, taking what he says in the ordinary significance of English words, no other criticism would fit them better than that of the Hibernian who said of a tale of similar truthfulness: "If you had been living in the time of Ananias and Sapphira you would have been dead now." A new novel by a great politician and successful novelist, many years ago, was brutally likened by one of the leading magazines of the day to the "gin-inspired dreams of a barber's apprentice." I don't wish to suggest any such crapulous condition in Mr. Maclean's case, but I do think a doctor should be called in.

The accounts of the doings of the Professional Photographers' Association, as published from time to time, are very satisfactory reading, and show that real substantial work is being done by its committees at its various centres. Take the question of Fire Insurance alone; it has brought home to photo-

graphers the fact that the sums that some of them have been paying are simply outrageous. I don't quite like the idea of the Fine Art Insurance Society's way of doing business: it is perilously akin to the one practice of all others that has been, and is, the bane of the photographer's existence—cutting prices. There is a certain foreign firm in London whose traveller would come round and ask for orders for, among other things, nitrate of silver. "What is your price?" "Oh, half-penny an ounce under anybody else." However, this is by the way, and the fact remains that the Society is a power, and a growing power. I have not often read a more eloquent and stirring letter than that given in these pages last week from Mr. Turner to the Liverpool branch. These various branches are doing much to break down the barriers of masked or open hostility that unfortunately too often, indeed, almost invariably, characterises the attitude of professional photographers to one another. Like the Photographic Convention the Professional Photographers' Association has brought together into amicable relations many worthy men who hitherto entertained for one another sentiments the reverse of amicable. But too many of the successful photographers still hold aloof, whether from pure inertia, or from disinclination to meet some of their professional brethren, it is difficult to say. Sydney Smith spoke in one of his sermons of the class of people who are so sorry for the poor, and "do wish someone would do something for them." And in the same way are depicted in Mr. Turner's letter those "too many good fellows who are writing for something to be done for them by someone else." That is the exact position, and if they are not careful they will be left in the lurch. Professional photography is passing through a great crisis at the present time: with few exceptions the whole country is bitterly complaining of bad business, and I fear it will be worse before it mends, if ever it does. Combination is wanted, and, in his own best interests, I urge every professional photographer to join the Professional Photographers' Association. There is, generally, a funny side to the most serious subject, and to an Englishman a big dinner is always a matter of moment, though, from all accounts, the dinner of the Liverpool Branch of the Professional Photographers' Association was a function very far from serious. I believe it was considered to be about as successful and enjoyable an evening as could be imagined. But that is not the point I was getting at. One of the visitors, or invited guests, in his speech was deploring that he had not been brought up as a photographer, for a reason shortly to be mentioned, because he said he should "keep his hair on." Now, in the face of another portion of Mr. Turner's letter—his unquestionably correct description of photography as "perhaps, the most harassing calling known to modern man," one would scarcely expect such views as those of the visitor. Yet I am credibly informed that of all the photographers present, not far short of fifty, there was not a single one who had not kept his hair on, not a single one who was either bald or showing even a tendency to be a "little thin on the top, sir." Here is a very fertile theme for discussion—why should photographers have such good heads of hair?

There is an excellent paper upon "Microscopic Photography" in last week's JOURNAL, though, by the way, that was not the title the author gave to his subject. Those who have not hitherto done any such work should carefully read this paper; it contains most useful reading, and it emphasises what should be learnt by every beginner in this branch of photography—you cannot get good negatives unless you have good slides to work from. Indeed, if it be required to make enlargements of any popular subject, such for example as that most hackneyed one, "the tongue of a blow-fly," seen in almost every beginner's

collection, it should always be borne in mind that the utmost care should be taken in obtaining or selecting an original of the very highest quality. Another word as to the practical work. Mr. Simmons recommends a piece of black paper to be put into the microscope tube to avoid reflections. If the eye-piece be removed for the work it will be found that unless this provision be made, most of the negatives will be entirely spoiled by fog. This is caused by reflections of the strong beam of light passing through the micro-objective being reflected from the blackened inner surface of the tube. Mr. Simmons recommends this to be got rid of by a piece of black paper being placed in. Now, there is black paper and black paper, and some of it might be no better than the inner surface of the tube itself. The plan I have adopted myself has been to get a piece of thin cardboard of such size that it will roll into a tube capable of passing into the micro-tube, and then to paste black velvet on this cardboard and insert it rolled up, velvet side visible, into the microscope. It is surprising to see how great an increase of brilliance will be seen in the negative.

SOME PRINCIPLES OF PAINTING APPLIED TO PHOTOGRAPHY.

[Reprinted from "The Journal of the Camera Club."]]

MR. RIMINGTON said he felt in the first place that he ought to make an apology for appearing there at all, as he was not a photographer. He would address the audience only from a painter's standpoint. It seemed to him that photography had invaded largely the fields once occupied almost exclusively by painting, such, for instance, as those of illustration for books, newspapers, and scientific purposes. It was also preparing to attack the ground of colour illustration, for which he was sure there was a great future. He thought painting and photography were more closely allied than some people imagined. Photography was an art and not merely a science. It had been said that a photograph was a raw slice of nature, and a picture was a cooked one, but there was a happy mean between these two extremes, and he thought that some of the principles of composition and selection which assisted painters might be more applicable to photography than had been quite realised. In considering these principles of painting, he would say a few words generally upon how far definite principles might help artistic feeling, in order to explain his position.

There were two great currents in art, one of which tended towards realism and the other towards decorativeness. Forty or fifty years ago there was a great movement towards extreme realism, personified first by the pre-Raphaelite school and others, and a very powerful movement it was. Then came, some ten or fifteen years ago, a reaction towards decorativeness, or, in other words, towards the belief that one of the first essentials for a good picture was that it should be a harmony of colour and an interesting and decorative piece of black and white or line and form. Personally, he thought that the true ideal lay between those two sets of pictorial conditions. It was quite possible for a picture to reproduce nature truthfully, and at the same time to be decorative, though a far easier course for the artist was to abandon the attempt to combine the two qualities and produce a literal and topographical transcript or a mere impressionistic colour and form pattern, with no idea behind it. Unless there was a desire to unite these positions and to use and develop the principles which had been handed down from the past, as well as take advantage of any modern technical methods, art would not advance as rapidly as it otherwise would. He assumed that was the position some of them

would like to take up. Those principles to which he referred were in any case derived directly or indirectly from nature. Any principle which had been handed down from the old masters meant their repeated observation and adoption of some striking effect, perhaps some telling contrast, or some delicate harmony of line or form, and its gradual interpretation in the light of some principle. There were many principles which were very broad, and upon which painters were all more or less agreed. If they went to India or Japan or the Far East, where non-European forms of art had been developed, they could still find some of these principles recognised and incorporated in the art of each country. He was quite sure, however, that some present would dissent from his views, and he put them forward with due deference to their opinions.

He would now go on to examine a few of those principles to which he had referred. The first he would take was the very broad one of concentration, or simplicity—familiar enough, no doubt, and apparently rather trite to give so prominent a position to, but it was constantly forgotten or overlooked, and yet it lay at the root of almost all great art. The painter should have one simple aim, one main idea to express, and all else should be more or less subservient to its expression. Turner's "Burial of Wilkie" appealed to one at a first glance, apart from its other fine qualities, by reason of its breadth of aim and composition. As one approached nearer further detail showed itself, and yet the broad main decorative effect was preserved. It would not be very difficult to apply this simple, yet far-reaching principle to photography. Many photographs were displeasing because they included too much, and nothing was subordinated to the general effect of the subject as a whole, which was too often frittered away and breadth lost in a crowd of details. A photographer could, however, choose his effect with an eye to breadth and unity, and a good deal could be done in the method of printing in obtaining simplicity and condensation, but it was unnecessary to labour the point. The second set of principles were those referring to line, to which all painters worthy of the name paid great attention, and knew how much depended upon them. Lines, to be harmonious and to be beautiful, must be grouped. If one took a tuft of grass or a group of foliage, one found their lines were usually grouped and harmonious. But if the same tuft of grass were converted into hay, the same line was there, but it was no longer orderly, and would become confused, meaningless, and more or less unpleasant to the eye. In art a very important thing was to have leading lines—lines which led to the picture, which helped the perspective and bound the picture together. Some classes of lines were more beautiful than others. The lines of the figure were almost all lines of low and subtle curvature approaching straight lines; the boughs of trees were also full of lines of mathematical curvature of great beauty. None of these very beautiful lines could be drawn by a compass, and are generally difficult of analysis. In the two Corots he had placed upon the wall, almost all the lines of the tree trunks were very subtle. One would find the same very beautiful character of line in portions of the reproductions of Alma Tadema and Burne-Jones, and in Turner's and Lord Leighton's pictures, which are also hanging there. From the very earliest times, lines of low curvature and belonging to radiative systems had been seized upon by sculptors and artists. In the sculptures of the Parthenon or in the Gothic statues of the Porches of Chartres, radiation played an important part and had been deliberately selected. Drapery arranged in lines which had some tendency to converge towards a point were exceptionally pleasant, and many other instances of beautiful radiative systems would occur to their minds in stone forms, shells, and plants. Now as to the application of

this to photography, which was, perhaps, not very obvious. Supposing a photographer had chosen his subject, the question then arose, where should he place his camera, and upon the choice of position the arrangement of the lines of his picture would largely depend. Suppose he were taking a photograph upon a heath with a road running across it, and he wished to take in the road—t slight movement of the camera will alter the whole position of the road, and the character of the lines of its edges. If he moved his camera a little to the right or left, the lines would be perhaps a little pleasanter, and his knowledge of what constituted good lines would help him. So, too, with regard to his relative position towards stems of trees, palings, margins of a lake or a stream, the contours of a recumbent figure, and so forth. Another set of principles in painting were those concerning quality or texture, which played an enormous part in suggesting substance, form, solidity, transparency, and luminosity. Textures might be classified to a certain extent into those which were granular, linear or fibrous, crystalline or reticulated, and those which were a combination of two or more of these. Texture helped to prevent monotony, to introduce variety, and to express scale. Contrasts and harmonies of texture played a considerable part in good pictures, and it undoubtedly performed a prime function in giving colour its true value in painting. In photography contrasts and harmonies of texture might be made of greater use. A photographer could, by choosing his time and position as regards lighting, degree of moisture, angles of reflection and absorption, modify relative textures more or less in his pictures. If the lighting were at the side of the subject of his photograph, instead of being immediately in front, the apparent texture would be largely increased, if behind it there would be very little texture. Dry and wet objects had more or less texture in many cases, and so forth. Atmosphere also played a large part with regard to texture—if there was much moisture in the air there would be less texture, especially in the case of objects at a distance. There was another very well-known pictorial principle, and that was that of balance. Without any balance at all, no picture was quite satisfactory—the balance need not be very obvious. There was the formal balance of the old masters and the extremely subtle balance of the Japanese. The Japanese were masters of artistic balance, and their decorative use of it was often extremely subtle and difficult to analyse, yet most beautiful, he thought. Turner understood balance in a way which very few people did, and there was a reaction towards more balance in many present-day schools of painting.

Closely associated with balance was the principle of interchange used quite unconsciously very often by the artist as most of those principles were, but often very deliberately carried out with great advantage in what would have been otherwise an unsuccessful picture. In those extraordinary beautiful Rembrandts a small portion of dark carried over into the light increased the luminosity of the light, and a small portion of light carried into the dark made the dark seem deeper and to give harmony to the picture. The lecturer instanced many examples upon the walls.

The next point was "relationship." Painters concentrated their efforts upon obtaining just values and true relationships. It was an absorbing study, and with many a matter of the greatest difficulty. There could, however, be no such thing as absolute truth of relationship and absolute truth of value. Nature had a much longer scale than the painter had. Her darks were far darker than those on his palette, and her lights a thousand times lighter. In order to obtain appearance of true value, the painter had to make adjustments more or less all along the scale. It was impossible to say that such and such a scheme of values was absolutely true. The photographer,

it seemed to him, was a good deal at the mercy of his medium, of his sensitised film, and of his system of development, but if he (the photographer) had studied fine pictures, he would be more likely to succeed in getting a suggestion of the truth and beauty of nature than if he had not. After all, in photography, as no value could be nearly right, convention came necessarily more into play, and it became really a question of obtaining pleasing ones and an artistic arrangement of them. Photography was halfway between a pencil sketch and a picture. In photography one had fewer resources than in painting, and had to make the most of them. With regard to both value and breadth, he ventured to touch upon two principles which were more or less recognised by a great number of artists, and which were a great source of beauty both in nature and painting—large masses of darks should be intensified and deepened and broadened, and as the counterpart of what he said just now about interchange, it should be remembered that lights were broadened and intensified and made more luminous by having other lights placed upon them, and *vice versa*. If one took a picture like "The Fighting Temeraire," of Turner, the lights were placed upon lights, as also in that Watts hung near it. In Rembrandt the principle of dark upon dark and light upon light was carried further than with any other artist, side by side with interchange, and in photography the advantages of this principle might well be borne in mind. In the photograph of a landscape, it very often became a question of whether a dark figure should be placed upon a dark background, or a light figure upon a light background. It would be merely a question of moving the figure to give either increased force in the one case, or increased subtlety and repose in the other. Delicate transition from dark to light was also a great source of beauty—the subtlety depends very much upon the transition from half-tone into light and from the half-darks into dark, and this could be remembered by the photographer in choosing or arranging his subject. The next point he would mention would be that of what for want of a better name he would call essential forms. What struck the eye in a picture very much more than the actual objects depicted were the forms of the colour patches or the shapes of the darks and lights, quite irrespective of what they represented, and upon these really depended the decorative effect of the picture. To take an example in the picture behind him, there was a tree casting a shadow on a field. That shadow really made more impression on the eye than the tree, and its form was more characteristic. In many cases that shadow would be of much more artistic importance than the shape of the object casting it. That applied not only to shadows but to half-tone and patches of colour, and the selection of their abstract forms was one of the great things that distinguish the really good painter and sculptor, and stamped him as a fine composer. Turner, their very greatest landscape painter, unrivalled in all the world, considered and felt out his essential forms more than anything else. The actual outlines and shapes of the material with which he dealt were to him of relative unimportance, as he knew the poetic impression could not be produced without beautiful essential forms. So, too, were Rembrandt and Sir Joshua. If they took "Christ Healing the Sick," of Rembrandt—the figures counted for little decoratively—it was the essential forms produced by their shadows, and those subtle half-tones distributed into the light, that, coupled with the beauty of the idea enshrined in them, made the etching one of the greatest, if not the greatest, the world had ever seen. The consideration of essential forms was one of the very greatest importance. The photographer would, he thought, gain by giving some of his attention to them deliberately, and learning to watch for, and abstract them, noting what happened during certain changes of light, or cloud, or atmosphere, and pose of figure. Art would make a very great step forward when

those forms were more fully considered than they were now, and those wonderful inter-relations more studied. In many cases one found a picture was almost universally admired, and yet that picture had very little actual intellectual interest in it; the reason often was that the forms were extremely beautiful.

Another very important principle in painting was the sacrifice of minor to major truths. In many cases it seemed impossible for the painter to express in one picture more than a few of the greater truths of poetic impression or colour or light, or whatever might be his object. He must make very considerable sacrifice of truth of tone, truth of elaborateness of detail, and truth of line, in order to be able to express some other more important quality. If one took a landscape with a large distance in it, a good deal of detail must be suppressed to get the major truths of space and atmosphere. A picture must, like a good speaker, sometimes say little in some interesting points in order to hit harder with the most important ones. Occasionally, in photography, the major truths of an effect could be better suggested by the lens being a little out of focus. On the other hand, we did not want all photographs to be blurred. The rendering of delicate and elaborate detail was one of the things in which photography excelled, and there is no reason that we should not with advantage have pre-Raphaelite photographs as well as impressionistic ones. The art was wide enough to include both, and one of the art diseases of the day was the narrowness of cliques and critics, and want of catholicity of view. Many of his brother artists felt very strongly as to this. The man of culture should be able to appreciate both pictures and photographs differing widely in aim, method, and idea.

His next point was individuality, or the personal element in art. There were two schools, one of which asserted that the personal element was everything, and everyone was more or less weary of the reiteration of this half-truth. The other and broader school knew the importance of individuality, but realised that it should develop itself without effort, and that the constant harping upon it and straining after it tended to produce an art of self-advertisement and mere eccentricity or sensationalism. Perhaps even in photography those two currents of feeling were to some extent also in existence, and some deductions might be drawn from what had happened in painting. Some people said there could be no poetry in photography (from which he absolutely dissented), some said that photography was a piece of nature spoilt. It would at any rate be admitted, even by those who were so fond of juggling with the words objective and subjective, that it was at least possible that there was some poetry in nature. If so, even a simple transcript from nature in a photograph might reflect some of that poetry.

Photography had enormous possibilities before it, and it was quite probable it would in the future occupy many more fields than it did at present. He saw no reason also why it should not prove to be a great help to painting, rather than a dangerous competitor. Photography would do, and was doing for painting to some extent, what the printing press had done for literature by its reproductions of pictures. Photography would undoubtedly in the future help to unravel some of the obscure problems of electricity and non-visible light, of astronomy and physiology. Certainly it could do a great deal in colour reproduction. Mr. Menpes' book on Japan showed what the three-plate process or four-plate process could do if the painter worked with it and assisted the printer.

In conclusion, Mr. Rimington said:—I am sure that we as painters realise to the full how very much we are indebted to photography in many ways; it has taught many of us new modes of looking at things, and dispelled some fallacies. We have realised artistic possibilities from photographs which we had

scarcely appreciated fully before, and, happily, the old prejudice against a new rival has been to some extent dispelled, and so I venture to hope that you will look with some leniency upon what I have said about the points of contact between the two arts, and perhaps think it worth while to consider some of these principles, which, rightly or wrongly, are dear to us painters.

A. WALLACE RIMINGTON.

THE Professional Photographers' Association.—There will be a meeting of the general committee at the rooms of the Royal Photographic Society, 66, Russell Square, W.C., this (Friday) evening at 7 p.m. Business: Report for members' meeting; exhibition of members' work; general business.

THE autumn season has produced a fair number of good engravings and etchings, though not so many as used to be the case fifteen years ago, before photogravure had completely established itself. It is a painful fact that nowadays there are only five or six mezzotinters who can command a market, so keen is the competition of "process." One must be a very first-rate engraver, and employed upon a very attractive picture, to be at all sure of success; and this fact is so well known to the print publishers that they naturally hold their hands or employ "process" in the majority of their reproductions.—"Times."

PROCESS WORK.—Mr. J. Wallace Bennetto writes us concerning the Miethe colour portrait, about which, as he very properly says, so much nonsense has been written. He informs us that so far back as 1896, he produced several portraits both in and out of the studio in colour prints which were considered perfect. The exposure in the studio was 30 seconds, and out of the studio (figure and landscape) 3½ seconds. Some of these were shown at the Society of Arts. Mr. Bennetto concludes by saying:—I can now take a portrait in the studio in 15 seconds—one exposure, one developing, and one printing—in three colours.—"Process Work."

THE British Association in South Africa.—Reuter's Agency is informed that the suggestion that the British Association should hold its annual meeting for 1905 in South Africa emanated from the new South African Association of Science, of which Sir D. Gill, Astronomer Royal for the Cape, is president. Before the last meeting of the British Association at Belfast invitations were sent from the municipalities of Cape Town, Kimberley, Bulawayo, and other centres in South Africa, and it is understood that these have been accepted, and that the session of 1905 will be held in South Africa. Scientific papers will be read at various centres in the South African Colonies, and visits will be paid to numerous places of interest. A sum of £7,000 has been collected in South Africa for the entertainment of the Association. While in Rhodesia the scientists will be the guests of the Chartered Company, who will place their railways at their disposal, and, among other things, take them by special train to the Zambesi, where they will stay at the new hotel to be erected near Victoria Falls. Probably the guests will leave England in a special steamer.

A PROTECTIVE Solution for Lantern Slide Bindings.—Messrs. George Houghton and Son, of 88 and 89, High Holborn, London, W.C., are placing a solution on the market for this purpose. As they properly point out, all who use lantern slides know the annoyance and trouble the binding or edging (usually paper) gives, owing to its frailty and liability to get torn up on the slightest provocation. "Limpet" solution, when painted over the binding of the slide, acts as a protective coating, and renders it perfectly waterproof and dustproof, and very durable, so that slides so treated can be properly washed, and even roughly handled without fear of the binding being thereby removed. This, of course, renders re-binding entirely unnecessary and greatly facilitates cleaning. The solution is of a sea-weed green colour, and transparent. It turns the ordinary deep purple binding paper black, and gives to it the appearance and feel of leather. It takes but a few minutes to dry, and when once dry never becomes sticky, not even with the heat from the lantern." We have put Limpet solution to practical test, and find it an admirable protective medium.

FROM Messrs. Newton and Co., 3, Fleet Street, E.C., we have received a supplementary list of lantern slides for the season 1902—1903. The following scenes are included:—Abide with me; Ambulance—First Aid; America, North; Armada, Story of the; Armies and Navies, Types; Asia, Central; Astronomy, "Knowledge" series; Astronomy; Nasmyth's Moons; Botanical series; Bright-line Spectra; British Birds; Cambridge and its neighbourhood; China; Coronation of Edward VII.; Coronation of English Sovereigns; Cromwell's Life and Times; Dickens, Characters from; Durham Cathedral and City; English Scenery; Famous Artists; Fiji Islands; Flowers; France; Garnot's Physics; Garden Produce; Good Samaritan; Henley Regatta; Herb Yielding Seed; Humorous Drawing by Phil May, and others; Hymns; India; King's Procession through London; "Knowledge" series of Slides; Kumatology; London; London Poor; Mexico; Milton, Life of; Miscellaneous Pictures; Miscellaneous Sacred Subjects; Moons; Motors; Navies and Armies, Types; National Gallery; Natural History; New Testament; New Zealand; Nitrifying Organisms in Soils; Old Testament; Ophir, Voyage in the; Paradise Lost; Paris; Peru; Portraits; Prayers, Church; Russia; Scenery at Bidford; Scripture Scenes; Sea Pictures; Sports and Pastimes; Straits Settlements; Teneriffe; Ten Virgins; Texts; Transvaal War; Trees and Plants; Up-to-date Subjects; Volcanoes; X-Ray Photographs; Zoological Gardens.

A NEW DEVICE FOR STEREOSCOPIC PHOTOMICROGRAPHY.

[Reprinted from the "Journal of the Franklin Institute."]

I HAVE recently made a one-plate-one-exposure stereoscopic photomicrographic camera, which is interchangeable with the single camera on the adjustable base, described in the "Journal of the Franklin Institute" for May, p. 375. It consists of a light telescopic box camera for plates $3\frac{1}{2}$ in. by 6in., which is provided at the front with a small prism box containing three equilateral prisms, so disposed as to divide the light at the eyepoint above the eyepiece of the microscope, and project the divided rays upward to form the two stereoscopic images. Fig 1 shows the parts drawn to scale. A is the camera, B B B' are the prisms, C is the microscope tube with objective and low-power eyepiece, D is the object slide, and the dotted lines show the path of the axial rays from the back of the objective.

It is the usual practice to divide the light at the back of of

eyepoint. This adjustment can be made by looking through the prisms from the back of the camera.

I think it is a mistake to divide the light anywhere back of the objective when working with high powers on transparent objects, because some of the diffraction pencils, which define very minute details, emerge from the half of the objective opposite to that which belongs to the respective dioptric projection. It is probably for this reason that the Wenham binocular cannot be made to perform satisfactorily with high powers. This stereoscopic camera, for precisely the same reason, should only be used for subjects which may be satisfactorily shown in the binocular microscope. With a 2in. Huyghenian eyepiece, amplifications from x10 (3in. objective and short tube and camera) to x120 ($\frac{1}{2}$ in. objective and long tube and camera) can be made satisfactorily by employing colour-sensitive plates and a yellow screen. With Zeiss's 16-millimeter apochromatic objective and the "finder" (2) compensation eyepiece, ordinary plates can be used without the colour screen.

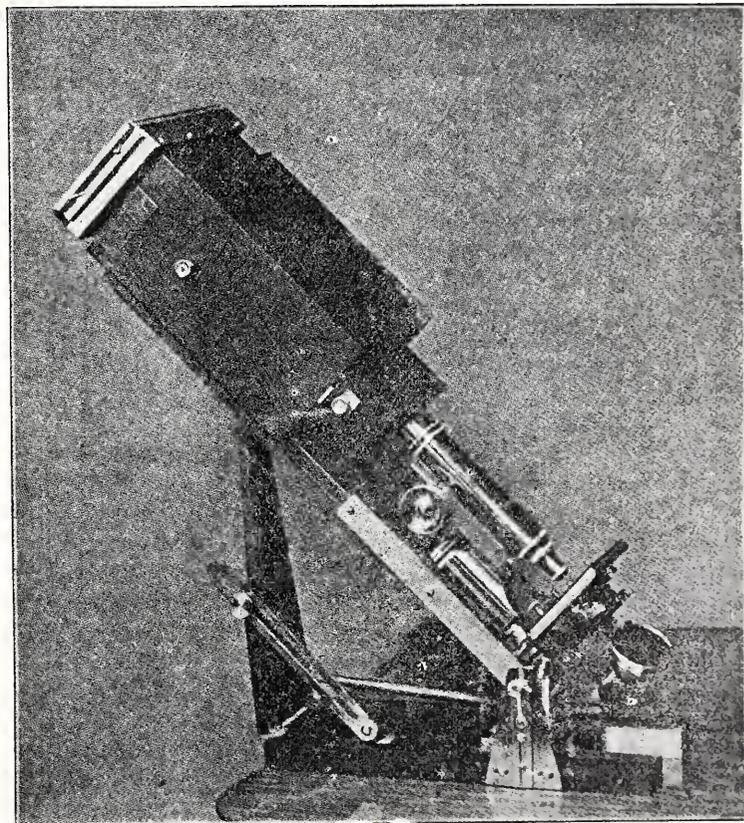

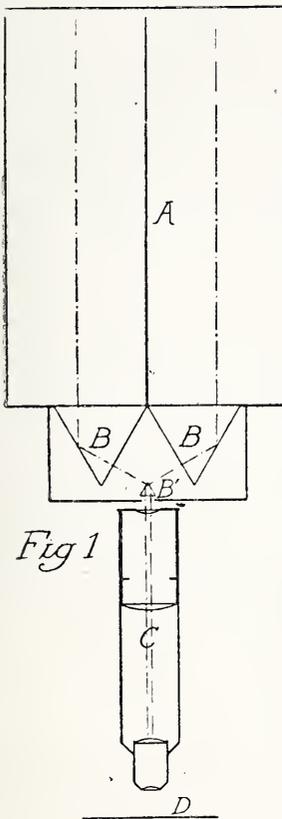

Fig. 2.

the objective, but inasmuch as the spot of light at the eyepoint, above the eyepiece, is an image of the back of the objective, it answers the same purpose, when working with an eyepiece, to divide the light at this point; and in the present device this is accomplished by the small equilateral prism. If this prism is perfectly accurate, the result is two images as perfectly stereoscopic and as perfectly defined and evenly illuminated as the images projected one at a time in the usual way; in fact, the images may be more evenly illuminated than is possible in the usual way when the objectives have long mounts.

By adding a lens of the focal length of the camera, for which there is room by using it as a cap for the eyepiece, the camera can be used without even refocussing, in the manner described in my communication already referred to.

The prism box has a lateral fine adjustment by screw on the camera front, in order to readily set it so that the apex of the small prism exactly bisects the circle of light at the

The negatives produced in this camera are ready for printing from, no transposition of images being necessary, and for this reason only I prefer it to two otherwise equally simple and efficient combinations with which I have worked.

Fig. 2 shows the stereoscopic camera used on my adjustable base, as recently improved. This combination can be adapted to the microscope at any inclination and brought into action in a few seconds; and, after exposing, it is removed as a rigid whole by a single rectilinear movement of one hand.

FREDERIC E. IVES.

THE Teb Competitions.—Messrs. Charles Tyler and England Bros. draw our attention to the fact that this competition closes on December 24th. The results will be published early in the new year. Prizes are awarded for every size of print from half-plate size to midget, and for quarter-plate size alone there is to be awarded no less than 33 prizes, ranging in value from £5 5s. to £1 1s. The competing prints will be judged by Messrs. R. Child Bayley, Thomas Bedding, Arthur C. Brookes, and A. Horsley Hinton. Prints may be by any process, the only stipulation of the competition being that the coupon, which is included in each box of mounts, shall be returned with the prints.

THE PHYSIOLOGY OF CERTAIN COLOURS.

Havelock Ellis, several months ago, had an article on "The Psychology of Red" in "Popular Science Monthly," in which he showed that red has an unmistakable effect on the psychical organism. Incidentally, he also demonstrated the fact that colour has likewise a physical effect both upon plants and upon animals. He does not, however, discuss the physiological causes for each effect. It is the purpose, therefore, of this brief paper, writes Mr. James Weir, junior, in "The Scientific American," to bring out the probable action of colour on the basic principles of life as far as we know them. Thousands of years ago, it was noticed that plants reared in darkness were colourless and of weak and fragile habit. It was also observed that men who passed their lives in darkness or semi-darkness were not as robust as those who lived in the light of day. So the general conclusion was reached very early in the history of the world that the light of the sun directly influenced both animal and plant life. Recently, it has been determined that the rays of the sun exert dynamic, chemic, and physiologic effects on the *vis vite* of plants and animals. The three forces through which the rays of the sun act, viz., the dynamic, the chemic, and the physiologic, are, to a certain extent, intercorrelated; therefore, they must be studied together. It will hardly be necessary to point out the fact that white light or daylight is a combination of all of the primary colours, violet, indigo, blue, green, yellow, orange, and red. It is highly important to my thesis, however, to demonstrate that certain of these colours exert a selective or elective influence on the physiology of animate organisms, and, individually, affect such organisms in some degree. Flammarion's beautiful experiments at Juvisy, have shown beyond question of doubt, the widely different effects of the red and violet rays on plants. The plants chosen were of the genus *Mimosa* or "Sensitive Plant," and were subjected to the same environments with the exception that some were reared beneath dark blue glass and others beneath red glass. In four months the plants grown under the red glass had attained extraordinary development, while those subjected to the violet rays had made no progress whatever. Similar effects were noted in the case of strawberries, and numerous other vines, plants, and shrubs. The plants grown beneath blue glass did not die, but seemed to remain in a dormant condition without growth or further development.

Zacharawietz, of Vaucluse, has also shown that plants are strongly affected along the lines of rapid growth and development by red and orange rays. As early as 1883 I demonstrated and published the fact that typhoid fever germs would not live when subjected to the blue or violet rays. Ward, Finsen, Berg-hold and others have shown that the blue, violet, and ultra-violet rays are fatal to bacteria and that the other colours are not, while Finsen has made successful use of this knowledge in the treatment of zymotic skin diseases, such as smallpox, measles, and scarlatina. It would appear from these observations that the red and orange rays have a distinctly favourable physiological action on plants, while the blue, violet, and ultra-violet rays are as distinctly deleterious. When we come to observe the action of the violet rays on animal life, we see that such action is, apparently, markedly different from that to be observed in vegetable life. But, as Davenport has pointed out, this difference is more apparent than real; for these effects on animal and plant physiology are due to the same chemical metabolic changes, but, "while plants succumb to the influence of the violet rays, animals, being more highly organised, are able to take advantage of them and flourish." In 1883, while studying tinctumutation or the colour-changing function in certain animals, I reared a large number of newts, or salamanders,

from the eggs. The eggs were placed in shallow vessels which were covered by coloured glasses, blue, orange, green, and red.

The eggs under the blue glass hatched out first; under the orange, second; under the red, third; and under the green, last of all. The young larvæ under the red glass were much more active, at first, than those under the other glasses, and attained full maturity several days earlier. The larvæ under the blue glass, however, grew to be much larger and in the end were much stronger and more agile. Under the green glass, the larvæ were sluggish, and of slow growth. I noticed, moreover, that whereas there were no monstrosities or deformed animals under any of the other glasses, there were many under the green and the orange glasses. The animals under the blue glass were distinctly darker than those under the other glasses, and, under the microscope, the chromatophores, or colour-bearing cells, were seen to be much more numerous.

The violet, and ultra-violet rays have a pronounced chemical as well as a physical effect on the human body. They have, also, in all probability, a dynamic effect, which is shown by the feeling of well-being or otherwise. The "summer-girl" who, in the early days of her vacation, cannot stand the sun, will, in the middle of summer, welcome the embraces of Phœbus Apollo and will revel in his kisses! She says that she has become accustomed to the rays of the sun and that she no longer feels them because it has become her "habit to walk abroad without hat, parasol, or umbrella." Thus she gives credit to the wrong agent; for her feeling of well-being is not due to habit, but to the thin brown veil of tan which the violet rays with ever busy brush have spread out on the surface of her body wherever it has been exposed to them. The violet rays thus erect a barrier against themselves, for they cannot pass the tan. Nature always takes care of her children, that is, if they will give her time, and do not in their ignorance, attempt to hasten her. It is true that, primarily, the violet rays are superficial in their effect; yet they are, nevertheless, sometimes destructive in a high degree. Ask the boy who awakes in the night after an afternoon in the river, and "moans, and moans, and moans" on account of the intolerable fire between his shoulder blades, what he thinks of the ultra-violet rays; or, ask the blind and helpless traveller who stumbles across the weary waste of Arctic snows what he thinks of them? Both sun-burn and snow-blindness are due to the violet and ultra-violet rays. Yet the violet rays are absolutely necessary in the up-building of the normal, healthy man. Their action must be, I take it, primarily through stimulation of the vaso-motor nerves, i.e., the nerves which control blood-vessel action. The first effect is dynamic in character; there is dilatation of the blood vessels with a consequent increased flow of blood. The second effect is chemical in nature, the increased flow of blood incites the blood-producing organs to manufacture new blood-cells, consequently the plasma of these cells differs chemically from the plasma of the old cells. There is, also, increased oxidation and oxygenation due to increased flow of blood through the lungs. The third effect is purely physiological. Owing to the increased flow of new blood cells to the tissues, cell growth is excited and new tissue is formed. Of course, waste is going on all the time; the violet rays merely act as a tonic in stimulating the organs of the animal economy towards repairment of waste by renewing and building up tissue. These beneficial rays are present in diffused daylight, hence the direct rays of the sun are not absolutely necessary in order to produce their good effects on the animal organism. Direct sunlight is, however, an exceedingly efficacious tonic when used moderately and understandingly, there can be intemperance however, in the use of every good that Nature has given us.

Exhibitions.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

The fourteenth annual exhibition of this flourishing society, which was held at its headquarters, Hanley Hall, Sparsholt Road, N., on the 1st, 2nd, and 3rd inst., showed that the reputation the society has earned for the excellence and soundness of its pictorial work is in no danger of being lost. The exhibition was confined entirely to the work of its own members, and there are no less than 206 pictures and 43 exhibitors, a striking testimony to the enthusiasm no less than to the industry of the members.

As the exhibition was not divided into classes the comparative popularity of the various branches of pictorial photography was not easily determined, but landscape naturally predominated, and, as at all exhibitions, was of the best average quality. Of course, a local society is not conducted on altruistic lines, and cannot be expected to keep its exhibitions open longer, at its own expense, than suits its immediate purpose, but such an exhibition as the North Middlesex organises yearly is worthy of being supported at the public expense, in consideration of the benefit the public would derive from it if the opportunity were offered.

Though there was no lack of variety in the subjects the members had chosen, the almost complete absence of portraits was noticeable, and the neglect of this, perhaps the most important of all the branches of pictorial photography, is very much to be regretted. The society is one of the few which adheres strictly to the custom of giving the printing process of the pictures, and from a summary published in the catalogue, it appears that of the 206 exhibits there were 91 bromide, 36, carbon, 21 gum bichromate, 44 platinum, 8 silver, and 6 not stated, a very interesting basis for comparison of the popularity of the various processes.

The judges, Messrs. John H. Gear and James A. Sinclair, made the following append to their list of awards: "The judges are pleased to congratulate the members on the high average standard of work, and which they think fully maintains the traditions of the society. They consider it the best exhibition of work confined to members only, which they have seen."

THE AWARDS.

"Across the Common," H. Smith; "The Wayfarer," S. E. Wall; "Evening," H. Stuart; "Evening," F. J. Pitts; "The Norman Transept of Winchester Cathedral," R. R. Rawkins; "The Japanese in China," S. H. Bentley; "A Son of Algiers," R. Child Bayley; "Chrysanthemums" (lantern slide), J. Carpenter; "A Fairy Tale" (lantern slide), A. H. Lissett.

STONEHOUSE CAMERA CLUB.

The second annual exhibition of the Stonehouse Camera Club was opened at the Kent Unity Hall, Stonehouse, last week. The entries, about 250, were not quite so numerous as last year, but the quality showed a great advance. The lantern slides formed a splendid collection. There were loan collections from Mr. J. Trouern Trend, Mr. G. T. Bayley, and Mr. Ralph H. Walling, the hon. secretary. Unfortunately, the loan collection from the Royal Photographic Society was despatched to Stonehouse, Gloucestershire.

In the unavoidable absence of Mr. John Lockie, M.P., who was in London, Dr. Waterfield declared the exhibition open. Although the entries were not so numerous this year as last, they were certainly better in detail, quality, and finish. They had enrolled some new members during the year, but they had lost several by removal. They had laboured under difficulties, but had been successful. There had been a rumour that they would be provided with accommodation at the Town Hall. Where there was a society like theirs, offering congenial employment to young men, it should be encouraged by the town. He was sorry there were not any members of the District Council present. In many towns the municipal authorities fitted up a room for photography. They were indebted to Mr. Bayley for providing a room, but they were cramped for accommodation. The exhibition was well worthy of patronage, and he hoped it would induce others to join the society. The awards were:—

Members.—Silver medal, "On the Lew," W. Luxton; first bronze medal, seascape, R. H. Walling; second bronze, "The Old Mill Wheel," W. G. Rose; third bronze, "Reflections," A. J. Catford; special bronze, portrait of a child, Dr. W. H. Waterfield. Certificates: "Plym Bridge," E. V. Hearn; "Barnpool and Drake's Island, from Mount Edgcumbe," W. Full.

Affiliated Societies.—First silver medal, "Harvesting," F. C. Bowtell, Plymouth Photographic Society; second silver, "Toilers of the Sea," A. J. Catford, Devonport Camera Club; first bronze, "A Study," W. Clayden, Plymouth Society; second bronze, "Loiterers," Captain E. H. Haig, R.E., Plymouth Society. Certificates: "Old Dave" and "The Nave, Winchester Cathedral," S. G. Kimber, Southampton Camera Club; "Farcham Creek," Captain Haig; "Critics," A. B. Fellowes Pryme, Plymouth Society.

Three Towns Amateurs.—First silver medal, "A Misty Morn," W. Clayden; first bronze, "The Age of Innocence," C. H. Dymond, Devonport; equal award, "Cattle, Valle Crucis Abbey," F. Johnson, Plymouth; bronze, "After a Storm," F. C. Bowtell. Certificates: "The Young Fisher," J. C. Smith, Stonehouse; "In Sutton Pool," R. H. Walling.

Class D, Open.—Silver medal, "Feeding Sheep," C. Walmsley, Ambleside; first bronze, "The Light Steals Softly Across the Aisle," W. R. Lathbury, Bristol; equal award, "The Hour of Rest," Graystone Bird, Bath. Certificates: "The Widower," R. Burley-Moss, Truro; "The Mill Stream," W. R. Lathbury; "Good Morning," Graystone Bird.

Lantern Slides, Open.—Silver medal, F. C. Bowtell; bronze, Graystone Bird. Certificates: Dr. G. H. Rodman, East Sheen; A. Bailey, Leicester; special, J. C. Smith.

The judges were Messrs. H. R. Babb, J. Trouern Trend, and W. D. Snell.

New Books.

"Knowledge Diary and Scientific Handbook for 1903." Published at 326, High Holborn, London, W.C.

Over 300 pages of this comely volume are set aside for the purposes of a diary; and the literary contents, as may be judged from the appended list of articles, appeal to workers in a variety of scientific fields. "Knowledge Diary" is one of the few books that reach us year by year which we set aside for leisurely reading when the mind craves for a change from the mass of ephemeral twaddle which the exigencies of modern civilisation oblige one to wade through. The articles referred to are as follows:—Practical work with the Spectroscope, by A. Fowler, F.R.A.S.; The choice of a Microscope, by M. I. Cross; Suggestions to Amateur Meteorological Observers, by Hugh Robert Mill, D.Sc.; Crustaceans: How to catch, keep and comprehend them, by the Rev. T. R. R. Stebbing, M.A., F.R.S.; Systematic Botany, by R. Lloyd Praeger, B.A.; Planetary Observation, by W. F. Denning, F.R.A.S.; On the Observations of Variable Stars, by E. E. Markwick, F.R.A.S.; Pond Life Collecting for the year, by Charles F. Rousselet, F.R.M.S.; The articles by Mr. Fowler, Mr. Cross, and Dr. Mill should prove of interest to photographers.

"White's Natural History of Selborne." Illustrated from photographs by Cherry and Richard Kearton. 320 pages. Published by Cassell and Co., Limited, La Belle Sauvage, Ludgate Hill, E.C.

A publisher's note informs us that some two years ago the Kearton Brothers conceived the idea of preparing a photographically illustrated edition of Gilbert White's "Natural History of Selborne," and have since that time been collecting pictures for it in almost every quarter of the British Isles. Many of the photographs have been taken at arm's length from the interiors of stuffed oxen, sheep, artificial rocks, and other ingenious contrivances. Over forty miles were tramped with camera and field-glass for one picture; days of patient waiting exhausted for another; a cold Highland loch waded and waited in armpit deep for a third; several pounds spent for the bare opportunity of trying, for a few minutes only, to take a fourth; a fifth that cost a round sum in plates alone; and a sixth that was actually secured whilst the photographer waited, with the airball of his apparatus in one hand and a loaded revolver in the other, for his subject to put in an appearance whilst momentarily expecting a mad bull. A number of photographs of Selborne as it is to-day have been specially taken by the illustrators. The plan adopted by the authors is to illustrate the text of most of the chapters of Gilbert White's classical work. The annotations and the introductions are by Mr. R. Kearton. Better natural history photographs, even by the Brothers Kearton, have never come under our observation. The book is a strikingly beautiful production, the outcome of a rare combination of skill and sympathy. The Kearton "White" must unquestionably rank high amongst the successes of the present publishing season; it is a book which, irrespective of the theme upon which it is based, does the very highest justice to photography in its best and most convincing aspect, namely, as a recording agency. Some of the representations of bird, animal, and insect life printed in these pages are really marvellous camera studies. We shall always cherish this fine volume.

New Apparatus, &c.

Kodak Pelloid Plates (cut films). Manufactured and sold by Kodak, Limited, 43, Clerkenwell Road, London.

From the November Kodak Trade Circular we take the following extract:—"We are prepared to enter the field with what are known as cut or flat films in a form that will do away with the inconvenience of glass plates. We have long had this in view. The Pelloid Plates as now to be issued are the first stage in our opening up along this line. It is the general and increasing demand for light and portable apparatus from the photographic public that has set us to work to perfect our plans and produce an article which will not be a fancy but a real substitute for the glass plate, a substitute possessing its special utilities without its disadvantages. Briefly, the Pelloid Plates consist of a light unbreakable film which is attached at the edges by metal retaining clips to a card support, and they are so devised that they can be used in ordinary plate holders or sheaths wherever glass plates can be used, and in precisely the same manner as glass plates, without any preparation whatever. The Pelloid Plates are developed and fixed in the manner usual with glass plates. Although thin, they lie quite flat. After washing, they are pinned up by one corner or edge to a lath, or shelf, or stretched cord to dry. No glycerine bath whatever is required, as they do not curl in drying. They are much thinner than the average cut film, and can therefore be printed from either side—an important point with carbon workers. The back also has a surface which can be worked upon, so that they can be retouched on both sides."

Much water will probably flow under the bridges before the often-threatened photographic glass plate is abolished; but there is no doubt that in the latest attack upon it the Kodak Company have shown considerable acumen. Hitherto one of the drawbacks to the general use of cut films has been the difficulty of providing sheaths, holders, or backing pieces which should be suitable for the ordinary dark slide, and not cause trouble to a person chronically indisposed to take trouble—the amateur photographer. Pelloid films step in to remedy this omission. Clipped to the card on all four sides, they handle, as it is claimed, as easily as a glass plate, from the moment they are taken from the package until after exposure. The thin clips are readily removed, and development proceeds as usual. Qualitatively the film appears excellent.

Commercial & Legal Intelligence

MESSRS. A. and M. Zimmermann (of 9 and 10, St. Mary-at-Hill), have removed to 3, Lloyds Avenue, London, E.C.

PHOTOGRAPHER'S Claim for Water.—At the Derby County Court on Thursday last, Frank Burch, photographer, of Victoria Street, Derby, claimed damages from Edward Clulow, stationer, also of Victoria Street, Derby, for cutting off his supply of water, and an injunction to restrain him from doing so. Mr. K. S. Clifford appeared for the plaintiff and Mr. J. E. Ducher for the defendant. The plaintiff's case was briefly as follows. The defendant sub-let the top portion of his premises to the plaintiff for the purposes of a photographic studio. The rent agreed upon was £50 per annum, payable quarterly, inclusive of rates, taxes, and water. Soon after the plaintiff entered into tenancy he found he was unable to obtain any supply of water for his business purposes after 7.15 on most nights of the week, whilst on Wednesdays (the early closing day) he found he was unable to obtain water after two o'clock. He saw Mr. Clulow about it. He said he (defendant) must safeguard his stock from possible damage by water by cutting it off at night. Mr. Ducher contended that it was understood from the first by the parties that the water should not be allowed to be turned on all night. The defendant, when sworn, said that when they were arranging terms the plaintiff pointed out that his predecessors (the Imperial Photographic Company) had intimated to him that it was inconvenient to have the water supply cut off at such an early hour as required by the defendant. He (the defendant) gave the plaintiff to understand that he closed his shop at 7.30 in the evening, and that he would not have the water turned on after that time having regard to the danger of the pipes bursting and spoiling his stock, etc. The plaintiff then accepted the terms. The water was now supplied as he agreed to supply it in the first instance. In cross-examination the defendant admitted that he did not allow the use of any water on the premises on Bank Holidays. His Honour accepted the defendant's statement concerning the original

arrangement as to the water supply as the correct one. He dismissed the action with costs.

THE Copyright of a Photograph.—*Boucas v. Cooke and others.*—This case came on for hearing in the King's Bench Division of the High Court on December 8th, before Mr. Justice Ridley and a common jury. The plaintiff, a photographer carrying on business in Mile End Road, brought this action to restrain the defendants, Mr. Claude Hanbury Cooke, the boy preacher, his manager, and a printer named Reynolds, from infringing the plaintiff's copyright in a photograph of the youth. The defendants denied that the plaintiff had the copyright in the photograph in question, and that consequently there had been no infringement by them. The plaintiff's case was that in January of this year Mr. Cooke and his manager called at the plaintiff's studio, when it was arranged that Cooke's photograph should be taken, and that some silver prints should be produced for the purpose of appearing in some pamphlets which were going to be distributed amongst the congregation at the Great Mission Hall, Mile End Road, where Mr. Cooke was then preaching. The copyright in the photograph was to be the property of the plaintiff, but in the event of the plaintiff receiving a sufficiently large order for copies, viz., several thousand, he (the plaintiff) would assign the copyright to Mr. Cooke. However, the parties could not agree as to the price to be charged for the copies, and the arrangement fell through, and the copyright consequently remained the property of the plaintiff. The defendants then, it seemed, entered into an agreement with Mr. Reynolds that he should print some 20,000 copies of the photograph, and the plaintiff now asked for an injunction to restrain this being done. The plaintiff having been called in support of his case, and other witnesses having been examined, the defendant, Mr. Claude H. Cooke, went into the witness box. He said he was a native of England, and was in his seventeenth year. He had preached for many years in London and the provinces to large congregations. He had also visited America. When he went to the plaintiff's studio, it was arranged that the negative of the photograph should remain his (the defendant's) property. The plaintiff would not agree to terms, and consequently the arrangement to print copies went off, and he suffered damages in consequence.—Cross-examined: He knew he was only in his seventeenth year because he had counted his birthdays since he was two years of age. (Laughter.) Mr. Colam and Mr. Dwyer appeared for the plaintiff, and the defendants were represented by Sir Arthur Collins, K.C., Mr. Herbert Reed, K.C., and Mr. Turrell. His Lordship, in summing up, said the only question for the jury to decide was whether or not the negative was the property of the photographer. The jury, after a short consultation, said that the negative was, in their opinion, the plaintiff's property, and they gave judgment for him for £20, and for £5 in respect of penalties under the Copyright Act. His Lordship granted an injunction against the defendants, restraining them from dealing with the copies in their possession and from producing further copies, and ordered all copies at present in their hands to be delivered up to the plaintiff.

WHY are the Germans ahead of us in chemistry asks "T. H." in "The Pharmaceutical Journal." The fact of the Germans having got ahead of us is of course an important factor in their being ahead of us, but any one who compares the system of things in Germany with the system of things in England, must come to the conclusion that they are very likely to keep their lead or even improve it. That is to say, unless we wake up in England. I now wish to draw the attention of the readers of this journal, not to the inferiority of the English method of making chemicals, but to the inferiority of the English method of making chemists. There are undoubtedly many who receive a special education as manufacturing chemists both in England and in Germany. With these and their training I do not propose to deal. It is often, however, in the laboratory of the apothecary that the inquisitiveness of the chemist first manifests itself, and to have served an apprenticeship to an apothecary in Germany is a good groundwork for the making of a chemist. Is this so in England? The English apprentice at the close of his apprenticeship knows that Epsom salt is sulphate of magnesia, that it is soluble in water, perhaps has learned the degree of its solubility, or even a little more if he is a curious youth; but he has the opportunity of spending a four-years' apprenticeship without learning a scrap of chemistry. This is not at all as it is in Germany. If the German chemist will have an apprentice at all he must bring him up to his profession. He is as responsible for the education of his apprentice as the English father is responsible for the education of his child. There is an Inspector of Apothecaries in Germany, as there is an Inspector of Schools in England. This may not sound well in the ear of the English chemist, but the result is that after a three years' apprenticeship the German youth can pass an examination which, it is safe to say, not one in fifty English youths at the close of their apprenticeship could pass. Then goes out the English youth as junior, dabbles a little in chemistry, learns a little botany, perhaps—and perhaps not. He may then go to college, study for six or nine months, and enter for his minor examination. If he has worked hard he may succeed in passing the same, but what he has learned during these months he cannot retain like the German chemist, whose term of study extends over six or seven years. During his time at college he has "no time." He is studying for his exam. If he has an inclination for research he is behind with his botany. If he has a turn for analysis he is behind with something else, and he has no time. From his examination he emerges again into business life, and after a few short years he has forgotten a great deal. He will tell you so himself, and it is impossible for one to disbelieve him. The German, on the other hand, after a probation of seven years, has become a chemist and remains a chemist—indeed, finds it a part of his business to be one. He will have an apprentice? Then he must teach him chemistry, he mus'

teach him his profession, or have him taught. The result is that the one learns and the other doesn't forget. In Germany there may be too much law. As to its sufficiency or over sufficiency I will not stop to question, but I venture to offer the opinion that this system is better than the English one, by which the one forgets and the other doesn't learn.

SCIENCE Teaching in Ireland.—Mr. W. A. McKeown writes to "The Times":—"There is an institution in Dublin named the College of Science, which was until recently under the direction of South Kensington. It was an excellent institution, gave a scientific education of the highest character, and had as its professors very eminent men. It has been transferred to the Agricultural and Technical Department, which is directed by clerical influences; and it would seem as if a deliberate attempt were being made to destroy science teaching in Ireland. There are 40 scholarships in connection with the Royal College of Science, and free education and the keep of these scholars costs the State between £3,000 and £4,000 a year. They are nice prizes, and should only be obtained on a stiff examination. I have received a copy of the paper set at the scholarship examination in 1902, of which the following is a copy:—1. Write an essay on any one of the following subjects: (a) The value of advertisements of his goods to a pharmaceutical chemist; (b) motor-cars; (c) the child is father to the man. 2. What do you consider the best English prose work written by an Irish author? Give a general outline of the work and point out its most striking features. 3. Give five lines from some well-known English poem by a poet born in Ireland. Briefly describe and criticise the poem from which the quotation is made. This is certainly a remarkable paper to set at such an examination. Not long ago some 40 students at this college were turned out by the professors because they did not possess a sufficient education to profit by instruction. It is surely time for the Government to interpose and prevent the ruin of this college and the grabbing of public money in clerical interests.

ROYAL INSTITUTION.—The following are the lecture arrangements at the Royal Institution, before Easter:—Professor H. S. Hele-Shaw, six lectures (adapted to young people) on Locomotion, on the Earth; through the Water; in the Air (experimentally illustrated); Professor Allan Macfadyen, Fullerian Professor of Physiology, R.I., six lectures on the Physiology of Digestion; Sir William Abney, three lectures on Recent Advances in Photographic Science; Sir Robert Ball, three lectures on Great Problems in Astronomy; Mr. A. J. Evans, three lectures on Pre-Phoenician Writing in Crete; and its bearings on the History of the Alphabet; Sir Clements Markham, three lectures on Arctic and Antarctic Exploration; Mr. G. R. M. Murray, three lectures on the Flora of the Open Ocean; Mr. C. H. Firth, three lectures on Society during the Commonwealth and Protectorate; Sir Frederick Bridge, three lectures on the Bi-Centenary of Samuel Pepys, his Musical Contemporaries, Criticisms and Compositions (with musical illustrations); Mr. A. B. Walkley, three lectures on Dramatic Criticism; and six lectures by the Right Hon. Lord Rayleigh. The lectures on Tuesdays and Thursdays during the season 1903 will be delivered at five o'clock instead of at three, as in previous years. The Christmas course of juvenile lectures and the Saturday lectures will continue to be delivered at three o'clock. The Friday evening meetings will begin on January 16th, when a discourse will be delivered by Professor Dewar on Low Temperature Investigations; succeeding discourses will probably be given by Dr. Tempest Anderson, Professor W. E. Dalby, The Right Hon. Sir Herbert Maxwell, Bart., M.P., Professor S. Delepine, Principal E. H. Griffiths, Dr. A. Liebmann, Professor J. G. McKendrick, Professor Karl Pearson, Professor E. A. Schafer, Professor W. A. Herdman, The Right Hon. Lord Rayleigh, and other gentlemen.

Who Discovered Photography?—The amateur photographer is usually averse to studying the base degrees by which his pastime has been rendered easy and inexpensive; but that is because the facts of history are generally presented in a bald and unattractive manner. Clothed with illustrations, and brightened with a touch or two of humour, a disquisition on photographic history proved interesting to members of the photographic section of the Croydon Natural History and Scientific Society. Most people probably put down Daguerre as the discoverer of photography, but from the lecture on Friday evening by Mr. George E. Brown, editor of "The Photogram," it was seen to be impossible to name any one man as the inventor or discoverer of the art-science. The camera was proved to be very much older than the photographic use of it, and some amusement was caused by the directions of an ancient writer to "correctly appropinquate" the picture upon the ground-glass. The lantern slides included portraits of the early workers to whose combined labours photography is due. The earliest was Niepce, whose camera was shown to be fitted with an iris diaphragm—a curious fact, inasmuch as only some years ago photo manufacturers were listing this addition as an instance of their up-to-dateness. Daguerre and Niepce together worked out a process, but no details of it were made public until six months after an Englishman named Fox Talbot had published a practical process, so that, as regards actual publication of methods, England is the home of photographic discovery. Moreover, Talbot's process produced a negative from which other positive prints could be made, whereas the Frenchman's process resulted only in one picture. Some interesting views of the dark-room used by Talbot, his printing establishment, and a collection of his cameras were shown. A print from the first negative on glass was also exhibited, in addition to many interesting scenes connected with the labours of these early workers.—"Croydon Advertiser."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Dec.	Name of Society.	Subject.
12.....	Croydon Natural History.....	<i>The Development of Bromide Papers.</i> J. H. Baldock, F.C.S.
12.....	Borough Polytechnic.....	<i>Trimming, Mounting, and Framing.</i> Mr. F. W. Bannister.
12.....	Photo. Society of Ireland.....	<i>In the Cevennes, &c.</i> Hugh Pollock.
15.....	Southampton Camera Club.....	<i>Resumé of the Summer Rambles.</i> Illustrated Lecture. Mr. G. T. Vivian.
15.....	Society of Arts.....	<i>The Future of Coal Gas and Allied Illuminants.</i> Professor Vivian B. Lewes.
15.....	Glasgow and West of Scotland.....	Demonstration of the "Lumière Process of Colour." Lumière N. A. Co., Ltd. Exhibition of "Photography" Prize Slides.
15.....	Camera Club.....	<i>French Stonehenge,</i> illustrated. Mr. Cato Worsfold.
16.....	Devonport Camera Club.....	<i>The Possibilities of a Modern Camera.</i> Mr. Wardell (London).
16.....	Birmingham Photo. Society.....	A Demonstration by Mr. Harry Wade.
16.....	Newcastle-on-Tyne Photo.....	<i>Pictorial Treatment of Architecture.</i> By Mr. Walter Seutt.
17.....	Society of Arts.....	<i>The South Russian Iron Industry.</i> Mr. Archibald P. Head.
17.....	North Middlesex Photographic.....	<i>Elementary Optics.</i> J. McIntosh.
17.....	Leeds Camera Club.....	<i>Kallitype.</i> Mr. E. Heslop Chapman.
17.....	Borough Polytechnic.....	Lantern Night. (Monthly Slide Competition.)
17.....	Photographic Club.....	<i>Latin Paper Printing: Formulae and Methods.</i> G. T. Harris, F.R.P.S.
17.....	Wolverhampton Photographic.....	Dutch Auction.
18.....	Richmond Camera Club.....	Demonstration by Mr. Cembrano.
18.....	London and Provincial.....	Illustrated paper by Mr. Thos. E. Freshwater.
18.....	N.-W. London Photo. Society.....	Demonstration: The Carbon Process. Thomas Illingworth & Co.
18.....	Liverpool Amateur Photo.....	Lantern Lecture. <i>A Month in Jamaica.</i> Mr. Geo. E. Thompson.
18.....	Camera Club.....	<i>A New Apparatus for Testing Lenses,</i> with demonstration. Mr. C. Beck.

PHOTOGRAPHIC CLUB.

NOVEMBER 26TH, Mr. J. R. Gotz in the chair.

Dr. Grun gave a paper on his fluid lens. He introduced his subject by describing briefly the difference between old and new achromats, and some of the conditions the optician endeavours to fulfil in designing a lens; and then gave a brief description of his own lens. He stated that purchasers could have at their desire either lenses with a flat field and little depth of field, or with a round field and greater depth, saying he had come to the conclusion that lenses with a round field had greater depth of field than those with a flat field. For cinematograph purposes lenses had been made by him with an aperture approaching f1, and in reply to a question said the focal length was 1.5 inches and aperture 1.25 inches. For general use on a quarter-plate camera a lens at that aperture was much too heavy and bulky; for instance, a 5" lens would require an aperture of 5" to work at f1. For most purposes an aperture of f2.5 was quite sufficient, and most of his pictures had been taken with such a lens. While allowing that lenses of that reputed aperture and larger were made by Dallmeyer, Voigtlander, and others, he claimed that his own lens was infinitely superior to them in rapidity, depth of field, and covering power. He had taken photographs in the theatre in two cameras side by side, one with his own lens and one with an ordinary lens with identical aperture and exposure, and at the same instant, and compared the results. While the one taken with his own lens gave a satisfactory negative, he could get nothing at all out of the other plate. The other lenses also had no depth of field, and very limited covering power. He passed round a 1-1 plate print of the interior of a room taken with one of his quarter-plate lenses, showing good definition all over. He could not say what aperture had been used, as it had been taken by a stranger. A large number of pictures taken with his lens, most of them at the Theatre Royal, Brighton, with ordinary stage lighting and unknown to the performers, were now shown by means of the lantern. The first two slides were photographs of a Rudolph's focimeter, with twelve angular vanes at 6" distance, giving a total distance of 6ft. between the first and last vanes. One of the slides was taken with a Grun lens and one with an anastigmat of identical focal length and aperture. Purporting to show the great depth of focus possessed by his lens, the conditions being dissimilar, the comparison was not fair. While both were supposed to be accurately focused on the middle vane, only the Grun lens was actually, the first and last vanes being shown fairly sharp. The anastigmat was actually focussed on the farthest vane, and only the last half of the vanes were in focus, the nearer ones getting more and more fuzzy as they approached the lens.

The Chairman, Mr. Conrady (designer of the Holostigmat), Mr. J. H. Agar Baugh, Mr. Purser, and Mr. W. Thomas, F.R.P.S., took part in the discussion which followed.

On Wednesday evening, December 3rd, Mr. Wilkins, of Messrs. R. and J. Beck, Ltd., attended and gave a lecture, illustrated with lantern slides, showing the work done with the firm's orthostigmat and telephoto lenses.

CAMERA CLUB.

THERE were two great travellers at the Camera Club on Monday night, and a most enjoyable evening was spent in their company. Mr. Cutcliffe Hyne, perhaps best known to the world as the creator of the redoubtable "Captain Kettle," gave a lecture on Arctic Lapland, and Sir Martin Conway, the conqueror of many peaks, undertook the more passive role of chairman. It is not generally known that Mr. Hyne travels even more than he writes, and that ten thousand miles is about his yearly record.

Sir Martin Conway said that he hardly knew what particular functions were expected of him in the exalted position of chairman, but he would endeavour to do his best. He could only express the great pleasure he felt in taking the chair for Mr. Cutcliffe Hyne. We had all been charmed by Mr. Hyne's well-known volumes, and were pleased to see him at the Club. For his own part, he was looking forward very keenly to what the lecturer had to say, for Mr. Hyne held the unusual position of one who could speak from personal experience of any part of the habitable globe. Lapland was a peculiar country, for it had no boundaries, and belonged to nobody; but it had inhabitants, and their lives gave an undoubted interest to the land. But he would not trespass upon the lecturer's province, but would at once ask him to tell his story.

Like many other lecturers, Mr. Cutcliffe Hyne began with an apology for the poor quality of the pictures he was about to show. He said that if he had known that the Camera Club members were such masters of the art of photography, as he judged them to be by the many beautiful specimens hanging on the walls, he should have waited long before he presented himself before them. His were all bad ones; some worse than that, and others again took a still lower grade of worseness. Arctic Lapland, although it was credited in the summer months with twenty-four hours' daylight, was only so described as a matter of courtesy. As a matter of fact, fog, rain, and other climatic disturbances reduced the twenty-four hours considerably. He took with him to Lapland a friend, in the person of Mr. C. Hayter, the artist, and a quarter-plate camera. He exposed 120 films, and got about 120 bad negatives. You could distinguish what some of them were meant for, but all were bad. The difficulties in obtaining pictures were great. Thus, he changed his first lot of films on board ship, and got the steward to carefully cover up a certain skylight while he did so. In the middle of the operation the steward came and uncovered the glass, and called out "Have you finished, sir?" I answered, "NO!"—at least, it wasn't no, but something equivalent. On other occasions he had to change his films with his head thrust into a sleeping sack, with sundry clothes above, and his friend sitting on top of all. "It was hot work, changing those films."

The travellers went north on the s.s. "Windward," the vessel which is identified with the Jackson-Harmsworth expedition, and the same which brought Nansen home on her return voyage. They disembarked at Vardo, on the northern coast of Lapland, and here they had an opportunity of studying the modern method of whale capture. The right whale is now almost extinct, and the animal now hunted is the Finner whale. The harpoon, with the boat towing after it at railroad speed, is a thing of the past, and the present method is to shoot the animal with a gun which carries a lyddite shell, which strikes the creature dead. A picture was here shown of two whales being towed behind the whaling steamer to the factory, the lecturer explaining that progress was necessarily slow with such a burden to drag through the water. (The rumour which was current some time back to the effect that Andree's balloon had been seen floating on the sea, probably originated in the circumstance of a blown-out dead whale having been seen at a distance. A photograph indicated how easily such a mistake might arise.) The whales are towed to a factory, which is generally situated in some quiet fiord, and are there cut up. Behind the towed whales there is an oily wake in the water, and a pungent smell which persists for at least twenty-five miles. The photograph of a whale factory gave the lecturer an opportunity of stating how the animal's oil, bone, etc., were utilised, and we trust that he exaggerated when he said the meat was canned and sent south as "beef," with a Chicago brand on the tin. "The whale factory also smells; nothing is wasted, even the smell is not wasted—the people appropriate it, and it sticks to them."

It was a venturesome overland journey which the travellers undertook when they decided to go on foot from Vardo to the Gulf of Bothnia. It looks a small distance on the map, but it in reality means a journey of about 800 miles. No horses were to be had, and the travellers had to content themselves with some very indifferent porters to carry their belongings; and even these deserted them after a time. At first there was no trace of vegetation, nothing but hills scantily coated with snow. But as they went inland, first moss appeared—the moss upon which the reindeer feed—and after a time birch trees, about six feet high, but very old.

Many photographs of Lapp families were shown, and the lecturer explained that they might be divided into three groups: Swedish, Norwegian, and Russian (Finland) Lapps. Some were fishers, others acted as herdsmen, and still others might be called farmers. The travellers were much troubled by mosquitoes, and although the speaker had had experience of these pests in tropical countries, those of Lapland are so much the worse, that he believes that they have the power of "biting at both ends." The country traversed was alternately rocky and swampy, and the best time for visiting it is in the winter, when sledges can be

used and there are no mosquitoes. "Only a fool of an Englishman would attempt to travel there in summer."

The natives live in turf-roofed bee-hive huts chiefly, but there are also wooden houses. A map bought in London gave the travellers an idea that there were roads and towns all over the country, and they had a notion that if they carried a few luxuries, such as foie gras, and larks in aspic, they would be able to purchase such simple things as bread, meat, cheese, etc. But they were disappointed. A place marked on the map as a town would turn out to be a log cabin, perhaps uninhabited except by the ubiquitous mosquito, and they could buy nothing, for there was nothing to buy. They were also told that there was plenty of game, but they saw none, and sold their guns in order to save weight of baggage. The wants of the Lapps themselves are very few. They get milk from their cows, and grow rye for bread-making. But their notions of farming are peculiar. They let the rye grow up encumbered with any amount of weeds, and then they cut it down, chop it up—weeds and all—and make it into bread. The loaves are flat cakes with a hole in the middle for the convenience of stringing them together. There are two varieties of bread, one like concrete and the other like rubber; the first is the preferable variety, but it takes so long to eat that you are finishing your breakfast when lunch time comes round. The milk is not drunk fresh, but sour, and fish is not considered eatable until it is half rotten.

The lecturer showed a number of pictures of reindeer, and gave many interesting particulars concerning these animals. The lecture was punctuated throughout with many little quaint conceits, which were much enjoyed by the audience.

Sir Martin Conway said that he was sure that Mr. Hyne deserved and would get a most cordial vote of thanks. He himself had long had a desire to traverse that same strip of country; but now that he had heard so much about it and its inhabitants he felt as if he did not hanker after it so much. Mosquitoes and stinking fish may be interesting to hear about, but he did not care for a close acquaintance with either. The lecturer had revived many reminiscences, and especially it called to his mind the overpowering, pungent, and all-pervading odour of the whale factories. He knew nothing that smelt quite so loudly as an old whale—old, he meant, since it had died. He should take the memory of that smell home with him to-night, and it would haunt his dreams. Then there was also the codfish smell, and the cod liver oil smell, and these together with the Lapps themselves, made up an olfactory symphony that was beyond description. As to the Lapp himself, it was like peeping back to neolithic, or perhaps palæolithic times; our own ancestors were probably like these people.

After a few remarks by Mr. O'Shea and others who had visited Lapland, the meeting closed with a hearty vote of thanks to Mr. Cutcliffe Hyne for his instructive and entertaining lecture.

CROYDON CAMERA CLUB.

"EXPERIENCES of a Holiday on the East Coast," being an anecdotal lecture by Mr. P. C. Harpur, a member of the Club, was the subject for Wednesday, the 3rd inst.

Mr. Harpur's narrative covered so wide a field that it is only possible to mention a few of the points he dealt with. He very strongly believed in the advisability of all amateurs joining a photographic society, and instanced himself as a "hopeless spoiler of plates" before he joined the throng he was addressing. Considering the quality of Mr. Harpur's present work, the moral is obvious, and one to rejoice the hearts of all honorary secretaries. Mr. Harpur also believed in the too-frequently neglected sky shade, and showed a very neat one constructed out of a piece of stiffened cloth, which fitted on to the hood of the lens by means of a circular piece of clock spring. His preference was to work against the light, and a shield against the direct rays of the sun was almost essential.

In dealing with groups, such as harvesters, fishermen, and the like, the lecturer thought far more failures resulted from trying to take them unawares, than in getting them to join in the proceedings, with a strict injunction that they were to appear oblivious of the camera. He generally found a willingness to enter into the spirit of the thing, though children had a misguided tendency not to miss anything that was going on.

Mr. Harpur spoke for over an hour, and much that he had to say was worthy of attention. A little judicious compression here and there, and interspersing the narrative between the slides, instead of showing the latter at the termination of his remarks, would have been preferable. This is offered as a suggestion, and in no wise detracting from a lecture which a hearty vote of thanks emphasised as excellent.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.

CARBON printing formed the subject of a lecture and demonstration before the members of the above Association, at the headquarters, Y.M.C.A., Blackett Street, Newcastle-on-Tyne, on Tuesday evening, December 2nd. The demonstrator was Mr. William Thompson, who in the course of his remarks said that of all printing processes, carbon undoubtedly yielded the most beautiful results, the ultimate colour of the print being absolutely determined by the selection of a suitable pigment, there being no possibility of double toning or degradation of the high lights as with printing-out papers, while errors in printing can be corrected by lowering or raising the temperature of the water used in

developing. The difference between single and double transfer was fully explained, the lecturer showing that the necessity for the double transfer process could be avoided by taking the negative with the glass side towards the lens, instead of the film side, or by using thin films and printing through them, the thickness of the film support making no appreciable difference in the definition. Several very fine prints were developed during the course of the demonstration, these being supplied by the Autotype Company and Messrs. T. Illingworth and Co., Ltd., to whom the lecturer expressed his great indebtedness for their kindness. Some excellent prints by Messrs. Thompson and Lee were also exhibited, and greatly admired.

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY.

MEMBERS of the photographic section of this Society had a very pleasant and profitable evening on Friday, when the monthly meeting took place in the Council Room at the Town Museum. Mr. Wardell (of London) gave the members of the section many useful and interesting hints in his address upon "The possibilities of the modern camera," which was illustrated by some very up-to-date photographic apparatus. Special attention was given by the speaker to telephotography, its difficulties and advantages, and the audience received with manifest interest a number of admirable pictures taken at distances varying from three-quarters of a mile to $1\frac{1}{2}$ miles—pictures, for instance, of the Clock Tower of the Houses of Parliament, the top of the Nelson Monument, etc., in which an astonishing amount of detail was apparent. Other matters of interest to devotees of the camera were touched on, and some knotty points elucidated.

The chairman of the section, Mr. H. Alfred Roehling, who presided, expressed thanks to the lecturer, who in acknowledging the compliment paid a tribute to the capabilities of Mr. A. Newton as the lanternist.

WEST LONDON PHOTOGRAPHIC SOCIETY.

THERE was a very full programme and a large audience on the 5th inst. A show of work done at the outdoor meeting was held, and the secretary exhibited and explained Messrs. Wallis Bros'. Perina camera, which affords a range of exposures from 1-5th to 1-1,000th second, by means of a focal plane shutter with a wide and narrow slit in the one blind, either being useable at will. A collection of prints upon Mattos paper, kindly lent by Mr. P. Leuthardt, were next passed round, and their fine tone, richness of image, and variety of surface were much admired. A series of stereoscopic prints from Stereo-weno negatives, as well as three Stereo Daguerrotypes (in perfect preservation) were then examined, and Mr. L. Selby afterwards explained the working of the Kodak developing machine, which he said had in his hands produced very satisfactory results.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

At the last meeting, Mr. Fred. Anyon, of Bootle, gave a demonstration specially for beginners on "The Management of the Camera, including Hand Camera Work and the Development of Negatives." The lecturer entered fully into the various movements of the modern camera, and explained the objects of them. He emphasised the advisability of amateurs mastering the stand camera before tackling the hand camera, and spoke of the difficulties attending the latter branch of the art. Speaking upon development, Mr. Anyon gave varying formulæ for different types of negative, and afterwards developed a negative in the presence of the members.

WOLVERHAMPTON PHOTOGRAPHIC SOCIETY.

ON December 1st, Mr. Harold Holcroft lectured upon "Mounting and the choice of Mounts." He dealt with the subject for the benefit of the amateur of all varieties, but more especially to assist the picture maker. The objects of picture mounting were stated to be:—

- (1) To preserve the print from mechanical injury, tearing, etc.
- (2) To hold the print flat so that it could be seen properly.
- (3) To isolate the picture from its surroundings.
- (4) To aid the effect of the picture by enhancing or minimising certain features.

He said that the mount should occupy a subordinate position to the picture, that the relation between them should be as the accompaniment to the song, as the dress to the man, and cautiously refrained from dogmatising upon the relationship between woman and dress. He pointed out that after some years of universal framing close up at the exhibitions, mounting of suitable subjects was now receiving proper attention, and that mounting must be necessarily largely a matter of individual taste and fashion of the moment; that this taste must be cultivated by observation, and especially by the careful study of the work of leading men.

In dealing with the effects of the different variations in mounts which effects were illustrated practically, he ventured to differ from the critics who condemn the plate mark as applied to a photographic holding that the maxim "Intention constitutes the crime" applied, that there was no intention to deceive, and that no person of reasonable intelligence

would mistake a photograph for an etching; but this use of a plate mark was not false pretences, but a legitimate borrowing from a sister art of a useful form of relief or ornament. A collection of many different kinds of paper, and other materials which may be effectively used for mounting was shown, amongst them being examples of the art mounts stocked by the "Photographic Art Journal," Percy Lund, Humphries and Co., and Messrs. Wesson and Co., The proper use of these materials for different kinds of prints was illustrated, and the application of ornament where the character of the subject would admit of it was dealt with. Some fine examples of mounted pictures by Pugo and Yarnall Abbott, from the Salon exhibitions, effectively enforced the various points of the lecture.

SOUTHAMPTON CAMERA CLUB.

A MEETING of the members of the above Club was held on the 8th inst., under the presidency of Mr. G. Vivian, when, after the usual preliminary business, Mr. Steadman, representing the Lumiere N.A. Co., gave a lecture and demonstration on the most advanced process of colour photography, and received a hearty vote of thanks for his elucidation of the subject.

News and Notes.

THE Royal Photographic Society's lantern lecture on Tuesday, December 16th, at 8 p.m., will be "Photography in the Hunting Field," by Mr. H. M. Lomas.

THE death is announced of Prof. O. N. Rood, known by his work in experimental physics. He was the author of "Modern Chromatics." Prof. Rood was born in 1831, and was professor of chemistry and physics at Troy University from 1858 to 1863. For the past thirty-nine years he had been professor of physics in Columbia University. He had been vice-president of the American Association for the Advancement of Science, and was a member of the National Academy of Sciences.

PATENT LAW Reform.—Notice has been given by the Commissioners of Works and Public Buildings that they intend to promote a Bill in the next session of Parliament for extending the existing buildings of the Patent Office. It is proposed to acquire the premises east of the existing office, and those to the north and south as far as Furnival Street and Staple Inn and Took's Court. This is the outcome of the recommendations of a committee appointed in May, 1900, while Mr. Ritchie was at the Board of Trade, and is in anticipation of the greatly increased accommodation necessary for carrying out the provisions of the Patent Amendment Bill which has just passed the third reading before the House of Lords. Some idea may be formed as to the effect which the new Bill is likely to have by comparison with the working of the United States Patent Office under the system of an absolute search for anticipations. The examination staff numbers 662, and cannot keep pace with the work. The staff at the British Patent Office, at present under a system of "no search," numbers 267. Under the present Bill a fifty years' search is guaranteed. The expenses of the American office amount to £242,356 yearly, and the income to £225,091; the present expenses of the British office yearly are £123,216, and the income £225,700.

MARPLE and District Photographic Society's First Annual Exhibition was held on Saturday, the 29th ult.. It was opened by Mr. C. F. Budenberg. The attendance during the afternoon was moderate in number, but influential in character. Mr. Budenberg, in the course of his introductory remarks, gave an exhaustive consideration of the value of photography in the principal arts and sciences, including an account of a recent visit he made to the Zeiss works, and the use at that place of stereoscopic photography for the purpose of astronomical measurements. He congratulated the Marple Society upon the excellence of their exhibition. About 250 pictures were displayed, two important sections being lent by members of the Manchester Amateur and the Ashton-under-Lyne Societies respectively, representing the best work at the exhibitions recently held by them. The spirit of goodwill shown by the two Societies named in thus helping a younger Society is most praiseworthy. The work shown by the Marple Society was highly creditable, having regard to the short time the Society has been in existence. The principal exhibitors were C. J. Atkinson, J. W. Wood, G. Holmes, and B. Leech. Other features were stereoscopic views, transparencies, microscopes, process printing blocks, etc. At 7.30, Mr. Atkinson, the President, gave his illustrated lecture, entitled "A Holiday at Hexham and Carlisle," which was very well received, and was followed by a general collection of lantern slides, chiefly by Mr. Chayne, of Ashton-under-Lyne. In the evening the attendance was quite large enough for the capacity of the room. The financial result will be a slight gain; and in all other respects the Society have received encouragement to repeat the venture. The present occasion was largely experimental, and was undertaken in the hope of increasing public interest in the art and practice of photography. It was a matter of surprise to many of the visitors upon finding that photography was something more than a mere hobby, and that it is indeed a capable medium for the expression of artistic feeling and cultured taste. The impression left by the exhibition is already taking form in the enrolment of new members; the Society has also gained a recognised position in public estimation as a social and educational influence.

A VISIT TO THE TATE GALLERY.

To the Editors.

Gentlemen,—Without seeking to enter into the doubtful controversy whether or not photography is an art, the assertion may be safely made that the photographer is at his best when he takes counsel of those truths which Art alone can teach him. An afternoon spent in contemplation of a good collection of paintings will send him forth with a keener relish for his work and a broadened horizon. The Londoner is especially favoured in this respect, for he can take his choice among several of the finest art collections in the world. Hardly second in interest to the famous National Gallery is that known as the Tate Gallery, at Vauxhall, whose light and graceful dome is a riverside beauty. A visit we lately paid there served to convince us more than ever of the immense value of a close study of pictures, such as are here contained, with special reference to their suggestiveness, photographically speaking. A few appreciative remarks on some of the many treasures here shown, and an endeavour to trace out one or two of their more obvious lessons for us, may not, perhaps, be without interest.

Entering, and pausing to admire the dainty fountain court under the glass roofed dome, with its tessellated pavement, slender columns, and arcaded gallery overhead, we pass into the room on the right by preference; curiously enough, everyone seems to do that, and we merely follow popular example. The first thing that immediately rivets our attention is that beautiful creation, "The Glitter, Grime, and Wealth of a Flowing Tide," by W. L. Wyllie, A.R.A. Carrying out our intention of looking at everything here with an eye for photographic hints and suggestions, we are at once impressed with the fact that this was eminently a subject for the camera, and one where photography would have fully distinguished itself. It is true that the silvery greys and low tones of the smoke-clouded river, with its crowd of shipping, are rendered by the painter with a superb harmony of colour that we cannot yet attain to; true, also, that the subject is idealised and rich in suggestiveness that only the artist could give; yet how many a chance have we photographers of catching instantly some fleeting effect of light and shade, some momentarily happy grouping of tall-masted ships, with a faithful naturalness of ripple and movement in the water peculiarly our own, as so many fine river pictures have already proved. "The Vigil," by J. Pettie, R.A., is an impressive and poetic presentment of a mediæval knight, keeping his silent midnight watch before some saintly altar. While admitting without cavil that in such subjects Art must always of necessity be easily first, it is certainly borne upon us that many most effective genre pictures might be accomplished by photographic means, in which the interiors of churches and similar buildings should form the suitable and fitting background. Of course, we know that such things are difficult of management, and are far from wishing to suggest anything that might tend to detract from the natural reverence that should be observed in such surroundings. We are fully aware also of the almost impossibility of avoiding artificiality when any kind of posing or arrangement of suitably dressed models is attempted; still, we think it must be admitted that much might be done in this direction, photographically, that has never even been attempted. As yet another example of what might at least be experimented in, though it need hardly be said that photography can scarcely hope to meet Art successfully entirely on its own ground, may be instanced the lovely painting, a little lower down, "Harmony," by Frank Dicksee, R.A. This picture is so well known that it is almost superfluous to describe it. Who has not seen prints or engravings of the lovely maiden playing the church organ, a soft and dreamy light falling upon her glorious auburn hair from a "storied window richly light?" At her side, leaning his face on his hand, is seated a handsome youth, whose eyes, full of affection and feeling, fixed upon the maiden, proclaim that the harmony indicated is not solely connected with music.

"Aysha," by Val. C. Prinsep, A.R.A., is a painting which the portrait photographer may study closely and attentively. It is one of those pictures which, lovely of colour though they be, owe their chief excellence to beauty of outline and lighting; in a word, it is a work which we can imagine would lose little if translated into monochrome. It represents a slender Eastern girl, with a proud, beautiful face, holding a large burnished copper water vase. The attitude, lighting, and entire expression of this successful picture are worthy of minute inspection, carrying, as they do, many valuable suggestions of photographic possibilities.

By this time we are content to wander aimlessly from room to room, looking rather at a specially striking work here and there than trying conscientiously to see all, in catalogue order, a method of inspecting artistic treasures, which to some minds robs the process of half its

charm. "St. Martin's in the Fields," by W. Logsdail, seems to have a peculiar fascination of its own. The handsome spire, so familiar to Londoners, the wet pavements, passing vehicles, newsboy running across the road with the "latest edition," the flower girl, offering bunches of primroses, are most realistically rendered, in a way that makes us at once acknowledge the truthfulness of the presentment. And yet throughout there is that evident touch of selection and suppression which the photographer, before all others, knows so well the necessity of, and can perhaps best appreciate. "Morning Glory," by M. Ridley Corbet, A.R.A., is so eminently photographic a subject that one might almost suspect the artist of having sought inspiration from the camera, although to be sure very much of the beauty of this picture depends on the glowing sunrise behind the sky line of tall, drooping trees. The photographer, however, in dealing with such a motive, would certainly have to make his foreground more interesting than the artist, in this case, relying more on the power of making colour take the place of outline, in subdued tones of green grasses, has done. The narrow curving path at the right is dexterously and cleverly introduced.

"Upland and Sky," by A. Stokes, is a most interesting study of a breezy hill top, with cattle browsing or in repose, sharply outlined, with telling effect, against a majestic cumulous sky. "Pilchards," by C. Napier Hemy, A.R.A., is a glorious triumph of colour, which must make the photographer frankly confess himself beaten. The splendid grouping of the many picturesquely dressed fishers, hauling in the shimmering, silvery burden of their laden nets, is, alas! beyond us. "Carnation Lily, Lily Rose," by J. S. Sargent, R.A., although essentially a triumph of colour, has many lessons for us. It is an admirable example of breadth and largeness of effect, and of how intention and suggestion may be subtly and tellingly expressed, yet in such a way that it is felt rather than seen. The intent, flushed faces of the two sweet young girls, lighting Chinese lanterns, amid an exotic wealth of tall, gorgeous flowers, form a picture that is not soon forgotten, but recalls itself with pleasant persistence, long after its rich colours and charming outlines have passed from the actual vision of the observer. "Ethel," by Ralph Peacock, is a most suggestive example of portraiture. The dark background of carved oak panelling, the naturalness of the golden-haired young girl seated against it, the unconventionality and careless abandon of the pose, have each a lesson for us. If a photographer had done it, it is questionable if it would be so much admired. We should have heard severe remarks passed on the commonplace and homely attitude, the absence of effort in the lighting, the lack of smartness and artificiality about it; in a word, condemnation of just those very things which the artist knows how to admire, and deliberately chooses. "The Pool of London," by Vicat Cole, R.A., has a superbly grand sky effect. The clouds of smoke, half obscuring the vista of multitudinous sails and masts, behind which, in the distance, keeps watch the weather-stained dome of St. Paul's; the air of busy labour and toil, the very romance and mystery of a great city, are here suggested and portrayed with wonderful intensity and power. "The Sisters," by Ralph Peacock, is another beautiful and refined portrait study, extremely interesting and instructive. The elder sister is reading a Bible, the younger, sitting by her side, but with her attention evidently wandering, a lovely expression of affection and trustfulness is visible in the attitudes and faces of both. The grouping, too, is an excellent example of well-balanced composition.

Yet another portrait, and we must leave specific discussion of the many gems to be found in this collection. "Mrs. William Morris," by Dante Gabriel Rossetti, is a work which, it goes without saying, cannot have justice done to it in a few minutes' inspection. It will well repay much longer attention, and the photographer may find food for thought in the admirable arrangement of the hands, and the extremely simple yet highly effective accessories. We have purposely avoided mention of the many world-famous pictures that may here be seen amid such architecturally beautiful surroundings. Who has not heard of Millais's "Huguenot," Calderon's "Renunciation," Leighton's "Bath of Psyche"—to mention but three out of a host? It is certain that the visitor to the Tate Gallery, be he photographic or not, will find the hours pass all too quickly, and hear, with surprise and regret, the voice of the attendant warning him of "closing time."—We are, yours, etc.

LENS, CAMERA, AND DRY PLATE.

December 8th, 1902.

THE BRENTFORD EXHIBITION.

To the Editors.

Gentlemen,—So as to make our annual exhibition more attractive, both for exhibitors and visitors, we purpose introducing a new feature. The exhibition, coming towards the end of March, always includes a lot of work that has already been the rounds of the exhibition, and is well known to us and to the judges also. Now, we want some new material, and I hope you can insert this letter in your next issue. This will give workers three months to prepare what we want.

We propose having one open class for pictures—any subject—that have never been previously shown at any other exhibition. A prize—choice of the winner—consisting of material or apparatus to the value of two guineas, will be given on the condition that there will not be less than twenty entries (1s. per frame entrance fee). The same picture may be entered in any one of the other "open" classes, and

may also stand a chance of winning a medal. As our rooms are within easy access of London, both by train and by tube and electric car, we are looking forward to a ready response to our offer and realisation of our desires. Entry forms will be ready shortly, and will be sent post free on receipt of a post card.—Yours, etc.,

HILTON GRUNDY.

30, Whitestile Road, Brentford.

December 5th, 1902.

A PHOTOGRAPHIC SOCIETY FOR WIMBLEDON.

To the Editors.

Gentlemen,—Will you allow me to announce, through the medium of your paper, that a photographic society is about to be formed in this district, and if those desiring particulars of same, or wishful of joining such a society will forward their names and addresses to me, I will appoint a time and place to hold the inaugural meeting, if they will kindly give a list of evenings in the week which would be convenient for them to attend a meeting for this purpose.

It is sincerely hoped that every inhabitant of this district interested in photography will send in their names, as they need not pledge themselves to join by so doing. Residents in the surrounding districts will be heartily welcomed, so that the proposed society may be a great success.—Thanking you in anticipation, I remain, yours faithfully,

C. F.

136, South Park Road, Wimbledon.

WHERE ARE WE DRIFTING?

To the Editors.

Gentlemen,—Although I never heard of Mr. Michael E. Banger until last week I have not the slightest doubt he is as highly esteemed by the photographic world as he evidently is by himself. His "still drifting" letter in this week's Journal induced me to read his former ones, and wonderful reading I found them. "Without top light, all power of concentration is lost," etc., is one of his statements, which, taking open-eyed, at the risk of being annihilated, I bluntly say is utter rubbish. Leaving, however, all his other assertions aside, I shall confine myself to the subject of "side lighting." Mr. Banger speaks from theory; I speak from nearly four years' practice. I work with one high window, which is fitted with three opaque blinds, to push upwards, and three to pull down. In less than a minute I can open and shut the lot. I can get any and every effect of lighting in about a quarter of the time it took to manipulate my old skylight studio, and I do not find the exposure anything different. As it happens, my acquaintance with portrait painters, eminent and otherwise, is extensive and peculiar. I cannot recall one that ever worked with a top light, or even had one to work with. Fifteen grown-up persons is the largest group I have attempted in my studio, and the work will bear comparison in every way with any I ever did in my old place. The truth is, Mr. Banger, and men like him, either forget or don't know that, whether the studio is side or sky lighted, everything depends on the man behind the camera.

As I shall probably be pulverised anyhow, I recklessly add that, when "Sidelight" says he'll take his dose of light through a keyhole if he thinks fit, it shows, in my opinion, he is a much greater artist than Mr. Michael E. Banger has proved so far.—I am, gentlemen, yours truly,

WM. RALSTON.

259, Sauchiehall Street, Glasgow.

December 5th, 1902.

To the Editors.

Gentlemen,—In reply to Mr. Banger's criticism of my recent article, "A Stray Conversation," I have only to say that I regret that he has misunderstood my meaning.

In endeavouring to emphasise the necessity of a complete correspondence with his environment on the part of a photographer claiming to be an artist, it was necessary for me to use, to a certain extent, metaphorical language, in order to at once introduce the reader to a fundamental principle of the ethical side of the subject.

Mr. Banger chooses to omit this in his criticism, and to regard it merely as literary veneer. This being so, the very essence of the dialogue—the string on which the whole conversation is hung—is destroyed, and what remains must necessarily be disconnected remarks. Criticism is therefore useless, and so I will not reply seriatim to your correspondent's complaints. The amateur I was thinking of is a very different person to the one your correspondent refers to; and, in conclusion, I would wish to remind Mr. Banger that among gentlemen of liberal education it is quite customary to introduce apt quotations into their conversation when these tend to make the meaning clearer, and that these should not be confounded with the extravagances of a fop.—Yours, etc.,

A. V. KENAH.

December 7th, 1902.

To the Editors.

Gentlemen,—I must call "Side Light" to order once more. In his jumble of distortions and misrepresentations which appeared in your JOURNAL last week, he commences with a wilful perversion of my meaning by saying: "Any person who attempts to take a portrait in a studio without the usual window in the roof, has less 'noble aims' than our friend Mr. Banger"—ascribing this sentiment

to me. This I think anyone will admit is a misrepresentation of my meaning. I said, "Happily for our profession, there are men of nobler aims than 'Side Light,' and less easily satisfied, referring to those photographers who desire to vindicate the art claims of our profession, and repel the attacks which are so often levelled at it by persons ignorant of its possibilities.

That he should term me "narrow minded" is rather amusing, as the designation is more appropriate to himself and those who, advocating the abandonment of top light, restrict themselves to the use of side light only.

In what I said about double lights and shadows I was merely stating facts, as it is well known that light travels in straight lines, and therefore two separate lights must cast two shadows. This may of course be modified by placing the sitter in certain positions, but the delineation cannot be so perfect as that obtained by proper studio lighting. In order to avert further misrepresentation by "Side Light," I will state that, while opposing the idea of constructing studios with side light only, any deprecating the abandonment of top light, I have said nothing against the use of side light in the studio, which we all know is most necessary in combination. My words were, "The ideal studio will then be the lecturer's abomination—i.e., with as much glass as possible," etc., etc.

I think my meaning is clear, and nothing but the mental obliquity of "Side Light" could misconstrue it.

The information he gives when saying that "No two persons who are photographed have features exactly alike," is peculiar and funny, as it seems to imply that all who are not photographed are alike in features; or does he mean that his side lighting differentiates the features of his sitters, and thus stamps his own personality upon their portraits?

That different faces require different lighting is true, and distinctly makes for my contention—viz., as much light as possible to be at the disposal of the artist.

As to my knowledge of light and shade, that is a quantity of which "Side Light" is quite incompetent to judge, and he rather gives himself away by sending me a parcel of his "natural living likenesses" to criticise after discounting my knowledge on this point. While thanking him for his recommendation of the book that "set him thinking" (save the mark), I can assure him that nothing he could say would be more surprising than the confidence he asserts in his own ability, although from the way in which "Side Light" occasionally expresses himself, such as calling the sky-light "a window in the roof," and specimens "samples," it would seem that he has had more experience behind a counter than in a studio. His proposal that I should send a "sample" of my work for him to compete with is declined with thanks, but should my idea of a Guild of Art Photography be ever realised I can promise him an opportunity for distinguishing himself.—Yours, etc.,

MICHAEL E. BANGER.

December 8th, 1902.

AN APPEAL.

To the Editors.

Gentlemen,—Will you allow me to bring to the notice of your many readers the sad case of an old photographer, named Webber. He is between 70 and 80 years of age, and came to Salisbury about two years ago, and has been living, sleeping, and working in one room, doing, I believe, chiefly lantern slides. He is now in the workhouse infirmary, having had a bad fit some eight or ten days ago, and is still very bad.

He is in debt to his landlady about £3, and as she is wanting her money and has other uses for his room, she intended to dispose of the few articles he has, such as camera, dishes, negatives, etc., and these being of an antiquated type would not realise much. So I have arranged to pay the debt and take the goods, intending to hold the same until the owner is able to redeem them (that is, if he recovers). The goods are worth very little, if any, more than the £3.

I believe he was at one time in business for himself, and is well known to many photographers in the country, and it is with the hope that they and others may feel disposed to help him, either by paying off his debt or providing him with clothes and food when he leaves the workhouse, that I am thus writing.

Any remittances which may be sent, shall be well and faithfully used, and, with your permission, Mr. Editor, I will acknowledge the same in the Journal.—Yours truly, H. C. MESSER, M.P.P.A.

(Member of the Board of Guardians).

Photo Stores, 29, Castle Street, Salisbury.

December 8th, 1902.

MR. W. F. SLATER of 5, Firs Parade, High Road, Lee, S.E., writes:—I beg to inform you that I have the following lantern lectures, which I shall be pleased to circulate amongst photographic societies: "A Trip up the Rhine with the S.L.P.S." by special arrangement with the South London Photographic Society, to whom the slides belong: "From Liverpool Street Station to the Continent" (the Great Eastern Railway Co.'s route via Harwich), this will be ready by January 1st, 1903, and will include Hamburg, Belgium, Bernese Oberland, Holland, Rhine, and Moselle; "The Land of Windmills," will be ready by February 1st,

1903, which is Holland from Brielle to the Zuyder Zee. Each of these lectures are illustrated with 200 slides, and occupy from 1½ to 1¾ hours. Conditions: (1) That a fee of 3s. 6d. be paid at the time of booking to cover working expenses; (2) That the Society borrowing the lecture pay carriage one or both ways; (3) That each Society be answerable for any damage done while in their possession; (4) That the slides be forwarded to address given directly after use, carriage paid.

THE Lumiere Film.—The Lumiere N.A. Co., Limited, of 4, Bloomsbury Street, New Oxford Street, write:—We beg to inform you that Messrs. Lumiere and Sons, of Lyons (of whose products we are sole proprietors for Great Britain, the Colonies, and North America), have acquired control, by purchase, of the Societe des Pellicules Francaises (Planchon Film) who have hitherto been licensed to supply film coated with the Lumiere emulsion. The enormous demand which followed the introduction of this film to the English market resulted in inability to cope with the volume of business received, and necessitated large additions to the manufacturing plant and buildings. In order to obviate any further shortage of supply, which has resulted solely from the overwhelming demand, the arrangements for manufacture have been largely extended, and the output considerably increased. Many improvements have also been made in the film itself, and it will re-appear under the name of the Lumiere Film (Planchon process).

Answers to Correspondents.

* * * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C."* Inattention to this ensures delay.

* * * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

* * * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.*

PHOTOGRAPHS REGISTERED:—

W. E. J. Church, 119 High Street, W., Sunderland. *Three photographs of the Mayor of Sunderland.*

ADDRESS WANTED.—H. WEBBER writes: "Will you kindly inform me where I can get the Shakespearean playing cards designed by Mr. F. C. Tilney?"—In reply: They are published by Messrs. Swann Sonnenschein and Co. We do not answer letters through the post.

ADDRESS WANTED.—F. W. CLIFFORD asks: "Could you kindly let me know where to get the paper by Dr. Rigollot on 'Electrical Actinometer' mentioned in your issue of April 12th, and oblige?"—In reply: We must trouble this correspondent to give us the correct date. No JOURNAL was published on April 12th of this year.

LENS QUERY.—HEHI says: "I have a lens engraved 'Ross, London. Actinic Triplet No. 4.' I should be glad if you would inform me what special kind of work it is for, if any; also value."—The lens is now obsolete, and is not now made by the firm. It may be used for any class of work, but it is slow in action as compared with modern lenses. You will find it a very good lens for copying. It has but little market value.

RECOVERY OF DEBT.—T. W. G. says: "I have an eighteen months' standing debt owing for photos. The goods were ordered by post, and sent per return. I have written many letters asking for remittance, which they decline, saying 'You can sue me in county court; I will not pay.' Now, the distance to travel to sue would cost me more for return fare by railway than the amount owing. Can I sue in my district, and so avoid the above expense?"—In reply: Sue in the county court of the district in which the debt was contracted. If that is where you are now living sue there.

WM. MELLING.—There are so many "tricks" by which alleged "spirit photographs" can be produced. The two specimens sent appear to have been made by exposing the plates to very indistinct transparencies, either before or after the plate was exposed in the camera—notwithstanding the alleged vigilance of the so-called investigator. We know nothing of the photographer who produced them, or his address. Of course, if you desire to produce spirit photographs you must have the "spirits" clothed in the orthodox white sheet when their portraits are taken.

FLASH LIGHT STUDIO.—FLASH LIGHT says: "I should be obliged if you could let me know if I can take good work with Maloni's patent studio lamp, as I am about to take premises where I cannot erect a studio for portraiture. I have not seen any work (portraiture) done by that light. Perhaps you may be able to give me some information?"—In reply: We have seen good portraits that were taken with the light. You ask if you can take good ones with it; of course, we cannot say, as, whatever light, whether daylight or artificial, be employed all must necessarily depend upon the skill of the operator as to whether the work is good or bad.

LIGHTING THE SITTER.—REMBRANDT says: "From time to time I have noticed in your valuable journal answers to questions in reference to the lighting of studios. Some of the queries have evidently been from amateurs or at least amateur professionals. Could you kindly let me know what you consider to be really the best text book published on the 'Lighting of the Figure in the Studio,' likely to be of assistance to a professional photographic portraitist?"

A reply will greatly oblige."—In reply: You will find either, or both, the following books useful to you: "Artistic Lighting," by James Inglis; "The Studio; and what to do in it," by H. P. Robinson. The former is published at 4s. 6d., and the latter at 2s. 6d. They may be had through any of the dealers, or through a bookseller.

DEFINITION OF TERMS.—COMPETITOR asks: "Will you kindly define what is a snap shot and a time exposure. In entering a competition, say a photo was taken with a camera on a tripod in 1-100 sec., and one was taken with camera held in the hand at 1-50, would they both be classed as snap shots, or would it be time exposure if the camera is fixed to tripod and a snap shot when held in hand, or at what speed of the shutter does a snap shot become a time exposure if snap shots are allowed on a tripod?"—In reply: The term "snap shot" is very vague. It is, however, generally applied to hand camera work, whatever the exposure may be. By time exposure it is generally assumed that the camera is used on a stand, and that a somewhat long exposure is given, such as may be made with the pncumatic bulb.

COLLODION EMULSION.—J. HUGHES writes: "Will you kindly give me the formulæ and directions for preparing this emulsion, also say about what period it will keep in good condition in its unwashed state? I have tried one or two emulsions as given in the B.J.A., but find them too slow to be of much service in regular work whilst some of the above supplied commercially was everything to be desired—except the price, which was too expensive—as compared with the regular wet plate work."—Formulæ for different collodion emulsions are given in the "Albumen" for the current year on pp. 1088-10, all of which are good. But whether any of them are the same formulæ as that of the makers whose name you mention we cannot say. Any collodion emulsion must, of course, come more expensive than wet collodion, and it is also much slower than a gelatine emulsion. In the unwashed state the emulsion will keep for several days.

LIGHTING—BACKGROUNDS.—H. W. B. writes: "I should esteem it a favour if you can tell me (1) By what means the effect is obtained in full length and three-quarter length figure portraits by some of the leading London photographers of the concentration of light about the head and falling away into shadow towards the extremities of the picture. It is evidently not done in the lighting of subject, as it would be impossible to concentrate daylight to produce such an effect? (2) I have several canvas backgrounds which have been discarded, and I wish to know if by first applying a strong solution of size over the existing scene (which I should say is painted in distemper) it would so fix the image that another scene could be effectually painted over it?"—In reply: (1) We scarcely understand the style of picture you desire information upon. If you send us a specimen we shall be able to help you. (2) Yes, but probably the backgrounds will require a coating of plain distemper, to effectually cover up the old scene, before the new one is painted.

INSTRUCTION IN PHOTOGRAPHY.—"PHOTOGRAPHIC NOVICE" sends the following letter: "Will you be good enough to give us a little information? We have the idea that by getting a good negative taken of the various machines we make we could print our own photos in quantity from these negatives after a little practice. If so, what number could be taken from one negative, what outfit, or what articles of equipment should we require, and about the cost of them—we mean for cabinet size prints? If you think our idea is a practical one we should be glad to receive any information and advice you feel disposed to give us."—We suggest that you get an elementary work on photography and learn how to print from negatives. When you have done that you will be able to judge what appliances you will require to produce the number of prints of your cycles that will supply your wants. The cost of them you can ascertain by consulting the catalogues of the firms that advertise in our columns. Are you sure that any good photographer will take negatives for your company and then hand them over to you to print from?"

* * * **NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

* * * **NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

Direct Photographs in Colours. We have already recorded the researches of Dr. Neuhauss and Herr Wörel in the direction of obtaining a mixture of light sensitive dyes which will bleach out under the action of light and give us prints in colours. Dr. Neuhauss has been continuing his experiments, first as to increase of sensitiveness, and secondly as to a more perfect method of fixation than the original one with copper salts. Numerous new dyes were tested and the addition of many oxygen-giving substances and the persulphates of ammonium and potassium were alone found of any value, and the former as preferable on account of its greater solubility in water. The mixture now recommended by Neuhauss is erythrosine, thiazol yellow, uranine, auramine, chlorophyll (fresh alcoholic solution from grass), and methylene blue, these with a 10 per cent. to 12 per cent. gelatine solution with hydrogen peroxide and a few drops of ammonium persulphate, proves to be most sensitive. A soft emulsion gelatine is the best. The method of fixing now recommended is to first wash the plates and then to bathe them in a 10 per cent. solution of tannin to which some sodium acetate is added for 15 minutes, and then rinse and immerse in a saturated solution of tartar emetic, then rinse and then immerse in a saturated solution of acetate of lead and again wash. The colours are in no way affected and will stand an hour's exposure to sunlight with-

out showing any change. At present Dr. Neuhauss states he has been unable to develop the plates, but it is obvious that considerable advances have been made, and we may yet hope for the ideal colour process—namely, one that will give us colours direct in the camera and enable us to print in colours from the results thus obtained.

* * *

Trichromatic Filters. Professor Dr. Fritsch recently read a paper before one of the Berlin societies upon the manufacture of trichromatic filters, the gist of which was to the following effect:—The best emulsion gelatine is soaked for two hours in sufficient distilled water to completely cover it, and then the excess of water poured off and the gelatine melted by the aid of a water bath. A sufficient quantity of the necessary dye is dissolved in distilled water and 5 per cent. alcohol added. To the dye solution half its volume of gelatine solution is added and the whole well stirred on the water bath and well cleaned patent plate glass, which must be accurately levelled, is then coated with the mixture, which should be filtered through a double thickness of mull muslin. For large filters to be used in contact with the plate it is advisable to coax the solution over the plate with a glass rod. When coated the glass should be covered with a bell jar, in order to prevent dust spots and a capsule of anhydrous calcium chloride or fuming sulphuric acid also placed under it, when the plates should dry in about 48 hours. Too much gelatine will cause striæ and too little gelatine separation of the dye in crystals on the surface, which can however, be removed by rinsing with water. Dr. Fritsch recommends cementing another plate glass to the front of the filter with thick Canada balsam dissolved in turpentine. (Mr. Alfred Watkins has pointed out that xylol is preferable as a solvent.) The dyes recommended are Congo red for the orange filter, brilliant green and naphthol yellow for the green filter, and Victoria blue for the blue-violet filter, or dahlia or methyl violet may be used for this, and by far the best green, or rather minus red, filter is one which is not green and is made with milon blue, or naphthol or double green may be used for this. Dr. Fritsch suggests the term "subtractive" filters for those used for negative making, and "additive" or zone filters for those used for positive work.

* * *

Eder's Filters. Dr. Eder, in that section of his famous Handbuch just published, which is entitled "Die Praxis der Photographie mit Gelatine-Emulsionen," suggests the following filters, the trichromatic inks being chrome yellow, Krapp lake (alizarine red), and milon blue (Prussian or Berlin blue). For the violet filter a solution of methyl

violet 1 in 10,000 of water, in a thickness of 1 centimetre. For the green or minus red filter he strongly recommends the use of a blue and a yellow dye, as by alteration of the proportions of one or other of the same the filter may be adjusted to the plate more correctly; thus, if the plate is not sufficiently sensitive to green, the yellow filter is lessened in strength, whilst if the yellow is wanting then the blue compound is weakened. With an erythrosine gelatine plate the formula runs:—

Water	80	ccm.
Ammonium picrate solution 1:200 ...	40	„
New Patent blue B solution 1:1000 ...	15	„

For Lumière yellow-green sensitive plates the blue in above formula should be reduced to 10 ccm. For eosine collodion or the more sensitive ethyresin collodion the above green filter is satisfactory, but if collodion sensitised with monobromofluorescine be used, then a yellow filter only is required, and 40 ccm. of ammonium picrate solution should be added to 100 ccm. of water. For the orange or minus blue filter, a solution of naphthol orange or orange II. (Badische anilin und soda fabrik) 1:500 is the best, and this may be used with commercial red sensitive plates or ordinary plates sensitised by bathing with wool black or dianil black N (Meister, Lucius, and Brunig) (for method see the forthcoming B.J. ALMANAC), and also for collodion sensitised with ethyl violet.

* * *

Urea as a Developer. The *Photographisches Wochenblatt* publishes a communication from Hendrik Lübke concerning the use of urea as a developer. The question is of more scientific than practical value. Dr. Reiss, in August last, published a statement, that from his observations fresh urea, with addition of an alkali, even in small quantity, would develop the latent image. General Waterhouse tested this statement, and found that urea with alkali alone did not possess any power of development. The Editor of the *Wochenblatt* remarked that under certain pathological conditions other reducing substances might be present. Herr Hendrik Lübke now points out that urea of human beings and horses sometimes contains catechol sulphuric acid, and that this combined with an alkali forms a developer.

* * *

A New Colour Sensitiser. It will interest those who are engaged in three-colour processes to learn that Professor Miethe gave a lecture on the 27th November, at the Charlottenburg Technical School, upon the advance made in this direction during the year. The interest, of course, centred in the work Professor Miethe has done, as illustrated in the German photographic Press a few months ago. We have made reference to it in these columns. Dr. Miethe's results seem to have been largely dependent upon the use of ethylroth as a sensitiser, by means of which a dipped orthochromatic plate, sensitive from the infra-red to the ultra-violet, can be obtained. Not only is the plate of good keeping quality, but its sensitiveness for red exceeds that for blue, and its speed is sufficient for instantaneous exposures. The dye should be used at the strength of 1 in 50,000, and the plates should be well washed after they have been dipped. A number of lantern slides by the three-colour process were shown to illustrate the sensitiveness and true rendering of these panchromatic plates. The subjects included genre studies, portraits, landscapes, a sunrise, forest glades, misty mornings, and other very effective pictures.

Photography through Water. We hear, from time to time, of adventurous individuals who take cameras with them on submarine excursions, and who tell of the wonderful things they have accomplished. For some reason or other these subaqueous pictures never get published; they are only talked about. Mr. Martin Duncan, who lectured at the Camera Club last week, on "A Naturalist's Rambles on the Seashore," was not content with talking of what he had done in the way of photographing living fishes and other denizens of the deep, but he showed what excellent work he had actually accomplished. It is true that he does not go down into the depths with his camera; he finds it more convenient to bring the fishes to terra firma, and to photograph them in a tank, or marine aquarium. This tank is made especially for the purpose, with a large pane of patent plate-glass in its front, free from spot or flaw. The sides are also of glass, but the back is of slate. In addition to this permanent back, Mr. Duncan has others covered with rock-work, seaweed, shells, etc., to help him in his picture-making, a series of solidly-built backgrounds in fact, any one of which he can introduce into the tank at will. The inmates make a terrible fuss whenever their abode is invaded by one of these rocky backs, but they gradually settle down again, and as soon as this is the case their ingenious proprietor commences to move the sheet of rock-work nearer and nearer to the front glass of the tank, until the space between it and the glass is reduced to a few inches. Once more the creatures in the tank are allowed to get accustomed to the circumscribed space, and then Mr. Duncan, waiting until the best pose is assumed by his unconscious "sitters," takes the photograph. All the work is done in the open air. Artificial illumination of different kinds has been tried, but it is found that the effects secured are not half as good as those afforded by daylight exposures. Moreover, the inhabitants of the tank are strongly opposed to any kind of illumination except that which nature provides, and manifest their displeasure by sundry movements which do not conduce to good photography. Perhaps the most effective of Mr. Duncan's pictures is one in which an octopus has seized a star-fish, preparatory to making a meal of him. The star-fish, in this case, is of the brittle variety, and one of his legs, or rays, has broken off in his struggles to get free from the awful embrace of the cephalopod.

* * *

A Trichromatic Carbon Process. M. Léon Vidal has been at some pains to work out the details of a three-colour printing process, and gives the benefit of his experiments to the readers of the *Moniteur de la Photographie*. The process may be described in a few words as a composite one, in which three images, in primary colours, are produced upon a transparent support of collodion, in pigments held in bichromated gelatine made insoluble by the action of light. These three images are then combined to form the picture, by cementing them together and mounting them upon white paper, if to be seen by reflected light, or upon glass for the production of a transparency. For the use of those who may wish to try the process, we give the following summary. Further particulars may be found in the *Moniteur*. Coat talced glass with tough collodion made by the following formula:—

Absolute alcohol	50	c.c.
Ether	50	„
Pyrroxiline (not powdery)	2	grammes.

When the film is dry coat the plates again with a solution

of very soft gelatine, such as Nelson's, in the following proportions:—

Gelatine	30 grammes
Water	200 „
Loaf sugar	6 „
Glycerine	6 „

The colouring matter should be added to this solution and selected from red, blue, and yellow pigments of the nearest shades to satisfy theoretical considerations. The pigments should be ground as fine as possible in gum-water, a tedious process, which may perhaps be avoided by using artists' water-colours, as supplied in tubes. The quantity of colour must be determined by experiment. Filter the solutions through muslin, coat the plates to a depth of 2 m.m. in each case, and when the gelatine is set transfer them to a drying cupboard containing trays of chloride of calcium. Sensitise the plates just before use with a 5 per cent. solution of bichromate of ammonium, in which they should be left during five to ten minutes. Place them again in the drying cupboard, and when perfectly dry cut round the margins with a knife and straight-edge, and strip the films ready for printing under the three negatives made for the primary colours, using an actinometer for the exposure. Develop the films with warm water, laying them down for this purpose on sheets of glass coated with—

Pure indiarubber	10 grammes.
Benzine (crystallisable)...	100 „

Wait until most of the benzine has evaporated, and whilst the indiarubber is still tacky lay the print upon it, collodion side downwards, and roll the film with a soft roller into perfect contact. After development, and when the film is perfectly dry, cut round the edges and strip. Clean off the indiarubber by friction with the finger. The three films may be cemented together with Canada balsam, if small, or with a 5 per cent. solution of gelatine, if large. Retouching may be done with pigment, before the films are cemented together, by mounting them once again upon glass with indiarubber cement. For making transparencies, instead of pigments, use aniline dyes, recommended by M. M. Lumière, according to the following formulæ:—

Red Bath.

	Grammes.
Water	1,000
3 per cent. solution of Erythrosine J No. 398.....	25

Blue Bath.

3 per cent. solution of pure blue diamine FF No. 192	50
15 per cent. solution of glue	70

Yellow Bath.

Water	1,000
Chrysophenine G No. 207	4
Dissolve at 70deg. C. and add alcohol	200

The red and blue dyes are from the catalogue of the Badische Anilin and Soda Fabrik, and the yellow dye from that of Leonhardt and Co. The red and yellow prints may be used without fixing, but the blue should be dipped in a 5 per cent. solution of sulphate of copper and then rinsed. The pigment prints, when cemented together, should be mounted on paper with a solution of gelatine. The process would be much simplified if suitable carbon tissues, true to colour, were purchasable.

* * *

Photography and the German Government. The organisation of industry proceeds apace in Germany, whether for good or ill. The following conditions have been laid down by the Government, as a direction to the

Chambers of Handicraft, for the examination of photographic assistants. They are required to produce as tests of proficiency:—

1. Six negatives, not under cabinet size.
2. Rough prints from each of these negatives.
3. Finished, mounted prints from each negative, after they have been retouched. At least two printing processes must be shown by these, and one must be in silver.
4. An enlargement at least 18 x 24 cm. from a carte de visite. Photo-mechanical assistants must show at least six negatives from line and half-tone subjects, suitable for some process of reproduction.

Further specimens may be shown, if in harmony with the nature of an examination for assistants, regard to time and expense being the chief considerations.

The specimens of work must be of a nature to show that the candidate has sufficient manipulatory skill in the usual course of photographic work. They must be done upon premises selected by the Board of Examiners.

If the candidate has taken up a special branch of work, he must show more proficiency in that branch, and the tests in others may be reduced in proportion.

In the theoretical examination the candidate should show a sufficient knowledge of the value, condition, conservation, use and treatment of the raw and subsidiary materials employed in photography; also of the underlying principles of the art, and the nature and use of photographic apparatus. As a rule this should begin with a discussion of the candidate's specimens and work-test, and should embrace the following questions:—

1. The discrimination and use of apparatus and accessories.
2. The discrimination and use of materials.
3. Knowledge of the outlines of photographic processes in general use.
4. The examination may also extend to the following questions, so far as the candidate may have had opportunity to acquire the necessary knowledge, by general education, or training at continuation classes, or at a technical school:—

- (a) A knowledge of the principles of chemistry and optics to the extent requisite for the comprehension of ordinary methods of work.
- (b) A knowledge of the most important historical facts in the development of photography.
- (c) A knowledge of the principal points in photographic copyright.

The Government order concludes with a request to the Chamber of Handicrafts to see that the examinations be framed in a manner to comply with these requirements, and that they be not exceeded.

THE Beverley Photographic and Sketching Society's public exhibition of photographs, paintings, and drawings, will be held in the society's room, Butcher Row, Beverley, on Thursday, Friday, and Saturday, January 28th, 29th, and 30th, 1903. The following are the photographic classes:— Section A (open): 1. Landscape, seascape, river scenery; section B (members): 1. Landscape, seascape, architecture; 2. Portraiture, figure studies. (Direct or enlarged prints alike eligible).

BOROUGH Polytechnic Photographic Society.—The eighth annual exhibition of the Borough Polytechnic Photographic Society will be opened on Saturday, December 27th, 1902, at 7 p.m., by Sir Wyke Bayliss, President of the Royal Society of British Artists, at the Borough Polytechnic Institute, 103, Borough Road, S.E., continuing open until the following Saturday, January 3rd, 1903. As in former years, the exhibition will consist exclusively of members' work, and will be open entirely free to the public. In addition to the exhibition, there will be a lantern entertainment each evening, and displays of animated photographs, X-rays, and wireless telegraphy at intervals, whilst photographic demonstrations for beginners will be given in the society's meeting room.

MR. SANGER SHEPHERD'S NEW COLOUR PROCESS.

THE problem of producing photographs in the colours of nature is one which must have occupied the thoughts of many men ever since the first camera obscura was devised, and long before that instrument joined partnership with the chemical laboratory. A picture as formed by the lens on the ground glass screen of the modern instrument, or indeed upon any suitable surface provided to receive it, is certainly one of the most beautiful things which the eye can look upon, perfect alike in form, and in purity and gradation of colour. How many men of artistic aspirations must in past times—and the first of such observations dates from the time of Aristotle—how many must have feasted their eyes on that chromatic wonder, and longed to have the power to make that permanent, which is, at best but ephemeral—"the baseless fabric of a vision?" Tradition has it that Daguerre himself was induced to prosecute his first experiments by the constant viewing of these pictures in colour daily revealed to him in the camera obscura, which he employed as a help in painting his famous dioramas.

Almost as soon as Daguerre had made public the process with which his name is associated, the adventurer appeared who had gone one better, and had, as was declared, succeeded in producing sun pictures in colour. He showed daguerreotypes which were most exquisitely tinted, and he deceived a number of persons, among them the astute Mr. Morse of telegraphic fame, into the belief that the colours owed their origin, like the image upon which they rested, to the bountiful light of the god of day. After collecting a goodly sum of money from his dupes under promise of revealing his secret, the gentleman, who appended the prefix "Rev." to his name, disappeared and was never heard of again. He has the unenviable distinction of being the prototype of a large class of swindlers who have during the past half century traded upon the ignorance of their fellows.

Colour photography is indeed a discovery which has cropped up regularly during that period at intervals of a few years, and Mr. Sanger Shepherd, in his address to the Camera Club last week, was not too severe upon the editors of certain journals when he suggested that they must keep an account of the discovery ready set up in type for use when space admitted. Everyone knew that the process which he had promised to describe would be something practical and that it would be founded upon scientific principles. In this there was no mistake. It will be seen from our report of the proceedings that the system advocated is a modification of the now well-known and successful method by which he produces transparencies for the lantern.

That it will be taken up readily by amateurs we have no doubt at all. For amateur photographers are greedy of novelties, and some are so eager in pursuits of new processes that they will try all that are presented to them. The amateur has time and means at his disposal as a rule, and it is good for all that he should act as he does, for a process receives a trial at his hands which will often decide whether it is worthy or not of general acceptance. This salutary ordeal the Sanger Shepherd process has yet to go through.

Mr. Shepherd devoted a portion of his discourse at the Camera Club to the advantage which would accrue to professional portraiture by the adoption of the new process, and it goes without saying that an efficient means of producing portraits in colour would cause a rush to the studios of people eager to benefit by the novelty. But the new method would necessitate such a revolution in apparatus,

as well as in procedure, to say nothing of a thorough revision in the scale of charges, that the professional man must seriously consider whether it is good enough to justify him in making such a thorough change.

Mr. Shepherd told his hearers the other night that any lens of decent quality would do the work, and that the necessary additions to a photographer's ordinary apparatus could be covered by an expenditure of two pounds sterling. But he was addressing an audience of amateurs, who would be satisfied with landscape, fruit, and flower studies, and perhaps an occasional open-air portrait. With the professional worker it is very different. If the photographer could hypnotise every sitter who came to him into a state of immobility directly a favourable pose and pleasing expression were secured, so that the subject would be perfectly still while three separate exposures were made, he might retain the camera with which he has always worked, it would merely want the addition of a repeating back furnished with the necessary three-colour filters. But we know that this is impossible. Nervous women and lively children make up a large proportion of his clientèle, there must be only one uncapping of the lens, and the operation must be a short one. This means that an entirely new form of camera must be brought into use. Ten years ago, Mr. Ives saw the necessity for a simultaneous exposure of the three negatives even for subjects other than portraits. He said, in one of his lectures, "In photographing objects in a changing light, landscapes, for instance, it is important that the three sensitive plates be exposed simultaneously, and in order to accomplish this I devised a triple camera, having three lenses." If such a provision is necessary in landscape, how much more is it called for in portraiture, albeit a three-lens apparatus is inadmissible for near objects, if the images are to be afterwards superposed, because of the stereoscopic difficulty.

Supposing that the professional worker has made up his mind to remodel his apparatus, he must next consider the serious question of skilled assistance. The printer of ordinary negatives needs little more skill than that exercised by a kitchen maid in toasting a slice of bread; in each operation exposure must be stopped at the right moment. But the work of printing the gelatine reliefs on celluloid, and still more the operation of charging each with its proper complement of dye, and transferring those coloured images to their final support, seems to demand the possession of qualities not generally found in the ordinary worker. We may pass over the necessity of having an extra well-lighted room in which the colour operations are carried on as a difficulty which is easier to meet.

Lastly there comes the very important item of the revision of the price list. It is obvious that a process which involves the production and employment of no fewer than six printing surfaces must be far more costly than that which requires but one, nor must we lose sight of the fact that when operations are multiplied the risk of failure and breakage is multiplied in the same proportion.

Such are some of the considerations which must be weighed by the professional photographer as he asks the question which we have suggested regarding the new process, "Is it good enough?" And in suggesting it, it must not be assumed that we wish in any way to detract from Mr. Sanger Shepherd's achievement. To him is due the credit of putting upon a practical footing the possibility of producing transparencies in colour of great excellence, and he has now shown how, by a modification of the method, pictures on paper may be made. It remains to be seen whether the process is certain enough in its results in ordinary hands to tempt the professional photographer to make a radical change in the work upon which his bread and butter depends.

FIFTH TRAILL TAYLOR MEMORIAL LECTURE,
Dec. 11th, 1902.

THE GREAT PHOTOGRAPHIC STAR MAP.
I.

LECTURER:—H. H. TURNER, D.Sc., F.R.S., Savilian Professor of Astronomy, Oxford.

IF there be a difficulty in selecting an astronomical topic on which to address photographers, it arises from the number and importance of suitable topics, and not from their scarcity. In almost every department of astronomy photographic methods are to-day in constant use, and have become indispensable. The surface of the sun is photographed daily at several observatories, and on the occasion of a total solar eclipse the observations made are chiefly photographic. The surface of the moon is being mapped and surveyed by means of photography; hundreds of new planets have been discovered by the inspection of photographic plates; pictures of comets supplied by the camera have practically superseded drawings, and in many instances provide the material for determining the orbits of these bodies; the configurations of stars and nebulae, which were imperfectly and laboriously recorded a quarter of a century ago by visual methods, are now caught with accuracy in a few minutes by the sensitive film; and prolonged exposures reveal to us objects of which even the existence was not previously suspected. I might go through the category of the heavenly bodies again, and point out in each case other photographic methods, as yet only imperfectly developed, which are certain to be used in the near future. In the case of the sun, for instance, Professor Hale and others have shown how we may photograph not only the spots and the ordinary solar surface, but the faculae and prominences; and there is no reason why a daily record of these by photography should not be added to that of the spots—no reason, that is to say, beyond the impossibility of answering all the bewildering new calls on the attention of astronomers which the photographic method has made. Or, in the case of the moon, I might point to several methods of observing her orbital motion by photography, which only await someone with time and energy to carry them out. I might go through the category a third time, and describe what has been done with the spectroscope added to the camera; and this would take us into a department of astronomy so vast as to be practically a separate science.

With so embarrassingly rich a choice, I may perhaps be forgiven if I felt it hopeless to determine what would be most likely to interest my audience, and took refuge in the less ambitious but safer alternative of speaking about my own particular work. For the last nine years the Oxford University Observatory has been steadily busy on its share—a one-eighteenth share—in the making of a great map of the stars by photography; and it is my hope that some account of this work—not a complete historical summary, but rather a few notes on points of photographic importance—may interest you to-night. Fortunately for me, though the topic was selected for a personal reason, it is one of both national and international interest. The eighteen observatories taking part in the work were selected from all countries at an International Conference held in Paris, in 1887; and the details of the work have been from time to time superintended by subsequent conferences of the same character. Of the eighteen partners six are British, so that our Empire is bearing a worthy share of the total burden. As an indication of the magnitude of this burden, it may be safely said that the map will not be completed within a quarter of a century of its incep-

tion; and when it is finished, it will be an almost imperative duty to begin it all over again, in order that we may see what changes have occurred in the heavens since the first survey. So that the work on this great star map will absorb a considerable fraction of the total available energy of astronomers in our time.

REASONS FOR A STAR MAP.

Those unfamiliar with the needs of astronomers may reasonably ask the question:—What are the precise objects in view in making a star map? The uses of terrestrial maps are well-known, and the chief of them may be classified under two heads:—

(a) Maps help us to find our way in unknown regions; and without them we might run risks of the gravest kind, as when navigating a ship, or marching in a hostile country.

(b) They preserve a definition of property, both individual and national.

Neither of these functions would seem capable of being discharged, in obvious counterpart, by maps of the stars. The idea of property in the eternal heavens is almost as ridiculous as that of danger in allowing our gaze to wander from one part of them to another; and how can we even lose our way when the whole sky lies open to our inspection? And yet there is a similarity between the two cases. With a terrestrial map we can trace our own puny journeyings to and fro: with a celestial we can follow with accuracy the sweep of the planets round the belt of heaven. A terrestrial map guards the rights of property by enabling us to recognise that some ill-doer has "moved his neighbour's landmark." A celestial map made to-day will show years or centuries hence how those celestial landmarks which we call stars, have been moved, not by any malicious agency, but by the majestic flow of the celestial motions. Nay more, we may detect the presence of some new star, hitherto invisible, which has blazed into prominence, like some submarine volcano which a terrestrial convulsion raises above the surface of the ocean: or we may detect a new planet. In the middle of the last century the planet Neptune was discovered by mathematical analysis; and the part played in this discovery by a star map was so dramatic that I venture to recall it as a striking illustration of the importance of star maps generally.

THE DISCOVERY OF NEPTUNE.

The story begins with the opening words of the immortal letter which Adams left at the Royal Observatory one afternoon in October, 1845:—

"According to my calculations, the observed irregularities in the motion of Uranus may be accounted for by supposing the existence of an exterior planet, the mass and orbit of which are as follows":—(Then follow the figures.)

The planet Uranus had for some years appeared in a position which could not be deduced theoretically from the attractions of other known planets; its motion shewed "irregularities." Working backwards from these with marvellous mathematical skill, J. C. Adams, then a B.A. at Cambridge, deduced the existence of a planet whose attraction was causing the irregularities: and he proceeded to give, in the remainder of the letter, approximate details of the position of the planet in the sky. From these details an astronomer armed with a star map of the region could have found the planet within a few hours on a clear night: but without a star map the labour required was much greater, in fact practically equivalent to the construction of such a map. The positions of at least 50 stars, any of which might be the planet, must be accurately measured on at least two occasions. Now, no such map was available at Greenwich: and partly for this reason, partly also from other unfortunate circumstances which need not now concern us, the planet was not looked for. Some months afterwards

Leverrier, in France, completed entirely independent calculations, and arrived at much the same result. He communicated it to a Berlin astronomer Galle, who by this time was in possession of just the right star map: and Galle found the planet the same night. Naturally a controversy arose as to who was the real discoverer—a controversy of considerable violence in which few concerned escaped “savage abuse”* at the hands of some one. In course of time this question was amicably settled by an equal division of credit between Adams and Leverrier; and in any case we need not consider the merits of it here. What does concern us is the vital difference which the possession of an adequate star map made: and secondly, the fact that this particular use of the map could not possibly have been foreseen when it was constructed. We learn, if we did not know it before, that we must provide for unforeseen contingencies as well as for familiar needs: and, therefore, you will perhaps be prepared to accept the statement that the most important reasons for making a star map are those which neither I nor anyone else can at present give.

EXISTING STAR MAPS.

Maps may be of various sizes, and the larger the map the more detail it is possible to insert. A map of the whole earth may be made on a sheet of note-paper, but it is not the kind of map which a cyclist would choose for finding his way about. He would prefer a map of the kind described as one mile to the inch, which would only represent a very small portion of the earth's surface, but would show the detail he requires. Similarly, a map of the whole heavens can be made on a single sheet of paper, but it is not the kind of map we should use to find the planet Neptune. For this we must have a small portion of the sky mapped in considerable detail. The map which was actually used may be described as on a scale of 140 miles to the inch. Not that the sky is to be measured in miles, or millions or billions of miles, but we can make this kind of comparison between celestial and terrestrial maps as follows. If maps of the whole surface of the earth were made on a scale of one mile to the inch, and combined into a globe, the diameter of this globe would be 8,000 inches (about one furlong), since there are 8,000 miles in the earth's diameter. Now celestial maps can be combined into a celestial globe, just as terrestrial into a terrestrial globe; and a celestial globe on the scale of the Berlin maps would have a diameter of only about 5ft., which is 140 times smaller than 8,000 inches, and may be called therefore a scale of 140 miles to the inch. This represents very nearly the limit of what had been done in the way of celestial map-making up to the year 1887. Some slight advance on the Berlin maps had been made by a celebrated German, called Argelander. He had made star maps which would cover a globe 7ft. in diameter; or rather *half* cover it, for he only worked at the northern hemisphere. The project I have to speak of to-night is that of making by photography the equivalent of a celestial globe 50ft.* in diameter, or what may be called on the analogy of terrestrial maps 14† miles to the inch. This is a notable advance on anything done before, though it still falls far short of what we may hope to do in the future, even if we aim no higher than the counterpart of the terrestrial mile-to-an-inch map. To illustrate the character of the advance, I may remark that while Argelander's maps are contained in a portfolio of moderate size, the photographic map will when completed form a pile of paper 30ft. high, weighing nearly two tons! The question of storage alone is a serious matter.

* “I was abused most savagely both by English and French.” (Autobiography of Sir G. B. Airy, p. 181.)

† These figures apply to the Enlargements which are twice the size (linear) of the plates.

THE ORIGIN OF THE PROJECT.

The train of circumstances which led to the inception of this project begins with the appearance of the comet of 1882, the last really respectable comet which we in the northern hemisphere have been privileged to witness. It was so fascinating an object that photographers tried to obtain pictures of it; but having only ordinary cameras, which are swept round by the earth in its daily motion, they could not get any results of value. The Director of the Cape Observatory, Sir David Gill, invited Mr. Allis to strap his camera to the equatorial of the observatory, which had clockwork for counteracting the earth's motion; and some beautiful pictures were then obtained. But it is not the central feature of these pictures, the comet itself, which immediately concerns us. A quite unexpected result was the appearance of a vast number of stars on the plate as well, and Sir David Gill immediately thought, why not make maps of the heavens by photography? With him to think was also to act, and he at once set about completing by photography the 5ft. globe above mentioned, of which Argelander had made the northern half. But these photographs also set others to work. Dr. Common in England showed that the nebulae could be photographed, and in France the brothers Henry, who were slowly and laboriously making a large scale map of a small portion of the heavens by old-fashioned methods, and had almost come to a standstill at one portion thickly studded with stars, caught eagerly at the promises suggested by these comet pictures, and tried whether photography would help them. The result was a very great success, though it was not attained without immense labour, skill, and the courageous support of Admiral Mouchez, the Director of the Paris Observatory, who made light of administrative difficulties. But when once satisfactory results were obtained, they were so completely successful that it seemed imperative to complete, not only the original project of the Brothers Henry, which included only a small portion of the heavens, but a map of the whole sky on the same scale.

THE CONFERENCE OF 1887.

For this, however, co-operation was necessary. To cover the whole sky with plates of the kind they were taking would require a total of 11,000 plates; and it was beyond the power of a single observatory to obtain these in a reasonable time. Accordingly Admiral Mouchez and Sir David Gill called together an International Conference at Paris in April, 1887, which was attended by eminent astronomers from different countries as follows:—France 20, British Empire eight, Germany six, Russia three, Holland three, U.S. America three, Austria two, Sweden two, Denmark two, Belgium one, Italy one, Spain one, Switzerland one, Portugal one, Brazil one, Argentine Rep. one. Many of the decisions of this Conference, arrived at after hard work and earnest discussion, and decisions which have had an important effect not only on this particular work, but on the progress of astronomy generally, we have not the time to consider to-night. It must here be briefly stated that 18 observatories were chosen to share the work: that they were all to use a standard pattern of telescope, similar to that which the brothers Henry had adopted (giving a scale of one minute of arc to a millimetre; or in the terms already made use of, a celestial globe of 25 feet in diameter); and that the sky was to be covered four times over, twice with plates of long exposure (originally defined as 20 minutes, subsequently extended to 40 minutes, and ultimately in some cases to an hour) and twice with plates of short exposure; thus giving about 1,200 plates of each exposure to each participating observatory. But two of the decisions are of great interest to photographers, and I propose to dwell on them specially.

THE RESEAU.

The first is something of a curiosity from the fact that it was arrived at with one object in view, and has served for another. It was decided to put what is now familiarly called a *réseau* on the plates, a series of accurately ruled cross lines 5mm. apart. I need only explain to photographers very briefly how this is done. Either before or after exposing a plate to the stars, it is placed behind a plate coated with metallic silver, in which the *réseau* of lines has been carefully ruled so as to cut away the silver; and exposed to a faint artificial light for a few seconds. On development both star images and *réseau* appear. The original object of this process was to guard against distortion of the film by development: for if such distortion occurred, not only the stellar configurations but the *réseau* also would be distorted; and the errors could be detected and allowed for. But experience has shown that no sensible distortion occurs in this way. If anyone is tempted to think that this result might have been foreseen, I would remind him that astronomers are concerned with displacements of extreme minuteness; and although it was previously known that there was no considerable distortion, there might have been small defects which no photographer would have, hitherto, been troubled by, and which would yet have embarrassed the astronomer greatly, unless precautions were taken against them. Fortunately, none have been found: and, fortunately, they were guarded against in this way, for the *réseau* has proved an incalculable advantage for a quite different purpose. It enables us to measure the position of any star on the plate with great ease. It does for us what the hour hand or the minute hand of a clock do as regards time; these break up the day into small pieces, and to specify the exact moment we have then only to watch the seconds and fractions. So the *réseau* lines break up the plate into small squares which we can recognise by merely counting the divisions; and to obtain the exact position of a star we have only to supplement this by measuring its position in its square. The labour thus saved is, perhaps, only to be realised by actual experience; but anyone who has had such experience knows what we owe to the happy, though so far mistaken, idea of guarding against distortion in development by using a *réseau*. I will add that, if for any purpose whatever, a photographer wishes to measure the positions of objects on a plate he cannot do better than use a *réseau*, which has now become a commercial article. A silver matrix costs a few pounds, but any number of photographic copies can be made from this matrix at the mere cost of the plates; and if the photograph to be measured has no *réseau* lines already on it, one of these *réseau* copies can be bound together in contact with it, film to film, which is almost as convenient as, and sometimes better than, having the lines actually on the picture itself.

CHOICE OF INSTRUMENT.

The second decision of the Conference to which I would direct special attention is perhaps the most important of all: I mean the choice of the instrument to be used for taking the plates. To a non-astronomical photographer the choice of a lens has a restricted meaning; there are plenty of lenses to choose from certainly, but they are all what we call doublets, made up of two pairs of lenses, with a space between, in which the stop is put. The photographs of the comet of 1882 at the Cape of Good Hope were taken with a lens of this kind; but those whom they stimulated to work adopted different types of instrument, because they wanted large instruments, and to make a large doublet is very costly. Each of the four lenses in a doublet has two faces, and to make eight glass surfaces optically true on a large scale is a serious matter. Dr. Common contented himself with one surface, reflecting light to a focus. His beautiful

photograph of the Orion nebula, which obtained the gold medal of the Royal Astronomical Society in 1883, was taken with a reflecting telescope of 3ft. aperture, which he obtained at a moderate cost. It is doubtful whether a doublet of this size can yet be made successfully; and when, in 1889, Prof. E. C. Pickering, of Harvard, was enabled by the liberality of Miss Catherine Bruce, to obtain one of 2ft. aperture, the sum placed at his disposal was £10,000. If instruments of this class had been adopted as the standard pattern by the Conference of 1887, eighteen observatories would not have been forthcoming as co-operators, nor eight; perhaps not even two. The pattern adopted was such that the actual camera could be purchased for less than £600; this, at any rate, was the sum presented by the late Dr. Warren De la Rue to the University of Oxford, to enable its observatory to take part in the work, and this sum provided for a camera 11ft. long, with a lens of 13in. aperture, and for its attachment to the already existing equatorial mounting. The optical part of the camera is neither a doublet of the kind familiar to photographers, nor a reflector of the kind used by Dr. Common; but a single lens (or rather pair of lenses), resembling the object glass of an ordinary telescope or a "landscape" lens, without any diaphragm. It was of a pattern arrived at after much experimental work by the Brothers Henry, who had, like Dr. Common, been stimulated by the Cape photographs to see what photography could do, and had, like him, chosen their own form of instrument; but, unlike him, had chosen what is called a refractor, instead of a reflector.

When the Conference met in 1887 they had, in fact, to make a choice between these three types of instrument, the doublet, the reflector, and the refractor. All three had been tried and found successful in different ways, but the information available, especially as to the accuracy of each, was very scanty. It may be stated in tabular form somewhat as follows:—

	Reflector.	Refractor.	Doublet.
Number of optical surfaces } (determining cost to a great extent)	1	4	8
Thickness of glass } (meaning loss of light)	0	1	>2
Available field	<2°	>2°	>5°
Accuracy	Good	Good	Unknown in 1887

From this statement it is seen that the doublet is undoubtedly the most costly, and there is a risk of loss of light: for not only are two compound lenses to be transversed, but a diaphragm or stop is generally inserted between the lenses, which cuts down the effective aperture. Hence I have represented the loss of light by the symbol for "greater than 2" as compared with the single lens of the refractor. On the other hand, the doublet has a much larger field than the others. At the present time it is rather difficult to put any definite limit to the possible field, and even in 1887 it was known that 5 degrees could be obtained. To realise the nature of this advantage, it must be remembered that the larger the field which can be covered at a single exposure, the fewer exposures are necessary to cover the whole sky. With the adopted instrument the diameter of the available field is 2 degrees, and 11,000 plates are necessary to cover the sky; but if the field could have been extended

to 5 degrees, the area covered by a single exposure, which varies as the square of the diameter, would have been increased in a ratio of 25 to 4, or more than 6 to 1, and the number of requisite plates diminished therefore to less than 2,000. This is such a striking advantage that we should expect it to be the determining factor in the choice, and when we are told that the refractor was selected in preference to the doublet, we naturally inquire what was the weighty consideration which could set aside so manifest a gain. We find it in that terrible spectre, "the Unknown," which scientific men are sometimes as reluctant to face as are all other living things. The accuracy of photographs taken with a doublet was unknown, and was accordingly mistrusted. The very fairness of the promises held out gave rise to an uneasy suspicion that there was treachery somewhere. So great was the mistrust that in the debate on the choice of instrument, in which twenty-six eminent astronomers took part, the doublet was never even mentioned, the discussion being confined entirely to the relative merits of reflector and refractor. Prof. E. C. Pickering, of Harvard, had sent a letter advocating the use of a doublet giving a field 5 degrees square, but he had no definite information to give as to the accuracy obtainable with it, and his letter attracted no attention. The keynote of the discussion was struck by the veteran astronomer, M. Janssen, in advocating the adoption of an instrument similar to that used by the Brothers Henry, when he said:—"On sait ce que cet instrument peut donner, il a fait ses preuves."

M. Janssen cannot be called an over-cautious man. He it was who, during the Siege of Paris, in 1870, left the city in a balloon with his telescope, because he wished to observe the total solar eclipse of that year. He it is who has planted an observatory on the top of Mont Blanc, a hazardous enterprise for a man past three score years and ten. But in a great work like the astrographic chart, he felt that we must be not merely hopeful, but certain, of our instrument, and as no one could present an unexceptionable character for the doublet, it was passed over in favour of the refractor.

We know now that first-rate credentials could have been presented if only some one had had time to make the necessary comprehensive tests, and I should like to say a few words on this point, however superfluous it may seem for an astronomer to commend to photographers their own familiar instrument.

ACCURACY OF THE DOUBLET.

In the first place, then, the doublet shows star images (and of course other objects) in their true positions on the plate, with an accuracy equal to that of the refractor, and probably greater than that of the reflector. This statement must be qualified by the admission that the accuracy of these instruments has only been tested up to a certain point as yet. For the purposes of the star map, it has not been possible to make measures of the greatest accuracy, because we have so many stars to deal with; we aim at measuring the position of a star image on our plates within about the ten thousandth of an inch, and up to this point it has been found that over a field 5 degrees in diameter the doublet is as accurate as the refractor adopted for the star map. The details of this investigation* are too technical to give here, but I may mention that it was carried out at the Oxford University Observatory, by measuring plates kindly lent by Professor Pickering, who had advocated the use of the doublet in 1887, and it was pleasant to be thus able to confirm the excellence of his advice.

CHEMISTS AND THE SALE OF POISONS.

IN view of the fact that the labours of the Privy Council Poisons Schedule Committee are now ended, it is interesting to recall the circumstance that the appointment of the Committee by the Duke of Devonshire, Lord President of the Council, was announced in June, 1901, and that the Committee originally consisted of the following members:—The Right Hon. Sir Herbert Maxwell, M.P., F.R.S. (chairman); Mr. Alexander Cross, M.P., Professor T. E. Thorpe, C.B., F.R.S., Professor W. A. Tilden, F.R.S., Dr. Thomas Stevenson, Mr. William Martindale, F.C.S., and Mr. J. H. Harrison. In February of the present year Mr. Walter Hills was appointed a member of the Committee, in the place of Mr. William Martindale, deceased, but there has been no other change in the constitution of the Committee, which was instructed by the Lord President "to consider the first Schedule (A) annexed to the Pharmacy Act, 1868, and to report to him the alterations therein, which they deem expedient." The terms of reference proceeded as follows:—"The Lord President desires the Committee to consider at the same time whether a third sub-division might not properly be added to the Schedule, containing substances which, whether sold by pharmaceutical chemists or not, should be labelled or otherwise distinguished, and, if so, to enumerate the substances which, in their opinion, should be thus treated."

The report of the Committee has now been signed, though it has not yet been published, says the *Pharmaceutical Journal*, and Mr. Walter Hills has been permitted by the Chairman of the Committee to state publicly that he has thought it his duty to write a minority report. The latter fact should suffice to show that the terms of the majority report are not such as are likely to commend themselves to registered chemists, and it seems desirable therefore that every member of the craft in Great Britain should prepare himself to take part in what may prove to be one of the most serious struggles in the history of pharmacy to maintain the principle that, so far as the sale of poisons is concerned, the technical education of the seller is the best protection for the public. It may appear to many readers of the *Journal* that it is a comparatively unimportant point whether certain poisonous preparations should, under special conditions, be permitted to be sold in future by persons other than registered chemists, but a grave question of principle is involved in that proposal, which therefore calls for the most thoughtful consideration. Such consideration is all the more necessary in view of the fact that the position may shortly be so serious as to render it necessary, in the interests of the public safety, to oppose strenuously what may prove to nothing less than the introduction of the thin end of a wedge which may split the whole protective structure erected by Parliament in 1852 and 1868.

In order to meet such a danger, suitable measures are already being taken at the headquarters of the Pharmaceutical Society, but the success of those measures will be largely dependent upon the support rendered by the Society's local officers and by chemists and druggists as a whole. Any opposition which may be offered by the Pharmaceutical Society to reactionary legislation based upon the majority report of the Privy Council Poisons Schedule Committee will probably be met with the taunt that the Society does not represent the entire trade. Such a statement, however, can easily be refuted, since the Society is the statutory representative of chemists and druggists as a class, while it also includes as subscribing members a majority of the registered chemists of Great Britain, who are engaged in business on their own account. At the same time, it should be obvious that a large influx of new members during the next few months would have a most salutary effect. Divisional

* See Monthly Notices of the Royal Astron. Soc. LIX p. 439.

secretaries should therefore neglect no opportunity of impressing unattached chemists and druggists with the peculiar gravity of the situation, while pharmaceutical associations throughout Great Britain should make the strengthening of the Pharmaceutical Society one of their chief objects for the time being, as the existence of chemists and druggists as a specially trained and, to some extent, privileged class may depend upon the result of the struggle which is almost certain to come. Due notice will be given by the Council of the Pharmaceutical Society as to the direction in which energy may be most usefully expended in defence of what is worthy of preservation in the existing Pharmacy Acts, but the notice may be but short, and the present warning is therefore given in order that every registered chemist may have time for reflection, and be prepared to take his part in the anticipated struggle.

NOTES FROM THE NILE.

Tahtah, on the Nile

Egypt,

December 2, 1902.

PRAY for the soul of Thomas Cook for inaugurating such a splendid service of steamers. I am now on the good ship "Nefert Ari," about three hundred miles up the Nile from Cairo (three days' sail). So much has been written on the Nile, I don't suppose I can add much to what has been published, except it may be of photographic interest. The cabins here are easily converted into dark rooms; a sheet or two of coloured paper placed over the sliding window and a rag hung over the doorway, does the trick. I am fortunate in having a cabin all to myself, and a plentiful supply of water at hand. The larger excursion steamers have well-organised dark rooms. I have got some fine negatives characteristic of the Arabs which I will have pleasure in exhibiting on my return home. The postal system is A1 in Egypt. Thanks to Cook and Son I get THE BRITISH JOURNAL OF PHOTOGRAPHY delivered on board at various stopping places. I am in receipt of a post-card from the worthy secretary of the P.C.U.K. (F. A. Bridge), in reply to my offer to give "a night" at Perth. The natives here are wonderfully intelligent. I overheard an amusing conversation the other night between Father Rev. Arthur Roberts and a number of Arab boys, eight to eighteen years of age. The wonderful geographical knowledge, not to be beaten by Johnston, when asked by the reverend interrogator to name the greatest country in the world.

Reply.—Africa.

R. I.—No. In England, where the sun never sets.

Arab boy.—Then I would not like England. It will be too hot.

A voice from a North Briton.—The English make it hot for you sometimes.

Arab boy.—The English get drunk.

Reverend.—No.

North Briton, only "fou."—Sometimes. Why don't you admit the soft impeachment? They would be more likely to believe you if you admitted that they had their faults.

One word more re developing. I lost six negatives in a manner difficult to determine. I used the same solutions and got nothing but chemical fog. Fresh solutions gave no better result. I then cooled down and heavily re-strained the developer, and now to-day my solutions are a trifle too cold,

but all right, in consequence of my placing my bottles in socks and keeping them wet by capillary action. Messrs. Cook have afforded me all facilities within their power to further my object. Yesterday I had three hours on shore and took two negatives of the new dam at Assiut about to be inaugurated by the Khedive in a few days. The structure is wonderful, but not to be confounded with the one to be opened on the 10th by the Duke of Connaught and the Khedive, which, at Assuan, I hope to have the pleasure of photographing. More anon.

Yours truly,

A. L. HENDERSON.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

COMMITTEE MEETING.

At a meeting of the General Committee, held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, Dec. 12th, the following were accepted as members: Chas. E. Hawley, 133, Rake Lane, Liscard, Cheshire; H. M. Rewse, 131, Fisherton Street, Salisbury; W. T. Scott (W. Scott and Co.), 804, Upper Holloway Road, N.; Chas. T. Fox (W. Scott and Co.), 804, Upper Holloway Road, N.; Samuel A. Freeman, Wellington Studio, Moreton-in-Marsh.

Proposed report of the Committee of the work of the Association since the Annual General Meeting in July was read and adopted.

The Hon. Secretary reported the result of inquiries made in reference to holding an exhibition of members' work. After discussion, the Hon. Secretary was directed to make further inquiries, and if necessary call a special meeting of the Committee to consider the matter.

Letter read from Mr. Harold Baker, reporting progress of the Birmingham branch, and enclosing draft circulars to be addressed to photographers in the Birmingham district.

Correspondence read in reference to gift of £2 2s. enlargements, the refusal of the Plate and Paper Makers' Association to grant dealers' terms to a member setting up as a dealer, the infringement of a member's copyright photograph by an illustrated newspaper, and an application for advice from a non-member. The Hon. Secretary was instructed thereon.

REPORT OF COMMITTEE.

Your Committee have to report that since the Annual General Meeting in July thirty-eight new members have joined the Association. Although they do not regard this as unsatisfactory, they hope for more rapid progress, and wish to impress upon members the importance of bringing the claims of the Association before their brother professional photographers. Three members have resigned, and in three cases letters addressed to members have been returned, marked "gone away." The number of members is now approximately 550.

Subscriptions have come in fairly well. Four-fifths of the members have paid. Subscriptions are coming in at a steady rate, and there is reason to believe that nearly all outstanding amounts will be collected.

Your Committee regret to record the death of their colleague, Mr. H. J. Dalby, of Woolwich.

The advice of the Committee continues to be sought upon very many subjects connected with professional work, and particularly upon questions of copyright. They believe that in many cases their recommendations have been of great service.

As a result of a meeting of those interested in copyright in works of art, held at Messrs. Agnew's Gallery, Bond Street, in

October, which was attended by five members of this Committee, a new Society has been formed to afford protection to artists and others owning copyrights. Your Committee have decided that this Association shall be represented in the Society by three members.

The branches of the Association at Hull, Liverpool, and Edinburgh have held successful meetings. These meetings have been reported in THE BRITISH JOURNAL OF PHOTOGRAPHY. At Birmingham a meeting has been held for the purpose of establishing a branch for the district, and was attended by Mr. Alfred Ellis, Hon. Secretary, and Mr. T. C. Turner, Hon. Secretary of the Local Branches Sub-committee. It resulted in all those attending the meeting joining the Association. The new branch seems to have every prospect of success.

During the autumn the Hon. Secretary received a visit from Monsieur Paul Nador, President of the *Chambre Syndicale de la Photographie*, of Paris, an organisation devoted to the interests of professional photographers in France, and therefore similar in its aims to our own Association. Your Committee have had much pleasure in exchanging fraternal greetings with our French confrères, and it has been agreed that the two Associations shall be corresponding Associations.

The arrangement made with the Fine Art and General Fire Insurance Co., to take over the existing fire policies of members and allow them a discount of 20 per cent. on the present premiums is working satisfactorily. About thirty members have already availed themselves of the privilege.

It has been arranged that on the date of the annual dinner, on March 13th, a reception room shall be open all the afternoon at the place of the dinner, the Criterion Restaurant, so as to afford members, especially those from the country, the opportunity of meeting and conversing.

ALFRED ELLIS, Hon. Sec.

MEMBERS' MEETING.

A Members' Meeting was held at the House of the Royal Photographic Society, on Friday, Dec. 12th, 1902, Mr. Wm. Grove, President, in the chair.

The Hon. Secretary read the report of the Committee of work done since the Annual General Meeting in July. This was adopted.

On the subject of the supply of electric current to photographers at price charged for current for motive purposes, Mr. T. C. Turner impressed the importance to professional photographers of using electric light. Especially was it their interest to do so in the winter season, when amateurs had packed up their cameras, and laid aside their printing frames, leaving the professionals in full possession of the field. He had observed, and he believed others had, that the demand for the ordinary colour-printed Christmas card was dying out, and it was his experience that people were increasingly coming to the photographer at Christmas time, not only for photographic greeting cards, but for photographs of other kinds. He calculated that about one-third of his turnover could be reckoned as Christmas trade. As daylight at the season of the year was at its shortest and worst, the importance to the up-to-date photographer of obtaining a powerful light at a reasonable cost was undoubted, and it was his opinion that in a few years no photographic establishment would be considered complete without an electric installation for printing, as well as lighting the sitter. It was well known that the price charged for current for motive purposes was much less, sometimes considerably under half the price that was charged for current for illumina-

tion, and it was to the interest of all the members of this Association that they should obtain from the companies the recognition that the current was used for business purposes.

Mr. Martin Jacolette explained that a considerable saving in cost resulted from running two or more arc lamps in circuit. When using one arc light it was necessary to employ a "resistance," which wasted a considerable amount of current. He found that with two arc lamps in series it was necessary to employ two coils less in the "resistance."

Mr. L. Langfrier expressed the opinion that at present the number of photographers using electric current in any quantity was so few that they would not be able to influence the companies.

Mr. Lang Sims explained his own studio artificial light installation, which consisted of fourteen incandescent gas lamps, which he found efficient as regards light, and also helpful in warming the studio. He offered to show his arrangement to anyone present interested in the matter. Where electricity was not available, gas would be found a very useful substitute.

On the subject of the reservation of copyright by notices on cards of terms, invoices, etc., the Hon. Secretary, Mr. Alfred Ellis, said the reason for putting the subject down for discussion was that more than one of the members have written to inquire whether it was possible to reserve the copyright in photographs taken for payment in the usual way by this method.

Mr. L. Langfrier said that if photographers wished to reserve the copyright in their sitters' photographs, there was only one legal method, and that was to obtain the signature of the sitter to an agreement at the time of sitting for a consideration. In his own practice the consideration was usually some slight reduction in charge from the ordinary price, and in some cases the giving of a few prints. Under these circumstances, he seldom had a refusal to fall in with his views.

The Hon. Secretary endorsed Mr. Langfrier's view of the legal position, and said his practice was to give reduced terms to theatrical and professional sitters only, in consideration of their signing an agreement, reserving the copyright in the photograph to him. He pointed out the danger to photographers of publishing photographs for which payment had been made without such an agreement.

Mr. M. Jacolette said it would be interesting to have an account from the Hon. Secretary of the meeting at Agnew's, referred to in the report of the Committee.

The Hon. Secretary said the original intention of the promoters of the meeting was to form a society for the protection of copyright in the Colonies, but the scope had been widened, and the meeting was held for the establishment of a society for the protection of copyright holders in works of art generally, and was attended by representatives of artist engravers, art publishers, and others interested in the question. Five members of the P.P.A. Committee attended. There was no disposition shown on the part of those present to recognise the claims of photography to equal rank with paintings, and it was not until Mr. Ernest Elliott pressed the right of photographers to be represented in the new society that they agreed to accept a representative of photography. It was common knowledge that a strenuous attempt was being made by painters and others to promote a new Copyright Bill, in which photographs would not be ranked with works of fine art, as in the present Act. The Committee was actively looking after the interests of photographers in copyright, and had appointed three of their body to represent the Association in the new society.

A general discussion took place on the subject of the best

means of dealing with itinerants who collect money for photographs which are never delivered.

Mr. H. J. Wright and others instanced cases in which their names had been used, and it was pointed out that as photographers were not directly the injured parties, they could not initiate proceedings; but if, whenever cases of the kind were brought to their notice, they obtained a personal description of the delinquents, and communicated with the Hon. Secretary, the record might be useful in strengthening the prosecution when the guilty parties were caught.

BIRMINGHAM BRANCH.

The following notice has been issued by Mr. Harold Baker, of 58, New Street, Birmingham:—

In pursuance of the notice forwarded to you, a meeting was held on November 6th to form a branch of the Professional Photographers' Association for this district. I enclose a report of the proceedings from the pages of the BRITISH JOURNAL OF PHOTOGRAPHY. Although the number of photographers who attended was smaller than we could have wished, on account of the weather, the meeting was most unanimous and cordial, and a local branch was formed, with Mr. Whitlock as chairman and myself as hon. secretary pro tem.

My object in writing to you is to urge upon you, not only the advisability, but the absolute necessity, of all photographers joining hands for mutual protection and help. It has, unfortunately, been a common idea amongst us that the other members of our profession are our natural enemies, to be kept at arm's length, as much as possible. I am quite sure that such an idea is not only a mistaken one, but distinctly mischievous to the well-being of the profession as a whole, and also to every individual member of it. I have found that friendly co-operation and goodwill have been of great advantage to me personally, and that it is possible for photographers who are rivals in business, even in the same street, to work together for their mutual advantage.

There are many questions that seriously affect our business, such as copyright, trade discount, fire insurance, and so on, that are becoming vital to our welfare. All photographers will admit that profits and remuneration of our labour are not what they should be, considering the skill and constant personal attention our business requires, and I am sure that we all find that this state of things, instead of getting better, is steadily becoming worse, year by year. Photographers find that the business which is theirs legitimately, is regarded as fair ground for poaching by chemists, tobacconists, hairdressers, stationers, etc.

Not only the middle-class man, but the highest and the lowest suffer. A great combination of photographers has been formed "to employ all legitimate means of upholding the rights and dignities of the profession," and great questions affecting the whole profession come before them; but in order that they may deal with such matters it is essential that they should be supported by all, or practically all, photographers in the country.

Apart from matters of great concern to photographers generally, there are many questions of local importance which can be dealt with more conveniently in local branches, and for each one of us to benefit personally, the whole country should be covered with local branches, holding meetings that members can attend and discuss local questions. In the branches already formed personal and technical matters of great importance to the members have been brought forward. It has been argued

that in a profession in which there is such a difference in the status of the members it will be impossible to induce them to work together for their mutual benefit. This difficulty has not been experienced in other places, and I would draw your special attention to the results of the Hull branch, where it has been found possible to fix a minimum price for certain work.

To take only one question, that of portraits for reproduction in local magazines, where we are often compelled to do the work for nothing, on the chance of obtaining an order from the sitter. If local Photographers would meet together an arrangement could be made whereby we could insist on being paid for such work.

Meeting together to discuss matters of common interest will go far towards destroying that feeling of mistrust and jealousy which has enabled the public to play off one Photographer against another to our loss.

In Mr. Whitlock we have a chairman who is universally respected, and his name should secure us the co-operation of every Photographer in the district; I, therefore, make a personal appeal to you to join us.

The annual subscription has been fixed at 5s. for the Professional Photographers' Association, and 2s. 6d. for the local Branches, 7s. 6d. in all. Members of the local Branches must be members of the main Association.

Exhibitions.

EXHIBITION AT FROME.

The first exhibition of the Mechanics' Institute Photographic Society of Frome was opened on Thursday, the 11th inst., by the president, Mr. E. A. Chill, M.D., F.R.G.S.

A capital collection had been got together, mainly by the exertions of the hon. secretary, Mr. Bernard J. Mitchell (as is usual in these exhibitions), and the exhibited works, to the number of 538, were admirably displayed on the walls of the spacious interior of the Mechanics' Hall.

The exhibition was open each day from 2.30, until 6 o'clock on Thursday, and 10 on Friday and Saturday. Admirable programmes were offered on each occasion by Messrs. H. and H. Grant's orchestral band, which were stationed on the main platform under the organ. The central portion of the hall was occupied by the arrangements for a ping-pong tournament, an entertaining innovation certainly, but only to be justified as an adjunct to a picture exhibition by such abundant floor space as afforded, in this instance, the possibility of easy progress round the walls without undue jostling or distraction.

Messrs. J. T. Ashby, F.R.P.S., and C. Barrow Keene, F.R.P.S., were the judges, and their awards were announced at the opening ceremony as follows:—

OPEN CLASSES.

Class A.—Landscape and Seascape: Silver medal, "Harvest," J. Fielder Haden. Bronze medals, "The Mill Stream," Wm. R. Lathbury; "Meadow Sweet," Graystone Bird; "Eventide," Mrs. M. C. Cottam.

Class B.—Portraiture, Figure Studies, etc.: Silver medals, "Playmates," Dan Fanning; "A Paritan Maid," Cyril Cuzner. Bronze medals, "The Haymaker," Fred. M. Barkway; "A Child of Anarchy," Hal Lawrence.

Class C.—Architecture: Silver medals, "To the Nave, Winchester," S. G. Kimber; "Helmsley," William A. Clark; "The Spiral Stair," H. R. Campion.

Class D. (Champion Class (pictures previously awarded prizes).—Silver medals, "Thoughts of Youth," Ed. W. Stroug; "On a Moorland Road," J. B. Johnston. Bronze medal, "Entrance, Litt's Cloisters, Gloucester," H. C. Leat.

Class E.—Collection: "We are of opinion that the collection exhibited by Bernard J. Mitchell, Nos. 242 to 255 inclusive, is of signal merit, but that, on grounds of general policy as affecting such competitive exhibitions as the present, it is inexpedient to grant a medal.

We are further of opinion that, for an initial effort, the average standard of excellence is of high order."—(Signed), J. T. Ashby, F.R.P.S.; (signed), C. Barrow Keene, F.R.P.S.

MEMBERS' CLASSES.

Class F.—Landscape and Seascape: Silver medal, "A Somerset Byway" and "An Old Yorkshire Mill," Bernard J. Mitchell. Bronze medal, "A Village Street," J. H. Wells.

Class G.—Architecture: Bronze medals: "Norman Doorway, Glastonbury Abbey," Bernard J. Mitchell; "Roman Baths, Bath," Cyril Cuzner.

Class H.—Portraiture, Figure Studies, etc.: Silver medal, for four pictures, Cyril Cuzner. Bronze medals, "Study of a Dog's Head," Wilfrid L. Watson; "A Young Musician," Geo. Moore.

Class I.—Sets of Three Negatives: Hon. mention to Bernard J. Mitchell, Geo. Moore, and Cyril Cuzner.

The open classes included many well-known works by such notable competitors as J. Fielder Haden, Graystone Bird, H. C. Leat, Mrs. M. C. Cottam, Wm. A. Clark, Percival W. Crane, E. W. Strong, Mrs. R. M. King, C. E. Walmley, H. E. Brightman, Harry Inkpen, S. G. Kimber, Warland Andrew, J. B. Johnston, Mrs. M. L. Pryce, C. Reid, W. A. J. Hensler, G. Parks, and E. W. Hawes.

Much of the members' work was of high quality, and considerable promise was apparent in every contribution, although the society is of very recent formation, and some of the pictures were, we understand, by first-year amateurs.

We congratulate president, secretary, and members on their successful enterprise.

The "Somerset Standard" contained the following account of the opening ceremony:—

"The exhibition is promoted by the photographic society, which was formed last April in connection with the Mechanics' Institute, and as far as this part of the country is concerned, the magnificent collection of some 340 pictures is a unique one. Large silver and bronze medals and other prizes were offered for competition, and the exhibition being open to the United Kingdom, the grand collection is drawn from all parts of the British Isles. Frome, which is known far beyond the confines of this country for its art metal works, is, perhaps, the natural home of art, but photography is a different branch, and this comparatively young society is to be warmly congratulated on the success of their efforts, the exhibition far exceeding the most sanguine expectations of its promoters. The energetic hon. secretary, Mr. Bernard J. Mitchell, who for some years has been an enthusiastic amateur photographer, has been the life and soul of the movement, and is deserving of the high compliments paid both by the eminent judges and the public generally. His efforts have been ably seconded by an enthusiastic committee, and the arrangements have been successfully carried out. The numerous pictures, all of which are suitably framed, are hung in sections on the walls of the hall, and the collection cannot fail to have a very fascinating interest to the general observer. It is hoped that the public will cordially support the enterprise of the committee, especially as it is suggested that any surplus funds shall be utilised in redecorating the hall, which is badly needed. This wonderfully good pictorial exhibition, which includes some 91 landscape and seascape views, 68 portraits, figure studies, animals, etc., and 56 architectures open to all, contributed by some of the best photographers in the kingdom. There are also 26 open to medalled pictures only, while there are collections exhibited by Mr. B. J. Mitchell, Mr. R. E. Bourne, and Mr. J. Chivers. Not the least interesting are the exhibits by members of the society, which largely consist of local landscape, architecture, and portraiture, and there are loan collections by the president and the hon. secretary. It is pleasing to note that local competitors have held their own among noted confrères, and Mr. Cyril Cuzner and Mr. Mitchell are to be complimented on the medals they secured.

"The president, in his opening remarks, said it had fallen to his lot, as president of the society, to open that exhibition. That was the first year of the society's existence, and he accepted the office of president on condition that he was not called upon to do any work. The committee had kept their word, and he had been left absolutely alone till that day. Therefore, the entire credit of that undertaking was due to their able and energetic secretary, Mr. Mitchell, supported by a band of photographic enthusiasts. Personally, he thanked them for the enormous labour and trouble they had taken in bringing to Frome such a magnificent collection of photographs, such as would do credit to a large city. He hoped the public spirit and enterprise shown by them would be rewarded by a most successful exhibition, and that at the end a substantial balance would be left towards the funds of the Mechanics' Institute.

"Dr. Chill then read a letter from one of the judges, Mr. J. T. Ashby, F.R.P.S., of Loughton, Essex, who expressed regret at being

unable to stay for the opening ceremony, and went on to say: 'I think it should be satisfactory to the members of your photographic society to know that Mr. Barrow Keene (of Derby, the other judge) expressed himself in perfect agreement with me in all our awards. It happens occasionally that the decisions of adjudicators are called in question upon an easy and perhaps superficial observation; but fortunately it happens also that more careful investigation usually reveals the basis upon which the judges' opinions have been founded. And I would suggest to your members that no more instructive exercise could be devised than an honest endeavour to understand the special merits of medalled pictures in an exhibition of this character. With regard to the exhibition, it is due to the hon. secretary of the society to say that as an initial effort it is a most remarkably successful display. Only those who have had experience in the planning and organisation of such movements can appreciate the amount of speculative enterprise of correspondence and other clerical work, and of real personal labour involved in bringing them to a successful issue. It promises well for the future of the society that its interests have been entrusted to the care of so enthusiastic and devoted a secretary as Mr. Mitchell, and there is further promise—I may say great promise—in the pictures exhibited by the members themselves, a good many of whom, I understand, to have been produced by workers of less than twelve months' experience. No doubt there are some whose modesty has stood in the way of their being presented on the present occasion; but if all be as earnest in their work as it is obvious that those who have competed must be the next exhibition should be a notable one. Your grandly picturesque old town and its beautiful surroundings should afford a profitable hunting ground to the amateur of pictorial photography. It is evident to me that many members appreciate this, and the establishment of your society should lead to a general development of taste and ability such as will demonstrate once more what has so often been proved—namely, that the pursuit of the fascinating hobby of pictorial photography for its own sake is both instructive and elevating, and carries with it an 'exceeding great reward.' The president then called on Mr. Mitchell, the originator and organiser of the exhibition, to read his report.

"Mr. Mitchell said, after the introductory remarks by the chairman, there was little need for him to say anything of the exhibition, but he desired to say a word or two about the society. It was formed the latter part of April by a few photographic members, and it now numbered 25 members. During the year they had had several meetings, at which there had been practical demonstrations, and they had also had several excursions, which had assisted in improving the photographic knowledge of the individual member, both pictorially and otherwise. He felt as a committee they could congratulate themselves upon that their first exhibition. When he mentioned it first he did not expect they would get such a large number of exhibits sent in by well-known exhibitors from all parts of the kingdom, some of whom were his own personal friends, but the success was largely attributable to the selection of the judges, whose names were household words in every photographic sphere, and when he saw them on Monday they expressed themselves more than satisfied with the way in which everything had been arranged for them, and more than pleased with the number of exhibits. They had some difficulty in making their awards in the architectural pictures, which were the best in the exhibition, and they got over it by awarding three medals. He then referred to the many picturesque old buildings in Frome and the immediate district, and suggested that the Urban Council should keep a pictorial register of the town, so as to keep a record of the old and beautiful landmarks in the town.

"The chairman, having congratulated Mr. Cyril Cuzner and Mr. Mitchell in keeping two of the open medals in Frome, said he was not going to weary them with a long account of the deeply interesting processes by which the art of photography had been developed from the beginning of the nineteenth century to the present time; from the primitive block printer of Thomas and Wedgwood, to the recent development of photography in colours. To him personally that exhibition was a revelation. During the past twenty-one years he had visited nearly every picture gallery in Europe, and it had come home to him how far behind, as a nation, we were in the art of painting, but in photography—and photography was an art—we could hold our hold with any Continental country. Thanks to the determination of his friend, Mr. Mitchell, they had been able to bring into Frome a unique collection of photographs from all parts of the British Isles. The advantages of photography were becoming daily more manifest, whether they considered them in an artistic, social, or educational point of view. Landscapes and natural scenes in far distant lands were brought home to them and depicted with a truthfulness only equaled by Nature herself; copies of celebrated works of art, both in painting and sculpture, might be multiplied indefinitely; and in all departments of science that art had become an important auxiliary. Viewed either as a branch of the fine arts or as a medium for furthering the cause of science and education, photography must be regarded as one of the most beautiful and useful inventions of our age. He had now the greatest pleasure in declaring the exhibition open, and wished it every success."

GLASGOW EASTERN PHOTOGRAPHIC ASSOCIATION.

The sixth annual open photographic exhibition, under the auspices of the Glasgow Eastern Photographic Association, was opened on Saturday, December 6, at 12½, Landressy Street, Bridgeton, Glasgow, and closed on December 13. The public were admitted without charge, and large attendances have been the rule. The work in competition is highly commendable, and in several instances a very high degree of excellence was attained. So far as numbers went this was the largest exhibition yet held by the society. In many cases the framing of the exhibits had evidently had special pains expended upon them, and in one or two instances they were models in every respect. The pictures were very tastefully hung, three or four deep, on a drapery of a green material, which was admirably adapted to display the pictures to the best advantage, and went far to make the general ensemble harmonious, effective, and thoroughly satisfactory. Altogether, the exhibition reflected great credit upon all those who had in any way contributed towards the achievement of so successful a result.

Landscape, architecture, and still life.—This class was very well supported, and the chief award—the president's medal for the best picture in the members' division—was secured by "A pastoral," by Alex Allan, jun., a most fortunate grouping of sheep, and a pleasant landscape of beautiful quality and much fine tonality. The bronze medalled bit of architecture, "In the Crypt, Glasgow Cathedral," well deserved its recognition. The point of view had been chosen with regard to producing the solemnity of the venerable pile. John Baird must be considered fortunate in getting a bronze with "Edge of the Loch." The composition was slightly rigid, and the colour was not very well chosen. Mr. Walker's "Haddon Hall" and Matt Crosbie's "Strife" received certificates, and call for no comment.

"Simplicity," a child study, by Alex Allan, jun., held the first place in portraiture, and was a natural and delightful print. "Very Shy," by Geo. R. Johnstone, received the bronze medal—clean, good, photography, nothing more. "A Study of Pastoral Life," by J. B. Haggart, won a certificate, and just missed being a remarkably good thing; it did not convey that effect of sunlight and its accompanying shade which was evidently intended. The work contributed by Messrs. Brough and Crocket should be noted.

The club outings class produced nothing of great moment. Silver medal, A. Allan, jun., "Sunset on the Clyde." Bronze medal, "When Clouds are drifting Dark Across the Sky," James Kennedy. Certificate, "A Sunlit Glade," John Brough.

The novices were out strong, the work being of fine technique, and the selection of subject generally evidencing care and forethought. Hy. Coleman well deserved his silver medal for "In summer Time." It is an exquisite piece of work, pictorially and technically. Bronze medal went to a well executed and arranged study, full of expression, entitled "Granny," by Geo. R. Johnstone. Mr. John Gillespie treated us to a fine riverscape, "On the Clyde," a distinctly meritorious production.

David C. Pratt's "Treasure Seekers" was a very fine bit of work, and took first place. Showery weather had its own charms, alike to the photographer as to the artist, and "Through the Rain," which secured the bronze award for Mr. Crocket, must be considered a fine rendering of a wet day; it really was wet, and the atmosphere was realistic. Certificates were awarded to "Toil and Pleasure," by Matt Wilson, and "Tramps," by John Gardiner, neither of which contained the qualities possessed by Nos. 112 and 114, the contributions of Messrs. Milroy and Johnstone.

Lantern slides were strong in point of numbers, but weak in quality. Members' class fell to a good set of forest scenes, by William Milroy, second place being held by W. S. Crocket, and third by Matt Wilson. In the open lantern slide class, Mr. Robert Burnie, of Glasgow, gained the silver medal for a medium lot of shipping scenery, Mr. Charles M. Wane, of Edinburgh, getting the bronze for his beautiful studies of swan life. Some striking and picturesque effects of sea and sky were the subjects of the certificate winner's set—viz., Mr. W. L. Primrose.

Coming to the open classes for pictures, let us at once say that the work was of a very uniform quality, nothing that might be said to be of outstanding merit, and very little of the commonplace. The principal award in the class for any subject other than portraits and figure work went to W. A. Clark, of Birmingham, for a fine piece of work, "Evening, Southwell," a bit of painstaking selection and remarkable technique. Bronze also went to an architectural work, entitled "The Light Steals Gently Across the Aisles," by W. R. Lathbury, Bristol. It was a notable work and an object lesson. Certificates fell to Messrs. Allan, jun., Richmond, and Walmsley for work that might easily have changed places with that shown by Messrs. Dunlop, Fenn, and Carswell.

In the open portrait and figure class, Mr. J. Peat Miller, of Beith, justly won the silver medal for a satisfying piece of genre work,

'The Last of the Spinners.' His other contribution was also very successful, and portrayed a young girl teaching a little one "a nursery rhyme." "The Mother and Child" of Miss Johnstone well merited the second award. Messrs. Mercier, of Perth, and Herdmann Newton, of Edinburgh, gained certificates for high class contributions that were particularly pleasing. The judging was kindly undertaken by J. Craig Annan, Esq., of Glasgow, and Archibald Cochrane, Esq., of Hurler.

New Books.

"The A.B.C. of Photography." By F. J. Clute. 85 pages, 25 cents. San Francisco: The Camera Craft Publishing Company.

Here in England we already have two "A.B.C.'s of Photography," one of them by the late W. K. Burton, which for practical value has not been surpassed. The author of the volume before us says in his preface: "In the following pages I shall presume that the reader knows absolutely nothing concerning photography. My own days of adolescence as an amateur photographer do not date back to the time when the wet-plate process held sway, and I did not learn to use dry plates and film through glasses stained by the silver bath of the old collodion and albumen processes. I have been in constant touch with the beginner in photography since the time when honours were easy between the veriest tyro and myself, and am to-day enjoying their companionship and sharing their troubles. To me, no one is as interesting or companionable as an enthusiastic amateur photographer." We have glanced through the book, which seems to be written from knowledge, and in a very lucid style. But, as we have before remarked, there are enough and to spare of "beginners' books" on the market; and if we had our way, the next aspiring author found guilty of an offence which is very common nowadays, should be chastised on the principle of making the punishment fit the crime, and compelled to read his own writings aloud four hours a day to an audience of New Cut Hooligans. Still, Mr. Clute's book is one of the best of its kind, and we wish it success.

From Messrs. Dawborn and Ward, Farringdon Avenue, E.C., we have received the bound volume of "The Photogram" for 1902. This makes a gift book of double value; it is pleasing from the nature of its pictorial contents, and instructive by reason of its many admirable technical and elucidatory articles.—The same firm forward us volume IV. of "The Useful Arts and Handicrafts" series. Herein Mr. Ward, Mr. Leland, Mr. Bolas, and the Rev. F. C. Lambert have stored up a great deal of serviceable information in a handy form. All sorts of decorative, useful, and fancy work are minutely described. We note an article on "Grangerising." How many of our readers could say off-hand what this is? We much appreciate this volume, and can cordially recommend it.

"A Manual of Photo-engraving." By H. Jenkins. 200 pages; price 2 dollars. New York: Published by "The Inland Printer," 160 Nassau Street.

This is a volume which we have no hesitation in praising. Fully illustrated in line, tone, wash, and three-colour from the works of prominent American artists, the details of the half-tone engraving process appear to be given very exhaustively. The renowned authority, Mr. F. E. Ives (whom we hope shortly to congratulate on the receipt of the too long deferred R.P.S. progress medal), deals with the half-tone and tri-chromatic process theories, while three-colour block making forms the subject of a chapter by Mr. S. H. Horgan, editor of "Process Notes" in "The Inland Printer." We accord very high commendation indeed to this useful and well-produced book, which should be in the possession of everyone interested in photo-engraving, be it monochrome or tri-colour. Admirers of American work should certainly procure it.

"Wellcome's Photographic Exposure Record and Diary, 1903." London: Published by Burroughs, Wellcome, and Co., Snow Hill Buildings.

We have carried a Wellcome in our pocket for the past twelve months, and remorseless Time has insisted upon the volume being gathered to its fathers. Some day the notes it contains may come in handy for autobiographical purposes, or the pleasures of memory. The new Wellcome is leather bound, has a wallet, and space for some of these little snap-shots which we all carry and show one another nowadays. Here are some of its other features, officially described:—The general arrangement of the letterpress so far as the first 60 pages are concerned is on the same lines as last year, but the matter has been carefully brought up to date. The article on exposure has been re-modelled to suit the attached calculator, and removed to the end of the book, so that the tables may be convenient for reference. The introduction of a mechanical means of calculating exposure has enabled considerable simplification to be effected both in the letterpress devoted to exposure and in the tables given at the beginning of each month in the diary portion. In the case of the Wellcome Calculator, only one movement of one scale is necessary. The movement is easily effected by slight pressure with the finger tips. The use of the calculator is not confined to one country, to one make of plate, or to one developer. Apart from its obvious and particular purpose, the Wellcome Diary will be found useful and informative by every photographer.

We have also received "Practical Photo-Micrography," by Andrew Pringle (Liffie); and "Penrose's Process Year Book," edited by William Gamble.

New Apparatus, &c.

"Tabloid" Pyro-Metol Developer. Manufactured and sold by Burroughs Wellcome and Co., London.

Messrs. Burroughs, Wellcome, and Co. have added to the series of their well-known "Tabloid" photographic chemicals a pyro-metol developer compounded according to the "Imperial" formula. Each tabloid of pyro-metol compound contains 1.375 grains of pyrogallie acid, 1.125 grains of metol, 3 grains of metabisulphite of potash, and .5 grains of bromide of potassium. One tabloid suffices for one fluid ounce of developer, and to it should be added one tabloid of accelerator. The units have to be multiplied by the number of ounces of solution required. It is scarcely necessary to say that the use of this developer is not restricted to "Imperial" plates. In trying the sample sent to us, we used another popular brand, and obtained negatives of excellent quality, full of detail, and free from any trace of stain. The plates had been exposed some months ago, but the developer did not reveal any sign of staleness. The negatives, in fact, were as good as though the plates had been developed immediately after the exposures were made. We desire to draw attention once again to the great convenience of "Tabloid" developers for travellers. Packed as they are, in well corked bottles, the possibility of deterioration is practically eliminated, and there is none of the risk and inconvenience which usually attends the carriage of solutions. For amateurs and others who only develop plates at intervals, tabloids should also be of considerable value. Solutions are at their best when freshly prepared, and the tabloid system ensures this, as well as the correctness of the proportions of the ingredients of which the developer is composed. Accurate work under the best conditions is thus secured.

Mariona Self-Toning Paper. Manufactured and sold by Marion and Co., Ltd., Soho Square, W.

Issued with both glossy and matt surfaces, this paper yields agreeable warm brown tones with the first of the undermentioned baths. The glossy prints are particularly rich in effect. The following are the directions for use. Print as with albumenised papers, slightly darker than required for the finished picture. After printing, place in the following solution for five minutes, keeping the prints constantly moving, viz., Powdered alum 1oz., ammonium sulphocyanide 40grs., made up with water to 20oz.; or for colder tones, ammonium sulphocyanide 40grs., chrome alum 40grs., common salt 1oz., made up with water to 20oz. On removal from either of these baths wash in several changes or in running water for ten minutes, then fix. Fixing bath: Dissolve 3oz. hypo in 1 pint of water. Final washing: In running water, or several changes of water, for at least two hours. Notes: Care must be taken to keep the prints moving in all the solutions. Drying: A convenient method is to place the prints face upwards on stout blotting boards bent over wooden rods.

** A number of reviews of books, notices of new apparatus, etc., are unavoidably held over.

Commercial & Legal Intelligence

THE Warwick Competition.—Entries for the Warwick Dry Plate Company's £50 prize close on the 31st inst.

THE Austin-Edwards Monthly Film Negative Competition.—The prize camera for the current month has been awarded to Dr. Lincoln de Castro, Italian Consulate, Aden, for his negative "Abyssinian Woman at Fountain."

In the Court of Session last week Lord Low gave judgment in an action of suspension and interdict by W. Ross Shearer, photographer, Kirkwood Street Studio, Rutherglen, against Wm. Ritchie and Sons, Limited, wholesale stationers, Elder Street, Edinburgh, in which complainer sought to have respondents interdicted from publishing or selling photographs entitled "Views of Rutherglen" unless each photograph larger than three inches long by two inches broad, was impressed with the words "Shearer Photo." Complainer photographed a number of places in and around Rutherglen, and in January last was approached by respondents with the view of having the photographs reproduced. He agreed to let them have the use of 16 negatives on condition that the words mentioned were used. He complained that respondents had used a number of the photographs in books and postcards, reproducing his views without fulfilling that condition. After the note was raised respondents proposed that they should print the words on a fly-slip on the front of the views, but this complainer declined. Subsequently respondents called in all the books and cards and stamped upon them the words "Shearer Photo." Lord Low last week held that this course was the proper one to have been followed. He therefore refused interdict, but found respondents liable in expenses.—"Edinburgh Evening News."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Dec	Name of Society.	Subject
19.....	Borough Polytechnic.....	<i>Miscellaneous Hints and Formulae.</i> Mr. F. W. Bannister.
19.....	Nottingham Camera Club.....	St. reoscopic Evening and "A. P." Prize Slides
19.....	Croydon Natural History.....	" <i>Photo-Micrography</i> " by T. E. Fresh water. Illustrated.
22.....	Oxford Camera Club.....	Exhibition of Members' Slides.
22.....	Edinburgh Photo. Society.....	<i>Lantern Slide Making.</i> A. H. Baird F. R. P. S.
23.....	Leeds Photographic Society.....	<i>Photographic Slides.</i> Lantern Evening.

ROYAL PHOTOGRAPHIC SOCIETY.—THE PROCEEDINGS OF COUNCIL.

A PHOTOGRAPHIC Studio.—In reference to the suggested provision of a photographic studio, the council have received a further communication stating that, so far as lack of funds was concerned, the writer was prepared to subscribe a sum of £5, if others desirous of this accommodation would join him in sufficient numbers to meet the expense of the structural alterations that would be necessary. In giving publicity to this offer the council wish it to be known that if sufficient help is forthcoming as a result of this announcement, they will be pleased to further consider the matter.

The Society's Jubilee.—The council received a preliminary report upon the proposed celebration of the fiftieth year of the society's existence. Until the matter is further advanced, however, no definite announcement of the method of celebration to be adopted can be given.

Progress Medal.—In accordance with the standing orders, the nomination of candidates for the Progress Medal took place. The discussion of the work of the nominees takes place at the December Meeting and the voting at the January meeting of the council.

Ordinary meeting, December 9th, Mr. J. C. S. Mummery in the chair.

Eight candidates were elected members of the society, and eleven names were proposed for membership.

Messrs. Calder Marshal, and Son were appointed hon. auditors of the society's accounts for the current year.

Dr. R. Norris Wolfenden then read a most interesting paper upon

PHOTOGRAPHY IN MARINE ZOOLOGY.

The object of the paper was to show the extent of the usefulness of photography in the researches of men like Dr. Wolfenden who spends a considerable portion of his time dredging in northern waters and dissecting and studying the numerous forms of life which his apparatus brings up from below the waves. Dr. Wolfenden had quite a number of specimens of these creatures which were passed round. In other cases photographic slides were thrown on the screen, the pictures showing the outward appearance of the object while X-ray pictures laid clear their internal structures. Photography with the microscope can be of considerable service to the marine zoologist in his studies and the ability to make radiographs of the animals, etc., that are brought to light greatly assists him. Dr. Wolfenden had a few words to say about the possibility of photographing these marine creatures in situ by means of a camera that would stand immersion at considerable depths, and later on held out his particular branch of study as an excellent field of work for the capable photographer in colour. He said a large number of things brought to the surface were most beautifully coloured for a time, but the colours were fleeting and could not be preserved except by means of drawings; and if somebody would devote himself to the preservation of accurate photographic records of these colours, he would be doing a good work. A number of microscopic specimens were also shown with the aid of the microscope attachment to the lantern.

A vote of thanks was passed to Dr. Wolfenden.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 11TH.—Mr. W. G. Barker in the chair. The exhibition of pictures for the hon. secretary's medal was held, a landscape by Mr. E. Featherstone being first, and one by Mr. J. S. Teape coming second.

Mr. A. Mackie showed two collodio-chloride prints which had been held together by rubber bands, the sulphur in the rubber having considerably reduced them where it had come in contact.

The Chairman, remarking on his endeavours to find a developer for cinematograph films that would be perfectly stainless in its action with prolonged development, had finally decided on "Dionol," which gave plenty of density, and was also very economical, 1oz. being taken to 200oz. of water, with the addition of 3oz. of soda sulphite.

CAMERA CLUB.

A somewhat novel field of photographic work has been tilled by Mr. Martin Duncan, who addressed the Camera Club on the 8th inst., and

showed numerous specimens of his skill. He called his subject "A Naturalist's Ramble on the Sea Shore," and throwing on the screen a view of the receding waves, he invited his hearers to accompany him on a walk along the wet margin of the sand. Another lantern slide exhibited the "outfit" which he adopts on these rambles, consisting of a few test tubes and bottles, a spoon, a landing net, and a pocket magnifier. With these implements he secures and examines seaweeds, which under the microscope turn out to be no seaweeds at all, but zoophytes, and all sorts of curious organisms, which occupy that strange borderland which lies between the animal and vegetable kingdoms. The larger creatures he keeps in a marine aquarium, and then, by certain clever artifices, he photographs them, and is thus able to illustrate their life history in a truly remarkable manner. The lecture was given entirely without notes, and the lecturer knew both his subject and his pictures, which, alas! is not always the case, even at the Camera Club.

Mr. Charters White, who, as an ardent microscopist, was in close touch with the lecturer, urged upon the members present to follow his example when on a visit to the seaside, and to forsake the joys of the Marine Parade for the more intellectual company of the crabs, lobsters, and octopuses, or octopi—we believe the word is one of the few which rejoices in a double plural. The lecture was much appreciated as a discourse which had been well delivered and unusually well illustrated.

On the following Thursday there was an almost record attendance at the Club, for it was the night appointed for Mr. Sanger Shepherd's exposition of his new process for producing photographs in colour on paper. He had promised some weeks back that the Camera Club, of which he is a member, should skim the cream of the novelty by being the first public body to know anything about it, and his fellow members were not slow to appreciate the compliment.

Dealing first with general principles, and acknowledging in a graceful manner the work of F. E. Ives, who laid the foundation of the trichromatic method, and owning his indebtedness to Sir William Abney's researches, and to Mr. Cadett's "Spectrum" plate, Mr. Sanger Shepherd at once plunged into his subject. For the benefit of the many visitors among the audience who were presumed to be ignorant of recent advances, he described his own method of producing lantern slides in colour. And he told how the process had been extensively adopted by scientific men, as well as by artists. He also mentioned incidentally that transparencies of large size, made by the same method, had won the regard of certain Indian potentates, who used the pictures for decorative purposes.

The new process on paper may be said to begin where the lantern slide process leaves off. The three negatives taken under colour filters are necessary, and so are the positives produced from those negatives in bichromated gelatine on celluloid. Each positive receives, as in the lantern slide process, a bath of aniline dye; that from the red filter being stained cyan blue; the prints from the green filter negative being coloured pink; and that from the blue filter negative yellow.

And now comes the new departure. The bichromated film is extremely hard and tough, but this does not prevent it absorbing a large amount of dye. While it holds this colouring matter, it is placed in a vessel of water, together with a sheet of paper specially coated with a very thin film of soft gelatine, which has been combined with a mordant. The two surfaces, after being placed face to face, are treated like a carbon print and its temporary support: they are squeegeed into intimate contact. Left thus for about fifteen minutes, the colour is attracted to the softer resting place offered by the mordanted gelatine on the paper. It leaves its hard pillow on the celluloid, and goes entirely to the softer bed. One colour having been transferred from celluloid to paper in this manner, the other two images on the celluloid are stained with their respective colours, and each in turn is superposed upon the first impression obtained. There is no difficulty in registration, for the soft, wet gelatine allows one to slide the celluloid film upon it until the correct place is reached, and this is done before the transfer of the colour has time to begin.

Such is the process which Mr. Sanger Shepherd has devised, and the specimens which he showed prove that it is a practical one. Moreover, it is a distinct novelty. Like so many other inventions and discoveries, a fortunate accident led an observant man to the goal which he had long been seeking. A stained positive film was carelessly laid upon a piece of blotting paper, and transferred the image which it bore to the more absorbent surface on which it rested.

The thing seems very simple and easy now that it is done, but we may be sure that many little details had to be considered, and many difficulties surmounted before ultimate success was reached. One of these Mr. Sanger Shepherd alluded to during his demonstration. He had, in his first attempt, successfully combined the red and yellow images, but when he added the blue, some disturbing element made its presence felt, and the picture entirely disappeared. The failure was traced to the circumstance that the blue dye in question had an acid reaction, whilst its two yoke fellows were alkaline. Such difficulties crop up by the score in the early stages of every new process, and it often calls for higher qualities to overcome them than it does to conceive the original idea.

Mr. Shepherd claims for his process that it is applicable not only to paper, but to satin, silk, and other textile fabrics. It may also be used, he thinks, to produce imitation miniatures on ivory, white opaque celluloid, and opal glass may also be employed as image supporters. But he laid great stress upon its employment for portraiture by the professional photographer, urging the facility with which the paper prints can be retouched by means of their own colouring matter as one of its chief recommendations for studio work. While the results are sufficiently good without any retouching whatever, the professional man could not afford to do without that aid to the production of a flattering portrait.

In the discussion which followed Mr. Shepherd's interesting demonstration, he was assailed with dozens of questions, but as they say in the law courts, cross-examination did not shake his evidence as to the excellence of the process, and these questions elicited from him further details of the method. He had found it necessary to devise a new set of dyes, for he had found that even the same maker could not guarantee the same qualities for every batch of dye of the same name.

Mr. Cadett was delighted to see such a large audience. He thought that photographers were getting tired of monochrome, and had long been surprised that, although Vogel had demonstrated the advantages of orthochromatic work, it was so little practised. Thanks to the Sanger Shepherd filters, it was now possible to secure correct luminosities. Improvements came slowly, but he thought that we were now on the eve of a change. In a coloured picture, the luminosities must be correct, and it should be the same in ordinary photography. He believed that the new process which had just been demonstrated would become very general.

Dr. Lindsay Johnson wanted to know if special lenses were necessary, and also if any difficulty arose from expansion of the paper. The first question was answered in the negative, and as to the second, Mr. Shepherd pointed out that as the paper was thoroughly wetted before contact with the dyed positive, the expansion difficulty was not an obstacle. By steeping paper in celluloid varnish it could be repeatedly soaked in water without stretching. With regard to permanency of results, it was curious that one dye would be "fast" on paper while it was fugitive on cotton or silk. Others, again, took kindly to one of those textiles, while it refused to be permanent on paper. He had prints which had been exposed for eight months without any apparent change, but he would not guarantee permanence. That was a matter for the manufacturer of the dyes.

A hearty vote of thanks brought the proceedings to a close at a late hour.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The weekly meeting was held on Thursday evening last week in the rooms, Eberle Street. Mr. Joseph Marples gave a lecture on Bridg-north—a resume of the last Easter tour of the society. His remarks were listened to with marked attention. The slides, to the number of about 150, were contributed by the various members who took part in the tour, and comprised a great many very fine pictures, chiefly architectural.

CROYDON CAMERA CLUB.

The seventieth public lantern show was held on Wednesday, the 10th inst., at the Art Galleries, before a large assembly of members and their friends.

The first slide shown on the screen consisted of a map of Surrey, and the President, who acted as a genial and critical spokesman, pointed out the various places investigated by his dauntless band of explorers during the summer season. That their ways lay in pleasant places was proved by the large number of slides subsequently shown.

Theatrical scenes, taken by Dr. Grun, of liquid lens and "depth of field" fame, were also projected and aroused much interest, as did the slides recording Lord Roberts's recent visit to the town. The chief attraction of the evening, however, consisted in a capital cinematograph display by means of Paul's animatograph, which included a wonderful representation of Dickens' "Christmas Carol," and magical illusions only possible on a moving film, which can see or be blind, at the will of the manipulator. There are several points in the animatograph deserving of notice. The shutter only covering 1-16 of the circle it revolves in, is of high efficiency, and a brilliant picture results. The lantern body moves laterally on rails, from the animatograph to the lantern projector. This permits a longer focus condenser to be used for slide projection, and is optically an advantage. Provision is also made for centering the disc on the screen. The projection lenses are interchangeable, and the operator is therefore independent of the varying length of the halls he may have to show in. The spools are of ample capacity, and are made to take from 1,000 to 15,000 feet of film.

A cordial vote of thanks to Mr. Paul and his manager, Mr. Smith, brought a pleasant evening to a close.

BOWES PARK AND DISTRICT PHOTOGRAPHIC SOCIETY.

A WELL-ATTENDED meeting of the above was held at 111, Myddleton Road, on Wednesday, the 10th inst., to consider rules, etc. A communication was read from Mr. J. C. S. Mummery, F.R.P.S., who regretted his inability to become president, but expressed a wish to join the society. Letters were also read from Dr. Allan and several other gentlemen who wished to become members.

After discussion the rules were passed, and the following officers elected for the ensuing year:—President, Mr. A. J. Craston; hon. treasurer, Mr. A. Bird; hon. secretary, Mr. A. Kernon; hon. librarian, Mr. F. Slater. The following gentlemen, with the officers, to form the council:—Messrs. H. C. Bird, Cobb, W. Driffield, Duncan, T. B. Read, Richardson, and Young.

It was decided that the society meet on the first and third Mondays in each month.

Mr. Mason, chemist, 128, Myddleton Road, has promised to fit up a dark room for the free use of members of the society.

Any information can be obtained of the hon. secretary, 25, Goring Road, Bowes Park, N.

LUTON CAMERA CLUB.

A MEETING of the members of the above club was held at the Franklin Institute on the 9th inst., when Mr. Frank Miall, representing the Lumiere N.A. Co., gave a lecture and demonstration of their advanced process of colour photography, and received a most hearty vote of thanks for the clear and concise manner in which he explained and demonstrated the extreme simplicity of the process, coupled with the excellent results obtained.

NORTHAMPTON NATURAL HISTORY AND FIELD CLUB.

A MEETING of the members of the above club was held at their club room on the 10th inst., when Mr. Frank Miall, representing the Lumiere N.A. Co., gave a lecture and demonstration of their up-to-date process of colour photography, and received a hearty vote of thanks for the explicit way in which he explained and showed the very simple method of obtaining the charming pictures thrown on the screen, each one being received by the audience with applause.

RICHMOND CAMERA CLUB.

THE modern amateur photographer is a being of infinite resource. The setting of the sun does not mark the cessation of his activities. The fact of darkness closing the earth merely signifies to him that he must change his methods, and set to work to record the many interesting effects only to be observed during the hours when mankind, through the medium of some amiable gas or electric company, itself looks after the illumination of its haunts and habitations. The many charming subjects available under these artificial conditions were exemplified in the course of a lecture by Mr. Elis Kilsey delivered before the club on Thursday, the 11th inst.

Night photography, it turns out, is merely a matter of rapid lenses, rapid plates, and patience. Give your lens time, and it will record upon the sensitive plate the most faintly lighted scene; but for respectable photographers who desire to conclude their operations short of midnight, the scene should be illuminated brightly. A highly-pictorial rendering of a frost-covered tree, lighted by a common street lamp, was shown in illustration of the lecturer's remark that the most every-day scenes contained gems for the night photographer. A wet or snowy night is the best, as the street reflect and re-reflect the lights in picturesque lines and patches. Some excellent views in Trafalgar Square and on the Thames Embankment were shown in illustration of this point. Even the humble candle, it appears, is sufficient to serve the purpose of the photographer, for the lecturer illustrated and explained a method by which he had photographed himself reclining in bed, posing before the camera for eleven minutes.

CROYDON NATURAL HISTORY AND SCIENTIFIC SOCIETY.

ON Friday evening, Mr. A. P. Hoole, of Sutton, lectured to the above Society on the "Development of Lantern Slides, and their after-treatment by Toning and Intensification." The lecturer showed numerous very beautiful slides, illustrative of the various methods of development, and of the results obtainable by various types of developers, etc. Examples made by the following developers, Thomas's plates being always used, were shown, i.e., pyro-soda, black and warm tones; pyroacetone; pyro-ammonia; hydroquinone soda, with and without metal; rodinal; amidol and ferrous oxalate. The result of prolonged exposure, with the suitable modification of the developer, was also shown and explained. Of toning solutions, gold and sulpho-cyanide, together with various salts of iron and copper, were exhibited. Intensification with mercury alone, or subsequent darkening with ammonia, sodia sulphide, Schippe's salt, ammonium sulphide, etc., was also shown by a large number of slides. The action, too, of Thomas's colour solution, by which various colours may be obtained on one slide, was also demonstrated. The proceedings terminated with a hearty vote of thanks, proposed by Mr. Baldock, who officiated at the lantern, which was unanimously accorded to Mr. Hoole for his very instructive and successful demonstration.

A VERY successful evening was spent at the headquarters of the South London Photographic Society on Monday last, when Messrs. W. E. Walker and H. Mann, of the Chiswick Camera Club, attended to act as judges in the annual competition for medals presented by various gentlemen on the executive of the Society. The proceedings, which commenced at eight o'clock, did not terminate until the clock showed eleven not far ahead. The medals and awards are as follows:—For the best lecturette illustrated by slides, not to exceed fifteen minutes in delivery, bronze medal presented by H. F. Mawbey, Esq., awarded to Mr. W. F. Slater, F.R.P.S.; for the best and second best prints made from negatives taken during the current year (only members who have not yet been awarded a medal are eligible), two bronze medals presented by C. Churchill, Esq., F.R.P.S., award, 1st, Mr. G. H. Lovegrove; 2nd, Mr. Gardner; for the best set of six lantern slides from negatives taken on at least three of the Society's excursions in 1902, silver medal presented by J. T. French, Esq., awarded to Mr. E. W. Taylor.

News and Notes.

DURING his recent visit, His Majesty the King of Portugal called at the London Stereoscopic Company's premises in Regent Street, and personally selected two of their best hand cameras for his own use.

MESSRS. GEORGE HOUGHTON AND SONS, of 83 and 89, High Holborn, W.C., write:—We have much pleasure in advising you that we have been appointed sole wholesale agents for "Metalotype" paper.

CHRISTMAS Holidays, 1902.—Messrs. Burroughs, Wellcome, and Co.'s offices, warehouses, etc., will be closed from Wednesday evening, December 24th, until Monday morning, December 29th.

At the Photographic Club on the 10th inst., Messrs. Geo. Houghton and Son showed the Sanderson hand and stand cameras with lantern slides illustrating its capabilities for architectural and telephoto work, dalo camera, and other novelties.

MR. W. B. CHAPLIN, of Messrs. J. Russell and Sons, Windsor Studio, was married to Miss E. Langton Cooper, at All Saints' Church, Windsor, on Saturday last, the Vicar of Windsor, Chaplain in Ordinary to the King, officiating at the ceremony.

MESSRS. Gothard and Co., picture frame makers, of the Steam Works, Plumstead Road, Woolwich, S.E., have submitted to us specimens of their frames for photographs. These are made in three shades, art green, dark green, and brown. The corners are mounted and finished in English gold. The frames are effective in appearance and moderate in price.

THE Science and Art Department.—I have seen a paragraph in the papers intimating that the principal assistant secretary at South Kensington has expressed a wish to retire. I most earnestly hope that the report is a false one, as the dignity, integrity, and usefulness of the department cannot but suffer sorely by his removal. One has heard of statements inserted one day to be contradicted the next. I trust that this may be one of them.—"A Fellow of the Royal Astronomical Society" in the "English Mechanic."

SOUTH London Photographic Society's Exhibition.—Messrs. H. W. Bennett, F.R.P.S.; J. C. S. Mummery, A.R.I.B.A., and J. A. Sinclair, F.R.P.S., have consented to act as judges at the coming exhibition. There are open classes for portraiture, architecture, landscape, lantern slides (sets of four), and stereoscopic slides (sets of four), in which silver and bronze medals will be awarded at the discretion of the judges. Entry forms will be ready in a few days, and may be obtained from the hon. secretary, Mr. W. Calder Marshall, F.C.A., 41, Glenton Road, Lee, S.E., who would also be pleased to hear from anyone desiring to join the society.

ITALIAN publishers and newspaper proprietors are said to be seriously interesting themselves in a new process of printing, for which important claims are made. The "Tribuna" of Rome states that the Genoese firm of Bacigalupi has acquired all rights in the new process, and that a few days since all the newspaper proprietors and leading printers of Milan assembled to witness a series of practical tests, which are all described as having been perfectly satisfactory. The invention consists in the substitution of celluloid for preparations of lead and antimony, and is said to give an admirable reproduction from all kinds of plates and blocks.

THE Grun Lens.—The following is from a "lay" contemporary:—"It is well known that some liquids have the power to refract rays of light much more than others. An inventor has taken advantage of this principle to make a photographic oil-containing lens which is so much more rapid than the most rapid all-glass lenses that with it an instantaneous photograph in a theatre, for instance, can be taken without a flashlight. So great is the light-refracting power of this new liquid lens that on a pitch-dark night a photograph can be taken out of doors with a 15-minute exposure, or when there is moonlight with an exposure of only one minute."

SCOTTISH Affiliation.—The first meeting in connection with the proposed Scottish Affiliation, or, as it should rather be called, Scottish Confederation scheme, will probably be held next month, after all the societies have had time to consider the matter. Already a decided majority of the Scottish societies have decided—most of them enthusiastically—to support the scheme, while a number have not yet decided either way; not one society, as far as we can hear, has condemned it. The photographic section of the Perthshire Society of Natural Science has invited the delegates to use its rooms for the first meeting, and the President of that body has kindly offered to entertain the delegates to tea.

"KNOWLEDGE" Programme for 1903.—It is intended in future to devote a larger amount of space to microscopy than hitherto, and by the co-operation of specialists to publish articles treating on different departments of both the popular and scientific sides. Among those who have promised to contribute are the following:—Mr. F. Noad Clark, "The Photography of Opaque Objects"; Mr. Sanger Shepherd, "Photo-Micrography in Natural Colours"; and other similar articles will appear. It is hoped that these new arrangements will greatly increase the value of the microscopical notes, and maintain the interest which has so far been evinced.

THE Kyrle Society.—On behalf of the Kyrle Society, 2, Manchester Street, an appeal has just been issued by Miss Octavia Hill and Lord Monkswell. The decorative branch of the society provides pictures and other decorations for hospitals, clubs for working men and women, and

similar institutions, and the gratuitous help of some fifty artists is at the disposal of the committee. The work is now at a standstill, however, owing to lack of funds for materials and the fixing of decorations. Among the dozen schemes for which money for materials is needed is one for the parish hall of St. Cuthbert's, Isle of Dogs, for which a beautiful design illustrating the "Coming of Spring" has been prepared by Mr. W. Savage Cooper. The cost of carrying out the scheme would not exceed £15, but this and other work cannot be entered on until the money is in hand, as the society during its existence of a quarter of a century has never incurred a debt.

THE post-card movement and trade in Great Britain are so large and have so many ramifications, says "The Picture Post-card and Collector's Chronicle," that only those "behind the scenes" can realise how overwhelming they are in their magnitude and importance. We have decided, therefore, after mature thought, that in order to show the general public, collectors, and even manufacturers themselves, to what heights—popular, artistic, and commercial—the English post-card pictorial has risen, to organise a British Picture Post-card Exhibition. This, to be thoroughly representative, must embrace every section of the post-card designing, publishing and distributing business; it should show everything of interest to the cartophilic world, from a unique post-card to a typical collection; from a design to a packet of post-cards. We have drawn up a scheme, particulars of which will appear in our next issue; meantime we invite anybody and everybody interested in the British post-card movement to communicate with us, and send us any suggestions, hints, or ideas that may help us to make a brilliant success of the first English Post-card Exhibition.

At the last meeting of the American Association for the Advancement of Science, Professor Robert W. Wood, who succeeded to the chair of physics in the John Hopkins University on the death of Henry A. Rowland, announced under the title of "A Substance with Remarkable Optical Properties, and Screens Transparent only to Ultra-Violet Light," a discovery which is said to be of great value in science, and which was a notable personal triumph for Professor Wood. He first described Tyndall's experiments with a screen that cut out all the visible rays of the spectrum, as well as the ultra-violet rays, and let through only heat rays. For the past thirty or forty years eminent physicists all over the world have been trying to find a similar screen that would cut out all the heat and all the visible rays and let through only the ultra-violet rays. Dr. Wood had for some time known that the substance called nitroso-dimethyl-aniline would keep out all the visible and heat rays, except some red and violet, and that it would also let through the ultra-violet. It has only been within the last few days that Dr. Wood has discovered the much-sought screen. He combined the known substance with cobalt glass and obtained a screen that lets through only ultra-violet. One striking peculiarity of the nitroso-dimethyl-aniline, which Dr. Wood dwelt upon and especially emphasized, is the fact that it gives a spectrum about thirty times as broad as that produced by ordinary quartz.

THE Effect of Light on Animal and Plant Life.—I note with interest a very able article, Mr. T. Ritchison writes to the "Scientific American," by Dr. James Weir, Jun., in which he describes the effect of light on plant and animal life, but with one probable error, which I shall endeavour to point out. He says among other things:—"Flammarion's beautiful experiments at the climatological station at Juvisy have shown beyond question of doubt the widely different effects of the red and violet rays on plants. The plants chosen were of the genus Mimosa, or 'sensitive plant,' and were subjected to the same environments with the exception that some were reared beneath dark blue glass, and others beneath red glass. In four months the plants grown under the red glass had attained extraordinary development, while those subjected to the violet rays had made no progress whatever. Similar effects were noted in the case of strawberries, and numerous other plants, vines, and shrubs. The plants grown beneath blue glass did not die, but seemed to remain in a dormant condition, without growth or further development. Zacharawietz, of Vaucuse, has also shown that plants are strongly affected along the lines of rapid growth and development by red and orange rays. As early as 1883 I demonstrated and published the fact that typhoid fever germs would not live when subjected to the blue or violet rays." From the foregoing one gets the impression that plants under a red glass are subjected to red rays of light, while the reverse must be true, as the red glass has absorbed all the red rays of light, and the remainder only have penetrated. Who has not observed that in a photographic dark room, where a red light is used, anything therein which is red will appear white, for there are no red rays in the room, all being absorbed by the red paper through which the light is filtered.

COMMONS Preservation Society and Private Bills.—A meeting of the executive committee of the Commons and Footpaths Preservation Society was held last week, under the presidency of Mr. G. Shaw Lefevre. The secretary's report upon private Bills to be introduced into Parliament during the ensuing session was considered. It appeared that altogether notice has been given of intention to introduce 72 Bills under which common land or open spaces would be absorbed or rights of way extinguished. Among the London open spaces which will be interfered with by railway Bills are Back Common and Acton Green, Chiswick; Shepherd's Bush Green, Hammersmith; Peckham Rye Common, and Tooting Bec Common. Over eleven acres of Tooting Bec Common are within the limits of deviation of the proposed London and Brighton Electric Express Railway. Several proposed tube railways will affect Hyde Park, St. James's Park, and Green Park, and the Metropolitan District Railway

seeks to acquire further land on the Victoria Embankment. It was further stated that 338 acres of common land in Yorkshire, Monmouth, Sussex, and Glamorgan would be acquired for purposes of water undertakings, and that various London improvement Bills would involve enclosures of portions of Wood Green Common, Eltham Common, and the old Brydewell Burial-ground. It was resolved to communicate with 442 local authorities within whose area rights of way would be interfered with by railway companies, and the solicitor was directed to report upon various Bills which affect common land. Among other matters considered at the meeting were the proposed extension of Hampstead Heath and the Hainault and Lambourne open space scheme. It was stated that the society had, since the last meeting of the committee, secured the re-opening of twelve obstructed rights of way and the restitution of a considerable area of common land.—"The Times."

HAINAULT Forest.—In an urgency report submitted for the approval of the London County Council at its meeting on Tuesday, the Parks and Open Spaces Committee state that they have received and carefully considered a memorial from the Commons and Footpaths Preservation Society, the Kyrle Society, the Metropolitan Public Gardens Association, and the National Trust for Places of Historic Interest or Natural Beauty asking the aid of the Council in securing 803 acres of land at Chigwell Row for the purpose of a public open space. The land is without the County of London, and is on the highest part of the ridge which separates the valley of the River Roding from the valley of the Thames. It is in its highest parts 300ft. above the Thames, and occupies a position commanding magnificent views of the surrounding country. The greater part of it is within a twelve-mile radius of the Bank of England, and is consequently within an easy distance of the East-end suburbs of London. It comprises the last remaining unenclosed portion of the historic Forest of Hainault, formerly part of the ancient Royal Forest of Waltham or Essex, the other part of which is now known as Epping Forest. The price named is £22,000 in round figures, and towards this the Council is asked to subscribe £10,000, that being the amount necessary to complete the purchase-money, it being understood that when acquired the land shall be vested in the Council to be maintained by it in perpetuity as a public open space. The committee point out that for the laying out of the ground when acquired very little expenditure on capital account would be necessary, the only work requisite being the sowing with grass seed the part at present under cultivation. For that a sum of £1,500 would suffice, and they estimated that £500 would be required for adapting the buildings at present on the land for use by the public and the staff. The maintenance charge would not exceed £150 a year.

ROYAL Photographic Society's technical meeting, Tuesday, December 23rd, at 66, Russell Square, at 8 p.m. Mr. C. W. Somerville will read a paper on "The Conversion of the Silver Image of Bromide Prints into Platinum."

Correspondence.

* * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

RED-HANDED PLAGIARISM

To the Editors.

Gentlemen,—Shakespeare says, "Who steals my purse steals trash." Evidently there are, hunting about in photographic circles and amongst its literature, unblushing plagiarists, who, on finding anything written by the more liberal-minded of our leaders, likely to answer to their designs, exultingly exclaim, "Who steals such brains steals cash," so here goes, thus appealing at once to the unwary with no other object than that of putting money into their own purse. Such were my thoughts on reading the paragraph in the current number of the Journal on "Daylight Development."

I well remember that in response to an invitation from Mr. Morgan, the late Mr. Jabez Hughes and myself witnessed a demonstration of the method as detailed in the paragraph alluded to, and at a meeting of the South London Society, held the same evening, Mr. Hughes, authorised, of course, by Mr. Morgan, explained, in his usual lucid manner, the whole operation.—I am, gentlemen, yours truly,

W. COBB.

Rochester House, Granville Street, Wood Green.
December 13th, 1902.

ELECTRICAL ACTINOMETERS.

To the Editors.

Gentlemen,—I see in your last issue that a correspondent is asking for information respecting Riggolot's treatise on electrical actinometers. Anticipating your reply to Mr. F. W. Clifford, he evidently refers to April 12th, 1901, on which date the Journal contained a

letter from me on this subject. The full title of the book is "Recherches Experimentales sur Quelques Actinometres," "Electro-Chimiques." I obtained a copy through Messrs. Williams and Norgate, 14, Henrietta Street, Covent Garden. Your correspondent will find in the lantern supplement of the Journal, April 5th, 1901, page 31, an article by me on this subject, which gives the method of making and using these actinometers.—I remain, yours truly,

JOHN A. RANDALL.

43, Tonsley Hill, Wandsworth, S.W.
December 15th, 1902.

AN APPEAL.

To the Editors.

Gentlemen,—I have an urgent appeal for help in a form which, I believe, can be very easily given, and I trust that you may be able, and willing, to do something personally, and also to invite your readers to assist. The applicant is a professional photographer, who was for very many years in a good position, but who is now close upon three score years and ten, and has been for ten years confined to his bed by a serious and painful illness. In those years the whole of his savings have been dissipated, and he now has to depend entirely upon a small sum received from the Guardians, and the precarious assistance given by a devoted daughter, who earns all she can by rough housework. The case is one which was thoroughly investigated by the Photographers' Benevolent Association, and to which a grant of some few shillings weekly was made for several years—a help which has been sorely missed since the funds of the Benevolent were finally exhausted.

This poor photographer asks that those who have a few spare lantern slides should send them to him, as he can make a few odd half-crowns during each winter by making these slides into little lectures which he lends to local school entertainments, and a few private people giving lantern parties. The subjects are not very important, so long as they are interesting and the slides are pretty good, but it will be a distinct advantage if, in each case, the title is given. Any contributions of slides that may be sent to you or to me I will gladly forward, and since we are already well into the winter, prompt response is important.

Another very charitable act towards the photographer in question would be to supply him with a quantity of reading matter, photographic or otherwise, and, preferably, illustrated. If any of your readers will undertake to send him a used magazine or paper weekly or monthly, I shall be glad to give his name and address for the purpose, but the applicant, while maintaining his interest in photography, has maintained some very proper pride, and prefers that his name (once very well known in the profession) be not published or generally handled about.

Should any of your readers wish to contribute in money towards this case, I shall be pleased to acknowledge, and bank subscriptions, and to remit the money in weekly sums so small as to prevent the withdrawal of the assistance of the Guardians.—Yours faithfully,

H. SNOWDEN WARD.

Effingham House, Arundel Street, Strand, London, W.C.
December 13th, 1902.

[The calls upon our time are so numerous that we cannot possibly give personal attention to this and many similar appeals that are made to us, but we shall be happy to receive contributions in money or kind, and forward them to Mr. Snowden Ward for the case he has so kindly taken in hand.—Eds. B.J.P.]

To the Editors.

Gentlemen,—Will you allow me to thank you for inserting my appeal last week on behalf of an old photographer, named Webber. I have received, in response, 5s. from a Friend in Barry (Glam.), 5s. from Y. E. S., and 1s. from a friend in N. Kensington: total, 11s. I am still hoping that others may feel disposed to help this very deserving old man, who has managed to work to keep himself so far, but now, at the age of eighty, finds himself, through sickness, in the workhouse. We require at least £5 to clear off his debt and give him a clear start when he comes out again. He is getting better and is anxious to get to work.—Again thanking you and the friends who have shown such practical sympathy, believe me, yours truly,

H. C. MESSER.

29, Castle Street, Salisbury.

December 16th, 1902.

A LONELY LADY PHOTOGRAPHER.

To the Editors.

Gentlemen,—Would you mind telling me if any of the clubs and photo societies would be open to having lady members. The reason is this, that I am a professional operator and retoucher (I don't profess

to be very tip top, but I do my best), and I would so much like to be able to gather ideas and information from those who know more than I do. I read, with interest, your weekly paper, and like it very much. The great drawback to me is, that, though I am considered clever at most things that I undertake and have an exceptionally good memory, I have no capacity for figures—that is, that printed explanations of quantities and articles on photographic chemistry, having references in figures, etc., convey no meaning to me at all, and I feel that if I were to mix with others of my profession that I would no doubt get practical illustrations of matters and enlarge my ideas. Do you think it would benefit me to attend classes in chemistry and printing in carbon and bromide? I believe there are such in the town, though I don't know a great deal of it, not being a resident. I hope I am not taking your time up needlessly.—Yours faithfully,

A LADY OPERATOR.

December 15th, 1902.

[By all means let our fair correspondent take advantage of the classes to which she refers. Few photographic societies encourage the attendance of lady members, except on special occasions. The experiment has been made in London several times, but not with success.—Eds. B.J.P.]

"BIBBY'S QUARTERLY."

To the Editors.

Gentlemen,—I am sending you under separate cover a copy of my current "Quarterly." You will see that the recent correspondence in your columns has borne fruit in that I now give photographer's name in all cases, except under pictures taken by our own photographer, Mr. Charles Reid, whose assistance I acknowledge in each number.

I do not know if you would care to notice this number of "Bibby's Quarterly" in your paper, by way of commenting on or criticising the photographs, and the reproduction of same in any way; but if the spirit leads you towards reviewing it in this way I hope you will not quench it, as it always does me good to see what experts think of any portion of my work as editor.—I am, yours faithfully,

J. W. BIBBY.

[With its wealth of phototypic pictures of cattle, pretty portrait and group studies, and discursive literary contents, this well-produced publication should make a pleasant companion for many a country fireside. Far from desiring to "quench" Mr. Bibby's venture, it may rely upon our commendation and encouragement so long as it recognises the right of the professional photographer to exact reasonable payment for his work, and proper recognition of it, whenever it is published.—Eds. B.J.P.]

A BRISTOL PRINTING HOUSE.

To the Editors.

Gentlemen,—I beg to ask your acceptance of the accompanying copy of "A Bristol Printing House," which is published as a chronicle of a building I have reared in this city in homage to the founders of the art of printing, and I have endeavoured in it to bring out of the past names revered in the world of printed literature, and to indicate that our cities and towns might be made beautifully poetic, were England to weave into her everyday architecture thoughts that do honour to men of greatness and symbols that cause the mind to be moved to some chaste and elevating feeling while in the wholesome humdrum of our daily toil.

Following a general survey of the modes of pictorial art is a fragment on "Artisanship," evoked by the regretful fact that England is not in a position to take English money for printing machines (as well as for much other machinery), owing to her loss of prestige in inventions. The criticism is not antagonistic to trade unions, although it seeks to show that if artisans were paid according to merit an era of mechanical progress would supplant the present effete condition of our industries.

If you should do the book the honour of recognition in your Journal I should, as one interested in the general welfare of printing and the craft, be very pleased.—Yours faithfully,

EDWARD EVERARD.

Stock Exchange Official Printer, Broad Street, Bristol.

December 11th, 1902.

[We congratulate Mr. Everard on the production of a most elegant volume, in which photo block printing, in monochrome and three colours, plays a large part.—Eds. B.J.P.]

COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—Some time ago I sent you some lantern slides, in support of my contention and in agreement with Professor Hitchcock, that the coloured rays forming white light impressed themselves, selec-

tively, on the photo plate, and that the selective action was carried on to the print, if only one could find means of developing their action. This subject has been recalled to my memory by finding a print of the same date (viz., 1885), as the lantern slides. This I now send you. Will you not allow that here there is a distinct selective action of blue in the sky, with shades of the same in the top of the glacier, and from the broken ice at foot, in contradistinction to the whiteness of the snow, and the usual brown tone of the rest of the print? Please examine by daylight.

R. O'HARA, Lieut.-Colonel.

West Lodge, Galway.

[Colonel O'Hara's letter and specimen reached us some weeks ago, and were accidentally overlooked. The colour effects in the positive print sent are precisely as our correspondent describes them; but that they are due to "selective" actions, in the sense conveyed by Colonel O'Hara, we are not prepared to admit. An excess of gold in the toning baths, or prolongation of toning, has been known to impart a bluish hue to prints, and this may be the explanation of the phenomena before us. However, we were much interested in seeing the specimen sent by Colonel O'Hara, and are much obliged to him for his courtesy.—Eds. B.J.P.]

WHERE ARE WE DRIFTING?

To the Editors.

Gentlemen,—Although hailing from the "land o' the Leal," it is difficult to recognise the canny Scot in your correspondent, Mr. Wm. Ralston, whose rashness places him at such a disadvantage, but I will be merciful and administer his dose of gruel as gently as possible, hoping that he will take it without a wry face. It is natural that Mr. Ralston should hasten to the aid of poor "Side Light," being himself a victim of the same illusions, but if he wishes his support to be of any value he must mind his p's and q's, and not vent his anathema before he has well considered the matter in debate. It is easy for him to condemn as utter rubbish anything which he may not like or understand; but he must show upon what grounds he bases his statements and opinions before any weight can attach to them.

I will not here defend the truth of my sentence that "without top light all power of concentration is lost," as that must be self evident to all who understand it. But I must disabuse your correspondent's mind of the impression that I speak from theory, having had a lifetime experience in photography and art, dating back to the days of wet plates.

When Mr. Ralston speaks of my letters as "wonderful reading," he unconsciously gives me my due, and reveals the reason of his hastily formed opinions of them, and the writer for "Wonder," according to the great Dr. Johnson, is the effect produced by novelty upon ignorance, and without wishing to impute the latter to Mr. Ralston, I will accept the former as an acknowledgment of the originality of my matter. The statement that the work he does with the side light is equal to the work he formerly did in his studio may be quite true and yet mean nothing, but I cannot quite believe that he finds no difference in the exposure. In the group of fifteen persons he mentions the lens would require stopping down to give the best result, and that with such a small area of light as could be obtained from a single window must mean an exposure of unusual length. He raises a smile when speaking of his extensive acquaintance with portrait painters, who never used a top light, by stating that they had no top light to use. Like Myn-Heer Van Dunk, who never got drunk, except when his liquor was handy.

He will find, on the contrary, that in all the masterpieces of portrait art, the dominant light comes from above, falling at an angle of about 45 degrees, and although this angle of light may be obtained from a high window, it is insufficient in quantity for the making of a perfect negative.

That the artistic merit of the picture should depend upon the man behind the camera goes without saying, and if Mr. Ralston had read my letters with more attention he would not have jumped at the conclusion that I either forgot or did not know this fact.—Yours, etc.,

MICHAEL E. BANGER.

December 14th, 1902.

To the Editors.

Gentlemen,—I must thank Mr. Kenah for his courteous reminder, and tender my sincere apology for having in any way misunderstood his meaning. He did not, perhaps, realise that his paper was written slightly over the heads of those who may be less fortunate than himself.—I am, gentlemen, yours truly,

MICHAEL E. BANGER.

December 14th, 1902.

To the Editors.

Gentlemen,—I have read carefully the last three letters about "Where are we Drifting?" signed by Wm. Ralston, O. V. Kenah, and M. E. Banger, and I must confess that from these gentlemanly

writings I am totally unable to understand which is the best—top light or side light, both or none. The principal result seems, so far, to be that one calls the other stupid, and is gratified in turn by being called ignorant. These words and sentences, however beautifully arranged, are no proof whatever of the value of one over the other. Why do these gentlemen, instead of this war of words, not give us a lengthy course, explaining their methods of working in the BRITISH JOURNAL OF PHOTOGRAPHY, with illustrations, if possible, and let us judge of the real value of their ideas and work. Voilà qui vaudrait mieux.—Yours very truly,

ALBERT LEVY.

Asnières (Seine),

December 13th, 1902.

To the Editors.

Gentlemen,—Mr. Banger appears to have abstracted a good deal of amusement from my letter of the 1st inst., so I must congratulate myself on having caused one ray of sunshine to enter his vexed and saddened life.

I sent the samples, specimens, patterns, or whatever he cares to call them, merely as a means of convincing him that a dozen or so styles of natural lighting could be obtained with a very small side light. I still term him narrow-minded, as he gives me the impression that the studio with a skylight, top light, or window in the roof is the only place where a natural portrait can be taken. It is an entire waste of valuable space, jangling about such a simple matter, as anyone who has studied beyond the limits of a sixpenny handbook, will know that natural and artistic portraits can be obtained almost under any conditions of light. If he would spend a little more time practising photography instead of "breaking lances" with "champions of error," he would not be so "ignorant of its possibilities." I have never held a situation behind a counter selling roof windows.

SIDE LIGHT

December 15th, 1902.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

J. C. Laird, 246, Union Street, Aberdeen. Photograph of Miss M. Hill.

C. Parkin, 31, Station Road, Chapeltown, near Sheffield. Photograph of Chapeltown Parish Church.

WALTER SMITH.—Your query seems to be a repetition of the one we answered for you last week.

MAKING PHOTOGRAPH COPYRIGHT.—CHAPELTOWN asks: "Will you please inform me what is the cost of making a photo copyright, and will you please do it?"—If you send us two copies of the photograph and 1s. 6d. in stamps, we will make the picture copyright for you.

CLOUD EFFECTS.—X. Y. Z. asks: "Will you please inform me what is the best to get cloud effects on bromide opals, and how to use it."—In reply: We do not understand this query. We must ask our correspondent to be a little more explicit.

R. K. H. MATHERS.—We have read through your long letter, but we cannot publish it as it would be of no interest to our readers. It seems to be a dispute between you and the parties to whom you gave the order, about a few pence for carriage. Why not communicate with them instead of with us? We know nothing of the matter.

MATTOS PAPER.—"In the JOURNAL, on page 958, there is an article on a new printing-out paper called 'Mattos.' Can you tell me where I can get the paper, or the address of the inventor, Mr. Tauxe?"—In reply: The address is The Mattos Photo-Chemical Company, care of P. Leuthart, 33, Rydal Gardens, Streatham, S.W.

OPAL ENLARGEMENTS.—OPAL asks: "Would you kindly instruct me how to coat and sensitise opal glass for making enlargements on by artificial light."—In reply: The space in this column is far too limited to give such detailed instructions in preparing opal plates for enlarging upon as would be of practical use. We recommend our correspondent to obtain Abney's book on "Photography with Emulsions."

ADDRESS WANTED.—ALFRED UNDERHILL writes: "I read an article on 'The Stereoscope in the Schoolroom,' reprinted from 'The Stereoscopic Photograph,' and as I have never heard of this publication, I shall be glad to know where and when it is published, and also

the price."—In reply: It is published by Messrs. Underwood and Underwood, Heddou Street, Regent Street, London. Price we do not know.

PHOTOGRAPHS ON WATCH CASE.—INQUIRER says: "I should be pleased if you would tell me the best process for printing photographs on the inside of a watch case. Is it done by the carbon double transfer process, and if so, would the case want specially preparing if used as final support? I should be pleased if you would help me with this."—In reply: Full working details of the method of producing photographs on jewellery were given in our issue for July 19th last year, to which we must refer our correspondent, as they are much too long to repeat in this column.

BLINDS, ETC.—LEODIS asks: "Can you give me the title and publisher of any publication that will assist me in the erection of blinds in a studio? Any information as to class of material, method of erection, and arrangement to get the various methods of lighting will be welcome."—In reply: Without knowing the form of the studio and its aspect we cannot advise, as so much depends upon conditions. If you will get the two books recommended to "Rembrandt" they will give you every information on the subject. If you fail to get the JOURNAL on Fridays our publishers will post it so that you will receive it on Friday mornings.

QUERY RE GLYCERINE.—C. W. RIVAZ asks: "Can you tell me if the fact of giving carbon prints a bath in a weak solution of glycerine (1 dr. to 5 oz. water) can possibly affect their permanence. I use this only for single transfer prints to prevent curling and crinkling when drying? If it does harm them, can you tell me any other way to keep them flat? The same question also applies to bromide papers."—We see no objection to the use of glycerine with carbon pictures, but is it necessary to use it? If they are rolled they should keep flat. With regard to bromide prints we should prefer not to employ it. They are best kept as dry as possible, and glycerine is attractive of moisture.

STEREOSCOPIC PHOTOGRAPHY.—W. B. HOSSACK writes: "In the 'British Journal Photographic Annual' of 1895, the then editor, in his second chapter on 'By-paths of Stereoscopic Photography,' mentions as having in his possession the line drawings and lithographs of statuary which Brewster used in 1849 when he exhibited his stereoscope to the British Association. As I have to give a paper on stereoscopic photography in February next year, I thought it would be interesting to show these, and I took the liberty of writing you, in the hope that you would be able to inform me if photo copies of these were to be had, and if so, where?"—In reply: Mr. Traill Taylor has been dead some years, and the whereabouts of the pictures referred to are unknown to us. Will this and other correspondents kindly note that we do not undertake to answer questions through the post?

BLUE PRINTS.—J. HOUGHTON writes: "Some few years ago, perhaps five or six years, there were some letters in the JOURNAL on 'Blue Printing,' and an electric apparatus was illustrated and described. I also think there was an article on this class of work; and I remember there was at one time a description with illustrations of some very large blue printing establishment. Can you oblige me with the dates these letters and articles appeared? as I cannot put my hands on the indexes of these last few volumes of the JOURNAL."—In reply: The series of articles on the iron processes, to which, no doubt, our correspondent refers, appeared in our volume for 1899, and were reprinted in the "Almanac" for 1900. The electric light apparatus referred to is manufactured by Messrs. B. J. Hale and Co., 39, Victoria Street, S.W., who will supply a prospectus of it on application. The same firm also do blue printing on a large scale.

REDUCING NEGATIVES.—R. MARLOTH writes: "Kindly explain the following difficulty:—For reducing negatives which are too dense in the high light only, but should not lose anything in the shadows, the ferricyanide methods cannot be employed, while a treatment with ammonium persulphate would leave the shadows untouched. I find, however, that my negatives do not take the reducer evenly, but that patches are caused which spoil the negatives. I thought at first that the alum bath might have acted unevenly, but found the same trouble with plates that had not been treated with alum. Then I thought traces of hypo might be the cause, and soaked the negative in running water for twelve hours, without getting better results. What may be the cause of the mischief? The method is certainly a very valuable one if it would work properly."—In reply: We cannot explain the cause of the stains, as we have never met with any when using the persulphate of ammonia reducer. The only suggestion we can make is that the negatives were not thoroughly fixed in the first instance. We should advise a longer time in the fixing bath.

COPYRIGHT QUERY.—H. BROWN says: "Last month I had a group of one officer and 49 non-commissioned officers copyrighted, and you did the business for me, and the notice of registration appeared in your journal of the 28th ult. I now find out that the 49 non-commissioned officers have had an enlargement done from one of the said groups, and presented it to the officer in the group, who has recently left the regiment. I had an interview with one of the principal n.c.o.'s who saw to this business, and warned him that I had made the group a copyright, in fact, it is printed on the mounts. He pooh-pooched the idea, and said we could only copyright the negative, and I never asked their permission to copyright it, therefore they could have enlargements done from it if they liked. Please inform me through the JOURNAL if I should have asked their permission; also, if I felt inclined to go further

into the matter, should I have to proceed against the n.c.o.'s, or against the person who enlarged it? If they would not say who did it, how should I proceed then?"—In reply: If you were paid for taking the group you have no copyright in it. If you were not, the copyright is vested in you, and you can obtain redress for its infringement. You can proceed against those who had the enlargement made, or against those who made it, or both.

GLAZING PRINTS.—GLAZING writes: "I note an answer to my query, and am sorry you do not understand my question, and I cannot see through your answer; but I will tell you what I want plainer. I am a professional, and want to know how to glaze prints professionally, that is to say, not a few at a time, but perhaps 100 or 150, and therefore a practical way of glazing prints, or, rather, producing glazed prints that can be mounted with glue at the edges, cotton wool in the middle, and go through embossing. I can do it one way, but what I want to know is, how to get the paper stuck on the back of the prints, so that they will be thicker (enough not to buckle when finished). I find that by using French chalk, and then pasting a piece of paper over the back of prints already on the glass, that when dry the paper simply sticks to the glass where there are no prints, and you cannot get the prints off satisfactorily. I say that I have heard of a spirit that is poured on the glass, then the prints put on the spirit, flooded, then the starched paper, and when dry all come off together. Kindly explain to me your method, or give me the name of liquid. The one you said, I noticed, you had to rub off dry again."—In reply: We know of no "spirit" that will do as you say. Large quantities of prints are enamelled in the same way as small quantities are done, except that two or more prints are usually put on one large plate instead of single prints on smaller ones. If the prints stick, it is because the plates are not properly prepared for stripping from. Try using paper a trifle smaller than the print, if the margins of it stick to the plate; also use a thicker paper for the backing.

SHABBY TREATMENT.—OPERATOR writes: "I should be glad to have your opinion and advice. I send you the following facts, which may be a warning to others. In July, a lady called at my studio, making an appointment for a sitting for her little child. No cabinets were required, only proofs, as it was for a 15 by 12 enlargement, and would I mind taking several positions. When the child arrived, her mother also brought a 5 by 4 hand camera with her, and just before I exposed my plates asked to be allowed to do the same, 'just for fun, you know.' While I was changing plates, etc., this good lady exposed several more of her own plates. After the proofs were sent home I heard no more until proofs were returned, not approved of; the child would sit again. However, the months have rolled past, and chancing to be in the same town last week as this lady resides, I was asked in to see some work an amateur had done for her, and to my surprise, on the wall hung an enlargement from one of the negatives taken at the sitting, executed by a trade enlarger from her own negative, as she liked the expression of her darling in her own negative better. I spent the best part of an hour in a busy part of the year using all my ability and the best of my knowledge, to be practically swindled out of my picture in this way; and as proofs were returned not approved of, and no chance has since been allowed me to take her again, I have nothing to claim for; and I have since found out many of the lady's friends and relatives have 5 by 4 photos of this same sitting. The lady thinks I have no cause for a grievance."—In reply: This is certainly very shabby treatment. But our correspondent did unwisely in allowing the lady to use her camera in his studio. We fear that now he has no redress, for, as the proofs were returned as not approved of, we do not think he could recover if he were to sue in the County Court for taking the child's portrait.

**** NOTICE TO THE TRADE, WHOLESALE AGENTS AND BOOKSELLERS.**—A Contents Bill is issued with each number of the JOURNAL, and copies may be had on application to the Publishers.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied as to what appears in the text portion of the paper.

EX CATHEDRA.

An Exhibition to be seen. If there be any serious desire among those photographers who clamour for admittance of their work into the magic circle of Art, there is at present open for inspection in the rooms of the Fine Art Society, Bond Street, London, a small collection of charcoal drawings which should teach them several lessons—what to attempt, what to avoid, and how to carry through both attempts, negative and positive. No finer object lesson need be sought by any earnest photographer than to spend an hour or two among the half-hundred sketches in charcoal now on exhibition at the above galleries. Here may be seen just such subjects as come within the capability of a camera to reproduce, when guided by those content to look nature in the face and treat it as some beings are wont to—natural subjects, dealt with in natural fashion. To such, Mr. Hopwood's pictures appeal, as being the interpretations of a sound healthy mind, content to present humanity as humanity, and not as bad imitations of imaginary Missing Links. If some of our Gum Bichromate friends, and a few of those discontented dabblers who are ever bewailing our pictorial stagnation, would pay a visit to the Fine Art Society's rooms just now, they might, perhaps, each find food for reflection, in examining how sunshine may be rendered with no further means than a little black substance properly placed on a sheet of white paper, and how the real artist is content to observe the limitations of whatever medium is for the moment being employed. Such

and other similar messages might they find, which, if observed, would doubtless prove useful when next preparing their gems for Piccadilly or Regent Street. Mr. Hopwood's sketches, for they pretend to be little further, are a feast to those capable of appreciating wholesome work, and, whatever the subject which has attracted his attention and skill, there has been a problem to solve, either of expression, motion, or fanciful play of light. Colour, which stands above and before all in an artist's mind, will be found wonderfully suggested in some of these pictures, although colour is entirely absent; indeed, so cleverly is the feeling of that rich, full colour his ordinary paintings are distinguished by, suggested, that only on passing out into the damp, gas-lit streets is it realised that they are only sketches, made with charred wood on white paper.

Lady Photographers. An article in a recent number of the "Art Journal," entitled "A Note on some Lady Photographers, with Selected Examples of their Art," by Mr. Fred Miller, is well worth reading by professional portrait photographers. Several pleasing reproductions from photographs depicting various styles of portrait work accompany the letterpress. In the course of his article, the author writes:—"While it is perfectly true that a negative does faithfully record the image before the lens, it by no means follows that what is developed is characteristic of the sitter, and that is after all what we mean by a likeness," a truism which must never be lost sight of by photographers who wish to please their clients and their friends. Whether photographers will agree with all the dicta of the author of the article referred to, depends very much as to which "school" they adhere to. He does not admire many of the exhibits at the Salon; he thinks to make a photograph look like a bad chalk drawing, or a poor one in sepia, is to bring the art into contempt. "Too many show photographers seem to wish to hide themselves beneath a sham pictorialness." The limitations of photography, the importance of effective posing and lighting are dealt with. "Much material is wasted in endeavouring to do the impossible in photography," he says. "A good deal of 'retouching' is not defensible, for it is nothing more than bad drawing," is another remark. He is not an admirer of genre studies. Referring to printing methods he says:—"The shining printing out paper which brings out everything in the negative is never used by artistic photographers, though in the provinces it appears to be the most popular medium," which certainly is open to question. Enough has been given to show the tenour of the author's remarks. Mr. Miller is an artist of some ability, and he has contributed several articles to

various journals, on art subjects. Latterly, he has given some attention to the practice of photography. A similar article to that referred to, by the same author, appeared in a ladies' monthly paper recently.

A Photographer's Paradise.

Sir Harry Johnston, G.C.M.G., K.C.B., in his notable piece of bookmaking, "The Uganda Protectorate," deals with that remarkable country in all its aspects. Sir Harry, as our readers are probably aware, was formerly Special Commissioner to the Uganda Protectorate. Besides being an able administrator, he is a man of wide knowledge, a clever artist, and a photographer of considerable ability; qualifications which he puts to good account in the book referred to, which is illustrated by means of a large number of reproductions from photographs taken by the author and others, including Mr. W. G. Doggett, who accompanied Sir Harry Johnston as a taxidermist and photographer. There are several striking coloured illustrations by the author of the book, depicting the curious animals, etc., peculiar to the country. Several of the photographs are remarkable. That by Mr. Doggett depicting "Andorobo drinking as primitive man drank," is extremely interesting. Another valuable photograph, though not very pleasant to our more fastidious tastes, depicts Andorobo devouring a dead waterbuck raw. And they seem to be enjoying it. The author, referring to the Andorobo, writes:—"Amongst the dense forests, the game-haunted wildernesses, and unfrequented plateau wanders a mongrel nomad race, the Andorobo, who represent a mixture of Nandi, Massai, and some antecedent Negro race of dwarfish, Bushman stock. These Andorobo reproduce in a most striking manner the life which we may suppose to have been led by our far-away ancestors or predecessors in the earliest Stone Age. They live entirely by the chase, often consuming the flesh of birds and beasts uncooked." Most of the photographic illustrations in the book are of the "record" type rather than the artistic, though many of them are both. Uganda might very well be described as a photographer's paradise. The landscape photographer, the animal photographer, and the bird photographer would each find full scope for the exercise of their pursuits. On Lake Hannington there are many thousands of flamingoes. Storks are common. There are many curious birds and beasts, including the Okapi, which the camera worker would desire to study photographically. The foliage and the mountain scenery in the district are both very beautiful. Unfortunately, Uganda is rather a long way off; it is not likely to be made the holiday haunt of the cheap tripper. But if we cannot go to Uganda we can read about it; and a more interesting book of its sort than that here briefly referred to, it would be difficult to conceive. Uganda is a country of very considerable possibilities, and Sir Harry Johnston, who tells us all about it, is hopeful concerning its future. Sir Harry might be induced to give a lecture at the Camera Club.

A Caution to Purchasers of Second-hand Apparatus.

We have recently received two or three letters from correspondents who have been victimised by a man dating from Ipswich. In each case they have sent cash, but have not received the apparatus. One of the writers encloses a letter he has received from the Chief Constable of the town, to whom he wrote on the matter. The letter is as follows:—"Re ——. In reply to your letter of the 10th inst. relative to the above, I would inform you that we do not at present hold a warrant for his apprehension, but I have informed other

persons who have been victimised, as also I do you, that they had better communicate with their local police ———'s present address is unknown." We should recommend all who have been fleeced to act on this advice without delay. One of our correspondents tells us that the communication he received was on a regular printed memorandum form, the man describing himself as a "photographic artist" and "trade photographer." This he says he thinks was got up for the occasion, as the man was only in the town for about a fortnight. It was, no doubt, this printed "memo heading" that inspired confidence and induced our correspondents to part with their money. We would once again caution our readers, in no case, when replying to advertisements, to part either with their cash or their apparatus, until they have some assurance of the bona fides of those with whom they are dealing. The correspondence being on the orthodox memorandum head, as in this case, goes for nothing.

Varnishes and Photographers who do not varnish their Varnishing.

negatives often have them completely ruined by silver stains that might have been avoided had they taken the trouble to varnish them. The trouble is but slight, and it is a matter of surprise that so many neglect this very simple work. It cannot be on account of cost, as a shilling bottle of varnish is sufficient for some scores of, say, quarter-plate negatives; or the varnish may be made by oneself, when it will cost less than the article purchased. It is not, we suspect, the cost of the varnish that deters its use so much as the little trouble involved in its application. Some amateurs complain that they cannot get varnish to flow evenly over the plate, and that they get as much on the back as they do on the film. When collodion processes were in vogue all negatives had perforce to be varnished before they were printed from, and amateurs could do it then, and why not now? It is quite true that a spirit varnish takes a little easier to the collodion film than it does to one of gelatine, but the difference is but slight. The difficulties which novices meet with in varnishing gelatine negatives may be attributed to one or two causes, the principal one being making the negative too hot before the varnish is poured on. When the film is very warm the varnish does not take so kindly to it as when it is cooler. The negative should be made thoroughly dry and warm before the fire, and then allowed to become nearly cold. The varnish is then poured on, flowed over, and then drained off into the bottle. After draining, the plate is held in front of the fire until it becomes quite hot. The varnish may even be applied to a quite cold plate, if that be warmed directly it is drained off, without fear of its chilling. The chief difficulty that novices meet with arises from their making the negatives too hot before the varnish is applied, though this seems not to be generally recognised by them. As to the varnish to be employed. All the varnishes now on the market are good, and we prefer those with a shellac, or celluloid, base as being the most durable. Sandarac also makes a good varnish, but the surface is more friable than shellac, but it has the advantage that it can be easily rubbed up for retouching upon. All formulæ for negative varnishes given in the ALMANAC can be relied upon by those who wish to make their own. The dammar varnish, that used to be employed for glass positives, is good for gelatine negatives, and it has the advantage that it can be applied cold, but it will not bear the rough usage that other varnishes will. It is made by simply dissolving dammar resin in benzol to the consistence desired. Thirty grains to the ounce is a good proportion with most samples of dammar.

Infringement of Copyright and Damages. The case reported in our issue of the 12th inst. is of special interest to those who so frequently complain of their copyright being infringed, as it shows that they can obtain substantial redress for the injury done. In the case referred to, the plaintiff recovered the sum of twenty pounds by way of damages, and another five pounds by way of penalties, with costs. The Judge also granted an injunction against the defendants, restraining them from dealing with the copies in their possession, and from producing further copies, and ordering all copies at present in their hands to be delivered up to the plaintiff. We call special attention to this case as it illustrates that photographers' rights cannot be infringed with impunity. Of course the photographer here had taken care to register his copyright, but that is what so many neglect to do before they let any prints go out of their possession. Registration does not cover prints issued before it was effected, and it is such prints that are frequently copied. Then the photographer has no remedy. We take this occasion again to caution our readers not to let any prints leave their hands until the copyright in the picture has been duly registered. When that is done there will be no question as to the recovery of damages for its infringement. Of course we are assuming that the photographer is really entitled to the copyright in the picture, which he is not if he was not paid for taking it.

PORTRAITS TAKEN IN THE STUDIO UNDER WINTRY ASPECTS.

IN these pages at times we have alluded to the inconvenience that winter brings to photographers, and indicated how some, at least, of them may be averted by a few timely precautions. We shall here make a suggestion or two that may be useful as hints to portraitists as to how they may possibly reap some commercial advantage out of a proverbial "good old-fashioned winter," should we happen to have one, as some weather prophets are bold enough to predict we shall, though personally we do not place much reliance on weather forecasts made some months in advance. We have already had a couple of severe cold snaps, and there is the possibility that we may have a longer and colder winter than we have had during the past few years. Severe weather usually brings stagnation to the business of portrait photographers, but these hints, if acted upon, may serve with some to give it a stimulant rather than otherwise.

Just now furs are very much in fashion, alike with ladies and gentlemen, and the former usually like to have their portraits in their latest costumes, whatever they may be. Now portraits of ladies clad in heavy furs make excellent and in most instances flattering pictures, but they are, unfortunately, too often marred by being taken with quite unsuitable backgrounds and surroundings—i.e., they do not accord with the dress. Only the other day we saw the portrait of a lady clad in apparently costly furs posed before an outdoor background that was highly suggestive of a bright summer scene, and the effect was anything but congruous—as might well be surmised. The background was really more suitable to a sitter in a muslin dress than one in heavy winter attire. Had the background depicted a winter scene, say a landscape with an indication of snow or winter, the whole thing would have been in unison, while as it was it was just the reverse.

Few photographers, we are aware, have backgrounds suggestive of winter scenes. The case is different in countries where a prolonged winter every year is general—Canada, America, and Russia, to wit. In such countries provision is made for taking portraits under seasonable aspects. We have before us a portrait sent by a correspondent in which the lady is clad in heavy winter clothing—furs being strongly in evidence—with a background representing a snowy scene, and, to add to the effect, snow is represented as falling on and around the figure. Our correspondent desires to know how to produce similar pictures. Such pictures as this are, or were, very general during the winter season in such countries as those just referred to, and have also been produced in this country, but only to a limited extent; though we have little doubt they would meet with a good demand here in the event of our having a long winter, and possibly one may be near at hand. Be that as it may, there is no reason why enterprising portraitists, who are on the look out for novelties, should not provide themselves with the means of making this class of picture, for to many they would be a novelty in this country.

We are not sure that winter backgrounds—that is such as represent snow scenes—are things of commerce here, but that is really of little moment, as almost any outdoor one may be readily converted into a snow-clad one. All that has to be done is to take a piece of chalk or a white crayon, and go over with it the upper sides of the branches of trees, twigs, buildings, or the like, or any parts where it may be imagined that snow would have settled or drifted, and the background is complete. If it is one in flatted oil the chalk can at any time be wiped off and the background restored to its original condition. Some outdoor accessories will also be required, such as a balustrade or steps, or similar properties. These should have some common white wadding laid on them, slightly overlapping, to convey the idea of having received a fall or drift of snow. And, to complete the effect, some sheets of wadding should be laid on the floor, which will give the appearance of a snow-clad ground. In this way, with a little ingenuity and judgment, a thoroughly wintry background can be extemporised, and with little or no expenditure and trouble.

In the picture before us snow is represented as falling thickly on and around the figure, and it is how to produce this effect that the sender desires information upon. It is obtained by spraying or splashing the negative over with an opaque colour. The most effective way is to just touch the ends of the bristles, say of a toothbrush, in the pigment—tube colour thinned with gum water, for example—and then to draw the back of a knife across them, so as to fleck the colour off, the face of the sitter having been protected with a mask of paper. The negative should be previously varnished, as then, if the result is not satisfactory at the first essay, the colour can be wholly or partly wiped off and redone. This could not be successfully done with an unvarnished negative. All the pictures of this description that we have seen have shown the snow as falling everywhere except just before the sitter's face. This looks incongruous enough, but, of course, the portrait is the principal desideratum. All incongruity may, however be avoided, and yet the face be clear, by getting the sitter to hold a small "property" umbrella lightly covered with wadding (stitched on). Everyone is supposed to use an umbrella out of doors when it is snowing, and this may be held in such a position as would protect the face if snow were actually falling. In this way the face will be unobscured and incongruity avoided. When the negative has been varnished in the first instance the splashes of

colour can be wiped off from the portions supposed to be protected, by the umbrella, so as to show the upper portions of the costume to the best advantage, yet still in unison with the other parts of the picture.

The best pigment to employ for producing the supposed falling snowflakes is Chinese white, as with that the effect on the negative will be better seen than when a darker colour is used. A few specimens of portraits in this style in show-cases at this season of the year would at least be attractive as well as a novelty to many in this country.

ON THE USES OF FORMALINE.

ON the first occasion of this chemical being mentioned in a scientific paper (a German periodical, dealing, *inter alia*, with microscopical matters), we ventured to predict a very important place for it in photographic chemistry. To a certain extent our expectations have been fulfilled, but not so much as we anticipated. It may be remembered by some of our readers that the hardening, when dry, of the gelatine used in micro-slide mounting was the subject of the recommendation we refer to; but no mention was then made of the fact that such use was patented. The comparatively limited employment of this substance we take to be mainly due to two causes—firstly, that, at the outset, many erroneous statements about its use were made, and secondly, to the circumstance that prominence has been given to the fact that its use for most photographic purposes is patented. But as regards the latter there need be not the slightest difficulty; the mere purchase of a bottle of this liquid (of Schering's make) confers on the purchaser the right to use that bottleful for hardening gelatine films and the like. So that the only possibility of objection lies on the need to make use of a particular maker's preparation; but, as that is of unsurpassed quality, no trouble need arise. We do not doubt that many people are unaware of the existence of patent rights in this direction; but they do exist, and we cannot but think that their existence is one cause, as we suggest, of the non-use of this valuable agent.

With regard to erroneous ideas as to its use, we more particularly refer to the recommendation to wash a negative well before fixing when formaline has been added to the developer to prevent frilling, as the formaline, it was said, would cause a precipitate of the silver dissolved by the hypo. Nothing could be further from the truth, as a simple experiment—which anyone could make—would prove. Let a small quantity of hypo solution, which has been used for fixing a number of plates have added to it a drachm or two of strong formaline: the liquid remains perfectly clear and shows no signs of precipitation—it follows, therefore, that, even if a plate were taken straight from the developer (to which formaline had been added) into the hypo, it would be uninjured. We would point out what a valuable property this is. Fortunately, frilling is far less common than was once the case, though certain makers recommend the use of alum before fixing under all circumstances, thus entailing extra labour and loss of time—a great objection nowadays, when rapidity of treatment is a particular requirement of amateur and professional alike. Yet under abnormal conditions of treatment, temperature, and climate, the best of plates may frill, and a simple and expeditious remedy should be valuable. If five

or six drops of formaline to the ounce of developer be added, the best remedy possible will be tried, and few are the cases where the remedy will not be found absolute. Formaline—solution of formic aldehyde—is of itself a reducer, so that no fear need be felt that the reducing action of the developer will be interfered with, save on the one ground of the tanning of the film preventing the penetration of the developer, as this in practice will not be found to take place. It is true that complaints have been made that in formaline-treated negatives the films have become so contracted that when dry they split away from the support; we can only say that in our own practice, keeping the strength low, no such contretemps has occurred, though we have so treated a large number of negatives.

Messrs. Lumière have shown that the ketones, with the aid of sulphite, are a sufficient addition to pyro, etc., to form complete developers, and looking upon formaline as a ketone it might be expected to act in this manner. It will do so. A solution of pyro, formaline, and sulphite of soda will develop a plate which, when fixed, may be dipped (after a slight washing) in boiling water without injury. This experiment suggests a reminder to our readers of the value of formaline in hastening the drying of a negative, a purpose for which it is in some respects superior to soaking in methylated spirit; for the latter, as is well known, is very liable to produce a milky deposit between film and plate when heat is applied to expedite matters. No such untoward end need be feared with the use of formaline. Before leaving this aspect of our subject we may say it has been suggested to us that plates known to be liable to frill might be rendered proof against the tendency by exposure, when dry, to the fumes of formaline.

We have lately put this action of tanning, or drying gelatine to a novel use. An accident having occurred to a large and rather costly glass measure—a piece knocked off the upper part—we cemented it with fish glue, and, after allowing it a week to dry, we placed a drachm or two of formaline, full strength, at the bottom of the glass and placed it in an air-tight cupboard for a few days, and now have it in regular use without, so far, showing any signs of separating at the junction. So long as it is not allowed to remain standing filled up with water we have no reason to apprehend its being in any way inferior to a perfectly new measure. In conclusion we may remind our readers that the action of formaline is not confined to dead matter. Quite apart from the fact that as a germicide it is almost unequalled, a property of slight photographic interest, it is capable of acting upon living human tissues, and hence care should be taken to avoid the inhalation of its odour, or allowing it to act upon the nostrils or the eyes, which would produce sensations the opposite of pleasant.

At the Halifax Camera Club Studio on Monday, December 15th, Mr. C. B. Howdill, A.R.I.B.A. (President of the Leeds Camera Club), gave a lecture and demonstration on the subject of "Natural Colour Photography." Tracing the progress of colour work as applied to lantern slides, Mr. Howdill gave a most interesting account of the process. The Sanger Shepherd process (of which Mr. Howdill is an able exponent) was explained and illustrated by means of many varied and beautiful examples passed through the lantern. A prism was utilised to show the parts of the spectrum cut off by the colour screens, proving that the plates most acceptable were those for which the respective screens were adjusted. Some very beautiful slides were shown of stained glass, obtained with the aid of the telephoto lens, a combination of telephotography and colour work which has been rarely attempted. The juxtaposition of red and green lines on the wings of a butterfly shown on the screen drew an explanation from the lecturer that a proper mixture of red and green light produced the effect of yellow in the retina. The richness of colour in another example, "The Jewish Bride" (Rembrandt), refutes the popular belief that the depth and quality of colour in "old masters" cannot be reproduced. Landscapes, architecture, fruit, flowers, and natural history subjects were shown, and Mr. Howdill's visit will long be remembered by those who had the privilege to hear him.

SOME ASPECTS OF PHOTOGRAPHIC DEVELOPMENT.

[A Paper read before the Society of Arts, and reprinted from its "Journal."]

DEVELOPMENT is the process of reducing those particles of silver salt which have been affected by light, to the black or metallic condition.

A finished negative consists of a contrast—or series of contrasts—between tones or densities. If the contrast obtained by reducing all the light-affected particles were always correct, the process of development would be simple and purely mechanical; for after devising a developer which did not attack the unaffected particles of silver salt, it would only be necessary to leave the exposed plate a sufficient time in the developer for it to do all its work, any longer time having no further action.

But practical photographers have long found out that with most plates and subjects a maximum amount of development, as above described, is injurious, and does not give the desired result, as the contrast between the tones is greater than represents the original object. A certain amount of judgment has therefore been necessary in deciding how far this reducing—or developing—action should be allowed to proceed. I must point out that this judgment or control has been—in the past—exercised in quite a different way from what I have indicated, and, as I shall try to point out, in a way the complications of which were quite unnecessary.

Instead of the photographer keeping the composition of his developer fixed, and controlling results by the time he allows it to act, he has been in the habit of keeping to his own time of development (varying, perhaps, only for temperature), and altering the composition of the developer to get greater or less contrast, or, to put it in another way, to get greater detail in one case, or greater density in another case. The photographer also has got into the habit of considering that he possesses the power (by altering the composition of developer) of doing more work either on the upper tones (adding density), or, in another case, on the lower tones (bringing up detail), whereas, in nine cases out of ten, he has merely attained a result identical with what he would have got with an unaltered developer acting for a certain time. This older point of view is partly a legacy from wet collodion development, where the presence of free silver nitrate in the developer actually built up the high light deposits in the negative, and partly arises from the use of an imperfect alkali (ammonia) in early dry-plate development. For the volatile nature of ammonia often made it necessary to add more of the alkali during the progress of development, and its tendency to fogging often made the addition of a restraining bromide necessary. These two procedures (adding more alkali to stimulate development, and adding bromide to restrain fog), both due to an imperfect alkali, have been continued when the use of a fixed alkali makes either of them unnecessary, and mysterious advantages have been attributed to them. In short, the development procedure of a few years ago resembled the medical knowledge of the eighteenth century, being built up on fads and formulæ, with no guiding principles to direct it.

It was the memorable paper of Messrs. Hurter and Driffield ("Journal Soc. Chem. Industry," May, 1890) which pulled the complacent practical photographer up with a jerk, and showed that his ideas on development would have to be re-constructed. The writers impressed on a strip of plate a series of exposures increasing in geometrical ratio, thus:—1, 2, 4, 8, 16, etc., and investigated the effect of alterations in the developer. They found that the results of alterations consisted chiefly in variations of steepness of gradation (or contrast between the tones) attained, but that this was mainly a question of time, for all the developers (given sufficient bulk and activity) were capable of attaining the maximum steepness, or amount of contrast if sufficient time to act were allowed. They named the degree of steepness or contrast the development factor, but it

was a weak point that the development factor was merely a record of a result attained, and not a help towards the attainment of the same result another time.

In the later paper by the same authors, published in the "Photographic Journal," January, 1898, and following months, a most important light was thrown upon the action of a bromide as a restrainer, and the great differences between the results obtained by different experiments (especially as regards the speed of a plate) were traced to the peculiar action of a bromide in the developer.

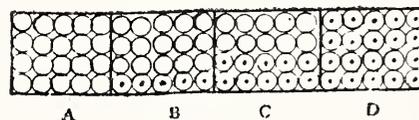

I shall not attempt in this paper to follow up the many proofs furnished by Messrs. Hurter and Driffield, but shall outline my own interpretation of the simple principles of development, using some illustrations borrowed from my recently-published manual on the subject, and shall pass on to some points arising from my own trials and investigations.

SIMPLE PROGRESS OF DEVELOPMENT.

I throw on the screen a strip of plate which has received an increasing series of exposures in steps, from 1-16th sec. to 512 secs. Incidentally this also shows the limits of the plate, for it will be seen that 64 is the maximum effective exposure, anything more than this having no increased action on the plate, while 1-16th is the minimum effective exposure, anything less than this having no action at all on the plate. The whole problem of exposure—which I am not expounding in this paper—is to bring all the light impressions which form the picture between these two limits. The upper strip is developed double the time, and the contrast between the tones is increased, for while the lowest tone has increased very little in opacity, the upper tones are greatly increased. Neither the maximum nor the minimum limits are altered by the longer development.

Fig. 1 is an imaginary section through an exposed film. Three exposures have been made on the plate, the part A being unexposed. The circles are supposed to represent the sensitive

FIG. 1.

particles of silver salt, those dotted being affected by light, and capable of development, those undotted being unaffected. I need scarcely explain that in a graphic diagram like this, no attempt is made at completeness; for instance, in the part D all the particles are shown light-affected, whereas with long exposures in a thick film only about 60 per cent. of the particles would be light-affected.

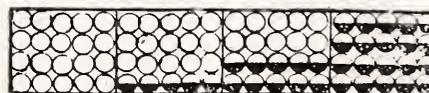

In Fig. 2 an attempt is made to represent graphically what occurs when an efficient developer has one quarter accomplished

FIG. 2.

its work, there being a comparatively feeble darkening in all three tones with little contrast between them. Fig. 3 indicates

FIG. 3.

the stage when development is half over; and Fig. 4 when

development is completed, and all light-affected particles com-

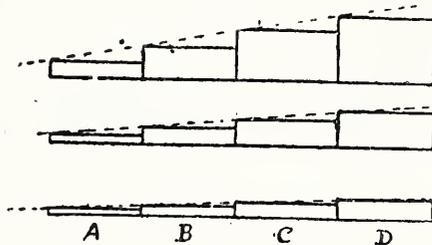

FIG. 4.

pletely reduced to the black metallic state. With a well-balanced developer there is no effect on those particles not affected by light, but an ill-balanced developer with excessive alkali will sometimes attack them, this being called fog. In these diagrams representing the simple course of development, it will be seen that the same proportion of work is done on each of the tones at each of the stages. But, as Messrs. Hurter and Driffield have pointed out, an arithmetical increase in the blackened silver results in a much greater (geometric) increase in its opacity or power of stopping light, and, therefore, in the natural course of development the contrast between the tones increases with the length of development. This rule applies with all developers, its limit being when fog commences and when all available light-affected silver is darkened in the darker tones.

Fig. 5 is an imaginary diagram of the silver representing the four tones compressed into steps, and at three stages of development. The diagonal lines indicate what is conveniently termed

FIG. 5.

the "steepness of gradation," and a register of this steepness is what Messrs. Hurter and Driffield term the development factor.

I make no attempt to discuss the question whether the reduction of the image is entirely a chemical or partly a physical process, and, in fact, I disclaim any qualification to throw light upon the chemical aspects of development.

CONTROL OF DEVELOPMENT BY TIME.

Although Messrs. Hurter and Driffield expounded the great importance of time in development, they gave no further help to uniformity in practice than the fact that, having once developed a plate to a required contrast or steepness of gradation, you could attain the same steepness (development factor) with another plate by using exactly the same developer, at exactly the same temperature, for exactly the same time. As it is difficult in practical work to ensure an exactly uniform developer (as regards alkali especially), and still more difficult to keep an exactly uniform temperature all the year, a practical working standard was still wanting. It is this aspect of development to which I have devoted most investigation.

In 1893, while testing a large number of plates for speed, and developing them together in one dish, I observed that some plates developed more readily than others, and attained contrast with greater rapidity; also that the image on these plates appeared more quickly than that on the others. In order to equalise the development, I adopted the plan of developing each plate for a fixed multiple of its time of appearance. In this particular case the time of appearance made correctly the

allowance due probably to the different character of gelatines used in the emulsions. But this led to a long series of experiments, in which I established the fact that the time of appearance made the correct allowance for alterations in the activity in the developer, due to the following causes:—Temperature (between 45 deg. and 75 deg.); alkali in developer; dilution of developer—pyro and amidol being an exception to this.

The time of appearance is the time elapsing between pouring on the developer and the first appearance of any trace of the image. The multiple used to attain the required result I have termed the multiplying factor. The multiplying factor varies with different developing agents, such as hydroquinone, pyro, metol, etc.

The multiplying factor is usually the same for different commercial plates, but I have found lately some plates which require a higher factor to secure sufficient contrast. These plates are some which makers seem to turn out in their efforts to secure a high speed reading, and I notice that they are a deeper yellow than usual. It seems, therefore, that an increased proportion of an iodide in the emulsion alters the multiplying factor. I have found, by the way, that a little iodide of potassium in the developer very much alters the law of appearance, the image appearing almost as quickly at the back of the plate as at the front. A bromide in the developer has quite an opposite effect. The use of a bromide or other restrainer in the developer alters the factor.

The experienced photographer using this timing system will sometimes alter the multiplying factor to bring an exceptionally wide range of tones in his subject within the limits of his printing process.

When investigating the laws of appearance, I found that the ratio of the appearances of all the various tones in an exposed plate was not altered by variations in the character and activity of the developer, and that if the times of appearance of a slip of plate exposed on the Hurter and Driffield plan, is plotted out in a similar way to the Hurter and Driffield method of plotting out densities, it is possible to read the speed of the plate by an observation of the diagram. I have made a recording instrument for observing these appearances, and recording them on a diagram, but do not propose to follow up this branch of the subject in this paper.

To return to the practical question of controlling results by time of development, I throw on the screen prints from negatives of the same subject and exposure developed in a 2 grain pyro soda developer $\frac{1}{2}$ grain bromide, for $3\frac{1}{2}$ times to give a soft contrast, to 5 times to give a medium or correct contrast, and for 8 times to give an exaggerated or hard contrast. The advantage of this plan of timing development is that the same contrasts can be secured at another time, even if the temperature is different and if the developer has not the same activity as regards alkali.

I do not propose to make this paper a complete practical exposition of this factorial method of development, for I have recently published a handbook on the subject; and I will pass on to examine those variations in the character or proportions of the developer which in the past have been relied upon to secure control of results.

It may be noticed that I have spoken of the main course of development quite independently of the developing agent used. This is because I find that all developers, after all the tones have appeared, and leaving fog out of the question, do the same proportion of work on the different tones and attain the same result if the right time is allowed to each.

COMPARISON OF DEVELOPERS.

But in comparing the different developing agents, some (such

as hydroquinone and strong pyro) will be found to give density in the upper tones quickly, and to bring out detail in the lower tones slowly. Another class of developers, as metol or rodinal, bring out all detail very early in the total stages of development, while density in the upper tones seems to follow slowly. I show on the screen three exposed slips each of three gradations, developed in rodinal, 1 grain pyro, and 8 grains pyro respectively, and each taken out the moment the lowest tone had appeared. The rodinal has only attained a very feeble density in the upper tone, the 8 grain pyro a considerable density, and the 1 grain pyro an intermediate amount. After this commencement, all three strips would pass through exactly the same stages of contrast. I should leave in rodinal for 40 times appearance, in 1 grain pyro (no bromide) 18 times, and in 8 grain pyro (no bromide) 6 times appearance, in order to attain the same final result, and these figures (40, 18, and 6) would be the multiplying factors for these developers.

I also show strips developed in metol and hydroquinone respectively, one strip of each being taken out of the developer at 1, 2, 3, 4, 5, and 6 minutes respectively. It will be seen that metol is very much ahead in stage of development at 1, 2, and 3 minutes, at 5 minutes hydroquinone has got level, and is identical in all the tones, while at 6 minutes it is the denser of the two in all the tones.

The different types of developers have, therefore, different ways of going to work; but I have never been able to discover that the final result differs if each is carried to the same stage of development, and no bromide is used. I show strips developed by five different developers to illustrate this, each carried to the same steepness of gradation. Even with hydroquinone, which brings out detail last of any, I find (provided no bromide is used) that the faintest detail rendered by the exposure is fully brought out when development is carried far enough for a suitable contrast for printing on P.O.P. A developer exceedingly strong in pyro seems to have slight restraining effect, and holds back the lower tones in the early stages.

I have explained at greater length the differences between developers in the "Photographic Journal," April, 1900.

I must, however, note that my experiments have not included ferrous oxalate developer, which has the reputation of giving a lower speed. It has, however, practically gone out of use for negative work, and is being abandoned even for testing purposes. There are also some indications that a few exceptional plates are a little more sensitive to a particular developer, but this variation seems scarcely sufficient to have any bearing on practical work.

INFLUENCE OF BROMIDE.

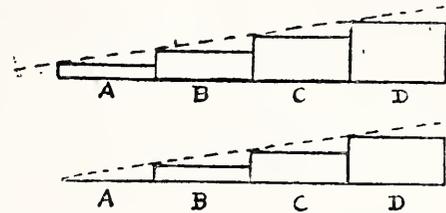

The restraining influence of a bromide in the developer has been explained by Hurter and Driffield in the "Photographic Journal," July, 1898. They explain how its "holding back" influence on the lower tones is chiefly exercised in the early stages of development, and becomes less and less as development proceeds, until at an advanced stage of development the result with bromide is exactly the same in all gradations, as if the same plate were developed without bromide and carried to the same steepness of gradation. Even fog is only held back by bromide in the early stages of development. This explains many of the perplexing differences of experience—especially as regards speed of plates—which have occurred between different experimenters. I show on the screen a series of slips illustrating this point.

The "holding back" power of bromide has in practice by far the greatest effect with developers of low multiplying factor,

such as hydroquinone and strong pyro, for these have already a tendency to hold back detail until late in development, and the two combined "holding back" tendencies are sufficient to keep back the lower tones until a steepness of gradation quite sufficient for printing purposes is reached.

Fig. 6 illustrates graphically the action of bromide in the developer, the upper illustration representing an imaginary

FIG. 6.

section of the densities of an exposed plate developed without bromide, and the lower illustration the same slip developed for the same time in the same developer with bromide added. It will be seen that the same steepness of gradation has been attained with both developers, but that the bromide has lessened the density in all the tones, and altogether prevented the lowest tones from appearing. With longer development, however, the lowest tone would come out, and the other tones increase in density to just the same extent as if no bromide were present. In these rough graphic diagrams, which are not intended to be exact, I have omitted the curves of under and over exposure.

The important part to remember is that this holding-back power is not exercised after the lowest tone has appeared; and it is therefore useless to add bromide some time after development has commenced. Most commercial plates of the present day develop sufficiently free from fog without the addition of a bromide, and I regard its use as quite unnecessary. Even in making lantern slides I have found that brilliant results can be secured without bromide in the developer.

WELL-BALANCED DEVELOPERS.

With each developing agent there is a strength which experience shows to have the most useful power without being in excess. This is usually from 2 to 4 grains to the ounce. There is also a proportion of alkali which gives sufficient energy without tendency to fog. This proportion with soda carbonate is about five or six times the weight of the developing agent. A developer thus proportioned is a well-balanced one. Changes in the amount of alkali alter the speed at which development proceeds, but have no other effect on the gradations, except that an excessive amount is apt to cause fog.

OLD METHODS OF CONTROL.

I continue to see that at photographic society demonstrations beginners are advised to "feel their way" in development, to begin with a small proportion of alkali, and add more in course of development. Not the smallest power is conferred by the proceeding, for the stages of development follow exactly the same course as if a standard solution were used from the commencement.

Let me also consider the procedure which the maker's instructions and the text-books have advocated for dealing with over and under exposure with pyro soda developers, when unknown beforehand.

It is usually advised that when the lower tones appear so slowly that under-exposure is feared, the developer should be diluted and more alkali added "to bring out detail." On the other hand, if all the tones come out in such rapid succession that over-exposure is revealed, the traditional advice is to add

more pyro at once—say, 2 grains to the ounce—and an equal quantity of bromide, or else mix up and apply a new developer exceedingly strong in pyro and bromide. It is certain that such a developer has a great power of holding back the lower tones and altering gradation when it is used from the commencement. But I have never been able to discover that any such selective power exists when once these lower tones have appeared, or that the methods I indicate above, and which are usually termed tentative development, confer any power which cannot be equally well exercised by using a standard developer from the commencement.

The following are the details of a comparative trial which I show on the screen. A Paget XXXXX plate was exposed in a long series of gradations, and cut up into strips, which were simultaneously developed in a 2 grain pyro soda developer—no bromide—some in one dish, the remainder in another. The first tone appeared in 40 seconds, and as soon as all the tones were out (in 150 seconds) the following alterations were made, being previously got ready in measures. To the first set of strips (marked O for supposed over exposure) 2 grains of pyro and 2 grains of bromide per ounce were added. To the second set of strips (marked U for supposed under exposure) double the previous amount of alkali, and an equal bulk of water was added.

The strips were taken out of each dish at intervals, and afterwards compared, to see if the gradations had been altered by these proceedings. There was no evidence of control by any such alteration, other than that given in both cases by length of development. I compare one O and one U strip, both having attained about equal contrast. All the tones are also equal, a little fog being added in the case of U.

COMPENSATING FOR VARIED EXPOSURES.

It was Hurter and Driffeld who proved that under and over exposures ought to receive the same time of development to secure the same contrast.

The strip of gradations on the screen having alongside bits of over, medium, and under exposed negatives all developed for the same time, illustrates this. The over exposed negative utilises the upper tones of the series, and is denser throughout. The under exposed negative utilises the lower tones of the series, and is thin throughout; but, except where they fringe on the extreme tones which are under or over the range of the plate, both negatives give prints of much the same detail and steepness of gradation. In this time development, therefore, the exposure decides the density of the negative.

I have often developed six negatives in a dish together—snapshots, interiors, and landscapes mixed; observed the time of appearance of the average high lights of the series (ignoring especially over exposed high light, such as a window in an interior), and developed for the fixed multiple of this time, knowing that a similar amount of contrast would be secured in all the negatives. No doubt the use of an actinometer (my own exposure meter) in gauging the exposures helped towards the uniformity of result; but a very considerable variation of exposure is allowable, the over exposures in such a series being dense, and the under exposures thin.

When I have had rollable films to develop, I have also followed the same plan of timing, developing the whole roll at once.

In fact, it is with rollable films that the method of developing different exposures for the same time has come into general use. Probably nine-tenths of the rollable films developed in the last year or two have been developed without cutting up the roll at all, perhaps in most cases on account of ease and

simplicity, without knowledge that it was the theoretically correct proceeding. I mention this because I notice that several photographers, in speaking of the results attained by roll film developing machines, seem to think it is a new thing to attain uniformity of results by developing the whole roll at once.

If known beforehand, over exposure can be compensated for by using a short factor developer with bromide. Under exposure, if known beforehand, cannot be improved; the use of more alkali or of a long factor developer such as rodinal does not bring out any more detail than the ordinary formula (no bromide) gives. The only hope lies in heated development.

SUMMARY OF PRINCIPLES.

Different developers vary in way of going to work, and speed of working, but not (bromide influence excepted) in final result.

Variation of the composition of a developer (bromide influence excepted) does not influence final result.

The bromide influence is not well under control, and cannot be exercised after all the tones have appeared. Bromide is best omitted from the developer, being unnecessary. The influence of time is quite sufficient for all control required.

THE TWO TIME METHODS.

There are two ways of deciding the time to develop, both depending on a previous trial. The first is my own factorial method, in which the method makes correct allowance of most changes in the developer, for (usually) different kinds of plates or films and—most important—for variations in temperature; it also allows for using the developer a second time. The second is the Hurter and Driffeld method—lately followed in film developing machines—of developing for a fixed time with a fixed developer. With this plan it must not be forgotten that the time is only right for that particular plate or film, and for exactly one composition of developer used for the first time, and for one temperature. The variation for temperature can, no doubt, be given in a table, but if it is ignored—as one demonstrator seems to have advised—summer results will be very different from winter results. A second use of the developer, or its dilution, also requires an increase in the standard time.

MECHANICAL APPLIANCES.

In carrying out principles certain appliances are often helpful. With my factorial method, for instance, I devised a clock for the dark-room with a ten minute dial and large minute divisions, as an ordinary watch, even a stop-watch, is not convenient. It is called the Eikronometer, and has a calculator for giving the time to develop. It is a great convenience, and its use has much increased lately. An ordinary metronome, or a half-second chain pendulum, is a great help in counting seconds for the appearance of the image, either being better than a stop-watch. But I have always frankly explained that all the benefits of my factorial method can be obtained, although not so conveniently, with an ordinary watch. I, therefore, feel no hesitation in referring to a similar fact with regard to the two film developing machines recently put on the market by two firms. They, no doubt, appeal to those who do not wish to use a dark-room; but exactly the same results can be attained in a dark-room by holding the whole roll of film in a U-shaped loop and see-sawing it, first through a bowl of water, and secondly through the developer in a basin for the standard time. These machines, of course, can only carry out the Hurter and Driffeld time method, not my factorial plan. In developing films it is important not to stint the bulk of the developer. It is possible to use so small a quantity that its developing power is exhausted before the requisite work is done. In fact,

if negatives always contained the same proportions of high light and shadow, it would be quite possible to control the steepness of gradation by limiting the total amount of developing salt.

ALFRED WATKINS.

DISCUSSION.

Mr. Chapman Jones said he had learnt much from the paper, although a great part of it travelled over old ground. But when Mr. Watkins made a diagrammatic representation of what had taken place in development, he often failed to represent fairly what he had demonstrated by his experiments. One of the first diagrams indicated the course of development, and showed how a certain number of particles, after exposure by light, were during development reduced in a certain proportion, and by further development in a further proportion. Mr. Watkins, however, showed that under many conditions of development the particles were not all acted upon simultaneously, but that there was a considerable amount of action in the high lights before there was any change in the shadows. The diagrams tended to show what he thought Mr. Watkins would like to show, rather than the fact which he demonstrated in the actual experiments. With regard to the control obtained by the use of bromide and by altering the concentration of the developer, he thought a good deal of control could be obtained; and, indeed, Mr. Watkins's experiments seemed to demonstrate this. The tendency of many people in the past appeared to have been to imagine that a good deal more control was obtained than was the case; but the tendency now he thought was in the opposite direction, people denying that one had control at all. The latter fact, however, was amply proved by Mr. Watkins, who had explained in a fair way that one could get over the difficulty of over exposure, if one only knew the fact beforehand, by the introduction of bromide. But it was said that bromide was of little use unless put in at first. That seemed to him (Mr. C. Jones) a statement which was very difficult to prove. If one started development and washed off the developer before it went too far, then it was possible to substitute a slow-acting developer. At any rate, it was difficult to prove that it was not possible. With regard to developing a long series of negatives for the same time and getting useful results, that had been argued a good deal lately, and he thought the two extremists were both wrong. Under certain circumstances, if one developed negatives having various exposures for the same time, there would be obtained many spoilt negatives; but if negatives all tended to under exposure, which was the usual case in Kodaks and such like cameras, it was impossible in many cases to over develop. There was no further change unless the film remained so long that there was fogging, and the fogging could be easily distinguished from the developing stage. He understood Mr. Watkins to say that one could deal with over exposure, but not with under exposure. He thought that quite wrong, as Mr. Watkins himself appeared to have shown. Of course, that which was not on a plate could not be developed from it, but in many plates there was a tendency to get a great density in the high lights before the detail and shadows had appeared, but by using a judicious developer, which brought out the details first, a harmonious range of gradations could be obtained, and the operator could stop at any stage he wished.

Mr. J. H. Gear said he did not hold with hard and fast time development, but whenever he had adopted time development he had always succeeded with his plates. A very considerable advantage in the timing of development was found when dealing with tricolour work. He did not know how it was possible to develop three negatives with equal opacity

where there was a different range of gradations, so to speak, caused by the various colours, and he felt that the timing method under such circumstances was the only reliable system in order to get the three colours at their correct opacity. With regard to the alteration in the factorial time, he had found plates of the same manufacture vary somewhat, for instance, Lumière's A plates and their B plates, and the plate sensitive to red. Taking the factor of 4 for the A plate and also for the red plate, that did not give the same opacity as the green plate; and in order to develop those plates with the factor, he had found it absolutely necessary to take 4 for the blue plate, 4 for the red plate, while $3\frac{1}{2}$ gave the same opacity for the green plate. He thought it must be admitted that there was not the control in development which had been previously imagined, if one adhered to the pyro and soda developer. He had no doubt that bromide had but little effect after once commencing development, and he would not expect to get the control in the development by the addition of bromide, but by the addition of sodium citrate. He felt the sodium citrate was practically the only control they possessed. When the plate was over exposed, the results were as Mr. Watkins had shown.

Rev. F. C. Lambert said he felt the following difficulty. If he had a slow plate giving a considerable range of exposure, was he to understand that one had to take the time from the pouring on of the developer to its first appearance, and multiply that for a constant factor under all conditions? Suppose the image appeared in 10 seconds, and the factor was 6, he must develop for 1 minute; if with that plate he gave the shortest possible exposure, and gave the other half of the plate the longest possible exposure, he would expect under those conditions that the time of the appearance of the image would be different; the more brief the exposure the slower would be the picture in appearing; but if he used the same factor in both cases, would he get the same result? He anticipated an opposite result, because he imagined that for the same degree of contrast, the longer exposure, which came out first, should have the higher multiplying factor.

Mr. W. Thomas, speaking as an ordinary practical photographer, said that what one wanted, as a rule, was the maximum result from light action in the shadows, and a very considerable stage of that maximum result of light action in higher stages. He thought highly of the work done by Mr. Watkins, and while agreeing with almost everything he had laid down, he could not bring himself to find that his own practice was in accordance with those doctrines. Taking a subject with white and as near dark as could be got, some parts lit with clear brilliant sunlight and the others in the shade, there was something to deal with beyond those; there was such a thing as light and shade, and such a thing as colour. Colour entered into such matters in a very important way, and he thought it was not taken sufficient note of in descriptions and lectures on the subject. It seemed strange to say that the results produced could not be altered and varied, and he said so with the more confidence after what he had heard that evening. He thought if there was lacking proof that control was possible and existed, that proof had been furnished by Mr. Watkins himself. With regard to the addition of bromide after the development had commenced, he understood the reader of the paper to say the result of his work had been to convince him that no saving alteration could be brought about by the addition of bromide once development had commenced. Such an experience was opposed to his own.

Mr. Friese Greene agreed that the bromide in the developer had only a kind of mechanical, and not a chemical action, but he wanted to bring before the meeting the fact that if the

continuous electric current were introduced at the beginning of the development where bromide was used, it seemed to enhance the retarding action of the bromide.

The Chairman, Sir William Abney, said Mr. Chapman Jones had dealt with much that he had intended touching upon. Everyone must admire the great care with which Mr. Watkins had conducted and recorded his experiments on development, and that gentleman had cast a new light on many manipulations in that process. Mr. Watkins had shown that there was a factor, which, if used, would enable the photographer always to arrive at the same degree or intensity of gradation. Of course, there was a certain difficulty in arriving at a factor. For instance, what was the first appearance? That was to a large extent a question of a personal equation, and with that he fully agreed. One person would see a black speck coming out on a negative before another person. He had often developed side by side with his assistants and friends, and it had often been difficult to decide at what exact time the image appeared. But that could be got over, and when once the personal equation had been arrived at, one could have a factor for different kinds of plates for development. He had made a great many experiments, and he had come to the conclusion that there was a great deal more control in developing a negative than Mr. Watkins liked to allow. He was not a professional photographer, and therefore he did not develop the plates because he was obliged to, but he looked upon the development of every plate as a kind of experiment; and if anything remarkable occurred during the process, he repeated it, to see what it meant. At the time of Hurter and Driffield's paper, there was a great controversy as to whether there could be an alteration brought about by variation of the developer. He had neither the time nor the inclination to enter into that controversy; he had a controversy on another point with those same gentlemen, but the experiments he had carried out left him no doubt that there was a control in development by means of varying the developer. On the screen was represented development by means of metol, and one by ortol. If one exposed two strips, as he had himself done, in the way Mr. Watkins had, one could leave the metol strip in for half a day without getting the same intensity or gradation as with the ortol. That was a matter of experiment, and without fog appearing in either. From the strips on the screen he would have expected to find that gradation would be the same in both cases. Perhaps Mr. Watkins would explain why that was not always the case; as it was not. With regard to the question of the dilution of the developer, looking at the matter from a chemical standpoint, he thought it would be seen that chemical action was always considerably altered in effect by dilution, and, whatever happened in ordinary chemical operations, one would expect to happen also in the chemical operation of development. He did not propose to enter into arguments, nor to give a history of any experiments there might be, but he might say generally that Mr. Watkins was right in his conclusions, but although generally he must allow a little more scope for those who held contrary views. He could quite support the remark made by Mr. Gear as to sodium citrate, and, moreover, the addition of citric acid was a well-known way by which one could retard the action of an over exposed plate. He believed Mr. Warnerke was very strong on the different materials with which an over exposed plate could be saved, even after the developer had been on. Mr. Watkins had almost convinced him that there was not much use in putting a large quantity of bromide on during development; but if the developer were washed off before the action had got very far, and if the development were restrained by means of a very dilute

solution of hydrochloric acid, there was obtained a decent negative from a very much over exposed plate. A remark had been made about developers and single solutions. A friend of his used to employ those one-man solutions, and to buy them in cartridges. He came to him (Sir W. Abney) in trouble one day, though he had used half a cartridge; but it appeared that he had used the top half and left the bottom half behind.

Mr. Watkins, in reply, reminded his hearers that he had not attempted to traverse the whole ground, and that his paper was entitled, "Some Aspects of Photographic Development." He had not asserted that no control existed. He would not wish to argue with Sir William Abney the points raised by that gentleman, because of his large experience. He admitted that the question of colour was a very important one, and that it had to be provided for and allowed for, but that must be done in exposure, not in development. He had not been able, in experiments, to find that any control existed by adding bromide after the tones had appeared. He had not experimented with sodium citrate, the substance mentioned by Mr. Gear. Mr. Lambert's question touched a weak point. The high light of an under exposure appeared in slightly different time to the high light of an over exposure, and this introduced a small error into the factorial method of development. It was, however, a very much smaller error than the advantages obtained by compensating for temperature and the amount of alkali. The difference in the high light was very little in under exposure compared with over exposure. Generally those who followed the timing development used an actinometer for getting the exposures. In practice he did not find it a difficult matter. His experience was that in an under exposed snapshot one must cut the development short.

FIFTH TRAILL TAYLOR MEMORIAL LECTURE,
Dec. 11th, 1902.

THE GREAT PHOTOGRAPHIC STAR MAP.
II.

LECTURER:—H. H. TURNER, D.Sc., F.R.S., Savilian Professor
of Astronomy, Oxford.

UNIFORMITY OF ILLUMINATION.

But there is another way in which the doublet is accurate, and actually superior to the refractor: it spreads star images over the plate uniformly. I have already referred to the *réseau*, the network of crosslines which is put on all the plates of the star map. It divides up the plate into little squares of exactly equal area. If we take a single plate on which a number of stars has been photographed, some of these squares may contain no stars at all, others one, two, perhaps four or five; the stars are scattered irregularly, and there will be no approach to uniformity of distribution. But if we take 100 plates, or 1,000 plates, and count all the stars which appear in any given square of the *réseau*, then the accidental irregularities of distribution disappear; and with an ideal lens we should hope to find the same total number of stars credited to each square of the *réseau*. This operation of counting the number of stars on a plate is one which is going on every day in the University Observatory, as a preliminary to the measurement; it is found to be a useful check on the quality of the photograph—if there are not enough stars, according to expectations which I need not here explain, it is only waste time measuring, and better to take another plate. The counting is quickly done—we use a "billiard-marker" to click off the stars mechanically—and tells us at once if the plate is good enough to measure. And

having, therefore, the counts of stars on many hundred plates, it occurred to me to inquire whether the average distribution of the images over the little squares of the *réseau* was uniform, as one might hope. It was soon seen that it was not—there were fewer stars at the edges than in the centre; but what seemed more surprising, the maximum number of stars per square was not at the centre, but in a ring about $1\frac{1}{2}$ in. from it (the plate being about 6 in. square). Was this a peculiarity of this particular object glass? Other plates taken at Paris, Algiers, Toulouse, and San Fernando with similar instruments were examined, and it was found that in each case the stars were thickest in a ring round the centre, being fewer both within and without this ring, though the diameter of the ring was not always the same. Comparison of the results led to the conclusion that the plates in each case are placed so as to be in accurate focus for the particular ring which shows most stars, the centre of the plate being thus slightly within the focus, and the edges slightly without. The rate at which the number of stars falls off as we leave the locality for true focus is the same for all these instruments, and if the plate were placed so that the centre was in best focus, the falling off would be as in the following table:—

For 100 stars per unit area at the centre there would be	96	„	„	at 20 mm. from centre.
	84	„	„	at 40 mm. „
	64	„	„	at 60 mm. „
	36	„	„	at 80 mm. „

Now this falling off is very decided, and shows that the lens does not cover the plate of 2 degrees square with any approach to uniformity. By putting the plate rather within the focus for the centre, we may improve things a little, but the defect seems to be inherent in the instrument. Since the paper* drawing attention to it was written, plates taken with the Potsdam instrument have been counted quite independently, and similar results found. So that we may accept it as characteristic of plates taken with refractors. But the doublet is apparently free from this grave defect, or, at any rate, can be rendered free from it. When counts are made on the plates taken at the Cape of Good Hope which have been already mentioned, it is found that equal areas in any part of the plate show the same number of stars, and this for a field not 2 degrees square, but 5 degrees square—six times the area. This must be accounted a conspicuous advantage of the doublet over the refractor, and undoubtedly over the reflector also, which is known to be even a greater sinner than the refractor in this respect. The reason of the loss of star images is perhaps too obvious to need explanation: when the light of a faint star is not brought accurately to focus, but is spread over a small area of the plate, it is rendered too faint to affect the film, and the star is lost. It would thus appear that with a doublet the focus can be tolerably exact over a large part of a flat plate, while with a refractor it is definitely restricted—in other words, the doublet can be made to have a really flat field, while that of the refractor is curved. Probably, therefore, curved plates would suit the latter better than flat plates, and some experiments have already been made with curved plates for both refractor and doublet, though I have not time to dwell upon them here. Indeed, I am aware that I have already somewhat digressed from my main theme; but the considerations determining the choice of an instrument for photography occupied so much of the attention of the late Mr. Traill Taylor, in whose honour these Lectures are given, that I will venture to make a few more remarks upon the topic before leaving it.

THE HARVARD STAR MAPS.

In the first place Professor Pickering, who recommended the use of the doublet for the star map in vain, nevertheless had the courage of his convictions. He has had several such instruments at work for some year, one the veritable giant already referred to, of two feet aperture, and $11\frac{1}{2}$ feet focal length. Some of them cover a field much more than 5 degrees in diameter: he has sent me plates of diameter 40 degrees and more; and though on measurement the images on these large plates are not free from displacement or distortion, this displacement seems to follow a regular and simple law which need not seriously interfere with the accuracy of measurement. Experiments on this point are, however, scarcely yet completed. As one consequence of being able to photograph so large a field at once, Professor Pickering has been able to chart the sky *many times over* while the 18 observatories have been laboriously doing it once: and we have yet to learn whether our more laborious methods have really any advantage over his rapid one. It may be that a “leap-in-the-dark” in 1887 would have saved us much and cost us nothing, except the anxiety of making it. But we must remember that Professor Pickering has not measured the stars, which is a labour independent of any process of taking the plates, and really does require the co-operation of many observatories. It is only for the taking of the plates, especially those of long exposure, that I think we should do well even now to adopt his advice.

BARNARD'S PORTRAIT LENS.

Secondly, I must make some reference, though it be but a mere passing mention, of the beautiful photographs taken by Professor E. E. Barnard with a portrait lens. As a boy Professor Barnard worked in a photographer's studio in Tennessee, and was familiar with every detail of portrait photography. But astronomy attracted him, and he became so skilful a discoverer of comets that at one time, having no other means, he supported himself entirely on the sums of money awarded in recognition of such discoveries. When the great Lick telescope was set up on Mount Hamilton he was offered a permanent appointment as one of the observers: and with this great telescope he discovered the tiny fifth satellite of Jupiter, which few people beside himself have ever seen. But he could not have the use of the great telescope every night, for various observers took turns, and he looked about for something to do on the night when it was not his turn. Among the miscellaneous property of the Lick Observatory he found a good portrait lens by Willard; and the memories of his early days coming back to him, he determined to try what sort of pictures he could get of the stars. He attached it to a disused equatorial mounting and set to work; and the results were marvellously beautiful. His pictures of the Milky Way are wonderful revelations of the structure of that wonderful region, and by making long exposures he discovered extremely faint nebulosity covering vast areas where it had never been suspected; nay, where its existence was at first stoutly denied by others who could not obtain a trace of it with instruments apparently more powerful. But there came an unfortunate moment when Professor Barnard must leave the Lick Observatory: and again a fortunate moment when he was called to the Yerkes Observatory near Chicago, where a still bigger telescope had been set up. Here he is now happily and successfully at work, with this exception—the Willard lens had to be left behind him in the Lick Observatory, and he cannot get another like it! He may be said to have searched the world for such a lens: for after trying all over the United States a couple of years ago, he came to Europe and tried several of the best maker's without success.

* Monthly Notices of Royal Astron. Soc. LXII p. 424.

I would have you remark that it is no mere question of taste or fancy in such a case: photographs of the stars supply absolute tests of the most delicate kind. I have already mentioned a numerical test which shows that the field of a doublet is more uniform than that of a refractor: the test which Professor Barnard applied to various lenses was also numerical; he tried which lens would, with a given exposure, shew most stars: and he could find no lens of equal aperture equal to his Willard lens.

WHERE ARE THE OLD LENSES?

This lens was a product of the old days of wet-plate photography, when rapidity could not be obtained in the plate, and it was all important to have it in the lens. It is essentially a very rapid portrait lens of which Professor Barnard is in search, and it almost seems as though the art of constructing really rapid lenses had been lost in the few years since the dry plate has been invented. But, even so, where are all the old lenses? Has anyone such a lens in a lumber room? There may be some possessing such lenses, and having no further use for them—large rapid portrait lenses dating from the old wet-plate days. These are the lenses which can be turned to good account in photographing faint widely diffused nebulae, and which astronomers such as Professor Barnard would find almost invaluable: and before they are, perhaps, lost sight of altogether, I would earnestly beg the attention of photographers generally to this astronomical need.

COLOUR SCREENS.

Thirdly, while on the subject of instruments for photographing the stars, I feel sure that an audience of photographers will be interested to learn that a simple device has recently been successfully used to transform a visual telescope into a photographic one. If we remove the eye-piece of an ordinary telescope and put a sensitive film at the focus, we might get a photograph, but it would be a wretchedly bad one, because the lens is arranged to focus the yellow or visual rays, and not the violet rays which are most photographically active. Hence existing large telescopes cannot be used as they stand for taking photographs. Various devices have been suggested for adapting them to photography: the most direct and most costly is to have an entirely new object glass as in the large Paris telescope shewn in the Exhibition of 1900; or an additional lens as in the Lick telescope: or to reverse the crown lens of the ordinary flint and crown combination, and alter the separation of the lenses, as in the 28in. refractor at Greenwich; or to have some correcting lens near the focus. All these methods have disadvantages of a serious kind. Mr. Ritchey, of the Yerkes Observatory, has adopted the much simpler plan of photographing with the yellow light, which is focussed, and stopping out the light which is not. He uses a yellow colour screen just in front of the sensitive film, and, of course, isochromatic plates. His pictures of the Moon with the great Yerkes telescope under these conditions are the best that have ever been taken; and he gets also wonderfully fine pictures of star clusters. The drawback to the method is that the exposure required is rather long, so that it is not applicable for faint objects: for these, however, we can use reflecting telescopes.

I have said enough, perhaps to show that the problem of the instrument to be used in photographing the stars is one of great complexity: and if the decision arrived at in 1887 with very imperfect knowledge was not quite the best that could have been arrived at, we may at least be thankful that it was no worse.

PROGRESS OF MAP.

We must now turn to the work on the great map itself, which is, I am glad to say, being made, though only slowly. In 1887 the time for completing the whole map was talked of hopefully as, perhaps, so little as five years. Fifteen years have elapsed since 1887, and some of the eighteen co-operating observatories have scarcely yet made a start, though others are happily well advanced with their work. It must be remembered that the resources of the eighteen observatories are widely different: for though many of them are national observatories, with government subsidies behind them, the resources of governments vary. In 1900 three of the original eighteen had made no start at all, were proclaimed defaulters, and were replaced by three others; and though these are setting vigorously to work they have not yet had time to do much. Indeed, the programme proposed is such as to strain the resources of the most wealthy observatories, and valuable time has been lost in consequence. But still, much has been done. The last general report of the state of the work was formulated in 1900, and is as follows:—The three observatories Monte Video, Cordoba, and Perth (West Australia) are those which have replaced the three defaulters, and thus their blank record is no discredit:—

Observatory.	Number of		
	Fields Assigned.	Catalogue Plates Measured.	Chart Plates Taken.
Greenwich	1,149	608	1,076
Rome	1,140	15	106
Catania	1,008	36	—
Helsingfors	1,008	380	?
Potsdam	1,232	250	—
Oxford	1,180	736	—
Paris	1,260	650	97
Bordeaux	1,260	293	17
Toulouse	1,080	135	45
Algiers	1,260	497	56
San Fernando	1,260	145	664
Tacubaya	1,260	203	—
Monte Video	1,260	—	—
Cordoba	1,360	—	—
Perth (West Australia)	1,376	—	—
Cape of Good Hope	1,512	106	1,134
Sydney	1,400	?	—
Melbourne	1,149	?	575
Total	22,154	4,054	3,770

It will be seen that less than one-fifth of the work had been done in 1900. Of course, much time has been spent in experiments, and the pace ought to improve rapidly: but there is ample room for such improvement if the whole is to be completed within a reasonable time; and it would be affectation not to admit that there is cause for grave anxiety on this head. But it will be more cheerful for us to-night if, instead of dwelling on the slow pace of the work, to turn to some of the results which are already beginning to come out of the measures: and as an example I will take some results which we have obtained at Oxford, because I know most about them.

MAGNITUDE EQUATION.

About 14,000 of the brighter stars in the zones now being photographed at Oxford were observed with the transit-circle at Cambridge about twenty years ago: and when we have measured the positions of these stars on our plates it is our first business to compare them with the positions found at Cambridge. When this is done for thousands of stars, a peculiarity of the Cambridge observations is made manifest. It is found that when the position of a bright star is determined by observing its transit (i.e., the instant of its passage over several spider-lines)

the observer nearly always records the instant too soon: i.e., sooner than he would for a faint star. This was known before the days of photography, for there are other visual methods of finding the relative places of stars without observing transits at all. With the heliometer, for instance, we can measure the distance between a bright star A and a faint star B, when both are kept apparently at rest; and find it to be (say) exactly five seconds. But if now we "take transits" of A and B, and A comes to the wires first, the interval will be recorded as greater than five seconds; if B comes first, the interval will be less than five seconds: shewing that in both cases the bright star A was observed too soon. Nearly all observers have this peculiarity, though not to the same extent: and it is called their "magnitude equation." We have heard of "personal equation," which has become almost a household word: though it originally meant that one observer records a transit systematically before or after another. "Magnitude equation" is not concerned with the difference between one observer and another, but between the observation, by the same person, of a bright star and a faint star.

Now photographs have no "magnitude equation," and when the Cambridge transit observations were compared with our plates it became very clear, not only that the transits of the bright stars had been observed too early, but how much too early they had been observed. In 1899, as the result of a comparison of about 5,000 star places, the following results were published, showing the Cambridge "magnitude equation" as determined in this way. Taking the faintest stars observed at Cambridge as correct (though we have no means of saying which class of stars is observed correctly; we only know the differences), we get

If stars of magnitude 10.0 are observed correctly	S
then stars of magnitude 9.0 are 0.10 too early.	
" 8.0 are 0.16 "	
" 7.0 are 0.19 "	
" 6.0 are 0.21 "	
" 5.0 are 0.23 "	

(The magnitude of a star is a measure of its brightness, each magnitude being 2½ times brighter than the next).

It will be seen that the peculiarity is by no means the same throughout the scale of magnitudes, but is always in the same direction.

ARE THE BRIGHT STARS REVOLVING?

Now, the photographs from which these results were obtained were taken some seventeen years after the observations had been made at Cambridge, and the question arises, had the stars moved in the meantime, and if so, would this motion affect the results? It is certain that many of the stars had appreciably moved: all the stars are in motion, though at their huge distances the movements are scarcely perceptible. But it does not necessarily follow that these motions would affect the above results: this only follows if the movements of bright stars are systematically different from those of faint stars, and there did not seem to be any reason to suspect this until about six months ago, when Sir David Gill announced that he had found such a difference in a belt of the heavens in the southern hemisphere. By comparing observations of stars in this belt, made at intervals of twenty years, he found that the bright stars seemed to be rotating round us, if we regard the faint stars as fixed. If this result were true of the whole heavens, it would involve the most serious consequences. Not only would it reveal perhaps a swirl or whirlpool in the universe of stars, but it would directly affect such eminently practical matters as the length of the year. We consider a year elapsed when the earth has travelled

completely round the sun, so as to come opposite the same star again, but if the star has been moving in the meantime, we must modify our figures. In view of the vital importance of the question, it was felt that the Oxford measures must be examined from this point of view at once, and the form in which the question presented itself in this instance was simply this:—Some of the plates were taken at Oxford as early as 1892, some as late as this year, 1902. Suppose we compare the earlier plates with the Cambridge observations, do we get exactly the same result as by comparing the later? If we do, then there is no systematic motion of the brighter stars in this region of the heavens; if we do not, there is such a motion. The two comparisons were accordingly made, and were found not to give the same result, but differences somewhat as shown in the following table:—

	Cambridge Magnitude Equation	
	From Oxford Measures in 1894.	From Oxford Measures in 1899.
Magnitude 6.0... ..	S 0.21	S 0.19
" 7.0... ..	0.19	0.18
" 8.0... ..	0.16	0.15
" 9.0... ..	0.10	0.10

It will be seen that there is a difference of 0s.02, or one-fiftieth of a second of time, between the results for stars of magnitude 6.0, taken at five years' interval. The quantity is extremely small, and those unfamiliar with such matters may be inclined to dismiss it contemptuously, as beneath notice, or perhaps be sceptical as to whether it can be relied upon. I am confident that it can be relied upon, for reasons which it would take too long to give here; and this small fiftieth of a second tells us several most important facts, for nearly all the most important facts of astronomy come from small differences like this. It tells us, firstly, that the bright stars in the northern hemisphere are moving, with respect to the faint, at about the pace which Sir David Gill found in the southern hemisphere; secondly, that they are going the opposite way to his bright stars, so that we cannot extend his result to the whole sky, that is, there is no general swirl or whirlpool, such as he suggested, and for the present we need not be anxious about the length of the year; thirdly, it suggests that we must look for another cause for both facts, and at the present moment I think such a cause has been found. The hypothesis is still on trial, and this brief mention must suffice at present.

CONCLUSION.

Enough has, however, been said to show that the great star map has not only a mere distant prospect of being useful: it is immediately wanted for the solution of pressing and important questions. It is true that these questions have only just arisen, and were not definitely foreseen in 1887, when the star map was projected. Even so, when Hour XXI of the Berlin charts was being constructed, no one foresaw that it would be wanted almost immediately for the discovery of Neptune. As already remarked, the most important uses to which scientific work will be put are seldom foreseen; we must work on in faith that the work will be valuable, but in a faith founded on solid results of past experience.

But it may be asked, if we can never foresee the best results of our work, how can we tell what is the best thing to do? Instead of making a star map, why should we not photograph a certain square yard of the ocean every half hour, and study the changes in it; or with a microscope photograph as many in-

dividual grains of sand as we can, and study the varieties of form? Who can tell what the ultimate result will be? My reply is that I do not think anyone can tell: I do not think there is in the nature of things any criterion which can tell us the value of any patient accumulation of facts, or assign a limit to the accumulation beyond which it becomes valueless. The only limits or reasons for selection which I know of are essentially human: if you work at certain things, you will get little human sympathy at present; if you attempt accumulations on too vast a scale, you will not have money enough; and, again, you may prefer to reach conclusions from your facts within the short spell of a human life. In human enterprises such considerations are determining factors, and in the particular case of the great photographic star map I am not sure that they have received sufficient attention. The question of the scale of the map is one of expense simply. No astronomer doubts for a moment that it would be better to make a 500ft. globe than a 50ft., if we had the money. No astronomer doubts for a moment that it would be better to measure the plates elaborately four or five, or fifty times over, if we had the time. We must consider available time and money, and the fact already mentioned that the work is going on rather slowly is a result of not considering these important matters sufficiently.

But I hope to have made it clear that a great work is being carried out, from which we may expect great results, a work scarcely dreamt of thirty years ago—to-day, not only possible, but comparatively easy of accomplishment. Photography owes something to a great astronomer, Sir John Herschel, who was the first to obtain photographic pictures on glass; but it has made an ample return, for among the debts of gratitude incurred by one science towards another, it would be difficult to find one greater than that which astronomy is proud to acknowledge towards photography, for that beautiful and simple invention which has rendered the great photographic star map a possibility—I mean, of course, the invention of the photographic dry plate.

REDUCTION OF AMMONIACAL SILVER SOLUTIONS BY ORGANIC SUBSTANCES.

[A Paper read before the Society of Chemical Industry, and reprinted from its Journal.]

THE detection of organic substances and the relegation of these compounds to their appropriate classes is a matter which now almost invariably forms part of the laboratory training of the student of chemistry, and the inclusion of this branch of analysis in the ordinary chemical curriculum, although a comparatively recent departure, is one which merits careful cultivation, because the analytical experience thus obtained is not only of great educational value, but also of considerable practical utility.

The fact that it is practically impossible to compile any tabular system of reactions capable of dealing with a tithe of the problems which the student is called upon to solve is a very pleasing feature of this work; but it is essential, in view of this circumstance, that the exercises given should be carefully graduated in order of difficulty, for it is frequently found that certain reliable tests, which can be safely employed to detect certain substances or groups of compounds, give ambiguous indications when applied indiscriminately to many of the innumerable combinations of compounds now placed at our disposal by organic chemistry.

This danger is strikingly manifested in the case of the well-known silver mirror test, which has long been employed in

the detection of the aldehydes and the easily oxidisable organic acids.

The experiments here recorded serve to show that many other groups of substances produce a similar result when treated with ammoniacal silver nitrate. The test was generally applied in aqueous solution containing about 5 per cent. of silver nitrate, although in a few cases the insolubility of the organic compound in water rendered it necessary to employ alcohol as the solvent.

Reduction of the silver salt occurred in almost all the classes of compounds enumerated below.

1. Aromatic Amines.—The fact that certain aromatic amines produce silver mirrors with ammoniacal silver nitrate has already been observed by Tombeck ("Ann. Chim. Phys.," 1900, 7, [21], 383), who showed that, under suitable conditions, the intermediate products of this reaction could be isolated, these substances being formed by the union of silver salt and the organic base in definite proportions.

The aromatic amines are all more or less soluble in water, and the silver mirror is best obtained by gently warming with the reagent, not the base itself, but its aqueous solution. This reaction appears to be perfectly general for all aromatic amines of the benzene and naphthalene series, and mirrors are obtained with equal facility from primary, secondary, and tertiary bases. The following amines were examined:—Aniline, *p*-toluidine, dimethylaniline, diphenylamine, the two naphthylamines, and their alkyl derivatives, *m*-phenylenediamine, *m*-tolylene-diamine, and 4.6-diamino-*m*-xylene.

A slight reduction is produced by acetanilide.

The behaviour of the pyridine bases stands out in marked contrast to that of the preceding amines, pyridine itself giving neither mirror nor reduced silver. Quinoline and β -dinaphthacridine give a slight reduction only, but no mirror; *iso*- β -dinaphthacridine, the labile isomeride of the latter base ("Jour. Chem. Soc. Trans.," 1898, 536), on the contrary, produces a brilliant mirror when left in contact with a warm alcoholic solution of ammoniacal silver nitrate. The hydro-genised pyridine ring is readily oxidised by this reagent, piperidine giving rise to a well-defined mirror.

2. Alkaloids.—Morphine formed a mirror with the greatest ease; quinine produced a very slight reduction, whilst strychnine gave a negative result in aqueous solution and a slight black precipitate in alcohol.

3. Hydrocarbons.—The hydrocarbons: benzene, toluene, and their halogen derivatives (the chloro-, bromo-, dichloro-, and dibromo-benzenes) and phenanthrene do not produce any appreciable reduction with aqueous or alcoholic solutions of the reagent, anthracene gives a mirror on standing, but this result may be partly due to the impurities which are so tenaciously retained by this hydrocarbon. Naphthalene gives a slight reduction in alcoholic solution.

4. Sulphur Derivatives.—Thiophene produces a very slight reduction after prolonged heating. The thiophenols are not affected by the oxidising agent, the two thionaphthols giving negative results. Benzenesulphonic acid, however, is oxidised and gives rise to a mirror.

5. Phenols.—The mono- and di-hydric phenols: phenol, α - and β -naphthols, catechol, resorcinol, and quinol produce brilliant mirrors, and the property seems to be retained by their alkyl ethers, anisol, phenetol, and 2:7-diethoxy-naphthalene producing a similar reduction.

The reduction of the silver salt by catechol takes place so readily that it may be employed as a lecture experiment for illustrating the formation of a silver mirror. Stronger solutions are employed in this case, 1 grm. of catechol dissolved in 15 c.c. of water being added to 25 c.c. of a 14 per cent. silver nitrate

solution containing a slight excess of ammonia. There is an appreciable rise of temperature, and the formation of the mirror, which commences immediately, is complete after a few minutes.

The trihydric phenols, phloroglucinol and pyrogallol, give copious black precipitates, but only very indistinct mirrors, and similar results were obtained with gallic and tannic acids.

6. Nitroxyl and Carboxyl Derivatives.—The introduction of nitroxyl and carboxyl radicles into the molecule of the phenols renders the products more stable towards the oxidising agent; *o*-nitrophenol gives a red colouration followed by a slight reduction, *p*-nitrophenol behaves similarly, whilst picric acid yields a precipitate of yellow needles, but no reduction.

Salicylic acid has only a slight reducing action.

Benzoic and phthalic acids remain entirely unaffected, benzamide and saccharine both yield crystalline precipitates of white needles, unaccompanied by reduction. Mandelic acid gives a precipitate of long pale yellow needles, dissolving in excess of ammonia to a colourless solution, which remains unaffected on prolonged heating. A globule of nitrobenzene, when allowed to remain in contact with warm ammoniacal silver nitrate solution, becomes coated with a layer of reduced silver.

7. Carbonyl Derivatives.—An appearance precisely similar to the one just described is presented by benzaldehyde. It is therefore a singular coincidence that the artificial and natural oils of Mirbane should in this respect behave in a similar manner. Quinone readily produces a mirror on warming, but yields a thick black precipitate in cold solutions. Dextrose and chloral hydrate both furnish mirrors with the greatest facility.

8. Azo and Diazo Derivatives.—A mirror is readily obtained with aminocazobenzene, but not with azobenzene or diazoaminobenzene, the latter compound yielding in alcoholic solution a yellow precipitate of its silver derivative.

9. Alcohols.—When pure, the monohydric alcohols give no reduction, although the precipitation of metallic silver is observed with impure specimens. Glycerol is stated to yield a mirror only in the presence of potassium hydroxide. We found, however, that, after leaving the warm solution of the trihydric alcohol and ammoniacal silver nitrate for one hour, a mirror was produced, even in the absence of the caustic alkali.

10. The Fatty Acids and their Derivatives.—The acids of the acetic series and oxalic acid do not produce any reduction, and negative results are obtained with oxamide and the metallic and ethereal oxalates. The blue potassium chromoxalate, $K_2Cr_2O_7 \cdot 6H_2O$, on the other hand, when gently heated with the reagent readily furnishes a very well-defined mirror; this result is, however, not obtained with its red isomeride.

11. Purine Derivatives.—Uric acid immediately yields a black precipitate, and the mixture after a time slowly gives rise to a mirror. Caffeine and theobromine give practically no reduction.

12. Unsaturated Compounds.—The compounds containing ethylenoid linkings resist the action of ammoniacal silver nitrate. Oleic acid gives a white precipitate, the colour of which slowly changes to red, but there is no production of metallic silver. Cinnamic acid and sodium cinnamate produce a nacreous white precipitate of the corresponding silver salt; this dissolves in excess of ammonia to a solution which remains quite clear, even after prolonged heating. Turpentine gives a very slight brown turbidity.

These results serve to emphasise the necessity of caution in the application of the well-known reaction for formic and tartaric acids, and the aliphatic aldehydes. In the presence of such commonly occurring substances as the phenols and the aromatic amines, this test is certain to lead to erroneous con-

clusions, and it is therefore always advisable to remove, as far as possible from the mixture under examination any substances likely to exert a reducing action on the reagent.

DISCUSSION.

Mr. W. T. Burgess said there was a practical side to this question, as to which he should like to make a suggestion. It would be interesting if the author would indicate those bodies which gave good silver mirrors. Many years ago he had occasion to silver large mirrors for reflecting telescopes, and there was sometimes considerable difficulty in producing satisfactory silver surfaces, and there might be a field for the practical application of some of the reducing substances mentioned in the author's paper. If Dr. Morgan could point out those which would give reliable mirrors over a surface, say, one foot in diameter, the knowledge might be extremely useful to the makers and owners of reflecting telescopes.

Mr. Otto Hehner referred to the bearing Dr. Morgan's work had on photographic practice. A developer, as a rule, was an aromatic amido or hydroxy body, and from that point of view many of Dr. Morgan's results presented nothing novel. So far as he knew, some of the other reducing substances had not been tried in photography; for instance, aniline, and it might be worth while to experiment with it. Concerning glycerin, it was very doubtful whether glycerol actually reduced ammoniacal silver solution, at least in a reasonably short time. One of the requirements for good dynamite glycerin was, as was well known, that it must not reduce silver solution. Many glycerins, although complying with that condition for a time, gradually reduced silver. But he was under the impression that, in the absence of air, the reduction was much less marked than when air was admitted. The reducing action of glycerin was more probably due to an impurity than to the glycerol itself.

Mr. Arthur R. Ling said that a possible reason why compounds containing a tertiary alcohol (carbinol) group, such as phenols, reduced ammoniacal silver solutions was that in some cases this group was capable of changing into a carbonyl group. It was possibly due to some change in the conformation of the alcohol groups in the sugars that they gave such irregular results with ammoniacal silver nitrates or with Fehling's solution. In the determination of reducing sugars, standard conditions had to be adopted in order to obtain good results.

Dr. Lewkowitsch asked whether Dr. Morgan had tried the higher homologues of pyridine. In one work where the dynamite glycerin was of bad quality, so as to reduce silver nitrate almost immediately, he had isolated from several cwts. of glycerin a few grammes of a substance he had reason to consider as lutidine. The presence of this base was no doubt due to the action of alkali on the albuminoids, from the cells in the badly-rendered fat. He ascribed, therefore, in that case the reducing action to the presence of the lutidine. He should also like to know a little more about the quality of glycerin used by Dr. Morgan, and how it was tested, because much of the so-called chemically pure glycerin sold would give a reduction, owing to imperfect refining. In the so-called perfumer's test the glycerin used for the best quality of toilet soap was tested with ammoniacal silver, and it was rejected if it did remain unreduced when standing for twenty-four hours in a dark cupboard. It was quite possible that a commercial glycerin might give a reducing action without the reaction being due to the glycerol itself.

Dr. Divers mentioned that the inorganic amino-compound, potassium amino-sulphate (sulphamate), silvered glass, when heated with silver nitrate and potassium hydroxide without addition of ammonia. He asked whether Dr. Morgan had tried

the use of potash in place of ammonia with amino-compounds.

Dr. Mollwo Perkin said he had frequently noticed in specimens of ordinary purified glycerin, such as one generally obtained, that they would sometimes reduce the silver very rapidly, but at other times it required a considerable time. It was also known that by the addition of a drop or two of alkali, either potash or soda, the reduction was greatly accelerated. He had never obtained glycerin which gave no reduction, provided it was heated for a sufficiently long time with ammoniacal silver.

The Chairman said that, although the paper on the face of it might appear theoretical, yet the discussion had been entirely practical. The subject had, as Mr. Burgess had said, a very practical bearing, because the making of silver mirrors was an important industry. Many years ago he played a part in introducing that industry into this country, and if at that time they had been aware that there were so many substances which would produce a good mirror, it might have been difficult to know which to adopt. At that time, however, there were very few such substances known. The best process was a French patent, which included an ammoniacal silver solution and a tartrate. There were then no silver mirrors in use, but now it would be difficult to find anyone who would produce a mercurial mirror. That showed the great advantage of technical chemistry; that extremely unhealthy industry of making mercurial mirrors had been entirely superseded without any official pressure, simply by the introduction of a new chemical reaction. The silver film was a very expensive material, compared with the tinfoil used in the mercurial process, but it was so easily applied that it entirely replaced the old and unhealthy process. There were two things which had to be considered in a reaction of this kind; one was temperature and the other dilution. In the mirror industry one had to get one's solutions of a certain strength, and many solutions which, when concentrated, produced a dark precipitate, apparently not metallic, would produce a bright metallic mirror if sufficiently diluted. Again, a solution which would not give a bright mirror at one temperature would give a very bright and satisfactory mirror at another. You put the plate of glass on a table, heated to a certain temperature with hot water underneath, and poured the solution on; if the temperature were right, you saw clouds gradually form on the glass, and by degrees the whole surface became metallic. If one were not very particular about the dilution, an amorphous, dark precipitate might be obtained. In those days grape sugar was tried as a reducing agent, and in some cases gave a good mirror, but in others none at all, so that you would not get a practical film from it. With regard to glycerin, it would be interesting to make tests of the reducing power of pure glycerin with a sample purified by the freezing process, which he found to be generally purer than any distilled glycerin.

Mr. Samuel Hall said that, about 1848, he was with Mr. Henry Deacon, and saw the first attempt at St. Helens to form mirrors. That was when Mr. Deacon was at Pilkington's. He took a little spirit lamp, and with a piece of platinum wire made some aldehyde, and precipitated some silver in a test-tube with it.

Dr. Morgan, in reply, said he thought there would be no difficulty in coating a surface 1ft. square with a silver mirror such as was produced in the catechol experiment. He had forgotten to point out that the mirrors produced by aromatic compounds had a darker sheen than that observed in the mirrors from aliphatic substances, the difference being probably due to the precipitation of organic matter in the former case.

In the case of glycerin, the result was obtained after heating

the solution of ammoniacal silver nitrate for one hour on the water-bath. The sample of glycerin employed in this experiment, although distilled under diminished pressure, had not been purified by the freezing process, and he did not therefore insist on its extreme purity. He had not examined lutidine from this standpoint, and was unable to say whether the methylated homologue of pyridine would bring about this reduction. He was inclined to think, however, that lutidine would not give a mirror. They had tried the experiment with pyridine, and had obtained a mirror which showed that the hydrogenised pyridine ring was susceptible to the action of the silver solution.

They had not tried the action of caustic potash and silver nitrate, because they were doing the test under the conditions employed by students in examining solutions for aldehydes, and therefore restricted their experiments to ammoniacal silver nitrate solution.

The observations of the Chairman were quite in accordance with their own. They found that they had continually to alter either the temperature or the degree of concentration in order to obtain the best effect.

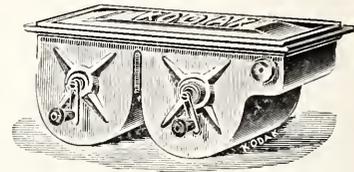

In some cases mirrors were obtained with strong solutions in the cold, and in others only with dilute solutions and warming. The catechol mirror is the best example of the effect of the former set of conditions, whilst that derived from aniline exemplifies the latter.

G. T. MORGAN, D.Sc., and F. M. G. MICKLETHWAIT, A.R.C.S.

New Apparatus, &c.

The Brownie Kodak Daylight Developing Machine. Manufactured and sold by Kodak, Ltd., 43, Clerkenwell Road, E.C.

This is a smaller pattern of the ingenious daylight developing machine introduced by the Kodak Co. a few months ago. It measures approximately 8in. by 4in. by 3in., takes ten ounces of solution, and costs 10s.

It is intended for spools used in the Nos. 1 and 2 Brownie Kodaks. Insertion of the reels in the machine is facilitated by a spring attachment, and the handles at the side are detachable. Well and neatly made in metal, the Brownie Kodak Developing Machine would form an excellent New Year's or Christmas present for a young photographer.

ASSOCIATION of Technical Institutions.—The report of the council of this Association, to be presented at the annual meeting on January 6th at the Goldsmiths' Hall, expresses satisfaction that the Education Bill was amended in several particulars in accordance with the suggestions of the Association in the direction—(1) of making it compulsory on county and borough councils to undertake the supervision of elementary education; (2) of giving increased financial support to education from various sources. The report also urges the claims of the Association to representation on the consultative committee of the Board of Education and the Teachers' Registration Council. The council have notified to the Board of Education their regret that no scheme of block grants has been applied to the adult day classes in technical institutions. Two members of the Association, Principals Reynolds and Wells, have been appointed by the Board of Education as representatives on the Examinations Board of the City and Guilds of London Institute. The council have circulated to members particulars as to students in German technical institutions. The council recommend Sir J. Wolfe Barry for nomination at the annual meeting as president for 1903.

PHOTOGRAPHING THE EMOTIONS.

("English Mechanic.")

We are inclined to regard the results here detailed, at any rate with some hesitation; but as they are vouched for by the discoverer, Dr. Hippolyte Baraduc, a Parisian physician, we give them. Certainly a sensitised photograph plate which records "radiating mentality" as accurately as the most perfect lens catches the features and form of man is the latest development of photography. The possibilities opened out are remarkable. Certainly when men can no longer conceal their thoughts from one another society must alter its whole structure. Criminal intent may be laid bare to the eye of the public scrutiny and the crime prevented. Psychology will become the greatest of studies.

Dr. Baraduc says: "My researches have been conducted with the object of diagnosing my patients, especially those suffering from nervous diseases or cerebral excitation. I have called my process 'Therapeutic Photography.' And I am making it of practical use from a physiological point. For the examination of patients suffering with hallucination and for others on the verge of madness the indications on the plate are extremely useful. When I am assured that a subject is the victim of insanity I can cure him with my method of electrification, which is effected with a special apparatus, and which scatters the demoniac images in the brain and disengages them. When the patient is restored to his normal health the plate records little or nothing. This diagnostic plate registers the mental excitement much as a thermometer records the degrees of heat. In my first experiment I laid a photographic plate between a sheet of heavy black paper, so that no light could possibly penetrate. I held the plate between my thumbs and forefingers, the thumbs about an inch apart. When I examined the plate I discovered that the salts of silver had been operated on by some invisible medium, which must be the living light exuding from the bodies of human beings. There was a 'fuidic' line connecting the thumbs. I rarely employ a camera in photographing vital energy, wrapping my plates in black paper, or conducting my experiments in a dark room. Success greatly depends upon atmospheric conditions, the electric tension in the air, and the degree of heat or cold. When it is warm, the force is much greater. This force is also especially strong in persons of highly nervous condition, those vibrant with the passion of love or hate.

"Subjects on the verge of madness leave their impression upon the plate in a decided manner. Held over the epigastrium of a fever patient, certain results are inevitable, the vibrations being projected in the form of a multitude of tiny globules. Tried on a person seized with a fit of anger, the photograph shows vortices of temper like the convolutions of a cyclone. I have taken photographs during the hours of sleep, the impressions of the dreaming brain being recorded by the chemicals. Different emotions leave different impressions. I have taken those of a person engaged in prayer, and the sacred aspirations scattered themselves about upon the plate like pearly beads. When the invocation was extremely ardent, it appeared like a tongue of fire. With a person whose heart is sad the emotion is expressed in a 'whirlwind of radiation' of lines. When there is joy, the emanations expand, and resemble the images of the Röntgen ray. Not only human beings, but animals, plants, and flowers, are subject to this law of radiation, which can be photographed. I have shown how the satisfied purr of a cat affected the plate, or even the soft coo of a pigeon. I made an analysis of the feelings of a frightened dove, whose alarm was projected in vitalised round spots. I have tested the force of the circulation of the blood taken warm from an animal just killed. Its radiation has the appearance of cirrus heart, and, whether elevated or degraded, is faithfully registered upon the tell-tale chemicals. It usually requires fifteen minutes to affect the plate. In order to take a vibratory picture I hold my plate near the forehead, the hand on the heart, or, in fact, any vital portion of body or poles of life. Placed over the heart the picture is rapidly made.

"A most curious thing is that all of these photographs of vital energy show evolutions either from left to right or from right to left. This movement I have designated as 'curved force.' I have deposited a paper dealing with the subject in the archives of the Academy of Sciences. In conjunction with M. Bacle, of the School of Engineering of the Polytechnique Institute, I have photographed bacilli, and we intend to pursue our researches. In water which has been magnetised the effect produced resembles a nebulous cloud. I have made another curious application of photography, which trenches

upon the domain of psychology. This I have designated 'telepathic photography, or the photography of the invisible.' These pictures are produced solely by concentration of thought, the person desiring to conjure up the image of a dead, absent friend being enabled to do so by the intensity of the idea with which he is imbued. These pictures, the result of the imagination, frequently show a great resemblance to the physical reality. It must be understood that there is no clear-cut defining of the lineaments, only a nebulous face, a shadowy suggestion of the brain created in the astral light. They resemble portraits made with a crayon in which there are no hard lines. I have also named these pictures 'soul images.' The hand shows how the magnetic fluid emanated from a person endowed with hypnotic power. All of the illustrations were taken without a camera and in the dark, except the portrait of the young girl. It was secured when she was in a fit of anger because her mother had boxed her ears. The face appears surrounded by coruscations of indignation, a vortex of sparks like those from a rocket. In order to perfect my psychic and therapeutic photography it would be necessary to invent a more highly sensitised plate capable of registering even the feeblest emotions. If unalterable gold salts could be employed this might be achieved. If such a plate could be manufactured it would make it possible to demonstrate the existence of the invisible forces which surround us, and are not perceptible except to supersensitive and impressionable natures. Some persons with leisure and a fortune might find it interesting to experiment in regard to this sensitised plate, but a special laboratory would be necessary. It is impossible for me to devote myself to the discovery of the means of producing it, as my time is too fully occupied with my practice."

THE AFFILIATION LANTERN SLIDE COMPETITION.

We have received the following circular:—The Executive Committee have decided to invite the members of the societies affiliated with the Royal Photographic Society to take part in a Lantern Slide Competition, the object of the competition being to foster the production of lantern slides, to promote a healthy competitive spirit amongst the societies affiliated with the parent society, and to bring together a number of slides from which new sets for circulation may be drawn.

The committee entertain the hope that the societies and their members will do all they can to ensure the success of the competition: the societies by giving it the fullest possible publicity and by exercising control over the work sent in, and the members by entering the competition in large numbers and with their best work.

RULES AND REGULATIONS.

The competition shall be open only to members of affiliated societies. Each competitor shall enter not more than six slides. Previously medalled work shall be eligible for the competition and for award. All slides, with the negatives from which they are printed, shall be entirely the work of the competitor. The slides shall be three and a quarter inches square. They shall be correctly spotted, and shall bear on their faces the title of the picture and the name of the competitor.

Every competitor shall send his slides through the secretary of the affiliated society, of which he is a member, and no slides received in other than this way will be regarded as eligible for the competition. Competitors shall furnish complete lists of their slides upon foolscap paper, with their name and address and the name of the affiliated society through which they send their work.

THE AWARDS.

The slides shall be judged by the Board of Judges annually appointed by the Executive Committee to deal with society competitions, and there will be no classification whatever. The judges shall have at their disposal six bronze medals, specially designed and struck for the occasion, which will be given to the makers of the six best slides received. No competitor shall take more than one medal, but in the event of his receiving more than one award a suitable record shall be made of his additional success.

All lantern slides which receive an award shall become the property of the affiliation. The committee reserve the right to purchase other slides at a fixed sum of two shillings and sixpence each. These slides will then be made up into a set for circulation amongst the societies. In the case of the medalled and purchased slides, the competitors will be required to furnish a full description of the subject (where it is necessary) for the purpose of preparing the descriptive notes which will accompany the slides on their travels. The committee are desirous that the societies themselves shall also participate in the competition, and it has therefore been decided to offer three specially designed and executed photogravure certificates, suitable for framing and hanging in the meeting room, to the societies sending in the best, second, and third best contributions of slides by their members for the foregoing competition.

No society shall be considered qualified to take a certificate unless it contributes slides by six or more of its members. The societies will therefore find that their positions will be strengthened if a large number of their members is persuaded to enter the competition. The societies will also find it of advantage to overlook the slides sent in by their members.

Entries will close on Saturday, February 14th, by which date the slides must be in the hands of the committee. Intending competitors will therefore deposit their slides with the societies to which they belong as soon as possible before that date, in order that the societies may exercise the supervision suggested in a former paragraph. The societies shall then despatch the slides, with the particulars previously described, carriage paid, to the secretary of the affiliation, 66, Russell Square, London, W.C., so as to arrive on or before Saturday, February 14th. The committee undertake no responsibility for the safety of the competing slides, but every possible precaution will be taken to preserve them from injury and loss.

News and Notes.

At the Rontgen Society's ordinary general meeting on Thursday, January 1st, 1903, at 20, Hanover Square, the chair will be taken at 8.30 p.m. Dr. G. M. Lowe (Lincoln) will read a paper on "X Ray Work in Private Practice."

THERE are now on exhibition at the Kodak Gallery, 40, Strand, W.C., some 3,000 post cards selected from a total of 5,000 sent in to the recent Kodak Sensitised Post Card Competition. The cards are very effectively displayed in large frames, the prize winning entries being prominently arranged in smaller frames.

THE new abridged catalogue of the Thornton-Pickard Manufacturing Co., Altrincham, consists of 40 pages, with illustrations. It gives full particulars of the various cameras, shutters, and other apparatus of the company's manufacture. The catalogue is being posted to 25,000 photographers in all parts of the world.

THE Patent Office.—An open competitive examination for not fewer than twelve situations as assistant examiner in the Patent Office will be held by the Civil Service Commissioners in February next. The examination will begin on the 17th of the month, and forms of application for admission to it will probably be ready for issue in the course of a few days; they will be obtainable, on request, addressed by letter to the Secretary, Civil Service Commission, Burlington Gardens, London, W.

THE "Gloucester Diary" for 1903 includes a "Directors' Calendar" and a note on each day throughout the diary to enable the periodic recurrence of fixed engagements to be recorded, such as board or council meetings, fixed to be held, for example, on the second Tuesday in each month. Among the notes for visitors to Gloucester particulars are given respecting many features of interest, including the Severn "Bore," the Gloucester "Mop," and the "Festival of the Three Choirs," which is the oldest and perhaps the most important annual musical meeting held in Great Britain (the Welsh Eisteddfodd alone excepted). This festival occurs in Hereford in September, 1903.

THE First Lord of the Treasury has appointed a committee to inquire and report as to the administration by the Meteorological Council of the existing Parliamentary grant, and as to whether any changes in its apportionment are desirable in the interests of meteorological science, and to make any further recommendations which may occur to them, with a view to increasing the utility of that grant. The committee will consist of:—The Right Hon. Sir Herbert E. Maxwell, Bart., M.P. (chairman), Mr. J. Dewar, M.P., Sir W. de W. Abney, K.C.B., F.R.S., Sir F. Hopwood, K.C.B., Board of Trade, Sir T. H. Elliott, K.C.B., Board of Agriculture, Dr. R. T. Glazebrook, F.R.S., Mr. T. L. Heath, Treasury, and Dr. J. Larmor, F.R.S. Mr. G. L. Barstow, of the Treasury, will act as secretary to the committee.—"Nature."

HER GRACE THE DUCHESS OF SERMONETA, who is herself a keen enthusiast and expert with the camera, has a most interesting collection of photographs, says "The Journal of the Camera Club," purchased from the great London exhibitions of the Photographic Salon and the R.P.S. Her Grace is most anxious that this collection should be of some public use, and she has, therefore, most generously consented to present a selection of some 40 or 50 of the best of the pictures to the Camera Club. Although possibly not quite up to date—the most recent examples, we understand, were purchased some three years ago—yet such a collection can hardly fail to be of the greatest interest, including, as it does, the masterpieces of the foremost men in the world of pictorial photography a few years ago. These pictures are now on exhibition in the Club Room, and it is particularly interesting to notice what strides have been made in the few short years since they were first introduced to the public.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Dec.	Name of Society.	Subject.
31..... Jan.	Leeds Camera Club	Annual Meeting and Election of Officers.
1.....	N.-W. London Photo. Society	<i>Lantern Slides and How to Make Them.</i> Sandell Films & Plates, Ltd.
2.....	Leicester Literary	<i>Beautiful Clouds: their Form and Adaptability to Artistic Photography.</i> Mr. J. Porritt, Vice-Chairman.
2.....	Borough Polytechnic.....	<i>Exposure and Development.</i> Mr. Ernest Human.
2.....	West London Photo. Society...	<i>Points of View.</i> Mr. C. O. Murray.

ROYAL PHOTOGRAPHIC SOCIETY.

LANTERN meeting, December 16th.—Mr. George Lamley in the chair.

Mr. H. M. Lomas gave an interesting chat upon the work to be done with the camera in the hunting field. He showed the results of several years' efforts on his own part, and amongst the lantern pictures which illustrated his remarks were a number of conspicuous merit. The nature of the country worked, and the methods followed by the huntsmen, both in fox, stag, and badger hunting, were very fully exemplified, and several slides depicting the "kill" were interspersed amongst the others. Photography in the hunting field is evidently a pursuit calling for much exercise of patience and perseverance, and Mr. Lomas is to be congratulated on the success which has attended his efforts.

At the next lantern meeting (January 20th), Prof. Garwood will lecture on the "Peaks and Glaciers of the Kangchenjunga Range."

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 18TH.—Mr. S. Herbert Fry in the chair.

The combined toning and fixing bath was again the subject of discussion. Mr. R. P. Drage spoke favourably of Fuerst's bath, which stopped its action when the gold was exhausted, and produced no change of colour. It was understood that the shilling bath toned eight sheets of paper. Mr. Drage added that he had followed the combined bath with a treatment of the print in fresh hypo solution.

Mr. A. Mackie enquired whether the last speaker made up into solution at once the whole of the material supplied for the bath, and then used the bath again and again until the eight sheets of paper were toned, or whether for a smaller batch of prints he dissolved a proportionate part of the ingredients.

Mr. Drage replied that he made the bath up at once and used the solution until the eight sheets had been toned, returning the solution each time to the stock bottle. Mr. Mackie observed that this was an unwise course. He thought it was generally agreed that a new bath for each batch of prints was the preferable procedure.

Mr. R. Beckett agreed that to repeatedly use a toning bath in the way described was not wise. When once used the composition of a bath was so upset as to destroy the good qualities of the unused solution.

Mr. Drage believed that the makers of the bath advised the course he followed. He could only say, however, that it behaved very satisfactorily.

Members then discussed the new Pelloid film, and it seemed to be a general opinion amongst those who had used it that the new article was distinctly good. One speaker urged the importance of soaking the film in water before putting it into the developing dish, to obviate its attaching itself to the bottom of the dish. Another member pointed out that this course must necessarily alter the character of the negative. The fineness of its grain was a matter of comment. It was stated that the speed was about 80 H. and D.

Mr. Drage thought the idea embodied in the preparation of the film of coating both sides was not new. It had, he believed, been adopted in several instances in years past.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the Edinburgh branch was held at 38, Castle Street, on Friday evening, 12th December, 1902, Mr. R. A. Heaven in the chair. Present, Messrs. Heaven, Auld, Patrick, Pursey, Bibbs, Crawford, Swan, Watson, and Moffat.

Apologies for absence were read from Messrs. Croke and Balmain. The subjects under discussion were plates and rejected proofs.

The Chairman said what photographers wanted was a very sensitive plate which would develop quickly. Mr. Moffat drew attention to the different ways in which various brands of plates developed. A certain plate gained density slowly along with detail, whereas another maker's plates, equally sensitive in a good light, required to look fully exposed

when the image first appeared. If this was not the case, a great deal of the detail would fix out in the hypo, leaving very thin shadows. Also that the plates which gained density gradually were more sensitive in a dull foggy light, comparatively, than the one in which the detail in shadows appeared at the start of the development. Mr. Auld thought that the first mentioned plate was really isochromatic in its nature, therefore it was more sensitive in a foggy light. If when developing he found the high lights were gaining density too rapidly, he put the plate in a dish of clean water and left it to steep for half an hour or so, and when it was removed it had gained detail without increasing the density in the lights. Messrs. Patrick, Bibbs, and Pursey also spoke on this subject. A very interesting discussion then ensued on the subject of rejected proofs, in which all the members present took part.

The next meeting was fixed for Friday, 13th February, 1903. Subject for discussion: Water supply for photographers, and mounts.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

At a meeting of the Liverpool Amateur Photographic Association, held on Thursday last in the rooms in Eberle Street, a very large audience of members and friends assembled to hear Mr. G. E. Thompson lecture on his trip to Jamaica, which took place in the early part of the year. Dr. Napier occupied the chair in the absence of the president, Mr. E. R. Dibdin. Mr. Thompson's lecture was most interesting, and he dealt with his subject in a delightfully humorous vein. His description of the voyage from Avonmouth in the Port Antonio, the various excursions, the journey to Constant Springs Hotel, the visit to a coffee plantation in the Blue Mountains, the visit to Messrs. Rowntree and Co.'s estate and Port Antonio, the various excursions to Fern Gully, Roaring River Falls, Montpellier, Montego Bay, Mandeville, and Spanish Town were followed with intense interest by the audience. On his return to Kingston, Mr. Thompson watched the loading of a steamer with bananas, and his description of the way in which the negro women work was very interesting. The lecture was illustrated by nearly 150 very fine lantern slides, all made from negatives taken by the lecturer. At the conclusion, a hearty vote of thanks was passed to Mr. Thompson on the motion of Dr. Napier.

SOUTHAMPTON CAMERA CLUB.

THE members of the above club held a meeting on the 15th instant at their headquarters, Philharmonic Hall, when the President, Mr. Burrough-Hill, occupied the chair.

After the election of several new members, Mr. G. Vivian was called upon to give a "Resume of the club outings during 1902." He treated the subject with his usual ability, and through his knowledge of the history of each rendezvous, made the lecture both instructive and interesting. The discourse was suitably enlivened by a large number of well-selected lantern slides, representative of the various localities, which comprised St. Cross, North Stoneham Park, Shawford, Salisbury Cathedral, New Forest, Cowes, and Beaulieu.

At the conclusion of the lecture, Mr. Vivian was accorded a well-deserved vote of thanks, and was eulogised by the President for the masterly manner in which he handled the subject.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.

THE difficult subject of the "Pictorial Treatment of Architecture" was the theme of a most interesting lecture by Mr. Walter Scutt before this Association on Tuesday, the 16th inst. The lecturer drew a distinction between pictorial treatment and the mere simple record of facts, there being, as a rule, nothing artistic in the latter, and remarked that most architectural photographs suffer from the attempt to include too much in the field of view, and show too much detail, thus losing breadth of effect and concentration of interest; pictorial effect depending upon certain qualities not inherent in the building itself; hence a pure technical reproduction of the work of the architect and mason is not necessarily or generally a picture, or pleasing to the cultivated taste. Mr. Scutt said that scattered lights and shades were to be avoided, while massing of the same was to be preferred; wide angle lenses and small stops were undesirable, causing violent perspective and loss of atmosphere, while suitable figures should be introduced whenever possible. Some very fine slides by the lecturer were put through the lantern, illustrating his remarks very aptly, and reproductions of pictorial treatment of architecture by famous artists, in particular Turner and Girtin, were handed round. In conclusion, Mr. Scutt recommended the use of orthochromatic plates or films, single lenses to obtain softness, and cameras with fixed backs and great range of rising and swing fronts over those with swing backs and limited rise of fronts. The Sanderson camera and Underwood's "Minster," both used by the lecturer in his own work, were, with other apparatus, exhibited as specially suitable.

Correspondence.

* * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* * * We do not undertake responsibility for the opinions expressed by our correspondents.

WHERE ARE WE DRIFTING?

To the Editors.

Gentlemen,—As Mr. Banger's latest letter is merely a commentary on mine it is not worth much notice. He is evidently a veteran of the old school, and we must try and remember that the progressive man of to-day will be more or less (less, we naturally hope) the same as he is to-morrow. Another correspondent mildly suggests that we stop throwing stones at each other's glass-houses, explain our method of work, and let him (and others) sit in judgment upon it. But there is nothing to explain. Mr. Banger asserted that concentrated top light was a sort of photographic Bovril, or essence of art. I, rather mildly, flatly contradicted him. He scoffed at side light studios. I endeavoured to show he was writing sheer nonsense. So far as light and shade is concerned, it would be absurd for any man to say that a side light is better than a skylight studio. On that point the one is as good as the other. All I contend for my style is less extreme of heat or cold, less soot and dust, no leakage, and fewer stairs to climb, and a bigger choice of locality. On no other point can I remember any difference between my old and new studios. Mr. Banger slightly implies that possibly my work was not up to much in either of my studios. He is unable to see I tried to avoid any word that could be construed into an advertisement. I can only repeat, the exposure for groups or single figures is as nearly the same now as it ever was in my skylight studios.

Trusting, gentlemen, you will allow me to have one more round with Mr. Banger before I retire, I go on to say, "Sidelight" appears to have sent him some "samples" of his work, but Mr. Banger loftily declines to return the compliment, until a "Guild of Art Photography" is invented or built. I am inclined to think this an old school style of spelling the word "funk." Now, I wonder (I "wonder," Mr. Banger), would he object to sending (with your permission) "samples" of his work to you. I shall be very pleased to send some of mine, and would be quite content if you said my lighting was as good as his, even if it happened to be better, or to be utterly condemned if it was worse.

I think this is a chance for Mr. Banger. He taught us, in a former letter, the difference between "poesy" and "poetry." This week he gives a brilliantly lucid definition of the word "wonder." I am sure that even you, gentlemen (though editors), are anxiously waiting to hear, not only where we have drifted to, but when we ought to have cast anchor.—I am, gentlemen, yours truly,

WM. RALSTON.

P.S.—On second thoughts I enclose with this some "samples" as a sort of "guarantee of good faith." May I be allowed to add, "Banger goes saxpence on postage?"

259, Sauchiehall Street, Glasgow.
December 20th, 1902.

THE OLD GIVETH PLACE TO THE NEW.

To the Editors.

Gentlemen,—Photographic pictures on silver plates gave place to pictures on silvered copper, these gave way to pictures on glass, these again gave way to positive pictures on paper, mounted on cardboard; these latter pictures found repose in albums, etc.; these pictures (I refer to portraits specially) were (to be successful) all from models, who were quite still. Now, a query as to the next change for the presentment of individuals, and groups of same, I think the time has arrived for the quite alert professional photographer to arm himself with cinematograph apparatus for the making of animated pictures, then persuade their customers to provide themselves with Kinora albums. With these latter the professional photographer should have a great help in his proposal to pass the inert and still portraits, providing for his clients animated pictures of themselves, their children, relatives, and friends, all showing the natural grace, or otherwise, of the photographed; then will father's familiar walk be recorded, gestures and play of features will be caught, and family peculiarities of movement, habit or trick, yield a permanent living record. Already a large company in London are offering the public animated private portraiture, 42s. per negative of 50 feet, reproductions 15s. each.

Will the professional photographer go at once for the new style or fashion? Or, will he wait until others, perhaps not yet in the business, show him the way, as the chemist showed him the possibilities of photographic dealing? Time will show.—Yours faithfully,
F. K. HURMAN.

P.S.—By Kinora Album, I mean an instrument for the table, in which the positive reproductions are placed, mechanical effort providing the movement which reproduces the animation of the scene caused by persistence of vision.

December 21st, 1902.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

PHOTOGRAPHS REGISTERED:—

A. C. Collis, Alexandra Road, Cleethorpes, Lincoln. Photograph of group of Cleethorpes views.

W. Martin, 29, Newmarket Street, Ayr, N.B. Photograph of R.S. Fusiliers' Memorial Statue.

F. W. WREN.—The address of "Bibby's Quarterly" is Liverpool.

FERROTYPE.—E. THORPE asks:—"Would you be kind enough to tell me where I can get a book on wet ferrotype as used by beach photographers."—In reply: A small work on the subject is published by Messrs. Jonathan Fallowfield, Charing Cross Road, W.C.

REGISTRATION OF DESIGN.—PHOTO says: "I have a design for portraits which I desire to copyright, and should be glad to know what particulars are necessary to enable me to do this."—In reply: If you write to the Patent Office, Designs and Trade Marks Department, enclosing stamp, printed instructions will be sent to you. From these you will see how to proceed.

COPYRIGHT UNION.—UBIQUE says: "I should like to join a copyright society, if such an institution exists, as I have a large quantity of view negatives to protect. Would you kindly let me know how to proceed."—In reply: There is the Photographic Copyright Union, of which Mr. Henry Gower is the secretary. Write to him for a prospectus. His address is London Chamber of Commerce, Botolph House, Eastcheap, E.C.

STAINS ON PRINTS.—SYDNEY REYNOLDS writes: "Would you give me information of the following prints? I developed the paper with metol-hydroquinone. The paper is Nikko bromide. I should like to know the cause of the stain, as it was not on when developed."—In reply: We cannot say the precise cause of the stain. All we can say is that it is due to carelessness in the work—possibly dirty dishes.

CLEANING ENGRAVINGS.—MARTREB asks: "Could you inform me the best way to clean some engravings? I have three; one is badly stained all over, the other two have dark brown spots on them. Could you give me a recipe of any solution that would eradicate these stains, and not injure the engravings, as they are very good ones, about 15 by 12 size."—In reply: There are different ways of cleaning engravings, and they are all dependent upon the bleaching action of chlorine. As our correspondent has had no experience in the work, we should recommend him to place the prints in the hands of one who is expert in "restoring" engravings. Many valuable prints have been ruined by novices in their attempts to clean them.

UNFULFILLED ENGAGEMENT.—J. WAKEFIELD writes as follows: "In your last week's issue I answered two advertisements for general assistant, both different addresses, and the advertiser, a Mr. — (German) came, and I engaged him, and arranged to give him the wages he asked, 30s., and was to start on Tuesday last. I have never seen him yet, and I see this week again he has two more advertisements. Could you advise this man for me not to humbug the trade and do other would-be good hands applying

from a long distance out of an early answer by this nonsense. It would set right the grievance complained of recently by assistants of having to wait so long for return of specimens and answer; and these are the sort that give the trouble, and give master men a bad name."—In reply: We insert our correspondent's letter, and that is all we can do in the matter.

STAINED NEGATIVE.—INQUIRER puts the following queries: "I should be much obliged if you would give me information on following points:—(1) How are the stains caused on enclosed negative, which appeared after intensification? Chloride of mercury and ammonia was used. (2) Can you recommend any better method of intensifying, as I frequently have negatives stained in using above formula. (3) Is there any advantage in portraits taken at a small stop on rapid plates over those taken at open aperture on slower plates? My lens works at f/5.6; is there any advantage, say, for large heads, in stopping down to f/8?"—In reply: (1) The stains appear to be due either to the negative not being perfectly fixed, or insufficiently washed afterwards. The plate also looks as if it was somewhat stale when used. (2) Several formulæ for intensifying solutions are given on pp. 1077-9 of the "Almanac" for the current year. (3) The advantage in using the lens stopped down is that the different planes of the picture are in better focus than when it is worked with its full aperture.

COLLODION EMULSION.—A. M. MORRISON writes: "On page 796 of the 'Almanac' for 1896 is an article by Edwin Banks on 'A modified emulsion (collodion).' Well, could you help me out of my difficulty? First, as to the solvents, is methylated ether at 2d. per ounce suitable, or must I use methylated sulphuric ether, costing about 8d. per ounce. I purchased the pyroxyline from —, of this city; it was sold to me in a wet state, kept moist with spirits, for safety, the shopman explained. I dissolved it in methylated ether sp. gr. 725, but it dissolved with difficulty, cloudy, and leaving sediment $\frac{1}{4}$ in. thick at bottom of bottle. Article says it should dissolve readily and leave no sediment. Please say where I am wrong. Secondly, can I prepare it in daylight right to the end? If not, at what point must I withdraw from daylight? Is it a usual thing for gun cotton to be sold in the wet state with spirits, as I explained above. Of course, I laid it out to dry before using it. I hope you will be able to put me right."—In reply: The solvents should be of good quality, but good methylated sulphuric ether should not cost more than about half-a-crown a pound. It is evident that the pyroxyline was unsuitable for the purpose. The emulsion should be kept in the dark after the silver and bromide are added. Pyroxyline is sometimes kept damp for safety's sake, and it should be made thoroughly dry before it is used.

RE Frederick Thomas James Morris, photographer, 137, Whiteladies Road, Clifton.—This debtor made an application for his discharge at the Bristol County Court on December 19th, before his honour Judge Austin. It appeared from the official receiver's report on the case, that the receiving order was made against the debtor in August last. He alleged his insolvency to have been brought about by keen competition and the electric trams carrying people past his premises. The only offence alleged against the debtor was that his assets were not equal to 10s. in the £, although a dividend of 9s. in the £ had been paid to the unsecured creditors. Eventually his honour granted the discharge upon debtor making up the dividend to 10s. in the £.

Continued on Page VII

FOR WINTER PHOTOGRAPHY in the STUDIO or OPEN AIR

The "PLANAR" & "UNAR" Lenses are unequalled.

The "PLANAR" is a symmetrical objective consisting of four separated lenses. It possesses the following important features: It is very rapid and yields sharply defined pictures, it is anastigmatically well corrected, and embraces a comparatively wide angle. The rapidity varies from $f/3.6$ to $f/6$, according to the size and application of the lens, and the angle embraced by it varies from 62° to 72° .

The "UNAR" LENS is introduced to provide an objective of extreme rapidity, combined with a field exceeding 60° , which is very flat and evenly illuminated.

The "UNAR" is specially recommended for rapid hand-camera work, portraits, groups, and photography under unfavourable conditions of lighting. It is also well suited for enlargements and reproductions.

The full aperture is $f/4.5$ in the $4\frac{1}{2}$ -in. and $5\frac{1}{2}$ -in. focus lenses, $f/5$ up to and including 12-in. focus, $f/5.3$ in the 15-in., and $f/5.6$ in the 18-in. focus lens.

Another Year Gone!

But we are still in business in spite
 of Foreign Competition.

For that our thanks are due to our
 customers, who evidently know **THE
 BEST** when they use it. **WE** know
 our goods are the best possible value
 for money, therefore our motto for the
 coming year will be the same as when
 we first started business, viz. :—

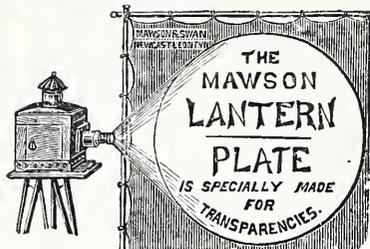

**"If you do not like
 our goods, you may
 throw them away
 (you need not
 trouble to return
 them) and we will
 refund your money
 in full. We ask no
 questions, and we
 most willingly take
 all the risk."**

THE LATEST ADVANCE IN PHOTOGRAPHIC OPTICS!

BAUSCH & LOMB'S NEW PLASTIGMAT LENS.

(U.S. Patent No. 660,747; Registered No. 237,806.)

F 6.8. More rapid than any other lens of equal aperture, on account of purity of glass used, which is colourless, and being hard does not oxidise. No soft glass used in their construction. It is two lenses in one. The back combination can be used as an instantaneous lens, of about double focus of combination, the single combination having the same-anastigmatic and aplanatic corrections as the doublet lens & the same brilliancy and freedom from distortion. **F 13.5.**

We fit Plastigmat Lenses to clients' Kodak Cameras with the New Unicum Shutter.

Why should I buy? —

JUST A FEW WORDS

Chosen at random from the numerous letters we have received this season as to the excellence and efficiency of the Wizard Cameras:—

“No Camera in my opinion is as good as the Wizard.”—“Delighted with my Wizard.”—
 “The Long Focus Wizard is a Champion Camera.”—“The adjustments so perfect I cannot help thinking I have got an Exhibition Camera.”—“The Interiors taken with your lenses exceed anything I ever expected.”—“A marvel of workmanship at the price.”—
 “The lens is simply perfect.”—“I have nothing but praise for it.”

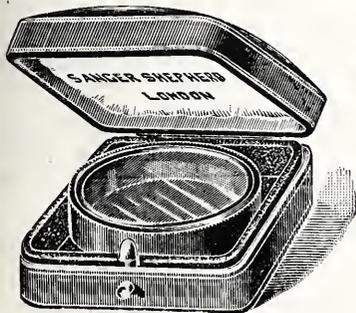

If YOU try one, we'll guarantee you satisfaction, and we think you also will have nothing but praise for the Wizard.

FOCUSSING COOKE LENSES

FOR HAND CAMERAS

contain within themselves a means of focussing objects at various distances from the camera. This is accomplished by turning the front ring of the mount, which has a scale of distances engraved upon it. This simple movement changes the focal length of the lens without moving it as a whole; and no bellows, slides, or rack-work are needed in the camera.

They cost but little more than ordinary Cooke Lenses.

THE NEW STIGMATIC LENS

SERIES II. F/6.

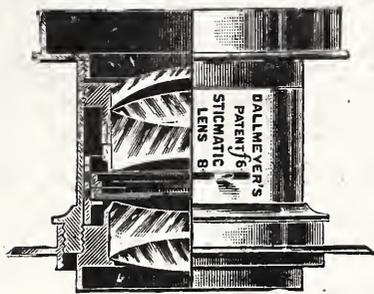

BRITISH DESIGN AND WORKMANSHIP.

Is the best All-round Lens for either Professional or Amateur use.

Each lens will give perfect definition with full aperture to the extreme corners of the plate it is sold to cover; with smaller stops it will cover at least two sizes larger, giving perfect sharpness all over the plate, and thus becoming a wide-angle lens of the highest excellence. Either combination may be used separately, giving foci of about 1½ and 2 times the length of that of the lens when used intact. The advantage of, thus being able to choose the best point of view, irrespective of distance, will be at once apparent to the artistic worker.

EQUIVALENT TO FOUR LENSES AT THE PRICE OF ONE.

Eleven Sizes are now ready from 3¼ to 18 inches eq. focus.

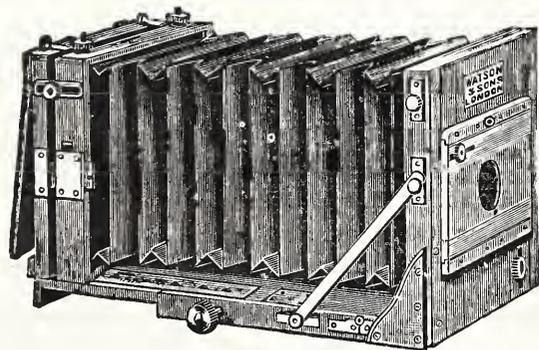

CATALOGUE OF HIGH-CLASS CAMERAS AND LENSES, POST FREE.

BRIN'S OXYGEN.

For Limelight, Medical, Metallurgical, and other purposes.

OXYGEN of guaranteed purity supplied in Cylinders of the best British manufacture, and complying with all the established Trade and Railway Regulations.

THE Public are respectfully informed that all Cylinders which are filled by the undermentioned Companies (whether their own or their Customers') are labelled with their Trade Mark. This label guarantees the purity of the Gas, and is a further guarantee that the Cylinder has been tested and proved sound in every respect by the Company which has filled it. Customers are requested to see that the Cylinders supplied to them bear this label, which is also stamped with the date on which the Cylinder was filled.

The Works of the Companies are open during business hours to Customers, who are at liberty to inspect the process of manufacturing Oxygen, and to witness their own Cylinders being tested and filled.

Price Lists of Gases, Cylinders, and all Accessories can be obtained from the Companies' accredited Agents, or will be sent post free on application.
